

The Temporal Ultraviolet Limit for Complex Bosonic Many-body Models

Tadeusz Balaban, Joel Feldman, Horst Knörrer
and Eugene Trubowitz

Abstract. We consider the partition function for a many-body model consisting of a weakly coupled gas of bosons at any temperature $T > 0$ and any chemical potential μ , but with both infrared and ultraviolet cutoffs imposed in both temporal and spatial directions. We take the limit as the ultraviolet cutoff in the temporal direction is removed and develop a representation for the limit that, hopefully, provides a suitable starting point for controlling the limit as the infrared cutoffs are removed.

1. Introduction

We are developing a set of tools and techniques for analyzing the large distance/infrared behaviour of a system of identical bosons, as the temperature tends to zero. In this paper we retain an infrared cutoff. That is, we consider bosons moving in the discrete torus $X = \mathbb{Z}^D/L\mathbb{Z}^D$, endowed with the standard Euclidean metric $d(\mathbf{x}, \mathbf{y})$. Our long term goal is to rigorously treat the infrared limit $L \rightarrow \infty$. See the introduction of [1].

The total energy of our many boson systems has two sources. First, each particle in the system has a kinetic energy. We shall denote the corresponding quantum mechanical observable by h . The most common is $-\frac{1}{2m}\Delta$, but, in this paper, more general operators are allowed. We assume that $h = \nabla^* \mathcal{H} \nabla$ where $\mathcal{H} : L^2(X^*) \rightarrow L^2(X^*)$ is a translation invariant, real, strictly positive, operator, X^* is the set of all bonds (ordered pairs of nearest neighbour points of X , but with the pair (\mathbf{y}, \mathbf{x}) viewed as $-(\mathbf{x}, \mathbf{y})$) and the gradient $(\nabla f)((\mathbf{x}, \mathbf{y})) = f(\mathbf{y}) - f(\mathbf{x})$. Second, the particles interact with each other through a two-body potential, $2v(\mathbf{x}, \mathbf{y})$, which is assumed to be real, symmetric, translation invariant and exponentially decaying. For stability, v is also required to be repulsive, in the sense that, viewed as the kernel of a convolution operator, it is strictly positive.

We assume that the system is in thermodynamic equilibrium and that expectations of observables are given by the grand canonical ensemble at temperature $T = \frac{1}{k\beta} > 0$ and chemical potential μ . We concentrate on the partition function $\text{Tr } e^{-\frac{1}{kT}(H-\mu N)}$. Here, H is the Hamiltonian and N is the number operator. The techniques developed here can also be applied to correlations functions. See (1.8).

In [2], we developed a functional integral representation for the partition function. See (1.2) below. The integration variable of this functional integral is a complex field $\alpha_\tau(\mathbf{x})$ depending on position $\mathbf{x} \in X$ and time/temperature $\tau \in (0, \frac{1}{kT}]$. Here, we have periodic boundary conditions, that is $\alpha_0 = \alpha_{\frac{1}{kT}}$. The representation of [2] can be viewed as a rigorous version of the formal representation

$$\text{Tr } e^{-\frac{1}{kT}(H-\mu N)} = \int \cdots \int \prod_{\substack{\mathbf{x} \in X \\ 0 \leq \tau \leq \frac{1}{kT}}} \frac{d\alpha_\tau^*(\mathbf{x}) d\alpha_\tau(\mathbf{x})}{2\pi i} e^{\mathcal{A}_X(\alpha^*, \alpha)}$$

where

$$\begin{aligned} & \mathcal{A}_X(\alpha^*, \alpha) \\ &= \int_0^{\frac{1}{kT}} d\tau \int_X d\mathbf{x} \left\{ \alpha_\tau(\mathbf{x})^* \frac{\partial}{\partial \tau} \alpha_\tau(\mathbf{x}) - \alpha_\tau(\mathbf{x})^* (\hbar \alpha_\tau)(\mathbf{x}) + \mu \alpha_\tau(\mathbf{x})^* \alpha_\tau(\mathbf{x}) \right\} \\ & - \int_0^{\frac{1}{kT}} d\tau \iint_{X^2} d\mathbf{x} d\mathbf{y} \alpha_\tau(\mathbf{x})^* \alpha_\tau(\mathbf{y})^* v(\mathbf{x}, \mathbf{y}) \alpha_\tau(\mathbf{x}) \alpha_\tau(\mathbf{y}) \end{aligned} \quad (1.1)$$

This formal representations is frequently used in the physics literature. See [11, (2.66)]. The ultraviolet problem is to integrate out, in this representation, all variables $\alpha_\tau(\mathbf{x})$ except for those having τ in a lattice with spacing of order one. In this paper, we treat the ultraviolet problem for our rigorous version of the formal representation above.

As pointed out in the introduction to [1], it is not possible to give rigorous mathematical meaning to the functional integral above in a straightforward way. For this reason, we derived (in Theorem 2.2 of [2]) the representation

$$\begin{aligned} & \text{Tr } e^{-\frac{1}{kT}(H-\mu N)} \\ &= \lim_{\varepsilon \rightarrow 0} \int \prod_{\tau \in \varepsilon \mathbb{Z} \cap (0, \frac{1}{kT}]} \left[d\mu_{R(\varepsilon)}(\alpha_\tau^*, \alpha_\tau) \zeta_\varepsilon(\alpha_{\tau-\varepsilon}, \alpha_\tau) \right. \\ & \times e^{\langle \alpha_{\tau-\varepsilon}^*, j(\varepsilon) \alpha_\tau \rangle - \varepsilon \langle \alpha_{\tau-\varepsilon}^* \alpha_\tau \vee \alpha_{\tau-\varepsilon}^* \alpha_\tau \rangle} \left. \right] \end{aligned} \quad (1.2)$$

Here, for any $r > 0$,

$$d\mu_r(\alpha^*, \alpha) = \prod_{\mathbf{x} \in X} \frac{d\alpha^*(\mathbf{x}) \wedge d\alpha(\mathbf{x})}{2\pi i} e^{-\alpha^*(\mathbf{x}) \alpha(\mathbf{x})} \chi(|\alpha(\mathbf{x})| < r)$$

denotes the unnormalized Gaussian measure, cut off at radius r , and $\zeta_\varepsilon(\alpha, \beta)$ is the characteristic function of

$$\{\alpha, \beta : \mathbb{C}^X \rightarrow \mathbb{C} \mid \|\alpha - \beta\|_\infty < p_0(\varepsilon)\}$$

The cutoffs $R(\varepsilon) > 0$ and $p_0(\varepsilon) \geq \ln \frac{1}{\varepsilon}$ are decreasing functions of ε defined for all $0 < \varepsilon \leq 1$ that obey

$$R(\varepsilon) \geq \frac{1}{\sqrt[4]{\varepsilon}} p_0(\varepsilon) \quad \text{and} \quad \lim_{\varepsilon \rightarrow 0} \sqrt{\varepsilon} R(\varepsilon) = 0$$

Furthermore, for any $t > 0$, the operator $j(t) = e^{-t(h-\mu)}$. We write the $(\mathbb{R}-$ style) scalar product, $\langle f, g \rangle = \sum_{x \in X} f(x)g(x)$ for any two fields $f, g : X \rightarrow \mathbb{C}$.¹

In this paper, we treat the ultraviolet problem in the representation (1.2). The final result is to write the partition function as a functional integral which involves α_τ for only finitely many values of τ , independent of ε . To achieve this, we have to integrate out all but a fixed number of fields α_τ in the representation (1.2). For $n \geq 1$ and $\varepsilon > 0$, set

$$\begin{aligned} I_n(\varepsilon; \alpha^*, \beta) &= \int \prod_{\tau \in \varepsilon \mathbb{Z} \cap (0, 2^n \varepsilon)} d\mu_{R(\varepsilon)}(\alpha_\tau^*, \alpha_\tau) \\ &\times \prod_{\tau \in \varepsilon \mathbb{Z} \cap (0, 2^n \varepsilon]} \left[\zeta_\varepsilon(\alpha_{\tau-\varepsilon}, \alpha_\tau) e^{\langle \alpha_{\tau-\varepsilon}^*, j(\varepsilon) \alpha_\tau \rangle - \varepsilon \langle \alpha_{\tau-\varepsilon}^* \alpha_\tau \nu \alpha_{\tau-\varepsilon}^* \alpha_\tau \rangle} \right] \end{aligned} \quad (1.3)$$

with $\alpha_0 = \alpha$ and $\alpha_{2^n \varepsilon} = \beta$. If $\varepsilon = \frac{1}{2^m} \frac{1}{pkT}$, for $m, p \in \mathbb{N}$, then

$$\begin{aligned} &\int \prod_{\tau \in \varepsilon \mathbb{Z} \cap (0, \frac{1}{pkT})} \left[d\mu_{R(\varepsilon)}(\alpha_\tau^*, \alpha_\tau) \zeta_\varepsilon(\alpha_{\tau-\varepsilon}, \alpha_\tau) \right. \\ &\quad \left. \times e^{\langle \alpha_{\tau-\varepsilon}^*, j(\varepsilon) \alpha_\tau \rangle - \varepsilon \langle \alpha_{\tau-\varepsilon}^* \alpha_\tau \nu \alpha_{\tau-\varepsilon}^* \alpha_\tau \rangle} \right] \\ &= \int \prod_{n=1}^p [d\mu_{R(\varepsilon)}(\phi_n^*, \phi_n) I_m(\varepsilon; \phi_{n-1}^*, \phi_n)] \end{aligned} \quad (1.4)$$

with the convention $\phi_0 = \phi_p$. Combining (1.2) and (1.4) we get

$$\text{Tr } e^{-\frac{1}{kT}(H-\mu N)} = \lim_{m \rightarrow \infty} \int \prod_{n=1}^p \left[d\mu_{R(\frac{1}{2^m pkT})}(\phi_n^*, \phi_n) I_m \left(\frac{1}{2^m pkT}; \phi_{n-1}^*, \phi_n \right) \right] \quad (1.5)$$

For a treatment of the ultraviolet problem in some related models, see [6, 7, 9, 10].

In this paper we show that, that for all sufficiently small² $\theta > 0$,

$$I_\theta(\alpha^*, \beta) = \lim_{m \rightarrow \infty} I_m(2^{-m}\theta; \alpha^*, \beta) \quad (1.6)$$

¹ Thus the usual scalar product over $\mathbb{C}^{|X|}$ is $\langle f^*, g \rangle$.

² The smallness condition on θ does not depend on the interaction v .

exists and we also exhibit properties of I_θ that we deem useful for a potential infrared analysis. If θ was chosen sufficiently small, we will write I_θ as the sum of a dominant part (which is shown to have a logarithm) and terms indexed by proper subsets of X and which are exponentially small in the size of the subsets.

The partition function can be written as

$$\text{Tr } e^{-\frac{1}{kT}(H-\mu N)} = \int \prod_{n=1}^p \left[\prod_{\mathbf{x} \in X} \frac{d\phi_n(\mathbf{x})^* \phi_n(\mathbf{x})}{2\pi\imath} e^{-\phi_n(\mathbf{x})^* \phi_n(\mathbf{x})} \right] I_\theta(\phi_{n-1}^*, \phi_n)$$

More generally, one also gets a representation for the Green's functions³

$$\frac{\text{Tr } e^{-\frac{1}{kT}(H-\mu N)} \mathbb{T} \prod_{j=1}^\ell \psi^{(\dagger)}(\beta_j, \mathbf{x}_j)}{\text{Tr } e^{-\frac{1}{kT}(H-\mu N)}} \quad (1.7)$$

with $\mathbf{x}_1, \dots, \mathbf{x}_\ell \in X$ and $0 \leq \beta_1, \dots, \beta_\ell \leq \frac{1}{kT}$. To this end, choose a sufficiently fine partition, $0 = \tau_0 < \tau_1 < \dots < \tau_p = \frac{1}{kT}$ that contains $\beta_1, \dots, \beta_\ell$. It follows from [2, Theorem 3.7] that the numerator of (1.7) is equal to

$$\begin{aligned} & \int \prod_{n=1}^p \left\{ \left[\prod_{\mathbf{x} \in X} \frac{d\phi_{\tau_n}(\mathbf{x})^* \phi_{\tau_n}(\mathbf{x})}{2\pi\imath} e^{-\phi_{\tau_n}(\mathbf{x})^* \phi_{\tau_n}(\mathbf{x})} \right] I_{\tau_n - \tau_{n-1}}(\phi_{\tau_{n-1}}^*, \phi_{\tau_n}) \right\} \\ & \times \prod_{j=1}^\ell \phi_{\beta_j}(\mathbf{x}_j)^* \end{aligned} \quad (1.8)$$

with $\phi_0 = \phi_{\frac{1}{kT}}$.

The functions $I_n(\varepsilon; \alpha^*, \beta)$ can also be defined recursively by

$$\begin{aligned} I_1(\varepsilon; \alpha^*, \beta) &= \int d\mu_{R(\varepsilon)}(\phi^*, \phi) \zeta_\varepsilon(\alpha^*, \phi) e^{\langle \alpha^*, j(\varepsilon)\phi \rangle + \langle \phi^*, j(\varepsilon)\beta \rangle} \\ &\times e^{-\varepsilon(\langle \alpha^* \phi, v \alpha^* \phi \rangle + \langle \phi^* \beta, v \phi^* \beta \rangle)} \zeta_\varepsilon(\phi^*, \beta) \end{aligned} \quad (1.9)$$

and

$$I_{n+1}(\varepsilon; \alpha^*, \beta) = \int d\mu_{R(\varepsilon)}(\phi^*, \phi) I_n(\varepsilon; \alpha^*, \phi) I_n(\varepsilon; \phi^*, \beta) \quad (1.10)$$

This recursive definition is called decimation, because we successively integrate out every second field. The description of and estimates on I_n will be obtained inductively.

The integrals (1.9) and (1.10) are oscillatory. Their dominant contributions are extracted by stationary phase. In [5], we describe the construction and estimates that one obtains if, in (1.9) and (1.10), one always ignores contributions far away from the critical point of the (“free part”) of the exponent. We call this the “stationary phase approximation”. To be somewhat more precise, fix a suitable (see [5, Hypothesis I.1]) non negative decreasing function $r(t)$, and assume that one keeps in (1.9) and (1.10) only the integral over fields that

³ Here $\psi(\beta_j, \mathbf{x}_j)$ and $\psi^\dagger(\beta_j, \mathbf{x}_j)$ are annihilation and creation operators, conjugated by $e^{\beta_j(H-\mu N)}$, and \mathbb{T} denotes time ordering.

are within distance $r(2^n \varepsilon)$ from the critical point of the exponent, evaluated at $v \equiv 0$. Then the dominant contribution to $I_n(\varepsilon; \alpha^*, \beta)$ is

$$I_n^{(\text{SP})}(\varepsilon; \alpha^*, \beta) = \mathcal{Z}_{2^n \varepsilon}(\varepsilon)^{|X|} e^{\langle \alpha^*, j(2^n \varepsilon) \beta \rangle + V_{2^n \varepsilon}(\varepsilon; \alpha^*, \beta) + E_{2^n \varepsilon}(\varepsilon; \alpha^*, \beta)}$$

where, for every δ that is an integer multiple of ε ,

$$\begin{aligned} V_\delta(\varepsilon; \alpha^*, \beta) \\ = -\varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \langle [j(\tau) \alpha^*] [j(\delta - \tau - \varepsilon) \beta], v [j(\tau) \alpha^*] [j(\delta - \tau - \varepsilon) \beta] \rangle \end{aligned}$$

and the functions E_δ are recursively defined by

$$\begin{aligned} E_\varepsilon(\varepsilon; \alpha^*, \beta) &= 0 \\ E_{2\delta}(\varepsilon; \alpha^*, \beta) &= E_\delta(\varepsilon; \alpha^*, j(\delta) \beta) + E_\delta(\varepsilon; j(\delta) \alpha^*, \beta) \\ &\quad + \log \frac{\int d\mu_{r(\delta)}(z^*, z) e^{\partial \mathcal{A}_\delta(\varepsilon; \alpha^*, \beta; z^*, z)}}{\int d\mu_{r(\delta)}(z^*, z)} \end{aligned} \quad (1.11)$$

with

$$\begin{aligned} \partial \mathcal{A}_\delta(\varepsilon; \alpha^*, \beta; z_*, z) &= [V_\delta(\varepsilon; \alpha^*, j(\delta) \beta + z) - V_\delta(\varepsilon; \alpha^*, j(\delta) \beta)] \\ &\quad + [V_\delta(\varepsilon; j(\delta) \alpha^* + z_*, \beta) - V_\delta(\varepsilon; j(\delta) \alpha^*, \beta)] \\ &\quad + [E_\delta(\varepsilon; \alpha^*, j(\delta) \beta + z) - E_\delta(\varepsilon; \alpha^*, j(\delta) \beta)] \\ &\quad + [E_\delta(\varepsilon; j(\delta) \alpha^* + z_*, \beta) - E_\delta(\varepsilon; j(\delta) \alpha^*, \beta)] \end{aligned}$$

The normalization constant $\mathcal{Z}_\delta(\varepsilon)$, which is extremely close to one, is chosen so that $E_\delta(\varepsilon; 0, 0) = 0$. See (1.7), (1.8) and (1.9) in [5]. The motivation for this recursion relation comes from a stationary phase construction and is given below and also in the section 2 of [5]. Theorem I.4 of [5] shows that, under suitable assumptions on the function $r(t)$ and the number θ , the logarithm in (1.11) always exists as an analytic function of the fields, and that one can get a good estimate on

$$E_\theta(\alpha^*, \beta) = \lim_{m \rightarrow \infty} E_\theta(2^{-m} \theta; \alpha^*, \beta)$$

To motivate the recursive definition (1.11) of $E_\delta(\varepsilon; \alpha^*, \beta)$ we replace I_n by

$$I_n^{(\text{SP})}(\varepsilon; \alpha^*, \beta) = \mathcal{Z}_{\varepsilon n}(\varepsilon)^{|X|} e^{\langle \alpha^*, j(\varepsilon n) \beta \rangle + V_{\varepsilon n}(\varepsilon; \alpha^*, \beta) + E_{\varepsilon n}(\varepsilon; \alpha^*, \beta)}$$

in the recursion relation (1.10). Here, $\varepsilon n = 2^n \varepsilon$. The resulting integral

$$\begin{aligned} &\int d\mu_{R(\varepsilon)}(\phi^*, \phi) I_n^{(\text{SP})}(\varepsilon; \alpha^*, \phi) I_n^{(\text{SP})}(\varepsilon; \phi^*, \beta) \\ &= \mathcal{Z}_{\varepsilon n}(\varepsilon)^{2|X|} \int d\mu_{R(\varepsilon)}(\phi^*, \phi) e^{\langle \alpha^*, j(\varepsilon n) \phi \rangle + \langle \phi^*, j(\varepsilon n) \beta \rangle} e^{V_{\varepsilon n}(\varepsilon; \alpha^*, \phi) + V_{\varepsilon n}(\varepsilon; \phi^*, \beta)} \\ &\quad \times e^{E_{\varepsilon n}(\varepsilon; \alpha^*, \phi) + E_{\varepsilon n}(\varepsilon; \phi^*, \beta)} \\ &= \mathcal{Z}_{\varepsilon n}(\varepsilon)^{2|X|} \int \left[\prod_{\mathbf{x} \in X} \frac{d\phi^*(\mathbf{x}) d\phi(\mathbf{x})}{2\pi\imath} \chi(|\phi(\mathbf{x})| < R(\varepsilon)) \right] e^{\mathcal{A}(\alpha^*, \beta; \phi^*, \phi)} \end{aligned} \quad (1.12)$$

with

$$\begin{aligned}\mathcal{A}(\alpha^*, \beta; \phi_*, \phi) &= -\langle \phi_*, \phi \rangle + \langle \alpha^*, j(\varepsilon_n) \phi \rangle + \langle \phi_*, j(\varepsilon_n) \beta \rangle \\ &\quad + V_{\varepsilon_n}(\varepsilon; \alpha^*, \phi) + V_{\varepsilon_n}(\varepsilon; \phi_*, \beta) + E_{\varepsilon_n}(\varepsilon; \alpha^*, \phi) + E_{\varepsilon_n}(\varepsilon; \phi_*, \beta)\end{aligned}$$

Here we have written \mathcal{A} as a function of four independent complex fields α^*, β, ϕ_* and ϕ . The activity in (1.12) is obtained by evaluating $\mathcal{A}(\alpha^*, \beta; \phi_*, \phi)$ with $\phi_* = \phi^*$, the complex conjugate of ϕ . The reason for introducing independent complex fields ϕ_* and ϕ lies in the fact that the critical point (with respect to the variables ϕ_*, ϕ) of the quadratic part

$$\begin{aligned}-\langle \phi_*, \phi \rangle + \langle j(\varepsilon_n) \alpha^*, \phi \rangle + \langle \phi_*, j(\varepsilon_n) \beta \rangle \\ = -\langle \phi_* - j(\varepsilon_n) \alpha^*, \phi - j(\varepsilon_n) \beta \rangle + \langle \alpha^*, j(\varepsilon_{n+1}) \beta \rangle\end{aligned}$$

of \mathcal{A} is “not real”. Precisely, the critical point is

$$\phi_*^{\text{crit}} = j(\varepsilon_n) \alpha^* \quad \phi^{\text{crit}} = j(\varepsilon_n) \beta \quad (1.13)$$

and in general $(\phi_*^{\text{crit}})^* \neq \phi^{\text{crit}}$.

It is reasonable to expect that the dominant contribution to the integral in (1.12) comes from the fields $\phi(\mathbf{x})$ in a neighbourhood of the critical point. We now sketch, approximately, the strategy that we use to verify that this is indeed the case. We decompose, for each $\mathbf{x} \in X$, the domain of integration $\{|\phi(\mathbf{x})| < R(\varepsilon)\}$ into the “small field region”, where $\phi^*(\mathbf{x})$ is close to $\phi_*^{\text{crit}}(\mathbf{x})$ and $\phi(\mathbf{x})$ is close to $\phi^{\text{crit}}(\mathbf{x})$, and the “large field region” where this is not the case. Precisely, write

$$\chi(|\phi(\mathbf{x})| < R(\varepsilon)) = \chi_{\mathbf{x}, \text{small}}(\phi(\mathbf{x}), \phi^*(\mathbf{x})) + \chi_{\mathbf{x}, \text{large}}(\phi(\mathbf{x}))$$

where

$$\chi_{\mathbf{x}, \text{small}}(\phi, \phi_*) = \begin{cases} 1 & \text{if } \phi_* = \phi^*, |\phi| < R(\varepsilon) \\ & \text{and } |\phi_* - \phi_*^{\text{crit}}(\mathbf{x})| < r(\varepsilon_n), |\phi - \phi^{\text{crit}}(\mathbf{x})| < r(\varepsilon_n) \\ 0 & \text{otherwise} \end{cases}$$

and

$$\chi_{\mathbf{x}, \text{large}}(\phi) = \chi(|\phi| < R(\varepsilon)) (1 - \chi_{\mathbf{x}, \text{small}}(\phi, \phi^*))$$

We multiply out the products of sums of characteristic functions and get that (1.12) is equal to

$$\begin{aligned}\sum_{\Lambda \subset X} \mathcal{Z}_{\varepsilon_n}(\varepsilon)^{2|X|} \left[\prod_{\mathbf{x} \in \Lambda} \int \frac{d\phi_*(\mathbf{x}) \wedge d\phi(\mathbf{x})}{2\pi i} \chi_{\mathbf{x}, \text{small}}(\phi(\mathbf{x}), \phi_*(\mathbf{x})) \right] \\ \times \left[\prod_{\mathbf{x} \in X \setminus \Lambda} \int \frac{d\phi^*(\mathbf{x}) \wedge d\phi(\mathbf{x})}{2\pi i} \chi_{\mathbf{x}, \text{large}}(\phi(\mathbf{x})) \right] e^{\mathcal{A}(\alpha^*, \beta; \phi_*, \phi)} \Big|_{\substack{\phi_*(\mathbf{x}) = \phi^*(\mathbf{x}) \\ \text{for } \mathbf{x} \in X \setminus \Lambda}}\end{aligned} \quad (1.14)$$

Select a term of (1.14), that is, a subset Λ of X . For points $\mathbf{x} \in \Lambda$, we introduce the “fluctuation variables” $z_*(\mathbf{x})$, $z(\mathbf{x})$ by the change of variables

$$\phi_*(\mathbf{x}) = \phi_*^{\text{crit}}(\mathbf{x}) + z_*(\mathbf{x}), \quad \phi(\mathbf{x}) = \phi^{\text{crit}}(\mathbf{x}) + z(\mathbf{x})$$

For points outside Λ , we do not perform any change of variables. So the fluctuation fields z_*, z are supported on Λ , and the change of variables is

$$\begin{aligned}\phi_* &= \Lambda\phi_*^{\text{crit}} + z_* + \Lambda^c\phi_* = \Lambda j(\varepsilon_n)\alpha^* + z_* + \Lambda^c\phi_* \\ \phi &= \Lambda\phi^{\text{crit}} + z + \Lambda^c\phi = \Lambda j(\varepsilon_n)\beta + z + \Lambda^c\phi\end{aligned}\quad (1.15)$$

Here, we also denote by Λ the operator “multiplication by the characteristic function of the set Λ ”. Under this change of variables the domain of integration

$$\{(\phi(\mathbf{x}), \phi_*(\mathbf{x})) \mid \chi_{\mathbf{x}, \text{small}}(\phi(\mathbf{x}), \phi_*(\mathbf{x})) = 1\}$$

is transformed into

$$\begin{aligned}D(\mathbf{x}) = \left\{ (z_*(\mathbf{x}), z(\mathbf{x})) \mid \begin{array}{l} (\phi_*^{\text{crit}}(\mathbf{x}) + z_*(\mathbf{x}))^* = \phi^{\text{crit}}(\mathbf{x}) + z(\mathbf{x}), \\ |\phi^{\text{crit}}(\mathbf{x}) + z(\mathbf{x})| < R(\varepsilon) \text{ and } |z_*(\mathbf{x})| \leq r(\varepsilon_n), |z(\mathbf{x})| \leq r(\varepsilon_n) \end{array} \right\}\end{aligned}\quad (1.16)$$

Observe that for $(z_*(\mathbf{x}), z(\mathbf{x})) \in D(\mathbf{x})$, in general $z_*(\mathbf{x}) \neq z^*(\mathbf{x})$.

The quadratic part of the effective action

$$\mathcal{A}(\alpha^*, \beta; \Lambda\phi_*^{\text{crit}} + z_* + \Lambda^c\phi_*, \Lambda\phi^{\text{crit}} + z + \Lambda^c\phi)$$

in the new variables is

$$\begin{aligned}-\langle \Lambda j(\varepsilon_n)\alpha^* + z_* + \Lambda^c\phi_*, \Lambda j(\varepsilon_n)\beta + z + \Lambda^c\phi \rangle \\ + \langle \alpha^*, j(\varepsilon_n)(\Lambda j(\varepsilon_n)\beta + z + \Lambda^c\phi) \rangle + \langle j(\varepsilon_n)(\Lambda j(\varepsilon_n)\alpha^* + z_* + \Lambda^c\phi_*), \beta \rangle \\ = -\langle z_*, z \rangle - \langle \Lambda^c\phi_*, \Lambda^c\phi \rangle + Q_\Lambda(\alpha^*, \beta; \Lambda^c\phi_*, \Lambda^c\phi)\end{aligned}$$

where

$$\begin{aligned}Q_\Lambda(\alpha^*, \beta; \Lambda^c\phi_*, \Lambda^c\phi) \\ = \langle \Lambda j(\varepsilon_n)\alpha^*, \Lambda j(\varepsilon_n)\beta \rangle + \langle \alpha^*, j(\varepsilon_n)\Lambda^c\phi \rangle + \langle j(\varepsilon_n)\Lambda^c\phi, \beta \rangle\end{aligned}\quad (1.17)$$

Observe that the terms linear in z_*, z cancelled, because we centered the change of variables at the critical point. Inserting this change of variables in (1.14), we see that (1.12) is equal to

$$\begin{aligned}\mathcal{Z}_{\varepsilon_n}(\varepsilon)^{2|X|} \sum_{\Lambda \subset X} \left[\prod_{\mathbf{x} \in \Lambda} \int \frac{dz_*(\mathbf{x}) \wedge dz(\mathbf{x})}{2\pi i} e^{-z_*(\mathbf{x})z(\mathbf{x})} \right] \\ \times \left[\prod_{\mathbf{x} \in \Lambda^c} \int \frac{d\phi^*(\mathbf{x}) d\phi(\mathbf{x})}{2\pi i} e^{-\phi^*(\mathbf{x})\phi(\mathbf{x})} \chi_{\mathbf{x}, \text{large}}(\phi(\mathbf{x})) \right] e^{\tilde{\mathcal{A}}_\Lambda(\alpha^*, \beta; \phi, z_*, z)}\end{aligned}\quad (1.18)$$

where

$$\begin{aligned}\tilde{\mathcal{A}}_\Lambda(\alpha^*, \beta; \phi, z_*, z) = Q_\Lambda(\alpha^*, \beta; \Lambda^c\phi^*, \Lambda^c\phi) \\ + V_{\varepsilon_n}(\varepsilon; \alpha^*, \Lambda\phi^{\text{crit}} + z + \Lambda^c\phi) \\ + V_{\varepsilon_n}(\varepsilon; \Lambda\phi_*^{\text{crit}} + z_* + \Lambda^c\phi^*, \beta)\end{aligned}$$

$$\begin{aligned}
& + E_{\varepsilon_n}(\varepsilon; \alpha^*, \Lambda \phi^{\text{crit}} + z + \Lambda^c \phi) \\
& + E_{\varepsilon_n}(\varepsilon; \Lambda \phi_*^{\text{crit}} + z_* + \Lambda^c \phi^*, \beta)
\end{aligned} \tag{1.19}$$

If we apply Stokes' Theorem (Lemma A.1 of [5]) with X replaced by Λ , $r = r(\varepsilon_n)$, $\sigma = \sigma_* = 0$ and $\rho = (\phi_*^{\text{crit}})^* - \phi^{\text{crit}}$ to (1.18) we see that (1.12) is equal to

$$\begin{aligned}
& \mathcal{Z}_{\varepsilon_n}(\varepsilon)^{2|X|} \sum_{\Omega \subset \Lambda \subset X} \left[\prod_{\mathbf{x} \in \Omega} \int_{|z(\mathbf{x})| \leq r(\varepsilon_n)} \frac{dz^*(\mathbf{x}) dz(\mathbf{x})}{2\pi i} e^{-|z(\mathbf{x})|^2} \right] \\
& \times \left[\prod_{\mathbf{x} \in \Lambda \setminus \Omega_C(\mathbf{x})} \int \frac{dz_*(\mathbf{x}) \wedge dz(\mathbf{x})}{2\pi i} e^{-z_*(\mathbf{x}) z(\mathbf{x})} \right] \\
& \times \left[\prod_{\mathbf{x} \in \Lambda^c} \int \frac{d\phi^*(\mathbf{x}) d\phi(\mathbf{x})}{2\pi i} e^{-|\phi(\mathbf{x})|^2} \chi_{\mathbf{x}, \text{large}}(\phi(\mathbf{x})) \right] e^{\tilde{\mathcal{A}}_\Lambda(\alpha^*, \beta; \phi, z_*, z)} \Big|_{\substack{z_*(\mathbf{x}) = z^*(\mathbf{x}) \\ \text{for } \mathbf{x} \in \Omega}}
\end{aligned} \tag{1.20}$$

where, for each $\mathbf{x} \in X$, $C(\mathbf{x})$ is a two real dimensional submanifold of \mathbb{C}^2 whose boundary is the union of “circles” $\partial D(\mathbf{x})$ and $\{(z_*(\mathbf{x}), z(\mathbf{x})) \in \mathbb{C}^2 \mid z_*(\mathbf{x}) = z(\mathbf{x}), |z(\mathbf{x})| = r(\varepsilon_n)\}$. For points $\mathbf{x} \in \Omega$, the domain of integration has been moved “back to the reals”.

Whenever $\chi_{\mathbf{x}, \text{large}}(\phi(\mathbf{x})) = 1$ or $(z_*(\mathbf{x}), z(\mathbf{x})) \in C(\mathbf{x})$ for some $\mathbf{x} \in X$, then $\tilde{\mathcal{A}}_\Lambda(\alpha^*, \beta; \phi, z_*, z)$ or $-z_*(\mathbf{x}) z(\mathbf{x})$ has extremely large negative real part and the contribution to the integral is very small. (See the discussion following Theorem 3.35.) For this reason we kept only the term of (1.20) with $\Omega = \Lambda = X$ for the “stationary phase approximation” in [5]. In this case, $Q_X(\alpha^*, \beta; \Lambda^c \phi^*, \Lambda^c \phi) = \langle \alpha^*, j(\varepsilon_{n+1}) \beta \rangle$. Thus, the stationary phase approximation to

$$\int d\mu_{R(\varepsilon)}(\phi^*, \phi) I_n^{(\text{SP})}(\varepsilon; \alpha^*, \phi) I_n^{(\text{SP})}(\varepsilon; \phi^*, \beta)$$

is

$$\begin{aligned}
& \mathcal{Z}_{\varepsilon_n}(\varepsilon)^{2|X|} e^{\langle \alpha^*, j(\varepsilon_{n+1}) \beta \rangle} \\
& \times \left[\prod_{\mathbf{x} \in X} \int_{|z(\mathbf{x})| < r(\varepsilon_n)} \frac{dz^*(\mathbf{x}) \wedge dz(\mathbf{x})}{2\pi i} e^{-|z(\mathbf{x})|^2} \right] e^{\tilde{\mathcal{A}}_X(\alpha^*, \beta; z^*, z)} \\
& = \mathcal{Z}_n^{2|X|} e^{\langle \alpha^*, j(\varepsilon_{n+1}) \beta \rangle} \int d\mu_{r(\varepsilon_n)}(z^*, z) e^{\tilde{\mathcal{A}}_X(\alpha^*, \beta; z^*, z)}
\end{aligned}$$

where

$$\begin{aligned}
\tilde{\mathcal{A}}_X(\alpha^*, \beta; z_*, z) &= V_{\varepsilon_n}(\varepsilon; \alpha^*, \phi^{\text{crit}} + z) + V_{\varepsilon_n}(\varepsilon; \phi_*^{\text{crit}} + z_*, \beta) \\
&+ E_{\varepsilon_n}(\varepsilon; \alpha^*, \phi^{\text{crit}} + z) + E_{\varepsilon_n}(\varepsilon; \phi_*^{\text{crit}} + z_*, \beta)
\end{aligned}$$

By construction

$$\begin{aligned} & V_{\varepsilon_n}(\varepsilon; \alpha^*, \phi^{\text{crit}}) + V_{\varepsilon_n}(\varepsilon; \phi_*^{\text{crit}}, \beta) \\ &= V_{\varepsilon_n}(\varepsilon; \alpha^*, j(\varepsilon_n)\beta) + V_{\varepsilon_n}(\varepsilon; j(\varepsilon_n)\alpha^*, \beta) \\ &= V_{\varepsilon_{n+1}}(\varepsilon; \alpha^*, \beta) \end{aligned}$$

so that

$$\begin{aligned} & V_{\varepsilon_n}(\varepsilon; \alpha^*, \phi^{\text{crit}} + z) + V_{\varepsilon_n}(\varepsilon; \phi_*^{\text{crit}} + z^*, \beta) \\ &= V_{\varepsilon_{n+1}}(\varepsilon; \alpha^*, \beta) + [V_{\varepsilon_n}(\varepsilon; \alpha^*, j(\varepsilon_n)\beta + z) - V_{\varepsilon_n}(\varepsilon; \alpha^*, j(\varepsilon_n)\beta)] \\ &\quad + [V_{\varepsilon_n}(\varepsilon; j(\varepsilon_n)\alpha^* + z^*, \beta) - V_{\varepsilon_n}(\varepsilon; j(\varepsilon_n)\alpha^*, \beta)] \end{aligned}$$

Consequently, the stationary phase approximation to

$$\int d\mu_{R(\varepsilon)}(\phi^*, \phi) I_n^{(\text{SP})}(\varepsilon; \alpha^*, \phi) I_n^{(\text{SP})}(\varepsilon; \phi^*, \beta)$$

can also be written as

$$\begin{aligned} & \mathcal{Z}_{\varepsilon_n}(\varepsilon)^{2|X|} e^{\langle \alpha^*, j(\varepsilon_{n+1})\beta \rangle + V_{\varepsilon_{n+1}}(\varepsilon; \alpha^*, \beta)} \\ & \times e^{E_{\varepsilon_n}(\varepsilon; \alpha^*, j(\varepsilon_n)\beta) + E_{\varepsilon_n}(\varepsilon; j(\varepsilon_n)\alpha^*, \beta)} \int d\mu_{r(\varepsilon_n)}(z^*, z) e^{\partial \mathcal{A}_{\varepsilon_n}(\varepsilon; \alpha^*, \beta; z^*, z)} \end{aligned}$$

This is compatible with (1.11) if we take

$$\mathcal{Z}_{\varepsilon_{n+1}}(\varepsilon) = \mathcal{Z}_{\varepsilon_n}(\varepsilon)^2 \int_{|z|< r(\varepsilon_n)} \frac{dz^* \wedge dz}{2\pi i} e^{-|z|^2} \quad (1.21)$$

It turns out that, for each fixed $\Omega \subset X$, the sum over all sets Λ with $\Omega \subset \Lambda \subset X$ in (1.20) can be written in the form

$$\mathcal{Z}_{\varepsilon_{n+1}}(\varepsilon)^{|X|} e^{\langle \alpha^*, j(\varepsilon_{n+1})\beta \rangle_\Omega} e^{V_{\Omega; \varepsilon_{n+1}}(\varepsilon; \alpha^*, \beta) + E_{\Omega; \varepsilon_{n+1}}(\varepsilon; \alpha^*, \beta)} \varphi_{\Omega; \varepsilon_{n+1}}(\varepsilon; \alpha^*, \beta) \quad (1.22)$$

where $V_{\Omega; \varepsilon_{n+1}}$ and $E_{\Omega; \varepsilon_{n+1}}$ depend only on $\alpha^*(\mathbf{x})$ and $\beta(\mathbf{x})$ with $\mathbf{x} \in \Omega$, and are given by the same formulae as $V_{\varepsilon_{n+1}}$ and $E_{\varepsilon_{n+1}}$ but with the total space X replaced by Ω everywhere, and where $\varphi_{\Omega; \varepsilon_{n+1}}$ is a very small function that encapsulates the sum over Λ and various integral operators.

The sets Λ , resp. Ω , introduced above are called “small field sets” of the first, resp. second, kind. The discussion of the previous paragraph shows that (1.20) is equal to

$$\int d\mu_{R(\varepsilon)}(\phi^*, \phi) I_n^{(\text{SP})}(\varepsilon; \alpha^*, \phi) I_n^{(\text{SP})}(\varepsilon; \phi^*, \beta)$$

and it indicates that $I_{n+1}^{(\text{SP})}(\varepsilon; \alpha^*, \phi)$ is its dominant contribution. The next decimation step would be to consider

$$\begin{aligned} & \int d\mu_{R(\varepsilon)}(\phi^*, \phi) \left[\int d\mu_{R(\varepsilon)}(\phi_1^*, \phi_1) I_n^{(\text{SP})}(\varepsilon; \alpha^*, \phi_1) I_n^{(\text{SP})}(\varepsilon; \phi_1^*, \phi) \right] \\ & \times \left[\int d\mu_{R(\varepsilon)}(\phi_2^*, \phi_2) I_n^{(\text{SP})}(\varepsilon; \phi^*, \phi_2) I_n^{(\text{SP})}(\varepsilon; \phi_2^*, \beta) \right] \end{aligned}$$

Inserting (1.20) and (1.22) for the two integrals in brackets gives a normalization constant times a sum over small field sets Ω_1 and Ω_2 of integrals

$$\int \left[\prod_{\mathbf{x} \in X} \frac{d\phi^*(\mathbf{x}) d\phi(\mathbf{x})}{2\pi i} \chi(|\phi(\mathbf{x})| < R(\varepsilon)) \right] \times e^{\mathcal{A}'(\alpha^*, \beta; \phi^*, \phi)} \varphi_{\Omega_1; \varepsilon_{n+1}}(\varepsilon; \alpha^*, \phi) \varphi_{\Omega_2; \varepsilon_{n+1}}(\varepsilon; \phi^*, \beta) \quad (1.23)$$

with

$$\begin{aligned} \mathcal{A}'(\alpha^*, \beta; \phi_*, \phi) = & -\langle \phi_*, \phi \rangle + \langle \alpha^*, j(\varepsilon_{n+1})\phi \rangle_{\Omega_1} + \langle \phi_*, j(\varepsilon_{n+1})\beta \rangle_{\Omega_2} \\ & + V_{\Omega_1; \varepsilon_{n+1}}(\varepsilon; \alpha^*, \phi) + V_{\Omega_2; \varepsilon_{n+1}}(\varepsilon; \phi_*, \beta) \\ & + E_{\Omega_1; \varepsilon_{n+1}}(\varepsilon; \alpha^*, \phi) + E_{\Omega_2; \varepsilon_{n+1}}(\varepsilon; \phi_*, \beta) \end{aligned}$$

This oscillatory integral is similar to (1.12). The small factors for points $\mathbf{x} \in (X \setminus \Omega_1) \cup (X \setminus \Omega_2)$ mentioned above are so strong that we only have to perform a stationary phase argument for points inside $\Omega_1 \cap \Omega_2$. That is, we would, as in (1.18), write (1.23) as

$$\sum_{\Lambda' \subset \Omega_1 \cap \Omega_2} \left[\prod_{\mathbf{x} \in \Lambda'} \int_{D'(\mathbf{x})} \frac{dz_*(\mathbf{x}) \wedge dz(\mathbf{x})}{2\pi i} e^{-z_*(\mathbf{x})z(\mathbf{x})} \right] \times \left[\prod_{\mathbf{x} \in X \setminus \Lambda'} \int \frac{d\phi^*(\mathbf{x}) d\phi(\mathbf{x})}{2\pi i} e^{-|\phi(\mathbf{x})|^2} \chi'_{\mathbf{x}, \text{large}}(\phi(\mathbf{x})) \right] e^{\tilde{\mathcal{A}}'(\alpha^*, \beta; z_*, z)} f'(\alpha^*, \beta; z_*, z)$$

where $D'(\mathbf{x})$ and $\chi'_{\mathbf{x}, \text{large}}$ are defined as were $D(\mathbf{x})$ and $\chi_{\mathbf{x}, \text{large}}$, but with ε_n replaced by ε_{n+1} , and where $\tilde{\mathcal{A}}'(\alpha^*, \beta; \phi, z_*, z)$ and $f'(\alpha^*, \beta; \phi, z_*, z)$ are obtained using the change of variables around the critical point of the quadratic form.

The next step would be to again apply Stokes' Theorem for the variables $z_*(\mathbf{x}), z(\mathbf{x})$ with $\mathbf{x} \in \Lambda$. Here, a small technical difficulty arises. Namely, the factor $f'(\alpha^*, \beta; z_*, z)$ in the integrand need not be analytic in z_*, z and the version of Stokes' Theorem presented in Appendix A of [5] cannot be applied directly. To circumvent this difficulty, we introduce a constant $c > 0$ and define the cut-off propagator

$$j_c(\tau)(\mathbf{x}, \mathbf{y}) = j(\tau)(\mathbf{x}, \mathbf{y}) \cdot \begin{cases} 1 & \text{if } d(\mathbf{x}, \mathbf{y}) \leq c \\ 0 & \text{if } d(\mathbf{x}, \mathbf{y}) > c \end{cases} \quad (1.24)$$

where $d(\mathbf{x}, \mathbf{y})$ is the distance on the torus X , replace $j(t)$ by $j_c(t)$ in the formulae above and control the error terms. We apply Stokes' theorem only for points $\mathbf{x} \in \Lambda'$ that have distance at least c from $(X \setminus \Omega_1) \cup (X \setminus \Omega_2)$. That is, we apply Stokes' theorem only in

$$\Lambda = \{1_{\mathbf{x} \in \Lambda'} \mid d(\mathbf{x}, \mathbf{y}) \geq c \text{ for all } \mathbf{y} \in (X \setminus \Omega_1) \cup (X \setminus \Omega_2)\}$$

With this construction, the analogue of $f'(\alpha^*, \beta; z_*, z)$ will not depend on the variables $z_*(\mathbf{x}), z(\mathbf{x})$ with $\mathbf{x} \in \Lambda$. The integrals for points in the “corridor”

$$\{\mathbf{x} \in \Lambda' \mid d(\mathbf{x}, \mathbf{y}) \leq c \text{ for some } \mathbf{y} \in (X \setminus \Omega_1) \cup (X \setminus \Omega_2)\}$$

can again be controlled by the small factors from the points $\mathbf{y} \in X \setminus \Lambda'$. This modification leads to the somewhat more involved formulae described in Sect. 2 below.

Obviously we want to iterate the procedure described above, starting with $n = 1$. In this way one creates a “hierarchy” of small field sets of the first and second kind. In Definition 2.4, this is made more precise, and enriched with more sets that are used to describe the various “large field conditions”.

The main results of this paper are estimates on all of the functions appearing in the functional integral representation of the partition function. For these estimates we use the norms developed in [3, 4]. One of the simplest versions of such a norm is defined as follows. Let $\kappa, m > 0$. We define the norm of the power series

$$f(\alpha^*, \beta) = \sum_{k, \ell \geq 0} \sum_{\substack{\mathbf{x}_1, \dots, \mathbf{x}_k \in X \\ \mathbf{y}_1, \dots, \mathbf{y}_\ell \in X}} \times a(\mathbf{x}_1, \dots, \mathbf{x}_k; \mathbf{y}_1, \dots, \mathbf{y}_\ell) \alpha(\mathbf{x}_1)^* \cdots \alpha(\mathbf{x}_k)^* \beta(\mathbf{y}_1) \cdots \beta(\mathbf{y}_\ell)$$

(with the coefficients $a(\mathbf{x}_1, \dots, \mathbf{x}_k; \mathbf{y}_1, \dots, \mathbf{y}_\ell)$ invariant under permutations of $\mathbf{x}_1, \dots, \mathbf{x}_k$ and of $\mathbf{y}_1, \dots, \mathbf{y}_\ell$) to be

$$\|f(\alpha^*, \beta)\|_{\kappa, m} = \sum_{k, \ell \geq 0} \max_{\mathbf{x} \in X} \max_{1 \leq i \leq k + \ell} \sum_{\substack{(\vec{\mathbf{x}}, \vec{\mathbf{y}}) \in X^k \times X^\ell \\ (\vec{\mathbf{x}}, \vec{\mathbf{y}})_i = \mathbf{x}}} \kappa^{k + \ell} e^{m\tau(\vec{\mathbf{x}}, \vec{\mathbf{y}})} |a(\vec{\mathbf{x}}; \vec{\mathbf{y}})| \quad (1.25)$$

where $\tau(\vec{\mathbf{x}}, \vec{\mathbf{y}})$ is the minimal length of a tree which contains vertices at the points of the set $\{\mathbf{x}_1, \dots, \mathbf{x}_k, \mathbf{y}_1, \dots, \mathbf{y}_\ell\}$.

Our main results, the description of and bounds on I_θ , are stated in Sect. 2.6 (Theorems 2.16 and 2.18). The subsections of Sect. 2 introduce the notation used in these Theorems. Section 3 gives an outline of the proof and contains discussions which might illuminate the concepts introduced in Sect. 2. The proof of Theorem 2.16 is split over Sects. 3–5. The proof of Theorem 2.18 is split over Sects. 3 and 6.

2. Formulation of the Main Theorem

Our main result is a representation of the “effective density” I_θ of (1.6) as a sum over subsets Ω of X . For each $\Omega \subset X$ the corresponding summand is the product of

- the exponential of a function that is analytic in the fields and that depends only on Ω .
- A function that involves all possible “hierarchies” (collections of large and small field sets—see Definition 2.4) that lead to Ω , which is not necessarily analytic, but can be proven to be very small (unless $\Omega = X$). Indeed, if $\Omega^c \neq \emptyset$, this function is $O(\|v\|^n)$ (this norm will be defined in (2.5)) for all $n \in \mathbb{N}$ and also decreases exponentially quickly with $|\Omega^c|$.

The first factor will be called the “small field part”. It is described in Sect. 2.1 below.

2.1. The Small Field Parts

Let Ω be a subset of X . For any kernel $w(\mathbf{x}, \mathbf{y})$ on X denote by

$$w_\Omega(\mathbf{x}, \mathbf{y}) = \begin{cases} w(\mathbf{x}, \mathbf{y}) & \text{if } \mathbf{x}, \mathbf{y} \in \Omega \\ 0 & \text{otherwise} \end{cases}$$

its truncation to Ω . For any $t > 0$, set

$$\begin{aligned} j_{(\Omega)}(t) &= \mathbb{1}_\Omega + \sum_{\ell=1}^{\infty} \frac{1}{\ell!} (-t(h - \mu)_\Omega)^\ell \\ &= e^{-t(h - \mu)_\Omega} - \mathbb{1}_{X \setminus \Omega} \end{aligned}$$

and

$$j_{(\Omega), \mathfrak{c}}(t)(\mathbf{x}, \mathbf{y}) = \begin{cases} j_{(\Omega)}(t)(\mathbf{x}, \mathbf{y}) & \text{if } d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c} \\ 0 & \text{if } d(\mathbf{x}, \mathbf{y}) > \mathfrak{c} \end{cases}$$

For each $0 < t \leq \frac{1}{2kT}$ and each analytic function $V(\alpha_*, \beta)$, that depends only on the variables $\alpha_*(\mathbf{x}), \beta(\mathbf{x})$ with $\mathbf{x} \in \Omega$, consider the formal renormalization group operator $\mathfrak{R}_{\Omega; t}(V; \cdot, \cdot)$ at scale t with “principal interaction V ” that is defined as the following generalization of (1.11). It associates to any two analytic functions⁴ $f_1(\alpha_*, \beta), f_2(\alpha_*, \beta)$ that depend only on the variables $\alpha_*(\mathbf{x}), \beta(\mathbf{x})$ with $\mathbf{x} \in \Omega$ the function

$$\begin{aligned} &\mathfrak{R}_{\Omega; t}(V; f_1, f_2)(\alpha_*, \beta) \\ &= f_1(\alpha_*, j_{(\Omega), \mathfrak{c}}(t)\beta) + f_2(j_{(\Omega), \mathfrak{c}}(t)\alpha_*, \beta) + \log \frac{\int d\mu_{\Omega, r(t)}(z^*, z) e^{\mathcal{A}(\alpha_*, \beta; z^*, z)}}{\int d\mu_{\Omega, r(t)}(z^*, z)} \\ &\quad - \langle [j_{(\Omega)}(t) - j_{(\Omega), \mathfrak{c}}(t)]\alpha_*, [j_{(\Omega)}(t) - j_{(\Omega), \mathfrak{c}}(t)]\beta \rangle \\ &\quad + V(\alpha_*, j_{(\Omega), \mathfrak{c}}(t)\beta) - V(\alpha_*, j_{(\Omega)}(t)\beta) \\ &\quad + V(j_{(\Omega), \mathfrak{c}}(t)\alpha_*, \beta) - V(j_{(\Omega)}(t)\alpha_*, \beta) \end{aligned}$$

where $\mathcal{A}(\alpha_*, \beta; z_*, z)$ is

$$\begin{aligned} &[f_1(\alpha_*, z + j_{(\Omega), \mathfrak{c}}(t)\beta) - f_1(\alpha_*, j_{(\Omega), \mathfrak{c}}(t)\beta)] \\ &\quad + [f_2(z_* + j_{(\Omega), \mathfrak{c}}(t)\alpha_*, \beta) - f_2(j_{(\Omega), \mathfrak{c}}(t)\alpha_*, \beta)] \\ &\quad + \langle [j_{(\Omega)}(t) - j_{(\Omega), \mathfrak{c}}(t)]\alpha_*, z \rangle + \langle z_*, [j_{(\Omega)}(t) - j_{(\Omega), \mathfrak{c}}(t)]\beta \rangle \\ &\quad + [V(\alpha_*, z + j_{(\Omega), \mathfrak{c}}(t)\beta) - V(\alpha_*, j_{(\Omega), \mathfrak{c}}(t)\beta)] \\ &\quad + [V(z_* + j_{(\Omega), \mathfrak{c}}(t)\alpha_*, \beta) - V(j_{(\Omega)}, \mathfrak{c}(t)\alpha_*, \beta)] \end{aligned}$$

and

$$d\mu_{\Omega, r}(z^*, z) = \prod_{\mathbf{x} \in \Omega} \frac{dz(\mathbf{x})^* \wedge dz(\mathbf{x})}{2\pi i} e^{-z(\mathbf{x})^* z(\mathbf{x})} \chi(|z(\mathbf{x})| < r)$$

⁴ We introduce the complex field α_* in order to clarify the analyticity properties of the functions f_1, f_2 . We shall usually evaluate α_* at α^* .

As “principal interaction” V in the renormalization group map, we use the dominant part of the interaction at the corresponding scale. Precisely, for every δ that is an integer multiple of ε , define

$$\begin{aligned} V_{\Omega,\delta}(\varepsilon; \alpha_*, \beta) &= -\varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta]} \langle [j_{(\Omega)}(\tau)\alpha_*] [j_{(\Omega)}(\delta-\tau-\varepsilon)\beta], v_\Omega [j_{(\Omega)}(\tau)\alpha_*] [j_{(\Omega)}(\delta-\tau-\varepsilon)\beta] \rangle \\ &\quad (2.1) \end{aligned}$$

Define recursively

$$\begin{aligned} \mathcal{D}_{\Omega;0}(\varepsilon; \alpha_*, \beta) &= 0 \\ \mathcal{D}_{\Omega;n+1}(\varepsilon; \alpha_*, \beta) &= \mathfrak{R}_{\Omega;2^n\varepsilon}(V_{\Omega;2^n\varepsilon}(\varepsilon; \cdot, \cdot); \mathcal{D}_{\Omega;n}(\varepsilon; \cdot, \cdot), \mathcal{D}_{\Omega;n}(\varepsilon; \cdot, \cdot)) \end{aligned}$$

If θ is small enough, this recursion defines analytic functions $\mathcal{D}_{\Omega;n}(\varepsilon; \alpha_*, \beta)$, when $2^n\varepsilon \leq \theta$, and furthermore

$$\mathcal{D}_{\Omega;\theta}(\alpha_*, \beta) = \lim_{m \rightarrow \infty} \mathcal{D}_{\Omega;m}(2^{-m}\theta; \alpha_*, \beta) \quad (2.2)$$

exists and fulfills the estimates of Proposition 2.1 and Theorem 2.16 below. Our representation of the effective density will be of the form

$$\begin{aligned} I_\theta(\alpha^*, \beta) &= \sum_{\Omega \subset X} \mathcal{Z}_\theta^{|\Omega|} e^{\langle \alpha^*, j_{(\Omega)}(\theta)\beta \rangle + V_{\Omega;\theta}(\alpha^*, \beta) + \mathcal{D}_{\Omega;\theta}(\alpha^*, \beta)} \chi_\theta(\Omega; \alpha, \beta) \varphi_{\Omega;\theta}(\alpha^*, \beta) \\ &\quad (2.3) \end{aligned}$$

where the normalization constant \mathcal{Z}_θ , which will be defined in Lemma 2.7, is very close to one,

$$\begin{aligned} V_{\Omega;\theta}(\alpha_*, \beta) &= \lim_{m \rightarrow \infty} V_{\Omega;\theta}(2^{-m}\theta; \alpha_*, \beta) \\ &= - \int_0^\theta dt \langle [j_{(\Omega)}(t)\alpha_*] [j_{(\Omega)}(\theta-t)\beta], v_\Omega [j_{(\Omega)}(t)\alpha_*] [j_{(\Omega)}(\theta-t)\beta] \rangle \\ &\quad (2.4) \end{aligned}$$

and $\chi_\theta(\Omega; \alpha, \beta)$ implements the small field conditions for the set Ω (see Theorem 2.16).

For our construction to work, we need exponential decay of the interaction v . Precisely, we assume that there is a “mass” $m > 0$ such that

$$\|v\| = \sup_{\mathbf{x} \in X} \sum_{\mathbf{y} \in X} e^{5m d(\mathbf{x}, \mathbf{y})} |v(\mathbf{x}, \mathbf{y})| \quad (2.5)$$

is finite.

Proposition 2.1. *There are constants $\text{const}, \kappa > 0$ such that for all sufficiently small θ and interactions v , and all $\Omega \subset X$, the function $\mathcal{D}_{\Omega;\theta}(\alpha_*, \beta)$ of (2.2)*

is well defined,⁵ and obeys

$$\|\mathcal{D}_{\Omega;\theta}\|_{\kappa,m} \leq \text{const } \|v\|$$

Here, we use the norm (1.25).

The proof of this Proposition is much the same as the proof of [5, Theorem I.4]. It is also a consequence of our complete analysis of I_θ in Theorem 2.16. There, we shall also state more properties of $\mathcal{D}_{\Omega;\theta}$.

2.2. Decomposition of Space into Large and Small Field Subsets

As indicated in the introduction, the functions φ_Ω of (2.3) are expressed in terms of “hierarchies” of large and small field subsets of X . Recall that we have chosen a function $r(t)$ that measures the size of the neighbourhood of a critical point at scale t in which Stokes’ argument is applied to move the domain of integration “back to the reals”.

We fix, in addition to the functions $R(t)$ and $r(t)$ of Sect. 1, another decreasing positive function $R'(t)$. If we are at scale t and, for some point \mathbf{x} , one of the fields $\alpha^*(\mathbf{x})$ or $\beta(\mathbf{x})$ is larger than $R(t)$ we shall get a controllable small factor. This leads us to introduce a further decomposition of X where the corresponding large field sets will be denoted by P_α and P_β , respectively. Also large values of the spatial gradients of the fields give rise to small factors. Spatial gradients are controlled in terms of the function $R'(t)$. The corresponding large field sets will be sets P'_α and P'_β of bonds in the lattice X . Similarly, large time derivatives cause small factors. The corresponding large field sets will be denoted by the letter Q . The sets where, in the application of Stokes’ theorem, the “side” $C(\mathbf{x})$ of the cylinder is chosen as the domain of integration, will be labelled by R .

All the sets in our construction should be separated by corridors. The width of these corridors is scale dependent and will be measured by a function $c(t)$. Later, in (2.18), we will make specific choices of all these functions. Their properties will be proven in Appendix F. Here, we concentrate on the purely set theoretic picture.

As indicated above, we will have to deal with bonds of the lattice X . We denote by X^* the set of all bonds (i.e. pairs of neighbouring points). Furthermore, for a subset Y of X , we set

$$\begin{aligned} Y^* &= \{\mathbf{x} \in X \mid \mathbf{x} \text{ is connected by a bond to a point of } Y\} \\ Y^* &= \{b \in X^* \mid b \text{ has at least one end point in } Y\} \end{aligned}$$

For $P' \subset X^*$, we denote by $\text{supp } P'$ the set of all end points of all bonds in P' .

The large and small field sets will be conveniently indexed by intervals whose length is related to the scale at which they were created.

Notation 2.2. (i) A decimation point for the interval $[0, \delta]$ is a point $\tau = \frac{p}{2^k} \delta$ with integers $k \geq 0$ and $0 \leq p \leq 2^k$.

(ii) A decimation interval in $[0, \delta]$ is an interval of the form $\mathcal{J} = [\frac{p}{2^k} \delta, \frac{p+1}{2^k} \delta]$ with $k \geq 0$ and $0 \leq p \leq 2^k - 1$.

⁵ That is, it is possible to take the logarithms involved and the limit.

- (iii) For a decimation point $\tau \neq 0, \delta$, there is a unique $k \geq 1$ such that $\tau \in \frac{\delta}{2^k} \mathbb{Z} \setminus \frac{\delta}{2^{k-1}} \mathbb{Z}$. This number k is called the decimation index $\mathfrak{d}(\tau)$ of τ in $[0, \delta]$. We also set $\mathfrak{d}(0) = \mathfrak{d}(\delta) = 0$. We call $s = 2^{-\mathfrak{d}(\tau)}\delta$ the scale of τ .

The unique decimation interval that has τ as its midpoint is

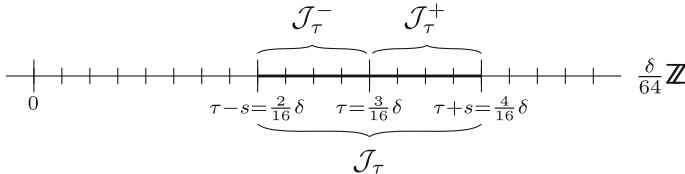

$$\mathcal{J}_\tau = [\tau - s, \tau + s]$$

Its left and right halves

$$\mathcal{J}_\tau^- = [\tau - s, \tau], \quad \mathcal{J}_\tau^+ = [\tau, \tau + s]$$

are also decimation intervals.

Example 2.3. For example, if $\tau = \frac{3}{16}\delta$, then $\tau \in \frac{\delta}{2^4} \mathbb{Z} \setminus \frac{\delta}{2^3} \mathbb{Z}$ so that $\mathfrak{d}(\tau) = 4$, $s = \frac{\delta}{16}$, $\mathcal{J}_\tau = [\frac{2}{16}\delta, \frac{4}{16}\delta]$, $\mathcal{J}_\tau^- = [\frac{2}{16}\delta, \frac{3}{16}\delta]$ and $\mathcal{J}_\tau^+ = [\frac{3}{16}\delta, \frac{4}{16}\delta]$.

If τ is a decimation point, then the field α_τ appears as an integration variable in the construction of $I_m(2^{-m}\delta; \alpha^*, \beta)$ for all $m \geq \mathfrak{d}(\tau)$. When this variable is integrated, large and small field sets are introduced. We choose to label them by \mathcal{J}_τ , because \mathcal{J}_τ carries the information about τ , and through its length, also about the scale $2^{-\mathfrak{d}(\tau)}\delta$.

Definition 2.4 (Hierarchy). A hierarchy, \mathfrak{S} , for scale $0 < \delta \leq \frac{1}{kT}$, of large and small field sets is a collection

- o $P_\alpha(\mathcal{J}), P_\beta(\mathcal{J}), Q(\mathcal{J})$ of subsets of X , called large field sets of the first kind
- o $P'_\alpha(\mathcal{J}), P'_\beta(\mathcal{J})$ of subsets of X^* , also called large field sets of the first kind
- o $R(\mathcal{J})$ of subsets of X , called large field sets of the second kind
- o $\Lambda(\mathcal{J}), \Omega(\mathcal{J})$ of subsets of X , called the small field sets of the first and second kind respectively.

These sets

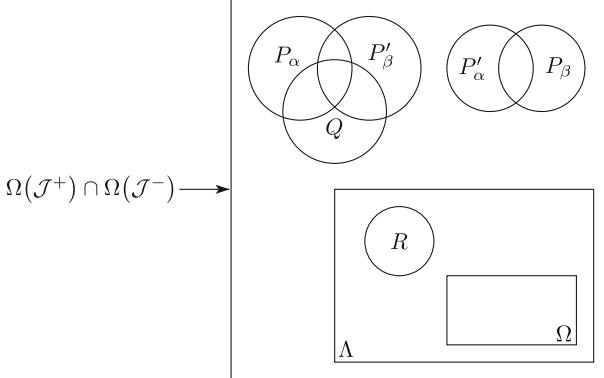

- o are indexed by all decimation intervals \mathcal{J} in $[0, \delta]$,
- o and obey the following “large/small field set” compatibility conditions. Let \mathcal{J} be a decimation interval in $[0, \delta]$, and \mathcal{J}^- and \mathcal{J}^+ be its left and right halves. Let $t = \text{length}(\mathcal{J}^+) = \text{length}(\mathcal{J}^-) = \frac{1}{2} \text{length}(\mathcal{J})$. Then
 - $P_\alpha(\mathcal{J}), P_\beta(\mathcal{J}) \subset \Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+)$ and $P'_\alpha(\mathcal{J}), P'_\beta(\mathcal{J}) \subset (\Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+))^*$ and $Q(\mathcal{J}) \subset (\Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+))^*$.
 - $\Lambda(\mathcal{J}) = \{x \in X \mid d(x, P_\alpha(\mathcal{J}) \cup P_\beta(\mathcal{J}) \cup Q(\mathcal{J})) > c(t),$

$$d(x, \text{supp } P'_\alpha(\mathcal{J}) \cup \text{supp } P'_\beta(\mathcal{J})) > c(t),$$

$$d(x, \Omega(\mathcal{J}^-)^c \cup \Omega(\mathcal{J}^+)^c) > c(t)\}$$
 - $R(\mathcal{J}) \subset \Lambda(\mathcal{J})$
 - $\Omega(\mathcal{J}) = \{x \in \Lambda(\mathcal{J}) \mid d(x, R(\mathcal{J})) > c(t)\}$

- There is a non-negative integer k_0 such that $\Lambda(\mathcal{J}) = \Omega(\mathcal{J}) = X$, and consequently $P_\alpha(\mathcal{J}) = P_\beta(\mathcal{J}) = P'_\alpha(\mathcal{J}) = P'_\beta(\mathcal{J}) = Q(\mathcal{J}) = R(\mathcal{J}) = \emptyset$, for all decimation intervals of lengths $2^{-k}\delta$ with $k \geq k_0$. The smallest such k_0 is called $\text{depth}(\mathfrak{S})$.

The following figure schematically illustrates the set relations amongst the various large and small field sets at a single scale, but is not metrically accurate.

Notation 2.5. Let \mathfrak{S} be a hierarchy of scale δ .

- We also denote, for example, $\Lambda(\mathcal{J})$ by $\Lambda_{\mathfrak{S}}(\mathcal{J})$, when we wish to emphasize its dependence on the hierarchy \mathfrak{S} .
- The “summits” $\Omega_{\mathfrak{S}}([0, \delta])$ and $\Lambda_{\mathfrak{S}}([0, \delta])$ are also denoted $\Omega_{\mathfrak{S}}$ and $\Lambda_{\mathfrak{S}}$, respectively.
- The decimation points, resp. intervals, in $[0, \delta]$ are called the decimation points, resp. intervals, for the hierarchy \mathfrak{S} .
- For a decimation point τ , we set

$$\Lambda_\tau = \begin{cases} \Lambda(\mathcal{J}_\tau) & \text{if } \tau \neq 0, \delta \\ \emptyset & \text{if } \tau = 0, \delta \end{cases}$$

Here, \mathcal{J}_τ is the unique decimation interval centered on τ . See Notation 2.2. Observe that

$$\Lambda_\tau = X \quad \text{if } \mathfrak{d}(\tau) > \text{depth}(\mathfrak{S})$$

Remark 2.6. It follows from the definition that, for decimation intervals $\mathcal{J}' \subsetneqq \mathcal{J}$

- $\Lambda(\mathcal{J}') \supset \Omega(\mathcal{J}') \supset \Lambda(\mathcal{J}) \supset \Omega(\mathcal{J})$
- $\Omega(\mathcal{J}')^c \cup P_\alpha(\mathcal{J}) \cup P_\beta(\mathcal{J}) \cup \text{supp } P'_\alpha(\mathcal{J}) \cup \text{supp } P'_\beta(\mathcal{J}) \cup Q(\mathcal{J}) \subset \Lambda(\mathcal{J})^c$ and $\Lambda(\mathcal{J})^c \cup \mathcal{R}(\mathcal{J}) \subset \Omega(\mathcal{J})^c$ and indeed if, $\emptyset \neq \Omega(\mathcal{J}') \neq X$, then $d(\Omega(\mathcal{J}')^c, \Omega(\mathcal{J})) \geq d(\Omega(\mathcal{J}')^c, \Lambda(\mathcal{J})) > \mathfrak{c}(|\mathcal{J}'|)$. Since X is a finite set and $\mathfrak{c}(t) \geq 1$ for all t , it then follows that there is a natural number k_X with the property that
- if \mathcal{J}' is a decimation interval with $\Omega(\mathcal{J}') \neq X$, then $\Omega(\mathcal{J}) = \Lambda(\mathcal{J}) = P_\alpha(\mathcal{J}) = P_\beta(\mathcal{J}) = P'_\alpha(\mathcal{J}) = P'_\beta(\mathcal{J}) = Q(\mathcal{J}) = R(\mathcal{J}) = \emptyset$ for all decimation intervals $\mathcal{J} \supsetneqq \mathcal{J}'$ with $\frac{|\mathcal{J}|}{|\mathcal{J}'|} \geq 2^{k_X}$.

In particular, for each $\delta > 0$, there are only finitely many hierarchies \mathfrak{S} for scale δ that have $\Omega_{\mathfrak{S}}([0, \delta]) \neq \emptyset$. Each such hierarchy has depth at most k_X .

2.3. The Large Field Integral Operator

The functions $\varphi_{\Omega; \theta}(\alpha^*, \beta)$ of (2.3) will be written as a sum

$$\varphi_{\Omega; \theta} = \sum_{\substack{\mathfrak{S} \text{ hierarchy for scale } \theta \\ \Omega_{\mathfrak{S}}([0, \theta]) = \Omega}} \varphi_{\mathfrak{S}; \theta} \quad (2.6)$$

Each of the functions $\varphi_{\mathfrak{S}; \theta}(\alpha^*, \beta)$ will be an integral over variables in the large field regions determined by the hierarchy \mathfrak{S} .

As we saw in the discussion of the stationary phase approximation in Sect. 1, we shall need normalization constants in the representation (2.3) of the effective densities. They should obey the recursion relation (1.21). We make a particular choice of normalization constants \mathcal{Z}_δ , by prescribing their asymptotic behaviour as $\delta \rightarrow 0$. This choice is made to simplify the proof that $\lim_{m \rightarrow \infty} I_m(2^{-m}\theta; \dots)$ exists.

Lemma 2.7. *There is a unique function $\delta \in (0, 1) \rightarrow \mathcal{Z}_\delta \in (0, 1)$ that obeys*

$$\mathcal{Z}_{2\delta} = \mathcal{Z}_\delta^2 \int_{|z| \leq r(\delta)} \frac{dz^* \wedge dz}{2\pi i} e^{-|z|^2} \quad \lim_{\varepsilon \rightarrow 0+} \frac{1}{\varepsilon} \log \mathcal{Z}_\varepsilon = 0$$

Furthermore,

$$|\ln \mathcal{Z}_\delta| \leq e^{-r(\delta)^2}$$

This lemma is proven in Appendix C.

The large field integral operator arises from the “left over” fields in the decimation procedure outlined in and after (1.12). The decimation steps are indexed by decimation points $\tau \in (0, \delta)$. When the field ϕ is being integrated out in such a step, one gets, as in (1.20), a sum over pairs of small field sets $\Omega(\mathcal{J}_\tau) \subset \Lambda(\mathcal{J}_\tau)$ and

- (i) the fluctuation integral with variables $|z(\mathbf{x})| \leq r(\frac{1}{2}|\mathcal{J}_\tau|)$ for $\mathbf{x} \in \Omega(\mathcal{J}_\tau)$
- (ii) the integral over the Stokes’ cylinders $C(\mathbf{x})$, $\mathbf{x} \in \Lambda(\mathcal{J}_\tau) \setminus \Omega(\mathcal{J}_\tau)$, with the variables $z_*(\mathbf{x})$, $z(\mathbf{x})$
- (iii) the “large field integral of the first kind” for points $x \in \Lambda(\mathcal{J}_\tau)^c$, with variables $\phi(\mathbf{x})$ which violated at least one of the small field conditions of the first kind.

In the decimation step, the fluctuation integral (i) is performed, while the integrals (ii) and (iii) are not performed explicitly and form part of the large field integral operator. For labelling purposes, the integration variables of (ii) are renamed $z_{*\tau}(\mathbf{x})$ and $z_\tau(\mathbf{x})$, and the integration variables of (iii) are renamed $\alpha_\tau(\mathbf{x})$. We call the fields $\alpha_\tau(\mathbf{x})$, $\mathbf{x} \in \Lambda(\mathcal{J}_\tau)^c$, and $z_{*\tau}(\mathbf{x})$, $z_\tau(\mathbf{x})$, $\mathbf{x} \in \Lambda(\mathcal{J}_\tau) \setminus \Omega(\mathcal{J}_\tau)$, the residual fields. The integral operator associated to a full hierarchy, \mathfrak{S} , is the concatenation of all integral operators associated to all decimation points τ for the hierarchy with decimation index $\mathfrak{d}(\tau) < \text{depth}(\mathfrak{S})$.

The definition of the integral operators involves the constant c and the cut-off propagator $j_c(\tau)$ of (1.24).

Definition 2.8. (Large field integral operator). Let \mathfrak{S} be a hierarchy for scale $\delta > 0$.

- (i) Let τ be a decimation point for \mathfrak{S} with $\mathfrak{d}(\tau) \leq \text{depth}(\mathfrak{S})$. The scale of τ is $s = 2^{-\mathfrak{d}(\tau)}\delta$, and its corresponding decimation interval is $\mathcal{J} = \mathcal{J}_\tau = [\tau_\ell, \tau_r]$ with $\tau_\ell = \tau - s$ and $\tau_r = \tau + s$. The integral operator associated to the decimation point τ is

$$\begin{aligned} \mathcal{I}_{(\mathcal{J}; \alpha^*, \beta)} &= \mathcal{I}_{(\mathcal{J}, \mathfrak{S}; \alpha^*, \beta)} \\ &= \left(\prod_{\mathbf{x} \in \Lambda(\mathcal{J}) \setminus (R(\mathcal{J}) \cup \Omega(\mathcal{J}))} \int_{|z_\tau(\mathbf{x})| \leq r(s)} \frac{dz_\tau(\mathbf{x})^* \wedge dz_\tau(\mathbf{x})}{2\pi i} e^{-z_\tau(\mathbf{x})^* z_\tau(\mathbf{x})} \right) \\ &\quad \times \left(\prod_{\mathbf{x} \in R(\mathcal{J})_{C_s(\mathbf{x}; \alpha^*, \beta)}} \int \frac{dz_{*\tau}(\mathbf{x}) \wedge dz_\tau(\mathbf{x})}{2\pi i} e^{-z_{*\tau}(\mathbf{x}) z_\tau(\mathbf{x})} \right) \\ &\quad \times \left(\prod_{\mathbf{x} \in X \setminus \Lambda(\mathcal{J})} \int \frac{d\alpha_\tau(\mathbf{x})^* \wedge d\alpha_\tau(\mathbf{x})}{2\pi i} \right) \chi_{\mathcal{J}}(\alpha, \alpha_\tau, \beta) \\ &\quad \times \mathcal{Z}_s^{|\Omega(\mathcal{J}^-) \setminus \Omega(\mathcal{J})|} \mathcal{Z}_s^{|\Omega(\mathcal{J}^+) \setminus \Omega(\mathcal{J})|} \end{aligned}$$

Here, for each $\mathbf{x} \in R(\mathcal{J})$, $C_s(\mathbf{x}; \alpha^*, \beta)$ is a two real dimensional surface in

$$\{(z_*, z) \in \mathbb{C}^2 \mid |z_*|, |z| < R(s)\}$$

whose boundary is the union of the circle $\{(z_*, z) \in \mathbb{C}^2 \mid z_*^* = z, |z| = r(s)\}$ and the curve bounding⁶

$$\begin{aligned} \{(z_*, z) \in \mathbb{C}^2 \mid &|z_* - ([1 - j_c(s)]\alpha^*)(\mathbf{x})| \leq r(s), \\ &|z - ([1 - j_c(s)]\beta)(\mathbf{x})| \leq r(s), z_*^* - z = (j_c(s)[\beta - \alpha])(\mathbf{x})\} \end{aligned} \quad (2.7)$$

Analyticity and Stokes' theorem ensures the action of the integral operator is independent of the choice of the surfaces $C_s(\mathbf{x}; \alpha^*, \beta)$. See [5, §II and Lemma A.1]. We choose $C_s(\mathbf{x}; \alpha^*, \beta)$ to depend only on the values of the fields α and β at points $\mathbf{y} \in X$ with $d(\mathbf{x}, \mathbf{y}) \leq c$. This is possible because the boundary curves have the same property, since $j_c(s)$ has range c .

The characteristic function $\chi_{\mathcal{J}}(\alpha, \alpha_\tau, \beta)$ implementing the large and small field conditions of the first kind is given in Appendix A.

If $\Omega(\mathcal{J}) = X$, we set $\mathcal{I}_{(\mathcal{J}; \alpha^*, \beta)} = 1$.

- (ii) The integral operator associated to the hierarchy \mathfrak{S} is

$$\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} = \prod_{n=0, \dots, \text{depth}(\mathfrak{S})} \prod_{\substack{\text{decimation intervals} \\ \mathcal{J} = [\tau_\ell, \tau_r] \subset [0, \delta] \\ \text{of length } 2^{-n}\delta}} \mathcal{I}_{(\mathcal{J}; \alpha_{\tau_\ell}^*, \alpha_{\tau_r})}$$

⁶ The set (2.7) is a technically precise variant of (1.16).

Observe that the arguments $\alpha_{\tau_\ell}^*, \alpha_{\tau_r}$ in each $\mathcal{I}_{(\mathcal{J}; \alpha_{\tau_\ell}^*, \alpha_{\tau_r})}$ are the integration variables for an integral appearing to its left. This is the reason for ordering the product $\prod_{n=0, \dots, \text{depth}(\mathfrak{S})}$ with larger values of n to the right.

(iii) We will bound, in Theorem 2.18, the “absolute value”

$$|\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}| = \prod_{n=0, \dots, \text{depth}(\mathfrak{S})} \prod_{\substack{\text{time intervals} \\ \mathcal{J} = [\tau_\ell, \tau_r] \subset [0, \delta] \\ \text{of length } 2^{-n}\delta}} |\mathcal{I}_{(\mathcal{J}; \alpha_{\tau_\ell}^*, \alpha_{\tau_r})}|$$

of the integral operator. Here $|\mathcal{I}_{(\mathcal{J}; \alpha^*, \beta)}|$ is constructed by replacing

$$\int_{C_s(\mathbf{x}; \alpha^*, \beta)} \frac{dz_{*\tau}(\mathbf{x}) \wedge dz_\tau(\mathbf{x})}{2\pi i} e^{-z_{*\tau}(\mathbf{x}) z_\tau(\mathbf{x})}$$

by

$$\int_{C_s(\mathbf{x}; \alpha^*, \beta)} \left| \frac{dz_{*\tau}(\mathbf{x}) \wedge dz_\tau(\mathbf{x})}{2\pi i} \right| e^{-\operatorname{Re} z_{*\tau}(\mathbf{x}) z_\tau(\mathbf{x})}$$

in the formula for $\mathcal{I}_{(\mathcal{J}; \alpha^*, \beta)}$ of part (i).

The integral operator $\mathcal{I}_{\mathfrak{S}}$ integrates over the fields $\alpha_\tau, z_{*\tau}, z_\tau$ with $\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)$, where $\varepsilon = 2^{-\text{depth}(\mathfrak{S})}\delta$. We introduce the shorthand notation

$$\vec{\alpha} = (\alpha_\tau)_{\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)}, \quad \vec{z} = (z_\tau)_{\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)}, \quad \vec{z}_* = (z_{*\tau})_{\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)} \quad (2.8)$$

for these “residual” fields.

In Theorem 2.18, we give an estimate on the integral operators $\mathcal{I}_{\mathfrak{S}}$.

2.4. The Background Field

In (1.17), we described the change of the quadratic part of the effective interaction after one decimation step. We iterate this procedure and are led to explicit, but relatively complicated expressions for the quadratic part of the effective action at a given scale. To organize the description of the quadratic part and also of the dominant quartic part, we introduce “background fields”. The effective action depends on the fields α_τ both directly and through their complex conjugates, but is an analytic function if we treat the complex conjugates as independent variables. Consequently we introduce new complex fields $\alpha_{*\tau}$ that will often be evaluated at α_τ^* .

Definition 2.9 (The background field). Let \mathfrak{S} be a hierarchy for scale δ . Set $\varepsilon = 2^{-n}\delta$ with the integer $n \geq \text{depth}(\mathfrak{S})$. Given fields $\alpha_*, \beta, \vec{\alpha}_* = (\alpha_{*\tau}(\mathbf{x}))_{\substack{\tau \in \varepsilon\mathbb{Z} \cap (0, \delta) \\ \mathbf{x} \in X}}$ and $\vec{\alpha} = (\alpha_\tau(\mathbf{x}))_{\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)}$, we define the background fields⁷ for \mathfrak{S} by

$$\Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) = \Gamma_{*\tau}^0(\mathfrak{S}) \alpha_* + \sum_{\tau' \in \varepsilon\mathbb{Z} \cap (0, \delta)} \Gamma_{*\tau'}^{*\tau}(\mathfrak{S}) \alpha_{*\tau'}$$

⁷ For each fixed $\tau \in (0, \delta)$, α_* and $\vec{\alpha}_*$, the background field $\Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*)$ is a function of $\mathbf{x} \in X$.

$$\Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) = \sum_{\tau' \in \varepsilon \mathbb{Z} \cap (0, \delta)} \Gamma_{\tau'}^{\tau'}(\mathfrak{S}) \alpha_{\tau'} + \Gamma_{\tau}^{\delta}(\mathfrak{S}) \beta$$

For $\tau \in (0, \delta)$ and decimation points $\tau' \in [0, \delta]$, the coefficients $\Gamma_{*\tau}^{\tau'}(\mathfrak{S}) = \Gamma_{*\tau}^{\tau'}$, with $\tau' \neq \delta$, and $\Gamma_{\tau}^{\tau'}(\mathfrak{S}) = \Gamma_{\tau}^{\tau'}$, with $\tau' \neq 0$, are defined as follows:

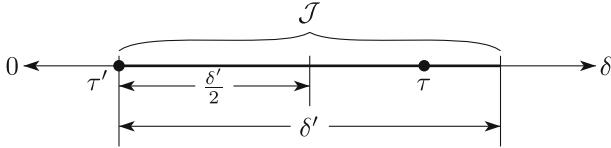

- o For $\tau = \tau' \in (0, \delta)$,

$$\Gamma_{*\tau}^{\tau} = \Gamma_{\tau}^{\tau} = \Lambda_{\tau}^c$$

Here, we use the following notation. If Y is a subset of X , the operator “multiplication by the characteristic function of Y ” is also denoted by Y .

- o For $\tau \neq \tau'$, $\Gamma_{*\tau}^{\tau'} = 0$ unless $\tau > \tau'$ and $[\tau', \tau]$ is strictly contained in a decimation interval with τ' as its left endpoint.⁸ If \mathcal{J} is the smallest such decimation interval and δ' its length, then

$$\Gamma_{*\tau}^{\tau'} = j\left(\tau - \tau' - \frac{\delta'}{2}\right) \Lambda(\mathcal{J}) j\left(\frac{\delta'}{2}\right) \Lambda_{\tau'}^c$$

- o Similarly for $\tau \neq \tau'$, $\Gamma_{\tau}^{\tau'} = 0$ unless $\tau < \tau'$ and $[\tau, \tau']$ is strictly contained in a decimation interval with τ' as its right endpoint. If \mathcal{J} is the smallest such interval and δ' its length, then

$$\Gamma_{\tau}^{\tau'} = j\left(\tau' - \tau - \frac{\delta'}{2}\right) \Lambda(\mathcal{J}) j\left(\frac{\delta'}{2}\right) \Lambda_{\tau'}^c$$

Remark 2.10. The Definition 2.9, of the background field, is independent of the choice of integer $n \geq \text{depth}(\mathfrak{S})$. To see this, let $\varepsilon_{\mathfrak{S}} = 2^{-\text{depth}(\mathfrak{S})} \delta$. The only place in the definition where ε appears is in the range of summation $\sum_{\tau' \in \varepsilon \mathbb{Z} \cap (0, \delta)}$. If $\tau' \in (\varepsilon \mathbb{Z} \setminus \varepsilon_{\mathfrak{S}} \mathbb{Z}) \cap (0, \delta)$, then $\mathfrak{d}(\tau') > \text{depth}(\mathfrak{S})$ so that $\Lambda_{\tau'}^c = \emptyset$ and $\Gamma_{\tau}^{\tau'}(\mathfrak{S}) = \Gamma_{*\tau}^{\tau'}(\mathfrak{S}) = 0$.

The dominant contributions to the quadratic part of the effective action associated to the hierarchy \mathfrak{S} for scale δ will be

$$Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) = Q_{\varepsilon, \delta}(\alpha_*, \beta; \Gamma_{*\mathfrak{S}}(\cdot; \alpha_*, \vec{\alpha}_*), \Gamma_{\mathfrak{S}}(\cdot; \vec{\alpha}, \beta)) \quad (2.9)$$

with $\varepsilon = 2^{-\text{depth}(\mathfrak{S})} \delta$, where

$$\begin{aligned} Q_{\varepsilon, \delta}(\alpha_*, \beta; \vec{\gamma}_*, \vec{\gamma}) &= \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta)} \langle \gamma_{*\tau}, \gamma_{\tau} \rangle - \langle \alpha_*, j(\varepsilon) \gamma_{\varepsilon} \rangle - \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta - \varepsilon)} \langle \gamma_{*\tau}, j(\varepsilon) \gamma_{\tau+\varepsilon} \rangle \\ &\quad - \langle \gamma_{*\delta-\varepsilon}, j(\varepsilon) \beta \rangle \end{aligned}$$

⁸ This implies that $\mathfrak{d}(\tau) > \mathfrak{d}(\tau')$ whenever τ is a decimation point. Observe that there is a maximal decimation interval with τ' as its left endpoint. If $\tau' \neq 0$, it is $[\tau', \tau' + 2^{-\mathfrak{d}(\tau')} \delta]$. If $\tau' = 0$ it is $[0, \delta]$.

$$\begin{aligned}
&= -\langle \alpha_*, j(\varepsilon) \gamma_\varepsilon \rangle + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta - \varepsilon)} \langle \gamma_{*\tau}, \gamma_\tau - j(\varepsilon) \gamma_{\tau+\varepsilon} \rangle \\
&\quad + \langle \gamma_{*\delta-\varepsilon}, \gamma_{\delta-\varepsilon} - j(\varepsilon) \beta \rangle \\
&= \langle \gamma_{*\varepsilon} - j(\varepsilon) \alpha_*, \gamma_\varepsilon \rangle + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (\varepsilon, \delta)} \langle \gamma_{*\tau} - j(\varepsilon) \gamma_{*\tau-\varepsilon}, \gamma_\tau \rangle \\
&\quad - \langle \gamma_{*\delta-\varepsilon}, j(\varepsilon) \beta \rangle
\end{aligned} \tag{2.10}$$

The dominant part to the quartic part of the effective action will be

$$\begin{aligned}
\mathcal{V}_S(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) &= - \int_0^\delta d\tau \langle \Gamma_{*S}(\tau; \alpha_*, \vec{\alpha}_*) \Gamma_S(\tau; \vec{\alpha}, \beta), v \Gamma_{*S}(\tau; \alpha_*, \vec{\alpha}_*) \Gamma_S(\tau; \vec{\alpha}, \beta) \rangle \\
&
\end{aligned} \tag{2.11}$$

The contributions characteristic of the small field set $\Omega_S([0, \delta])$ are not being integrated over. Therefore we set

$$\begin{aligned}
Q_S^{res}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) &= Q_S(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) - \langle \alpha_*, j_{(\Omega)}(\delta) \beta \rangle \\
\mathcal{V}_S^{res}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) &= \mathcal{V}_S(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) - V_{\Omega; \delta}(\alpha_*, \beta)
\end{aligned} \tag{2.12}$$

2.5. Norms

Our main result will be, that for sufficiently small $0 < \theta \leq \frac{1}{kT}$, the effective density can be represented in the form

$$\begin{aligned}
I_\theta(\alpha^*, \beta) &= \sum_{\Omega \subset X} Z_\theta^{|\Omega|} e^{\langle \alpha^*, j_{(\Omega)}(\theta) \beta \rangle + V_{\Omega; \theta}(\alpha^*, \beta) + \mathcal{D}_{\Omega; \theta}(\alpha^*, \beta)} \chi_\theta(\Omega; \alpha, \beta) \\
&\times \sum_{\substack{S \text{ hierarchy for scale } \theta \\ \Omega_S = \Omega}} \mathcal{I}_{(S; \alpha^*, \beta)} \\
&\times \left(e^{-Q_S^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{V}_S^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})} e^{\mathcal{B}_S(\alpha^*, \beta; \vec{\rho}_\dagger) + \mathcal{L}_S(\alpha^*, \beta; \vec{\rho}_\dagger)} \right)
\end{aligned} \tag{2.13}$$

In this formula, $V_{\Omega; \theta}$, Q_S^{res} and \mathcal{V}_S^{res} are explicit functions; their definitions have been given in (2.4), (2.10), (2.11) and (2.12). Observe that they are evaluated with $\alpha_* = \alpha^*$. The pure small field part $\mathcal{D}_{\Omega; \theta}$ has been constructed in (2.2). The functions \mathcal{L}_S and \mathcal{B}_S depend on the “residual fields” $\vec{\alpha}, \vec{z}_*, \vec{z}$ that are the integration variables of \mathcal{I}_S . Again we choose to write them as analytic functions of

$$\vec{\rho} = (\vec{\alpha}_*, \vec{\alpha}, \vec{z}_*, \vec{z})$$

as well as α^* and β . When they appear inside the integral operator we evaluate them at

$$\vec{\rho}_\dagger = (\vec{\alpha}_*, \vec{\alpha}, \vec{z}_*, \vec{z}) \Big|_{\substack{\vec{\alpha}_* = \vec{\alpha}^* \\ z_{*\tau}(\mathbf{x}) = z_\tau(\mathbf{x})^* \text{ for } \mathbf{x} \in \Lambda(\mathcal{J}_\tau) \setminus (R(\mathcal{J}_\tau) \cap \Omega(\mathcal{J}_\tau))}}$$

The function $\mathcal{L}_S(\alpha_*, \beta; \vec{\rho})$ will be analytic in the fields and depends only on the values of the fields $\alpha_{*\tau}(\mathbf{x}), \alpha_\tau(\mathbf{x})$ for points $\mathbf{x} \in X \setminus \Omega$. It is called the “pure

large field contribution". The function $\mathcal{B}_S(\alpha_*, \beta; \vec{\rho})$ depends on the fields at points \mathbf{x} both inside and outside Ω and is called the "boundary contribution".

In Proposition 2.1, we gave estimates on $\mathcal{D}_{\Omega; \theta}$, expressed in terms of the norms (1.25). The norms that we use to measure \mathcal{L}_S and \mathcal{B}_S are similar to the ones introduced in (1.25), but are more sophisticated. They weight the variables $\alpha_{*\tau}(\mathbf{x}), \alpha_\tau(\mathbf{x})$ so as to take into account their maximum possible magnitudes on \mathcal{I}_S 's domain of integration. The abstract framework for these norms was developed in [4, §II]. For the convenience of the reader, we review it. In Definition 2.13, we introduce the concrete weight factors used in this paper.

Definition 2.11. (i) A *weight factor* on X is a function $\kappa : X \rightarrow (0, \infty]$.

- (ii) Let n_1, \dots, n_s be nonnegative integers and $\vec{\mathbf{x}}_1 \in X^{n_1}, \dots, \vec{\mathbf{x}}_s \in X^{n_s}$. If δ is any metric on X , we define the tree size $\tau_\delta(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s)$ as the length (with respect to the metric δ) of the shortest tree in X whose set of vertices contains $\mathbf{x}_{1,1}, \mathbf{x}_{1,2}, \dots, \mathbf{x}_{1,n_1}, \dots, \mathbf{x}_{s,n_s}$.
- (iii) For any subset Ω of X we construct a metric d_Ω on X as follows: Denote by $\bar{\Omega}$ the union of closed unit cubes centered at the points of Ω . For a curve γ in \mathbb{R}^n we set

$$\text{length}_\Omega(\gamma) = 2 \cdot \text{length}(\gamma \cap \bar{\Omega}) + \text{length}(\gamma \cap (\mathbb{R}^n \setminus \bar{\Omega}))$$

where length is the ordinary length in X .

For any two points $\mathbf{x}, \mathbf{y} \in X$ define

$$d_\Omega(\mathbf{x}, \mathbf{y}) = \inf \{m \text{length}_\Omega(\gamma) \mid \gamma \text{ a curve joining } \mathbf{x} \text{ to } \mathbf{y}\}$$

where m is the "mass" introduced just before (1.25). Clearly,

$$m d \leq d_\Omega \leq 2m d \quad (2.14)$$

Recall that d is the standard metric on X .

If $\Omega \subset \Omega' \subset X$ and the set $S = \{\mathbf{x}_{1,1}, \mathbf{x}_{1,2}, \dots, \mathbf{x}_{1,n_1}, \dots, \mathbf{x}_{s,n_s}\}$ contains both a point of Ω and of $X \setminus \Omega'$ then

$$\tau_{d_\Omega}(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s) \leq \tau_{d_{\Omega'}}(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s) - m \text{dist}(\bar{\Omega}, \mathbb{R}^n \setminus \bar{\Omega'}) \quad (2.15)$$

where, for subsets U, V of \mathbb{R}^n

$$\text{dist}(U, V) = \inf \{\text{length}(\gamma) \mid \gamma \text{ a curve joining a point of } U \text{ to a point of } V\}$$

Definition 2.12. Let ϕ_1, \dots, ϕ_s be a collection of fields on X .

- (i) Let $f(\phi_1, \dots, \phi_s)$ be a function which is defined and analytic on a neighbourhood of the origin in $\mathbb{C}^{s|X|}$. Then f has a unique expansion of the form

$$f(\phi_1, \dots, \phi_s) = \sum_{n_1, \dots, n_s \geq 0} \sum_{(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s) \in X^{n_1} \times \dots \times X^{n_s}} a(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s) \phi_1(\vec{\mathbf{x}}_1) \cdots \phi_s(\vec{\mathbf{x}}_s)$$

with the coefficients $a(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s)$ invariant under permutations of the components of each vector $\vec{\mathbf{x}}_j$. The functions $a(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s)$ are called the (symmetric) coefficient system for f .

- (ii) For any $n_1, \dots, n_s \geq 0$ and any function $b(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s)$ on $X^{n_1} \times \dots \times X^{n_s}$, we define the norm $\|b\|_{n_1, \dots, n_s}$ as follows:

- o If there is at least one field, that is if $\sum_{j=1}^s n_j \neq 0$, then

$$\|b\|_{n_1, \dots, n_s} = \max_{\mathbf{x} \in X} \max_{\substack{1 \leq j \leq s \\ n_j \neq 0}} \max_{1 \leq i \leq n_j} \sum_{\substack{\vec{\mathbf{x}}_\ell \in X^{n_\ell} \\ 1 \leq \ell \leq s \\ (\vec{\mathbf{x}}_j)_i = \mathbf{x}}} |b(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s)|$$

- o For the constant term, that is if $\sum_{j=1}^s n_j = 0$,

$$\|b\|_{n_1, \dots, n_s} = |b(-, \dots, -)|$$

- (iii) Given weight factors $\kappa_1, \dots, \kappa_s$, and a metric δ on X , the weight system with metric δ that associates the weight factor κ_j to the field ϕ_j is defined by

$$w_\delta(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s) = e^{\tau_\delta(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s)} \prod_{j=1}^s \prod_{\ell=1}^{n_j} \kappa_j(\mathbf{x}_{j,\ell})$$

for all $(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s) \in X^{n_1} \times \dots \times X^{n_s}$ and all nonnegative integers n_1, \dots, n_s .

If Ω is a subset of X , the weight system with core Ω that associates the weight factor κ_j to the field ϕ_j (and the weight factor one to the history field) is w_{d_Ω} .

- (iv) Let $f(\phi_1, \dots, \phi_s)$ be a function which is defined and analytic on a neighbourhood of the origin in $\mathbb{C}^{s|X|}$ and a the symmetric coefficient system of f . We define the norm, with weight w , of f to be

$$\|f\|_w = \sum_{n_1, \dots, n_s \geq 0} \|w(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s) a(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s)\|_{n_1, \dots, n_s}$$

The functions $\mathcal{B}_\mathfrak{S}(\alpha_*, \beta; \vec{\rho})$ and $\mathcal{L}_\mathfrak{S}(\alpha_*, \beta; \vec{\rho})$ in (2.13) depend on the fields α_* , β and, in addition, on the residual fields $\vec{\rho} = (\vec{\alpha}_*, \vec{\alpha}, \vec{z}_*, \vec{z})$ that are integrated over in the large field integral operator $\mathcal{I}_\mathfrak{S}$. The weight factors that we associate to these variables depend on the functions $r(t)$ and $R(t)$ introduced before. Recall that $r(t)$ measures the size of the region close to a critical point where the stationary phase construction at scale t is performed (see the Introduction just after (1.10)). $R(t)$ is the threshold between ‘‘large’’ and ‘‘small’’ fields for scale t , see the beginning of Sect. 2.2.

Definition 2.13 (Weight factors). Let \mathfrak{S} be a hierarchy for scale δ .

- (i) We define the weight factor $\kappa_{*\mathfrak{S},0}$ for the field α_* by

$$\kappa_{*\mathfrak{S},0}(\mathbf{x})$$

$$= \min \left\{ 2R(t) \mid \mathbf{x} \in \Lambda([0, t]) \text{ such that } [0, t] \text{ is a decimation interval} \right\}$$

and, for τ a decimation point in $(0, \delta)$, the weight factor $\kappa_{*\mathfrak{S},\tau}$ for the field $\alpha_{*\tau}$ by

$$\kappa_{*\mathfrak{S},\tau}(\mathbf{x})$$

$$= \begin{cases} \infty & \text{if } \mathbf{x} \in \Lambda_\tau \\ \min \left\{ R(t) \mid \mathbf{x} \in \Lambda([\tau, \tau+t]), [\tau, \tau+t] \text{ a decimation interval} \right\} & \text{otherwise} \end{cases}$$

Similarly we define the weight factor $\kappa_{\mathfrak{S},\delta}$ for the field β by

$$\kappa_{\mathfrak{S},\delta}(\mathbf{x}) = \min \left\{ 2 R(t) \mid \mathbf{x} \in \Lambda([\delta - t, \delta]), [\delta - t, \delta] \text{ a decimation interval} \right\}$$

and, for τ a decimation point in $(0, \delta)$, the weight factor $\kappa_{\mathfrak{S},\tau}$ for the field α_τ by

$$\begin{aligned} \kappa_{\mathfrak{S},\tau}(\mathbf{x}) \\ = \begin{cases} \infty & \text{if } \mathbf{x} \in \Lambda_\tau \\ \min \left\{ R(t) \mid \mathbf{x} \in \Lambda([\tau - t, \tau]), [\tau - t, \tau] \text{ a decimation interval} \right\} & \text{otherwise} \end{cases} \end{aligned}$$

The significance of the “ ∞ ” lines is the following. If $\mathfrak{d}(\tau) \leq \text{depth}(\mathfrak{S})$ and $\mathbf{x} \in \Lambda_\tau$, then the integration variables $\alpha_{*\tau}(\mathbf{x}), \alpha_\tau(\mathbf{x})$ have been replaced by the integration variable $z_{*\tau}(\mathbf{x}), z_\tau(\mathbf{x})$ during the decimation step for τ . Thus $\alpha_{*\tau}(\mathbf{x}), \alpha_\tau(\mathbf{x})$ no longer appear as arguments. If $\mathfrak{d}(\tau) > \text{depth}(\mathfrak{S})$, that is if $\alpha_{*\tau}$ and α_τ do not appear as integration variables in $\mathcal{I}_{\mathfrak{S}}$ at all, then $\Lambda_\tau = X$ and $\kappa_{*,\tau}(\mathbf{x}) = \kappa_\tau(\mathbf{x}) = \infty$ for all \mathbf{x} .

The spatial decay of these weight factors is discussed in Appendix B.

- (ii) We define weight factors λ_τ for the “residual” fields $z_{*\tau}, z_\tau$, τ a decimation point in $(0, \delta)$ by

$$\lambda_{\mathfrak{S},\tau}(\mathbf{x}) = \begin{cases} 32 r(2^{-\mathfrak{d}(\tau)} \delta) & \text{if } \mathbf{x} \in \Lambda_\tau \setminus \Omega(\mathcal{J}_\tau) \\ \infty & \text{otherwise} \end{cases}$$

- (iii) We denote by $w_{\mathfrak{S}}$ the weight system with core $\Omega_{\mathfrak{S}}$ that associates the weight factor $\kappa_{*,\mathfrak{S},0}$ to the field α_* , the weight factor $\kappa_{\mathfrak{S},\delta}$ to the field β , and, for $\tau \in (0, \delta)$, the weight factors $\kappa_{*,\mathfrak{S},\tau}, \kappa_{\mathfrak{S},\tau}, \lambda_{\mathfrak{S},\tau}$ and $\lambda_{\mathfrak{S},\tau}$ to the fields $\alpha_{*\tau}, \alpha_\tau, z_{*\tau}$ and z_τ , respectively. We will generally write $\|\cdot\|_{\mathfrak{S}}$ in place of $\|\cdot\|_{w_{\mathfrak{S}}}$.

Our main result (Theorem 2.16 below) states, that, under suitable assumptions on the functions $R(t)$ and $r(t)$ the decomposition (2.13) of I_θ exists, and gives bounds on $\|\mathcal{B}_{\mathfrak{S}}\|_{\mathfrak{S}}$ and $\|\mathcal{L}_{\mathfrak{S}}\|_{\mathfrak{S}}$.

2.6. Summary and Statement of the Main Theorems

We are studying many particle systems of Bosons on the finite lattice X whose single particle Hamiltonian is of the form $h = \nabla^* \mathcal{H} \nabla$ with a translation invariant, strictly positive operator $\mathcal{H} : L^2(X^*) \rightarrow L^2(X^*)$. For our construction, we assume that there are constants $0 < c_{\mathcal{H}} < C_{\mathcal{H}}$ such that all of its eigenvalues lie between $c_{\mathcal{H}}$ and $C_{\mathcal{H}}$. Also we assume that

$$D_{\mathcal{H}} = \sum_{\substack{\mathbf{x} \in X \\ 1 \leq i, j \leq d}} e^{6 \text{md}(\mathbf{x}, 0)} |\mathcal{H}(b_i(0), b_j(\mathbf{x}))| < \infty \quad (2.16)$$

where m is the mass used in (2.5). Here, for each $1 \leq i \leq d$ and $\mathbf{x} \in X$, $b_i(\mathbf{x}) = (\mathbf{x}, \mathbf{x} + e_i)$ denotes the bond with base point \mathbf{x} and direction e_i . The interactions $v(\mathbf{x}, \mathbf{y})$ we allow are assumed to be translation invariant, repulsive

and exponentially decaying in that the norm

$$\|v\| = \sup_{\mathbf{x} \in X} \sum_{\mathbf{y} \in X} e^{5m d(\mathbf{x}, \mathbf{y})} |v(\mathbf{x}, \mathbf{y})|$$

introduced in (2.5), is sufficiently small. We discuss the system at temperature $T = \frac{1}{k\beta} > 0$ and chemical potential μ .

The representation (2.13) of the effective density that we want to achieve depends on

- the functions $R(t)$ and $R'(t)$ that implement the large field conditions at scale t .
- the function $r(t)$ that gives the size of the region near the critical point at scale t where stationary phase is applied.
- the function $c(t)$ that measures the size of the “corridors” in the hierarchies.
- the constant c that measures the size of the cut off of the single particle operator that is needed for the analyticity in Stokes’ argument (see (1.24)).
- a constant $v > 0$ that measures, roughly speaking, the size of the interaction v . The precise conditions relating v and v are given in Hypothesis 2.14, below.
- a constant $c_v > 0$ that, roughly speaking, imposes a lower bound on the smallest eigenvalue, v_1 , of v , viewed as the kernel of a convolution operator acting on $L^2(X)$. Again, see Hypothesis 2.14, below. Clearly $v_1 \leq \|v\| \leq \|v\|$.
- the chemical potential μ

Hypothesis 2.14. *The two-body potential $v(\mathbf{x}, \mathbf{y})$ is a real, symmetric, translation invariant function on $X \times X$ that obeys*

$$\frac{1}{4}v \leq \|v\| \leq \frac{1}{2}v \quad \text{and} \quad v_1 \geq c_v \|v\|$$

For our construction, we fix strictly positive exponents e_r , e_R , $e_{R'}$ and e_μ that obey

$$\begin{aligned} 3e_R + 4e_r < 1 & \quad 1 \leq 4e_R + 2e_r \quad 2(e_R + e_r) < e_\mu \leq 1 \\ e_{R'} + e_r < 1 & \quad \frac{1}{2} \leq e_{R'} \end{aligned} \tag{2.17}$$

and a constant $K_\mu > 0$. We make the particular, v -dependent, choices

$$\begin{aligned} r(t) &= \left(\frac{1}{tv} \right)^{e_r} & R(t) &= \left(\frac{1}{tv} \right)^{e_R} r(t) & R'(t) &= \left(\frac{1}{t} \right)^{e_{R'}} r(t) \\ c &= \log^2 \frac{1}{v} & c(t) &= \log^2 \frac{1}{tv} \end{aligned} \tag{2.18}$$

and assume that

$$|\mu| \leq K_\mu v^{e_\mu} \tag{2.19}$$

Example 2.15. Natural choices for e_R and $e_{R'}$ are $e_R = \frac{1}{4}$, $e_{R'} = \frac{1}{2}$. It is also natural to choose e_μ bigger than, but close to $\frac{1}{2}$.

We are working with a Riemann sum approximation to the quartic term in (1.1) which is, roughly speaking, (-2 times) a sum over $\tau \in \varepsilon\mathbb{Z} \cap [0, \frac{1}{kT}]$ of $\varepsilon \langle \alpha_\tau^* \alpha_\tau, v \alpha_\tau^* \alpha_\tau \rangle \geq \varepsilon v_1 \sum_{\mathbf{x} \in X} |\alpha_\tau(\mathbf{x})|^4 \geq \varepsilon v_1 R(\varepsilon)^4 |\{\mathbf{x} \in X \mid |\alpha_\tau(\mathbf{x})| > R(\varepsilon)\}|$

The coefficient $\varepsilon v_1 R(\varepsilon)^4 = \frac{v_1}{v} \varepsilon v R(\varepsilon)^4$ would be exactly $\frac{v_1}{v}$, which is of order one, for the choice $e_R = \frac{1}{4}$, if e_r were zero. We think of e_r as being small.

Similarly, the h term in (1.1) is, roughly speaking, a sum over $\tau \in \varepsilon\mathbb{Z} \cap [0, \frac{1}{kT}]$ of (minus)

$$\varepsilon \|\nabla \alpha_\tau\|_{L^2(X^*)} \geq \varepsilon R'(\varepsilon)^2 |\{b \in X^* \mid |\nabla \alpha_\tau(b)| > R'(\varepsilon)\}|$$

The coefficient $\varepsilon R'(\varepsilon)^2$ would be exactly one, for the choice $e_{R'} = \frac{1}{2}$, if e_r were zero.

The combined v and μ terms in (1.1) are, roughly speaking, a sum over $\tau \in \varepsilon\mathbb{Z} \cap [0, \frac{1}{kT}]$ of ($-\varepsilon$ times)

$$\begin{aligned} \frac{1}{2} \langle \alpha_\tau^* \alpha_\tau, v \alpha_\tau^* \alpha_\tau \rangle - \mu \|\alpha_\tau\|^2 &\geq \sum_{\mathbf{x} \in X} \left[\frac{1}{2} v_1 |\alpha_\tau(\mathbf{x})|^4 - \mu |\alpha_\tau(\mathbf{x})|^2 \right] \\ &= \sum_{\mathbf{x} \in X} \left[\frac{1}{2} v_1 \left(|\alpha_\tau(\mathbf{x})|^2 - \frac{\mu}{v_1} \right)^2 - \frac{\mu^2}{2v_1} \right] \\ &\geq - \sum_{\mathbf{x} \in X} \frac{\mu^2}{2v_1} \end{aligned}$$

With this choice of e_μ , the right hand side is small. Making e_μ larger would make the right hand side smaller, but would also make the critical value, $\frac{\mu}{v_1}$, of $|\alpha_\tau(\mathbf{x})|$ smaller too. This is not desirable for generating symmetry breaking in the infrared regime.

With these choices, (2.17) is satisfied if $e_r > 0$ is small enough.

Our main theorems are Theorems 2.16 and 2.18, below. They are proven in Sect. 3.8.

Theorem 2.16. *There is a constant K , such that for all sufficiently⁹ small $v, \theta > 0$, the limit $I_\theta(\alpha^*, \beta) = \lim_{m \rightarrow \infty} I_m(2^{-m}\theta; \alpha^*, \beta)$ exists and has the representation*

$$\begin{aligned} I_\theta(\alpha^*, \beta) &= \sum_{\Omega \subset X} Z_\theta^{|\Omega|} e^{\langle \alpha^*, j_{(\Omega)}(\theta) \beta \rangle + V_{\Omega; \theta}(\alpha^*, \beta) + \mathcal{D}_{\Omega; \theta}(\alpha^*, \beta)} \chi_\theta(\Omega; \alpha, \beta) \\ &\times \sum_{\substack{\mathfrak{S} \text{ hierarchy for scale } \theta \\ \Omega_{\mathfrak{S}} = \Omega}} \mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} \\ &\times \left(e^{-Q_{\mathfrak{S}}^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}}^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})} e^{\mathcal{B}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}_l) + \mathcal{L}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}_l)} \right) \end{aligned}$$

with the following properties.

⁹ See Hypothesis F.7.

- $V_{\Omega;\theta}$ and $\mathcal{D}_{\Omega;\theta}$ are the functions defined in (2.4) and (2.2). Furthermore, $\mathcal{D}_{\Omega;\theta}$ can be decomposed in the form

$$\mathcal{D}_{\Omega;\theta}(\alpha_*, \beta) = \mathcal{R}_{\Omega;\theta}(\alpha_*, \beta) + \mathcal{E}_{\Omega;\theta}(\alpha_*, \beta)$$

with a function $\mathcal{R}_{\Omega;\theta}(\alpha_*, \beta)$ that is bilinear in α_* and β , is independent¹⁰ of the interaction v , and fulfills the estimate

$$\|\mathcal{R}_{\Omega;\theta}\|_{2R(\theta), 2m} \leq K e^{-2m\epsilon} \theta^2 r(\theta)^2 R(\theta)^2 \leq K \theta v^{m \log \frac{1}{v}}$$

and a function $\mathcal{E}_{\Omega;\theta}(\alpha_*, \beta)$ that has degree at least two¹¹ both in α_* and in β and fulfills the estimate

$$\|\mathcal{E}_{\Omega;\theta}\|_{2R(\theta), 2m} \leq K \theta^2 \|v\|^2 r(\theta)^2 R(\theta)^6 \leq K \left(\frac{\|v\|}{v} \right)^2$$

- $\chi_\theta(\Omega; \alpha, \beta)$ is the characteristic function imposing the small field conditions. It is one if
 - $|\alpha(\mathbf{x})|, |\beta(\mathbf{x})| \leq R(\theta)$ for all $\mathbf{x} \in \Omega$ and
 - $|\nabla \alpha(b)|, |\nabla \beta(b)| \leq R'(\theta)$ for all bonds b on X that have at least one end in Ω and
 - $|\alpha(\mathbf{x}) - \beta(\mathbf{x})| \leq r(\theta)$ for all \mathbf{x} within a distance one from Ω and it is zero otherwise
- For each hierarchy \mathfrak{S} for scale θ , $\mathcal{B}_{\mathfrak{S}}(\alpha_*, \beta; \vec{r})$ is an analytic function of its arguments and fulfills the estimate

$$\|\mathcal{B}_{\mathfrak{S}}\|_{\mathfrak{S}} \leq K \theta \|v\| r(\theta) R(\theta)^3 \leq K \frac{\|v\|}{v}$$

- For each hierarchy \mathfrak{S} for scale θ , $\mathcal{L}_{\mathfrak{S}}$ has the decomposition

$$\mathcal{L}_{\mathfrak{S}}(\alpha_*, \beta; \vec{r}) = \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \theta]}} \mathcal{L}_{\mathfrak{S}}(\mathcal{J}; \alpha_*, \beta; \vec{r})$$

where, for each decimation interval $\mathcal{J} \subset [0, \theta]$, the function $\mathcal{L}_{\mathfrak{S}}(\mathcal{J}; \alpha_*, \beta; \vec{r})$ is an analytic function of its arguments that

- is “large field with respect to the interval \mathcal{J} ” (that is, it depends only on values of the fields at points $\mathbf{x} \in X \setminus \Omega_{\mathfrak{S}}(\mathcal{J})$ and depends only on the variables $\alpha_{*\tau}, \alpha_\tau, z_{*\tau}, z_\tau$ with $\tau \in \mathcal{J}$. (If $\tau = 0 \in \mathcal{J}$, then replace $\alpha_{*0}(\mathbf{x})$ by $\alpha_*(\mathbf{x})$. If $\tau = \theta \in \mathcal{J}$, then replace $\alpha_\theta(\mathbf{x})$ by $\beta(\mathbf{x})$)
- and fulfills the estimate

$$\|\mathcal{L}_{\mathfrak{S}}(\mathcal{J}; \cdot)\|_{\mathfrak{S}} \leq K \delta \|v\| r(\delta) R(\delta)^3 = K \frac{\|v\|}{v} (\delta v)^{1-3e_R-4e_r}$$

where δ is the length of the time interval \mathcal{J} .

- The functions $\mathcal{R}_{\Omega;\theta}$, $\mathcal{E}_{\Omega;\theta}$, $\mathcal{B}_{\mathfrak{S}}$ and $\mathcal{L}_{\mathfrak{S}}(\mathcal{J})$ are all invariant under $\alpha_* \rightarrow e^{-i\theta} \alpha_*$, $\beta \rightarrow e^{i\theta} \beta$, $\vec{r} = (\vec{\alpha}_*, \vec{\alpha}, \vec{z}_*, \vec{z}) \rightarrow (e^{-i\theta} \vec{\alpha}_*, e^{i\theta} \vec{\alpha}, e^{-i\theta} \vec{z}_*, e^{i\theta} \vec{z})$.
- For each hierarchy \mathfrak{S} for scale θ , $\mathcal{I}_{\mathfrak{S}}$ is the integral operator of Definition 2.8. Its properties are described in Theorem 2.18, below.

¹⁰ $\mathcal{R}_{\Omega;\theta}$ is constructed like $\mathcal{D}_{\Omega;\theta}$, but with $v = 0$.

¹¹ By this we mean that every monomial appearing in the power series expansion of these functions contains a factor of the form $\alpha_*(\mathbf{x}_1) \alpha_*(\mathbf{x}_2) \beta(\mathbf{x}_3) \beta(\mathbf{x}_4)$.

Definition 2.17. Let $\Omega \subset X$ and $\theta, \mathfrak{v} > 0$. We define the technical small field regulator

$$\text{Reg}_{SF}(\Omega; \alpha, \beta) = \text{Reg}_{SF}^{(2)}(\Omega; \alpha, \beta) + \text{Reg}_{SF}^{(4)}(\Omega; \alpha, \beta)$$

with

$$\begin{aligned} \text{Reg}_{SF}^{(2)}(\Omega; \alpha, \beta) &= K_{\text{reg}} \theta |\mu| [\|\alpha\|_{\Omega}^2 + \|\beta\|_{\Omega}^2] \\ \text{Reg}_{SF}^{(4)}(\Omega; \alpha, \beta) &= K_{\text{reg}} \theta \mathfrak{v} \left\{ \|\alpha\|_{L^4(\Omega)}^3 + \|\beta\|_{L^4(\Omega)}^3 \right\} \left\{ \|\alpha - \beta\|_{L^4(\tilde{\Omega})} \right. \\ &\quad + \theta \left[\mu + e^{-5\mathfrak{m}\mathfrak{c}(\theta)} \right] \left[\|\alpha\|_{L^4(\tilde{\Omega})} \right. \\ &\quad \left. \left. + \|\beta\|_{L^4(\tilde{\Omega})} \right] + \theta \left[\|\nabla \alpha\|_{L^4(\tilde{\Omega}^*)} + \|\nabla \beta\|_{L^4(\tilde{\Omega}^*)} \right] \right\} \end{aligned}$$

Here $\tilde{\Omega}$ is the set of points of X that are within a distance $\mathfrak{c}(\theta)$ of Ω , and $K_{\text{reg}} = 2^9 \exp \{20e^{12m_D} D_{\mathcal{H}}\}$.

In addition to the constants of (2.17), we choose $0 < e_\ell < 2e_r$ and set

$$\ell(t) = \left(\frac{1}{t\mathfrak{v}} \right)^{e_\ell} \quad (2.20)$$

Theorem 2.18. Let $\Omega \subset X$ and assume that α and β obey the small field conditions $\chi_\theta(\Omega; \alpha, \beta) = 1$. Then,

$$\begin{aligned} &e^{-\frac{1}{2}\|\alpha\|^2 - \frac{1}{2}\|\beta\|^2} e^{\operatorname{Re}(\langle \alpha^*, j_{(\Omega)}(\theta)\beta \rangle + V_{\Omega, \theta}(\alpha^*, \beta))} e^{-\text{Reg}_{SF}(\Omega; \alpha, \beta)} \\ &\times \sum_{\substack{\text{hierarchies } \mathfrak{S} \\ \text{for scale } \theta \\ \text{with } \Omega_{\mathfrak{S}} = \Omega}} |\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}| \left(e^{\operatorname{Re}(-Q_{\mathfrak{S}}^{res} + \mathcal{V}_{\mathfrak{S}}^{res}) + |\mathcal{B}_{\mathfrak{S}}| + |\mathcal{L}_{\mathfrak{S}}|} \right) \\ &\leq e^{-\frac{1}{4}\ell(\theta)|\Omega^c|} \left[\prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \frac{1}{1 + |\beta(\mathbf{x})|^3} \right] \end{aligned}$$

In the above theorem,

- o the factor $\prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \frac{1}{1 + |\beta(\mathbf{x})|^3}$ on the right hand side ensures the left hand side, which is a function of $\{\alpha(\mathbf{x}), \beta(\mathbf{x})\}_{\mathbf{x} \in X}$ is integrable,
- o the factor $e^{-\ell(\theta)|\Omega^c|}$ on the right hand side tells us that when the large field region Ω^c is large, then the left hand side is small and

A stronger bound than that of Theorems 2.18 is given in (3.22).

3. Strategy of the Proof

Our proof of Theorem 2.16 goes roughly as follows. In a first step, we fix $\varepsilon = 2^{-k}\theta$ for some $k \in \mathbb{N}$ and show that there is a representation for $I_k(\varepsilon; \alpha^*, \beta)$ similar to (2.13), but with a sum over hierarchies for scale θ which have depth at most k . In a second step we compare the resulting representations for $I_k(2^{-k}\theta; \alpha^*, \beta)$ and $I_{k+1}(2^{-(k+1)}\theta; \alpha^*, \beta)$ in order to take the limit $k \rightarrow \infty$.

For the first step, we use the decimation strategy sketched in the introduction. We construct, for $n = 1, 2, \dots, k$ a representation of $I_n(\varepsilon; \alpha^*, \beta)$ similar

to (2.13), but with a sum over hierarchies for scale $2^n \varepsilon = 2^{n-k} \theta$. In the step (1.10) from n to $n+1$,

$$I_{n+1}(\varepsilon; \alpha^*, \beta) = \int d\mu_{R(\varepsilon)}(\phi^*, \phi) I_n(\varepsilon; \alpha^*, \phi) I_n(\varepsilon; \phi^*, \beta)$$

write the representation of $I_n(\varepsilon; \alpha^*, \phi)$ resp. $I_n(\varepsilon; \phi^*, \beta)$ as a sum over such hierarchies \mathfrak{S}_1 resp. \mathfrak{S}_2 and write the integral as a sum of integrals, indexed by $(\mathfrak{S}_1, \mathfrak{S}_2)$. One such integral leads to the sum of terms in the representation of I_{n+1} that are associated to the hierarchies for scale $2^{n+1} \varepsilon = 2^{n-k+1} \theta$ that are preceded by $(\mathfrak{S}_1, \mathfrak{S}_2)$ in the following sense.

Definition 3.1. A pair $(\mathfrak{S}_1, \mathfrak{S}_2)$ of hierarchies for scale δ is said to precede the hierarchy \mathfrak{S} for scale 2δ if

$$S_{\mathfrak{S}}(\mathcal{J}) = S_{\mathfrak{S}_1}(\mathcal{J}) \quad \text{and} \quad S_{\mathfrak{S}}(\delta + \mathcal{J}) = S_{\mathfrak{S}_2}(\mathcal{J})$$

for all $S = \Lambda, \Omega, P_\alpha, P_\beta, P'_\alpha, P'_\beta, Q, R$ and all decimation intervals \mathcal{J} in $[0, \delta]$. In this case, we write

$$(\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S}$$

We also denote, for any field $\vec{\alpha} = (\alpha_\tau(\mathbf{x}))_{\substack{\tau \in \varepsilon \mathbb{Z} \cap (0, 2\delta) \\ \mathbf{x} \in X}}$, the left and right half fields to be

$$\vec{\alpha}_l = (\alpha_\tau(\mathbf{x}))_{\substack{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta) \\ \mathbf{x} \in X}} \quad \vec{\alpha}_r = (\alpha_{\tau+\delta}(\mathbf{x}))_{\substack{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta) \\ \mathbf{x} \in X}}$$

Given hierarchies $\mathfrak{S}_1, \mathfrak{S}_2$ for scale δ , the choice of a hierarchy \mathfrak{S} with $(\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S}$ amounts to the choice of

- (i) the small/large field sets of the first kind

$$\begin{aligned} P_\alpha([0, 2\delta]), \quad P_\beta([0, 2\delta]) &\subset \Omega_{\mathfrak{S}_1} \cap \Omega_{\mathfrak{S}_2} \\ P'_\alpha([0, 2\delta]), \quad P'_\beta([0, 2\delta]) &\subset (\Omega_{\mathfrak{S}_1} \cap \Omega_{\mathfrak{S}_2})^* \\ Q([0, 2\delta]) &\subset (\Omega_{\mathfrak{S}_1} \cap \Omega_{\mathfrak{S}_2})^* \end{aligned}$$

By Definition 2.4, these sets determine $\Lambda([0, 2\delta])$.

- (ii) the large field set of the second kind $R([0, 2\delta]) \subset \Lambda([0, 2\delta])$. Again, by Definition 2.4, this set determines the new small field set of the second kind $\Omega([0, 2\delta])$.

In a decimation step as outlined above, we start with two hierarchies $\mathfrak{S}_1, \mathfrak{S}_2$ for scale δ . Then we first decompose $\Omega_{\mathfrak{S}_1} \cap \Omega_{\mathfrak{S}_2}$ into large/small field sets of the first kind, and afterwards decompose the resulting small field sets Λ according to the choice of the regions where “stationary phase” is applied. To formalize the first step, we use

Definition 3.2. Let $\Omega_0 \subset X$ and $\delta > 0$. We denote by $F_\delta(\Omega_0)$ the set of all choices of “small/large field sets of the first kind”

$$\mathfrak{A} = (\Lambda, P_\alpha, P_\beta, P'_\alpha, P'_\beta, Q)$$

with

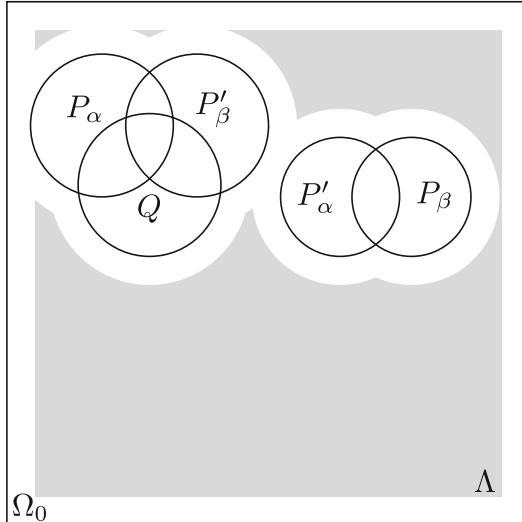

- o $\Lambda, P_\alpha, P_\beta \subset \Omega_0, P'_\alpha, P'_\beta \subset \Omega_0^*$ and $Q \subset \Omega_0^*$

$$\circ \quad \Lambda = \left\{ \mathbf{x} \in X \mid d\left(\mathbf{x}, P_\alpha \cup P_\beta \cup Q \cup \text{supp } P'_\alpha \cup \text{supp } P'_\beta \cup \Omega_0^c\right) > \mathfrak{c}(\delta) \right\}$$

3.1. History Fields

As described in the previous section, the decimation step from scale δ to scale 2δ involves integrals of products of pairs of terms like in (2.13), indexed by two hierarchies of $\mathfrak{S}_1, \mathfrak{S}_2$ for scale δ . The result of this integral will be represented as a sum over all hierarchies \mathfrak{S} of scale 2δ that are preceded by $(\mathfrak{S}_1, \mathfrak{S}_2)$. Each such term should contain a factor

$$e^{\langle \alpha^*, j_{(\Omega_{\mathfrak{S}})}(2\delta)\beta \rangle + V_{\Omega_{\mathfrak{S}}, 2\delta}(\varepsilon; \alpha^*, \beta) + \mathcal{D}_{\Omega_{\mathfrak{S}}, 2\delta}(\varepsilon; \alpha^*, \beta)}$$

For the construction of $\mathcal{D}_{\Omega_{\mathfrak{S}}, 2\delta}(\varepsilon; \cdot, \cdot)$ out of $\mathcal{D}_{\Omega_{\mathfrak{S}_1}, \delta}(\varepsilon; \cdot, \cdot)$ and $\mathcal{D}_{\Omega_{\mathfrak{S}_2}, \delta}(\varepsilon; \cdot, \cdot)$ we need to know which contributions to $\mathcal{D}_{\Omega_{\mathfrak{S}_i}, \delta}(\varepsilon; \cdot, \cdot)$ involved points outside the new small field region $\Omega_{\mathfrak{S}}$.

To keep track of precisely which points were involved in the construction of each contribution, we introduce the concept of a history field. This is a field on X that takes only the values 0 and 1. In particular

$$\mathfrak{h}^2 = \mathfrak{h}$$

The history field is never integrated over. We put in a history field at each point where some construction is performed. That is, we shall always work with ‘‘history complete’’ functions in the following sense.

Definition 3.3. (i) A function $f(\phi_1, \dots, \phi_s; \mathfrak{h})$ in the fields $\phi_1, \dots, \phi_s, \mathfrak{h}$ is called history complete if it is in fact a function of $\phi_1 \mathfrak{h}, \dots, \phi_s \mathfrak{h}, \mathfrak{h}$. If f is a history complete analytic function, any non trivial monomial in its power series expansion that contains a factor $\phi_i(\mathbf{x})$ automatically also contains a factor $\mathfrak{h}(\mathbf{x})$.

(ii) Given a power series $f(\phi_1, \dots, \phi_s; \mathfrak{h})$ and a subset Ω of X we set

$$f|_{\Omega} = f(\phi_1, \dots, \phi_s; \mathfrak{h}) \Big|_{\mathfrak{h}(\mathbf{x})=0 \text{ for } \mathbf{x} \in X \setminus \Omega}$$

If f is history complete, $f|_{\Omega}$ depends only on the fields $\phi_1(\mathbf{x}), \dots, \phi_s(\mathbf{x})$, $\mathfrak{h}(\mathbf{x})$ with $\mathbf{x} \in \Omega$.

The starting points of our construction are the single particle Hamiltonian $\mathbf{h} = \nabla^* \mathcal{H} \nabla$ and the interaction v . Already at this point, we have to monitor the points in space involved in the construction, for example in the exponential $j(t) = e^{t(\mathbf{h}-\mu)}$. This is the motivation for the notion of \mathfrak{h} -operator introduced in [4, Definition IV.1]. For the convenience of the reader, we repeat some of the concepts introduced in [4].

Definition 3.4. (i) An \mathfrak{h} -operator or \mathfrak{h} -linear map A on \mathbb{C}^X is a linear operator on \mathbb{C}^X whose kernel is of the form

$$A(\mathbf{x}, \mathbf{y}) = \sum_{\ell=0}^{\infty} \sum_{(\mathbf{x}_1, \dots, \mathbf{x}_{\ell}) \in X^{\ell}} A(\mathbf{x}; \mathbf{x}_1, \dots, \mathbf{x}_{\ell}; \mathbf{y}) \mathfrak{h}(\mathbf{x}) \mathfrak{h}(\mathbf{x}_1) \cdots \mathfrak{h}(\mathbf{x}_{\ell}) \mathfrak{h}(\mathbf{y})$$

(ii) The composition $A \circ B$ of two \mathfrak{h} -operators A, B on \mathbb{C}^X is by definition the \mathfrak{h} -operator with kernel

$$\begin{aligned} (A \circ B)(\mathbf{x}, \mathbf{y}) &= \sum_{\mathbf{z} \in X} A(\mathbf{x}, \mathbf{z}) B(\mathbf{z}, \mathbf{y}) \\ &= \sum_{\mathbf{z} \in X} \sum_{\ell, \ell' \geq 0} \sum_{\substack{\mathbf{x}_1, \dots, \mathbf{x}_{\ell} \\ \mathbf{y}_1, \dots, \mathbf{y}_{\ell'}}} A(\mathbf{x}; \mathbf{x}_1, \dots, \mathbf{x}_{\ell}; \mathbf{z}) B(\mathbf{z}; \mathbf{y}_1, \dots, \mathbf{y}_{\ell'}; \mathbf{y}) \\ &\quad \times \mathfrak{h}(\mathbf{x}) \mathfrak{h}(\mathbf{x}_1) \cdots \mathfrak{h}(\mathbf{x}_{\ell}) \mathfrak{h}(\mathbf{z}) \mathfrak{h}(\mathbf{y}_1) \cdots \mathfrak{h}(\mathbf{y}_{\ell'}) \mathfrak{h}(\mathbf{y}) \end{aligned}$$

Here we used that $\mathfrak{h}^2 = \mathfrak{h}$.

(iii) For an “ordinary” linear operator J on \mathbb{C}^X with kernel $J(\mathbf{x}, \mathbf{y})$, we define the associated \mathfrak{h} -operator by

$$\bar{J}(\mathbf{x}, \mathbf{y}) = \mathfrak{h}(\mathbf{x}) J(\mathbf{x}, \mathbf{y}) \mathfrak{h}(\mathbf{y})$$

and the associated \mathfrak{h} -exponential as

$$\text{exph}(J) = \mathfrak{h} + \sum_{\ell=1}^{\infty} \frac{1}{\ell!} \bar{J}^{\ell} = \mathfrak{h} e^{\mathfrak{h} J \mathfrak{h}} = e^{\mathfrak{h} J \mathfrak{h}} \mathfrak{h}$$

The \mathfrak{h} -exponential obeys the product rule $\text{exph}(J_1) \text{exph}(J_2) = \text{exph}(J_1 + J_2)$, provided the operators \bar{J}_1 and \bar{J}_2 commute.

(iv) If ϕ is any field on X and A an \mathfrak{h} -operator, we set

$$\begin{aligned} (A\phi)(\mathbf{x}) &= \sum_{\mathbf{y} \in X} A(\mathbf{x}, \mathbf{y}) \phi(\mathbf{y}) \\ &= \sum_{\ell=0}^{\infty} \sum_{\mathbf{x}_1, \dots, \mathbf{x}_{\ell}, \mathbf{y}} A(\mathbf{x}; \mathbf{x}_1, \dots, \mathbf{x}_{\ell}; \mathbf{y}) \mathfrak{h}(\mathbf{x}) \mathfrak{h}(\mathbf{x}_1) \cdots \mathfrak{h}(\mathbf{x}_{\ell}) \mathfrak{h}(\mathbf{y}) \phi(\mathbf{y}) \end{aligned}$$

To keep the notation simple, we shall frequently use the same symbol for a history complete function or \mathfrak{h} -operator as we used in Sect. 2 for the function or operator one gets if one sets $\mathfrak{h}(\mathbf{x}) = 1$ for all $\mathbf{x} \in X$. So we shall again write v for the operator \bar{v} , and set

$$j(t) = \text{exph}(-t(\mathbf{h} - \mu)) \tag{3.1}$$

Observe that

$$j(t) \Big|_{\begin{subarray}{l} \mathfrak{h}(\mathbf{x})=0 \text{ for } \mathbf{x} \in X \setminus \Omega \\ \mathfrak{h}(\mathbf{x})=1 \text{ for } \mathbf{x} \in \Omega \end{subarray}} = j_{(\Omega)}(t)$$

with the operator $j_{(\Omega)}(t)$ introduced at the beginning of Sect. 2.1. Again we define

$$j_{\mathfrak{c}}(\tau)(\mathbf{x}, \mathbf{y}) = j(\tau)(\mathbf{x}, \mathbf{y}) \cdot \begin{cases} 1 & \text{if } d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c} \\ 0 & \text{if } d(\mathbf{x}, \mathbf{y}) > \mathfrak{c} \end{cases} \quad (3.2)$$

3.2. Properties of the Background Fields

Here, and through the rest of the paper, use the same definition as before for background fields (that is Definition 2.9, just with $j(t)$ being interpreted as the \mathfrak{h} -operator of (3.1)). Here, we want to study some of their properties. In particular, we develop a recursion relation (Proposition 3.6).

Remark 3.5. (The structure of the background fields) Let \mathfrak{S} be a hierarchy for scale δ .

(i) When the history field is identically zero, the background field becomes

$$\Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) \Big|_{\mathfrak{h}=0} = \Lambda_\tau^c \alpha_{*\tau} \quad \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) \Big|_{\mathfrak{h}=0} = \Lambda_\tau^c \alpha_\tau$$

The differences $\Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) - \Lambda_\tau^c \alpha_{*\tau}$ and $\Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) - \Lambda_\tau^c \alpha_\tau$ are history complete. Their restrictions to the small field region $\Omega_{\mathfrak{S}}$ are

$$\begin{aligned} \Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) \Big|_{\Omega_{\mathfrak{S}}} - \Lambda_\tau^c \alpha_{*\tau} &= j(\tau) \alpha_* \Big|_{\Omega_{\mathfrak{S}}}, \\ \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) \Big|_{\Omega_{\mathfrak{S}}} - \Lambda_\tau^c \alpha_\tau &= j(\delta - \tau) \beta \Big|_{\Omega_{\mathfrak{S}}} \end{aligned}$$

(ii) Let $\tau = \delta \sum_{k=1}^{\mathfrak{d}(\tau)} \frac{a_k}{2^k}$, $a_k \in \{0, 1\}$, be the “binary expansion” of the decimation point $\tau \in (0, \delta)$, and let $\tau' \in (0, \delta)$ be another decimation point different from τ . Then $\Gamma_{*\tau}^{\tau'} = 0$ unless τ' is one of the “binary approximations” $\delta \sum_{k=1}^d \frac{a_k}{2^k}$ ($1 \leq d < \mathfrak{d}(\tau)$, $a_d = 1$) of τ . In this case, let $d' = \min \{k > d \mid a_k = 1\}$. Then

$$\Gamma_{*\tau}^{\tau'} = j \left(\tau - \tau' - \frac{\delta}{2^{d'}} \right) \Lambda \left([\tau', \tau' + \frac{\delta}{2^{d'-1}}] \right) j \left(\frac{\delta}{2^{d'}} \right) \Lambda_{\tau'}^c$$

In particular, $\Gamma_{*\tau}^{\tau'} = 0$ whenever $\tau' > \tau$ or $\mathfrak{d}(\tau') > \mathfrak{d}(\tau)$.

Analogous statements hold for $\Gamma_{\tau}^{\tau'}$, in terms of the binary expansions of $\delta - \tau$ and $\delta - \tau'$. In particular, $\Gamma_{\tau}^{\tau'} = 0$ whenever $\tau' < \tau$ or $\mathfrak{d}(\tau') > \mathfrak{d}(\tau)$.

- (iii) If $\tau \neq \tau'$, then $\Gamma_{*\tau}^{\tau'}$ and $\Gamma_{\tau}^{\tau'}$ are always of the form $j(\tau_1) \Lambda_1 j(\tau_2) \Lambda_2^c$ with $\tau_1, \tau_2 \geq 0$, $\tau_1 + \tau_2 = |\tau - \tau'|$ and Λ_1 and Λ_2^c being (possibly trivial) characteristic functions.
- (iv) Let $\tau \in (0, \delta)$ and $\tau' \in [0, \delta]$ be decimation points with $\mathfrak{d}(\tau) > \mathfrak{d}(\tau')$. (For $\tau' = 0, \delta$, set $\mathfrak{d}(\tau') = 0$.) Furthermore let $0 < t \leq \frac{\delta}{2^{\mathfrak{d}(\tau)}}$. If τ is not of

the form $\tau' + \frac{\delta}{2^d}$ for any $\mathfrak{d}(\tau') \leq d \leq \text{depth}(\mathfrak{S})$, then $\Gamma_{*\tau}^{\tau'} = j(t) \Gamma_{*\tau-t}^{\tau'}$. If τ is not of the form $\tau' - \frac{\delta}{2^d}$ for any $\mathfrak{d}(\tau') \leq d \leq \text{depth}(\mathfrak{S})$, then $\Gamma_{\tau}^{\tau'} = j(t) \Gamma_{\tau+t}^{\tau'}$. For more information, see Lemma E.16.

- (v) If $\mathfrak{d}(\tau') > \text{depth}(\mathfrak{S})$ then $\Gamma_{*\tau}^{\tau'} = \Gamma_{\tau}^{\tau'} = 0$ for all $\tau \in (0, \delta)$.

Proof. (i) Since $j(t)$ vanishes when \mathfrak{h} is identically zero, $\Gamma_{*\tau}^{\tau'}|_{\mathfrak{h}=0} = \Gamma_{\tau}^{\tau'}|_{\mathfrak{h}=0} = 0$ for all $\tau' \neq \tau$. For all $\tau' \in (0, \delta)$, $\Omega_{\mathfrak{S}} \cap \Lambda_{\tau'}^c = \emptyset$ and hence $\Gamma_{*\tau}^{\tau'}|_{\Omega_{\mathfrak{S}}} = \Gamma_{\tau}^{\tau'}|_{\Omega_{\mathfrak{S}}} = 0$ whenever $\tau' \neq \tau$. Finally,

$$\begin{aligned} \Gamma_{*\tau}^0|_{\Omega_{\mathfrak{S}}} &= j\left(\tau - \frac{\delta'}{2}\right) \Omega_{\mathfrak{S}} j\left(\frac{\delta'}{2}\right)|_{\Omega_{\mathfrak{S}}} = j\left(\tau - \frac{\delta'}{2}\right) j\left(\frac{\delta'}{2}\right)|_{\Omega_{\mathfrak{S}}} = j(\tau)|_{\Omega_{\mathfrak{S}}} \\ \text{and } \Gamma_{\tau}^{\delta}|_{\Omega_{\mathfrak{S}}} &= j(\delta - \tau)|_{\Omega_{\mathfrak{S}}}. \end{aligned}$$

- (ii) Assume that $\Gamma_{*\tau}^{\tau'} \neq 0$. Denote by \mathcal{J} the smallest decimation interval with τ' as its left endpoint that strictly contains $[\tau', \tau]$. As \mathcal{J} is a decimation interval, there is $d' \geq \mathfrak{d}(\tau') + 1$ such that $\mathcal{J} = [\tau', \tau' + \frac{\delta}{2^{d'-1}}]$. Since $[\tau', \tau' + \frac{\delta}{2^{d'}}]$ is also a decimation interval, but does not contain τ in its interior, we have $\tau' + \frac{\delta}{2^{d'}} \leq \tau < \tau' + \frac{\delta}{2^{d'-1}}$.

Set $d = \mathfrak{d}(\tau') < \mathfrak{d}(\tau)$ and let $\tau' = \delta \sum_{k=1}^d \frac{b_k}{2^k}$, $b_k \in \{0, 1\}$ be the “binary expansion” of τ' . As $\frac{\delta}{2^{d'}} \leq \tau - \tau' < \frac{\delta}{2^{d'-1}}$ and $d' > d$ we have

$$a_k = b_k \text{ for } k = 1, \dots, d, \quad a_d = 1, \quad a_{d+1} = \dots = a_{d'-1} = 0, \quad a_{d'} = 1$$

So τ' is a binary approximation of τ . The remaining claims follow directly from the Definition 2.9 of the background fields.

- (iii) follows by inspection. Recall that $j(0) = \mathfrak{h}$.

- (iv) We consider $\Gamma_{*\tau}^{\tau'}$. By part (ii) we may assume that $\tau > \tau'$. Observe that $[\tau', \tau' + \frac{\delta}{2^{\mathfrak{d}(\tau')}}]$ is the maximal decimation interval with τ' as left endpoint. If τ does not lie in this interval, then $\tau - t \geq \tau - \frac{\delta}{2^{\mathfrak{d}(\tau')}} \geq \tau' + \frac{\delta}{2^{\mathfrak{d}(\tau')}}$, and consequently $\Gamma_{*\tau}^{\tau'} = \Gamma_{*\tau-t}^{\tau'} = 0$. So we may assume that $\tau \in (\tau', \tau' + \frac{\delta}{2^{\mathfrak{d}(\tau)}})$. Let $\mathcal{J} = [\tau', \tau' + \frac{\delta}{2^{d-1}}]$, $d > \mathfrak{d}(\tau')$ be the smallest decimation interval with τ' as left endpoint such that $[\tau', \tau] \subsetneq \mathcal{J}$. Then $\tau' + \frac{\delta}{2^d} \leq \tau < \tau' + \frac{\delta}{2^{d-1}}$. If $\tau \neq \tau' + \frac{\delta}{2^d}$ then, again, $\tau - t \geq \tau - \frac{\delta}{2^{\mathfrak{d}(\tau)}} \geq \tau' + \frac{\delta}{2^d}$ and consequently

$$\begin{aligned} \Gamma_{*\tau}^{\tau'} - j(t) \Gamma_{*\tau-t}^{\tau'} &= \left[j\left(\tau - \tau' - \frac{\delta}{2^d}\right) - j(t) j\left(\tau - t - \tau' - \frac{\delta}{2^d}\right) \right] \Lambda(\mathcal{J}) j\left(\frac{\delta}{2^d}\right) \Lambda_{\tau'}^c \\ &= 0 \end{aligned}$$

If $\tau = \tau' + \frac{\delta}{2^d}$, but $d > \text{depth}(\mathfrak{S})$, then $\Lambda(\mathcal{J}) = X$ and

$$\Gamma_{*\tau}^{\tau'} = \Lambda(\mathcal{J}) j\left(\frac{\delta}{2^d}\right) \Lambda_{\tau'}^c = j(\tau - \tau') \Lambda_{\tau'}^c, \quad \Gamma_{*\tau-t}^{\tau'} = j(\tau - t - \tau') \Lambda_{\tau'}^c,$$

- (v) In this case $\Lambda_{\tau'}^c = \emptyset$. □

In the decimation step from scale δ to scale 2δ , we are passing from the product of the terms indexed by hierarchies $\mathfrak{S}_1, \mathfrak{S}_2$ for scale δ to a sum of terms indexed by hierarchies \mathfrak{S} that are preceded by $(\mathfrak{S}_1, \mathfrak{S}_2)$ in the sense of Definition 3.1. For this reason, we need

Proposition 3.6. (Recursion relation for the background fields) *Let $(\mathfrak{S}_1, \mathfrak{S}_2)$ be a pair of hierarchies for scale δ that precede the hierarchy \mathfrak{S} for scale 2δ . Let $\tau \in (0, 2\delta)$ be a decimation point. Then*

$$\begin{aligned} & \Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) \\ &= \begin{cases} \Gamma_{*\mathfrak{S}_1}(\tau; \alpha_*, \vec{\alpha}_{*l}) & \text{if } \tau \in (0, \delta) \\ \Lambda_{\mathfrak{S}} j(\delta) \alpha_* + \Lambda_{\mathfrak{S}}^c \alpha_{*\delta} & \text{if } \tau = \delta \\ \Gamma_{*\mathfrak{S}_2}(\tau - \delta; \Lambda_{\mathfrak{S}} j(\delta) \alpha_* + \Lambda_{\mathfrak{S}}^c \alpha_{*\delta}, \vec{\alpha}_{*r}) + \partial \Gamma_{*\tau} \alpha_* & \text{if } \tau \in (\delta, 2\delta) \end{cases} \end{aligned}$$

Here, for $\tau \in (\delta, 2\delta)$, the difference operator $\partial \Gamma_{*\tau}$ is defined as follows. Let \mathcal{J} be the smallest decimation interval for \mathfrak{S} with left endpoint δ such that $[\delta, \tau]$ is strictly contained in \mathcal{J} , and let δ' be the length of \mathcal{J} . Then

$$\partial \Gamma_{*\tau} = j\left(\tau - \delta - \frac{\delta'}{2}\right) \Lambda_{\mathfrak{S}}(\mathcal{J})^c j\left(\frac{\delta'}{2}\right) \Lambda_{\mathfrak{S}} j(\delta)$$

Similarly,

$$\Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) = \begin{cases} \Gamma_{\mathfrak{S}_1}(\tau; \vec{\alpha}_l, \Lambda_{\mathfrak{S}} j(\delta) \beta + \Lambda_{\mathfrak{S}}^c \alpha_\delta) + \partial \Gamma_\tau \beta & \text{if } \tau \in (0, \delta) \\ \Lambda_{\mathfrak{S}} j(\delta) \beta + \Lambda_{\mathfrak{S}}^c \alpha_\delta & \text{if } \tau = \delta \\ \Gamma_{\mathfrak{S}_2}(\tau - \delta; \vec{\alpha}_r, \beta) & \text{if } \tau \in (\delta, 2\delta) \end{cases}$$

Here, for $\tau \in (0, \delta)$, the difference operator $\partial \Gamma_\tau$ is defined as follows. Let \mathcal{J} be the smallest decimation interval for \mathfrak{S} with right endpoint δ such that $[\tau, \delta]$ is strictly contained in \mathcal{J} , and let δ' be the length of \mathcal{J} . Then

$$\partial \Gamma_\tau = j\left(\delta - \tau - \frac{\delta'}{2}\right) \Lambda_{\mathfrak{S}}(\mathcal{J})^c j\left(\frac{\delta'}{2}\right) \Lambda_{\mathfrak{S}} j(\delta)$$

Proof. If $\tau \in (0, \delta)$ and $0 \leq \tau' \leq \tau$ is a decimation point, then $\Gamma_{*\tau}^{\tau'}(\mathfrak{S}) = \Gamma_{*\tau}^{\tau'}(\mathfrak{S}_1)$ by Definition 2.9. By Remark 3.5(ii), $\Gamma_{*\tau}^{\tau'}(\mathfrak{S}) = 0$ and $\Gamma_{*\tau}^{\tau'}(\mathfrak{S}_1) = 0$ whenever $\tau' > \tau$.

If $\tau = \delta$ then $\Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) = \Lambda_{\mathfrak{S}} j(\delta) \alpha_* + \Lambda_{\mathfrak{S}}^c \alpha_{*\delta}$ directly by Definition 2.9.

Now let $\tau \in (\delta, 2\delta)$. Directly from Definition 2.9,

$$\Gamma_{*\tau}^{\tau'}(\mathfrak{S}) = \begin{cases} \Gamma_{*\tau-\delta}^0(\mathfrak{S}_2) \Lambda_{\mathfrak{S}}^c & \text{if } \tau' = \delta \\ \Gamma_{*\tau-\delta}^{\tau'-\delta}(\mathfrak{S}_2) & \text{if } \delta < \tau' < 2\delta \\ 0 & \text{if } 0 < \tau' < \delta \end{cases}$$

so that

$$\begin{aligned} & \Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) - \Gamma_{*\mathfrak{S}_2}(\tau - \delta; \Lambda_{\mathfrak{S}} j(\delta) \alpha_* + \Lambda_{\mathfrak{S}}^c \alpha_{*\delta}, \vec{\alpha}_{*r}) \\ &= \Gamma_{*\tau}^0(\mathfrak{S}) \alpha_* - \Gamma_{*\tau-\delta}^0(\mathfrak{S}_2) \Lambda_{\mathfrak{S}} j(\delta) \alpha_* \end{aligned}$$

Let \mathcal{J} be the interval defined in the Proposition, and set $\mathcal{J}' = \{t - \delta \mid t \in \mathcal{J}\}$. Then $\Lambda_{\mathfrak{S}}(\mathcal{J}) = \Lambda_{\mathfrak{S}_2}(\mathcal{J}')$ and

$$\begin{aligned} & \Gamma_{*\tau}^0(\mathfrak{S}) - \Gamma_{*\tau-\delta}^0(\mathfrak{S}_2) \Lambda_{\mathfrak{S}} j(\delta) \\ &= j(\tau - \delta) \Lambda_{\mathfrak{S}} j(\delta) - j\left(\tau - \delta - \frac{\delta'}{2}\right) \Lambda_{\mathfrak{S}_2}(\mathcal{J}') j\left(\frac{\delta'}{2}\right) \Lambda_{\mathfrak{S}} j(\delta) \end{aligned}$$

$$= j \left(\tau - \delta - \frac{\delta'}{2} \right) \Lambda_{\mathfrak{S}_2} (\mathcal{J}')^c j \left(\frac{\delta'}{2} \right) \Lambda_{\mathfrak{S}} j(\delta) = \partial \Gamma_{*\tau}$$

Here, we used $j(\tau - \delta) = j(\tau - \delta - \frac{\delta'}{2}) (\Lambda_{\mathfrak{S}_2} (\mathcal{J}')^c + \Lambda_{\mathfrak{S}_2} (\mathcal{J}')) j(\frac{\delta'}{2})$.

The recursion representation for $\Gamma_{\mathfrak{S}}$ is proven similarly. \square

Further properties and alternative definitions of the background fields are given in Appendix E.

3.3. The Explicit Quadratic and Quartic Terms in the Effective Action

In (2.9), we defined the prospective dominant contribution to the quadratic part of the effective action associated to a hierarchy \mathfrak{S} for scale δ to be

$$Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) = Q_{\varepsilon, \delta}(\alpha_*, \beta; \Gamma_{*\mathfrak{S}}(\cdot; \alpha_*, \vec{\alpha}_*), \Gamma_{\mathfrak{S}}(\cdot; \vec{\alpha}, \beta)) \quad (3.3)$$

where $Q_{\varepsilon, \delta}$ was defined in (2.10) and ε was chosen to be $2^{-\text{depth}(\mathfrak{S})}\delta$. Here, and through the rest of the paper, we use the same definition but with $j(t)$ being interpreted as the \mathfrak{h} -operator of (3.1) and with the background fields $\Gamma_{*\mathfrak{S}}$, $\Gamma_{\mathfrak{S}}$ of Sect. 3.2.

Part (i) of the following Lemma shows that, in (3.3), we could have chosen $\varepsilon = 2^{-n}\delta$ for any $n \geq \text{depth}(\mathfrak{S})$. Part (ii) isolates the pure small field part and the history-independent part. Part (iii) gives a recursion relation.

Lemma 3.7. (i) Let \mathfrak{S} be a hierarchy at scale δ . For all $k, n \geq \text{depth}(\mathfrak{S})$

$$\begin{aligned} & Q_{\frac{\delta}{2^k}, \delta}(\alpha_*, \beta; \Gamma_{*\mathfrak{S}}(\cdot; \alpha_*, \vec{\alpha}_*), \Gamma_{\mathfrak{S}}(\cdot; \vec{\alpha}, \beta)) \\ &= Q_{\frac{\delta}{2^n}, \delta}(\alpha_*, \beta; \Gamma_{*\mathfrak{S}}(\cdot; \alpha_*, \vec{\alpha}_*), \Gamma_{\mathfrak{S}}(\cdot; \vec{\alpha}, \beta)) \end{aligned}$$

(ii) Let \mathfrak{S} be a hierarchy at scale δ . When the history field is identically zero,

$$Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})|_{\mathfrak{h}=0} = \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta)} \langle \Lambda_{\tau}^c \alpha_{*\tau}, \Lambda_{\tau}^c \alpha_{\tau} \rangle$$

where $\varepsilon = 2^{-\text{depth}(\mathfrak{S})}\delta$. The difference $Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) - \sum_{\tau} \langle \Lambda_{\tau}^c \alpha_{*\tau}, \Lambda_{\tau}^c \alpha_{\tau} \rangle$ is history complete. Its restriction to the small field region $\Omega_{\mathfrak{S}}$ is

$$Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})|_{\Omega_{\mathfrak{S}}} - \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta)} \langle \Lambda_{\tau}^c \alpha_{*\tau}, \Lambda_{\tau}^c \alpha_{\tau} \rangle = -\langle \alpha_*, j(\delta)\beta \rangle|_{\Omega_{\mathfrak{S}}}$$

(iii) Let $\mathfrak{S}_1, \mathfrak{S}_2$ be hierarchies of scale δ such that $(\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S}$, where \mathfrak{S} is a hierarchy of scale 2δ . Then

$$\begin{aligned} & Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \\ &= Q_{\mathfrak{S}_1}(\alpha_*, \Lambda j(\delta)\beta + \Lambda^c \alpha_{\delta}; \vec{\alpha}_{*l}, \vec{\alpha}_l) \\ &+ Q_{\mathfrak{S}_2}(\Lambda j(\delta)\alpha_* + \Lambda^c \alpha_{*\delta}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) \\ &+ \langle \Lambda j(\delta)\alpha_*, \Lambda j(\delta)\beta \rangle + \langle \Lambda^c \alpha_{*\delta}, \Lambda^c \alpha_{\delta} \rangle \\ &+ \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta]} \langle \Gamma_{*\mathfrak{S}_1}(\tau; \alpha_*, \vec{\alpha}_{*l}), (\partial \Gamma_{\tau} - j(\varepsilon) \partial \Gamma_{\tau+\varepsilon}) \beta \rangle \\ &+ \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta]} \langle (\partial \Gamma_{*\delta+\tau} - j(\varepsilon) \partial \Gamma_{*\delta+\tau-\varepsilon}) \alpha_*, \Gamma_{\mathfrak{S}_2}(\tau; \vec{\alpha}_r, \beta) \rangle \end{aligned}$$

where $\Lambda = \Lambda_{\mathfrak{S}}$, $\varepsilon = 2^{-\text{depth}(\mathfrak{S})}$ and the differences $\partial\Gamma_{*\tau}$, $\partial\Gamma_\tau$ were defined in Proposition 3.6 for $\tau \in (\delta, 2\delta)$ and $\tau \in (0, \delta)$, respectively. Here, we have also set $\partial\Gamma_{*\delta} = \partial\Gamma_{*2\delta} = \partial\Gamma_0 = \partial\Gamma_\delta = 0$ and $\Gamma_{*\mathfrak{S}_1}(0; \cdot) = \alpha_*$, $\Gamma_{\mathfrak{S}_2}(\delta; \cdot) = \beta$.

- (iv) Let \mathfrak{S} be a hierarchy of scale δ . Then for any fields ϕ_*, ϕ

$$\begin{aligned} & Q_{\mathfrak{S}}(\alpha_*, \Lambda j(\delta)\beta + \Lambda^c\phi; \vec{\alpha}_*, \vec{\alpha}) - Q_{\mathfrak{S}}(\alpha_*, \Lambda j_c(\delta)\beta + \Lambda^c\phi; \vec{\alpha}_*, \vec{\alpha}) \\ &= \sum_{\tau \in \varepsilon\mathbb{Z} \cap [0, \delta)} \langle \Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*), (\Gamma_\tau^\delta - j(\varepsilon)\Gamma_{\tau+\varepsilon}^\delta) \Lambda (j(\delta) - j_c(\delta)) \beta \rangle \\ & Q_{\mathfrak{S}}(\Lambda j(\delta)\alpha_* + \Lambda^c\phi_*, \beta; \vec{\alpha}_*, \vec{\alpha}) - Q_{\mathfrak{S}}(\Lambda j_c(\delta)\alpha_* + \Lambda^c\phi_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \\ &= \sum_{\tau \in \varepsilon\mathbb{Z} \cap (0, \delta]} \langle (\Gamma_{*\tau}^0 - j(\varepsilon)\Gamma_{*\tau-\varepsilon}^0) \Lambda (j(\delta) - j_c(\delta)) \alpha_*, \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) \rangle \end{aligned}$$

where $\Lambda = \Lambda_{\mathfrak{S}}$ and, again, $\varepsilon = 2^{-\text{depth}(\mathfrak{S})}$. Here, we have also set $\Gamma_{*\delta}^0 = \Gamma_\delta^\delta = 0$ and $\Gamma_{*\mathfrak{S}}(0; \cdot) = \alpha_*$, $\Gamma_{\mathfrak{S}}(\delta; \cdot) = \beta$ and, correspondingly, $\Gamma_{*0}^0 = \Gamma_\delta^0 = \mathbb{1}$.

Proof. (i) It suffices to prove this in the case that $k > \text{depth}(\mathfrak{S})$ and $n = k - 1$. To simplify notation, set $\varepsilon = 2^{-k}\delta$,

$$\gamma_{*\tau} = \begin{cases} \Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) & \text{if } \tau \neq 0 \\ \alpha_* & \text{if } \tau = 0 \end{cases} \quad \gamma_\tau = \begin{cases} \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) & \text{if } \tau \neq \delta \\ \beta & \text{if } \tau = \delta \end{cases}$$

If τ, τ' are decimation points with $\mathfrak{d}(\tau) = k$ and $\mathfrak{d}(\tau') \leq \text{depth}(\mathfrak{S})$, then by Remark 3.5(iv), $\Gamma_{*\tau}^{\tau'} = j(\varepsilon)\Gamma_{*\tau-\varepsilon}^{\tau'}$. Combining this with Remark 3.5(v), we see that

$$\gamma_{*\tau} = j(\varepsilon)\gamma_{*\tau-\varepsilon} \quad \text{if } \mathfrak{d}(\tau) = k$$

So by (2.10)

$$\begin{aligned} & Q_{\varepsilon, \delta}(\alpha_*, \beta; \vec{\gamma}_*, \vec{\gamma}) \\ &= \sum_{\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)} \langle \gamma_{*\tau} - j(\varepsilon)\gamma_{*\tau-\varepsilon}, \gamma_\tau \rangle - \langle \gamma_{*\delta-\varepsilon}, j(\varepsilon)\beta \rangle \\ &= \sum_{\tau \in 2\varepsilon\mathbb{Z} \cap (0, \delta)} \langle \gamma_{*\tau} - j(\varepsilon)\gamma_{*\tau-\varepsilon}, \gamma_\tau \rangle - \langle j(\varepsilon)\gamma_{*\delta-2\varepsilon}, j(\varepsilon)\beta \rangle \\ &= \sum_{\tau \in 2\varepsilon\mathbb{Z} \cap (0, \delta)} \langle \gamma_{*\tau} - j(\varepsilon)j(\varepsilon)\gamma_{*\tau-2\varepsilon}, \gamma_\tau \rangle - \langle \gamma_{*\delta-2\varepsilon}, j(\varepsilon)j(\varepsilon)\beta \rangle \\ &= Q_{2\varepsilon, \delta}(\alpha_*, \beta; \vec{\gamma}_*, \vec{\gamma}) \end{aligned}$$

- (ii) Define $\gamma_{*\tau}$ and γ_τ as above. By Remark 3.5(i),

$$j(\varepsilon)\gamma_{*\tau-\varepsilon}|_{\mathfrak{h}=0} = 0 \quad j(\varepsilon)\gamma_{*\tau-\varepsilon}|_{\Omega_{\mathfrak{S}}} = j(\tau)\alpha_*|_{\Omega_{\mathfrak{S}}}$$

Both equations follow from the definition (2.10) and Remark 3.5(i).

- (iii) Let $\varepsilon = 2^{-\text{depth}(\mathfrak{S})}(2\delta) = 2^{-(\text{depth}(\mathfrak{S})-1)}\delta$. Define $\gamma_{*\tau}$ and γ_τ as above, but with δ replaced by 2δ . By Proposition 3.6

$$\gamma_{*\tau} = \begin{cases} \gamma_{*\tau}^{(1)} & \text{if } \tau \in (0, \delta) \\ \Lambda j(\delta)\alpha_* + \Lambda^c \alpha_{*\delta} & \text{if } \tau = \delta \\ \gamma_{*\tau-\delta}^{(2)} + \partial \Gamma_{*\tau} \alpha_* & \text{if } \tau \in (\delta, 2\delta) \end{cases}$$

$$\gamma_\tau = \begin{cases} \gamma_\tau^{(1)} + \partial \Gamma_\tau \beta & \text{if } \tau \in (0, \delta) \\ \Lambda j(\delta)\beta + \Lambda^c \alpha_\delta & \text{if } \tau = \delta \\ \gamma_{\tau-\delta}^{(2)} & \text{if } \tau \in (\delta, 2\delta) \end{cases}$$

where $\Lambda = \Lambda_{\mathfrak{S}}$ and

$$\gamma_{*\tau}^{(1)} = \Gamma_{*\mathfrak{S}_1}(\tau; \alpha_*, \vec{\alpha}_{*l}) \quad \gamma_\tau^{(1)} = \Gamma_{\mathfrak{S}_1}(\tau; \vec{\alpha}_l, \Lambda j(\delta)\beta + \Lambda^c \alpha_\delta)$$

$$\gamma_{*\tau}^{(2)} = \Gamma_{*\mathfrak{S}_2}(\tau; \Lambda j(\delta)\alpha_* + \Lambda^c \alpha_{*\delta}, \vec{\alpha}_{*r}) \quad \gamma_\tau^{(2)} = \Gamma_{\mathfrak{S}_2}(\tau; \vec{\alpha}_r, \beta)$$

Then

$$\begin{aligned} Q_{\mathfrak{S}} = & \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta)} \langle \gamma_{*\tau}^{(1)} - j(\varepsilon) \gamma_{*\tau-\varepsilon}^{(1)}, \gamma_\tau^{(1)} + \partial \Gamma_\tau \beta \rangle \\ & + \langle \Lambda j(\delta)\alpha_* + \Lambda^c \alpha_{*\delta} - j(\varepsilon) \gamma_{*\delta-\varepsilon}^{(1)}, \Lambda j(\delta)\beta + \Lambda^c \alpha_\delta \rangle \\ & + \left\langle \gamma_{*\varepsilon}^{(2)} + \partial \Gamma_{*\delta+\varepsilon} \alpha_* - j(\varepsilon)(\Lambda j(\delta)\alpha_* + \Lambda^c \alpha_{*\delta}), \gamma_\varepsilon^{(2)} \right\rangle \\ & + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (\varepsilon, \delta)} \left\langle \gamma_{*\tau}^{(2)} + \partial \Gamma_{*\delta+\tau} \alpha_* - j(\varepsilon)(\gamma_{*\tau-\varepsilon}^{(2)} + \partial \Gamma_{*\delta+\tau-\varepsilon} \alpha_*), \gamma_\tau^{(2)} \right\rangle \\ & - \left\langle \gamma_{*\delta-\varepsilon}^{(2)} + \partial \Gamma_{*2\delta-\varepsilon} \alpha_*, j(\varepsilon) \beta \right\rangle \\ = & \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta)} \langle \gamma_{*\tau}^{(1)} - j(\varepsilon) \gamma_{*\tau-\varepsilon}^{(1)}, \gamma_\tau^{(1)} \rangle - \langle j(\varepsilon) \gamma_{*\delta-\varepsilon}^{(1)}, \Lambda j(\delta)\beta + \Lambda^c \alpha_\delta \rangle \\ & + \left\langle \gamma_{*\varepsilon}^{(2)} - j(\varepsilon)(\Lambda j(\delta)\alpha_* + \Lambda^c \alpha_{*\delta}), \gamma_\varepsilon^{(2)} \right\rangle \\ & + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (\varepsilon, \delta)} \left\langle \gamma_{*\tau}^{(2)} - j(\varepsilon) \gamma_{*\tau-\varepsilon}^{(2)}, \gamma_\tau^{(2)} \right\rangle - \left\langle \gamma_{*\delta-\varepsilon}^{(2)}, j(\varepsilon) \beta \right\rangle \\ & + \langle \Lambda j(\delta)\alpha_*, \Lambda j(\delta)\beta \rangle + \langle \Lambda^c \alpha_{*\delta}, \Lambda^c \alpha_\delta \rangle \\ & + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta)} \langle \gamma_{*\tau}^{(1)} - j(\varepsilon) \gamma_{*\tau-\varepsilon}^{(1)}, \partial \Gamma_\tau \beta \rangle \\ & + \left\langle \partial \Gamma_{*\delta+\varepsilon} \alpha_*, \gamma_\varepsilon^{(2)} \right\rangle + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (\varepsilon, \delta)} \langle \partial \Gamma_{*\delta+\tau} \alpha_* - j(\varepsilon) \partial \Gamma_{*\delta+\tau-\varepsilon} \alpha_*, \gamma_\tau^{(2)} \rangle \\ & - \langle \partial \Gamma_{*2\delta-\varepsilon} \alpha_*, j(\varepsilon) \beta \rangle \\ = & Q_{\mathfrak{S}_1}(\alpha_*, \Lambda j(\delta)\beta + \Lambda^c \alpha_\delta; \vec{\alpha}_{*l}, \vec{\alpha}_l) + Q_{\mathfrak{S}_2}(\Lambda j(\delta)\alpha_* + \Lambda^c \alpha_{*\delta}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) \\ & + \langle \Lambda j(\delta)\alpha_*, \Lambda j(\delta)\beta \rangle + \langle \Lambda^c \alpha_{*\delta}, \Lambda^c \alpha_\delta \rangle \end{aligned}$$

$$+ \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \left\langle \gamma_{*\tau}^{(1)}, (\partial \Gamma_\tau - j(\varepsilon) \partial \Gamma_{\tau+\varepsilon}) \beta \right\rangle \\ + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta]} \left\langle (\partial \Gamma_{*\delta+\tau} - j(\varepsilon) \partial \Gamma_{*\delta+\tau-\varepsilon}) \alpha_*, \gamma_\tau^{(2)} \right\rangle$$

with $\partial \Gamma_0 = \partial \Gamma_\delta = \partial \Gamma_{*\delta} = \partial \Gamma_{*2\delta} = 0$.

(iv) The first equality follows from (2.10) and the fact that

$$\Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \Lambda j(\delta) \beta + \Lambda^c \phi; \vec{\alpha}) - \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \Lambda j_c(\delta) \beta + \Lambda^c \phi; \vec{\alpha}) \\ = \Gamma_\tau^\delta \Lambda(j(\delta) - j_c(\delta)) \beta$$

The second equality follows from (2.10) and the fact that

$$\Gamma_{*\mathfrak{S}}(\tau; \Lambda j(\delta) \alpha_* + \Lambda^c \phi_*; \vec{\alpha}_*) - \Gamma_{*\mathfrak{S}}(\tau; \Lambda j_c(\delta) \alpha_* + \Lambda^c \phi_*; \vec{\alpha}_*) \\ = \Gamma_{*\tau}^0 \Lambda(j(\delta) - j_c(\delta)) \alpha_*$$

□

The quartic part of the interaction for a given decimation step depends on the scale at which the process has been started. To keep track of this we need the Riemann sums approximating (2.11).

Definition 3.8. (i) Let \mathfrak{S} be a hierarchy for scale δ , and let $\varepsilon = 2^{-n}\delta$ with $n \geq \text{depth}(\mathfrak{S})$. We define

$$\mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) = \varepsilon \mathcal{V}_n(\alpha_*, \beta; \Gamma_{*\mathfrak{S}}(\cdot; \alpha_*, \vec{\alpha}_*), \Gamma_{\mathfrak{S}}(\cdot; \vec{\alpha}, \beta))$$

where

$$\mathcal{V}_n(\alpha_*, \beta; \vec{\gamma}_*, \vec{\gamma}) = - \left[\langle \alpha_* \gamma_\varepsilon, v \alpha_* \gamma_\varepsilon \rangle + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta-\varepsilon)} \langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle \right. \\ \left. + \langle \gamma_{*\delta-\varepsilon} \beta, v \gamma_{*\delta-\varepsilon} \beta \rangle \right]$$

and $\Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*)$, $\Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta)$ are the background fields.

(ii) In the remark below we shall identify the small field part of $\mathcal{V}_{\mathfrak{S}}$. For that purpose, we define for any subset Ω of X and every δ that is an integer multiple of ε

$$V_{\Omega, \delta}(\varepsilon; \alpha_*, \beta) \\ = -\varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \langle [j(\tau) \alpha^*] [j(\delta - \tau - \varepsilon) \beta], v [j(\tau) \alpha^*] [j(\delta - \tau - \varepsilon) \beta] \rangle \Big|_{\Omega}$$

(Evaluating this at $\hbar = 1$ gives the $V_{\Omega, \delta}(\varepsilon; \alpha_*, \beta)$ of (2.1).)

Clearly, $\mathcal{V}_{\mathfrak{S}}$ is history complete (in particular $\mathcal{V}_{\mathfrak{S}}|_{\hbar=0} = 0$). It follows from Remark 3.5(i) that

Remark 3.9. (i) If $\varepsilon = 2^{-n}\delta$ with $n \geq \text{depth}(\mathfrak{S})$ then $\mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})|_{\Omega} = V_{\Omega, \delta}(\varepsilon; \alpha_*, \beta)$ for all $\Omega \subset \Omega_{\mathfrak{S}}$.

(ii) $V_{\Omega, \delta}(\varepsilon; \alpha_*, j(\delta) \beta) + V_{\Omega, \delta}(\varepsilon; j(\delta) \alpha_*, \beta) = V_{\Omega, 2\delta}(\varepsilon; \alpha_*, \beta)$

3.4. Properties of the Large Field Integral Operator

In our representation of $I_n(\varepsilon; \alpha^*, \beta)$, we persist in using the integral operator $\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}$ of Definition 2.8, except that the surface $C_s(\mathbf{x}; \alpha^*, \beta)$ is now \mathfrak{h} -dependent through the operators $j_{\mathfrak{c}}(s)$ of (2.7). Note that the characteristic functions $\chi_{\mathcal{J}}(\alpha, \alpha_{\tau}, \beta)$ and the cutoff Gaussian measures do not depend on \mathfrak{h} .

Lemma 3.10. (i) Let $(\mathfrak{S}_1, \mathfrak{S}_2)$ be a pair of hierarchies for scale δ that precede the hierarchy \mathfrak{S} for scale 2δ . We have the recursion relation

$$\begin{aligned} & \mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} [d\mu(\vec{\alpha}, \vec{z}_*, \vec{z})] \\ &= \mathcal{I}_{([0, 2\delta], \mathfrak{S}; \alpha^*, \beta)} [\mathcal{I}_{(\mathfrak{S}_1; \alpha^*, \alpha_{\delta})} [d\mu(\vec{\alpha}_l, \vec{z}_{*l}, \vec{z}_l)] \mathcal{I}_{(\mathfrak{S}_2; \alpha_{\delta}^*, \beta)} [d\mu(\vec{\alpha}_r, \vec{z}_{*r}, \vec{z}_r)]] \end{aligned}$$

(ii) Let \mathfrak{S} be a hierarchy for scale δ and set $\varepsilon = 2^{-\text{depth}(\mathfrak{S})}\delta$. The large field operator $\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} [d\mu(\vec{\alpha}, \vec{z}_*, \vec{z})]$ depends on $\alpha(\mathbf{y})$ and $\beta(\mathbf{y})$ only for $\mathbf{y} \in \Omega_{\mathfrak{S}}^c$.

Proof. Part (i) is trivial. To prove part (ii) by induction, it suffices to show that $\mathcal{I}_{([0, 2\delta], \mathfrak{S}; \alpha^*, \beta)}$ depends on $\alpha(\mathbf{y})$ and $\beta(\mathbf{y})$ only for $\mathbf{y} \in \Omega([0, 2\delta])^c$. The dependence of $\mathcal{I}_{([0, 2\delta], \mathfrak{S}; \alpha^*, \beta)}$ on $\alpha(\mathbf{y})$ and $\beta(\mathbf{y})$ arises only through two mechanisms. First, through the integration domain $C_{\delta}(\mathbf{x}; \alpha^*, \beta)$ with $\mathbf{x} \in R([0, 2\delta])$. By construction, this integration domain depends only on $\alpha(\mathbf{y})$ and $\beta(\mathbf{y})$ for \mathbf{y} within a distance \mathfrak{c} of $R([0, 2\delta])$. Since $\Omega([0, 2\delta])$ is the set of all points of $\Lambda([0, 2\delta])$ whose distance from $R([0, 2\delta])$ is at least $\mathfrak{c}(\delta)$, any such \mathbf{y} is in $\Omega([0, 2\delta])^c$. The second dependence is through the characteristic function $\chi_{[0, 2\delta]}(\alpha, \alpha_{\delta}, \beta)$. One sees by direct inspection of its definition in Appendix A that this characteristic function is independent of $\alpha(\mathbf{y})$ and $\beta(\mathbf{y})$ for all $\mathbf{y} \in \Omega([0, 2\delta])$. \square

Remark 3.11. Let \mathfrak{S} be a hierarchy for scale δ and set $\varepsilon = 2^{-\text{depth}(\mathfrak{S})}\delta$. The integral operator $\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} [d\mu(\vec{\alpha}, \vec{z}_*, \vec{z})]$ acts on the space of functions that are defined and measurable in the variables

$$\begin{array}{lll} z_{\tau}(\mathbf{x}) & \mathbf{x} \in \Lambda(\mathcal{J}) \setminus (R(\mathcal{J}) \cup \Omega(\mathcal{J})) & \text{with } |z_{\tau}(\mathbf{x})| \leq r(s) \\ z_{*\tau}(\mathbf{x}), z_{\tau}(\mathbf{x}) & \mathbf{x} \in R(\mathcal{J}) & \text{with } |z_{*\tau}(\mathbf{x})|, |z_{\tau}(\mathbf{x})| \leq R(s) \\ \alpha_{\tau}(\mathbf{x}) & \mathbf{x} \in \Lambda(\mathcal{J})^c & \text{with } |\alpha_{\tau}(\mathbf{x})| \leq R(\varepsilon) \end{array}$$

and analytic in the variables $z_{*\tau}(\mathbf{x}), z_{\tau}(\mathbf{x}), \mathbf{x} \in R(\mathcal{J}_{\tau})$. Here $\mathcal{J} = \mathcal{J}_{\tau}$ runs over all decimation intervals in $[0, \delta]$ of length $2\varepsilon \leq 2s \leq \delta$.

Proof. The first two restrictions appear explicitly in the limits of integration in Definition 2.8. The restriction $|\alpha_{\tau}(\mathbf{x})| \leq R(\varepsilon)$ is an immediate consequence of Lemma A.4(a). \square

We shall prove a bound on these large field integral operators, with $\mathfrak{h} \equiv 1$, in Theorem 2.18. To obtain a good bound, we make a specific choice of $C_s(\mathbf{x}; \alpha^*, \beta)$. Roughly speaking, each point $\mathbf{x} \in R(\mathcal{J})$ will provide a very small factor for the size of the integral over $C_s(\mathbf{x}; \alpha^*, \beta)$ which arises from the factor $e^{-z_{*\tau}(\mathbf{x})z_{\tau}(\mathbf{x})}$. This will be established in Proposition 3.38, below.

3.5. Norms and the Renormalization Group Map

In our description of the effective density in Theorem 2.16, the non-explicit quantities $\mathcal{D}_{\Omega_{\mathfrak{S}}}$, $\mathcal{B}_{\mathfrak{S}}$ and $\mathcal{L}_{\mathfrak{S}}$ are estimated with the help of the norms $\|\cdot\|_{\mathfrak{S}}$. These norms were defined abstractly in Definition 2.12 and then made concrete by the choice of the weight factors in Definition 2.13. In the construction itself, all functions involve history fields. For this reason, we extend, in Definition 3.12 below, the abstract definition of norms to the case of functions that depend on a history field too. In this abstract setting, we recall the main theorem from [4, §II] that will allow us to control the fluctuation integrals (Theorem 3.14). A fluctuation integral is performed for every triple $(\mathfrak{S}_1, \mathfrak{S}_2, \mathfrak{S})$ of hierarchies with $(\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S}$. (See the discussion before Definition 3.1.) Therefore, we discuss, in Remark 3.17, how the weight factors for \mathfrak{S}_1 , \mathfrak{S}_2 and \mathfrak{S} are related.

In each decimation step, the fluctuation integral is introduced through coordinates that are centred on the critical point of the quadratic part of the effective interaction. This change of variables affects our norms and is controlled using the operator norm of Definition 3.18, below.

Definition 3.12. Let ϕ_1, \dots, ϕ_s be a collection of fields on X and let \mathfrak{h} be a history field on X .

- (i) Let $f(\phi_1, \dots, \phi_s; \mathfrak{h})$ be a function which is defined and analytic on a neighbourhood of the origin in $\mathbb{C}^{(s+1)|X|}$. Then f has a unique expansion of the form

$$f(\phi_1, \dots, \phi_s; \mathfrak{h}) = \sum_{n_1, \dots, n_{s+1} \geq 0} \sum_{(\vec{x}_1, \dots, \vec{x}_{s+1}) \in X^{n_1} \times \dots \times X^{n_{s+1}}} \\ \times a(\vec{x}_1, \dots, \vec{x}_s; \vec{x}_{s+1}) \phi_1(\vec{x}_1) \cdots \phi_s(\vec{x}_s) \mathfrak{h}(\vec{x}_{s+1})$$

with the coefficients $a(\vec{x}_1, \dots, \vec{x}_s; \vec{x}_{s+1})$ invariant under permutations of the components of each vector \vec{x}_j . The functions $a(\vec{x}_1, \dots, \vec{x}_s; \vec{x}_{s+1})$ are called the (symmetric) coefficient system for f .

- (ii) For any $n_1, \dots, n_{s+1} \geq 0$ and any function $b(\vec{x}_1, \dots, \vec{x}_s; \vec{x}_{s+1})$ on $X^{n_1} \times \dots \times X^{n_{s+1}}$, we define the norm $\|b\|_{n_1, \dots, n_{s+1}}$ as follows:
 - o If there is at least one nonhistory field, that is if $\sum_{j=1}^s n_j \neq 0$, then

$$\|b\|_{n_1, \dots, n_{s+1}} = \max_{\mathbf{x} \in X} \max_{\substack{1 \leq j \leq s \\ n_j \neq 0}} \max_{\substack{1 \leq i \leq n_j \\ (\vec{x}_j)_i = \mathbf{x}}} \sum_{\substack{\vec{x}_\ell \in X^{n_\ell} \\ 1 \leq \ell \leq s+1}} |b(\vec{x}_1, \dots, \vec{x}_s; \vec{x}_{s+1})|$$

Here $(\vec{x}_j)_i$ is the i th component of the n_j -tuple \vec{x}_j .

- o If there are only history fields, that is if $\sum_{j=1}^s n_j = 0$, but $n_{s+1} \neq 0$, then we take the pure L^1 norm

$$\|b\|_{n_1, \dots, n_{s+1}} = \sum_{\vec{x}_{s+1} \in X^{n_{s+1}}} |b(-, \dots, -; \vec{x}_{s+1})|$$

- o Finally, for the constant term, that is if $\sum_{j=1}^{s+1} n_j = 0$,

$$\|b\|_{n_1, \dots, n_{s+1}} = |b(-, \dots, -)|$$

- (iii) Given weight factors $\kappa_1, \dots, \kappa_s$, and a metric d on X , the weight system with metric d that associates the weight factor κ_j to the field ϕ_j (and the weight factor one to the history field) is defined by

$$w_d(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s; \vec{\mathbf{x}}_{s+1}) = e^{\tau_d(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_{s+1})} \prod_{j=1}^s \prod_{\ell=1}^{n_j} \kappa_j(\mathbf{x}_{j,\ell})$$

for all $(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s; \vec{\mathbf{x}}_{s+1}) \in X^{n_1} \times \dots \times X^{n_s} \times X^{n_{s+1}}$ and all nonnegative integers n_1, \dots, n_{s+1} .

If Ω is a subset of X , the weight system with core Ω that associates the weight factor κ_j to the field ϕ_j (and the weight factor one to the history field) is w_{d_Ω} . The metric d_Ω was specified in Definition 2.11(iii).

- (iv) Let $f(\phi_1, \dots, \phi_s; \mathfrak{h})$ be a function which is defined and analytic on a neighbourhood of the origin in $\mathbb{C}^{(s+1)|X|}$ and a the symmetric coefficient system of f . We define the norm, with weight w , of f to be

$$\|f\|_w = \sum_{n_1, \dots, n_{s+1} \geq 0} \|w(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s, \vec{\mathbf{x}}_{s+1}) a(\vec{\mathbf{x}}_1, \dots, \vec{\mathbf{x}}_s, \vec{\mathbf{x}}_{s+1})\|_{n_1, \dots, n_{s+1}}$$

Remark 3.13. Let $f(\phi_1, \dots, \phi_s; \mathfrak{h})$ be a power series and Ω a subset of X .

- (i) For any weight system w

$$\left\| f(\phi_1, \dots, \phi_s; \mathfrak{h}) \Big|_{\begin{subarray}{l} \mathfrak{h}(\mathbf{x})=1 \text{ for } \mathbf{x} \in \Omega \\ \mathfrak{h}(\mathbf{x})=0 \text{ for } \mathbf{x} \in X \setminus \Omega \end{subarray}} \right\|_w \leq \|f|_\Omega\|_w \leq \|f\|_w$$

- (ii) For any measure $d\mu(\phi_s)$ that is independent of \mathfrak{h} ,

$$\int d\mu(\phi_s) (f(\phi_1, \dots, \phi_s; \mathfrak{h})|_\Omega) = \left[\int d\mu(\phi_s) f(\phi_1, \dots, \phi_s; \mathfrak{h}) \right] |_\Omega$$

Theorem III.4 of [4, §II] uses norms as in Definitions 2.12 and 3.12 to control a renormalization group step. For the reader's convenience, we repeat its statement as well as the main result of [4, Corollary III.5] here.

Theorem 3.14. *Let $f(\phi_1, \dots, \phi_s; z_*, z; \mathfrak{h})$ be a function which is defined and analytic on a neighbourhood of the origin in $\mathbb{C}^{(s+3)|X|}$. Let $r \geq 0$ and denote by $d\mu(z^*, z)$ the measure*

$$d\mu(z^*, z) = \prod_{\mathbf{x} \in X} \chi(|z(\mathbf{x})| \leq r) e^{-z(\mathbf{x})^* z(\mathbf{x})} \frac{dz^*(\mathbf{x}) \wedge dz(\mathbf{x})}{2\pi i}$$

Furthermore let $\kappa_1, \dots, \kappa_{s+2}$ be weight factors such that $\kappa_{s+1}(\mathbf{x}), \kappa_{s+2}(\mathbf{x}) \geq 4r$ for all $\mathbf{x} \in X$, and let $m \geq 0$ and $\Omega \subset X$. Denote by w the weight system with core Ω that associates the weight factor κ_j to the field ϕ_j , and the weight factors $\kappa_{s+1}, \kappa_{s+2}$ to the fields z^* and z respectively.

If $\|f\|_w < \frac{1}{16}$, then there is an analytic function $g(\phi_1, \dots, \phi_s)$ such that

$$\frac{\int e^{f(\phi_1, \dots, \phi_s; z^*, z)} d\mu(z^*, z)}{\int e^{f(0, \dots, 0; z^*, z)} d\mu(z^*, z)} = e^{g(\phi_1, \dots, \phi_s)} \quad (3.4)$$

and

$$\|g\|_w \leq \frac{\|f\|_w}{1 - 16\|f\|_w}$$

If, in addition, $\|f\|_w < \frac{1}{32}$ and the symmetric coefficient system $a(\vec{x}_1, \dots, \vec{x}_s; \vec{y}_*, \vec{y}; \vec{x})$ of f obeys $a(\vec{x}_1, \dots, \vec{x}_s; \vec{y}_*, \vec{y}; \vec{x}) = 0$ whenever $\vec{y} = \vec{y}_*$, then

$$\|g\|_w \leq \left(\frac{\|f\|_w}{\frac{1}{20} - \|f\|_w} \right)^2 \quad (3.5)$$

- Definition 3.15.** (i) We also use the weight system $w_{\mathfrak{S}}$ of Definition 2.13(iii) for functions that depend on the history field, giving weight one to the history field as in Definition 3.12(iii). We again write $\|\cdot\|_{\mathfrak{S}}$ for $\|\cdot\|_{w_{\mathfrak{S}}}$.
(ii) For any $\kappa, m > 0$, we use $w_{\kappa, m}$ to denote the weight system with metric $m d$ that associates the constant weight factor κ to the fields α^* and β and the weight factor 1 to the history field. The norm $\|f(\alpha^*, \beta; \mathfrak{h})\|_{\kappa, m} = \|f\|_{w_{\kappa, m}}$.

Remark 3.16. For a function $f(\alpha_*, \beta)$ that depends only on $\alpha_*(\mathbf{x})$ and $\beta(\mathbf{x})$ with $\mathbf{x} \in \Omega_{\mathfrak{S}}$,

$$\|f\|_{2R(\delta), m} \leq \|f\|_{\mathfrak{S}} \leq \|f\|_{2R(\delta), 2m}$$

For the decimation step, we need

Remark 3.17 (Weight factor recursion relation). Let $(\mathfrak{S}_1, \mathfrak{S}_2)$ be a pair of hierarchies for scale δ that precede the hierarchy \mathfrak{S} for scale 2δ . Then weight factors of Definition 2.13 obey

$$\kappa_{*\mathfrak{S}, \tau}(\mathbf{x}) = \begin{cases} 2R(2\delta) = \frac{R(2\delta)}{R(\delta)} \kappa_{*\mathfrak{S}_1, 0}(\mathbf{x}) & \text{if } \tau = 0, \mathbf{x} \in \Lambda_{\mathfrak{S}} \\ \kappa_{*\mathfrak{S}_1, 0}(\mathbf{x}) & \text{if } \tau = 0, \mathbf{x} \notin \Lambda_{\mathfrak{S}} \\ \kappa_{*\mathfrak{S}_1, \tau}(\mathbf{x}) & \text{if } 0 < \tau < \delta \\ \infty & \text{if } \tau = \delta, \mathbf{x} \in \Lambda_{\mathfrak{S}} \\ \frac{1}{2} \kappa_{*\mathfrak{S}_2, 0}(\mathbf{x}) & \text{if } \tau = \delta, \mathbf{x} \notin \Lambda_{\mathfrak{S}} \\ \kappa_{*\mathfrak{S}_2, \tau-\delta}(\mathbf{x}) & \text{if } \delta < \tau < 2\delta \end{cases}$$

and

$$\kappa_{\mathfrak{S}, \tau}(\mathbf{x}) = \begin{cases} 2R(2\delta) = \frac{R(2\delta)}{R(\delta)} \kappa_{\mathfrak{S}_2, \delta}(\mathbf{x}) & \text{if } \tau = 2\delta, \mathbf{x} \in \Lambda_{\mathfrak{S}} \\ \kappa_{\mathfrak{S}_2, \delta}(\mathbf{x}) & \text{if } \tau = 2\delta, \mathbf{x} \notin \Lambda_{\mathfrak{S}} \\ \kappa_{\mathfrak{S}_2, \tau-\delta}(\mathbf{x}) & \text{if } \delta < \tau < 2\delta \\ \infty & \text{if } \tau = \delta, \mathbf{x} \in \Lambda_{\mathfrak{S}} \\ \frac{1}{2} \kappa_{\mathfrak{S}_1, \delta}(\mathbf{x}) & \text{if } \tau = \delta, \mathbf{x} \notin \Lambda_{\mathfrak{S}} \\ \kappa_{\mathfrak{S}_1, \tau}(\mathbf{x}) & \text{if } 0 < \tau < \delta \end{cases}$$

and

$$\lambda_{\mathfrak{S},\tau}(\mathbf{x}) = \begin{cases} \lambda_{\mathfrak{S}_1,\tau}(\mathbf{x}) & \text{if } 0 < \tau < \delta \\ 32 r(\delta) & \text{if } \tau = \delta, \mathbf{x} \in \Lambda_{\mathfrak{S}} \setminus \Omega_{\mathfrak{S}} \\ \infty & \text{if } \tau = \delta, \mathbf{x} \notin \Lambda_{\mathfrak{S}} \setminus \Omega_{\mathfrak{S}} \\ \lambda_{\mathfrak{S}_2,\tau-\delta}(\mathbf{x}) & \text{if } \delta < \tau < 2\delta \end{cases}$$

We will deal with linear changes in the ϕ -fields which may be compositions of several such changes of variables. For the convenience of the reader we repeat the [4, Definition IV.2] of the operator norms we use.

Definition 3.18 (Weighted L^1-L^∞ operator norms). Let $\kappa, \kappa' : X \rightarrow (0, \infty]$ be weight factors and δ an arbitrary metric and let A be an \mathfrak{h} -linear map on \mathbb{C}^X . We define the operator norm

$$N_\delta(A; \kappa, \kappa') = \left\| \sum_{\substack{\mathbf{x}, \mathbf{y} \in X \\ \vec{\mathbf{x}} \in X^{(1)}}} A(\mathbf{x}; \vec{\mathbf{x}}; \mathbf{y}) \mathfrak{h}(\mathbf{x}) \beta_l(\mathbf{x}) \mathfrak{h}(\vec{\mathbf{x}}) \mathfrak{h}(\mathbf{y}) \beta_r(\mathbf{y}) \right\|_\omega$$

where ω is the weight system with metric δ that associates the weight $\frac{1}{\kappa}$ to β_l , the weight κ' to β_r and the weight 1 to \mathfrak{h} .

For an ordinary operator J on \mathbb{C}^X , we set $N_\delta(J; \kappa, \kappa') = N_\delta(\bar{J}; \kappa, \kappa')$. Observe that if J is multiplication by the characteristic function of a set Y , then

$$N_\delta(J; \kappa, \kappa') = \sup_{\mathbf{x} \in Y} \frac{\kappa'(\mathbf{x})}{\kappa(\mathbf{x})} \quad (3.6)$$

In [4, Remark IV.3], we gave a more explicit reformulation of the definition of $N_\delta(A; \kappa, \kappa')$.

The main change of variables formula [4, Proposition IV.4] is

Proposition 3.19. *Let A_j , $1 \leq j \leq s$, be \mathfrak{h} -operators on \mathbb{C}^X , and let $f(\phi_1, \dots, \phi_s; \mathfrak{h})$ be an analytic function on a neighbourhood of the origin in $\mathbb{C}^{(s+1)|X|}$. Define \tilde{f} by*

$$\tilde{f}(\phi_1, \dots, \phi_s; \mathfrak{h}) = f(A_1 \phi_1, \dots, A_s \phi_s; \mathfrak{h})$$

Let $\kappa_1, \dots, \kappa_s$, $\tilde{\kappa}_1, \dots, \tilde{\kappa}_s$ be weight factors. Denote by w and \tilde{w} the weight systems with metric δ that associate to the field ϕ_j the weight factor κ_j and $\tilde{\kappa}_j$ respectively.

If $N_\delta(A_j; \kappa_j, \tilde{\kappa}_j) \leq 1$ for $1 \leq j \leq s$, then

$$\|\tilde{f}\|_{\tilde{w}} \leq \|f\|_w$$

In [4] and Appendix G, we also state variants and corollaries of this Proposition.

Most of the times, the metric δ used in Definition 3.18 will be a multiple of the standard metric d . Therefore we introduce the notation

$$\mathcal{N}_\mu(A; \kappa, \kappa') = N_{\mu d}(A; \kappa, \kappa')$$

for any $\mu \geq 0$, any \mathfrak{h} -operator A and any weight factors κ, κ' . By (2.14), for any $\Omega \subset X$

$$N_{d_\Omega}(A; \kappa, \kappa') \leq \mathcal{N}_{2m}(A; \kappa, \kappa') \quad (3.7)$$

Specifically, we shall use

Definition 3.20.

$$\|A\| = \mathcal{N}_{5m}(A; 1, 1)$$

This is consistent with the definition of $\|v\|$ of (2.5).

The most important operators for our considerations are the propagator

$$j(t) = \text{exph}(-t(\mathbf{h} - \mu))$$

introduced in (3.1), and the cutoff propagator

$$j_c(t)(\mathbf{x}, \mathbf{y}) = j(t)(\mathbf{x}, \mathbf{y}) \cdot \begin{cases} 1 & \text{if } d(\mathbf{x}, \mathbf{y}) \leq c \\ 0 & \text{if } d(\mathbf{x}, \mathbf{y}) > c \end{cases}$$

introduced in (3.2). They fulfill the estimates

Lemma 3.21. Set $K_j = \mathcal{N}_{6m}(\mathbf{h} - \mu; 1, 1)$. For all $t \geq 0$,

- (i) $\|j(t)\| \leq \mathcal{N}_{6m}(j(t); 1, 1) \leq e^{K_j t}$
- (ii) $\|j(t) - \mathfrak{h}\| \leq \mathcal{N}_{6m}(j(t) - \mathfrak{h}; 1, 1) \leq t K_j e^{K_j t}$
- (iii) $\|j_c(t) - j(t)\| \leq t K_j e^{K_j t} e^{-m c}$.

Proof. These estimates follow directly from parts (ii), with $A = j(t) - \mathfrak{h}$, and (iv) of Remark G.4. \square

Further estimates on $j(t)$ are given in Appendix D.

3.6. Decimation

The first step in our proof of Theorem 2.16 is the construction of the “large field/ small field” decomposition of $I_n(\varepsilon; \alpha^*, \beta)(n = 0, 1, \dots, [\log_2 \theta/\varepsilon])$ for fixed $\varepsilon > 0$. The recursion step for this construction is Theorem 3.26, below. Recall that we are assuming that the two-body potential v satisfies Hypothesis 2.14, and in particular that $\|v\| \leq \frac{1}{2} \mathfrak{v}$.

As in Sect. 2.1, the small field parts of the term associated to a hierarchy will depend only on the small field set, not on the hierarchy. Its description is similar to that in Sect. 2.1. First, we introduce the analogue of the renormalization group map $\mathfrak{R}_{\Omega, \delta}$ for history complete functions:

Definition 3.22. Let $\Omega \subset X$. If $f_1(\alpha_*, \beta; \mathfrak{h}), f_2(\alpha_*, \beta; \mathfrak{h}), V(\alpha_*, \beta; \mathfrak{h})$ are history complete functions that are supported in Ω (i.e. $f_i|_\Omega = f_i$) we define

$$\begin{aligned} & \bar{\mathfrak{R}}_{\Omega;t}(V; f_1, f_2)(\alpha_*, \beta; \mathfrak{h}) \\ &= \left\{ f_1(\alpha_*, j_{\mathfrak{c}}(t)\beta) + f_2(j_{\mathfrak{c}}(t)\alpha_*, \beta) + \log \frac{\int d\mu_{\Omega,\mathfrak{r}(t)}(z^*, z) e^{\mathcal{A}(\alpha_*, \beta; z^*, z)}}{\int d\mu_{\Omega,\mathfrak{r}(t)}(z^*, z)} \right. \\ &\quad - \langle [j(t) - j_{\mathfrak{c}}(t)]\alpha_*, [j(t) - j_{\mathfrak{c}}(t)]\beta \rangle \\ &\quad \left. + V(\alpha_*, j_{\mathfrak{c}}(t)\beta) - V(\alpha_*, j(t)\beta) + V(j_{\mathfrak{c}}(t)\alpha_*, \beta) - V(j(t)\alpha_*, \beta) \right\} \Big|_{\Omega} \end{aligned}$$

where $\mathcal{A}(\alpha_*, \beta; z_*, z)$ is

$$\begin{aligned} & [f_1(\alpha_*, z + j_{\mathfrak{c}}(t)\beta) - f_1(\alpha_*, j_{\mathfrak{c}}(t)\beta)] + [f_2(z_* + j_{\mathfrak{c}}(t)\alpha_*, \beta) - f_2(j_{\mathfrak{c}}(t)\alpha_*, \beta)] \\ &+ \langle [j(t) - j_{\mathfrak{c}}(t)]\alpha_*, z \rangle + \langle z_*, [j(t) - j_{\mathfrak{c}}(t)]\beta \rangle \\ &+ [V(\alpha_*, z + j_{\mathfrak{c}}(t)\beta) - V(\alpha_*, j_{\mathfrak{c}}(t)\beta)] \\ &+ [V(z_* + j_{\mathfrak{c}}(t)\alpha_*, \beta) - V(j_{\mathfrak{c}}(t)\alpha_*, \beta)] \end{aligned}$$

Since $j(t)|_{\Omega}|_{\mathfrak{h}=1} = j_{(\Omega)}(t)$ and $j_{\mathfrak{c}}(t)|_{\Omega}|_{\mathfrak{h}=1} = j_{(\Omega),\mathfrak{c}}(t)$,

$$\bar{\mathfrak{R}}_{\Omega;t}(V; f_1, f_2)|_{\mathfrak{h}=1} = \mathfrak{R}_{\Omega;t}\left(V|_{\mathfrak{h}=1}; f_1|_{\mathfrak{h}=1}, f_2|_{\mathfrak{h}=1}\right)$$

Remark 3.23. If $\Omega' \subset \Omega$

$$\bar{\mathfrak{R}}_{\Omega';t}(V|_{\Omega'}; f_1|_{\Omega'}, f_2|_{\Omega'}) = \bar{\mathfrak{R}}_{\Omega;t}(V; f_1, f_2)|_{\Omega'}$$

We control the small field part in one decimation step by the following

Theorem 3.24. Set $K_R = 2^{12}K_j^2$ and $K_E = 2^{23}$. There are constants $\Theta, \mathfrak{v}_0 > 0$ such that, for all $\delta \leq \frac{1}{2}\Theta$ and $\mathfrak{v} \leq \mathfrak{v}_0$, the following holds for all $\Omega \subset X$:

Let $\mathcal{R}_1(\alpha_*, \beta; \mathfrak{h})$, $\mathcal{R}_2(\alpha_*, \beta; \mathfrak{h})$ and $\mathcal{E}_1(\alpha_*, \beta; \mathfrak{h})$, $\mathcal{E}_2(\alpha_*, \beta; \mathfrak{h})$ be history complete functions that are supported on Ω (that is $\mathcal{R}_i|_{\Omega} = \mathcal{R}_i$, $\mathcal{E}_i|_{\Omega} = \mathcal{E}_i$ for $i = 1, 2$) with the following properties

- o \mathcal{R}_1 and \mathcal{R}_2 are both bilinear in α_* and β and fulfill the estimates

$$\|\mathcal{R}_i\|_{2R(\delta),2m} \leq K_R \delta^2 r(\delta)^2 R(\delta)^2 e^{-2m\mathfrak{c}}$$

- o \mathcal{E}_1 and \mathcal{E}_2 both have degree at least two both in α_* and in β and fulfill the estimates

$$\|\mathcal{E}_i\|_{2R(\delta),2m} \leq K_E (\delta \mathfrak{v})^2 r(\delta)^2 R(\delta)^6$$

- o All four of these functions are invariant under $\alpha_* \rightarrow e^{-i\theta}\alpha_*$, $\beta \rightarrow e^{i\theta}\beta$.
Let ε be a divisor of δ . Then there are history complete functions $\mathcal{R}(\alpha_*, \beta; \mathfrak{h})$ and $\mathcal{E}(\alpha_*, \beta; \mathfrak{h})$ that are supported on Ω such that

$$\bar{\mathfrak{R}}_{\Omega;\delta}(V_{\Omega,\delta}(\varepsilon; \cdot); \mathcal{R}_1 + \mathcal{E}_1, \mathcal{R}_2 + \mathcal{E}_2) = \mathcal{R} + \mathcal{E}$$

and which have the following properties:

- o \mathcal{R} is bilinear in α_* and β and fulfills the estimates

$$\|\mathcal{R}\|_{2R(2\delta),2m} \leq K_R (2\delta)^2 r(2\delta)^2 R(2\delta)^2 e^{-2m\mathfrak{c}}$$

Furthermore \mathcal{R} is the quadratic part of $\bar{\mathfrak{R}}_{\Omega;\delta}(0; \mathcal{R}_1, \mathcal{R}_2)$ and, in particular, is independent of $V_{\Omega,\delta}(\varepsilon; \cdot)$, \mathcal{E}_1 and \mathcal{E}_2 .

- o \mathcal{E} has degree at least two both in α_* and in β and fulfills the estimates

$$\|\mathcal{E}\|_{2R(2\delta),2m} \leq K_E (2\delta v)^2 r(2\delta)^2 R(2\delta)^6$$

- o Both functions are invariant under $\alpha_* \rightarrow e^{-i\theta}\alpha_*$, $\beta \rightarrow e^{i\theta}\beta$.

The proof of Theorem 3.24 is similar to that of [5, Proposition III.3] and is given in Sect. 4.

Remark 3.25. By the definitions (2.18)

$$\begin{aligned} \delta^2 r(\delta)^2 R(\delta)^2 e^{-2m\epsilon} &= (\delta v)^{2(1-e_R-2e_r)} \frac{e^{-2m\epsilon}}{v^2} \\ (\delta v)^2 r(\delta)^2 R(\delta)^6 &= (\delta v)^{2(1-3e_R-4e_r)} \end{aligned}$$

Both quantities go to zero with δ by (2.17).

The last Theorem allows us to recursively control the “small field parts”. We now consider the full model.

Theorem 3.26. Set $K_D = 2^{35}e^{6K_j}$ and $K_L = 2^{48}e^{6K_j}$. There are constants $\Theta, v_0 > 0$ such that, for all $\delta \leq \frac{1}{2}\Theta$ and $v \leq v_0$, the following holds:

Let \mathfrak{S}_1 and \mathfrak{S}_2 be hierarchies for scale δ with summits $\Omega_1 = \Omega_{\mathfrak{S}_1}$ and $\Omega_2 = \Omega_{\mathfrak{S}_2}$. Let $\varepsilon = 2^{-n}\delta$ with $n \geq \max\{\text{depth}(\mathfrak{S}_1), \text{depth}(\mathfrak{S}_2)\}$.

Furthermore let $\mathcal{D}_1(\alpha_*, \beta; \vec{p}; \mathfrak{h})$, $\mathcal{D}_2(\alpha_*, \beta; \vec{p}; \mathfrak{h})$, $b_1(\alpha_*, \beta; \vec{p}; \mathfrak{h})$ and $b_2(\alpha_*, \beta; \vec{p}; \mathfrak{h})$ be history complete functions with the following properties

- o For $i = 1, 2$, $\mathcal{D}_i(0, 0; \vec{0}; 0) = 0$ and

$$\|\mathcal{D}_i\|_{\mathfrak{S}_i} \leq 1 \quad \|\mathcal{D}_i|_{\Omega_i}\|_{\mathfrak{S}_i} \leq 2^{-20}$$

- o The “pure large field parts” $\mathcal{D}_1|_{\Omega_1^c}$ and $\mathcal{D}_2|_{\Omega_2^c}$ vanish. On the other hand, b_1 and b_2 are purely large field. That is, $b_1 = b_1|_{\Omega_1^c}$ and $b_2 = b_2|_{\Omega_2^c}$.
- o $\mathcal{D}_1, \mathcal{D}_2$ are invariant under $\alpha_* \rightarrow e^{-i\theta}\alpha_*$, $\beta \rightarrow e^{i\theta}\beta$, $\vec{p} = (\vec{\alpha}_*, \vec{\alpha}, \vec{z}_*, \vec{z}) \rightarrow (e^{-i\theta}\vec{\alpha}_*, e^{i\theta}\vec{\alpha}, e^{-i\theta}\vec{z}_*, e^{i\theta}\vec{z})$

Set, for $i = 1, 2$,

$$\begin{aligned} I_i(\alpha^*, \beta) &= \mathcal{Z}_\delta^{|\Omega_i|} \chi_\delta(\Omega_i; \alpha, \beta) \mathcal{I}_{(\mathfrak{S}_i; \alpha^*, \beta)} \\ &\times \left(e^{-Q_{\mathfrak{S}_i}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}_i}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{D}_i(\alpha^*, \beta; \vec{p})} b_i(\alpha^*, \beta; \vec{p}) \right) \end{aligned}$$

where $\chi_\delta(\Omega_i; \alpha, \beta)$ is the characteristic function introduced in Theorem 2.16. Also set

$$I(\alpha^*, \beta) = \int d\mu_{R(\varepsilon)}(\phi^*, \phi) I_1(\alpha^*, \phi) I_2(\phi^*, \beta)$$

Then

$$I(\alpha^*, \beta) = \sum_{\substack{\text{hierarchies} \\ (\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S}}} \mathcal{Z}_{2\delta}^{|\Omega_{\mathfrak{S}}|} \chi_{2\delta}(\Omega_{\mathfrak{S}}; \alpha, \beta) \mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}$$

$$\begin{aligned} & \times \left(e^{-Q_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})} e^{\mathcal{D}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}_l)} \right. \\ & \quad \left. b_1(\alpha^*, \alpha_\delta; \vec{\rho}_l) b_2(\alpha_\delta^*, \beta; \vec{\rho}_r) e^{\mathcal{L}'_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}_l)} \right) \end{aligned}$$

where, for each hierarchy \mathfrak{S} that is preceded by $(\mathfrak{S}_1, \mathfrak{S}_2)$ as in Definition 3.1, $\mathcal{D}_{\mathfrak{S}}$ and $\mathcal{L}'_{\mathfrak{S}}$ are analytic history complete functions that fulfill

- o The “pure large field part” $\mathcal{D}_{\mathfrak{S}}|_{\Omega_{\mathfrak{S}}^c}$ of $\mathcal{D}_{\mathfrak{S}}$ vanishes. Also,

$$\begin{aligned} \|\mathcal{D}_{\mathfrak{S}}\|_{\mathfrak{S}} & \leq \frac{1}{2} K_D (2\delta \mathfrak{v}) r(2\delta) R(2\delta)^3 + 2^{14} e^{-m\epsilon(\delta)} (\|\mathcal{D}_1\|_{\mathfrak{S}_1} + \|\mathcal{D}_2\|_{\mathfrak{S}_2}) \\ & \quad + 2^{14} (\|\mathcal{D}_1|_{\Omega_1}\|_{\mathfrak{S}_1} + \|\mathcal{D}_2|_{\Omega_2}\|_{\mathfrak{S}_2}) \end{aligned}$$

The “pure small field part” $\mathcal{D}_{\mathfrak{S}}|_{\Omega_{\mathfrak{S}}}$ is determined by $\mathcal{D}_1|_{\Omega_{\mathfrak{S}}}$ and $\mathcal{D}_2|_{\Omega_{\mathfrak{S}}}$ through

$$\mathcal{D}_{\mathfrak{S}}|_{\Omega_{\mathfrak{S}}} = \bar{\mathfrak{R}}_{\Omega_{\mathfrak{S}}; \delta} \left(\mathcal{V}_{\Omega_{\mathfrak{S}}; \delta}(\varepsilon; \cdot); \mathcal{D}_1|_{\Omega_{\mathfrak{S}}}, \mathcal{D}_2|_{\Omega_{\mathfrak{S}}} \right)$$

- o $\mathcal{L}'_{\mathfrak{S}}$ is “pure large field” (that is $\mathcal{L}'_{\mathfrak{S}} = \mathcal{L}'_{\mathfrak{S}}|_{\Omega_{\mathfrak{S}}^c}$) and fulfills the estimate
- $$\|\mathcal{L}'_{\mathfrak{S}}\|_{\mathfrak{S}} \leq \frac{1}{2} K_L (2\delta \mathfrak{v}) r(2\delta) R(2\delta)^3 + 2^8 (\|\mathcal{D}_1\|_{\mathfrak{S}_1} + \|\mathcal{D}_2\|_{\mathfrak{S}_2})$$
- o $\mathcal{D}_{\mathfrak{S}}$ and $\mathcal{L}'_{\mathfrak{S}}$ are invariant under $\alpha_* \rightarrow e^{-i\theta} \alpha_*$, $\beta \rightarrow e^{i\theta} \beta$, $\vec{\rho} = (\vec{\alpha}_*, \vec{\alpha}, \vec{z}_*, \vec{z}) \rightarrow (e^{-i\theta} \vec{\alpha}_*, e^{i\theta} \vec{\alpha}, e^{-i\theta} \vec{z}_*, e^{i\theta} \vec{z})$

This Theorem allows the construction of $I_m(2^{-m}\theta; \cdot, \cdot)$ for each fixed m , and Theorem 3.24 provides control of its small field parts. See Propositions 3.32 and 3.29, with $n = m$, below. The second step in the proof of Theorem 2.16 is the comparison of $I_m(2^{-m}\theta; \cdot, \cdot)$ and $I_{m+1}(2^{-(m+1)}\theta; \cdot, \cdot)$, leading to the limit $m \rightarrow \infty$. To do this, we compare $I_n(2^{-m}\theta; \cdot, \cdot)$ and $I_{n+1}(2^{-(m+1)}\theta; \cdot, \cdot)$ for $1 \leq n \leq m$.

For the pure small field part the essential comparison step is

Theorem 3.27. *Under the hypotheses of Theorem 3.24, assume that there is a second set $\tilde{\mathcal{R}}_1(\alpha_*, \beta; \mathfrak{h})$, $\tilde{\mathcal{R}}_2(\alpha_*, \beta; \mathfrak{h})$ and $\tilde{\mathcal{E}}_1(\alpha_*, \beta; \mathfrak{h})$, $\tilde{\mathcal{E}}_2(\alpha_*, \beta; \mathfrak{h})$ of history complete functions that have similar properties to \mathcal{R}_1 , \mathcal{R}_2 , \mathcal{E}_1 , \mathcal{E}_2 and are close to these functions. Precisely, we assume that*

- o $\tilde{\mathcal{R}}_1$ and $\tilde{\mathcal{R}}_2$ are both bilinear in α_* and β and fulfill the estimates
- $$\|\tilde{\mathcal{R}}_i\|_{2R(\delta), 2m} \leq K_R \delta^2 r(\delta)^2 R(\delta)^2 e^{-2m\epsilon}$$
- o \mathcal{E}_1 and \mathcal{E}_2 both have degree at least two both in α_* and in β and fulfill the estimates

$$\|\tilde{\mathcal{E}}_i\|_{2R(\delta), 2m} \leq K_E (\delta \mathfrak{v})^2 r(\delta)^2 R(\delta)^6$$

Let

$$\bar{\mathfrak{R}}_{\Omega; \delta} \left(V_{\Omega, \delta} \left(\frac{\varepsilon}{2}; \cdot \right); \tilde{\mathcal{R}}_1 + \tilde{\mathcal{E}}_1, \tilde{\mathcal{R}}_2 + \tilde{\mathcal{E}}_2 \right) = \tilde{\mathcal{R}} + \tilde{\mathcal{E}}$$

be the decomposition of Theorem 3.24. Then

$$\|\tilde{\mathcal{R}} - \mathcal{R}\|_{2R(2\delta), 2m} \leq 2\Delta_{\mathcal{R}}$$

$$\|\tilde{\mathcal{E}} - \mathcal{E}\|_{2R(2\delta), 2m} \leq \Delta_{\mathcal{E}} + K_{\Delta}(2\delta\mathfrak{v}) r(2\delta)^2 R(2\delta)^2 (\Delta_{\mathcal{R}} + \varepsilon(2\delta\mathfrak{v}) R(2\delta)^4)$$

where $K_{\Delta} = 2^{40}e^{10K_j}$ and

$$\begin{aligned}\Delta_{\mathcal{R}} &= \frac{1}{2} \left(\|\tilde{\mathcal{R}}_1 - \mathcal{R}_1\|_{2R(\delta), 2m} + \|\tilde{\mathcal{R}}_2 - \mathcal{R}_2\|_{2R(\delta), 2m} \right) \\ \Delta_{\mathcal{E}} &= \frac{1}{2} \left(\|\tilde{\mathcal{E}}_1 - \mathcal{E}_1\|_{2R(\delta), 2m} + \|\tilde{\mathcal{E}}_2 - \mathcal{E}_2\|_{2R(\delta), 2m} \right)\end{aligned}$$

For the full model the essential comparison step is

Theorem 3.28. *Under the hypotheses of Theorem 3.26, assume that there is a second set $\tilde{\mathcal{D}}_1(\alpha_*, \beta; \vec{p}; \mathfrak{h})$, $\tilde{\mathcal{D}}_2(\alpha_*, \beta; \vec{p}; \mathfrak{h})$, $\tilde{b}_1(\alpha_*, \beta; \vec{p}; \mathfrak{h})$ and $\tilde{b}_2(\alpha_*, \beta; \vec{p}; \mathfrak{h})$ of history complete functions such that $\|\tilde{\mathcal{D}}_i\|_{\mathfrak{S}_i} \leq 1$ and $\|\tilde{\mathcal{D}}_i\|_{\Omega_i} \|_{\mathfrak{S}_i} \leq 2^{-20}$. Set*

$$\begin{aligned}\tilde{I}_i(\alpha^*, \beta) &= \mathcal{Z}_{\delta}^{|\Omega_i|} \chi_{\delta}(\Omega_i; \alpha, \beta) \mathcal{I}_{(\mathfrak{S}_i; \alpha^*, \beta)} \left(e^{-Q_{\mathfrak{S}_i} + V_{\mathfrak{S}_i}(\varepsilon/2; \cdot) + \tilde{\mathcal{D}}_i} \tilde{b}_i \right) \\ \tilde{I}(\alpha^*, \beta) &= \int d\mu_{R(\frac{\varepsilon}{2})}(\phi^*, \phi) \tilde{I}_1(\alpha^*, \phi) \tilde{I}_2(\phi^*, \beta)\end{aligned}$$

and let

$$\begin{aligned}\tilde{I}(\alpha^*, \beta) &= \sum_{\substack{\text{hierarchies} \\ \mathfrak{S} \text{ for scale } 2\delta \\ (\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S}}} \mathcal{Z}_{2\delta}^{|\Omega_{\mathfrak{S}}|} \chi_{2\delta}(\Omega_{\mathfrak{S}}; \alpha, \beta) \mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} \left(e^{-Q_{\mathfrak{S}} + V_{\mathfrak{S}}(\varepsilon/2; \cdot)} e^{\tilde{\mathcal{D}}_{\mathfrak{S}}} \tilde{b}_1 \tilde{b}_2 e^{\tilde{\mathcal{L}}'_{\mathfrak{S}}} \right)\end{aligned}$$

be its representation as in Theorem 3.26. Then

$$\begin{aligned}\|\mathcal{D}_{\mathfrak{S}} - \tilde{\mathcal{D}}_{\mathfrak{S}}\|_{\mathfrak{S}} &\leq \frac{1}{2} K_D \varepsilon(2\delta\mathfrak{v}) r(2\delta) R(2\delta)^3 + 2^{16} e^{-mc(\delta)} \left(\|\mathcal{D}_1 - \tilde{\mathcal{D}}_1\|_{\mathfrak{S}_1} \right. \\ &\quad \left. + \|\mathcal{D}_2 - \tilde{\mathcal{D}}_2\|_{\mathfrak{S}_2} \right) \\ &\quad + 2^{16} \left(\left\| (\mathcal{D}_1 - \tilde{\mathcal{D}}_1)|_{\Omega_1} \right\|_{\mathfrak{S}_1} + \left\| (\mathcal{D}_2 - \tilde{\mathcal{D}}_2)|_{\Omega_2} \right\|_{\mathfrak{S}_2} \right) \\ \|\mathcal{L}'_{\mathfrak{S}} - \tilde{\mathcal{L}}'_{\mathfrak{S}}\|_{\mathfrak{S}} &\leq \frac{1}{2} K_L \varepsilon(2\delta\mathfrak{v}) r(2\delta) R(2\delta)^3 \\ &\quad + 2^8 \left(\|\mathcal{D}_1 - \tilde{\mathcal{D}}_1\|_{\mathfrak{S}_1} + \|\mathcal{D}_2 - \tilde{\mathcal{D}}_2\|_{\mathfrak{S}_2} \right)\end{aligned}$$

Theorems 3.24 and 3.27 will be proven in Sect. 4. Theorems 3.26 and 3.28 will be proven in Sect. 5.

In the proof of Theorem 2.16, the analysis of the “pure small field part” can be treated almost independently from the rest. To do this, we define, as in Sect. 2.1 (but now with history complete functions)

$$\begin{aligned}\mathcal{D}_{\Omega;0}(\varepsilon; \alpha_*, \beta) &= 0 \\ \mathcal{D}_{\Omega;n+1}(\varepsilon; \alpha_*, \beta) &= \bar{\mathfrak{R}}_{\Omega; 2^n \varepsilon} (V_{\Omega; 2^n \varepsilon}(\varepsilon; \cdot, \cdot); \mathcal{D}_{\Omega;n}(\varepsilon; \cdot, \cdot), \mathcal{D}_{\Omega;n}(\varepsilon; \cdot, \cdot))\end{aligned}\tag{3.8}$$

By Remark 3.23

$$\mathcal{D}_{\Omega';n}(\varepsilon; \cdot) = \mathcal{D}_{\Omega;n}(\varepsilon; \cdot)|_{\Omega'} \quad \text{when } \Omega' \subset \Omega\tag{3.9}$$

Proposition 3.29. *There are constants $\Theta, \mathfrak{v}_0 > 0$ such that, for all $\theta \leq \Theta$ and $\mathfrak{v} \leq \mathfrak{v}_0$, the following holds for all $\Omega \subset X$:*

For each $\varepsilon > 0$ and each integer $1 \leq n \leq \log_2 \frac{\theta}{\varepsilon}$ the function $\mathcal{D}_{\Omega;n}(\varepsilon; \cdot)$ is the sum of a function $\mathcal{R}_{\Omega;n}(\varepsilon; \cdot)$ that is bilinear in α_ and β and an analytic function $\mathcal{E}_{\Omega;n}(\varepsilon; \cdot)$ that has degree at least two both in α_* and in β . They fulfill the estimates*

$$\begin{aligned}\|\mathcal{R}_{\Omega;n}(\varepsilon; \cdot)\|_{2R(2^n\varepsilon),2m} &\leq K_R (2^n\varepsilon)^2 r(2^n\varepsilon)^2 R(2^n\varepsilon)^2 e^{-2m\mathfrak{c}} \\ \|\mathcal{E}_{\Omega;n}(\varepsilon; \cdot)\|_{2R(2^n\varepsilon),2m} &\leq K_E (2^n\varepsilon \mathfrak{v})^2 r(2^n\varepsilon)^2 R(2^n\varepsilon)^6\end{aligned}$$

Furthermore

$$\begin{aligned}\left\| \mathcal{R}_{\Omega;n}(\varepsilon; \cdot) - \mathcal{R}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^n\varepsilon),2m} &\leq K_R 2^n \varepsilon^2 r(\varepsilon)^2 R(\varepsilon)^2 e^{-2m\mathfrak{c}} \\ \left\| \mathcal{E}_{\Omega;n}(\varepsilon; \cdot) - \mathcal{E}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^n\varepsilon),2m} &\leq 2K_E (\varepsilon \mathfrak{v})^2 r(\varepsilon)^2 R(\varepsilon)^6\end{aligned}\quad (3.10)$$

Proof. We first prove, by induction on n , the statement of the Proposition but with the second line of (3.10) replaced by

$$\begin{aligned}\left\| \mathcal{E}_{\Omega;n}(\varepsilon; \cdot) - \mathcal{E}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^n\varepsilon),2m} &\leq K_E (\varepsilon \mathfrak{v})^2 r(\varepsilon)^2 R(\varepsilon)^6 \\ &\quad + K_\Delta \varepsilon^{1-2e_R-4e_r} \left(\sum_{k=1}^n (2^k \varepsilon \mathfrak{v})^2 r(2^k \varepsilon)^2 R(2^k \varepsilon)^6 \right)\end{aligned}\quad (3.11)$$

This induction argument is similar to that of Theorems I.3 and I.4 in [5].

The induction starts with $n = 0$. Observe that

$$\mathcal{R}_{\Omega;0}(\varepsilon; \cdot) = \mathcal{E}_{\Omega;0}(\varepsilon; \cdot) = 0$$

while

$$\mathcal{R}_{\Omega;1}\left(\frac{\varepsilon}{2}; \cdot\right) + \mathcal{E}_{\Omega;1}\left(\frac{\varepsilon}{2}; \cdot\right) = \bar{\mathfrak{R}}_{\Omega,\frac{\varepsilon}{2}}\left(V_{\Omega,\frac{\varepsilon}{2}}\left(\frac{\varepsilon}{2}; \cdot\right); 0, 0\right)$$

By Theorem 3.24, with $\delta = \frac{\varepsilon}{2}$,

$$\begin{aligned}\left\| \mathcal{R}_{\Omega;1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(\varepsilon),2m} &\leq K_R \varepsilon^2 r(\varepsilon)^2 R(\varepsilon)^2 e^{-2m\mathfrak{c}} \\ \left\| \mathcal{E}_{\Omega;1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(\varepsilon),2m} &\leq K_E (\varepsilon \mathfrak{v})^2 r(\varepsilon)^2 R(\varepsilon)^6\end{aligned}$$

For the induction step from n to $n+1$ we apply Theorems 3.24 and 3.27 with $\delta = 2^n \varepsilon$

$$\begin{aligned}\mathcal{R}_1 &= \mathcal{R}_2 = \mathcal{R}_{\Omega;n}(\varepsilon; \cdot, \cdot) \quad \tilde{\mathcal{R}}_1 = \tilde{\mathcal{R}}_2 = \mathcal{R}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot, \cdot\right) \\ \mathcal{E}_1 &= \mathcal{E}_2 = \mathcal{E}_{\Omega;n}(\varepsilon; \cdot, \cdot) \quad \tilde{\mathcal{E}}_1 = \tilde{\mathcal{E}}_2 = \mathcal{E}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot, \cdot\right)\end{aligned}$$

By the inductive hypothesis and Theorem 3.24,

$$\begin{aligned}\mathcal{D}_{\Omega;n+1}(\varepsilon; \alpha_*, \beta) &= \bar{\mathfrak{R}}_{\Omega,2^n\varepsilon}(V_{\Omega,2^n\varepsilon}(\varepsilon; \cdot, \cdot); \mathcal{R}_{\Omega;n}(\varepsilon; \cdot, \cdot) + \mathcal{E}_{\Omega;n}(\varepsilon; \cdot, \cdot), \\ &\quad \mathcal{R}_{\Omega;n}(\varepsilon; \cdot, \cdot) + \mathcal{E}_{\Omega;n}(\varepsilon; \cdot, \cdot))\end{aligned}$$

has the decomposition

$$\mathcal{D}_{\Omega;n+1}(\varepsilon; \alpha_*, \beta) = \mathcal{R}_{\Omega;n+1}(\varepsilon; \alpha_*, \beta) + \mathcal{E}_{\Omega;n+1}(\varepsilon; \alpha_*, \beta)$$

where $\mathcal{R}_{\Omega;n+1}(\varepsilon; \cdot)$ and $\mathcal{E}_{\Omega;n+1}(\varepsilon; \cdot)$ have all of the required properties. Furthermore, by Theorem 3.27,

$$\begin{aligned} & \left\| \mathcal{R}_{\Omega;n+1}(\varepsilon; \cdot) - \mathcal{R}_{\Omega;n+2}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^{n+1}\varepsilon), 2m} \\ & \leq 2 \left\| \mathcal{R}_{\Omega;n}(\varepsilon; \cdot) - \mathcal{R}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^n\varepsilon), 2m} \\ & \leq K_R 2^{n+1} \varepsilon^2 r(\varepsilon)^2 R(\varepsilon)^2 e^{-2m\epsilon} \end{aligned}$$

and

$$\begin{aligned} & \left\| \mathcal{E}_{\Omega;n+1}(\varepsilon; \cdot) - \mathcal{E}_{\Omega;n+2}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^{n+1}\varepsilon), 2m} \\ & \leq \left\| \mathcal{E}_{\Omega;n}(\varepsilon; \cdot) - \mathcal{E}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^n\varepsilon), 2m} \\ & \quad + K_\Delta (2\delta v) r(2\delta)^2 R(2\delta)^2 \left(\left\| \mathcal{R}_{\Omega;n}(\varepsilon; \cdot) - \mathcal{R}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^n\varepsilon), 2m} \right. \\ & \quad \left. + \varepsilon (2\delta v) R(2\delta)^4 \right) \\ & \leq \left\| \mathcal{E}_{\Omega;n}(\varepsilon; \cdot) - \mathcal{E}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^n\varepsilon), 2m} \\ & \quad + K_\Delta (2\delta v) r(2\delta)^2 R(2\delta)^2 (K_R \delta \varepsilon r(\varepsilon)^2 R(\varepsilon)^2 e^{-2m\epsilon} + \varepsilon (2\delta v) R(2\delta)^4) \\ & \leq \left\| \mathcal{E}_{\Omega;n}(\varepsilon; \cdot) - \mathcal{E}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^n\varepsilon), 2m} \\ & \quad + K_\Delta \varepsilon (2\delta v)^2 r(2\delta)^2 R(2\delta)^2 \left(\frac{1}{2} K_R r(\varepsilon)^2 R(\varepsilon)^2 \frac{e^{-2m\epsilon}}{v} + R(2\delta)^4 \right) \\ & \leq \left\| \mathcal{E}_{\Omega;n}(\varepsilon; \cdot) - \mathcal{E}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^n\varepsilon), 2m} \\ & \quad + K_\Delta \varepsilon (2\delta v)^2 r(2\delta)^2 R(2\delta)^2 \left(\frac{1}{\varepsilon^{2e_R+4e_r}} + R(2\delta)^4 \right) \\ & \leq K_E (\varepsilon v)^2 r(\varepsilon)^2 R(\varepsilon)^6 + K_\Delta \varepsilon^{1-2e_R-4e_r} \left(\sum_{k=1}^n (2^k \varepsilon v)^2 r(2^k \varepsilon)^2 R(2^k \varepsilon)^6 \right) \\ & \quad + K_\Delta \varepsilon^{1-2e_R-4e_r} (2\delta v)^2 r(2\delta)^2 R(2\delta)^6 \\ & = K_E (\varepsilon v)^2 r(\varepsilon)^2 R(\varepsilon)^6 + K_\Delta \varepsilon^{1-2e_R-4e_r} \left(\sum_{k=1}^{n+1} (2^k \varepsilon v)^2 r(2^k \varepsilon)^2 R(2^k \varepsilon)^6 \right) \end{aligned}$$

For the fourth inequality, we used that, by (F.4b) and Hypothesis F.7(ii),

$$\frac{1}{2} K_R r(\varepsilon)^2 R(\varepsilon)^2 \frac{e^{-2m\epsilon}}{\mathfrak{v}} = \frac{1}{\varepsilon^{2e_R+4e_r}} \frac{1}{2} K_R \mathfrak{v}^{1-2e_R-4e_r} \frac{e^{-2m\epsilon}}{\mathfrak{v}^2} \leq \frac{1}{\varepsilon^{2e_R+4e_r}}$$

This completes the induction argument.

It remains only to prove that (3.11) implies the second line of (3.10). Summing the geometric series in (3.11) gives

$$\begin{aligned} & \left\| \mathcal{E}_{\Omega;n}(\varepsilon; \cdot) - \mathcal{E}_{\Omega;n+1}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{2R(2^n\varepsilon), 2m} \\ & \leq K_E (\varepsilon \mathfrak{v})^{2-6e_R-8e_r} + \frac{K_\Delta}{1-2^{-(2-6e_R-8e_r)}} \varepsilon^{1-2e_R-4e_r} (2^n \varepsilon \mathfrak{v})^{2-6e_R-8e_r} \\ & = (\varepsilon \mathfrak{v})^{2-6e_R-8e_r} \left(K_E + \frac{2^{17} e^{10K_j} K_E}{1-2^{-(2-6e_R-8e_r)}} \varepsilon^{1-2e_R-4e_r} (2^n)^{2-6e_R-8e_r} \right) \\ & \leq (\varepsilon \mathfrak{v})^{2-6e_R-8e_r} K_E \left(1 + \frac{2^{17} e^{10K_j}}{1-2^{-(2-6e_R-8e_r)}} (2^n \varepsilon)^{1-2e_R-4e_r} \right) \\ & \leq 2K_E (\varepsilon \mathfrak{v})^{2-6e_R-8e_r} \end{aligned}$$

by (2.17) and Hypothesis F.7(i). \square

Corollary 3.30. *For each subset Ω of X*

$$\mathcal{D}_{\Omega,\theta}(\alpha_*, \beta) = \lim_{m \rightarrow \infty} \mathcal{D}_{\Omega,m}(2^{-m}\theta; \alpha_*, \beta)$$

exists.¹² It has a decomposition

$$\mathcal{D}_{\Omega,\theta} = \mathcal{R}_{\Omega,\theta} + \mathcal{E}_{\Omega,\theta}$$

where

- $\mathcal{R}_{\Omega;\theta}(\alpha_*, \beta)$ is bilinear in α_* and β and fulfills the estimate

$$\|\mathcal{R}_{\Omega;\theta}\|_{2R(\theta), 2m} \leq K_R \theta^2 r(\theta)^2 R(\theta)^2 e^{-2m\epsilon}$$

- $\mathcal{E}_{\Omega;\theta}(\alpha_*, \beta)$ has degree at least two both in α_* and in β and fulfills the estimate

$$\|\mathcal{E}_{\Omega;\theta}\|_{2R(\theta), 2m} \leq K_E (\theta \mathfrak{v})^2 r(\theta)^2 R(\theta)^6$$

Proof. As

$$\begin{aligned} 2^n \varepsilon^2 r(\varepsilon)^2 R(\varepsilon)^2 e^{-2m\epsilon} &= 2^n (\varepsilon \mathfrak{v})^{2-2e_R-4e_r} \frac{e^{-2m\epsilon}}{\mathfrak{v}^2} \\ (\varepsilon \mathfrak{v})^2 r(\varepsilon)^2 R(\varepsilon)^6 &= (\varepsilon \mathfrak{v})^{2-6e_R-8e_r} \end{aligned}$$

and the exponents $2-2e_R-4e_r$ and $2-6e_R-8e_r$ are strictly positive, Proposition 3.29, with $n=m$, implies that the limits

$$\lim_{m \rightarrow \infty} \mathcal{R}_{\Omega;m}(2^{-m}\theta; \cdot) \quad \lim_{m \rightarrow \infty} \mathcal{E}_{\Omega;m}(2^{-m}\theta; \cdot)$$

exist. \square

¹² The convergence is with respect to the norm $\|\cdot\|_{2R(\theta), 2m}$.

We now describe the construction of the functions $\mathcal{D}_{\Omega;\theta}$, $\mathcal{B}_{\mathfrak{S}}$ and $\mathcal{L}_{\mathfrak{S}}$ of Theorem 2.16 from Theorems 3.24, 3.26, 3.27 and 3.28.

In each of the four theorems mentioned above we assert the existence of constants \mathfrak{v}_0 and Θ such that for all interactions and “times” bounded by \mathfrak{v}_0 resp. Θ , the conclusions are true. Now choose \mathfrak{v}_0 and Θ as the smallest of the constants from the three theorems.

Fix an interaction v obeying Hypothesis 2.14. For each $0 < \varepsilon < \Theta/2$ and each natural number $1 \leq n \leq \log_2 \frac{\Theta}{\varepsilon}$ define, for each α and β obeying $|\alpha(\mathbf{x})|, |\beta(\mathbf{x})| \leq R(\varepsilon)$ for all $\mathbf{x} \in X$, the effective density $I_n^\bullet(\varepsilon; \alpha^*, \beta)$ recursively by

$$\begin{aligned} I_1^\bullet(\varepsilon; \alpha^*, \beta) &= \mathcal{Z}_\varepsilon^{2|X|} \int d\mu_{R(\varepsilon)}(\phi^*, \phi) \zeta_\varepsilon(\alpha^*, \phi) e^{\langle \alpha^*, j(\varepsilon)\phi \rangle + \langle \phi^*, j(\varepsilon)\beta \rangle} \\ &\quad \times e^{-\varepsilon(\langle \alpha^*\phi, v\alpha^*\phi \rangle + \langle \phi^*\beta, v\phi^*\beta \rangle)} \zeta_\varepsilon(\phi^*, \beta) \\ I_{n+1}^\bullet(\varepsilon; \alpha^*, \beta) &= \int d\mu_{R(\varepsilon)}(\phi^*, \phi) I_n^\bullet(\varepsilon; \alpha^*, \phi) I_n^\bullet(\varepsilon; \phi^*, \beta) \end{aligned} \quad (3.12)$$

with the \mathcal{Z}_ε of Lemma 2.7.

Remark 3.31. For each $n \geq 1$ we have

$$\begin{aligned} I_n^\bullet(\varepsilon; \alpha^*, \beta) &= \mathcal{Z}_\varepsilon^{2^n|X|} \prod_{\tau \in \varepsilon\mathbb{Z} \cap (0, 2^n\varepsilon)} d\mu_{R(\varepsilon)}(\alpha_\tau^*, \alpha_\tau) \prod_{\tau \in \varepsilon\mathbb{Z} \cap (0, 2^n\varepsilon]} \\ &\quad \times \left[\zeta_\varepsilon(\alpha_{\tau-\varepsilon}, \alpha_\tau) e^{\langle \alpha_{\tau-\varepsilon}^*, j(\varepsilon)\alpha_\tau \rangle - \varepsilon \langle \alpha_{\tau-\varepsilon}^* \alpha_\tau \circ \alpha_{\tau-\varepsilon}^* \alpha_\tau \rangle} \right] \end{aligned}$$

with $\alpha_0 = \alpha$ and $\alpha_{2^n\varepsilon} = \beta$. Comparing this with (1.3), we see that

$$I_n^\bullet(\varepsilon; \alpha^*, \beta)|_{\mathfrak{h}=1} = \mathcal{Z}_\varepsilon^{2^n|X|} I_n(\varepsilon; \alpha^*, \beta)$$

In Sect. 3.7, we shall prove that

$$I_\theta^\bullet(\alpha^*, \beta) = \lim_{m \rightarrow \infty} I_m^\bullet(2^{-m}\theta; \alpha^*, \beta)|_{\mathfrak{h}=1}$$

exists. Using the initial condition in Lemma 2.7, it will then follow that $I_\theta(\alpha^*, \beta) = \lim_{m \rightarrow \infty} I_m(2^{-m}\theta; \alpha^*, \beta)$ also exists and

$$I_\theta(\alpha^*, \beta) = I_\theta^\bullet(\alpha^*, \beta)$$

Theorem 3.26 allows us to recursively construct a representation of $I_n^\bullet(\varepsilon; \cdot)$ similar to that of Theorem 2.16. To do so, fix $\mathfrak{v} \leq \mathfrak{v}_0$ and an interaction v obeying Hypothesis 2.14. In the following, we use the constants K_D and K_L of Theorem 3.26.

Proposition 3.32. *For each ε , sufficiently small, and integer $n \geq 0$ with $2^n\varepsilon \leq \Theta$, the effective density $I_n^\bullet(\varepsilon; \alpha^*, \beta)$ has, for all α, β obeying $\sup_{\mathbf{x} \in X} |\alpha(\mathbf{x})|, \sup_{\mathbf{x} \in X} |\beta(\mathbf{x})| \leq R(\varepsilon)$, a representation*

$$\begin{aligned} I_n^\bullet(\varepsilon; \alpha^*, \beta) &= \sum_{\substack{\mathfrak{S} \text{ hierarchy} \\ \text{for scale } 2^n\varepsilon \\ \text{of depth at most } n}} \mathcal{Z}_{2^n\varepsilon}^{|\Omega_{\mathfrak{S}}|} \chi_{2^n\varepsilon}(\Omega_{\mathfrak{S}}; \alpha, \beta) \\ \mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} &= \left(e^{-Q_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})} e^{\mathcal{D}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\rho}_1) + \mathcal{L}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\rho}_1)} \right) \end{aligned}$$

Here, for each $\varepsilon > 0$, sufficiently small, and hierarchy \mathfrak{S} for scale $2^n\varepsilon \leq \Theta$, with depth at most n , $\mathcal{D}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\rho})$ and $\mathcal{L}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\rho})$ are analytic functions that have the following properties

- The “pure large field part of $\mathcal{D}_{\mathfrak{S}}(\varepsilon; \cdot)$ vanishes, that is $\mathcal{D}_{\mathfrak{S}}|_{\Omega_{\mathfrak{S}}} = 0$. The “pure small field part”

$$\mathcal{D}_{\mathfrak{S}}(\varepsilon; \cdot)|_{\Omega_{\mathfrak{S}}} = \mathcal{D}_{\Omega_{\mathfrak{S}}, n}(\varepsilon; \cdot)$$

as in (3.8) and Proposition 3.29. Also

$$\|\mathcal{D}_{\mathfrak{S}}(\varepsilon; \cdot)\|_{\mathfrak{S}} \leq K_D (2^n \varepsilon \mathfrak{v}) r(2^n \varepsilon) R(2^n \varepsilon)^3$$

- The “pure large field part” $\mathcal{L}_{\mathfrak{S}}$ has the decomposition

$$\mathcal{L}_{\mathfrak{S}}(\varepsilon; \alpha_*, \beta; \vec{\rho}) = \sum_{\substack{\text{decimation intervals } \mathcal{J} \\ \text{for } [0, 2^n \varepsilon] \text{ of length} \\ \text{at least } 2^{n-\text{depth}(\mathfrak{S})+1} \varepsilon}} \mathcal{L}_{\mathfrak{S}}(\mathcal{J}, \varepsilon; \alpha_*, \beta; \vec{\rho})$$

where, for each decimation interval \mathcal{J} in the sum, the function $\mathcal{L}_{\mathfrak{S}}(\mathcal{J}, \varepsilon; \alpha_*, \beta; \vec{\rho})$ is an analytic function of its arguments that

- is “large field with respect to the interval \mathcal{J} ” (that is, it depends only on values of the fields at points $\mathbf{x} \in X \setminus \Omega_{\mathfrak{S}}(\mathcal{J})$ and depends only on the variables $\alpha_{*\tau}, \alpha_\tau, z_{*\tau}, z_\tau$ with $\tau \in \mathcal{J} \cap (2^{-\text{depth}(\mathfrak{S})} \theta) \mathbb{Z}$.
- and fulfills the estimate

$$\|\mathcal{L}_{\mathfrak{S}}(\mathcal{J}, \varepsilon; \cdot)\|_{\mathfrak{S}} \leq K_L \delta \mathfrak{v} r(\delta) R(\delta)^3$$

where δ is the length of the time interval \mathcal{J} .

- The functions $\mathcal{D}_{\mathfrak{S}}$ and $\mathcal{L}_{\mathfrak{S}}(\mathcal{J})$ are all history complete and invariant under $\alpha_* \rightarrow e^{-i\theta} \alpha_*$, $\beta \rightarrow e^{i\theta} \beta$, $\vec{\rho} = (\vec{\alpha}_*, \vec{\alpha}, \vec{z}_*, \vec{z}) \rightarrow (e^{-i\theta} \vec{\alpha}_*, e^{i\theta} \vec{\alpha}, e^{-i\theta} \vec{z}_*, e^{i\theta} \vec{z})$

Furthermore, for each hierarchy \mathfrak{S} for scale $2^n \varepsilon$, of depth at most n , and each decimation interval $\mathcal{J} \subset [0, 2^n \varepsilon]$, of length at least $2^{n-\text{depth}(\mathfrak{S})+1} \varepsilon$,

$$\begin{aligned} \left\| \mathcal{D}_{\mathfrak{S}}(\varepsilon; \cdot) - \mathcal{D}_{\mathfrak{S}}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{\mathfrak{S}} &\leq (\varepsilon^2 \mathfrak{v})^{1-3e_R-4e_r} \\ \left\| \mathcal{L}_{\mathfrak{S}}(\mathcal{J}, \varepsilon; \cdot) - \mathcal{L}_{\mathfrak{S}}\left(\mathcal{J}, \frac{\varepsilon}{2}; \cdot\right) \right\|_{\mathfrak{S}} &\leq 2^{10} (\varepsilon^2 \mathfrak{v})^{1-3e_R-4e_r} \end{aligned}$$

Proof of Proposition 3.32 from Theorems 3.24, 3.26, 3.27 and 3.28. We introduce, in addition to the effective densities I_1, I_2, \dots of (3.12), the initial effective density

$$I_0^\bullet(\varepsilon; \alpha^*, \beta) = \mathcal{Z}_\varepsilon^{|X|} \chi_{R(\varepsilon)}(X, \alpha) \chi_{R(\varepsilon)}(X, \beta) \zeta_\varepsilon(\alpha^*, \beta) e^{\langle \alpha^*, j(\varepsilon) \beta \rangle} e^{-\varepsilon \langle \alpha^* \beta, v \alpha^* \beta \rangle}$$

where $\chi_R(X, \alpha)$ is the characteristic function which restricts $|\alpha(\mathbf{x})| \leq R$ for each $\mathbf{x} \in X$. Then the recursion relation of (3.12) still holds for the step from $n = 0$ to $n = 1$.

We prove the Proposition by induction on n , starting with $n = 0$. There is only a single hierarchy \mathfrak{S} of scale ε and depth 0, namely that with $\Omega_{\mathfrak{S}} = X$.

For ε sufficiently small, the initial effective density I_0 may also be written

$$I_0^\bullet(\varepsilon; \alpha^*, \beta) = \mathcal{Z}_\varepsilon^{|X|} \chi_\varepsilon(X; \alpha, \beta) e^{\langle \alpha^*, j(\varepsilon)\beta \rangle} e^{-\varepsilon \langle \alpha^* \beta, v \alpha^* \beta \rangle}$$

because $|\nabla \alpha(b)|, |\nabla \beta(b)| \leq 2R(\varepsilon) \leq R'(\varepsilon)$ for all $b \in X^*$. It satisfies the conclusions of the Proposition, with $\mathcal{D}_{\mathfrak{S}}(\varepsilon) = \mathcal{L}_{\mathfrak{S}}(\varepsilon) = 0$ and $\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}$ the identity operator. Since $\Omega_{\mathfrak{S}} = X$, we have $\mathcal{L}_{\mathfrak{S}}(\frac{\varepsilon}{2}) = 0$ and, in the notation of Proposition 3.29,

$$\mathcal{D}_{\mathfrak{S}}\left(\frac{\varepsilon}{2}\right) = \mathcal{D}_{X,1}\left(\frac{\varepsilon}{2}\right) = \mathcal{R}_{X,1}\left(\frac{\varepsilon}{2}\right) + \mathcal{E}_{X,1}\left(\frac{\varepsilon}{2}\right)$$

so that

$$\begin{aligned} & \|\mathcal{D}_{\mathfrak{S}}(\varepsilon) - \mathcal{D}_{\mathfrak{S}}\left(\frac{\varepsilon}{2}\right)\|_{\mathfrak{S}} \\ &= \left\| \mathcal{D}_{\mathfrak{S}}\left(\frac{\varepsilon}{2}\right) \right\|_{2R(\varepsilon), 2m} \leq K_R \varepsilon^2 r(\varepsilon)^2 R(\varepsilon)^2 e^{-2m\epsilon} + K_E (\varepsilon v)^2 r(\varepsilon)^2 R(\varepsilon)^6 \\ &= K_R (\varepsilon v)^{2-2e_R-4e_r} \frac{e^{-2m\epsilon}}{v^2} + K_E (\varepsilon v)^{2-6e_R-8e_r} \\ &\leq (\varepsilon^2 v)^{1-3e_R-4e_r} \end{aligned}$$

by (F.6a) and (F.4b), if ε is small enough.

For the induction step from n to $n+1$, set $\delta = 2^n \varepsilon$. By definition and the induction hypothesis

$$I_{n+1}^\bullet(\varepsilon; \alpha^*, \beta) = \sum_{\substack{\mathfrak{S}_1, \mathfrak{S}_2 \text{ hierarchies} \\ \text{for scale } \delta \text{ and} \\ \text{depth at most } n}} \int d\mu_{R(\varepsilon)}(\phi^*, \phi) I_{\mathfrak{S}_1}(\varepsilon; \alpha^*, \phi) I_{\mathfrak{S}_2}(\varepsilon; \phi^*, \beta)$$

where

$$\begin{aligned} I_{\mathfrak{S}_i}(\varepsilon; \alpha^*, \beta) &= \mathcal{Z}_\delta^{|\Omega_{\mathfrak{S}_i}|} \chi_\delta(\Omega_{\mathfrak{S}_i}; \alpha, \beta) \\ &\quad \mathcal{I}_{(\mathfrak{S}_i; \alpha^*, \beta)} \left(e^{-Q_{\mathfrak{S}_i}(\alpha^*, \beta; \vec{\alpha}, \vec{\alpha})} + \mathcal{V}_{\mathfrak{S}_i}(\varepsilon; \alpha^*, \beta; \vec{\alpha}, \vec{\alpha}) + \mathcal{D}_{\mathfrak{S}_i}(\varepsilon; \alpha^*, \beta; \vec{\rho}) e^{\mathcal{L}_{\mathfrak{S}_i}(\varepsilon; \alpha^*, \beta; \vec{\rho})} \right) \end{aligned}$$

By the induction hypothesis, Remark 3.16, Proposition 3.29, (F.4b) and (F.6a),

$$\begin{aligned} & \|\mathcal{D}_{\mathfrak{S}_i}(\varepsilon; \cdot)\|_{\mathfrak{S}_i} \leq K_D(\delta v) r(\delta) R(\delta)^3 \leq 1 \\ & \left\| \mathcal{D}_{\mathfrak{S}_i}(\varepsilon; \cdot) \right\|_{\Omega_{\mathfrak{S}_i}} \leq \left\| \mathcal{D}_{\Omega_{\mathfrak{S}_i}, n}(\varepsilon; \cdot) \right\|_{2R(\delta), 2m} \\ & \leq \left\| \mathcal{R}_{\Omega_{\mathfrak{S}_i}, n}(\varepsilon; \cdot) \right\|_{2R(\delta), 2m} + \left\| \mathcal{E}_{\Omega_{\mathfrak{S}_i}, n}(\varepsilon; \cdot) \right\|_{2R(\delta), 2m} \\ & \leq K_R \delta^2 r(\delta)^2 R(\delta)^2 e^{-2m\epsilon} + K_E (\delta v)^2 r(\delta)^2 R(\delta)^6 \\ & \leq 2^{-17} K_D(2\delta v) r(2\delta) R(2\delta)^3 \leq 2^{-20} \end{aligned}$$

Hence, for each pair of hierarchies \mathfrak{S}_1 and \mathfrak{S}_2 , we may apply Theorem 3.26 to the integral $\int d\mu_{R(\varepsilon)}(\phi^*, \phi) I_{\mathfrak{S}_1}(\varepsilon; \alpha^*, \phi) I_{\mathfrak{S}_2}(\varepsilon; \phi^*, \beta)$. We apply it with $\mathcal{D}_i = \mathcal{D}_{\mathfrak{S}_i}$ and $b_i = e^{\mathcal{L}_i}$. It gives the representation

$$I_{n+1}^\bullet(\varepsilon; \alpha^*, \beta) = \sum_{\substack{\mathfrak{S}_1, \mathfrak{S}_2 \text{ hierarchies} \\ \text{for scale } \delta \text{ and} \\ \text{depth at most } n}} \sum_{\substack{\text{hierarchies } \mathfrak{S} \\ \text{for scale } 2\delta \\ \text{with } (\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S}}} \mathcal{Z}_{2\delta}^{|\Omega_{\mathfrak{S}}|} \chi_{2\delta}(\Omega_{\mathfrak{S}}; \alpha, \beta)$$

$$\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} \left(e^{-Q_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{D}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\rho}_l)} \right. \\ \left. e^{\mathcal{L}'_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\rho}_l) + \mathcal{L}_{\mathfrak{S}_1}(\varepsilon; \alpha^*, \alpha_\delta; \vec{\rho}_l) + \mathcal{L}_{\mathfrak{S}_2}(\varepsilon; \alpha_\delta^*, \beta; \vec{\rho}_r)} \right)$$

The resulting functions $\mathcal{D}_{\mathfrak{S}}$ fulfill $\mathcal{D}_{\mathfrak{S}}(\varepsilon; \cdot)|_{\Omega_{\mathfrak{S}}} = 0$,

$$\mathcal{D}_{\mathfrak{S}}(\varepsilon; \cdot)|_{\Omega_{\mathfrak{S}}} = \bar{\mathfrak{R}}_{\Omega_{\mathfrak{S}}; \delta} \left(V_{\Omega_{\mathfrak{S}}; \delta}(\varepsilon; \cdot); \mathcal{D}_{\Omega_{\mathfrak{S}_1}, n}(\varepsilon; \cdot)|_{\Omega_{\mathfrak{S}}}, \mathcal{D}_{\Omega_{\mathfrak{S}_2}, n}(\varepsilon; \cdot)|_{\Omega_{\mathfrak{S}}}, \mathcal{D}_{\Omega_{\mathfrak{S}}, n}(\varepsilon; \cdot) \right) \\ = \bar{\mathfrak{R}}_{\Omega_{\mathfrak{S}}; \delta} \left(V_{\Omega_{\mathfrak{S}}; \delta}(\varepsilon; \cdot); \mathcal{D}_{\Omega_{\mathfrak{S}}, n}(\varepsilon; \cdot), \mathcal{D}_{\Omega_{\mathfrak{S}}, n}(\varepsilon; \cdot) \right) \\ = \mathcal{D}_{\Omega_{\mathfrak{S}}, n+1}(\varepsilon; \cdot)$$

by the inductive hypothesis, (3.9) and (3.8), and

$$\|\mathcal{D}_{\mathfrak{S}}(\varepsilon; \cdot)\|_{\mathfrak{S}} \\ \leq \frac{1}{2} K_D (2\delta \mathfrak{v}) r(2\delta) R(2\delta)^3 + 2^{14} e^{-m\mathfrak{c}(\delta)} (\|\mathcal{D}_{\mathfrak{S}_1}(\varepsilon; \cdot)\|_{\mathfrak{S}_1} + \|\mathcal{D}_{\mathfrak{S}_2}(\varepsilon; \cdot)\|_{\mathfrak{S}_2}) \\ + 2^{14} \left(\|\mathcal{D}_{\mathfrak{S}_1}(\varepsilon; \cdot)|_{\Omega_{\mathfrak{S}_1}}\|_{\mathfrak{S}_1} + \|\mathcal{D}_{\mathfrak{S}_2}(\varepsilon; \cdot)|_{\Omega_{\mathfrak{S}_2}}\|_{\mathfrak{S}_2} \right) \\ \leq \frac{1}{2} K_D (2\delta \mathfrak{v}) r(2\delta) R(2\delta)^3 + 2^{15} e^{-m\mathfrak{c}(\delta)} K_D (\delta \mathfrak{v}) r(\delta) R(\delta)^3 \\ + \frac{1}{4} K_D (2\delta \mathfrak{v}) r(2\delta) R(2\delta)^3 \\ \leq K_D (2\delta \mathfrak{v}) r(2\delta) R(2\delta)^3$$

by (F.4c). The resulting functions $\mathcal{L}'_{\mathfrak{S}}$ fulfill $\mathcal{L}'_{\mathfrak{S}} = \mathcal{L}'_{\mathfrak{S}}|_{\Omega_{\mathfrak{S}}}$ and

$$\|\mathcal{L}'_{\mathfrak{S}}\|_{\mathfrak{S}} \leq \frac{1}{2} K_L (2\delta \mathfrak{v}) r(2\delta) R(2\delta)^3 + 2^8 (\|\mathcal{D}_1\|_{\mathfrak{S}_1} + \|\mathcal{D}_2\|_{\mathfrak{S}_2}) \\ \leq \frac{1}{2} K_L (2\delta \mathfrak{v}) r(2\delta) R(2\delta)^3 + 2^9 K_D (\delta \mathfrak{v}) r(\delta) R(\delta)^3 \\ \leq K_L (2\delta \mathfrak{v}) r(2\delta) R(2\delta)^3$$

since $K_L \geq 2^{13} K_D$. If \mathcal{J} is a decimation interval for \mathfrak{S} , we set

$$\mathcal{L}_{\mathfrak{S}}(\mathcal{J}, \varepsilon; \alpha_*, \beta; \vec{\rho}) = \begin{cases} \mathcal{L}_{\mathfrak{S}_1}(\mathcal{J}, \varepsilon; \alpha_*, \alpha_\delta; \vec{\rho}_l) & \text{if } \mathcal{J} \subset [0, \delta] \\ \mathcal{L}_{\mathfrak{S}_2}(\mathcal{J} - \delta, \varepsilon; \alpha_{*\delta}, \beta; \vec{\rho}_r) & \text{if } \mathcal{J} \subset [\delta, 2\delta] \\ \mathcal{L}'_{\mathfrak{S}}(\varepsilon; \alpha, \beta; \vec{\rho}) & \text{if } \mathcal{J} = [0, 2\delta] \end{cases}$$

Now let \mathfrak{S} , \mathfrak{S}_1 and \mathfrak{S}_2 be hierarchies with $(\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S}$. By the induction hypothesis and Proposition 3.29,

$$\left\| \mathcal{D}_{\mathfrak{S}_i}(\varepsilon; \cdot) - \mathcal{D}_{\mathfrak{S}_i} \left(\frac{\varepsilon}{2}; \cdot \right) \right\|_{\mathfrak{S}_i} \\ \leq (\varepsilon^2 \mathfrak{v})^{1-3e_R-4e_r} \left\| \mathcal{D}_{\mathfrak{S}_i}(\varepsilon; \cdot)|_{\Omega_{\mathfrak{S}_i}} - \mathcal{D}_{\mathfrak{S}_i} \left(\frac{\varepsilon}{2}; \cdot \right)|_{\Omega_{\mathfrak{S}_i}} \right\|_{\mathfrak{S}_i} \\ \leq \left\| \mathcal{R}_{\Omega_{\mathfrak{S}_i}, n}(\varepsilon; \cdot) - \mathcal{R}_{\Omega_{\mathfrak{S}_i}, n} \left(\frac{\varepsilon}{2}; \cdot \right) \right\|_{2R(\delta), 2m} \\ + \left\| \mathcal{E}_{\Omega_{\mathfrak{S}_i}, n}(\varepsilon; \cdot) - \mathcal{E}_{\Omega_{\mathfrak{S}_i}, n} \left(\frac{\varepsilon}{2}; \cdot \right) \right\|_{2R(\delta), 2m}$$

$$\begin{aligned}
&\leq K_R \varepsilon \delta r(\varepsilon)^2 R(\varepsilon)^2 e^{-2m\mathfrak{c}} + 2K_E (\varepsilon \mathfrak{v})^2 r(\varepsilon)^2 R(\varepsilon)^6 \\
&= K_R \delta (\varepsilon \mathfrak{v})^{1-2e_R-4e_r} \frac{e^{-2m\mathfrak{c}}}{\mathfrak{v}} + 2K_E (\varepsilon \mathfrak{v})^{2-6e_R-8e_r} \\
&\leq 3K_E (\varepsilon \mathfrak{v})^{2-6e_R-8e_r}
\end{aligned}$$

if ε is small enough. We apply Theorem 3.28 with $\mathcal{D}_i = \mathcal{D}_{\mathfrak{S}_i}(\varepsilon; \cdot)$, $\tilde{\mathcal{D}}_i = \mathcal{D}_{\mathfrak{S}_i}(\frac{\varepsilon}{2}; \cdot)$, $b_i = e^{\mathcal{L}_{\mathfrak{S}_i}(\varepsilon; \cdot)}$ and $\tilde{b}_i = e^{\mathcal{L}_{\mathfrak{S}_i}(\frac{\varepsilon}{2}; \cdot)}$. It gives

$$\begin{aligned}
&\left\| \mathcal{D}_{\mathfrak{S}}(\varepsilon; \cdot) - \mathcal{D}_{\mathfrak{S}}\left(\frac{\varepsilon}{2}; \cdot\right) \right\|_{\mathfrak{S}} \\
&\leq \frac{1}{2} K_D \varepsilon (2\delta \mathfrak{v}) r(2\delta) R(2\delta)^3 + 2^{17} e^{-m\mathfrak{c}(\delta)} (\varepsilon^2 \mathfrak{v})^{1-3e_R-4e_r} \\
&\quad + 2^{17} (3K_E (\varepsilon \mathfrak{v})^{2-6e_R-8e_r}) \\
&= \frac{1}{2} K_D (2\delta)^{1-3e_R-4e_r} \varepsilon \mathfrak{v}^{1-3e_R-4e_r} + 2^{17} e^{-m\mathfrak{c}(\delta)} (\varepsilon^2 \mathfrak{v})^{1-3e_R-4e_r} \\
&\quad + 3 \cdot 2^{17} K_E \mathfrak{v}^{1-3e_R-4e_r} (\varepsilon^2 \mathfrak{v})^{1-3e_R-4e_r} \\
&\leq (\varepsilon^2 \mathfrak{v})^{1-3e_R-4e_r}
\end{aligned}$$

by (F.4c) and (F.6a), if ε is small enough, and

$$\begin{aligned}
&\left\| \mathcal{L}_{\mathfrak{S}}([0, 2\delta], \varepsilon; \cdot) - \mathcal{L}_{\mathfrak{S}}([0, 2\delta], \frac{\varepsilon}{2}; \cdot) \right\|_{\mathfrak{S}} \\
&\leq \frac{1}{2} K_L \varepsilon (2\delta \mathfrak{v}) r(2\delta) R(2\delta)^3 + 2^9 (\varepsilon^2 \mathfrak{v})^{1-3e_R-4e_r} \\
&\leq 2^{10} (\varepsilon^2 \mathfrak{v})^{1-3e_R-4e_r}
\end{aligned}$$

if ε is small enough. \square

Corollary 3.33. *Let \mathfrak{S} be a hierarchy of scale θ . Then the limit*

$$\mathcal{D}_{\mathfrak{S}}(\alpha_*, \beta; \vec{\rho}) = \lim_{m \rightarrow \infty} \mathcal{D}_{\mathfrak{S};m}(2^{-m}\theta; \alpha_*, \beta; \vec{\rho})$$

exists.¹³ Its “pure large field part” vanishes, that is $\mathcal{D}_{\mathfrak{S}}|_{\Omega_{\mathfrak{S}}^c} = 0$. The “pure small field part”

$$\mathcal{D}_{\mathfrak{S}}|_{\Omega_{\mathfrak{S}}} = \mathcal{D}_{\Omega_{\mathfrak{S}}, \theta}$$

as in Corollary 3.30. Also

$$\|\mathcal{D}_{\mathfrak{S}}\|_{\mathfrak{S}} \leq K_D (\theta \mathfrak{v}) r(\theta) R(\theta)^3$$

For each decimation interval \mathcal{J} in $[0, \theta]$, the limit

$$\mathcal{L}_{\mathfrak{S}}(\mathcal{J}; \alpha_*, \beta; \vec{\rho}) = \lim_{m \rightarrow \infty} \mathcal{L}_{\mathfrak{S};m}(\mathcal{J}, 2^{-m}\theta; \alpha_*, \beta; \vec{\rho})$$

exists⁽²⁾. The function $\mathcal{L}_{\mathfrak{S}}(\mathcal{J}; \alpha_*, \beta; \vec{\rho})$ is an analytic function of its arguments that

- is “large field with respect to the interval \mathcal{J} ” (that is, it depends only on values of the fields at points $\mathbf{x} \in X \setminus \Omega_{\mathfrak{S}}(\mathcal{J})$ and depends only on the variables $\alpha_{*\tau}, \alpha_\tau, z_{*\tau}, z_\tau$ with $\tau \in \mathcal{J} \cap (2^{-\text{depth}(\mathfrak{S})}\theta) \mathbb{Z}$.

¹³ The convergence is with respect to the norm $\|\cdot\|_{\mathfrak{S}}$.

- and fulfills the estimate

$$\|\mathcal{L}_{\mathfrak{S}}(\mathcal{J}; \cdot)\|_{\mathfrak{S}} \leq K_L \delta \|v\| r(\delta) R(\delta)^3$$

where δ is the length of the time interval \mathcal{J} .

The functions $\mathcal{D}_{\mathfrak{S}}$ and $\mathcal{L}_{\mathfrak{S}}(\mathcal{J})$ are all history complete and invariant under $\alpha_* \rightarrow e^{-i\theta} \alpha_*$, $\beta \rightarrow e^{i\theta} \beta$, $\vec{\rho} = (\vec{\alpha}_*, \vec{\alpha}, \vec{z}_*, \vec{z}) \rightarrow (e^{-i\theta} \vec{\alpha}_*, e^{i\theta} \vec{\alpha}, e^{-i\theta} \vec{z}_*, e^{i\theta} \vec{z})$.

The remaining ε dependent term in the representation of Proposition 3.32 is $\mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})$. We now show that its limit as ε tends to zero is the interaction

$$\begin{aligned} & \mathcal{V}_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \\ &= - \int_0^\delta d\tau \langle \Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta), v \Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) \rangle \end{aligned}$$

This agrees with (2.11), though of course v now implicitly depends on \mathfrak{h} .

Lemma 3.34. *Let \mathfrak{S} be a hierarchy for scale θ . Then, for each $\alpha^*, \beta, \vec{\alpha}^*, \vec{\alpha}$,*

$$\lim_{m \rightarrow \infty} \mathcal{V}_{\mathfrak{S}}(2^{-m}\theta; \alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) = \mathcal{V}_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$$

The convergence is uniform on compact sets. Furthermore

$$\mathcal{V}_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})|_{\Omega_{\mathfrak{S}}} = V_{\Omega_{\mathfrak{S}}; \theta}(\alpha_*, \beta)$$

where $V_{\Omega; \theta}(\alpha_*, \beta)$ is defined as in (2.4), but with history fields included.

Proof. We use the shorthand notations

$$\gamma_{*\tau} = \begin{cases} \Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) & \text{if } \tau \in (0, \theta) \\ \alpha_{*0} = \alpha_* & \text{if } \tau = 0 \end{cases} \quad \gamma_\tau = \begin{cases} \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) & \text{if } \tau \in (0, \theta) \\ \alpha_\theta = \beta & \text{if } \tau = \theta \end{cases}$$

Set $\varepsilon = 2^{-m}\theta$ and write

$$\begin{aligned} & \mathcal{V}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) - \mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) \\ &= - \int_0^\theta d\tau \langle \gamma_{*\tau} \gamma_\tau, v \gamma_{*\tau} \gamma_\tau \rangle + \varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \theta)} \langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle \\ &= \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \theta)} \int_0^\varepsilon dt [\langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle - \langle \gamma_{*\tau+t} \gamma_{\tau+t}, v \gamma_{*\tau+t} \gamma_{\tau+t} \rangle] \end{aligned}$$

Consequently

$$\begin{aligned} & |\mathcal{V}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) - \mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})| \\ &\leq \theta \sup_{\substack{\tau \in \varepsilon \mathbb{Z} \cap [0, \theta) \\ 0 \leq t \leq \varepsilon}} |\langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle - \langle \gamma_{*\tau+t} \gamma_{\tau+t}, v \gamma_{*\tau+t} \gamma_{\tau+t} \rangle| \\ &\leq \theta \sup_{\substack{\tau \in \varepsilon \mathbb{Z} \cap [0, \theta) \\ 0 \leq t \leq \varepsilon}} \left\{ |\langle (\gamma_{*\tau} - \gamma_{*\tau+t}) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \right. \end{aligned}$$

$$+ |\langle \gamma_{*\tau+t}(\gamma_{\tau+\varepsilon} - \gamma_{\tau+t}), v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| + |\langle \gamma_{*\tau+t} \gamma_{\tau+t}, v (\gamma_{*\tau} - \gamma_{*\tau+t}) \gamma_{\tau+\varepsilon} \rangle| \\ + |\langle \gamma_{*\tau+t} \gamma_{\tau+t}, v \gamma_{*\tau+t} (\gamma_{\tau+\varepsilon} - \gamma_{\tau+t}) \rangle| \}$$

We bound the first term. The bounds on the remaining three terms are virtually identical. For all $\tau \in \varepsilon \cap [0, \theta)$,

$$|\langle (\gamma_{*\tau} - \gamma_{*\tau+t}) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\ = |\langle (j(t) - \mathfrak{h}) \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\ \leq K_j t e^{K_j t} \|v\| |X| \max_{\mathbf{x} \in X} |\gamma_{*\tau}(\mathbf{x})|^2 \max_{\mathbf{x} \in X} |\gamma_{\tau+\varepsilon}(\mathbf{x})|^2$$

by Lemmas E.14 and 3.21(ii), and

$$\max_{\mathbf{x} \in X} |\gamma_{\tau+\varepsilon}(\mathbf{x})| \leq K_\alpha \equiv 2 + 5e^{K_j} \max_{\tau' \in \cap(0, \theta]} \max_{\mathbf{x} \in \Lambda_{\tau'}^c} |\alpha_{\tau'}(\mathbf{x})| \\ \max_{\mathbf{x} \in X} |\gamma_{*\tau}(\mathbf{x})| \leq K_{\alpha*} \equiv 2 + 5e^{K_j} \max_{\tau' \in \cap[0, \theta)} \max_{\mathbf{x} \in \Lambda_{\tau'}^c} |\alpha_{*\tau'}(\mathbf{x})|$$

by Lemma E.8. Hence

$$|\mathcal{V}_S(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) - \mathcal{V}_S(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})| \leq (4\theta e^{2K_j} \|v\| |X| K_\alpha^2 K_{\alpha*}^2) \varepsilon$$

clearly converges to zero, uniformly on compacta, as $\varepsilon \rightarrow 0$. \square

3.7. Bounds on the Large Field Integral Operator

In this section, we bound the large field integral operators $\mathcal{I}_{(S; \alpha^*, \beta)}$ when the history field is identically one. So we set $\mathfrak{h} \equiv 1$ throughout this section. Recall that $\mathcal{I}_{(S; \alpha^*, \beta)}$ and its absolute value $|\mathcal{I}_{(S; \alpha^*, \beta)}|$ were defined in Definition 2.8.

Proposition 3.32 gives a representation for $I_m^\bullet(2^{-m}\theta; \alpha^*, \beta)$ that is analogous to the representation for $I_\theta(\alpha^*, \beta) = \lim_{m \rightarrow \infty} I_m^\bullet(2^{-m}\theta; \alpha^*, \beta)|_{\mathfrak{h}=1}$ given in our main Theorem 2.16. To take the limit and prove Theorem 2.16, we shall apply the dominated convergence theorem to the sum over hierarchies in Proposition 3.32. To do so, we apply a result, Theorem 3.35, below, that is slightly more general than Theorem 2.18.

Fix $0 < \theta \leq \Theta$. Let $m \in \mathbb{N}$ and set $\varepsilon = 2^{-m}\theta$. Assume that α and β obey the small field conditions $\chi_\theta(\Omega; \alpha, \beta) = 1$.

Theorem 3.35. *For any bounded measurable function $f(\alpha, \beta; \vec{\rho})$ and subset $\Omega \subset X$,*

$$e^{-\frac{1}{2}\|\alpha\|^2 - \frac{1}{2}\|\beta\|^2} e^{-\text{Reg}_{SF}(\Omega; \alpha, \beta)} \sum_{k=1}^m e^{\ell(2^{-k+1}\theta)} \\ \times \sum_{\substack{\text{hierarchies } S \\ \text{for scale } \theta \\ \text{of depth } k \\ \text{with } \Omega_S = \Omega}} e^{\omega_S} |\mathcal{I}_{(S; \alpha^*, \beta)}| e^{\text{Re}(-Q_S + \mathcal{V}_S(\varepsilon))} |f| \\ \leq e^{-\frac{1}{4}\ell(\theta)|\Omega^c|} \left[\prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \frac{1}{1 + |\beta(\mathbf{x})|^3} \right] \sup |f|$$

with the $\text{Reg}_{SF}(\Omega; \alpha, \beta)$ of Definition 2.17 and

$$\omega_{\mathfrak{S}} = \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \theta]}} \frac{1}{2} |\Omega(\mathcal{J})^c|$$

The small factors that lead to Theorem 3.35 arise from three sources.

- o For each decimation interval \mathcal{J} , there is a large positive contribution to the main quadratic part of the action, $Q_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})$, for each point of the “large field sets of the first kind” $P'_\alpha(\mathcal{J})$, $P'_\beta(\mathcal{J})$ and $Q(\mathcal{J})$ that were introduced in the Definition 2.4 of a hierarchy. This is made precise in Proposition 3.36, below.
- o For each decimation interval \mathcal{J} , there is a large negative contribution to the main quartic part of the action, $\mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})$, for each point of the “large field sets of the first kind” $P_\alpha(\mathcal{J})$ and $P_\beta(\mathcal{J})$, that were introduced in the Definition 2.4 of a hierarchy. This is made precise in Proposition 3.37, below.
- o For each decimation interval \mathcal{J} of length $2s$, the integral operator $\mathcal{I}_{(\mathcal{J}, \mathfrak{S}; \alpha^*, \beta)}$, of Definition 2.8, includes an integral

$$\int_{C_s(\mathbf{x}; \alpha^*, \beta)} \frac{dz_{*\tau}(\mathbf{x}) \wedge dz_\tau(\mathbf{x})}{2\pi i} e^{-z_{*\tau}(\mathbf{x}) z_\tau(\mathbf{x})}$$

for each point \mathbf{x} in the “large field set of the second kind” $R(\mathcal{J})$. Proposition 3.38, below, shows that we may choose the domain of integration $C_s(\mathbf{x}; \alpha^*, \beta)$ in such a way that $\text{Re } z_{*\tau}(\mathbf{x}) z_\tau(\mathbf{x})$ is large on the entire surface $C_s(\mathbf{x}; \alpha^*, \beta)$.

At the end of this section, we show how Theorem 3.35 is deduced from these three propositions, which, in turn, will be proven in Sect. 6. The three propositions involve a constant $C_L > 0$, that is defined in Lemma F.5 and depends only on h and the constants of Hypothesis 2.14, (2.18), (2.19) and (2.20). For these three propositions, we fix an integer $0 \leq n \leq m$ and a hierarchy \mathfrak{S} for scale $\delta = 2^n \varepsilon$ of depth at most n and write

$$\gamma_{*\tau} = \begin{cases} \alpha^* & \text{if } \tau = 0 \\ \Gamma_{*\mathfrak{S}}(\tau; \alpha^*, \vec{\alpha}^*) & \text{if } \tau \in (0, \delta) \\ \beta^* & \text{if } \tau = \delta \end{cases} \quad \gamma_\tau = \begin{cases} \alpha & \text{if } \tau = 0 \\ \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) & \text{if } \tau \in (0, \delta) \\ \beta & \text{if } \tau = \delta \end{cases}$$

Proposition 3.36.

$$\begin{aligned} & -\text{Re} \left[\frac{1}{2} \|\alpha\|^2 + Q_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \frac{1}{2} \|\beta\|^2 \right] \\ & \leq -C_L \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \theta]}} r(|\mathcal{J}|)^2 \left\{ |\tilde{Q}(\mathcal{J})| + |\tilde{P}'_\alpha(\mathcal{J})| + |\tilde{P}'_\beta(\mathcal{J})| \right\} \\ & \quad - \frac{1}{16} \sum_{\tau \in [0, \delta)} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^\varepsilon \cup \Lambda_{\tau+\varepsilon}^\varepsilon}^2 \end{aligned}$$

$$\begin{aligned}
& + \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \delta]}} \frac{1}{8} |\Omega(\mathcal{J})^c| + |e^{\varepsilon\mu} - 1| \sum_{\tau \in [0, \delta]} [\|\gamma_\tau\|_{\Omega^c}^2 + \|\gamma_{*\tau}\|_{\Omega^c}^2] \\
& + \text{Reg}_{SF}^{(2)}(\Omega; \alpha, \beta)
\end{aligned}$$

where $\text{Reg}_{SF}^{(2)}(\Omega; \alpha, \beta)$ is given in Definition 2.17 and, for each decimation interval \mathcal{J} ,

$$\begin{aligned}
\tilde{P}'_\alpha(\mathcal{J}) &= \{b \in P'_\alpha(\mathcal{J}) \mid d(b, \Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c) > 2\mathfrak{c}(|\mathcal{J}^\pm|)\} \\
\tilde{P}'_\beta(\mathcal{J}) &= \{b \in P'_\beta(\mathcal{J}) \mid d(b, \Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c) > 2\mathfrak{c}(|\mathcal{J}^\pm|)\} \\
\tilde{Q}(\mathcal{J}) &= \{\mathbf{x} \in Q(\mathcal{J}) \mid d(\mathbf{x}, \Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c) > 2\mathfrak{c}(|\mathcal{J}^\pm|)\}
\end{aligned}$$

Proposition 3.37.

$$\begin{aligned}
& \text{Re} \left[\mathcal{V}_\mathfrak{S}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) - \text{Reg}_{SF}^{(4)}(\alpha, \beta) \right] \\
& \leq -C_L \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \delta]}} r(|\mathcal{J}|)^2 \left\{ |\tilde{P}'_\alpha(\mathcal{J})| + |\tilde{P}'_\beta(\mathcal{J})| \right\} \\
& \quad - \frac{1}{4} \sum_{\tau \in [0, \delta]} \varepsilon \langle \gamma_{*\tau}^* \gamma_{*\tau}, v \gamma_{*\tau}^* \gamma_{*\tau} \rangle - \frac{1}{4} \sum_{\tau \in (0, \delta]} \varepsilon \langle \gamma_\tau^* \gamma_\tau, v \gamma_\tau^* \gamma_\tau \rangle \\
& \quad + \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \delta]}} \frac{1}{8} |\Omega(\mathcal{J})^c| + \sum_{\tau \in [0, \delta)} \frac{1}{16} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c}^2
\end{aligned}$$

where $\text{Reg}_{SF}^{(4)}(\alpha, \beta)$ is given in Definition 2.17 and, for each decimation interval \mathcal{J} ,

$$\begin{aligned}
\tilde{P}_\alpha(\mathcal{J}) &= \{\mathbf{x} \in P_\alpha(\mathcal{J}) \mid d(\mathbf{x}, \Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c) > 2\mathfrak{c}\left(\frac{1}{2}|\mathcal{J}|\right)\} \\
\tilde{P}_\beta(\mathcal{J}) &= \{\mathbf{x} \in P_\beta(\mathcal{J}) \mid d(\mathbf{x}, \Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c) > 2\mathfrak{c}\left(\frac{1}{2}|\mathcal{J}|\right)\}
\end{aligned}$$

Proposition 3.38. Let \mathcal{J} be a decimation interval for \mathfrak{S} with length $2s$ and centre τ , and $\mathbf{x} \in \Lambda(\mathcal{J})$. We may choose the surface $C_s(\mathbf{x}; \alpha^*, \beta)$ of Definition 2.8 so that the following holds. Assume that α and β are such that the characteristic functions $\chi_{2s}(\Lambda(\mathcal{J}); \alpha, \beta)$ and $\chi_{\mathcal{J}}(\alpha, \alpha_\tau, \beta)$ are nonzero. Then

- (i) $C_s(\mathbf{x}; \alpha^*, \beta) \subset \{(z_*, z) \in \mathbb{C}^2 \mid |z_*|, |z| \leq 2r(s)\}$.
- (ii) For all $(z_*, z) \in C_s(\mathbf{x}; \alpha^*, \beta)$,

$$\text{Re}(z_* z) \geq C_L r(s)^2$$

- (iii) The area of $C_s(\mathbf{x}; \alpha^*, \beta)$ is bounded by $40\pi r(s)^2$.

Proof of Theorem 3.35. We still fix a hierarchy \mathfrak{S} for scale $\delta = 2^n\varepsilon$. For bounding the “absolute value” $|\mathcal{I}_\mathfrak{S}| = |\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}|$, we introduce the auxiliary integral

operator

$$\bar{\mathcal{I}}_{\mathfrak{S}} = \prod_{k=0, \dots, \text{depth}(\mathfrak{S})} \prod_{\substack{\text{decimation intervals} \\ \mathcal{J} = [\tau_l, \tau_r] \subset [0, \delta] \\ \text{of length } 2^{-k} \delta}} \bar{\mathcal{I}}_{(\mathcal{J}; \alpha_{\tau_\ell}^*, \alpha_{\tau_r})}$$

where $\bar{\mathcal{I}}_{(\mathcal{J}; \alpha^*, \beta)}$ is constructed by replacing

$$\int_{C_s(\mathbf{x}; \alpha^*, \beta)} \frac{dz_{*\tau}(\mathbf{x}) \wedge dz_\tau(\mathbf{x})}{2\pi i} e^{-z_{*\tau}(\mathbf{x}) z_\tau(\mathbf{x})} \quad \text{by} \quad \int_{C_s(\mathbf{x}; \alpha^*, \beta)} \left| \frac{dz_{*\tau}(\mathbf{x}) \wedge dz_\tau(\mathbf{x})}{2\pi i} \right|$$

in the formula for $\mathcal{I}_{(\mathcal{J}; \alpha^*, \beta)}$ in Definition 2.8. Then,

$$|\mathcal{I}_{\mathfrak{S}}| = \bar{\mathcal{I}}_{\mathfrak{S}} \prod_{\substack{\text{decimation intervals} \\ \mathcal{J} \subset [0, \delta] \text{ with centre } \tau}} \prod_{\mathbf{x} \in R(\mathcal{J})} e^{-\operatorname{Re} z_{*\tau}(\mathbf{x}) z_\tau(\mathbf{x})} \quad (3.13a)$$

By Proposition 3.38,

$$\prod_{\substack{\text{decimation intervals} \\ \mathcal{J} \subset [0, \delta] \text{ with centre } \tau}} \prod_{\mathbf{x} \in R(\mathcal{J})} e^{-\operatorname{Re} z_{*\tau}(\mathbf{x}) z_\tau(\mathbf{x})} \leq \prod_{\substack{\text{decimation intervals} \\ \mathcal{J} \subset [0, \delta]}} e^{-C_L |R(\mathcal{J})| r(\frac{1}{2} |\mathcal{J}|)^2} \quad (3.13b)$$

on the domain of integration. \square

Lemma 3.39.

$$\begin{aligned} & \operatorname{Re} \left[-\frac{1}{2} \|\alpha\|^2 - Q_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) - \frac{1}{2} \|\beta\|^2 + \mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) \right] \\ & \quad - \operatorname{Reg}_{SF}(\Omega; \alpha, \beta) \\ & \leq -C_L \sum_{\substack{\text{decimation intervals} \\ \mathcal{J} \subset [0, \delta]}} r(|\mathcal{J}|)^2 \left\{ |\tilde{Q}(\mathcal{J})| + |\tilde{P}'_\alpha(\mathcal{J})| + |\tilde{P}'_\beta(\mathcal{J})| + |\tilde{P}_\alpha(\mathcal{J})| + |\tilde{P}_\beta(\mathcal{J})| \right\} \\ & \quad + \sum_{\substack{\text{decimation intervals} \\ \mathcal{J} \subset [0, \delta]}} \frac{1}{2} |\Omega(\mathcal{J})^c| \end{aligned}$$

Proof. We assume that ε is sufficiently small that $|e^{\varepsilon\mu} - 1| \leq \frac{1}{8}$, which implies that $|e^{\varepsilon\mu} - 1| \leq 2\varepsilon|\mu|$. It suffices to apply Propositions 3.36 and 3.37 together with

$$\begin{aligned} & -\frac{1}{4} \varepsilon v_1 \sum_{\tau \in (0, \delta]} \|\gamma_\tau^* \gamma_\tau\|_{\Omega^c}^2 + 2|e^{\varepsilon\mu} - 1| \sum_{\tau \in (0, \delta]} \|\gamma_\tau\|_{\Omega^c}^2 \\ & = -\frac{1}{4} \varepsilon v_1 \sum_{\tau \in (0, \delta]} \sum_{\mathbf{x} \in \Omega^c} \left\{ |\gamma_\tau(\mathbf{x})|^4 - 8 \frac{|e^{\varepsilon\mu} - 1|}{\varepsilon v_1} |\gamma_\tau(\mathbf{x})|^2 \right\} \\ & = -\frac{1}{4} \varepsilon v_1 \sum_{\tau \in (0, \delta]} \sum_{\mathbf{x} \in \Omega^c} \left\{ \left[|\gamma_\tau(\mathbf{x})|^2 - 4 \frac{|e^{\varepsilon\mu} - 1|}{\varepsilon v_1} \right]^2 - 16 \frac{|e^{\varepsilon\mu} - 1|^2}{\varepsilon^2 v_1^2} \right\} \end{aligned}$$

$$\begin{aligned}
&\leq 4\varepsilon v_1 \sum_{\tau \in (0, \delta]} \sum_{\mathbf{x} \in \Omega^c} \frac{|e^{\varepsilon\mu} - 1|^2}{\varepsilon^2 v_1^2} = 4\delta \frac{|e^{\varepsilon\mu} - 1|^2}{\varepsilon^2 v_1} |\Omega^c| \leq 16\delta \frac{\mu^2}{v_1} |\Omega^c| \\
&\leq 64 \frac{K_\mu^2}{c_v} \delta \mathfrak{v}^{2e_\mu - 1} |\Omega^c| \quad \text{by Hypothesis II(14)} \\
&\leq \frac{1}{8} |\Omega^c| \quad \text{by Hypothesis F.7(i) and the fact that } e_\mu > \frac{1}{2}
\end{aligned}$$

and

$$\begin{aligned}
&-\frac{1}{4}\varepsilon v_1 \sum_{\tau \in [0, \delta)} \|\gamma_{*\tau}^* \gamma_{*\tau}\|_{\Omega^c}^2 + 2|e^{\varepsilon\mu} - 1| \sum_{\tau \in [0, \delta)} \|\gamma_{*\tau}\|_{\Omega^c}^2 \\
&\leq 4\delta \frac{|e^{\varepsilon\mu} - 1|^2}{\varepsilon^2 v_1} |\Omega^c| \leq \frac{1}{8} |\Omega^c|
\end{aligned}$$

□

Consequently, by (3.13) and Lemma 3.39,

$$\begin{aligned}
&e^{-\frac{1}{2}\|\alpha\|^2 - \frac{1}{2}\|\beta\|^2} e^{-\text{Reg}_{SF}(\Omega; \alpha, \beta)} e^{\omega_{\mathfrak{S}}} |\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}| e^{\text{Re}(-Q_{\mathfrak{S}} + \mathcal{V}_{\mathfrak{S}}(\varepsilon))} |f| \\
&\leq e^{-L(\mathfrak{S})} \bar{\mathcal{I}}_{\mathfrak{S}} |f|
\end{aligned} \tag{3.14}$$

where

$$\begin{aligned}
L(\mathfrak{S}) &= C_L \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \delta]}} r(|\mathcal{J}|)^2 \\
&\times \left\{ |\tilde{Q}(\mathcal{J})| + |\tilde{P}'_\alpha(\mathcal{J})| + |\tilde{P}'_\beta(\mathcal{J})| + |\tilde{P}_\alpha(\mathcal{J})| + |\tilde{P}_\beta(\mathcal{J})| + |R(\mathcal{J})| \right\} \\
&- \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \delta]}} |\Omega(\mathcal{J})^c|
\end{aligned}$$

The quantity $L(\mathfrak{S})$ is defined in terms of the number of points at which there are violations of the various small field conditions (the sets $Q(\mathcal{J})$, etc.). Lemma 3.40, which is proven in Sect. 6, provides a lower bound for $L(\mathfrak{S})$ purely in terms of the large field sets $\Omega(\mathcal{J})^c$.

Lemma 3.40. *We have*

$$\begin{aligned}
&C_L \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \delta]}} r(|\mathcal{J}|)^2 \left\{ |\tilde{Q}(\mathcal{J})| + |\tilde{P}'_\alpha(\mathcal{J})| + |\tilde{P}'_\beta(\mathcal{J})| + |\tilde{P}_\alpha(\mathcal{J})| + |\tilde{P}_\beta(\mathcal{J})| + |R(\mathcal{J})| \right\} \\
&\geq \ell(\mathfrak{S}) + \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \delta]}} |\Omega(\mathcal{J})^c|
\end{aligned}$$

where

$$\ell(\mathfrak{S}) = \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \delta]}} \ell(|\mathcal{J}|) |\Omega(\mathcal{J})^c|$$

Applying (3.14) and Lemma 3.40, we have

$$\begin{aligned} & e^{-\frac{1}{2}\|\alpha\|^2 - \frac{1}{2}\|\beta\|^2} e^{-\text{Reg}_{SF}(\Omega; \alpha, \beta)} e^{\omega_{\mathfrak{S}}} |\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}| e^{\text{Re}(-Q_{\mathfrak{S}} + \mathcal{V}_{\mathfrak{S}}(\varepsilon))} |f| \\ & \leq e^{-\ell(\mathfrak{S})} \bar{\mathcal{I}}_{\mathfrak{S}} |f| \end{aligned} \quad (3.15)$$

Theorem 3.35 is an immediate consequence of (3.15) and

Proposition 3.41. *For any (small field) subset $\Omega \subset X$, any $0 \leq n \leq m$, and any bounded function $f(\alpha, \beta; \vec{\rho})$,*

$$\begin{aligned} & \sum_{\substack{\text{hierarchies } \mathfrak{S} \\ \text{for scale } 2^n \varepsilon \\ \text{with } \Omega_{\mathfrak{S}} = \Omega \text{ and} \\ 0 < \text{depth}(\mathfrak{S}) \leq n}} e^{\lambda_{\mathfrak{S}}} e^{-\ell(\mathfrak{S})} \bar{\mathcal{I}}_{\mathfrak{S}} |f| \\ & \leq e^{-\frac{1}{4}\ell(2^n \varepsilon) |\Omega^c|} \left[\prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \frac{1}{1 + |\beta(\mathbf{x})|^3} \right] \sup |f| \end{aligned}$$

where

$$\lambda_{\mathfrak{S}} = \begin{cases} \ell(2^{n-\text{depth}(\mathfrak{S})+1} \varepsilon) & \text{if } \text{depth } (\mathfrak{S}) > 0 \\ 0 & \text{if } \text{depth } (\mathfrak{S}) = 0 \end{cases}$$

Here $2^{n-\text{depth}(\mathfrak{S})+1} \varepsilon$ is the length of the shortest decimation interval \mathcal{J} with $\Omega_{\mathfrak{S}}(\mathcal{J}) \neq X$.

Proof. The proof is by induction on n . The case $n = 0$ is trivial as is the case that $\Omega^c = \emptyset$.

Assume that the statement holds for some $0 \leq n < m$ and that $\Omega^c \neq \emptyset$. Set $\delta = 2^n \varepsilon$. Given subsets $\Omega_1, \Omega_2, \Lambda$ of X containing Ω and hierarchies $\mathfrak{S}_1, \mathfrak{S}_2$ for scale δ with $\Omega_{\mathfrak{S}_1} = \Omega_1$ and $\Omega_{\mathfrak{S}_2} = \Omega_2$, a hierarchy \mathfrak{S} with $\Lambda_{\mathfrak{S}} = \Lambda$, $\Omega_{\mathfrak{S}} = \Omega$ and $(\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S}$ is specified by the sets

$$\begin{aligned} P_{\alpha}, P_{\beta} & \subset \Omega_1 \cap \Omega_2 \cap \Lambda^c \quad P'_{\alpha}, P'_{\beta} \subset (\Omega_1 \cap \Omega_2 \cap \Lambda^c)^* \quad Q \subset (\Omega_1 \cap \Omega_2)^* \cap \Lambda^c \\ \text{and} \quad R & \subset \Lambda \cap \Omega^c \end{aligned}$$

See Definition 2.4. There are at most

$$2^{2|\Omega_1 \cap \Omega_2 \cap \Lambda^c|} 2^{4D|\Omega_1 \cap \Omega_2 \cap \Lambda^c|} 2^{2|\Omega_1^* \cap \Omega_2^* \cap \Lambda^c|} 2^{|\Lambda \cap \Omega^c|} \leq e^{(5+4D)|\Omega^c|} \quad (3.16)$$

(where D is the dimension of space) such choices. For each hierarchy \mathfrak{S} as above (see Definition 2.8 and Appendix A)

$$\begin{aligned} \bar{\mathcal{I}}_{\mathfrak{S}} |f| &= \left(\prod_{\mathbf{x} \in \Lambda \setminus (R \cup \Omega)} \int_{|z_{\delta}(\mathbf{x})| \leq r(\delta)} \frac{dz_{\delta}(\mathbf{x})^* \wedge dz_{\delta}(\mathbf{x})}{2\pi i} e^{-z_{\delta}(\mathbf{x})^* z_{\delta}(\mathbf{x})} \right) \\ &\times \left(\prod_{\mathbf{x} \in R_{C_{\delta}(\mathbf{x}; \alpha^*, \beta)}} \int \left| \frac{dz_{*\delta}(\mathbf{x}) \wedge dz_{\delta}(\mathbf{x})}{2\pi i} \right| \right) \end{aligned}$$

$$\begin{aligned}
& \times \left(\prod_{\mathbf{x} \in X \setminus \Lambda_{|\alpha_\delta(\mathbf{x})| \leq R(\varepsilon)}} \int \frac{d\alpha_\delta(\mathbf{x})^* \wedge d\alpha_\delta(\mathbf{x})}{2\pi i} \right) \chi_{[0,2\delta]}(\alpha, \alpha_\delta, \beta) \\
& \quad \times \mathcal{Z}_\delta^{|\Omega_1 \setminus \Omega|} \mathcal{Z}_\delta^{|\Omega_2 \setminus \Omega|} \bar{\mathcal{I}}_{\mathfrak{S}_1} \bar{\mathcal{I}}_{\mathfrak{S}_2} \sup |f| \\
& \leq (40\pi r(\delta))^{|R|} \chi_{R(\delta)}(\Omega_1 \cap \Lambda^c, \alpha) \chi_{R(2\delta)}(\Lambda \cap \Omega^c, \alpha) \\
& \quad \times \chi_{R(\delta)}(\Omega_2 \cap \Lambda^c, \beta) \chi_{R(2\delta)}(\Lambda \cap \Omega^c, \beta) \\
& \quad \times \left(\prod_{\mathbf{x} \in X \setminus \Lambda_{|\alpha_\delta(\mathbf{x})| \leq R(\varepsilon)}} \int \frac{d\alpha_\delta(\mathbf{x})^* \wedge d\alpha_\delta(\mathbf{x})}{2\pi i} \right) \\
& \quad \times \chi_{R(\delta)}((\Omega_1 \cup \Omega_2) \cap \Lambda^c, \alpha_\delta) \bar{\mathcal{I}}_{\mathfrak{S}_1} \bar{\mathcal{I}}_{\mathfrak{S}_2} \sup |f| \tag{3.17}
\end{aligned}$$

Here we used Lemma A.4.a, which ensures that the integral over $\alpha_\delta(\mathbf{x})$ is restricted to $|\alpha_\delta(\mathbf{x})| \leq R(\varepsilon)$. For the inequality, we used that $\int_{\mathbb{C}} \frac{dz_\delta(\mathbf{x})^* \wedge dz_\delta(\mathbf{x})}{2\pi i} e^{-z_\delta(\mathbf{x})^* z_\delta(\mathbf{x})} = 1$, that the area of $C_\delta(\mathbf{x}; \alpha^*, \beta)$ is at most $40\pi r(\delta)^2$ (by Lemma 3.38(iii)), that $\mathcal{Z}_\delta \leq 1$, and the definition of $\chi_{[0,2\delta]}(\alpha, \alpha_\delta, \beta)$ (given in Appendix A).

Since

$$\begin{aligned}
\lambda_{\mathfrak{S}} - \ell(\mathfrak{S}) &= -\ell(2\delta)|\Omega^c| - \ell(\mathfrak{S}_1) - \ell(\mathfrak{S}_2) \\
&+ \begin{cases} \max\{\lambda_{\mathfrak{S}_1}, \lambda_{\mathfrak{S}_2}\} & \text{if depth } (\mathfrak{S}) > 1 \\ \ell(2\delta) & \text{if depth } (\mathfrak{S}) = 1 \end{cases} \\
&\leq -\ell(2\delta)[|\Omega^c| - 1] + \lambda_{\mathfrak{S}_1} - \ell(\mathfrak{S}_1) + \lambda_{\mathfrak{S}_2} - \ell(\mathfrak{S}_2)
\end{aligned}$$

(3.16), (3.17) and the induction hypothesis give that

$$\begin{aligned}
& \sum_{\substack{\mathfrak{S}_1, \mathfrak{S}_2 \\ \Omega_{\mathfrak{S}_1} = \Omega_1 \\ \Omega_{\mathfrak{S}_2} = \Omega_2}} \sum_{\substack{\mathfrak{S} \\ (\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S} \\ \Omega_{\mathfrak{S}} = \Omega, \Lambda_{\mathfrak{S}} = \Lambda}} e^{\lambda_{\mathfrak{S}} - \ell(\mathfrak{S})} \bar{\mathcal{I}}_{\mathfrak{S}} |f| \\
& \leq e^{-\ell(2\delta)[|\Omega^c| - 1]} e^{(5+4D)|\Omega^c|} (40\pi r(\delta))^{|R|} \\
& \quad \times \chi_{R(\delta)}(\Omega_1 \cap \Lambda^c, \alpha) \chi_{R(2\delta)}(\Lambda \cap \Omega^c, \alpha) \chi_{R(\delta)}(\Omega_2 \cap \Lambda^c, \beta) \chi_{R(2\delta)}(\Lambda \cap \Omega^c, \beta) \\
& \quad \times \left(\prod_{\mathbf{x} \in X \setminus \Lambda_{|\alpha_\delta(\mathbf{x})| \leq R(\varepsilon)}} \int \frac{d\alpha_\delta(\mathbf{x})^* \wedge d\alpha_\delta(\mathbf{x})}{2\pi i} \right) \chi_{R(\delta)}((\Omega_1 \cup \Omega_2) \cap \Lambda^c, \alpha_\delta) \\
& \quad \times \left\{ \sum_{\substack{\mathfrak{S}_1 \\ \Omega_{\mathfrak{S}_1} = \Omega_1}} e^{\lambda_{\mathfrak{S}_1} - \ell(\mathfrak{S}_1)} \bar{\mathcal{I}}_{\mathfrak{S}_1} \right\} \left\{ \sum_{\substack{\mathfrak{S}_2 \\ \Omega_{\mathfrak{S}_2} = \Omega_2}} e^{\lambda_{\mathfrak{S}_2} - \ell(\mathfrak{S}_2)} \bar{\mathcal{I}}_{\mathfrak{S}_2} \right\} \sup |f| \\
& \leq e^{-\ell(2\delta)[|\Omega^c| - 1]} e^{(5+4D)|\Omega^c|} e^{[5+2\ln r(\delta)]|\Omega^c|} \\
& \quad \times \chi_{R(\delta)}(\Omega_1 \cap \Lambda^c, \alpha) \chi_{R(2\delta)}(\Lambda \cap \Omega^c, \alpha) \chi_{R(\delta)}(\Omega_2 \cap \Lambda^c, \beta) \chi_{R(2\delta)}(\Lambda \cap \Omega^c, \beta)
\end{aligned}$$

$$\begin{aligned}
& \times \left(\prod_{\mathbf{x} \in X \setminus \Lambda} \int_{|\alpha_\delta(\mathbf{x})| \leq R(\varepsilon)} \frac{d\alpha_\delta(\mathbf{x})^* \wedge d\alpha_\delta(\mathbf{x})}{2\pi i} \right) \chi_{R(\delta)}((\Omega_1 \cup \Omega_2) \cap \Lambda^c, \alpha_\delta) \\
& \times e^{-\frac{1}{4}\ell(\delta)|\Omega_1^c|} \left[\prod_{\mathbf{x} \in \Omega_1^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \frac{1}{1 + |\alpha_\delta(\mathbf{x})|^3} \right] e^{-\frac{1}{4}\ell(\delta)|\Omega_2^c|} \\
& \times \left[\prod_{\mathbf{x} \in \Omega_2^c} \frac{1}{1 + |\alpha_\delta(\mathbf{x})|^3} \frac{1}{1 + |\beta(\mathbf{x})|^3} \right] \sup |f|
\end{aligned} \tag{3.18}$$

For any $t > 1$,

$$\chi_t(\alpha) \leq \frac{(1+t)^3}{1+|\alpha|^3} \leq \frac{8t^3}{1+|\alpha|^3} \leq e^{\ln 8 + 3 \ln t} \frac{1}{1+|\alpha|^3}$$

which yields the bound

$$\begin{aligned}
& \chi_{R(\delta)}(\Omega_1 \cap \Lambda^c, \alpha) \chi_{R(2\delta)}(\Lambda \cap \Omega^c, \alpha) \prod_{\mathbf{x} \in \Omega_1^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \\
& \leq \chi_{R(\delta)}(\Omega_1 \cap \Omega^c, \alpha) \prod_{\mathbf{x} \in \Omega_1^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \\
& \leq e^{[\ln 8 + 3 \ln R(\delta)] |\Omega^c|} \prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3}
\end{aligned}$$

Similarly

$$\begin{aligned}
& \chi_{R(\delta)}(\Omega_2 \cap \Lambda^c, \beta) \chi_{R(2\delta)}(\Lambda \cap \Omega^c, \beta) \prod_{\mathbf{x} \in \Omega_2^c} \frac{1}{1 + |\beta(\mathbf{x})|^3} \\
& \leq e^{[\ln 8 + 3 \ln R(\delta)] |\Omega^c|} \prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\beta(\mathbf{x})|^3}
\end{aligned}$$

To bound the α_δ integrals, we use

$$\begin{aligned}
& \left(\prod_{\mathbf{x} \in \Lambda^c} \int_{|\alpha_\delta(\mathbf{x})| \leq R(\varepsilon)} \frac{d\alpha_\delta(\mathbf{x})^* \wedge d\alpha_\delta(\mathbf{x})}{2\pi i} \right) \chi_{R(\delta)}((\Omega_1 \cup \Omega_2) \cap \Lambda^c, \alpha_\delta) \\
& \times \prod_{\mathbf{x} \in \Omega_1^c} \frac{1}{1 + |\alpha_\delta(\mathbf{x})|^3} \prod_{\mathbf{x} \in \Omega_2^c} \frac{1}{1 + |\alpha_\delta(\mathbf{x})|^3} \\
& \leq \prod_{\mathbf{x} \in (\Omega_1 \cap \Omega_2)^c} \frac{1}{\pi} \int \frac{d^2 \alpha_\delta(\mathbf{x})}{1 + |\alpha_\delta(\mathbf{x})|^3} \prod_{\mathbf{x} \in \Omega_1 \cap \Omega_2 \cap \Lambda^c} \frac{1}{\pi} \int_{|\alpha_\delta(\mathbf{x})| \leq R(\delta)} d^2 \alpha_\delta(\mathbf{x}) \\
& \leq 3^{|\Omega_1 \cap \Omega_2|^c} R(\delta)^{2|\Omega_1 \cap \Omega_2 \cap \Lambda^c|} \\
& \leq e^{[\ln 3 + 2 \ln R(\delta)] |\Lambda^c|}
\end{aligned}$$

Inserting the last estimates into (3.18) gives

$$\begin{aligned}
& \sum_{\substack{\mathfrak{S} \\ \Omega_{\mathfrak{S}} = \Omega, \Lambda_{\mathfrak{S}} = \Lambda \\ \Omega_{\mathfrak{S}}([0, \delta]) = \Omega_1 \\ \Omega_{\mathfrak{S}}([\delta, 2\delta]) = \Omega_2}} e^{\lambda_{\mathfrak{S}} - \ell(\mathfrak{S})} \bar{\mathcal{I}}_{\mathfrak{S}} |f| \\
& \leq e^{-\ell(2\delta)[|\Omega^c| - 1]} e^{(5+4D)|\Omega^c|} e^{[5+2\ln R(\delta)]|\Omega^c|} e^{2[\ln 8 + 3\ln R(\delta)]|\Omega^c|} \\
& \quad \times \prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \frac{1}{1 + |\beta(\mathbf{x})|^3} e^{[\ln 3 + 2\ln R(\delta)]|\Lambda^c|} \sup |f| \\
& \leq e^{-\frac{1}{2}\ell(2\delta)|\Omega^c|} e^{[16+4D+10\ln R(\delta)]|\Omega^c|} \prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \frac{1}{1 + |\beta(\mathbf{x})|^3} \sup |f|
\end{aligned}$$

Summing over the subsets $\Omega_1^c, \Omega_2^c, \Lambda^c \subset \Omega^c$,

$$\begin{aligned}
& \sum_{\substack{\mathfrak{S} \\ \Omega_{\mathfrak{S}} = \Omega}} e^{\lambda_{\mathfrak{S}} - \ell(\mathfrak{S})} \bar{\mathcal{I}}_{\mathfrak{S}} |f| \leq e^{-\frac{1}{2}\ell(2\delta)|\Omega^c|} e^{[19+4D+10\ln R(\delta)]|\Omega^c|} \\
& \quad \times \prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \frac{1}{1 + |\beta(\mathbf{x})|^3} \sup |f| \\
& \leq e^{-\frac{1}{4}\ell(2\delta)|\Omega^c|} \prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \frac{1}{1 + |\beta(\mathbf{x})|^3} \sup |f|
\end{aligned}$$

by (F.6d). \square

3.8. Proof of Theorems 2.16 and 2.18

As we saw in Remark 3.31, it suffices, for the proof of Theorems 2.16, to prove the convergence of $I_m^\bullet(2^{-m}\theta; \cdot) \Big|_{\mathfrak{h}=1}$ to the desired limit. By Proposition 3.32, with $\varepsilon = 2^{-m}\theta$ and $n = m$,

$$\begin{aligned}
I_m^\bullet(2^{-m}\theta; \alpha^*, \beta) &= \sum_{\Omega \subset X} \mathcal{Z}_\theta^{|\Omega|} e^{\langle \alpha^*, j(\theta)\beta \rangle_{\Omega} + V_{\Omega, \theta}(\varepsilon; \alpha^*, \beta) + \mathcal{D}_{\Omega, m}(\varepsilon; \alpha^*, \beta)} \chi_\theta(\Omega; \alpha, \beta) \\
&\quad \times \sum_{\substack{\mathfrak{S} \text{ hierarchy} \\ \text{for scale } \theta \\ \text{depth}(\mathfrak{S}) \leq m \\ \text{with } \Omega_{\mathfrak{S}} = \Omega}} \mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} \left(e^{-Q_{\mathfrak{S}}^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}}^{res}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})} \right. \\
&\quad \left. \times e^{\mathcal{B}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\rho}) + \mathcal{L}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\rho})} \right) \Big|_{\varepsilon=2^{-m}\theta} \tag{3.19}
\end{aligned}$$

where

$$\begin{aligned}
Q_{\mathfrak{S}}^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) &= Q_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \langle \alpha^*, j(\theta)\beta \rangle_{\Omega_{\mathfrak{S}}} \\
\mathcal{V}_{\mathfrak{S}}^{res}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) &= \mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) - V_{\Omega_{\mathfrak{S}}, \theta}(\varepsilon; \alpha^*, \beta) \\
\mathcal{B}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\rho}) &= \mathcal{D}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\rho}) - \mathcal{D}_{\Omega_{\mathfrak{S}}, m}(\varepsilon; \alpha^*, \beta)
\end{aligned}$$

with the $V_{\Omega, \theta}(\varepsilon; \cdot)$ of Definition 3.8.ii and the $\mathcal{D}_{\Omega, m}(\varepsilon; \cdot)$ of (3.8).

By (2.4) and Corollary 3.30, for any fixed $\Omega \subset X$,

$$\begin{aligned}
& \lim_{m \rightarrow \infty} \chi_\theta(\Omega; \alpha, \beta) e^{V_{\Omega, \theta}(2^{-m}\theta; \alpha^*, \beta) + \mathcal{D}_{\Omega, m}(2^{-m}\theta; \alpha^*, \beta)} \\
& = \chi_\theta(\Omega; \alpha, \beta) e^{V_{\Omega, \theta}(\alpha^*, \beta) + \mathcal{D}_{\Omega, \theta}(\alpha^*, \beta)}
\end{aligned} \tag{3.20}$$

uniformly in α and β . Fix any hierarchy \mathfrak{S} for scale θ with $\Omega_{\mathfrak{S}} = \Omega$ and set

$$\begin{aligned}\mathcal{V}_{\mathfrak{S}}^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) &= \mathcal{V}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) - V_{\Omega_{\mathfrak{S}}, \theta}(\alpha^*, \beta) \\ \mathcal{B}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}) &= \mathcal{D}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}) - \mathcal{D}_{\Omega_{\mathfrak{S}}, \theta}(\alpha^*, \beta)\end{aligned}$$

By Lemma 3.34 and Corollary 3.33,

$$\chi_{\theta}(\Omega; \alpha, \beta) e^{\mathcal{V}_{\mathfrak{S}}^{res}(2^{-m}\theta; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})} e^{\mathcal{B}_{\mathfrak{S}}(2^{-m}\theta; \alpha^*, \beta; \vec{\rho}) + \mathcal{L}_{\mathfrak{S}}(2^{-m}\theta; \alpha^*, \beta; \vec{\rho})}$$

converges as $m \rightarrow \infty$ to

$$\chi_{\theta}(\Omega; \alpha, \beta) e^{\mathcal{V}_{\mathfrak{S}}^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})} e^{\mathcal{B}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}) + \mathcal{L}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho})}$$

uniformly for $\vec{\rho}$ in the domain of integration of $\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}$ and (α, β) in the support of $\chi_{\theta}(\Omega; \alpha, \beta)$. By Remark 3.11, the domain of integration for $\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}$ is compact. Consequently, as $Q_{\mathfrak{S}}^{res}$ is a polynomial,

$$\begin{aligned}\lim_{m \rightarrow \infty} \chi_{\theta}(\Omega; \alpha, \beta) \mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} &\left(e^{-Q_{\mathfrak{S}}^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}}^{res}(2^{-m}\theta; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})} \right. \\ &\times \left. e^{\mathcal{B}_{\mathfrak{S}}(2^{-m}\theta; \alpha^*, \beta; \vec{\rho}) + \mathcal{L}_{\mathfrak{S}}(2^{-m}\theta; \alpha^*, \beta; \vec{\rho})} \right) \\ &= \chi_{\theta}(\Omega; \alpha, \beta) \mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} \left(e^{-Q_{\mathfrak{S}}^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}}^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})} \right. \\ &\times \left. e^{\mathcal{B}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}) + \mathcal{L}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho})} \right) \quad (3.21)\end{aligned}$$

uniformly for (α, β) in the support of $\chi_{\theta}(\Omega; \alpha, \beta)$.

By (3.20) and (3.21), the (Ω, \mathfrak{S}) term on the right hand side of (3.19) converges to

$$\begin{aligned}\mathcal{Z}_{\theta}^{|\Omega|} e^{(\alpha_*, j(\theta)\beta)|\Omega| + V_{\Omega, \theta}(\alpha^*, \beta) + \mathcal{D}_{\Omega, \theta}(\alpha^*, \beta)} \chi_{\theta}(\Omega; \alpha, \beta) \\ \times \mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} \left(e^{-Q_{\mathfrak{S}}^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}}^{res}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})} e^{\mathcal{B}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}) + \mathcal{L}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho})} \right)\end{aligned}$$

as $m \rightarrow \infty$. Setting $\mathfrak{h} = 1$ gives the (Ω, \mathfrak{S}) term on the right hand side of the representation of $I_{\theta}(\alpha^*, \beta)$ in Theorem 2.16. The properties and estimates of the various functions in Theorem 2.16 follow from Corollaries 3.30 and 3.33. It remains to prove the convergence of the sum over Ω and \mathfrak{S} .

Recall that X is a finite set. We saw in Remark 2.6 that, for any $\emptyset \neq \Omega \subset X$, the corridor condition in the definition of a hierarchy ensures that there are only finitely many hierarchies \mathfrak{S} with $\Omega_{\mathfrak{S}} = \Omega$. If $\Omega = \emptyset$, then $Q_{\mathfrak{S}}^{res} = Q_{\mathfrak{S}}$, $\mathcal{V}_{\mathfrak{S}}^{res} = \mathcal{V}_{\mathfrak{S}}$ and $\mathcal{B}_{\mathfrak{S}} = \mathcal{D}_{\mathfrak{S}} = 0$. Therefore it suffices to prove the convergence, as $m \rightarrow \infty$, of

$$\sum_{k=1}^m \mathcal{F}_{k, m}(\alpha^*, \beta)$$

where

$$\begin{aligned}\mathcal{F}_{k, m}(\alpha^*, \beta) &= \sum_{\substack{\mathfrak{S} \text{ hierarchy} \\ \text{for scale } \theta \\ \text{depth}(\mathfrak{S}) = k \\ \text{with } \Omega_{\mathfrak{S}} = \emptyset}} \mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)} \left(e^{-Q_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}}(2^{-m}\theta; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha})} e^{\mathcal{L}_{\mathfrak{S}}(2^{-m}\theta; \alpha^*, \beta; \vec{\rho})} \right) \Big|_{\mathfrak{h}=1}\end{aligned}$$

We already know the convergence, for each fixed k , of $\mathcal{F}_{k,m}(\alpha^*, \beta)$ as $m \rightarrow \infty$. By Theorem 3.35 and Lemma 3.42, below,

$$|\mathcal{F}_{k,m}(\alpha^*, \beta)| \leq e^{\frac{1}{2}\|\alpha\|^2 + \frac{1}{2}\|\beta\|^2} e^{-\ell(2^{-k+1}\theta)}$$

As this bound is summable in k , the dominated convergence theorem gives the desired limit. This completes the proof of Theorems 2.16. \square

Lemma 3.42. *Let \mathfrak{S} be a hierarchy for scale θ . Then, on the domain of integration for $\mathcal{I}_{\mathfrak{S}}$,*

$$|\mathcal{B}_{\mathfrak{S}}| + |\mathcal{L}_{\mathfrak{S}}| \leq \omega_{\mathfrak{S}}$$

where $\omega_{\mathfrak{S}}$ was defined in Theorem 3.35.

Proof. Let $\varepsilon = 2^{-\text{depth}(\mathfrak{S})\theta}$. On the domain of integration,

$$|\alpha_{\tau}(\mathbf{x})| \leq \min\{\kappa_{\mathfrak{S},\tau}(\mathbf{x}), \kappa_{*\mathfrak{S},\tau}(\mathbf{x})\} \quad |\alpha(\mathbf{x})| \leq \kappa_{*\mathfrak{S},0}(\mathbf{x}) \quad |\beta(\mathbf{x})| \leq \kappa_{\mathfrak{S},\theta}(\mathbf{x})$$

for all $\tau \in \varepsilon\mathbb{Z} \cap (0, \theta)$ and $\mathbf{x} \in X$. By Proposition 3.32 and [4, Lemma B.1],

$$\begin{aligned} |\mathcal{B}_{\mathfrak{S}}| &\leq K_d K_D(\theta) r(\theta) R(\theta)^3 |\Omega_{\mathfrak{S}}^c| \\ |\mathcal{L}_{\mathfrak{S}}| &\leq \sum_{\substack{\text{decimation} \\ \text{intervals}}} K_d K_L(|\mathcal{J}|) r(|\mathcal{J}|) R(|\mathcal{J}|)^3 |\Omega_{\mathfrak{S}}(\mathcal{J})^c| \end{aligned}$$

where $K_d = \sup_{\mathbf{y} \in X} \sum_{\mathbf{x} \in X} e^{-d(\mathbf{x}, \mathbf{y})}$. The result now follows by (F.6a). \square

Proof of Theorem 2.18. Set $\mathfrak{h} = 1$ and let f be any bounded measurable function. First consider any fixed hierarchy \mathfrak{S} for scale θ with $\Omega_{\mathfrak{S}} = \Omega$. By Remark 3.11, the domain of integration for the large field integral operator $|\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}|$ is compact. By Lemma 3.34, $\mathcal{V}_{\mathfrak{S}}(2^{-m}\theta; \alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$ converges uniformly on this domain to

$$\mathcal{V}_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) = V_{\Omega; \theta}(\alpha_*, \beta) + \mathcal{V}_{\mathfrak{S}}^{res}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$$

as $m \rightarrow \infty$. Consequently,

$$\begin{aligned} &\lim_{m \rightarrow \infty} |\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}| e^{\operatorname{Re}(-Q_{\mathfrak{S}} + \mathcal{V}_{\mathfrak{S}}(2^{-m}\theta))} |f| \\ &= e^{\operatorname{Re}(\langle \alpha^*, j_{(\Omega)}(\theta)\beta \rangle + V_{\Omega; \theta}(\alpha_*, \beta))} |\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}| e^{\operatorname{Re}(-Q_{\mathfrak{S}}^{res} + \mathcal{V}_{\mathfrak{S}}^{res})} |f| \end{aligned}$$

For any natural number k , there are only finitely many hierarchies for scale θ of depth k . So, by Theorem 3.35,

$$\begin{aligned} &e^{-\frac{1}{2}\|\alpha\|^2 - \frac{1}{2}\|\beta\|^2} e^{-\operatorname{Reg}_{SF}(\Omega; \alpha, \beta)} \sum_{k=1}^{k_0} e^{\ell(2^{-k+1}\theta)} \\ &\times \sum_{\substack{\text{hierarchies } \mathfrak{S} \\ \text{for scale } \theta \\ \text{of depth } k \\ \text{with } \Omega_{\mathfrak{S}} = \Omega}} e^{\omega_{\mathfrak{S}}} e^{\operatorname{Re}(\langle \alpha^*, j_{(\Omega)}(\theta)\beta \rangle + V_{\Omega; \theta}(\alpha_*, \beta))} |\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}| e^{\operatorname{Re}(-Q_{\mathfrak{S}}^{res} + \mathcal{V}_{\mathfrak{S}}^{res})} |f| \\ &\leq e^{-\frac{1}{4}\ell(\theta)|\Omega^c|} \left[\prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \frac{1}{1 + |\beta(\mathbf{x})|^3} \right] \sup |f| \end{aligned}$$

for all $k_0 \in \mathbb{N}$. As all terms on the left hand side are nonnegative,

$$\begin{aligned} & e^{-\frac{1}{2}\|\alpha\|^2 - \frac{1}{2}\|\beta\|^2} e^{\operatorname{Re}(\langle \alpha^*, j_{(\Omega)}(\theta)\beta \rangle + V_{\Omega;\theta}(\alpha_*, \beta))} e^{-\operatorname{Reg}_{SF}(\Omega; \alpha, \beta)} \\ & \times \sum_{k=1}^{\infty} e^{\ell(2^{-k+1}\theta)} \sum_{\substack{\text{hierarchies } \mathfrak{S} \\ \text{for scale } \theta \\ \text{of depth } k \\ \text{with } \Omega_{\mathfrak{S}} = \Omega}} |\mathcal{I}_{(\mathfrak{S}; \alpha^*, \beta)}| e^{\operatorname{Re}(-Q_{\mathfrak{S}}^{res} + \mathcal{V}_{\mathfrak{S}}^{res}) + \omega_{\mathfrak{S}}} |f| \\ & \leq e^{-\frac{1}{4}\ell(\theta)|\Omega^c|} \left[\prod_{\mathbf{x} \in \Omega^c} \frac{1}{1 + |\alpha(\mathbf{x})|^3} \frac{1}{1 + |\beta(\mathbf{x})|^3} \right] \sup |f| \end{aligned} \quad (3.22)$$

The theorem now follows by setting $f \equiv 1$ and applying Lemma 3.42. \square

4. The “Small Field” Part of the Decimation Step

The “small field decimation step” is formulated in Theorems 3.24 and 3.27, which we are going to prove in this section. It deals with the “stationary phase approximation” to the construction on a fixed subset Ω of X . As the estimates do not depend on Ω , we may, for simplicity of notation, assume that $\Omega = X$. We shall write $\bar{\mathfrak{R}}_\delta$ in place of $\mathfrak{R}_{\Omega; \delta}$ and V_δ in place of $V_{\Omega, \delta}$. Also write

$$\begin{aligned} r &= r(\delta) & R &= R(\delta) \\ r_+ &= r(2\delta) & R_+ &= R(2\delta) \end{aligned}$$

Observe that, by (2.18)

$$\frac{r_+}{r} = \frac{1}{2^{e_r}} \quad \frac{R_+}{R} = \frac{1}{2^{e_R + e_r}} \quad (4.1)$$

We also write $\|\cdot\|_\delta$ for $\|\cdot\|_{2R(\delta), 2m}$.

The proofs of Theorem 3.24 and 3.27 are similar to [5]. The main technical differences are the presence of the history field and the additional terms created by the fact that the cut off propagator $j_c(t)$ of (3.2) is not a semi-group—in contrast to the original propagator $j(t) = \operatorname{exph}(-t(h - \mu))$.

It turns out that the dominant contribution to $\mathfrak{R}_\delta(V_\delta(\varepsilon; \cdot); f_1, f_2)$ in Definition 3.22 is $f_1(\alpha_*, j_c(t)\beta) + f_2(j_c(t)\alpha_*, \beta)$. To estimate it, we use

Lemma 4.1. *Let $f(\alpha_*, \beta; h)$ be an analytic function. Let $\delta \leq \Theta$.*

(i) *If f is bilinear in α_* , β then*

$$\|f(\alpha_*, j_c(\delta)\beta)\|_{2\delta}, \|f(j_c(\delta)\alpha_*, \beta)\|_{2\delta} \leq e^{\delta K_j} \left(\frac{R_+}{R} \right)^2 \|f\|_\delta$$

(ii) *If f has degree at least two both in α_* and β*

$$\|f(\alpha_*, j_c(\delta)\beta)\|_{2\delta}, \|f(j_c(\delta)\alpha_*, \beta)\|_{2\delta} \leq e^{2\delta K_j} \left(\frac{R_+}{R} \right)^4 \|f\|_\delta$$

Proof. Both in cases (i) and (ii), we prove the first inequality. To do so, we introduce the auxiliary weight system w_{aux} with metric $2md$ that associates the constant weight factor $2R$ to the field α_* and the constant weight factor $2e^{-\delta K_j}R$ to the field β . To control the change of variables from $f(\alpha_*, \beta)$ to $f(\alpha_*, j_c(\delta)\beta)$, we use the weighted L^1-L^∞ operator norm $N_{2md}(j_c(\delta); 2R, 2e^{-\delta K_j}R)$ of [4, Definition IV.2]. In the notation of this paper,

$$N_{2md}(j_c(\delta); 2R, 2e^{-\delta K_j}R) \leq e^{-\delta K_j} \|j_c(\delta)\| \leq 1$$

by Lemma 3.21.i. Hence, by [4, Proposition IV.4]

$$\|f(\alpha_*, j_c(\delta)\beta)\|_{w_{\text{aux}}} \leq \|f\|_\delta$$

If f is bilinear in α_*, β then

$$\begin{aligned} \|f(\alpha_*, j_c(\delta)\beta)\|_{2\delta} &= \left(\frac{2R_+}{2R} \right) \left(\frac{2R_+}{2e^{-\delta K_j}R} \right) \|f(\alpha_*, j_c(\delta)\beta)\|_{w_{\text{aux}}} \leq e^{\delta K_j} \left(\frac{R_+}{R} \right)^2 \|f\|_\delta \end{aligned}$$

If f has degree at least two both in α_* and β

$$\begin{aligned} \|f(\alpha_*, j_c(\delta)\beta)\|_{2\delta} &\leq \left(\frac{2R_+}{2R} \right)^2 \left(\frac{2R_+}{2e^{-\delta K_j}R} \right)^2 \|f(\alpha_*, j_c(\delta)\beta)\|_{w_{\text{aux}}} \\ &\leq e^{2\delta K_j} \left(\frac{R_+}{R} \right)^4 \|f\|_\delta \end{aligned}$$

since $e^{-\delta K_j} \geq \frac{R_+}{R} = \frac{1}{2^{e_R+e_r}}$ by Hypothesis F.7(i). \square

To treat the fluctuation integral in Definition 3.22, we introduce a second auxiliary weight system w_{fluct} with metric $2md$ that gives weight $2R_+$ both to α_* and β , and weight $32r$ to the fields z_* and z . We write $\|\cdot\|_{\text{fluct}}$ for $\|\cdot\|_{w_{\text{fluct}}}$. If $f(\alpha_*, \beta, z_*, z)$ happens to be independent of z_* and z , then $\|f\|_{\text{fluct}} = \|f\|_{2\delta}$. For the first two terms in the effective action \mathcal{A} of Definition 3.22, we have

Lemma 4.2. *For any history complete analytic function $f(\alpha_*, \beta)$*

$$\begin{aligned} \|f(\alpha_*, z + j_c(\delta)\beta) - f(\alpha_*, j_c(\delta)\beta)\|_{\text{fluct}} &\leq \|f\|_\delta \\ \|f(z_* + j_c(\delta)\alpha_*, \beta) - f(j_c(\delta)\alpha_*, \beta)\|_{\text{fluct}} &\leq \|f\|_\delta \end{aligned}$$

for all $\delta \leq \Theta$.

Proof. We prove the first inequality. By [4, Corollary IV.6],

$$\begin{aligned} \|f(\alpha_*, z + j_c(\delta)\beta) - f(\alpha_*, j_c(\delta)\beta)\|_{\text{fluct}} &\leq \|f(\alpha_*, z + j_c(\delta)\beta)\|_{\text{fluct}} \leq \|f(\alpha_*, \beta)\|_\delta \end{aligned}$$

since, by Lemma 3.21(i)

$$\begin{aligned} N_{2md}(1; 2R, 32r) + N_{2md}(j_c(\delta); 2R, 2R_+) &\leq \|1\| \frac{32r}{2R} + \|j_c(\delta)\| \frac{R_+}{R} \\ &\leq \frac{16r}{R} + e^{\delta K_j} \frac{R_+}{R} = 16(\delta v)^{e_R} + \frac{e^{\delta K_j}}{2^{e_R+e_r}} \leq 1 \end{aligned}$$

by Hypothesis F.7(i). \square

The remaining summands in Definition 3.22 are explicit quadratic and quartic terms. The quadratic terms all involve the difference $j_c(\delta) - j(\delta)$ and are consequently exponentially small with c .

Lemma 4.3.

$$\begin{aligned} \|\langle [j(\delta) - j_c(\delta)]\alpha_*, [j(\delta) - j_c(\delta)]\beta \rangle\|_{2\delta} &\leq 4\delta^2 K_j^2 e^{2K_j\delta} R_+^2 e^{-2m c} \\ \|\langle [j(\delta) - j_c(\delta)]\alpha_*, z \rangle\|_{\text{fluct}}, \quad \|\langle z_*, [j(\delta) - j_c(\delta)]\beta \rangle\|_{\text{fluct}} \\ &\leq 64\delta K_j e^{K_j\delta} r R_+ e^{-m c} \end{aligned}$$

Proof. By definition

$$\|\langle \alpha_*, \beta \rangle\|_{2\delta} = 4R_+^2$$

Therefore, by Lemma G.2(a),

$$\begin{aligned} \|\langle [j(\delta) - j_c(\delta)]\alpha_*, [j(\delta) - j_c(\delta)]\beta \rangle\|_{2\delta} &\leq 4R_+^2 N_{2\text{md}}(j(\delta) - j_c(\delta); 2R_+, 2R_+)^2 \\ &= 4R_+^2 N_{2\text{md}}(j(\delta) - j_c(\delta); 1, 1)^2 \\ &\leq 4R_+^2 \|j(\delta) - j_c(\delta)\|^2 \\ &\leq 4\delta^2 K_j^2 e^{2K_j\delta} R_+^2 e^{-2m c} \end{aligned}$$

In the last line, we used Lemma 3.21(iii). Similarly

$$\begin{aligned} \|\langle [j(\delta) - j_c(\delta)]\alpha_*, z \rangle\|_{\text{fluct}} &\leq 64 R_+ r N_{2\text{md}}(j(\delta) - j_c(\delta); 2R_+, 2R_+) \\ &\leq 64\delta K_j e^{K_j\delta} r R_+ e^{-m c} \end{aligned}$$

□

The explicit quartic terms in $\bar{\mathfrak{R}}_\delta(V_\delta(\varepsilon; \cdot); \mathcal{R}_1 + \mathcal{E}_1, \mathcal{R}_2 + \mathcal{E}_2)$ are

$[V_\delta(\varepsilon; \alpha_*, j_c(\delta)\beta) - V_\delta(\varepsilon; \alpha_*, j(\delta)\beta)] + [V_\delta(\varepsilon; j_c(\delta)\alpha_*, \beta) - V_\delta(\varepsilon; j(\delta)\alpha_*, \beta)]$
“downstairs”, and

$$\begin{aligned} &[V_\delta(\varepsilon; \alpha_*, z + j_c(\delta)\beta) - V_\delta(\varepsilon; \alpha_*, j_c(\delta)\beta)] \\ &+ [V_\delta(\varepsilon; z_* + j_c(\delta)\alpha_*, \beta) - V_\delta(\varepsilon; j_c(\delta)\alpha_*, \beta)] \end{aligned}$$

as a contribution to the effective action. The term “downstairs” again involves the difference $j_c(\delta) - j(\delta)$ and is exponentially small with c .

Lemma 4.4. *If $\delta \leq \Theta$, then*

$$\begin{aligned} \|V_\delta(\varepsilon; \alpha_*, j_c(\delta)\beta) - V_\delta(\varepsilon; \alpha_*, j(\delta)\beta)\|_{2\delta} &\leq 64K_j e^{8K_j\delta} \delta^2 \|v\| R_+^4 e^{-m c} \\ \|V_\delta(\varepsilon; j_c(\delta)\alpha_*, \beta) - V_\delta(\varepsilon; j(\delta)\alpha_*, \beta)\|_{2\delta} &\leq 64K_j e^{8K_j\delta} \delta^2 \|v\| R_+^4 e^{-m c} \end{aligned}$$

and

$$\begin{aligned} \|V_\delta(\varepsilon; \alpha_*, z + j_c(\delta)\beta) - V_\delta(\varepsilon; \alpha_*, j_c(\delta)\beta)\|_{\text{fluct}} &\leq 2^{11} \delta \|v\| r R_+^3 \\ \|V_\delta(\varepsilon; z_* + j_c(\delta)\alpha_*, \beta) - V_\delta(\varepsilon; j_c(\delta)\alpha_*, \beta)\|_{\text{fluct}} &\leq 2^{11} \delta \|v\| r R_+^3 \end{aligned}$$

Proof. We prove the first in each pair of inequalities. By Definition 3.8

$$V_\delta(\varepsilon; \alpha_*, \beta) = -\varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle$$

with

$$\gamma_{*\tau} = j(\tau) \alpha_* \quad \gamma_\tau = j(\delta - \tau) \beta$$

For the first inequality, we write

$$\begin{aligned} & V_\delta(\varepsilon; \alpha_*, j_\epsilon(\delta)\beta) - V_\delta(\varepsilon; \alpha_*, j(\delta)\beta) \\ &= \varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} [\langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle - \langle \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon} \rangle] \end{aligned}$$

with

$$g_\tau = j(\delta - \tau) j(\delta) \beta \quad \tilde{g}_\tau = j(\delta - \tau) j_\epsilon(\delta) \beta$$

By definition

$$\|\langle \alpha_* \beta, v \alpha_* \beta \rangle\|_{2\delta} \leq 16 \|v\| R_+^4$$

We apply Corollary G.3.ii, with d and d' both replaced by $2md$, $\delta = 0$, $r = 4$, $s = 2$, $h(\gamma_1, \dots, \gamma_4) = \langle \gamma_1 \gamma_2, v \gamma_3 \gamma_4 \rangle$, $\alpha_1 = \alpha_*$, $\alpha_2 = \beta$ and

$$\begin{aligned} \Gamma_1^1 = \Gamma_3^1 &= j(\tau) \quad \Gamma_1^2 = \Gamma_3^2 = 0 \quad \Gamma_2^1 = \Gamma_4^1 = 0 \quad \Gamma_2^2 = \Gamma_4^2 = j(\delta - \tau - \varepsilon) j(\delta) \\ \tilde{\Gamma}_1^1 = \tilde{\Gamma}_3^1 &= j(\tau) \quad \tilde{\Gamma}_1^2 = \tilde{\Gamma}_3^2 = 0 \quad \tilde{\Gamma}_2^1 = \tilde{\Gamma}_4^1 = 0 \quad \tilde{\Gamma}_2^2 = \tilde{\Gamma}_4^2 = j(\delta - \tau - \varepsilon) j_\epsilon(\delta) \end{aligned}$$

As

$$\begin{aligned} \sigma &= \max \{N_{2md}(j(\tau); 2R_+, 2R_+), N_{2md}(j(\delta - \tau - \varepsilon) j(\delta); 2R_+, 2R_+), \\ &\quad N_{2md}(j(\delta - \tau - \varepsilon) j_\epsilon(\delta); 2R_+, 2R_+)\} \\ &\leq \max \{\|j(\tau)\|, \|j(\delta - \tau - \varepsilon) j(\delta)\|, \|j(\delta - \tau - \varepsilon) j_\epsilon(\delta)\|\} \\ &\leq e^{2K_j \delta} \tag{4.2} \\ \sigma_\delta &= N_{2md}(j(\delta - \tau - \varepsilon) [j(\delta) - j_\epsilon(\delta)]; 2R_+, 2R_+) \\ &\leq \|j(\delta - \tau - \varepsilon)\| \|j(\delta) - j_\epsilon(\delta)\| \\ &\leq \delta K_j e^{2K_j \delta} e^{-m \epsilon} \end{aligned}$$

by Lemma 3.21, it gives, for each $\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)$

$$\begin{aligned} & \|\langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle - \langle \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon} \rangle\|_{2\delta} \\ &\leq 64 \|v\| R_+^4 \sigma_\delta \sigma^3 \\ &\leq 64 \|v\| R_+^4 \delta K_j e^{8K_j \delta} e^{-m \epsilon} \end{aligned}$$

Summing over τ and multiplying with ε gives the desired estimate.

For the third inequality, we write

$$\begin{aligned} & V_\delta(\varepsilon; \alpha_*, z + j_\epsilon(\delta)\beta) - V_\delta(\varepsilon; \alpha_*, j_\epsilon(\delta)\beta) \\ &= -\varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} [\langle \gamma_{*\tau} \hat{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \hat{g}_{\tau+\varepsilon} \rangle - \langle \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon} \rangle] \end{aligned}$$

with

$$\hat{g}_\tau = j(\delta - \tau) (z + j_\epsilon(\delta)\beta) = j(\delta - \tau) z + j(\delta - \tau) j_\epsilon(\delta) \beta$$

This time, we apply Corollary G.3(ii), with d and d' both replaced by $2md$, $\delta = 0$, $r = 4$, $s = 3$, $h(\gamma_1, \dots, \gamma_4) = \langle \gamma_1\gamma_2, v\gamma_3\gamma_4 \rangle$, $\alpha_1 = \alpha_*$, $\alpha_2 = \beta$, $\alpha_3 = z$ and

$$\begin{aligned}\hat{\Gamma}_1^1 &= \hat{\Gamma}_3^1 = j(\tau) & \hat{\Gamma}_2^2 &= \hat{\Gamma}_4^2 = j(\delta - \tau - \varepsilon)j_c(\delta) & \hat{\Gamma}_2^3 &= \hat{\Gamma}_4^3 = j(\delta - \tau - \varepsilon) \\ \hat{\tilde{\Gamma}}_1^1 &= \hat{\tilde{\Gamma}}_3^1 = j(\tau) & \hat{\tilde{\Gamma}}_2^2 &= \hat{\tilde{\Gamma}}_4^2 = j(\delta - \tau - \varepsilon)j_c(\delta) & \hat{\tilde{\Gamma}}_2^3 &= \hat{\tilde{\Gamma}}_4^3 = 0\end{aligned}\quad (4.3)$$

with all other $\hat{\Gamma}_i^j$'s and $\hat{\tilde{\Gamma}}_i^j$'s being zero. Then

$$\begin{aligned}\hat{\sigma} &= \max \{N_{2\text{md}}(j(\tau); 2R_+, 2R_+), N_{2\text{md}}(j(\delta - \tau - \varepsilon)j_c(\delta); 2R_+, 2R_+), \\ &\quad N_{2\text{md}}(j(\delta - \tau - \varepsilon); 2R_+, 32r) + N_{2\text{md}}(j(\delta - \tau - \varepsilon)j_c(\delta); 2R_+, 2R_+)\} \\ &\leq \max \left\{ \|j(\tau)\|, \|j(\delta - \tau - \varepsilon)j_c(\delta)\|, \right. \\ &\quad \left. 16 \frac{r}{R_+} \|j(\delta - \tau - \varepsilon)\| + \|j(\delta - \tau - \varepsilon)j_c(\delta)\| \right\} \\ &\leq (1 + 16(\delta v)^{e_R}) e^{2K_j \delta} \\ \hat{\sigma}_\delta &= N_{2\text{md}}(j(\delta - \tau - \varepsilon); 2R_+, 32r) \\ &\leq 16 \frac{r}{R_+} \|j(\delta - \tau - \varepsilon)\| \\ &\leq 16 \frac{r}{R_+} e^{K_j \delta}\end{aligned}\quad (4.4)$$

So, as before, for each $\tau \in \varepsilon\mathbb{Z} \cap [0, \delta)$

$$\begin{aligned}\|\langle \gamma_{*\tau} \hat{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \hat{g}_{\tau+\varepsilon} \rangle - \langle \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon} \rangle\|_{\text{fluct}} &\leq 64 \|v\| R_+^4 \hat{\sigma}_\delta \hat{\sigma}^3 \\ &\leq 2^{11} \|v\| r R_+^3\end{aligned}$$

by Hypothesis F.7(i). Summing over τ gives the desired result. \square

Proof of Theorem 3.24. Set

$$\begin{aligned}\mathcal{R}^{(1)}(\alpha_*, \beta) &= \mathcal{R}_1(\alpha_*, j_c(\delta)\beta) + \mathcal{R}_2(j_c(\delta)\alpha_*, \beta) \\ &\quad - \langle [j(\delta) - j_c(\delta)]\alpha_*, [j(\delta) - j_c(\delta)]\beta \rangle \\ \mathcal{E}^{(1)}(\alpha_*, \beta) &= \mathcal{E}_1(\alpha_*, j_c(\delta)\beta) + \mathcal{E}_2(j_c(\delta)\alpha_*, \beta) + V_\delta(\varepsilon; \alpha_*, j_c(\delta)\beta) \\ &\quad - V_\delta(\varepsilon; \alpha_*, j(\delta)\beta) + V_\delta(\varepsilon; j_c(\delta)\alpha_*, \beta) - V_\delta(\varepsilon; j(\delta)\alpha_*, \beta)\end{aligned}$$

and

$$\begin{aligned}\mathcal{R}_l(\alpha_*, z) &= \mathcal{R}_1(\alpha_*, z) + \langle [j(\delta) - j_c(\delta)]\alpha_*, z \rangle \\ \mathcal{R}_r(\alpha_*, z) &= \mathcal{R}_2(z_*, \beta) + \langle z_*, [j(\delta) - j_c(\delta)]\beta \rangle \\ \mathcal{E}_l(\alpha_*, \beta, z) &= [\mathcal{E}_1(\alpha_*, z + j_c(\delta)\beta) - \mathcal{E}_1(\alpha_*, j_c(\delta)\beta)] \\ &\quad + [V_\delta(\varepsilon; \alpha_*, z + j_c(\delta)\beta) - V_\delta(\varepsilon; \alpha_*, j_c(\delta)\beta)] \\ \mathcal{E}_r(z_*, \alpha_*, \beta) &= [\mathcal{E}_2(z_* + j_c(\delta)\alpha_*, \beta) - \mathcal{E}_2(z_* + j_c(\delta)\alpha_*, \beta)] \\ &\quad + [V_\delta(\varepsilon; z_* + j_c(\delta)\alpha_*, \beta) - V_\delta(\varepsilon; j_c(\delta)\alpha_*, \beta)]\end{aligned}$$

Clearly, $\mathcal{R}^{(1)}(\alpha_*, \beta)$ is bilinear in α_*, β and $\mathcal{E}^{(1)}(\alpha_*, \beta)$ has degree at least two both in α_* and β . Furthermore, by Lemmas 4.1, 4.3 and 4.4

$$\begin{aligned}\|\mathcal{R}^{(1)}\|_{2\delta} &\leq e^{\delta K_j} \left(\frac{R_+}{R}\right)^2 (\|\mathcal{R}_1\|_\delta + \|\mathcal{R}_2\|_\delta) + 4\delta^2 K_j^2 e^{2K_j\delta} R_+^2 e^{-2m\epsilon} \\ \|\mathcal{E}^{(1)}\|_{2\delta} &\leq e^{2\delta K_j} \left(\frac{R_+}{R}\right)^4 (\|\mathcal{E}_1\|_\delta + \|\mathcal{E}_2\|_\delta) + 128 K_j e^{8K_j\delta} \delta^2 \|v\| R_+^4 e^{-m\epsilon}\end{aligned}\quad (4.5)$$

Also, \mathcal{R}_l is bilinear in α_*, z , and \mathcal{R}_r is bilinear in z_*, β . By Lemma 4.2 and Lemma 4.3

$$\begin{aligned}\|\mathcal{R}_l\|_{\text{fluct}} &\leq \|\mathcal{R}_1\|_\delta + 64\delta K_j e^{K_j\delta} r R_+ e^{-m\epsilon} \\ \|\mathcal{R}_r\|_{\text{fluct}} &\leq \|\mathcal{R}_2\|_\delta + 64\delta K_j e^{K_j\delta} r R_+ e^{-m\epsilon}\end{aligned}\quad (4.6)$$

Furthermore, $\mathcal{E}_l(\alpha_*, \beta, z)$ has degree at least two in the variable α_* ; and the sums of the degrees of the variables β and z in each monomial of its power series expansion is also at least two. Also, by Lemmas 4.2 and 4.4

$$\|\mathcal{E}_l\|_{\text{fluct}} \leq \|\mathcal{E}_1\|_\delta + 2^{11}\delta \|v\| r R_+^3 \quad (4.7)$$

There is the analogous statement for \mathcal{E}_r .

By construction, the effective density in Definition 3.22 in the situation of Theorem 3.24 is

$$\mathcal{A}(\alpha_*, \beta; z_*, z) = \mathcal{R}_l(\alpha_*, z) + \mathcal{E}_l(\alpha_*, \beta, z) + \mathcal{R}_r(z_*, \beta) + \mathcal{E}_r(z_*, \alpha_*, \beta)$$

so that

$$\begin{aligned}\bar{\mathfrak{R}}_\delta(V_\delta(\varepsilon; \cdot); \mathcal{R}_1 + \mathcal{E}_1, \mathcal{R}_2 + \mathcal{E}_2) \\ = \mathcal{R}^{(1)} + \mathcal{E}^{(1)} + \log \frac{1}{Z} \int d\mu_r(z^*, z) e^{\mathcal{R}_l(\alpha_*, \beta, z) + \mathcal{E}_l(\alpha_*, \beta, z) + \mathcal{R}_r(z^*, \beta) + \mathcal{E}_r(z^*, \alpha_*, \beta)}\end{aligned}$$

where $Z = \int d\mu_r(z^*, z)$. Set

$$\mathcal{R}^{(2)}(\alpha_*, \beta) = \frac{1}{Z} \int d\mu_r(z^*, z) \mathcal{R}_l(\alpha_*, z) \mathcal{R}_r(z^*, \beta)$$

By [4, Remark III.3.ii]

$$\left\| \mathcal{R}^{(2)} \right\|_{2\delta} = \left\| \mathcal{R}^{(2)} \right\|_{\text{fluct}} \leq \|\mathcal{R}_l\|_{\text{fluct}} \|\mathcal{R}_r\|_{\text{fluct}}$$

Expanding the exponential in Definition 3.22 and using the fact that the $d\mu_r(z^*, z)$ integral is zero unless there are the same number of z 's and z^* 's, one sees that

$$\mathcal{E}^{(2)}(\alpha_*, \beta) = \log \frac{1}{Z} \int d\mu_r(z^*, z) e^{\mathcal{A}(\alpha_*, \beta; z^*, z)} - \mathcal{R}^{(2)}(\alpha_*, \beta)$$

has degree at least two both in α_* and in β . By [4, Corollary III.5], with $n = 2$, there is a function $\mathcal{E}'(\alpha_*, \beta)$ such that

$$\begin{aligned}\log \frac{1}{Z} \int d\mu_r(z^*, z) e^{\mathcal{A}(\alpha_*, \beta; z^*, z)} \\ = \mathcal{E}'(\alpha_*, \beta) + \frac{1}{2Z} \int d\mu_r(z^*, z) [\mathcal{R}_l + \mathcal{E}_l + \mathcal{R}_r + \mathcal{E}_r]^2 \\ = \mathcal{E}'(\alpha_*, \beta) + \mathcal{R}^{(2)}(\alpha_*, \beta) + \frac{1}{Z} \int d\mu_r(z^*, z) [\mathcal{R}_l \mathcal{E}_r + \mathcal{E}_l \mathcal{R}_r + \mathcal{E}_l \mathcal{E}_r]\end{aligned}$$

and

$$\|\mathcal{E}'\|_{2\delta} \leq \left(\frac{\|\mathcal{A}\|_{\text{fluct}}}{\frac{1}{20} - \|\mathcal{A}\|_{\text{fluct}}} \right)^3 \quad (4.8)$$

(The hypothesis that $\|\mathcal{A}\|_{\text{fluct}} < \frac{1}{32}$ is verified below.) Clearly

$$\mathcal{E}^{(2)} = \mathcal{E}' + \frac{1}{Z} \int d\mu_r(z^*, z) [\mathcal{R}_l \mathcal{E}_r + \mathcal{E}_l \mathcal{R}_r + \mathcal{E}_l \mathcal{E}_r]$$

and, by [4, Remark III.3.ii]

$$\|\mathcal{E}^{(2)}\|_{2\delta} \leq \|\mathcal{E}'\|_{2\delta} + \|\mathcal{R}_l\|_{\text{fluct}} \|\mathcal{E}_r\|_{\text{fluct}} + \|\mathcal{E}_l\|_{\text{fluct}} \|\mathcal{R}_r\|_{\text{fluct}} + \|\mathcal{E}_l\|_{\text{fluct}} \|\mathcal{E}_r\|_{\text{fluct}}$$

We set

$$\mathcal{R} = \mathcal{R}^{(1)} + \mathcal{R}^{(2)}, \quad \mathcal{E} = \mathcal{E}^{(1)} + \mathcal{E}^{(2)}$$

By construction

$$\mathfrak{R}_\delta(V_\delta(\varepsilon; \cdot); \mathcal{R}_1 + \mathcal{E}_1, \mathcal{R}_2 + \mathcal{E}_2) = \mathcal{R} + \mathcal{E}$$

Furthermore, $\mathcal{R}(\alpha_*, \beta)$ is bilinear in α_* , β , and $\mathcal{E}(\alpha_*, \beta)$ has degree at least two both in α_* and β . Hence \mathcal{R} is the quadratic part of $\mathfrak{R}_\delta(V_\delta(\varepsilon; \cdot); \mathcal{R}_1 + \mathcal{E}_1, \mathcal{R}_2 + \mathcal{E}_2)$, which coincides with the quadratic part of $\mathfrak{R}_\delta(0; \mathcal{R}_1, \mathcal{R}_2)$. Also

$$\begin{aligned} \|\mathcal{R}\|_{2\delta} &\leq \|\mathcal{R}^{(1)}\|_{2\delta} + \|\mathcal{R}^{(2)}\|_{2\delta} \\ &\leq \|\mathcal{R}^{(1)}\|_{2\delta} + \|\mathcal{R}_l\|_{\text{fluct}} \|\mathcal{R}_r\|_{\text{fluct}} \\ &\leq e^{\delta K_j} \left(\frac{R_+}{R} \right)^2 (\|\mathcal{R}_1\|_\delta + \|\mathcal{R}_2\|_\delta) + (2\delta)^2 K_j^2 e^{2K_j \delta} R_+^2 e^{-2m\epsilon} \\ &\quad + (\|\mathcal{R}_1\|_\delta + 64\delta K_j e^{K_j \delta} r R_+ e^{-m\epsilon}) (\|\mathcal{R}_2\|_\delta + 64\delta K_j e^{K_j \delta} r R_+ e^{-m\epsilon}) \end{aligned}$$

The hypotheses on $\|\mathcal{R}_1\|_\delta$ and $\|\mathcal{R}_2\|_\delta$ imply that

$$\begin{aligned} \|\mathcal{R}\|_{2\delta} &\leq 2e^{\delta K_j} \left(\frac{R_+}{R} \right)^2 K_R \delta^2 r^2 R^2 e^{-2m\epsilon} + (2\delta)^2 K_j^2 e^{2K_j \delta} R_+^2 e^{-2m\epsilon} \\ &\quad + (K_R \delta^2 r^2 R^2 e^{-2m\epsilon} + 64\delta K_j e^{K_j \delta} r R_+ e^{-m\epsilon})^2 \\ &\leq K_R (2\delta)^2 r_+^2 R_+^2 e^{-2m\epsilon} \left[\frac{e^{\delta K_j}}{2^{1-2e_r}} + \frac{K_j^2 e^{2K_j \delta}}{K_R} (2\delta v)^{2e_r} \right. \\ &\quad \left. + \left(\frac{\sqrt{K_R}}{2^{1-e_R-2e_r}} \frac{\delta e^{-m\epsilon}}{(\delta v)^{e_R+2e_r}} + \frac{2^{5+e_r} K_j e^{K_j \delta}}{\sqrt{K_R}} \right)^2 \right] \\ &\leq K_R (2\delta)^2 r_+^2 R_+^2 e^{-2m\epsilon} \end{aligned}$$

by (F.8a). Similarly

$$\begin{aligned} \|\mathcal{E}\|_{2\delta} &\leq \|\mathcal{E}^{(1)}\|_{2\delta} + \|\mathcal{E}^{(2)}\|_{2\delta} \\ &\leq \|\mathcal{E}^{(1)}\|_{2\delta} + \|\mathcal{E}'\|_{2\delta} + \|\mathcal{R}_l\|_{\text{fluct}} \|\mathcal{E}_r\|_{\text{fluct}} \\ &\quad + \|\mathcal{E}_l\|_{\text{fluct}} \|\mathcal{R}_r\|_{\text{fluct}} + \|\mathcal{E}_l\|_{\text{fluct}} \|\mathcal{E}_r\|_{\text{fluct}} \end{aligned} \quad (4.9)$$

By (4.5) and the hypotheses in Theorem 3.24

$$\begin{aligned}\|\mathcal{E}^{(1)}\|_{2\delta} &\leq 2e^{2\delta K_j} \left(\frac{R_+}{R}\right)^4 K_E (\delta v)^2 r^2 R^6 + 64 K_j e^{8K_j \delta} \delta^2 v R_+^4 e^{-m c} \\ &\leq (2\delta v)^2 r_+^2 R_+^6 \left(K_E \frac{e^{2\delta K_j}}{2^{1-(2e_R+4e_r)}} + \frac{16K_j e^{8K_j \delta} e^{-m c}}{r_+^2 R_+^2 v}\right)\end{aligned}$$

By (4.6), (4.7) and the hypotheses of the Theorem

$$\begin{aligned}\|\mathcal{R}_l\|_{\text{fluct}}, \|\mathcal{R}_r\|_{\text{fluct}} &\leq K_R \delta^2 r^2 R^2 e^{-2m c} + 64 \delta K_j e^{K_j \delta} r R_+ e^{-m c} \\ &\leq \delta r_+ R_+ e^{-m c} \left(2^{e_R+2e_r} K_R \frac{\delta e^{-m c}}{(\delta v)^{e_R+2e_r}} + 64 K_j 2^{e_r} e^{\delta K_j}\right) \\ &\leq \delta r_+ R_+ e^{-\frac{1}{2}m c} \\ \|\mathcal{E}_l\|_{\text{fluct}}, \|\mathcal{E}_r\|_{\text{fluct}} &\leq K_E (\delta v)^2 r^2 R^6 + 2^{11} \delta \|v\| r R_+^3 \\ &\leq (2\delta v) r_+ R_+^3 (K_E 2^{3e_R+4e_r-1} (\delta v) r R^3 + 2^9 e^{e_r}) \\ &\leq 2^{10} (2\delta v) r_+ R_+^3\end{aligned}$$

by (F.4b), Hypothesis F.7(i,ii), (F.6a) and the fact that $e_r \leq 0.1$. Consequently, by (F.4b),

$$\begin{aligned}\|\mathcal{A}\|_{\text{fluct}} &= \|\mathcal{R}_l + \mathcal{R}_r + \mathcal{E}_l + \mathcal{E}_r\|_{\text{fluct}} \leq (2\delta v) r_+ R_+^3 \left(\frac{e^{-\frac{1}{2}m c}}{v R_+^2} + 2^{11}\right) \\ &\leq 2^{12} (2\delta v) r_+ R_+^3\end{aligned}\tag{4.10}$$

By (F.6a), this number is smaller than $\frac{1}{60}$. Therefore, by (4.8),

$$\|\mathcal{E}'\|_{2\delta} \leq (30)^3 \|\mathcal{A}\|_{\text{fluct}}^3 \leq 2^{51} (2\delta v)^3 r_+^3 R_+^9$$

Inserting all these estimates into (4.9) gives

$$\begin{aligned}\|\mathcal{E}\|_{2\delta} &\leq (2\delta v)^2 r_+^2 R_+^6 \left[K_E \frac{e^{2\delta K_j}}{2^{1-(2e_R+4e_r)}} + \frac{16K_j e^{8K_j \delta} e^{-m c}}{r_+^2 R_+^2 v}\right. \\ &\quad \left.+ 2^{51} (2\delta v) r_+ R_+^3 + \frac{2^{10} e^{-\frac{1}{2}m c}}{v R_+^2} + 2^{20}\right] \\ &\leq K_E (2\delta v)^2 r_+^2 R_+^6\end{aligned}$$

by (F.8b). □

The additional ingredient that we need for the proof of Theorem 3.27 is

Lemma 4.5. *Set*

$$W(\alpha_*, \beta) = V_\delta(\varepsilon; \alpha_*, \beta) - V_\delta\left(\frac{\varepsilon}{2}; \alpha_*, \beta\right)$$

Then

$$\begin{aligned}\|W(\alpha_*, j(\delta)\beta) - W(\alpha_*, j_c(\delta)\beta)\|_{2\delta} &\leq 2^8 e^{10K_j} \varepsilon \delta^2 \|v\| R_+^4 e^{-m c} \\ \|W(j(\delta)\alpha_*, \beta) - W(j_c(\delta)\alpha_*, \beta)\|_{2\delta} &\leq 2^8 e^{10K_j} \varepsilon \delta^2 \|v\| R_+^4 e^{-m c}\end{aligned}$$

and

$$\begin{aligned}\|W(\alpha_*, z + j_c(\delta)\beta) - W(\alpha_*, j_c(\delta)\beta)\|_{\text{fluct}} &\leq 2^{12} e^{9K_j} \varepsilon \delta \|v\| R_+^3 \\ \|W(z_* + j_c(\delta)\alpha_*, \beta) - W(j_c(\delta)\alpha_*, \beta)\|_{\text{fluct}} &\leq 2^{12} e^{9K_j} \varepsilon \delta \|v\| R_+^3\end{aligned}$$

Proof. We prove the first of each of the two pairs of inequalities and use the same notation as in Lemma 4.4. By definition

$$W(\alpha_*, \beta) = W_1(\alpha_*, \beta) + W_2(\alpha_*, \beta)$$

with

$$\begin{aligned}W_1(\alpha_*, \beta) &= \frac{\varepsilon}{2} \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} [\langle \gamma_{*\tau} \gamma_{\tau+\frac{\varepsilon}{2}}, v \gamma_{*\tau} \gamma_{\tau+\frac{\varepsilon}{2}} \rangle - \langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle] \\ W_2(\alpha_*, \beta) &= \frac{\varepsilon}{2} \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} [\langle \gamma_{*\tau+\frac{\varepsilon}{2}} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau+\frac{\varepsilon}{2}} \gamma_{\tau+\varepsilon} \rangle - \langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle]\end{aligned}$$

Now, using the g_τ and \tilde{g}_τ of Lemma 4.4,

$$\begin{aligned}W_1(\alpha_*, j(\delta)\beta) - W_1(\alpha_*, j_c(\delta)\beta) &= \frac{\varepsilon}{2} \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} [\langle \gamma_{*\tau} g_{\tau+\frac{\varepsilon}{2}}, v \gamma_{*\tau} g_{\tau+\frac{\varepsilon}{2}} \rangle - \langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle \\ &\quad - \langle \gamma_{*\tau} \tilde{g}_{\tau+\frac{\varepsilon}{2}}, v \gamma_{*\tau} \tilde{g}_{\tau+\frac{\varepsilon}{2}} \rangle + \langle \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon} \rangle] \\ &= \frac{\varepsilon}{2} \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} [\langle \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) g_{\tau+\varepsilon}, v \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) g_{\tau+\varepsilon} \rangle - \langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle \\ &\quad - \langle \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) \tilde{g}_{\tau+\varepsilon}, v \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) \tilde{g}_{\tau+\varepsilon} \rangle + \langle \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon} \rangle]\end{aligned}$$

We apply Corollary G.3(iii), with the metrics d and d' both replaced by $2md$, the metric $\delta = 0$, and with the same substitutions as in the first bound on Lemma 4.4, namely,

$$\begin{aligned}\Gamma_1^1 = \Gamma_3^1 &= j(\tau) \quad \Gamma_1^2 = \Gamma_3^2 = 0 \quad \Gamma_2^1 = \Gamma_4^1 = 0 \quad \Gamma_2^2 = \Gamma_4^2 = j(\delta - \tau - \varepsilon)j(\delta) \\ \tilde{\Gamma}_1^1 = \tilde{\Gamma}_3^1 &= j(\tau) \quad \tilde{\Gamma}_1^2 = \tilde{\Gamma}_3^2 = 0 \quad \tilde{\Gamma}_2^1 = \tilde{\Gamma}_4^1 = 0 \quad \tilde{\Gamma}_2^2 = \tilde{\Gamma}_4^2 = j(\delta - \tau - \varepsilon)j_c(\delta)\end{aligned}$$

and, in addition,

$$A_1 = \tilde{A}_1 = A_3 = \tilde{A}_3 = 1 \quad A_2 = A_4 = j\left(\frac{\varepsilon}{2}\right) \quad \tilde{A}_2 = \tilde{A}_4 = \mathfrak{h} \quad (4.11)$$

The Corollary bounds the $\|\cdot\|_{2\delta}$ norm of the τ term in terms of the σ and σ_δ of (4.2) and

$$\begin{aligned}a &\leq \max \left\{ \|\mathbf{1}\|, \|j\left(\frac{\varepsilon}{2}\right)\| \right\} \leq e^{K_j \frac{\varepsilon}{2}} \\ a_\delta &= N_{2md} \left(j\left(\frac{\varepsilon}{2}\right) - \mathfrak{h}; 2R_+, 2R_+ \right) \leq \|j\left(\frac{\varepsilon}{2}\right) - \mathfrak{h}\| \leq \frac{\varepsilon}{2} K_j e^{K_j \frac{\varepsilon}{2}} \quad (4.12)\end{aligned}$$

by Lemma 3.21. Summing over τ and multiplying by $\frac{\varepsilon}{2}$, we get

$$\begin{aligned}\|W_1(\alpha_*, j_c(\delta)\beta) - W_1(\alpha_*, j(\delta)\beta)\|_{2\delta} &\leq \frac{\varepsilon}{2} \frac{\delta}{\varepsilon} 4^2 16 \|v\| R_+^4 \sigma_\delta a_\delta (\sigma a)^3 \\ &\leq 2^7 e^{10K_j} \varepsilon \delta^2 \|v\| R_+^4 e^{-m \mathfrak{c}}\end{aligned}$$

The same estimate holds for $\|W_2(\alpha_*, j_c(\delta)\beta) - W_2(\alpha_*, j(\delta)\beta)\|_{2\delta}$.

For the first of the second pair of inequalities, write, using the \hat{g}_τ and \tilde{g}_τ of Lemma 4.4,

$$\begin{aligned} & W_1(\alpha_*, z + j_c(\delta)\beta) - W_1(\alpha_*, j_c(\delta)\beta) \\ &= \frac{\varepsilon}{2} \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta]} \left[\langle \gamma_{*\tau} \hat{g}_{\tau+\frac{\varepsilon}{2}}, v \gamma_{*\tau} \hat{g}_{\tau+\frac{\varepsilon}{2}} \rangle - \langle \gamma_{*\tau} \hat{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \hat{g}_{\tau+\varepsilon} \rangle \right. \\ &\quad \left. - \langle \gamma_{*\tau} \tilde{g}_{\tau+\frac{\varepsilon}{2}}, v \gamma_{*\tau} \tilde{g}_{\tau+\frac{\varepsilon}{2}} \rangle + \langle \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon} \rangle \right] \\ &= \frac{\varepsilon}{2} \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta]} \left[\left\langle \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) \hat{g}_{\tau+\varepsilon}, v \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) \hat{g}_{\tau+\varepsilon} \right\rangle - \langle \gamma_{*\tau} \hat{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \hat{g}_{\tau+\varepsilon} \rangle \right. \\ &\quad \left. - \left\langle \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) \tilde{g}_{\tau+\varepsilon}, v \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) \tilde{g}_{\tau+\varepsilon} \right\rangle + \langle \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon}, v \gamma_{*\tau} \tilde{g}_{\tau+\varepsilon} \rangle \right] \end{aligned}$$

This time, we apply Corollary G.3(iii) using the $\hat{\Gamma}_i^j$'s and $\tilde{\Gamma}_i^j$'s of (4.3) together with the A_i 's and \tilde{A}_i 's of (4.11). By (4.4) and (4.12)

$$\begin{aligned} \|W_1(\alpha_*, z + j_c(\delta)\beta) - W_1(\alpha_*, j_c(\delta)\beta)\|_{\text{fluct}} &\leq \frac{\varepsilon}{2} \frac{\delta}{\varepsilon} 4^2 16 \|v\| R_+^4 \hat{\sigma}_\delta a_\delta (\hat{\sigma} a)^3 \\ &\leq 2^{11} e^{9K_j} \varepsilon \delta \|v\| R_+^3 \end{aligned}$$

The same estimate holds for $\|W_2(\alpha_*, z + j_c(\delta)\beta) - W_2(\alpha_*, j_c(\delta)\beta)\|_{\text{fluct}}$. \square

Proof of Theorem 3.27. We use the same notation as in the proof of Theorem 3.24. Define $\tilde{\mathcal{R}}^{(1)}$, $\tilde{\mathcal{E}}^{(1)}$, $\tilde{\mathcal{R}}_l$, $\tilde{\mathcal{R}}_r$, $\tilde{\mathcal{E}}_l$, $\tilde{\mathcal{E}}_r$ and $\tilde{\mathcal{A}}$ in the same way as the corresponding “untitled” quantities were defined at the beginning of the proof of Theorem 3.24. They fulfill the same bounds as their untitled siblings. Furthermore

$$\begin{aligned} & \left\| \tilde{\mathcal{R}}^{(1)} - \mathcal{R}^{(1)} \right\|_{2\delta} \\ &\leq \left\| (\tilde{\mathcal{R}}_1 - \mathcal{R}_1)(\alpha_*, j_c(\delta)\beta) \right\|_{2\delta} + \left\| (\tilde{\mathcal{R}}_2 - \mathcal{R}_2)(j_c(\delta)\alpha_*, \beta) \right\|_{2\delta} \\ &\leq 2e^{\delta K_j} \left(\frac{R_+}{R} \right)^2 \Delta_{\mathcal{R}} \\ & \left\| \tilde{\mathcal{E}}^{(1)} - \mathcal{E}^{(1)} \right\|_{2\delta} \\ &\leq \left\| (\tilde{\mathcal{E}}_1 - \mathcal{E}_1)(\alpha_*, j_c(\delta)\beta) \right\|_{2\delta} + \left\| (\tilde{\mathcal{E}}_2 - \mathcal{E}_2)(j_c(\delta)\alpha_*, \beta) \right\|_{2\delta} \\ &\quad + \|W(\alpha_*, j_c(\delta)\beta) - W(\alpha_*, j(\delta)\beta)\|_{2\delta} \\ &\quad + \|W(j_c(\delta)\alpha_*, \beta) - W(j(\delta)\alpha_*, \beta)\|_{2\delta} \\ &\leq 2e^{2\delta K_j} \left(\frac{R_+}{R} \right)^4 \Delta_{\mathcal{E}} + 2^9 e^{10K_j} \varepsilon \delta^2 \|v\| R_+^4 e^{-m c} \end{aligned}$$

by Lemmas 4.1 and 4.5. Also

$$\begin{aligned} \left\| \tilde{\mathcal{R}}_l - \mathcal{R}_l \right\|_{\text{fluct}} &= \left\| \tilde{\mathcal{R}}_1(\alpha_*, z) - \mathcal{R}_1(\alpha_*, z) \right\|_{\text{fluct}} \\ &= \frac{R_+}{R} \frac{16r}{R} \left\| \tilde{\mathcal{R}}_1(\alpha_*, \beta) - \mathcal{R}_1(\alpha_*, \beta) \right\|_\delta \end{aligned}$$

$$\begin{aligned} \|\tilde{\mathcal{E}}_l - \mathcal{E}_l\|_{\text{fluct}} &\leq \left\| (\tilde{\mathcal{E}}_1 - \mathcal{E}_1)(\alpha_*, z + j_c(\delta)\beta) - (\tilde{\mathcal{E}}_1 - \mathcal{E}_1)(\alpha_*, j_c(\delta)\beta) \right\|_{\text{fluct}} \\ &\quad + \|W(\alpha_*, z + j_c(\delta)\beta) - W(\alpha_*, j(\delta)\beta)\|_{\text{fluct}} \\ &\leq \|\tilde{\mathcal{E}}_1 - \mathcal{E}_1\|_\delta + 2^{12} e^{9K_j} \varepsilon \delta \|v\| r R_+^3 \end{aligned}$$

by Lemmas 4.2 and 4.5. Similarly

$$\begin{aligned} \|\tilde{\mathcal{R}}_r - \mathcal{R}_r\|_{\text{fluct}} &= \frac{R_+}{R} \frac{16r}{R} \|\tilde{\mathcal{R}}_2 - \mathcal{R}_2\|_\delta \\ \|\tilde{\mathcal{E}}_r - \mathcal{E}_r\|_{\text{fluct}} &\leq \|\tilde{\mathcal{E}}_2 - \mathcal{E}_2\|_\delta + 2^{12} e^{9K_j} \varepsilon \delta \|v\| r R_+^3 \end{aligned}$$

Consequently

$$\|\tilde{\mathcal{A}} - \mathcal{A}\|_{\text{fluct}} \leq \frac{32r}{R} \Delta_{\mathcal{R}} + 2\Delta_{\mathcal{E}} + 2^{13} e^{9K_j} \varepsilon \delta \|v\| r R_+^3$$

For the fluctuation integral, we have

$$\begin{aligned} \tilde{\mathcal{R}}^{(2)} - \mathcal{R}^{(2)} &= \frac{1}{Z} \int d\mu_r(z^*, z) \left[(\tilde{\mathcal{R}}_l - \mathcal{R}_l)(\alpha_*, z) \tilde{\mathcal{R}}_r(z^*, \beta) + \mathcal{R}_l(\alpha_*, z) (\tilde{\mathcal{R}}_r - \mathcal{R}_r)(z^*, \beta) \right] \end{aligned}$$

By [4, Remark III.3.ii] and (4.6),

$$\begin{aligned} \|\tilde{\mathcal{R}}^{(2)} - \mathcal{R}^{(2)}\|_{2\delta} &= \|\tilde{\mathcal{R}}^{(2)} - \mathcal{R}^{(2)}\|_{\text{fluct}} \\ &\leq \|\tilde{\mathcal{R}}_l - \mathcal{R}_l\|_{\text{fluct}} \|\tilde{\mathcal{R}}_r\|_{\text{fluct}} + \|\mathcal{R}_l\|_{\text{fluct}} \|\tilde{\mathcal{R}}_r - \mathcal{R}_r\|_{\text{fluct}} \\ &\leq (K_R \delta^2 r^2 R^2 e^{-2m\epsilon} + 64 \delta K_j e^{K_j \delta} r R_+ e^{-m\epsilon}) \frac{32r}{R} \Delta_{\mathcal{R}} \\ &\leq 2^{12} e^{2K_j} \delta r_+^2 e^{-m\epsilon} \Delta_{\mathcal{R}} \end{aligned}$$

by (F.4b) and (F.6a). Furthermore

$$\begin{aligned} &\left(\tilde{\mathcal{E}}^{(2)} - \mathcal{E}^{(2)} \right)(\alpha_*, \beta) \\ &= \log \frac{1}{Z} \int d\mu_r(z^*, z) e^{\tilde{\mathcal{A}}(\alpha_*, \beta; z^*, z)} - \log \frac{1}{Z} \int d\mu_r(z^*, z) e^{\mathcal{A}(\alpha_*, \beta; z^*, z)} \\ &\quad - (\tilde{\mathcal{R}}^{(2)} - \mathcal{R}^{(2)})(\alpha_*, \beta) \end{aligned}$$

We apply [4, Corollary III.6] to the difference of the two logarithms of integrals. Since each monomial of \mathcal{A} and $\tilde{\mathcal{A}}$ contains either only z 's or only z^* 's, and hence integrates to zero, the first hypothesis of this corollary is satisfied. For the second hypothesis, we have, by (4.10),

$$\begin{aligned} &\|\mathcal{A}\|_{\text{fluct}} + \|\tilde{\mathcal{A}} - \mathcal{A}\|_{\text{fluct}} \\ &\leq 2^{12} (2\delta v) r_+ R_+^3 + \frac{16r}{R} \left(\|\tilde{\mathcal{R}}_1 - \mathcal{R}_1\|_\delta + \|\tilde{\mathcal{R}}_2 - \mathcal{R}_2\|_\delta \right) \\ &\quad + \left(\|\tilde{\mathcal{E}}_1 - \mathcal{E}_1\|_\delta + \|\tilde{\mathcal{E}}_2 - \mathcal{E}_2\|_\delta \right) + 2^{13} e^{9K_j} \varepsilon \delta \|v\| r R_+^3 \\ &\leq 2^{13} (2\delta v) r_+ R_+^3 + \frac{16r}{R} \left(\|\tilde{\mathcal{R}}_1\|_\delta + \|\mathcal{R}_1\|_\delta + \|\tilde{\mathcal{R}}_2\|_\delta + \|\mathcal{R}_2\|_\delta \right) \end{aligned}$$

$$\begin{aligned}
& + \left(\|\tilde{\mathcal{E}}_1\|_\delta + \|\mathcal{E}_1\|_\delta + \|\tilde{\mathcal{E}}_2\|_\delta + \|\mathcal{E}_2\|_\delta \right) \\
& \leq 2^{14}(2\delta\mathfrak{v})r_+R_+^3 \leq \frac{1}{34}
\end{aligned}$$

by Hypothesis F.7(i) and (F.6a). The corollary gives

$$\begin{aligned}
& \left\| \tilde{\mathcal{E}}^{(2)} - \mathcal{E}^{(2)} \right\|_{2\delta} \\
& \leq 4(34)^2 (2^{14}(2\delta\mathfrak{v})r_+R_+^3) \left(\frac{32r}{R} \Delta_{\mathcal{R}} + 2\Delta_{\mathcal{E}} + 2^{13}e^{9K_j} \varepsilon\delta \|v\| r R_+^3 \right) \\
& \quad + \left\| \tilde{\mathcal{R}}^{(2)} - \mathcal{R}^{(2)} \right\|_{2\delta} \\
& \leq 2^{33}e^{2K_j}(2\delta\mathfrak{v})r_+^2R_+^2 \Delta_{\mathcal{R}} + 2^{28}(2\delta\mathfrak{v})r_+R_+^3 \Delta_{\mathcal{E}} + 2^{39}e^{9K_j} \varepsilon(2\delta\mathfrak{v})^2r_+^2R_+^6
\end{aligned}$$

Combining the above bounds, we have

$$\begin{aligned}
\left\| \tilde{\mathcal{R}} - \mathcal{R} \right\|_{2\delta} & \leq \left\| \tilde{\mathcal{R}}^{(1)} - \mathcal{R}^{(1)} \right\|_{2\delta} + \left\| \tilde{\mathcal{R}}^{(2)} - \mathcal{R}^{(2)} \right\|_{2\delta} \\
& \leq \left(2e^{\delta K_j} \left(\frac{R_+}{R} \right)^2 + 2^{12}e^{2K_j} \delta r_+^2 e^{-m\mathfrak{c}} \right) \Delta_{\mathcal{R}} \\
& \leq 2\Delta_{\mathcal{R}} \\
\left\| \tilde{\mathcal{E}} - \mathcal{E} \right\|_{2\delta} & \leq \left\| \tilde{\mathcal{E}}^{(1)} - \mathcal{E}^{(1)} \right\|_{2\delta} + \left\| \tilde{\mathcal{E}}^{(2)} - \mathcal{E}^{(2)} \right\|_{2\delta} \\
& \leq \left(2e^{2\delta K_j} \left(\frac{R_+}{R} \right)^4 + 2^{28}(2\delta\mathfrak{v})r_+R_+^3 \right) \Delta_{\mathcal{E}} + 2^{33}e^{2K_j}(2\delta\mathfrak{v})r_+^2R_+^2 \Delta_{\mathcal{R}} \\
& \quad + 2^9e^{10K_j} \varepsilon\delta^2 \|v\| R_+^4 e^{-m\mathfrak{c}} + 2^{39}e^{9K_j} \varepsilon(2\delta\mathfrak{v})^2r_+^2R_+^6 \\
& \leq \Delta_{\mathcal{E}} + 2^{33}e^{2K_j}(2\delta\mathfrak{v})r_+^2R_+^2 \Delta_{\mathcal{R}} + 2^{40}e^{10K_j} \varepsilon(2\delta\mathfrak{v})^2r_+^2R_+^6
\end{aligned}$$

by (F.4b), (F.6a), Hypothesis F.7(i) and (F.8c). \square

5. The Decimation Step in all of Space

The “decimation step” for all large and small field regions is formulated in Theorems 3.26 and 3.28. We shall prove them in this section. As in Sect. 4, write

$$\begin{aligned}
r &= r(\delta) & R &= R(\delta) & R' &= R'(\delta) \\
r_+ &= r(2\delta) & R_+ &= R(2\delta) & R'_+ &= R'(2\delta)
\end{aligned}$$

Recall that, by (2.18),

$$\frac{r_+}{r} = \frac{1}{2^{e_r}} \frac{R_+}{R} = \frac{1}{2^{e_R+e_r}} \frac{R'_+}{R'} = \frac{1}{2^{e_{R'}+e_r}} \tag{5.1}$$

The hierarchies \mathfrak{S}_1 and \mathfrak{S}_1 of Theorem 3.26 each specify the large and small field sets for decimation intervals of length at most δ . For a decimation interval

\mathcal{J} of length at most δ contained in $[0, 2\delta]$, we set, for $\mathcal{X} = \Lambda, \Omega, P_\alpha, P_\beta, P'_\alpha, P'_\beta, Q, R$

$$\mathcal{X}(\mathcal{J}) = \begin{cases} \mathcal{X}_{\mathfrak{S}_1}(\mathcal{J}) & \text{if } \mathcal{J} \subset [0, \delta] \\ \mathcal{X}_{\mathfrak{S}_2}(\mathcal{J} - \delta) & \text{if } \mathcal{J} \subset [\delta, 2\delta] \end{cases}$$

Then $\mathcal{X}(\mathcal{J}) = \mathcal{X}_{\mathfrak{S}}(\mathcal{J})$ for all hierarchies \mathfrak{S} of scale 2δ with $(\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S}$ and all \mathcal{J} contained in either $[0, \delta]$ or $[\delta, 2\delta]$.

We also set $\Omega_0 = \Omega_1 \cap \Omega_2$.

5.1. The New Small Field/Large Field Decomposition of the First Kind

By hypothesis, the integrand of the integral defining $I(\alpha^*, \beta)$ in Theorem 3.26 contains the product $\chi_\delta(\Omega_1; \alpha^*, \phi) \chi_\delta(\Omega_2; \phi^*, \beta)$ of characteristic functions. These characteristic functions impose small field conditions for the decimation intervals $[0, \delta]$ and $[\delta, 2\delta]$. For example, the first characteristic function contains a factor which vanishes unless $|\alpha(\mathbf{x})| \leq R(\delta)$ for each $\mathbf{x} \in \Omega_1$. The representation for $I(\alpha^*, \beta)$ in the conclusion of Theorem 3.26 contains the characteristic function $\chi_{2\delta}(\Omega_{\mathfrak{S}}; \alpha, \beta)$ which imposes small field conditions for the decimation interval $[0, 2\delta]$. For example, it vanishes unless $|\alpha(\mathbf{x})| \leq R(2\delta)$ for each $\mathbf{x} \in \Omega_{\mathfrak{S}}$.

The first step in the proof of Theorem 3.26 builds $\chi_{2\delta}(\Omega_{\mathfrak{S}}; \alpha, \beta)$ from the product $\chi_\delta(\Omega_1; \alpha^*, \phi) \chi_\delta(\Omega_2; \phi^*, \beta)$. To illustrate the construction procedure, we consider the conditions on $|\alpha(\mathbf{x})|$. We expand the existing conditions on $|\alpha(\mathbf{x})|$, for $\mathbf{x} \in \Omega_0 = \Omega_1 \cap \Omega_2$, to

$$\begin{aligned} \chi_{R(\delta)}(\Omega_0, \alpha) &= \prod_{\mathbf{x} \in \Omega_0} \chi_{R(\delta)}(\alpha(\mathbf{x})) \\ &= \prod_{\mathbf{x} \in \Omega_0} [\chi_{R(2\delta)}(\alpha(\mathbf{x})) + \chi_{R(2\delta), R(\delta)}(\alpha(\mathbf{x}))] \\ &= \sum_{P_\alpha \subset \Omega_0} \chi_{R(2\delta)}(\Omega_0 \setminus P_\alpha, \alpha) \chi_{R(2\delta), R(\delta)}(P_\alpha, \alpha) \end{aligned}$$

where we are using

Notation 5.1. Set, for $0 < r < R$, $t \in \mathbb{C}$, any set Y and any complex valued function f on Y

$$\chi_r(t) = \begin{cases} 1 & \text{if } |t| \leq r \\ 0 & \text{otherwise} \end{cases} \quad \chi_{r,R}(t) = \begin{cases} 1 & \text{if } r < |t| \leq R \\ 0 & \text{otherwise} \end{cases}$$

and

$$\chi_r(Y, f) = \prod_{x \in Y} \chi_r(f(x)) \quad \chi_{r,R}(Y, f) = \prod_{x \in Y} \chi_{r,R}(f(x))$$

The characteristic function $\chi_{R(2\delta)}(\Omega_0 \setminus P_\alpha, \alpha)$ successfully imposes the new small field condition of scale 2δ on $|\alpha(\mathbf{x})|$ at each point of $\Omega_0 \setminus P_\alpha$. The characteristic function $\chi_{R(2\delta), R(\delta)}(P_\alpha, \alpha)$ says that $|\alpha(\mathbf{x})|$ violates the new small

field condition at each $\mathbf{x} \in P_\alpha$. In Lemma A.3, we perform a similar expansion for the other small field conditions as well. The conclusion of that Lemma is

$$\begin{aligned} & \chi_\delta(\Omega_1; \alpha, \phi) \chi_\delta(\Omega_2; \phi, \beta) \\ = & \sum_{\mathfrak{A} \in F_\delta(\Omega_0)} \chi_{2\delta}(\Lambda_{\mathfrak{A}}; \alpha, \beta) \chi_r(\Lambda_{\mathfrak{A}}, \alpha - \phi) \chi_r(\Lambda_{\mathfrak{A}}, \phi - \beta) \\ & \times \chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta) \end{aligned} \quad (5.2)$$

where $F_\delta(\Omega_0)$ is the set of possible configurations of large field/small field sets for the decimation interval $[0, 2\delta]$ that are compatible with $(\mathfrak{S}_1, \mathfrak{S}_2)$ (see Definition 3.2) and the associated characteristic function $\chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta)$ is given in Definition A.1. Note, for future reference, that the factor $\chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta)$ does not depend on the values of the fields α, ϕ and β at points of Λ .

Recall, from Definition 3.1, the notation

$$\vec{\alpha}_l = (\alpha_\tau(\mathbf{x}))_{\substack{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta) \\ \mathbf{x} \in X}} \quad \vec{\alpha}_r = (\alpha_{\tau+\delta}(\mathbf{x}))_{\substack{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta) \\ \mathbf{x} \in X}}$$

for a system $\vec{\alpha} = (\alpha_\tau(\mathbf{x}))_{\tau \in \varepsilon \mathbb{Z} \cap (0, 2\delta)}$ of fields.

As an immediate consequence of (5.2) we have that the $I(\alpha^*, \beta)$ of Theorem 3.26 is

$$\begin{aligned} I(\alpha^*, \beta) = & \sum_{\mathfrak{A} \in F_\delta(\Omega_0)} \mathcal{Z}_\delta^{2|\Lambda_{\mathfrak{A}}|} \int \prod_{\mathbf{x} \in \Lambda_{\mathfrak{A}}} \frac{d\phi(\mathbf{x})^* \wedge d\phi(\mathbf{x})}{2\pi i} \text{Int}_{(\mathfrak{A}; \alpha^*, \beta)} e^{-\langle \phi^*, \phi \rangle} \\ & \times \chi_{2\delta}(\Lambda_{\mathfrak{A}}; \alpha, \beta) \chi_r(\Lambda_{\mathfrak{A}}, \alpha - \phi) \chi_r(\Lambda_{\mathfrak{A}}, \phi - \beta) \\ & \times e^{-Q_{\mathfrak{S}_1}(\alpha^*, \phi; \vec{\alpha}_l^*, \vec{\alpha}_l) - Q_{\mathfrak{S}_2}(\phi^*, \beta; \vec{\alpha}_r^*, \vec{\alpha}_r)} e^{\mathcal{V}_{\mathfrak{S}_1}(\varepsilon; \alpha^*, \phi; \vec{\alpha}_l^*, \vec{\alpha}_l) + \mathcal{V}_{\mathfrak{S}_2}(\varepsilon; \phi^*, \beta; \vec{\alpha}_r^*, \vec{\alpha}_r)} \\ & \times e^{\mathcal{D}_1(\alpha^*, \phi; \rho_{\vec{l}}) + \mathcal{D}_2(\phi^*, \beta; \rho_{\vec{r}})} b_1(\alpha^*, \phi; \rho_{\vec{l}}) b_2(\phi^*, \beta; \rho_{\vec{r}}) \end{aligned}$$

where $\text{Int}_{(\mathfrak{A}; \alpha^*, \beta)}$ is the integral operator

$$\begin{aligned} & \text{Int}_{(\mathfrak{A}; \alpha^*, \beta)} [d\mu(\phi^*, \phi; \vec{\alpha}, \vec{z}_*, \vec{z})] \\ = & \mathcal{Z}_\delta^{|\Omega_1 \setminus \Lambda_{\mathfrak{A}}|} \mathcal{Z}_\delta^{|\Omega_2 \setminus \Lambda_{\mathfrak{A}}|} \int \prod_{\mathbf{x} \in X \setminus \Lambda_{\mathfrak{A}}} \frac{d\phi(\mathbf{x})^* \wedge d\phi(\mathbf{x})}{2\pi i} \chi_{R(\varepsilon)}(\phi(\mathbf{x})) \chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta) \\ & \times \mathcal{I}_{(\mathfrak{S}_1; \alpha^*, \phi)} [d\mu(\vec{\alpha}_l, \vec{z}_l, \vec{z}_l)] \mathcal{I}_{(\mathfrak{S}_2; \phi^*, \beta)} [d\mu(\vec{\alpha}_r, \vec{z}_r, \vec{z}_r)] \\ = & \mathcal{Z}_\delta^{|\Omega_1 \setminus \Lambda_{\mathfrak{A}}|} \mathcal{Z}_\delta^{|\Omega_2 \setminus \Lambda_{\mathfrak{A}}|} \int \prod_{\mathbf{x} \in X \setminus \Lambda_{\mathfrak{A}}} \frac{d\phi(\mathbf{x})^* \wedge d\phi(\mathbf{x})}{2\pi i} \chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta) \\ & \times \mathcal{I}_{(\mathfrak{S}_1; \alpha^*, \phi)} [d\mu(\vec{\alpha}_l, \vec{z}_l, \vec{z}_l)] \mathcal{I}_{(\mathfrak{S}_2; \phi^*, \beta)} [d\mu(\vec{\alpha}_r, \vec{z}_r, \vec{z}_r)] \end{aligned}$$

by Lemma A.4(b). By Lemma 3.10(ii), $\mathcal{I}_{(\mathfrak{S}_1; \alpha^*, \phi)}$ and $\mathcal{I}_{(\mathfrak{S}_2; \phi^*, \beta)}$ are independent of $\phi(\mathbf{x})$ for all $\mathbf{x} \in \Lambda_{\mathfrak{A}}$. Inspection of the definition of $\chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta)$ in Definition A.1 shows that it is also independent of $\phi(\mathbf{x})$ for all $\mathbf{x} \in \Lambda_{\mathfrak{A}}$. By hypothesis, $b_1(\alpha^*, \phi; \rho_{\vec{l}})$ and $b_2(\phi^*, \beta; \rho_{\vec{r}})$ are pure large field and thus independent of $\phi_*(\mathbf{x}), \phi(\mathbf{x})$ for all $\mathbf{x} \in \Lambda_{\mathfrak{A}}$. Therefore we may move the integral $\int \prod_{\mathbf{x} \in \Lambda_{\mathfrak{A}}} \frac{d\phi(\mathbf{x})^* \wedge d\phi(\mathbf{x})}{2\pi i}$ to the right to give

Corollary 5.2.

$$\begin{aligned}
I(\alpha^*, \beta) = & \sum_{\mathfrak{A} \in F_\delta(\Omega_0)} \text{Int}_{(\mathfrak{A}; \alpha^*, \beta)} b_1(\alpha^*, \phi; \vec{\rho}_l) b_2(\phi^*, \beta; \vec{\rho}_r) \chi_{2\delta}(\Lambda_{\mathfrak{A}}; \alpha, \beta) \\
& \times \mathcal{Z}_\delta^{2|\Lambda_{\mathfrak{A}}|} \int \prod_{\mathbf{x} \in \Lambda_{\mathfrak{A}}} \frac{d\phi(\mathbf{x})^* \wedge d\phi(\mathbf{x})}{2\pi i} e^{-\langle \phi^*, \phi \rangle} \chi_r(\Lambda_{\mathfrak{A}}, \alpha - \phi) \chi_r(\Lambda_{\mathfrak{A}}, \phi - \beta) \\
& \times e^{-Q_{\mathfrak{S}_1}(\alpha^*, \phi; \vec{\alpha}_l) - Q_{\mathfrak{S}_2}(\phi^*, \beta; \vec{\alpha}_r)} e^{\mathcal{V}_{\mathfrak{S}_1}(\varepsilon; \alpha^*, \phi; \vec{\alpha}_l^*, \vec{\alpha}_l) + \mathcal{V}_{\mathfrak{S}_2}(\varepsilon; \phi^*, \beta; \vec{\alpha}_r^*, \vec{\alpha}_r)} \\
& \times e^{\mathcal{D}_1(\alpha^*, \phi; \vec{\rho}_l) + \mathcal{D}_2(\phi^*, \beta; \vec{\rho}_r)}
\end{aligned}$$

Observe that the integrand above is independent of the variables $z_{*\delta}, z_\delta$ and $\alpha_{*\delta}, \alpha_\delta$. We will shortly introduce $z_* = z_{*\delta}$ and $z = z_\delta$ as the fluctuation fields associated to ϕ^*, ϕ , and $\alpha_{*\delta}, \alpha_\delta$ as the values of ϕ^*, ϕ in the new large field region of the second kind where no fluctuation fields are introduced.

5.2. Approximate Diagonalization of the Quadratic Form

In this subsection, we fix $\mathfrak{A} \in F_\delta(\Omega_0)$ and study the small field integral, that is the integral over the variables $\phi(\mathbf{x}), \mathbf{x} \in \Lambda_{\mathfrak{A}}$, in the conclusion of Corollary 5.2. To simplify notation, write $\Lambda = \Lambda_{\mathfrak{A}}$. So, we study the integral

$$\begin{aligned}
J_{\mathfrak{A}}(\alpha_*, \beta; \vec{\rho}_l, \vec{\rho}_r; \Lambda^c \phi^*, \Lambda^c \phi) = & \int \prod_{\mathbf{x} \in \Lambda} \frac{d\phi(\mathbf{x})^* \wedge d\phi(\mathbf{x})}{2\pi i} \chi_r(\Lambda, \alpha - \phi) \chi_r(\Lambda, \phi - \beta) \\
& \times e^{-Q_{\mathfrak{S}_1}(\alpha_*, \phi; \vec{\alpha}_{*l}, \vec{\alpha}_l) - \langle \phi^*, \phi \rangle - Q_{\mathfrak{S}_2}(\phi^*, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r)} \\
& \times e^{\mathcal{V}_{\mathfrak{S}_1}(\varepsilon; \alpha_*, \phi; \vec{\alpha}_{*l}, \vec{\alpha}_l) + \mathcal{V}_{\mathfrak{S}_2}(\varepsilon; \phi^*, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r)} e^{\mathcal{D}_1(\alpha_*, \phi; \vec{\rho}_l) + \mathcal{D}_2(\phi^*, \beta; \vec{\rho}_r)} \quad (5.3)
\end{aligned}$$

To “compute” this integral, we use “stationary phase” in many complex variables as discussed in Sect. 1. As we saw there, if we treat ϕ^* and ϕ as independent variables, the critical value of ϕ^* for the quadratic part of the effective action is not the complex conjugate of the critical value of ϕ . To produce a mathematically rigorous argument we introduce independent complex variables $\phi_*(\mathbf{x}), \phi(\mathbf{x})$ in \mathbb{C}^Λ and write (5.3) as

$$\begin{aligned}
J_{\mathfrak{A}} = & \int_{D(\alpha_*, \beta)} \prod_{\mathbf{x} \in \Lambda} \frac{d\phi_*(\mathbf{x}) \wedge d\phi(\mathbf{x})}{2\pi i} e^{-Q_{\mathfrak{S}_1}(\alpha_*, \phi; \vec{\alpha}_{*l}, \vec{\alpha}_l) - \langle \phi_*, \phi \rangle - Q_{\mathfrak{S}_2}(\phi_*, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r)} \\
& \times e^{\mathcal{V}_{\mathfrak{S}_1}(\varepsilon; \alpha_*, \phi; \vec{\alpha}_{*l}, \vec{\alpha}_l) + \mathcal{V}_{\mathfrak{S}_2}(\varepsilon; \phi_*, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r)} e^{\mathcal{D}_1(\alpha_*, \phi; \vec{\rho}_l) + \mathcal{D}_2(\phi_*, \beta; \vec{\rho}_r)} \quad (5.4)
\end{aligned}$$

where the domain of integration is $D(\alpha_*, \beta) = \bigcup_{\mathbf{x} \in \Lambda} D(\mathbf{x}; \alpha_*, \beta)$ with

$$\begin{aligned}
D(\mathbf{x}; \alpha_*, \beta) = & \left\{ (\phi_*(\mathbf{x}), \phi(\mathbf{x})) \in \mathbb{C}^2 \mid \phi_*(\mathbf{x}) = \phi(\mathbf{x}) \right. \\
& \left. |\phi_*(\mathbf{x}) - \alpha_*(\mathbf{x})| \leq r, |\phi(\mathbf{x}) - \beta(\mathbf{x})| \leq r \right\} \quad (5.5)
\end{aligned}$$

A good approximation to the critical point of the bilinear form

$$Q_{\mathfrak{S}_1}(\alpha_*, \phi; \vec{\alpha}_{*l}, \vec{\alpha}_l) + \langle \phi_*, \phi \rangle + Q_{\mathfrak{S}_2}(\phi_*, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r)$$

(in the variables ϕ_*, ϕ , with $\alpha_*, \vec{\alpha}_*, \vec{\alpha}, \beta$ considered as parameters) is¹⁴

$$\phi_*^{\text{cr}} = \Lambda j_c(\delta) \alpha_* \quad \phi^{\text{cr}} = \Lambda j_c(\delta) \beta$$

where the cut off propagator j_c was defined in (1.24). We shall expand around the approximate critical point. Therefore we make a change of variables from $\phi_*(\mathbf{x}), \phi(\mathbf{x})$, $\mathbf{x} \in \Lambda$ to variables $z_*(\mathbf{x}), z(\mathbf{x})$ with $\mathbf{x} \in \Lambda$ by

$$\phi_*(\mathbf{x}) = z_*(x) + [j_c(\delta) \alpha_*](\mathbf{x}), \quad \phi(\mathbf{x}) = z(x) + [j_c(\delta) \beta](\mathbf{x}) \quad \text{when } \mathbf{x} \in \Lambda$$

Under this change of variables, we have, on Λ ,

$$\begin{aligned} \phi_*^* - \phi &= z_*^* - z + j_c(\delta) [\alpha_*^* - \beta] \\ \phi_* - \alpha_* &= z_* - [\mathbb{1} - j_c(\delta)] \alpha_* \\ \phi - \beta &= z - [\mathbb{1} - j_c(\delta)] \beta \end{aligned}$$

Thus the change of variables transforms the domain $D(\mathbf{x}; \alpha_*, \beta)$ of (5.5) into

$$\begin{aligned} D'(\mathbf{x}; \alpha_*, \beta) = \left\{ (\mathbf{x}; \mathbf{z}) \in \mathbb{C}^2 \mid |z_*(\mathbf{x}) - ([\mathbb{1} - j_c(\delta)] \alpha_*)(\mathbf{x})| \leq r, \right. \\ |z(\mathbf{x}) - ([\mathbb{1} - j_c(\delta)] \beta)(\mathbf{x})| \leq r, \\ \left. z(\mathbf{x}) - z_*(\mathbf{x})^* = (j_c(\delta) [\alpha_*^* - \beta])(\mathbf{x}) \right\} \end{aligned} \quad (5.6)$$

Observe that $D'(\mathbf{x}; \alpha_*, \beta)$ depends only on the values of the fields α_* and β at points $\mathbf{y} \in X$ with $d(\mathbf{x}, \mathbf{y}) \leq c$. Also $D'(\mathbf{x}; \alpha_*, \beta)$ depends on \mathfrak{h} through $j_c(\delta)$.

For convenience, we rename $\phi(\mathbf{x}) = \alpha_\delta(\mathbf{x})$ and $\phi_*(\mathbf{x}) = \alpha_{*\delta}(\mathbf{x})$ when $\mathbf{x} \in \Lambda^c$, and also define $z(\mathbf{x}) = z_*(\mathbf{x}) = 0$ for all $\mathbf{x} \in \Lambda^c$ and $\alpha_{*\delta}(\mathbf{x}) = \alpha_\delta(\mathbf{x}) = 0$ for $\mathbf{x} \in \Lambda$.

To this point, we have obtained the following expression for the function $J_{\mathfrak{A}}$ of (5.3).

Lemma 5.3. Set $D'(\alpha_*, \beta) = \bigcup_{\mathbf{x} \in \Lambda} D'(\mathbf{x}; \alpha_*, \beta)$. Then

$$\begin{aligned} J_{\mathfrak{A}}(\alpha_*, \beta; \vec{\rho}_l, \vec{\rho}_r, \alpha_{*\delta}, \alpha_\delta) \\ = \int_{D'(\alpha_*, \beta)} \prod_{\mathbf{x} \in \Lambda} \left[\frac{dz_*(\mathbf{x}) \wedge dz(\mathbf{x})}{2\pi i} e^{-z_*(\mathbf{x}) z(\mathbf{x})} \right] e^{f_{\mathfrak{A}}(\alpha_*, \beta; \vec{\rho}; z_*, z)} \end{aligned}$$

where

$$\begin{aligned} f_{\mathfrak{A}}(\alpha_*, \beta; \vec{\rho}; z_*, z) &= f_{\mathfrak{A}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}, \vec{z}_*, \vec{z}; z_*, z) \\ &= -\langle z_*, \Lambda j_c(\delta) \beta \rangle - \langle \Lambda j_c(\delta) \alpha_*, z \rangle - \langle \alpha_{*\delta}^{\text{cr}}, \alpha_\delta^{\text{cr}} \rangle \\ &\quad - Q_{\mathfrak{S}_1}(\alpha_*, z + \alpha_\delta^{\text{cr}}; \vec{\alpha}_l^*, \vec{\alpha}_l) - Q_{\mathfrak{S}_2}(z_* + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) \\ &\quad + \mathcal{V}_{\mathfrak{S}_1}(\varepsilon; \alpha_*, z + \alpha_\delta^{\text{cr}}; \vec{\alpha}_l^*, \vec{\alpha}_l) + \mathcal{V}_{\mathfrak{S}_2}(\varepsilon; z_* + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) \\ &\quad + \mathcal{D}_1(\alpha_*, z + \alpha_\delta^{\text{cr}}; \vec{\rho}_l) + \mathcal{D}_2(z_* + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) \end{aligned}$$

and

$$\alpha_{*\delta}^{\text{cr}} = \alpha_{*\delta}^{\text{cr}}(\alpha_*, \alpha_{*\delta}) = \Lambda j_c(\delta) \alpha_* + \Lambda^c \alpha_{*\delta} \quad \alpha_\delta^{\text{cr}} = \alpha_\delta^{\text{cr}}(\alpha_\delta, \beta) = \Lambda j_c(\delta) \beta + \Lambda^c \alpha_\delta$$

¹⁴ If one approximated $Q_{\mathfrak{S}_1}(\alpha_*, \phi; \cdot)$ and $Q_{\mathfrak{S}_2}(\phi_*, \beta; \cdot)$ by their pure small field parts $-\langle \alpha_*, j(\delta) \phi \rangle$ and $-\langle \phi_*, j(\delta) \beta \rangle$, respectively (see Lemma 3.7(ii)), the critical point would be exactly $\phi_*^{\text{crit}} = j(\delta) \alpha_*$, $\phi^{\text{crit}} = j(\delta) \beta$ as in (1.13). The cutoff $j_c(\delta)$ was motivated near (1.24). See also Lemma 3.10(ii), which was used to give Corollary 5.2.

By Lemma 3.7(ii),

$$f_{\mathfrak{A}}|_{\mathfrak{h}=0} = - \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, 2\delta)} \langle \Lambda_{\tau}^c \alpha_{*\tau}, \Lambda_{\tau}^c \alpha_{\tau} \rangle$$

Furthermore, $f_{\mathfrak{A}} + \sum_{\tau} \langle \Lambda_{\tau}^c \alpha_{*\tau}, \Lambda_{\tau}^c \alpha_{\tau} \rangle$ is history complete.

5.3. Stokes' Theorem and the Small Field/Large Field Decomposition of the Second Kind

We apply [5, Lemma A.1] to the integral in Lemma 5.3 with X replaced by Λ , with $\rho(\mathbf{x}) = (j_{\mathfrak{c}}(\delta)[\alpha_*^* - \beta])(\mathbf{x})$, $\sigma_*(\mathbf{x}) = ([\mathbb{1} - j_{\mathfrak{c}}(\delta)]\alpha_*)(\mathbf{x})$, $\sigma(\mathbf{x}) = ([\mathbb{1} - j_{\mathfrak{c}}(\delta)]\beta)(\mathbf{x})$ and with $r = r$. We block the resulting sum over R into

$$\sum_{R \subset \Lambda} = \sum_{\Omega \subset \Lambda} \sum_{\substack{R \subset \Lambda \\ \Omega = \Lambda \setminus L(\mathfrak{c}(\delta), R)}}$$

where $L(\mathfrak{c}(\delta), R)$ is the set of points of X that are within a distance $\mathfrak{c}(\delta)$ of R . This gives

$$\begin{aligned} J_{\mathfrak{A}} &= \sum_{\Omega \subset \Lambda} \sum_{\substack{R \subset \Lambda \\ \Omega = \Lambda \setminus L(\mathfrak{c}(\delta), R)}} \prod_{\mathbf{x} \in R} \left(\int_{C(\mathbf{x}; \alpha_*, \beta)} \frac{dz_*(\mathbf{x}) \wedge dz(\mathbf{x})}{2\pi i} e^{-z_*(\mathbf{x}) z(\mathbf{x})} \right) \\ &\quad \times \prod_{\mathbf{x} \in \Lambda \setminus R} \left(\int_{|z(\mathbf{x})| \leq r} \frac{dz(\mathbf{x})^* \wedge dz(\mathbf{x})}{2\pi i} e^{-z(\mathbf{x})^* z(\mathbf{x})} \right) e^{f_{\mathfrak{A}}(\alpha_*, \beta; \vec{\rho}; z_*, z)} \Big|_{\substack{z_*(\mathbf{x}) = z(\mathbf{x})^* \\ \text{for } \mathbf{x} \in \Lambda \setminus R}} \end{aligned} \tag{5.7}$$

with, for each $\mathbf{x} \in \Lambda$, $C(\mathbf{x}; \alpha_*, \beta)$ a two real dimensional surface in

$$\mathcal{P}(\mathbf{x}) = \{(z_*(\mathbf{x}), z(\mathbf{x})) \in \mathbb{C}^2 \mid |z_*(\mathbf{x})|, |z(\mathbf{x})| < R\}$$

whose boundary is the union of the circle $\{(z_*(\mathbf{x}), z(\mathbf{x})) \in \mathbb{C}^2 \mid z_*(\mathbf{x}) = z(\mathbf{x})^*, |z(\mathbf{x})| = r\}$ and the curve bounding $D'(\mathbf{x}; \alpha_*, \beta)$.

We now verify the hypotheses of [5, Lemma A.1], for arguments that appear in the integral operator. For this, we must show that the function $f_{\mathfrak{A}}(\alpha^*, \beta; \vec{\rho}; z_*, z)$ is analytic in $\mathsf{X}_{\mathbf{x} \in \Lambda} \mathcal{P}(\mathbf{x})$, for all allowed $(\alpha^*, \beta; \vec{\rho})$, and that, for each $\mathbf{x} \in \Lambda$, the two boundary curves are contained in $\mathcal{P}(\mathbf{x})$.

- o As $\|\mathcal{D}_i\|_{\mathfrak{S}_i}$, $i = 1, 2$ are finite, $\mathsf{X}_{\mathbf{x} \in \Lambda} \mathcal{P}(\mathbf{x})$ will be contained in the domain of analyticity of $f_{\mathfrak{A}}(\alpha_*, \beta; \vec{\rho}; z_*, z)$ provided

$$|z_*(\mathbf{x}) + \alpha_{*\delta}^{\text{cr}}(\mathbf{x})| < \kappa_{*\mathfrak{S}_2, 0}(\mathbf{x}) = 2R \quad |z(\mathbf{x}) + \alpha_{\delta}^{\text{cr}}(\mathbf{x})| < \kappa_{\mathfrak{S}_1, \delta}(\mathbf{x}) = 2R$$

for all $\mathbf{x} \in \Lambda$ and $(z_*(\mathbf{x}), z(\mathbf{x})) \in \mathcal{P}(\mathbf{x})$. This is the case because

$$\begin{aligned} |\alpha_{*\delta}^{\text{cr}}(\mathbf{x})| &= |(j_{\mathfrak{c}}(\delta)\alpha^*)(\mathbf{x})| \\ &\leq \|j_{\mathfrak{c}}(\delta)\| \sup_{\substack{\mathbf{y} \in X \\ d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c}}} |\alpha(\mathbf{y})| \leq \|j_{\mathfrak{c}}(\delta)\| R_+ \leq e^{K_j \delta} R_+ < R \end{aligned}$$

The second inequality follows from the observation that $|\alpha(\mathbf{y})| \leq R_+$ for all \mathbf{y} within a distance \mathfrak{c} of Λ . When $\mathbf{y} \in \Lambda$, this is enforced by the characteristic function $\chi_{2\delta}(\Lambda_{\mathfrak{A}}; \alpha, \beta)$ in Corollary 5.2. When \mathbf{y} is not in Λ , but is within a distance \mathfrak{c} of Λ , this is enforced by the factor of $\chi_{R_{2\delta}}(\Omega_0 \setminus (P_\alpha \cup \Lambda), \alpha)$ in the characteristic function¹⁵ $\chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \alpha_\delta, \beta)$ appearing in the definition of $\text{Int}_{\mathfrak{A}, \varepsilon}$ in Corollary 5.2. (Recall that $d(\Lambda, P_\alpha \cup \Omega_0^c) > \mathfrak{c}(\delta) \geq \mathfrak{c}$. The third inequality follows from Lemma 3.21(i). The fourth is implied by Hypothesis F.7(i).

- Since $r < R$, the boundary circle $\{z_*^*(\mathbf{x}) = z(\mathbf{x}), |z(\mathbf{x})| = r\} \subset \mathcal{P}(\mathbf{x})$.
- The boundary of $D'(\mathbf{x}; \alpha^*, \beta)$ is contained in $\mathcal{P}(\mathbf{x})$ provided

$$|([1 - j_{\mathfrak{c}}(\delta)]\alpha^*)(\mathbf{x})| + r, |([1 - j_{\mathfrak{c}}(\delta)]\beta)(\mathbf{x})| + r < R$$

If $\mathfrak{h}(\mathbf{x}) = 0$, this condition reduces to $|\alpha(\mathbf{x})| + r < R$ and $|\beta(\mathbf{x})| + r < R$. Since $\mathbf{x} \in \Lambda$, both follow from $R_+ + r < R$. See (F.3d) in Appendix F. If $\mathfrak{h}(\mathbf{x}) = 1$,

$$|([1 - j_{\mathfrak{c}}(\delta)]\alpha^*)(\mathbf{x})| \leq \|\mathfrak{h} - j_{\mathfrak{c}}(\delta)\| \sup_{\substack{\mathbf{y} \in X \\ d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c}}} |\alpha^*(\mathbf{y})| \leq \delta K_j e^{K_j \delta} R_+ < R - r$$

by Lemma 3.21(ii), (F.3d) and Hypothesis F.7(i).

Under Stokes' theorem we may choose any surface $C(\mathbf{x}; \alpha^*, \beta)$ that has the specified boundary and lies in the domain of analyticity of the integrand. We choose $C(\mathbf{x}; \alpha^*, \beta)$ to depend only on the values of the fields α and β at points $\mathbf{y} \in X$ with $d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c}$. This is possible because $D'(\mathbf{x}; \alpha^*, \beta)$ has the same property.

Combining Corollary 5.2, (5.3), and (5.7) gives

$$\begin{aligned} I(\alpha^*, \beta) &= \sum_{\mathfrak{A} \in F_\delta(\Omega_0)} \text{Int}_{(\mathfrak{A}; \alpha^*, \beta)} b_1(\alpha^*, \alpha_\delta, \vec{\rho}_l) b_2(\alpha_\delta^*, \beta, \vec{\rho}_r) \chi_{2\delta}(\Lambda_{\mathfrak{A}}; \alpha, \beta) \\ &\quad \times \mathcal{Z}_\delta^{2|\Lambda_{\mathfrak{A}}|} \sum_{\substack{R \subset \Lambda_{\mathfrak{A}} \\ \Omega = \Lambda_{\mathfrak{A}} \setminus L(\mathfrak{c}(\delta), R)}} \sum_{\mathbf{x} \in R} \prod_{C(\mathbf{x}; \alpha^*, \beta)} \left(\int_{C(\mathbf{x}; \alpha^*, \beta)} \frac{dz_*(\mathbf{x}) \wedge dz(\mathbf{x})}{2\pi i} e^{-z_*(\mathbf{x})z(\mathbf{x})} \right) \\ &\quad \times \int d\mu_{(\Lambda_{\mathfrak{A}} \setminus R), r}(z^*, z) e^{f_{\mathfrak{A}}(\alpha^*, \beta; \vec{\rho}_l; z_*, z)} \Big|_{\substack{z_*(\mathbf{x}) = z(\mathbf{x})^* \\ \text{for } \mathbf{x} \in \Lambda_{\mathfrak{A}} \setminus R}} \end{aligned}$$

with, for each $\mathbf{x} \in X \setminus \Lambda_{\mathfrak{A}}$, the integration variable $\phi(\mathbf{x})$ of $\text{Int}_{(\mathfrak{A}; \alpha^*, \beta)}$ renamed to $\alpha_\delta(\mathbf{x})$. Renaming the fields $z_*(\mathbf{x}), z(\mathbf{x})$ with $\mathbf{x} \in \Lambda_{\mathfrak{A}} \setminus \Omega$ to $z_{*\delta}(\mathbf{x}), z_\delta(\mathbf{x})$,

$$\begin{aligned} I &= \sum_{\mathfrak{A} \in F_\delta(\Omega_0)} \sum_{\Omega \subset \Lambda_{\mathfrak{A}}} \sum_{\substack{R \subset \Lambda_{\mathfrak{A}} \\ \Omega = \Lambda_{\mathfrak{A}} \setminus L(\mathfrak{c}(\delta), R)}} \text{Int}_{(\Omega, R, \mathfrak{A}; \alpha^*, \beta)} \\ &\quad \times b_1(\alpha^*, \alpha_\delta, \vec{\rho}_l) b_2(\alpha_\delta^*, \beta, \vec{\rho}_r) \chi_{2\delta}(\Omega; \alpha, \beta) \\ &\quad \times \mathcal{Z}_\delta^{2|\Omega|} \int d\mu_{\Omega, r}(z^*, z) e^{f_{(\Omega, R, \mathfrak{A})}(\alpha^*, \beta; \vec{\rho}_l; z_*, z)} \Big|_{\substack{z_{*\delta}(\mathbf{x}) = z_\delta(\mathbf{x})^* \\ \text{for } \mathbf{x} \in \Lambda_{\mathfrak{A}} \setminus R}} \end{aligned}$$

¹⁵ The characteristic function $\chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \alpha_\delta, \beta)$ is defined in Definition A.1.

where

$$\begin{aligned} \text{Int}_{(\Omega, R, \mathfrak{A}; \alpha^*, \beta)} &= \text{Int}_{(\mathfrak{A}; \alpha^*, \beta)} Z_\delta^{2|\Lambda_{\mathfrak{A}} \setminus \Omega|} \chi_{2\delta}(\Lambda_{\mathfrak{A}} \setminus \Omega; \alpha, \beta) \\ &\times \prod_{\mathbf{x} \in R} \left(\int_{C(\mathbf{x}; \alpha^*, \beta)} \frac{dz_{*\delta}(\mathbf{x}) \wedge dz_\delta(\mathbf{x})}{2\pi i} e^{-z_{*\delta}(\mathbf{x}) z_\delta(\mathbf{x})} \right) \int d\mu_{\Lambda_{\mathfrak{A}} \setminus (R \cup \Omega), r}(z_\delta^*, z_\delta) \end{aligned}$$

and $f_{(\Omega, R, \mathfrak{A})}$ is obtained from the function $f_{\mathfrak{A}}$ of Lemma 5.3 by

$$f_{(\Omega, R, \mathfrak{A})}(\alpha_*, \beta; \vec{\rho}; z_*, z) = f_{\mathfrak{A}}(\alpha_*, \beta; \vec{\rho}; (\Lambda \setminus \Omega) z_{*\delta} + \Omega z_*, (\Lambda \setminus \Omega) z_\delta + \Omega z) \quad (5.8)$$

$z_{*\delta}(\mathbf{x}), z_\delta(\mathbf{x})$ with $\mathbf{x} \in \Lambda \setminus \Omega$ are also “residual variables” and subsumed in $\vec{\rho}$. The fields $z_*(\mathbf{x}), z(\mathbf{x})$ with $\mathbf{x} \in \Omega$ are the “fluctuation fields” to be integrated out.

For each $\Omega, R, \mathfrak{A} = (\Lambda, P_\alpha, \dots, Q)$ in the above sum, we define the hierarchy \mathfrak{S} with $(\mathfrak{S}_1, \mathfrak{S}_2) < \mathfrak{S}$ by setting $\mathcal{X}([0, 2\delta]) = \mathcal{X}$ for $\mathcal{X} = \Omega, R, \Lambda, \dots, Q$. Using the recursion relation of Lemma 3.10(i), we have $\text{Int}_{(\Omega, R, \mathfrak{A}; \alpha^*, \beta)} = I_{(\mathfrak{S}; \alpha^*, \beta)}$. We set $f_{\mathfrak{S}} = f_{(\Omega, R, \mathfrak{A})}$. Then

Lemma 5.4.

$$\begin{aligned} I(\alpha^*, \beta) &= \sum_{\substack{\mathfrak{S} \text{ hierarchies} \\ (\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S} \text{ for scale } 2\delta}} I_{(\mathfrak{S}; \alpha^*, \beta)} b_1(\alpha^*, \alpha_\delta, \rho_{\vec{l}}) b_2(\alpha_\delta^*, \beta, \rho_{\vec{r}}) \chi_{2\delta}(\Omega_{\mathfrak{S}}; \alpha, \beta) \\ &\times Z_\delta^{2|\Omega_{\mathfrak{S}}|} \int d\mu_{\Omega_{\mathfrak{S}}, r}(z^*, z) e^{f_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}; z^*, z)} \Big|_{\substack{z_{*\delta}(\mathbf{x}) = z_\delta(\mathbf{x})^* \\ \text{for } \mathbf{x} \in \Lambda_{\mathfrak{S}} \setminus R}} \end{aligned}$$

where $f_{\mathfrak{S}}$ is given by (5.8).

Under the hypotheses of Theorem 3.28, we have the analogous representation

$$\begin{aligned} \tilde{I}(\alpha^*, \beta) &= \sum_{\substack{\mathfrak{S} \text{ hierarchies} \\ (\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S} \text{ for scale } 2\delta}} I_{(\mathfrak{S}; \alpha^*, \beta)} \tilde{b}_1(\alpha^*, \alpha_\delta, \rho_{\vec{l}}) \tilde{b}_2(\alpha_\delta^*, \beta, \rho_{\vec{r}}) \chi_{2\delta}(\Omega_{\mathfrak{S}}; \alpha, \beta) \\ &\times Z_\delta^{2|\Omega_{\mathfrak{S}}|} \int d\mu_{\Omega_{\mathfrak{S}}, r}(z^*, z) e^{\tilde{f}_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}; z^*, z)} \Big|_{\substack{z_{*\delta}(\mathbf{x}) = z_\delta(\mathbf{x})^* \\ \text{for } \mathbf{x} \in \Lambda_{\mathfrak{S}} \setminus R}} \end{aligned} \quad (5.9)$$

In Remark 5.5, below, we give explicit descriptions of $f_{\mathfrak{S}}$ and $\tilde{f}_{\mathfrak{S}}$.

5.4. Preparing for the Analysis of the Fluctuation Integral

Fix a hierarchy \mathfrak{S} of scale 2δ . If \mathcal{J} is a decimation interval for \mathfrak{S} , write $\Omega(\mathcal{J}) = \Omega_{\mathfrak{S}}(\mathcal{J})$ and $\Lambda(\mathcal{J}) = \Lambda_{\mathfrak{S}}(\mathcal{J})$. Again, we use the notation $\Omega = \Omega_{\mathfrak{S}}([0, 2\delta])$, $\Lambda = \Lambda_{\mathfrak{S}}([0, 2\delta])$. We will sometimes also shorten $\Omega z_* + (\Lambda \setminus \Omega) z_{*\delta}$ to $z_* + z_{*\delta}$ and $\Omega z + (\Lambda \setminus \Omega) z_\delta$ to $z + z_\delta$.

Remark 5.5. The function $f_{\mathfrak{S}}(\alpha_*, \beta; \vec{\rho}; z_*, z)$ of (5.8) that appears in Lemma 5.4 is the sum of

(i) the quadratic part

$$\begin{aligned} & -\langle z_* + z_{*\delta}, \Lambda j_c(\delta)\beta \rangle - \langle \Lambda j_c(\delta)\alpha_*, z + z_\delta \rangle - \langle \alpha_{*\delta}^{\text{cr}}, \alpha_\delta^{\text{cr}} \rangle \\ & - Q_{\mathfrak{S}_1}(\alpha_*, z + z_\delta + \alpha_\delta^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) - Q_{\mathfrak{S}_2}(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) \end{aligned}$$

which, by the bilinearity of Q and the observation that

$$\begin{aligned} \Gamma_{*\mathfrak{S}_2}(\cdot; z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \vec{\alpha}_{*r}) &= \Gamma_{*\mathfrak{S}_2}(\cdot; z_*, 0) + \Gamma_{*\mathfrak{S}_2}(\cdot; z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \vec{\alpha}_{*r}) \\ \Gamma_{\mathfrak{S}_1}(\cdot; \vec{\alpha}_l, z + z_\delta + \alpha_\delta^{\text{cr}}) &= \Gamma_{\mathfrak{S}_1}(\cdot; 0, z) + \Gamma_{\mathfrak{S}_1}(\cdot; \vec{\alpha}_l, z_\delta + \alpha_\delta^{\text{cr}}) \end{aligned}$$

can be written in the form

$$\begin{aligned} & -Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) + \delta Q(\alpha_*, \beta; \vec{\rho}) \\ & - [(\Omega j_c(\delta)\beta) + Q_{\mathfrak{S}_2}(z_*, \beta; 0, \vec{\alpha}_r)] - [\langle \Omega j_c(\delta)\alpha_*, z \rangle + Q_{\mathfrak{S}_1}(\alpha_*, z; \vec{\alpha}_{*l}, 0)] \end{aligned}$$

where

$$\begin{aligned} & \delta Q(\alpha_*, \beta; \vec{\rho}) \\ & = Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*) - Q_{\mathfrak{S}_1}(\alpha_*, z_\delta + \alpha_\delta^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) - Q_{\mathfrak{S}_2}(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) \\ & \quad - \langle \alpha_{*\delta}^{\text{cr}}, \alpha_\delta^{\text{cr}} \rangle - \langle z_{*\delta}, (\Lambda \setminus \Omega) j_c(\delta)\beta \rangle - \langle (\Lambda \setminus \Omega) j_c(\delta)\alpha_*, z_\delta \rangle \\ & = [Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*) - Q_{\mathfrak{S}_1}(\alpha_*, \alpha_\delta^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) \\ & \quad - Q_{\mathfrak{S}_2}(\alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) - \langle \alpha_{*\delta}^{\text{cr}}, \alpha_\delta^{\text{cr}} \rangle] \\ & \quad - [(z_{*\delta}, (\Lambda \setminus \Omega) j_c(\delta)\beta) + Q_{\mathfrak{S}_2}(z_{*\delta}, \beta; 0, \vec{\alpha}_r)] \\ & \quad - [(\Lambda \setminus \Omega) j_c(\delta)\alpha_*, z_\delta) + Q_{\mathfrak{S}_1}(\alpha_*, z_\delta; \vec{\alpha}_{*l}, 0)] \end{aligned} \tag{5.10}$$

- (ii) the quartic part $\mathcal{V}_{\mathfrak{S}_1}(\varepsilon; \alpha_*, z + z_\delta + \alpha_\delta^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) + \mathcal{V}_{\mathfrak{S}_2}(\varepsilon; z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r)$ and
- (iii) $\mathcal{D}_1(\alpha_*, z + z_\delta + \alpha_\delta^{\text{cr}}; \vec{\rho}_l) + \mathcal{D}_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)$ from the non large field terms.

Remark 5.6.

$$\begin{aligned} f_{\mathfrak{S}}|_{\Omega} &= \langle \alpha_*, j(2\delta)\beta \rangle|_{\Omega} - \langle [j(\delta) - j_c(\delta)]\alpha_*, [j(\delta) - j_c(\delta)]\beta \rangle|_{\Omega} \\ &+ \langle z_*, [j(\delta) - j_c(\delta)]\beta \rangle|_{\Omega} + \langle [j(\delta) - j_c(\delta)]\alpha_*, z \rangle|_{\Omega} \\ &- \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, 2\delta)} \langle \Lambda_{\tau}^c \alpha_{*\tau}, \Lambda_{\tau}^c \alpha_{\tau} \rangle \\ &+ [V_{\Omega, \delta}(\varepsilon; \alpha_*, z + j_c(\delta)\beta) + V_{\Omega, \delta}(\varepsilon; z_* + j_c(\delta)\alpha_*, \beta)]|_{\Omega} \\ &+ [\mathcal{D}_1(\alpha_*, z + j_c(\delta)\beta; 0) + \mathcal{D}_2(z_* + j_c(\delta)\alpha_*, \beta; 0)]|_{\Omega} \end{aligned}$$

Proof. By its definition in Lemma 5.3

$$\alpha_{*\delta}^{\text{cr}}|_{\Omega} = j_c(\delta)\alpha_*|_{\Omega} + \Lambda^c \alpha_{*\delta} \quad \alpha_\delta^{\text{cr}}|_{\Omega} = j_c(\delta)\beta|_{\Omega} + \Lambda^c \alpha_\delta \tag{5.11}$$

By Lemma 3.7(ii), the quadratic part of $f_{\mathfrak{S}}|_{\Omega}$ is equal to

$$\begin{aligned} & -\langle z_*, j_c(\delta)\beta \rangle|_{\Omega} - \langle j_c(\delta)\alpha_*, z \rangle|_{\Omega} - \langle j_c(\delta)\alpha_*, j_c(\delta)\beta \rangle|_{\Omega} - \langle \Lambda^c \alpha_{*\delta}, \Lambda^c \alpha_\delta \rangle \\ & + \langle \alpha_*, j(\delta)(z + j_c(\delta)\beta) \rangle|_{\Omega} - \sum_{\tau \in (0, \delta)} \langle \Lambda_{\tau}^c \alpha_{*\tau}, \Lambda_{\tau}^c \alpha_{\tau} \rangle \\ & + \langle z_* + j_c(\delta)\alpha_*, j(\delta)\beta \rangle|_{\Omega} - \sum_{\tau \in (\delta, 2\delta)} \langle \Lambda_{\tau}^c \alpha_{*\tau}, \Lambda_{\tau}^c \alpha_{\tau} \rangle \end{aligned}$$

$$\begin{aligned}
&= \langle \alpha_*, j(2\delta)\beta \rangle |_{\Omega} - \langle [j(\delta) - j_c(\delta)]\alpha_*, [j(\delta) - j_c(\delta)]\beta \rangle |_{\Omega} \\
&\quad + \langle z_*, [j(\delta) - j_c(\delta)]\beta \rangle |_{\Omega} + \langle [j(\delta) - j_c(\delta)]\alpha_*, z \rangle |_{\Omega} - \sum_{\tau \in (0, 2\delta)} \langle \Lambda_{\tau}^c \alpha_{*\tau}, \Lambda_{\tau}^c \alpha_{\tau} \rangle
\end{aligned}$$

By Remark 3.9.i and (5.11), the restriction of the explicit quartic part in Remark 5.5(ii) is $[V_{\Omega, \delta}(\varepsilon; \alpha_*, z + j_c(\delta)\beta) + \mathcal{V}_{\Omega, \delta}(\varepsilon; z_* + j_c(\delta)\alpha_*, \beta)]|_{\Omega}$, and the restriction of the term in Remark 5.5.iii is obvious. \square

This enables us to control the small field part in Lemma 5.4.

Corollary 5.7.

$$\begin{aligned}
&\int d\mu_{\Omega, r}(z^*, z) e^{f_{\Theta}(\alpha_*, \beta; \vec{\rho}; z^*, z)} |_{\Omega} \\
&= e^{\langle \alpha_*, j(2\delta)\beta \rangle |_{\Omega} + V_{\Omega, 2\delta}(\varepsilon; \alpha_*, \beta)} e^{D(\alpha_*, \beta)} \prod_{\tau \in (0, 2\delta)} e^{-\langle \Lambda_{\tau}^c \alpha_{*\tau}, \Lambda_{\tau}^c \alpha_{\tau} \rangle}
\end{aligned}$$

where

$$D = \bar{\mathfrak{R}}_{\Omega, \delta}(V_{\Omega, \delta}(\varepsilon; \cdot); \mathcal{D}_1(\cdot; 0)|_{\Omega}, \mathcal{D}_2(\cdot; 0)|_{\Omega})$$

Proof. By Remark 5.6 and Definition 3.22,

$$\begin{aligned}
&\int d\mu_{\Omega, r}(z^*, z) e^{f_{\Theta}(\alpha_*, \beta; \vec{\rho}; z^*, z)} |_{\Omega} \\
&= e^{\langle \alpha_*, j(2\delta)\beta \rangle |_{\Omega} + V_{\Omega, \delta}(\varepsilon; \alpha_*, j(\delta)\beta) + V_{\Omega, \delta}(\varepsilon; j(\delta)\alpha_*, \beta)} e^{D(\alpha_*, \beta)} \prod_{\tau \in (0, 2\delta)} e^{-\langle \Lambda_{\tau}^c \alpha_{*\tau}, \Lambda_{\tau}^c \alpha_{\tau} \rangle}
\end{aligned}$$

Now apply Remark 3.9(ii). \square

From the contributions in Remark 5.5, we shall split off the part that is independent of the fluctuation fields z_*, z . The remaining parts, that truly contain fluctuation fields, will be integrated out. Proposition 5.14 below gives the decomposition just mentioned and thus prepares for the fluctuation integral. Lemmas 5.10 and 5.11 and Propositions 5.12 and 5.13 below are used in the proof of Proposition 5.14.

To estimate the fluctuation integral we shall apply Theorem 3.14 with the weight system of the following definition.

Definition 5.8 (Fluctuation integral weight systems). Let w_{fluct} be the weight system with core Ω that associates

- o the weight factors $(\kappa_{*\tau})_{\tau \in [0, 2\delta]}$ to the fields $\alpha_*, \vec{\alpha}_*$, the weight factors $(\kappa_{\tau})_{\tau \in (0, 2\delta]}$ to the fields $\vec{\alpha}, \beta$,
- o the weight factors λ_{τ} to the fields $z_{*\tau}$ and z_{τ} with $\tau \in (0, 2\delta)$, and
- o to the fluctuation fields z_*, z the weight factor

$$\tilde{\lambda}(\mathbf{x}) = \begin{cases} 32r & \text{if } \mathbf{x} \in \Omega \\ \infty & \text{otherwise} \end{cases} \quad (5.12)$$

- o and the constant weight factor 1 to the history field \mathfrak{h} .

We write $\|f\|_{\text{fluct}}$ instead of $\|f\|_{w_{\text{fluct}}}$.

Remark 5.9. w_{fluct} extends the weight system $w_{\mathfrak{S}}$ of Definition 3.15.i by weight factors for the fluctuation fields. Thus, for a function h that is independent of the fluctuation fields, $\|h\|_{\text{fluct}} = \|h\|_{\mathfrak{S}}$. Also, it is an extension of the weight system w_{fluct} introduced just before Lemma 4.2.

The following Lemma shall be applied with $g_i = \mathcal{D}_i$ or $g_i = \mathcal{D}_i - \tilde{\mathcal{D}}_i$.

Lemma 5.10. *Let $g_1(\alpha_*, \beta; \vec{\rho}_l)$ and $g_2(\alpha_*, \beta; \vec{\rho}_r)$ be history complete analytic functions. Then*

$$\begin{aligned} \|g_1(\alpha_*, z_\delta + \alpha_\delta^{\text{cr}}; \vec{\rho}_l)|_{\Omega^c}\|_{\mathfrak{S}} &\leq 2^8 \|g_1\|_{\mathfrak{S}_1} \\ \|g_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)|_{\Omega^c}\|_{\mathfrak{S}} &\leq 2^8 \|g_2\|_{\mathfrak{S}_2} \end{aligned}$$

and

$$\begin{aligned} &\left\| g_1(\alpha_*, z_\delta + \alpha_\delta^{\text{cr}}; \vec{\rho}_l) - g_1(\alpha_*, z_\delta + \alpha_\delta^{\text{cr}}; \vec{\rho}_l)|_{\Omega^c} \right\|_{\mathfrak{S}} \\ &\leq 2^8 \left(e^{-m\mathfrak{c}(\delta)} \|g_1\|_{\mathfrak{S}_1} + \left\| g_1|_{\Omega_1} \right\|_{\mathfrak{S}_1} \right) \\ &\left\| g_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) - g_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)|_{\Omega^c} \right\|_{\mathfrak{S}} \\ &\leq 2^8 \left(e^{-m\mathfrak{c}(\delta)} \|g_2\|_{\mathfrak{S}_2} + \left\| g_2|_{\Omega_2} \right\|_{\mathfrak{S}_2} \right) \end{aligned}$$

Also

$$\begin{aligned} &\|g_1(\alpha_*, z + z_\delta + \alpha_\delta^{\text{cr}}; \vec{\rho}_l) - g_1(\alpha_*, z_\delta + \alpha_\delta^{\text{cr}}; \vec{\rho}_l)\|_{\text{fluct}} \\ &\leq 2^8 \left(e^{-m\mathfrak{c}(\delta)} \|g_1\|_{\mathfrak{S}_1} + \left\| g_1|_{\Omega_1} \right\|_{\mathfrak{S}_1} \right) \\ &\|g_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) - g_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)\|_{\text{fluct}} \\ &\leq 2^8 \left(e^{-m\mathfrak{c}(\delta)} \|g_2\|_{\mathfrak{S}_2} + \left\| g_2|_{\Omega_2} \right\|_{\mathfrak{S}_2} \right) \end{aligned}$$

Proof. We estimate the g_2 -terms. Observe that $g_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)$ is obtained from $g_2(\alpha_*, \beta; \vec{\rho}_r)$ by substituting

$$\mathfrak{h} [\Omega z_* + (\Lambda \setminus \Omega) z_{*\delta} + \Lambda j_{\mathfrak{c}}(\delta) \alpha_* + \Lambda^c \alpha_{*\delta}]$$

for α_* . Introduce the auxiliary weight system \tilde{w}_{aux} that has the same weight factors as w_{fluct} , but core Ω_2 instead of $\Omega = \Omega_{\mathfrak{S}}$. We shall apply Proposition G.1, with $\nu = \frac{20}{19}$ and $C_{\nu} = \frac{4\nu}{(\epsilon \ln \nu)^2} < 2^8$, to prove

$$\|g_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)\|_{\tilde{w}_{\text{aux}}} \leq 2^8 \|g_2\|_{\mathfrak{S}_2} \quad (5.13)$$

The weight factors for the fields $\beta, \vec{\rho}_r$ in \tilde{w}_{aux} (namely $\kappa_{\mathfrak{S}, 2\delta}$ and $\kappa_{*\mathfrak{S}, \tau}, \kappa_{\mathfrak{S}, \tau}, \lambda_{\mathfrak{S}, \tau}$ with $\delta < \tau < 2\delta$) are smaller than the weight factors for the corresponding fields in $w_{\mathfrak{S}_2}$ (namely $\kappa_{\mathfrak{S}_2, \delta}$ and $\kappa_{*\mathfrak{S}_2, \tau}, \kappa_{\mathfrak{S}_2, \tau}, \lambda_{\mathfrak{S}_2, \tau}$ with $0 < \tau < \delta$). Consequently, the hypothesis of Proposition G.1 is satisfied if

$$\begin{aligned} &N_{d_{\Omega_2}}(\Omega; \kappa_{*\mathfrak{S}_2, 0}, \tilde{\lambda}) + N_{d_{\Omega_2}}(\Lambda \setminus \Omega; \kappa_{*\mathfrak{S}_2, 0}, \lambda_{\mathfrak{S}, \delta}) \\ &+ N_{d_{\Omega_2}}(\Lambda j_{\mathfrak{c}}(\delta); \kappa_{*\mathfrak{S}_2, 0}, \kappa_{*\mathfrak{S}, 0}) \leq \frac{19}{20} \end{aligned} \quad (5.14)$$

$$N_{d_{\Omega_2}}(\Lambda^c; \kappa_{*\mathfrak{S}_2,0}, \kappa_{*\mathfrak{S},\delta}) \leq \frac{19}{20}$$

Since $\tilde{\lambda}(\mathbf{x}) = 32r$ for all $\mathbf{x} \in \Omega$, $\kappa_{*\mathfrak{S}_2,0}(\mathbf{x}) = 2R$ for all $\mathbf{x} \in \Omega_{\mathfrak{S}_2}$, $\lambda_{\mathfrak{S},\delta} = 32r$ for all $\mathbf{x} \in \Lambda \setminus \Omega$, $\kappa_{*\mathfrak{S},0}(\mathbf{x}) = 2R_+$ for all $\mathbf{x} \in \Lambda$ and, by Remark 3.17, $\kappa_{*\mathfrak{S},\delta}(\mathbf{x}) = \frac{1}{2}\kappa_{*\mathfrak{S}_2,0}(\mathbf{x})$ for all $\mathbf{x} \in \Lambda^c$, (3.6) yields

$$\begin{aligned} \mathcal{N}_{2m}(\Omega; \kappa_{*\mathfrak{S}_2,0}, \tilde{\lambda}) &\leq \frac{32r}{2R} \quad \mathcal{N}_{2m}(\Lambda \setminus \Omega; \kappa_{*\mathfrak{S}_2,0}, \lambda_{\mathfrak{S},\delta}) \leq \frac{32r}{2R} \\ \mathcal{N}_{2m}(\Lambda \setminus \Omega; \kappa_{*\mathfrak{S}_2,0}, \kappa_{*\mathfrak{S},0}) &\leq \frac{R_+}{R} \quad \mathcal{N}_{2m}(\Lambda^c; \kappa_{*\mathfrak{S}_2,0}, \kappa_{*\mathfrak{S},\delta}) \leq \frac{1}{2} \end{aligned}$$

By Remark G.4(iii), Lemma B.1(i) and Lemma 3.21(ii),

$$\begin{aligned} \mathcal{N}_{2m}(\Lambda (j_{\mathfrak{c}}(\delta) - \mathfrak{h}); \kappa_{*\mathfrak{S}_2,0}, \kappa_{*\mathfrak{S},0}) &= \frac{R_+}{R} \mathcal{N}_{2m}(\Lambda (j_{\mathfrak{c}}(\delta) - \mathfrak{h}); \kappa_{*\mathfrak{S},0}, \kappa_{*\mathfrak{S},0}) \\ &\leq 2 \frac{R_+}{R} \mathcal{N}_{\frac{7}{3}m}(\Lambda (j_{\mathfrak{c}}(\delta) - \mathfrak{h}); 1, 1) \\ &\leq 2 \frac{R_+}{R} K_j \delta e^{K_j \delta} \end{aligned}$$

Since $d_{\Omega_2} \leq 2md$, the left hand side of the top inequality in (5.14) is bounded by

$$\begin{aligned} &\frac{16r}{R} + \frac{16r}{R} + \mathcal{N}_{2m}(\Lambda \setminus \Omega; \kappa_{*\mathfrak{S}_2,0}, \kappa_{*\mathfrak{S},0}) + \mathcal{N}_{2m}(\Lambda (j_{\mathfrak{c}}(\delta) - \mathfrak{h}); \kappa_{*\mathfrak{S}_2,0}, \kappa_{*\mathfrak{S},0}) \\ &\leq \frac{32r}{R} + \frac{R_+}{R} + 2 \frac{R_+}{R} K_j \delta e^{K_j \delta} \\ &\leq \frac{19}{20} \end{aligned}$$

by (F.3f) and Hypothesis F.7(i), since $\frac{R_+}{R} = \frac{1}{2^{e_R + e_r}} \leq \frac{1}{\sqrt[3]{2}} < \frac{19}{20} - \frac{1}{16}$, by (2.17). The left hand side of the bottom inequality in (5.14) is bounded by $\frac{1}{2} < \frac{19}{20}$. This proves (5.13).

Since $d_{\Omega} \leq d_{\Omega_2}$, (5.13) gives that

$$\begin{aligned} \left\| g_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) \Big|_{\Omega^c} \right\|_{\mathfrak{S}} &= \left\| g_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) \Big|_{\Omega^c} \right\|_{\text{fluct}} \\ &\leq \|g_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)\|_{\tilde{w}_{\text{aux}}} \leq 2^8 \|g_2\|_{\mathfrak{S}_2} \end{aligned}$$

As

$$\begin{aligned} &\|g_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) - g_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)\|_{\text{fluct}} \\ &\quad + \left\| g_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) - g_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) \Big|_{\Omega^c} \right\|_{\text{fluct}} \\ &= \left\| g_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) - g_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) \Big|_{\Omega^c} \right\|_{\text{fluct}} \end{aligned}$$

it now suffices to prove that

$$\begin{aligned} &\left\| g_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) - g_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) \Big|_{\Omega^c} \right\|_{\text{fluct}} \\ &\leq 2^8 \left(e^{-mc(\delta)} \|g_2\|_{\mathfrak{S}_2} + \left\| g_2 \Big|_{\Omega_2} \right\|_{\mathfrak{S}_2} \right) \end{aligned} \tag{5.15}$$

Write

$$g_2 = \mathcal{B} + \mathcal{S}$$

with $\mathcal{B} = g_2 - g_2|_{\Omega_2}$ its “ \mathfrak{S}_2 –boundary part” and $\mathcal{S} = g_2|_{\Omega_2}$ “its \mathfrak{S}_2 –small field part”. Each nonzero monomial in the power series expansion of \mathcal{B} contains at least one factor $\mathfrak{h}(\mathbf{x})$ with $\mathbf{x} \in \Omega_2^c$. Also, each nonzero monomial in the power series expansion of $\mathcal{B}(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) - \mathcal{B}(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)|_{\Omega^c}$ contains at least one factor $\mathfrak{h}(\mathbf{y})$ with $\mathbf{y} \in \Omega$. Therefore, by (2.15) and (5.13)

$$\begin{aligned} & \left\| \mathcal{B}(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) - \mathcal{B}(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) \right\|_{\Omega^c} \\ & \leq e^{-m d(\bar{\Omega}, \bar{\Omega}_2^c)} \left\| \mathcal{B}(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) - \mathcal{B}(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) \right\|_{\Omega^c} \|_{\tilde{w}_{\text{aux}}} \\ & \leq e^{-m d(\bar{\Omega}, \bar{\Omega}_2^c)} \|\mathcal{B}(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)\|_{\tilde{w}_{\text{aux}}} \\ & \leq e^{-m d(\bar{\Omega}, \bar{\Omega}_2^c)} \|g_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)\|_{\tilde{w}_{\text{aux}}} \\ & \leq 2^8 e^{-m\epsilon(\delta)} \|g_2\|_{\mathfrak{S}_2} \end{aligned}$$

Finally

$$\begin{aligned} & \left\| \mathcal{S}(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) - \mathcal{S}(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r) \right\|_{\Omega^c} \\ & \leq \|\mathcal{S}(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\rho}_r)\|_{w_{\text{aux}}} \\ & \leq 2^8 \|\mathcal{S}\|_{\mathfrak{S}_2} \end{aligned}$$

by (5.13), with g_2 replaced by \mathcal{S} . \square

Parts (i) and (ii) of Remark 5.5 (quadratic and quartic terms) implicitly involve the substitution of the critical fields $\alpha_{\delta}^{\text{cr}}$, $\alpha_{*\delta}^{\text{cr}}$ (defined in Lemma 5.3) in the concrete background fields $\Gamma_{*\mathfrak{S}_1}, \Gamma_{\mathfrak{S}_1}$ and $\Gamma_{*\mathfrak{S}_2}, \Gamma_{\mathfrak{S}_2}$. To control it, set

$$\begin{aligned} \tilde{\Gamma}_*(\tau; \alpha_*, \vec{\alpha}_*) &= \begin{cases} \Gamma_{*\mathfrak{S}_1}(\tau; \alpha_*, \vec{\alpha}_{*l}) & \text{if } \tau \in \varepsilon\mathbb{Z} \cap (0, \delta) \\ \alpha_{*\delta}^{\text{cr}} & \text{if } \tau = \delta \\ \Gamma_{*\mathfrak{S}_2}(\tau - \delta; \alpha_{*\delta}^{\text{cr}}, \vec{\alpha}_{*r}) & \text{if } \tau \in \varepsilon\mathbb{Z} \cap (\delta, 2\delta) \end{cases} \\ \tilde{\Gamma}(\tau; \vec{\alpha}, \beta) &= \begin{cases} \Gamma_{\mathfrak{S}_1}(\tau; \vec{\alpha}_l, \alpha_{\delta}^{\text{cr}}) & \text{if } \tau \in \varepsilon\mathbb{Z} \cap (0, \delta) \\ \alpha_{\delta}^{\text{cr}} & \text{if } \tau = \delta \\ \Gamma_{\mathfrak{S}_2}(\tau - \delta; \vec{\alpha}_r, \beta) & \text{if } \tau \in \varepsilon\mathbb{Z} \cap (\delta, 2\delta) \end{cases} \end{aligned} \quad (5.16)$$

Observe that (5.16) is very similar to the recursion relation of Proposition 3.6. Indeed, replacing $\alpha_{*\delta}^{\text{cr}}$ and $\alpha_{\delta}^{\text{cr}}$ by

$$\begin{aligned} \Lambda j(\delta) \alpha_* + \Lambda^c \alpha_{*\delta} &= \alpha_{*\delta}^{\text{cr}} + \Lambda[j(\delta) - j_c(\delta)] \alpha_* \\ \text{and } \Lambda j(\delta) \beta + \Lambda^c \alpha_{\delta} &= \alpha_{\delta}^{\text{cr}} + \Lambda[j(\delta) - j_c(\delta)] \beta \end{aligned}$$

respectively, in (5.16) gives the recursion relation of Proposition 3.6, except for the $\partial\Gamma_{*\tau}\alpha_*$ and $\partial\Gamma_{\tau}\beta$ terms. For convenience, we set

$$j_{\delta} = j(\delta) - j_c(\delta) \quad (5.17)$$

Lemma 3.21(iii) gives the estimate $\|j_\delta\| \leq \delta K_j e^{K_j \delta} e^{-mc}$. This discussion shows that

$$\begin{aligned}\Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) - \tilde{\Gamma}_*(\tau; \alpha_*, \vec{\alpha}_*) &= \partial_c \Gamma_{*\tau} \alpha_* \\ \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) - \tilde{\Gamma}(\tau; \vec{\alpha}, \beta) &= \partial_c \Gamma_\tau \beta\end{aligned}\quad (5.18)$$

where we set

$$\begin{aligned}\partial_c \Gamma_{*\tau} &= \begin{cases} 0 & \text{if } \tau \in [0, \delta) \text{ or } \tau = 2\delta \\ \Lambda j_\delta & \text{if } \tau = \delta \\ \partial \Gamma_{*\tau} + \Gamma_{*\tau-\delta}^0(\mathfrak{S}_2) \Lambda j_\delta & \text{if } \tau \in (\delta, 2\delta) \end{cases} \\ \partial_c \Gamma_\tau &= \begin{cases} \partial \Gamma_\tau + \Gamma_\tau^\delta(\mathfrak{S}_1) \Lambda j_\delta & \text{if } \tau \in (0, \delta) \\ \Lambda j_\delta & \text{if } \tau = \delta \\ 0 & \text{if } \tau \in (\delta, 2\delta] \text{ or } \tau = 0 \end{cases}\end{aligned}\quad (5.19)$$

Under the conventions of parts (iii) and (iv) of Lemma 3.7, we may also write $\partial_c \Gamma_{*\tau} = \partial \Gamma_{*\tau} + \Gamma_{*\tau-\delta}^0(\mathfrak{S}_2) \Lambda j_\delta$ for $\tau = \delta, 2\delta$ and $\partial_c \Gamma_\tau = \partial \Gamma_\tau + \Gamma_\tau^\delta(\mathfrak{S}_1) \Lambda j_\delta$ for $\tau = 0, \delta$. The operators $\partial_c \Gamma_{*\tau}, \partial_c \Gamma_\tau$ are estimated in Lemma E.18.

We use the shorthand notations

$$\gamma_{*\tau} = \begin{cases} \Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) & \text{if } \tau \in (0, 2\delta) \\ \alpha_* & \text{if } \tau = 0 \end{cases} \quad \gamma_\tau = \begin{cases} \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) & \text{if } \tau \in (0, 2\delta) \\ \beta & \text{if } \tau = 2\delta \end{cases}\quad (5.20)$$

By the recursion relation Proposition 3.6,

$$\Gamma_{*\mathfrak{S}_1}(\tau; \alpha_*, \vec{\alpha}_*) = \gamma_{*\tau} \quad \Gamma_{\mathfrak{S}_2}(\tau; \vec{\alpha}, \beta) = \gamma_{\tau+\delta} \quad \text{for all } 0 < \tau < \delta \quad (5.21)$$

Bound on the Quadratic Part of the Fluctuation Action

In part (i) of Remark 5.5 we wrote the “quadratic part” as the sum of $-Q_{\mathfrak{S}}, \delta Q$,

$$\begin{aligned}-\langle z_*, \Omega j_c(\delta) \beta \rangle - Q_{\mathfrak{S}_2}(z_*, \beta; 0, \vec{\alpha}_r) \\ = \langle z_*, \Omega j_\delta \beta \rangle - \langle z_*, \Omega j(\delta) \beta \rangle - Q_{\mathfrak{S}_2}(z_*, \beta; 0, \vec{\alpha}_r)\end{aligned}$$

and

$$\begin{aligned}-\langle \Omega j_c(\delta) \alpha_*, z \rangle - Q_{\mathfrak{S}_1}(\alpha_*, z; \vec{\alpha}_{*l}, 0) \\ = \langle \Omega j_\delta \alpha_*, z \rangle - \langle \Omega j(\delta) \alpha_*, z \rangle - Q_{\mathfrak{S}_1}(\alpha_*, z; \vec{\alpha}_{*l}, 0)\end{aligned}$$

We bound these quantities in Proposition 5.12, below. By way of preparation for the bound on δQ , recall from (5.10) that

$$\begin{aligned}\delta Q &= Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) - Q_{\mathfrak{S}_1}(\alpha_*, \alpha_\delta^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) - Q_{\mathfrak{S}_2}(\alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) - \langle \alpha_{*\delta}^{\text{cr}}, \alpha_\delta^{\text{cr}} \rangle \\ &\quad - [\langle z_{*\delta}, (\Lambda \setminus \Omega) j(\delta) \beta \rangle + Q_{\mathfrak{S}_2}(z_{*\delta}, \beta; 0, \vec{\alpha}_r)] + \langle z_{*\delta}, (\Lambda \setminus \Omega) j_\delta(\delta) \beta \rangle \\ &\quad - [\langle (\Lambda \setminus \Omega) j(\delta) \alpha_*, z_\delta \rangle + Q_{\mathfrak{S}_1}(\alpha_*, z_\delta; \vec{\alpha}_{*l}, 0)] + \langle (\Lambda \setminus \Omega) j_\delta(\delta) \alpha_*, z_\delta \rangle\end{aligned}\quad (5.22)$$

We start by rewriting the first line of the right hand side.

Lemma 5.11.

$$Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) - Q_{\mathfrak{S}_1}(\alpha_*, \alpha_{\delta}^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) - Q_{\mathfrak{S}_2}(\alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) - \langle \alpha_{*\delta}^{\text{cr}}, \alpha_{\delta}^{\text{cr}} \rangle \\ \times \sum_{\tau \in (0, 2\delta]} \langle \partial_j \Gamma_{*\tau} \alpha_*, \gamma_{\tau} \rangle + \sum_{\tau \in [0, 2\delta)} \langle \gamma_{*\tau}, \partial_j \Gamma_{\tau} \beta \rangle - \langle \Lambda j_{\delta} \alpha_*, \Lambda j_{\delta} \beta \rangle$$

where

$$\partial_j \Gamma_{*\tau} = \partial_{\mathfrak{c}} \Gamma_{*\tau} - j(\varepsilon) \partial_{\mathfrak{c}} \Gamma_{*\tau-\varepsilon} \quad \partial_j \Gamma_{\tau} = \partial_{\mathfrak{c}} \Gamma_{\tau} - j(\varepsilon) \partial_{\mathfrak{c}} \Gamma_{\tau+\varepsilon}$$

Proof. By parts (iii) and (iv) of Lemma 3.7 and (5.21),

$$Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) - Q_{\mathfrak{S}_1}(\alpha_*, \alpha_{\delta}^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) - Q_{\mathfrak{S}_2}(\alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) - \langle \alpha_{*\delta}^{\text{cr}}, \alpha_{\delta}^{\text{cr}} \rangle \\ = Q_{\mathfrak{S}_1}(\alpha_*, \Lambda j(\delta) \beta + \Lambda^c \alpha_{\delta}; \vec{\alpha}_{*l}, \vec{\alpha}_l) - Q_{\mathfrak{S}_1}(\alpha_*, \Lambda j_{\mathfrak{c}}(\delta) \beta + \Lambda^c \alpha_{\delta}; \vec{\alpha}_{*l}, \vec{\alpha}_l) \\ + Q_{\mathfrak{S}_2}(\Lambda j(\delta) \alpha_* + \Lambda^c \alpha_{*\delta}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) - Q_{\mathfrak{S}_2}(\Lambda j_{\mathfrak{c}}(\delta) \alpha_* + \Lambda^c \alpha_{*\delta}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) \\ + \langle \Lambda j(\delta) \alpha_*, \Lambda j(\delta) \beta \rangle + \langle \Lambda^c \alpha_{*\delta}, \Lambda^c \alpha_{\delta} \rangle \\ - \langle \Lambda j_{\mathfrak{c}}(\delta) \alpha_*, \Lambda j_{\mathfrak{c}}(\delta) \beta + \Lambda^c \alpha_{\delta} \rangle \\ + \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \langle \gamma_{*\tau}, (\partial \Gamma_{\tau} - j(\varepsilon) \partial \Gamma_{\tau+\varepsilon}) \beta \rangle \\ + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta]} \langle (\partial \Gamma_{*\delta+\tau} - j(\varepsilon) \partial \Gamma_{*\delta+\tau-\varepsilon}) \alpha_*, \gamma_{\delta+\tau} \rangle \\ = \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \langle \gamma_{*\tau}, (\Gamma_{\tau}^{\delta}(\mathfrak{S}_1) - j(\varepsilon) \Gamma_{\tau+\varepsilon}^{\delta}(\mathfrak{S}_1)) \Lambda j_{\delta} \beta \rangle \\ + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta]} \langle (\Gamma_{*\tau}^0(\mathfrak{S}_2) - j(\varepsilon) \Gamma_{*\tau-\varepsilon}^0(\mathfrak{S}_2)) \Lambda j_{\delta} \alpha_*, \gamma_{\delta+\tau} \rangle \\ + \langle \Lambda j(\delta) \alpha_*, \Lambda j(\delta) \beta \rangle - \langle \Lambda j_{\mathfrak{c}}(\delta) \alpha_*, \Lambda j_{\mathfrak{c}}(\delta) \beta \rangle \\ + \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \langle \gamma_{*\tau}, (\partial \Gamma_{\tau} - j(\varepsilon) \partial \Gamma_{\tau+\varepsilon}) \beta \rangle \\ + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (0, \delta]} \langle (\partial \Gamma_{*\delta+\tau} - j(\varepsilon) \partial \Gamma_{*\delta+\tau-\varepsilon}) \alpha_*, \gamma_{\delta+\tau} \rangle \\ = \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \langle \gamma_{*\tau}, (\partial_{\mathfrak{c}} \Gamma_{\tau} - j(\varepsilon) \partial_{\mathfrak{c}} \Gamma_{\tau+\varepsilon}) \beta \rangle \\ + \sum_{\tau \in \varepsilon \mathbb{Z} \cap (\delta, 2\delta]} \langle (\partial_{\mathfrak{c}} \Gamma_{*\tau} - j(\varepsilon) \partial_{\mathfrak{c}} \Gamma_{*\tau-\varepsilon}) \alpha_*, \gamma_{\tau} \rangle \\ + \langle \Lambda j(\delta) \alpha_*, \Lambda j(\delta) \beta \rangle - \langle \Lambda j_{\mathfrak{c}}(\delta) \alpha_*, \Lambda j_{\mathfrak{c}}(\delta) \beta \rangle$$

This is the desired equation, since

$$\partial_j \Gamma_{*\tau} = \begin{cases} 0 & \text{if } 0 < \tau < \delta \\ \Lambda j_{\delta} & \text{if } \tau = \delta \end{cases} \quad \partial_j \Gamma_{\tau} = \begin{cases} 0 & \text{if } \delta < \tau < 2\delta \\ \Lambda j_{\delta} & \text{if } \tau = \delta \end{cases} \\ \gamma_{\delta} = \Lambda^c \alpha_{\delta} + \Lambda j(\delta) \beta \quad \gamma_{*\delta} = \Lambda^c \alpha_{*\delta} + \Lambda j(\delta) \alpha_*$$

so that

$$\langle \partial_j \Gamma_{*\tau} \alpha_*, \gamma_\tau \rangle = \begin{cases} 0 & \text{if } 0 < \tau < \delta \\ \langle \Lambda j_\delta \alpha_*, \Lambda j(\delta) \beta \rangle & \text{if } \tau = \delta \end{cases} \quad (5.23)$$

$$\langle \gamma_{*\tau}, \partial_j \Gamma_\tau \beta \rangle = \begin{cases} 0 & \text{if } \delta < \tau < 2\delta \\ \langle \Lambda j(\delta) \alpha_*, \Lambda j_\delta \beta \rangle & \text{if } \tau = \delta \end{cases}$$

□

Proposition 5.12. Set $K_Q = 2^9 e^{2K_j}$.

(i)

$$\begin{aligned} \|\langle z_*, \Omega j_\epsilon(\delta) \beta \rangle + Q_{\mathfrak{S}_2}(z_*, \beta; 0, \vec{\alpha}_r)\|_{\text{fluct}} &\leq K_Q \left[e^{-m\epsilon(\delta)} + \delta r R_+ e^{-m\epsilon} \right] \\ \|\langle \Omega j_\epsilon(\delta) \alpha_*, z \rangle + Q_{\mathfrak{S}_1}(\alpha_*, z; \vec{\alpha}_{*l}, 0)\|_{\text{fluct}} &\leq K_Q \left[e^{-m\epsilon(\delta)} + \delta r R_+ e^{-m\epsilon} \right] \end{aligned}$$

(ii)

$$\|\delta Q(\alpha_*, \beta; \vec{\rho})\|_{\mathfrak{S}} \leq K_Q \left[e^{-\frac{1}{4}m\epsilon(\delta)} + \delta r R_+ e^{-m\epsilon} \right]$$

Proof. (i) We prove the second inequality. The proof of the first is analogous. Observe that, by the definition (3.3),

$$Q_{\mathfrak{S}_1}(\alpha_*, z; \vec{\alpha}_{*l}, 0) = Q_{\epsilon, \delta}(\alpha_*, z; \Gamma_{*\mathfrak{S}_1}(\cdot; \alpha_*, \vec{\alpha}_{*l}), \Gamma_{\mathfrak{S}_1}(\cdot; 0, z))$$

with the $Q_{\epsilon, \delta}$ of (2.10). Since z is supported in Ω ,

$$\begin{aligned} &(j_\delta \alpha_*, z) + [\langle \Omega j_\epsilon(\delta) \alpha_*, z \rangle + Q_{\epsilon, \delta}(\alpha_*, z; \Gamma_{*\mathfrak{S}_1}(\cdot; \alpha_*, \vec{\alpha}_{*l}), \Gamma_{\mathfrak{S}_1}(\cdot; 0, z))] \\ &= \langle \Omega j(\delta) \alpha_*, z \rangle + Q_{\epsilon, \delta}(\alpha_*, z; \Gamma_{*\mathfrak{S}_1}(\cdot; \alpha_*, \vec{\alpha}_{*l}), \Gamma_{\mathfrak{S}_1}(\cdot; 0, z)) \\ &= \sum_{\tau \in [0, \delta]} \langle \gamma_{*\tau}, (\Gamma_\tau^\delta(\mathfrak{S}_1) - j(\epsilon) \Gamma_{\tau+\epsilon}^\delta(\mathfrak{S}_1)) \Omega z \rangle \end{aligned}$$

evaluated at

$$\gamma_{*\tau} = \begin{cases} \alpha_* & \text{if } \tau = 0 \\ \Gamma_{*\mathfrak{S}_1}(\tau; \alpha_*, \vec{\alpha}_{*l}) = \Gamma_{*\tau}^0(\mathfrak{S}_1) \alpha_* + \sum_{\tau' \in (0, \tau] \cap \epsilon \mathbb{Z}} \Gamma_{*\tau'}^\tau(\mathfrak{S}_1) \alpha_{*\tau'} & \text{if } \tau \in (0, \delta) \end{cases}$$

and with the conventions that $\Gamma_0^\delta(\mathfrak{S}_1) = j(\delta)$ and $\Gamma_\delta^\delta(\mathfrak{S}_1) = \mathfrak{h}$.

To bound this, we first claim that for any two \mathfrak{h} -operators A and A'

$$\|\langle A' \alpha_{*\tau'}, A z \rangle\|_{\text{fluct}} \leq N_{d_\Omega} \left(A'; e^{m d(\mathbf{x}, \Omega)}, \kappa_{*\tau'} \right) N_{d_\Omega} \left(A; e^{-m d(\mathbf{x}, \Omega)}, \tilde{\lambda} \right) \quad (5.24)$$

As $\langle A' \alpha_{*\tau'}, A z \rangle$ is obtained from $\langle \varphi, \psi \rangle$ by the substitution $\varphi = A' \alpha_{*\tau'}$, $\psi = A z$, this inequality follows Lemma G.2.a with $s = 2$, $d = d_\Omega$, $\kappa'_1 = \kappa_{*\tau'}$, $\kappa'_2 = \tilde{\lambda}$, $\kappa_1(\mathbf{x}) = e^{md(\mathbf{x}, \Omega)}$ and $\kappa_2(\mathbf{x}) = e^{-md(\mathbf{x}, \Omega)}$.

Applying the estimates (5.24) and (3.7) we get

$$\begin{aligned} & \| \langle \Omega j(\delta) \alpha_*, z \rangle + Q_{\varepsilon, \delta}(\alpha_*, z; \Gamma_{*\mathfrak{S}_1}(\cdot; \alpha_*, \vec{\alpha}_{*l}), \Gamma_{\mathfrak{S}_1}(\cdot; 0, z)) \|_{\text{fluct}} \\ & \leq \sum_{\tau \in [0, \delta)} a_\tau \mathcal{N}_{2m} \left((\Gamma_\tau^\delta(\mathfrak{S}_1) - j(\varepsilon) \Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)) \Omega; e^{-m d(\mathbf{x}, \Omega)}, \tilde{\lambda} \right) \end{aligned}$$

where

$$a_\tau = \begin{cases} \mathcal{N}_{2m} (1; e^{m d(\mathbf{x}, \Omega)}, \kappa_{*0}) & \text{if } \tau = 0 \\ \sum_{\tau' \in [0, \delta)} \mathcal{N}_{2m} \left(\Gamma_{*\tau'}^\delta(\mathfrak{S}_1); e^{m d(\mathbf{x}, \Omega)}, \kappa_{*\tau'} \right) & \text{if } \tau \in (0, \delta) \end{cases}$$

By Lemma B.1(ii), Lemma E.13 and the observation that $e^{-md(\mathbf{x}, \Omega)} \leq e^{-\frac{m}{2}d(\mathbf{x}, \Omega)} \leq e^{-\frac{m}{2}d(\mathbf{x}, \Lambda_{\mathfrak{S}_1})}$, we have $a_\tau \leq 16e^{K_j} R$, for all $\tau \in [0, \delta)$. Therefore, by Lemma E.15(ii) with $\lambda = \tilde{\lambda}$, $O = \Omega$ and $\Omega_{\mathfrak{S}}$ replaced by Ω_1

$$\begin{aligned} & \| \langle j_\delta \alpha_*, z \rangle + [\langle \Omega j_\delta(\delta) \alpha_*, z \rangle + Q_{\varepsilon, \delta}(\alpha_*, z; \Gamma_{*\mathfrak{S}_1}(\cdot; \alpha_*, \vec{\alpha}_{*l}), \Gamma_{\mathfrak{S}_1}(\cdot; 0, z))] \|_{\text{fluct}} \\ & \leq 16e^{K_j} R \sum_{\tau \in [0, \delta)} \mathcal{N}_{2m} \left((\Gamma_\tau^\delta(\mathfrak{S}_1) - j(\varepsilon) \Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)) \Omega; e^{-m d(\mathbf{x}, \Omega)}, \tilde{\lambda} \right) \\ & \leq 2^{11} e^{2K_j} r R e^{-2md(\Omega, \Omega_1^c)} \\ & \leq e^{-mc(\delta)} \end{aligned}$$

since $8 \leq 16e^{K_j} r \leq 16e^{K_j} R \leq e^{\frac{1}{4}mc(\delta)}$, by (F.6b), and $d(\Omega, \Omega_1^c) \geq c(\delta)$.

The function $\langle j_\delta \alpha_*, z \rangle$ is obtained from $\langle \varphi, z \rangle$ by the linear substitution $\varphi = \Omega j_\delta \alpha_*$. Let ω be the weight system with core Ω that associates the constant weight factor 1 to the fields φ and z . Clearly, $\| \langle \varphi, z \rangle \|_\omega = 1$. It follows from Lemma G.2.a (with $s = 2$, $\tilde{w} = w_{\text{fluct}}$, $w = \omega$) that

$$\begin{aligned} \| \langle j_\delta \alpha_*, z \rangle \|_{\text{fluct}} &= \| \langle \Lambda j_\delta \alpha_*, \Omega z \rangle \|_{\text{fluct}} \leq N_{d_\Omega}(\Lambda j_\delta; 1, \kappa_{*\mathfrak{S},0}) N_{d_\Omega}(\Omega; 1, \tilde{\lambda}) \\ &\leq 4K_j e^{K_j \delta} \delta R_+ e^{-m c} 32r \end{aligned}$$

since, by (3.7), Remark G.4(i), Lemma B.1(i) and Lemma 3.21(iii),

$$\begin{aligned} N_{d_\Omega}(\Lambda j_\delta; 1, \kappa_{*\mathfrak{S},0}) &\leq \mathcal{N}_{2m}(\Lambda j_\delta; 1, \kappa_{*\mathfrak{S},0}) \\ &\leq 4 \| j_\delta \| R_+ \leq 4K_j e^{K_j \delta} \delta R_+ e^{-m c} \end{aligned}$$

This completes the proof of the second inequality.

As in part (i) one shows that

$$\begin{aligned} & \| \langle z_{*\delta}, (\Lambda \setminus \Omega) j_\delta \beta \rangle \|_{\mathfrak{S}} \leq 2^7 K_j e^{K_j} \delta r R_+ e^{-m c} \\ & \| \langle z_{*\delta}, (\Lambda \setminus \Omega) j(\delta) \beta \rangle + Q_{\mathfrak{S}_2}(z_{*\delta}, \beta; 0, \vec{\alpha}_r) \|_{\mathfrak{S}} \leq e^{-m c(\delta)} \\ & \| \langle (\Lambda \setminus \Omega) j_\delta \alpha_*, z_\delta \rangle \|_{\mathfrak{S}} \leq 2^7 K_j e^{K_j} \delta r R_+ e^{-m c} \\ & \| \langle (\Lambda \setminus \Omega) j(\delta) \alpha_*, z_\delta \rangle + Q_{\mathfrak{S}_1}(\alpha_*, z_\delta; \vec{\alpha}_{*l}, 0) \|_{\mathfrak{S}} \leq e^{-m c(\delta)} \end{aligned} \tag{5.25}$$

This bounds the last four terms of (5.22).

It remains to bound the first four terms of (5.22), which form the left hand side of Lemma 5.11. By (5.23), the first sum on the right hand side of Lemma 5.11 is

$$\begin{aligned}
\sum_{\tau \in (0, 2\delta]} \langle \partial_j \Gamma_{*\tau} \alpha_*, \gamma_\tau \rangle &= \langle j(\delta) \Lambda j_\delta \alpha_*, \beta \rangle \\
&\quad + \sum_{\tau \in (\delta, 2\delta)} \langle \partial_j \Gamma_{*\tau} \alpha_*, \gamma_\tau \rangle + \langle \partial_j \Gamma_{*2\delta} \alpha_*, \gamma_{2\delta} \rangle \\
&= \sum_{\tau \in (\delta, 2\delta)} \langle \partial_j \Gamma_{*\tau} \alpha_*, \gamma_\tau \rangle \\
&\quad + \langle (\partial_j \Gamma_{*2\delta} + j(\delta) \Lambda j_\delta) \alpha_*, \gamma_{2\delta} \rangle
\end{aligned} \tag{5.26}$$

As in (5.24) one sees for all \mathfrak{h} -operators A and B

$$\| \langle A \alpha_*, B \alpha_{\tau'} \rangle \|_{\mathfrak{S}} \leq \mathcal{N}_{d_\Omega} \left(A ; e^{-\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \mathcal{N}_{d_\Omega} \left(B ; e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{\tau'} \right)$$

Hence,

$$\begin{aligned}
&\left\| \sum_{\tau \in (\delta, 2\delta)} \langle \partial_j \Gamma_{*\tau} \alpha_*, \gamma_\tau \rangle + \langle (\partial_j \Gamma_{*2\delta} + j(\delta) \Lambda j_\delta) \alpha_*, \gamma_{2\delta} \rangle \right\|_{\mathfrak{S}} \\
&\leq \sum_{\tau \in (\delta, 2\delta)} a_\tau \mathcal{N}_{2m} \left(\partial_j \Gamma_{*\tau} ; e^{-\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\
&\quad + a_{2\delta} \mathcal{N}_{2m} \left(\partial_j \Gamma_{*2\delta} + j(\delta) \Lambda j_\delta ; e^{-\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right)
\end{aligned}$$

where

$$a_\tau = \begin{cases} \mathcal{N}_{2m} \left(\mathbb{1} ; e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{2\delta} \right) & \text{if } \tau = 2\delta \\ \sum_{\tau' \in (0, 2\delta]} \mathcal{N}_{2m} \left(\Gamma_{\tau'}' ; e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{\tau'} \right) & \text{if } \tau \in (\delta, 2\delta) \end{cases}$$

By Lemma B.1(ii) and Lemma E.13, we have $a_\tau \leq 16e^{K_j} R_+$ for all $\tau \in (0, 2\delta]$. Therefore, by (5.26), and Lemma E.20(ii), the first sum on the right hand side of Lemma 5.11 is bounded by

$$\left\| \sum_{\tau \in (0, 2\delta]} \langle \partial_j \Gamma_{*\tau} \alpha_*, \gamma_\tau \rangle \right\|_{\mathfrak{S}} \leq 16e^{K_j} R_+ e^{-\frac{1}{2} m c(\delta)} \leq e^{-\frac{1}{4} m c(\delta)}$$

by (F.6b). The second sum is bounded in the same way. Combining this with (5.22) and (5.25) gives

$$\begin{aligned}
&\| \delta Q(\alpha_*, \beta; \vec{\rho}) + \langle \Lambda j_\delta \alpha_*, \Lambda j_\delta \beta \rangle \|_{\mathfrak{S}} \\
&\leq 2 \left\{ e^{-\frac{1}{4} m c(\delta)} + e^{-m c(\delta)} + 2^7 K_j e^{K_j} \delta R_+ e^{-m c} \right\}
\end{aligned} \tag{5.27}$$

As $\langle \Lambda j_\delta \alpha_*, \Lambda j_\delta \beta \rangle$ is obtained from $\langle \varphi, \psi \rangle$ by the substitution $\varphi = \Lambda j_\delta \alpha_*$, $\psi = \Lambda j_\delta \beta$, an application of Lemma G.2(a) with $s = 2$, $d = d_\Omega$, $\kappa'_1 = \kappa_{*0}$, $\kappa'_2 = \kappa_{2\delta}$, and $\kappa_1(\mathbf{x}) = \kappa_2(\mathbf{x}) = 1$ yields

$$\begin{aligned}
\| \langle \Lambda j_\delta \alpha_*, \Lambda j_\delta \beta \rangle \|_{\mathfrak{S}} &\leq N_{d_\Omega}(\Lambda j_\delta; 1, \kappa_{*0}) N_{d_\Omega}(\Lambda j_\delta; 1, \kappa_{2\delta}) \\
&\leq (4R_+ \| j_\delta \|)^2 \leq 16K_j^2 e^{2K_j} \delta^2 e^{-2m c} R_+^2
\end{aligned} \tag{5.28}$$

by (3.7), Remark G.4(i), Lemma B.1(i) and Lemma 3.21(iii).

Combining (5.27) and (5.28), we have

$$\begin{aligned}\|\delta Q(\alpha_*, \beta; \vec{\rho})\|_{\mathfrak{S}} &\leq 4e^{-\frac{1}{4}mc(\delta)} + \left\{2^8 K_j e^{K_j} + 16K_j^2 e^{2K_j} \delta R_+ e^{-mc}\right\} \delta r R_+ e^{-mc} \\ &\leq 4e^{-\frac{1}{4}mc(\delta)} + \left\{2^8 K_j e^{K_j} + \frac{1}{40}\right\} \delta r R_+ e^{-mc}\end{aligned}$$

by (F.4b) and (F.6a). \square

Bound on the Quartic Part of the Fluctuation Action. Finally, we treat the quartic contribution to $f_{\mathfrak{S}}(\alpha_*, \beta; \vec{\rho}; z_*, z)$ identified in Remark 5.5(ii). We write it as

$$\begin{aligned}\mathcal{V}_{\mathfrak{S}_1}(\varepsilon; \alpha_*, z + z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) + \mathcal{V}_{\mathfrak{S}_2}(\varepsilon; z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) \\ = \mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) + \delta \mathcal{V}(\varepsilon; \alpha_*, \beta; \vec{\rho}) + \mathcal{V}_l(\varepsilon; \alpha_*, \beta; \vec{\rho}; z) \\ + \mathcal{V}_r(\varepsilon; \alpha_*, \beta; \vec{\rho}; z_*)\end{aligned}\quad (5.29)$$

where

$$\begin{aligned}\delta \mathcal{V} &= -\mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}_1}(\varepsilon; \alpha_*, z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) \\ &\quad + \mathcal{V}_{\mathfrak{S}_2}(\varepsilon; z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) \\ \mathcal{V}_l &= \mathcal{V}_{\mathfrak{S}_1}(\varepsilon; \alpha_*, z + z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) - \mathcal{V}_{\mathfrak{S}_1}(\varepsilon; \alpha_*, z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) \\ \mathcal{V}_r &= \mathcal{V}_{\mathfrak{S}_2}(\varepsilon; z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r) - \mathcal{V}_{\mathfrak{S}_2}(\varepsilon; z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r)\end{aligned}$$

Similarly,

$$\begin{aligned}\mathcal{V}_{\mathfrak{S}_1}\left(\frac{\varepsilon}{2}; \alpha_*, z + z_\delta + \alpha_{\delta}^{\text{cr}}; \dots\right) + \mathcal{V}_{\mathfrak{S}_2}\left(\frac{\varepsilon}{2}; z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \dots\right) \\ = \widetilde{\mathcal{V}}\left(\frac{\varepsilon}{2}\right) + \delta \widetilde{\mathcal{V}} + \tilde{\mathcal{V}}_l + \tilde{\mathcal{V}}_r\end{aligned}$$

where

$$\begin{aligned}\widetilde{\mathcal{V}} &= -\mathcal{V}_{\mathfrak{S}}\left(\frac{\varepsilon}{2}; \alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}\right) + \mathcal{V}_{\mathfrak{S}_1}\left(\frac{\varepsilon}{2}; \alpha_*, z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l\right) \\ &\quad + \mathcal{V}_{\mathfrak{S}_2}\left(\frac{\varepsilon}{2}; z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r\right) \\ \tilde{\mathcal{V}}_l &= \mathcal{V}_{\mathfrak{S}_1}\left(\frac{\varepsilon}{2}; \alpha_*, z + z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l\right) - \mathcal{V}_{\mathfrak{S}_1}\left(\frac{\varepsilon}{2}; \alpha_*, z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l\right) \\ \tilde{\mathcal{V}}_r &= \mathcal{V}_{\mathfrak{S}_2}\left(\frac{\varepsilon}{2}; z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r\right) - \mathcal{V}_{\mathfrak{S}_2}\left(\frac{\varepsilon}{2}; z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r\right)\end{aligned}$$

Proposition 5.13. Set $K_{\mathcal{V}} = 2^{25}e^{6K_j}$.

(i)

$$\begin{aligned}\|\mathcal{V}_l\|_{\text{fluct}}, \quad \|\mathcal{V}_r\|_{\text{fluct}} &\leq K_{\mathcal{V}} \delta \|v\| r R_+^3 \\ \|\mathcal{V}_l - \tilde{\mathcal{V}}_l\|_{\text{fluct}}, \quad \|\mathcal{V}_r - \tilde{\mathcal{V}}_r\|_{\text{fluct}} &\leq K_{\mathcal{V}} \varepsilon \delta \|v\| r R_+^3\end{aligned}$$

(ii)

$$\begin{aligned}\|\delta \mathcal{V}\|_{\mathfrak{S}} &\leq K_{\mathcal{V}} \delta \|v\| r R_+^3 \\ \|\delta \mathcal{V} - \widetilde{\mathcal{V}}\|_{\mathfrak{S}} &\leq K_{\mathcal{V}} \varepsilon \delta \|v\| r R_+^3\end{aligned}$$

Proof. (i) We treat \mathcal{V}_l . By (5.16), (5.18) and (5.20)

$$\begin{aligned}\Gamma_{*\mathfrak{S}_1}(\tau; \alpha_*, \vec{\alpha}_{*l}) &= \tilde{\Gamma}_*(\tau; \alpha_*, \vec{\alpha}_*) = \Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) = \gamma_{*\tau} \\ \Gamma_{\mathfrak{S}_1}(\tau; \vec{\alpha}_l, z + z_\delta + \alpha_\delta^{\text{cr}}) &= \Gamma_\tau^\delta(\mathfrak{S}_1)z + \Gamma_\tau^\delta(\mathfrak{S}_1)z_\delta + \Gamma_{\mathfrak{S}_1}(\tau; \vec{\alpha}_l, \alpha_\delta^{\text{cr}}) \\ &= \Gamma_\tau^\delta(\mathfrak{S}_1)z + \Gamma_\tau^\delta(\mathfrak{S}_1)z_\delta + \tilde{\Gamma}(\tau; \vec{\alpha}, \beta) \\ &= \Gamma_\tau^\delta(\mathfrak{S}_1)z + \Gamma_\tau^\delta(\mathfrak{S}_1)z_\delta + \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) - \partial_{\mathfrak{c}} \Gamma_{\tau\beta} \\ &= \Gamma_\tau^\delta(\mathfrak{S}_1)z + \Gamma_\tau^\delta(\mathfrak{S}_1)z_\delta + \gamma_\tau - \partial_{\mathfrak{c}} \Gamma_{\tau\beta}\end{aligned}$$

for all $\tau \in (0, \delta)$. When $\tau = 0$, the right hand side $\gamma_{*\tau} = \alpha_*$ and, with the convention $\Gamma_\delta^\delta(\mathfrak{S}_1) = \mathbb{1}$, when $\tau = \delta$ the right hand side $\Gamma_\tau^\delta(\mathfrak{S}_1)z + \Gamma_\tau^\delta(\mathfrak{S}_1)z_\delta + \tilde{\Gamma}(\delta; \vec{\alpha}, \beta) = z + z_\delta + \alpha_\delta^{\text{cr}}$. Similarly,

$$\begin{aligned}\Gamma_{*\mathfrak{S}_2}(\tau - \delta; z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \vec{\alpha}_{*r}) &= \Gamma_{*\tau-\delta}^0(\mathfrak{S}_2)z_* + \Gamma_{*\tau-\delta}^0(\mathfrak{S}_2)z_{*\delta} + \gamma_{*\tau} - \partial_{\mathfrak{c}} \Gamma_{*\tau} \alpha_* \\ \Gamma_{\mathfrak{S}_2}(\tau - \delta; \vec{\alpha}_r, \beta) &= \gamma_\tau\end{aligned}$$

for all $\tau \in (\delta, 2\delta)$. So, by the Definition 3.8.i of $\mathcal{V}_{\mathfrak{S}_1}$,

$$\begin{aligned}\mathcal{V}_{\mathfrak{S}_1}(\varepsilon; \alpha_*, z + z_\delta + \alpha_\delta^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) &= -\varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \langle \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}), v \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}) \rangle\end{aligned}$$

where

$$\begin{aligned}g_\tau &= \Gamma_\tau^\delta(\mathfrak{S}_1)z_\delta + \gamma_\tau - \partial_{\mathfrak{c}} \Gamma_{\tau\beta} \\ g_{*\tau} &= \Gamma_{*\tau-\delta}^0(\mathfrak{S}_2)z_{*\delta} + \gamma_{*\tau} - \partial_{\mathfrak{c}} \Gamma_{*\tau} \alpha_*\end{aligned}\tag{5.30}$$

Consequently,

$$\begin{aligned}\mathcal{V}_l &= -\varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} [\langle \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}), v \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}) \rangle \\ &\quad - \langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle]\end{aligned}\tag{5.31}$$

To each term, we apply Corollary G.3(ii), $r = 4$,

$$h(\gamma_1, \dots, \gamma_4) = \langle \gamma_1 \gamma_2, v \gamma_3 \gamma_4 \rangle \quad \lambda_1 = \lambda_2 = \lambda_3 = \lambda_4 = 1$$

and the s fields $\alpha_1, \dots, \alpha_s$ being $z, z_\delta, \beta, \alpha_*, \alpha_{*\varepsilon}, \dots, \alpha_{*\delta-\varepsilon}, \alpha_\varepsilon, \dots, \alpha_{2\delta-\varepsilon}$. Recalling that

$$\begin{aligned}\gamma_{*\tau} &= \Gamma_{*\tau}^0(\mathfrak{S})\alpha_* + \sum_{\tau' \in \varepsilon \mathbb{Z} \cap (0, \delta)} \Gamma_{*\tau}^{\tau'}(\mathfrak{S})\alpha_{*\tau'} \\ g_{\tau+\varepsilon} &= \Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z_\delta + \sum_{\tau'' \in \varepsilon \mathbb{Z} \cap (0, 2\delta)} \Gamma_{\tau+\varepsilon}^{\tau''}(\mathfrak{S})\alpha_{\tau''} + \Gamma_{\tau+\varepsilon}^{2\delta}(\mathfrak{S})\beta - \partial_{\mathfrak{c}} \Gamma_{\tau+\varepsilon}\beta\end{aligned}$$

we have, as coefficients for the substitution,

$$\begin{aligned}\Gamma_1^{\alpha_*} &= \Gamma_3^{\alpha_*} = \Gamma_{*\tau}^0(\mathfrak{S}) &= \tilde{\Gamma}_1^{\alpha_*} = \tilde{\Gamma}_3^{\alpha_*} \\ \Gamma_1^{\alpha_{*\tau'}} &= \Gamma_3^{\alpha_{*\tau'}} = \Gamma_{*\tau}^{\tau'}(\mathfrak{S}) &= \tilde{\Gamma}_1^{\alpha_{*\tau'}} = \tilde{\Gamma}_3^{\alpha_{*\tau'}} \\ \Gamma_2^z &= \Gamma_4^z = \Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)\Omega &= \tilde{\Gamma}_2^z = \tilde{\Gamma}_4^z = 0 \\ \Gamma_2^{z_\delta} &= \Gamma_4^{z_\delta} = \Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)(\Lambda \setminus \Omega) &= \tilde{\Gamma}_2^{z_\delta} = \tilde{\Gamma}_4^{z_\delta} \\ \Gamma_2^\beta &= \Gamma_4^\beta = \Gamma_{\tau+\varepsilon}^{2\delta}(\mathfrak{S}) - \partial_{\mathfrak{c}} \Gamma_{\tau+\varepsilon} &= \tilde{\Gamma}_2^\beta = \tilde{\Gamma}_4^\beta \\ \Gamma_2^{\alpha_{\tau''}} &= \Gamma_4^{\alpha_{\tau''}} = \Gamma_{\tau+\varepsilon}^{\tau''}(\mathfrak{S}) &= \tilde{\Gamma}_2^{\alpha_{\tau''}} = \tilde{\Gamma}_4^{\alpha_{\tau''}}\end{aligned}$$

with $\tau' \in \varepsilon\mathbb{Z} \cap (0, \delta)$, $\tau'' \in \varepsilon\mathbb{Z} \cap (0, 2\delta)$ and with all other Γ_i^j 's and $\tilde{\Gamma}_i^j$'s being zero. We apply Corollary G.3(ii) with $L = \Lambda$, d replaced by $4md$, $d' = d_\Omega$ and $\delta = \frac{m}{2}d$. The Corollary gives

$$\begin{aligned} & \left\| \langle \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}), v \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}) \rangle \right. \\ & \quad \left. - \langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle \right\|_{\text{fluct}} \leq 4 \|v\| \sigma_\delta \sigma^3 \end{aligned}$$

where

$$\begin{aligned} \sigma &\leq \max \{\sigma_{*\tau}, \sigma_{\tau+\varepsilon}\} \\ \sigma_\delta &\leq N_{d_\Omega} \left(\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1) \Omega; e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \tilde{\lambda} \right) \end{aligned}$$

with

$$\begin{aligned} \sigma_{*\tau} &= \sum_{\tau' \in [0, \delta]} N_{d_\Omega} \left(\Gamma_{*\tau'}^\tau(\mathfrak{S}); e^{\frac{m}{2}d(\mathbf{x}, \Lambda)}, \kappa_{*\tau'} \right) \\ \sigma_\tau &= N_{d_\Omega} \left(\Gamma_\tau^\delta(\mathfrak{S}_1) \Omega; e^{\frac{m}{2}d(\mathbf{x}, \Lambda)}, \tilde{\lambda} \right) + N_{d_\Omega} \left(\Gamma_\tau^\delta(\mathfrak{S}_1)(\Lambda \setminus \Omega); e^{\frac{m}{2}d(\mathbf{x}, \Lambda)}, \lambda_\delta \right) \\ &\quad + N_{d_\Omega} \left(\partial_\mathbf{c} \Gamma_\tau; e^{\frac{m}{2}d(\mathbf{x}, \Lambda)}, \kappa_{2\delta} \right) + \sum_{\tau'' \in (0, 2\delta]} N_{d_\Omega} \left(\Gamma_{\tau''}^\tau(\mathfrak{S}); e^{\frac{m}{2}d(\mathbf{x}, \Lambda)}, \kappa_{\tau''} \right) \end{aligned}$$

Below we prove that

$$\begin{aligned} \sigma_\delta &\leq 32e^{K_j} r \\ \sigma_{*\tau} &\leq 16e^{K_j \tau} R_+ \\ \sigma_\tau &\leq 32e^{K_j} R_+ \end{aligned} \tag{5.32}$$

Consequently, the fluctuation norm of each term in (5.31) is bounded by

$$4 \|v\| (32e^{K_j} r) (32e^{K_j} R_+)^3 \leq 2^{22} e^{4K_j} \|v\| r R_+^3$$

Summing over τ and multiplying by ε gives the desired bound on \mathcal{V}_l .

By (5.31),

$$\mathcal{V}_l - \tilde{\mathcal{V}}_l = \mathcal{W}_1 + \mathcal{W}_2$$

where

$$\begin{aligned} \mathcal{W}_1 &= -\frac{\varepsilon}{2} \sum_{\tau \in \varepsilon\mathbb{Z} \cap [0, \delta)} [\langle \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}), v \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}) \rangle \\ &\quad - \langle \gamma_{*\tau} \left(\Gamma_{\tau+\frac{\varepsilon}{2}}^\delta(\mathfrak{S}_1)z + g_{\tau+\frac{\varepsilon}{2}} \right), v \gamma_{*\tau} \left(\Gamma_{\tau+\frac{\varepsilon}{2}}^\delta(\mathfrak{S}_1)z + g_{\tau+\frac{\varepsilon}{2}} \right) \rangle \\ &\quad - \langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle + \langle \gamma_{*\tau} g_{\tau+\frac{\varepsilon}{2}}, v \gamma_{*\tau} g_{\tau+\frac{\varepsilon}{2}} \rangle] \end{aligned}$$

and

$$\begin{aligned} \mathcal{W}_2 &= -\frac{\varepsilon}{2} \sum_{\tau \in \varepsilon\mathbb{Z} \cap [0, \delta)} [\langle \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}), v \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}) \rangle \\ &\quad - \langle \gamma_{*\tau+\frac{\varepsilon}{2}} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}), v \gamma_{*\tau+\frac{\varepsilon}{2}} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}) \rangle \\ &\quad - \langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle + \langle \gamma_{*\tau+\frac{\varepsilon}{2}} g_{\tau+\varepsilon}, v \gamma_{*\tau+\frac{\varepsilon}{2}} g_{\tau+\varepsilon} \rangle] \end{aligned}$$

By Lemma E.14, (5.30), (5.19) and Remark E.19,

$$\Gamma_{\tau+\frac{\varepsilon}{2}}^\delta(\mathfrak{S}_1) = j\left(\frac{\varepsilon}{2}\right)\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1) \quad g_{\tau+\frac{\varepsilon}{2}} = j\left(\frac{\varepsilon}{2}\right)g_{\tau+\varepsilon} \quad \gamma_{*\tau+\frac{\varepsilon}{2}} = j\left(\frac{\varepsilon}{2}\right)\gamma_{*\tau}$$

for all $\tau \in \varepsilon\mathbb{Z} \cap [0, \delta]$. Therefore the τ term of \mathcal{W}_1 is

$$\begin{aligned} & \langle \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}), v \gamma_{*\tau} (\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + g_{\tau+\varepsilon}) \rangle \\ & - \langle \gamma_{*\tau} \left(j\left(\frac{\varepsilon}{2}\right)\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + j\left(\frac{\varepsilon}{2}\right)g_{\tau+\varepsilon} \right), \\ & v \gamma_{*\tau} \left(j\left(\frac{\varepsilon}{2}\right)\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)z + j\left(\frac{\varepsilon}{2}\right)g_{\tau+\varepsilon} \right) \rangle \\ & - \langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle + \langle \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right)g_{\tau+\varepsilon}, v \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right)g_{\tau+\varepsilon} \rangle \end{aligned}$$

We again apply Corollary G.3, this time part (iii), but with the same metrics, h , Γ_i^j 's and $\tilde{\Gamma}_i^j$'s as before and with, in addition,

$$A_1 = \tilde{A}_1 = A_3 = \tilde{A}_3 = \mathbf{1} \quad A_2 = A_4 = \mathfrak{h} \quad \tilde{A}_2 = \tilde{A}_4 = j\left(\frac{\varepsilon}{2}\right)$$

The corollary bounds the fluctuation norm of the τ term by $16 \|v\| \sigma_\delta a_\delta (\sigma a)^3$ where

$$\begin{aligned} a &\leq \max \left\{ \| \mathbf{1} \|, \| j\left(\frac{\varepsilon}{2}\right) \| \right\} \leq e^{K_j \frac{\varepsilon}{2}} \\ a_\delta &\leq \| j\left(\frac{\varepsilon}{2}\right) - \mathfrak{h} \| = K_j \frac{\varepsilon}{2} e^{K_j \frac{\varepsilon}{2}} \end{aligned} \tag{5.33}$$

by Lemma 3.21. By this and (5.32)

$$\begin{aligned} 16 \|v\| \sigma_\delta a_\delta (\sigma a)^3 &\leq 16 \|v\| (32e^{K_j} r) \left(K_j \frac{\varepsilon}{2} e^{K_j \frac{\varepsilon}{2}} \right) (32e^{K_j} R_+ e^{K_j \frac{\varepsilon}{2}})^3 \\ &\leq 2^{23} e^{6K_j} \varepsilon \|v\| r R_+^3 \end{aligned}$$

Summing over τ and multiplying by $\frac{\varepsilon}{2}$ shows that

$$\|\mathcal{W}_1\|_{\text{fluct}} \leq 2^{22} e^{6K_j} \varepsilon \delta \|v\| r R_+^3$$

The same bound applies to $\|\mathcal{W}_2\|_{\text{fluct}}$. This gives the desired bound on $\mathcal{V}_l - \tilde{\mathcal{V}}_l$.

Finally, we prove (5.32). By (3.7) and Lemma E.13,

$$\begin{aligned} \sum_{\tau' \in [0, 2\delta)} N_{d_\Omega} \left(\Gamma_{*\tau'}^\tau(\mathfrak{S}); e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{*\tau'} \right) &\leq 16e^{K_j \tau} R_+ \\ \sum_{\tau' \in (0, 2\delta]} N_{d_\Omega} \left(\Gamma_{\tau'}^\tau(\mathfrak{S}); e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{\tau'} \right) &\leq 16e^{K_j \tau} R_+ \end{aligned} \tag{5.34}$$

This gives the second line of (5.32).

If \mathcal{J} is the smallest decimation interval that strictly contains $[\tau, \delta]$ and has δ as its right endpoint and if $\tau_{\mathcal{J}}$ denotes the midpoint of \mathcal{J} , then

$$\begin{aligned} N_{d_\Omega} \left(\Gamma_\tau^\delta(\mathfrak{S}_1) \Omega; e^{-\frac{3}{2} m d(\mathbf{x}, \Lambda)}, \tilde{\lambda} \right) \\ = N_{d_\Omega} \left(j(\tau_{\mathcal{J}} - \tau) \Lambda(\mathcal{J}) j(\delta - \tau_{\mathcal{J}}) \Omega; e^{-\frac{3}{2} m d(\mathbf{x}, \Lambda)}, \tilde{\lambda} \right) \\ \leq 32r \|j(\tau_{\mathcal{J}} - \tau)\| \|j(\delta - \tau_{\mathcal{J}})\| \\ \leq 32e^{K_j} r \end{aligned} \tag{5.35}$$

by (3.7) and Lemma G.5(ii) with d replaced by d_Ω , R replaced by $32r$ and

$$\begin{aligned} L_1 &= X, \quad L_2 = \Lambda(\mathcal{J}), \quad L_3 = \Omega, \quad O_1 = \Lambda, \quad O_2 = X \\ \delta_1 &= \frac{3}{2}md, \quad \delta_2 = 0, \quad \delta = 0, \quad \tilde{d} = 4md, \quad \kappa = \tilde{\lambda} \end{aligned}$$

(The hypothesis that $\kappa(\mathbf{x}) = \tilde{\lambda}(\mathbf{x}) \leq R = 32r$ for all $\mathbf{x} \in L_3 = \Omega$ is fulfilled by the definition (5.12) of $\tilde{\lambda}$). This gives the first line of (5.32).

Similarly

$$\begin{aligned} N_{d_\Omega} \left(\Gamma_\tau^\delta(\mathfrak{S}_1)(\Lambda \setminus \Omega); e^{\frac{m}{2}d(\mathbf{x}, \Lambda)}, \lambda_\delta \right) \\ \leq N_{d_\Omega} \left(\Gamma_\tau^\delta(\mathfrak{S}_1)(\Lambda \setminus \Omega); e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \lambda_\delta \right) \leq 32 e^{K_j} r \end{aligned} \quad (5.36)$$

By Lemma E.18

$$\begin{aligned} N_{d_\Omega} \left(\partial_c \Gamma_\tau; e^{\frac{m}{2}d(\mathbf{x}, \Lambda)}, \kappa_{2\delta} \right) &\leq N_{d_\Omega} \left(\partial_c \Gamma_\tau; e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{2\delta} \right) \\ &\leq 4 e^{2K_j} R_+ \left(\delta e^{-m c} + e^{-mc(\delta)} \right) \end{aligned} \quad (5.37)$$

Combining these two bounds with (5.34) and (5.35) gives

$$\begin{aligned} \sigma_\tau &\leq 32 e^{K_j} r + 32 e^{K_j} r + 4 e^{2K_j} R_+ \left(\delta e^{-m c} + e^{-mc(\delta)} \right) + 16 e^{K_j \tau} R_+ \\ &\leq 32 e^{K_j} R_+ \end{aligned}$$

This completes the proof of part (i) of the proposition.

(ii) With the notation (5.30) we have

$$\delta \mathcal{V} = \delta \mathcal{V}_1(\varepsilon) + \delta \mathcal{V}_2(\varepsilon)$$

where

$$\delta \mathcal{V}_1(\varepsilon) = \varepsilon \sum_{\tau \in [0, \delta]} \{ \langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle - \langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle \}$$

$$\delta \mathcal{V}_2(\varepsilon) = \varepsilon \sum_{\tau \in [\delta, 2\delta]} \{ \langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle - \langle g_{*\tau} \gamma_{\tau+\varepsilon}, v g_{*\tau} \gamma_{\tau+\varepsilon} \rangle \}$$

We bound $\delta \mathcal{V}_1$. To treat the τ^{th} term, we again apply Corollary G.3.ii with $r = 4$,

$$h(\gamma_1, \dots, \gamma_4) = \langle \gamma_1 \gamma_2, v \gamma_3 \gamma_4 \rangle \quad \lambda_1 = \lambda_2 = \lambda_3 = \lambda_4 = 1$$

This time the s fields $\alpha_1, \dots, \alpha_s$ are $z_\delta, \beta, \alpha_*, \alpha_{*\varepsilon}, \dots, \alpha_{*\delta-\varepsilon}, \alpha_\varepsilon, \dots, \alpha_{2\delta-\varepsilon}$. Recalling that

$$\begin{aligned} \gamma_{*\tau} &= \Gamma_{*\tau}^0(\mathfrak{S}) \alpha_* + \sum_{\tau' \in \varepsilon \mathbb{Z} \cap (0, \delta)} \Gamma_{*\tau}^{\tau'}(\mathfrak{S}) \alpha_{*\tau'} \\ \gamma_{\tau+\varepsilon} &= \sum_{\tau' \in \varepsilon \mathbb{Z} \cap (0, 2\delta)} \Gamma_{\tau+\varepsilon}^{\tau'}(\mathfrak{S}) \alpha_{\tau'} + \Gamma_{\tau+\varepsilon}^{2\delta}(\mathfrak{S}) \beta \\ g_{\tau+\varepsilon} &= \Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1) z_\delta + \sum_{\tau' \in \varepsilon \mathbb{Z} \cap (0, 2\delta)} \Gamma_{\tau+\varepsilon}^{\tau'}(\mathfrak{S}) \alpha_{\tau'} + \Gamma_{\tau+\varepsilon}^{2\delta}(\mathfrak{S}) \beta - \partial_c \Gamma_{\tau+\varepsilon} \beta \end{aligned}$$

we have, as coefficients for the substitution,

$$\begin{aligned} \Gamma_1^{\alpha_*} &= \Gamma_3^{\alpha_*} = \Gamma_{*\tau}^0(\mathfrak{S}) = \tilde{\Gamma}_1^{\alpha_*} = \tilde{\Gamma}_3^{\alpha_*} \\ \Gamma_1^{\alpha_{*\tau'}} &= \Gamma_3^{\alpha_{*\tau'}} = \Gamma_{*\tau'}^0(\mathfrak{S}) = \tilde{\Gamma}_1^{\alpha_{*\tau'}} = \tilde{\Gamma}_3^{\alpha_{*\tau'}} \\ \Gamma_2^{z\delta} &= \Gamma_4^{z\delta} = 0 & \tilde{\Gamma}_2^{z\delta} = \tilde{\Gamma}_4^{z\delta} = \Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)(\Lambda \setminus \Omega) \\ \Gamma_2^\beta &= \Gamma_4^\beta = \Gamma_{\tau+\varepsilon}^{2\delta}(\mathfrak{S}) & \tilde{\Gamma}_2^\beta = \tilde{\Gamma}_4^\beta = \Gamma_{\tau+\varepsilon}^{2\delta}(\mathfrak{S}) - \partial_\mathbf{c} \Gamma_{\tau+\varepsilon} \\ \Gamma_2^{\alpha_{\tau''}} &= \Gamma_4^{\alpha_{\tau''}} = \Gamma_{\tau+\varepsilon}^{\alpha_{\tau''}}(\mathfrak{S}) = \tilde{\Gamma}_2^{\alpha_{\tau''}} = \tilde{\Gamma}_4^{\alpha_{\tau''}} \end{aligned} \quad (5.38)$$

with $\tau' \in \varepsilon\mathbb{Z} \cap (0, \delta)$, $\tau'' \in \varepsilon\mathbb{Z} \cap (0, 2\delta)$ and with all other Γ_i^j 's and $\tilde{\Gamma}_i^j$'s being zero. We apply Corollary G.3(ii) with $L = \Lambda$, d replaced by $4md$, $d' = d_\Omega$ and $\delta = \frac{m}{2}d$. The Corollary gives

$$\|\langle \gamma_{*\tau}\gamma_{\tau+\varepsilon}, v \rangle - \langle \gamma_{*\tau}g_{\tau+\varepsilon}, v \rangle\|_{\text{fluct}} \leq 4\|v\| \sigma'_\delta \sigma'^3$$

where

$$\begin{aligned} \sigma' &\leq \max\{\sigma'_{*\tau}, \sigma'_{\tau+\varepsilon}\} \\ \sigma'_\delta &= N_{d_\Omega} \left(\Gamma_{\tau+\varepsilon}^\delta(\mathfrak{S}_1)(\Lambda \setminus \Omega); e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \lambda_\delta \right) + N_{d_\Omega} \left(\partial_\mathbf{c} \Gamma_\tau; e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{2\delta} \right) \\ &\leq 32e^{K_j} r + 4e^{2K_j} R_+ \left(\delta e^{-mc} + e^{-mc(\delta)} \right) \quad \text{by (5.36) and (5.37)} \end{aligned}$$

with

$$\begin{aligned} \sigma'_{*\tau} &= \sum_{\tau' \in [0, \delta]} N_{d_\Omega} \left(\Gamma_{*\tau}^{\tau'}(\mathfrak{S}); e^{\frac{m}{2}d(\mathbf{x}, \Lambda)}, \kappa_{*\tau'} \right) = \sigma_{*\tau} \leq 16e^{K_j} R_+ \\ \sigma'_\tau &= N_{d_\Omega} \left(\Gamma_\tau^\delta(\mathfrak{S}_1)(\Lambda \setminus \Omega); e^{\frac{m}{2}d(\mathbf{x}, \Lambda)}, \lambda_\delta \right) + N_{d_\Omega} \left(\partial_\mathbf{c} \Gamma_\tau; e^{\frac{m}{2}d(\mathbf{x}, \Lambda)}, \kappa_{2\delta} \right) \\ &\quad + \sum_{\tau'' \in (0, 2\delta]} N_{d_\Omega} \left(\Gamma_\tau^{\tau''}(\mathfrak{S}); e^{\frac{m}{2}d(\mathbf{x}, \Lambda)}, \kappa_{\tau''} \right) \\ &\leq \sigma_\tau \leq 32e^{K_j} R_+ \end{aligned}$$

by (5.32), twice. Hence

$$\begin{aligned} &\|\langle \gamma_{*\tau}\gamma_{\tau+\varepsilon}, v \rangle - \langle \gamma_{*\tau}g_{\tau+\varepsilon}, v \rangle\|_{\text{fluct}} \\ &\leq 4\|v\| \left[32e^{K_j} r + 4e^{2K_j} R_+ \left(\delta e^{-mc} + e^{-mc(\delta)} \right) \right] \left[32e^{K_j} R_+ \right]^3 \\ &\leq 2^{22} e^{4K_j} \|v\| \left[r + e^{K_j} R_+ \left(\delta e^{-mc} + e^{-mc(\delta)} \right) \right] R_+^3 \\ &\leq 2^{23} e^{4K_j} \|v\| r R_+^3 \end{aligned} \quad (5.39)$$

by (F.4b), (F.6a) and (F.6b). Summing over τ and multiplying by ε bounds $\|\delta\mathcal{V}_1\|_{\text{fluct}}$ by $2^{23} e^{4K_j} \delta \|v\| r R_+^3$. The δV_2 contribution obeys the same bound.

We now move onto the bound of $\|\delta\mathcal{V} - \widetilde{\delta\mathcal{V}}\|_{\mathfrak{S}}$. Then

$$\delta\mathcal{V} - \widetilde{\delta\mathcal{V}} = \delta\mathcal{V}_1(\varepsilon) - \delta\mathcal{V}_1\left(\frac{\varepsilon}{2}\right) + \delta\mathcal{V}_2(\varepsilon) - \delta\mathcal{V}_2\left(\frac{\varepsilon}{2}\right)$$

Write

$$\delta\mathcal{V}_1(\varepsilon) - \delta\mathcal{V}_1\left(\frac{\varepsilon}{2}\right) = \delta\mathcal{W}_1 + \delta\mathcal{W}_2$$

where

$$\begin{aligned} \delta\mathcal{W}_1(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) &= \frac{\varepsilon}{2} \sum_{\tau \in \varepsilon\mathbb{Z} \cap [0, \delta)} [\langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle \\ &\quad - \langle \gamma_{*\tau} \gamma_{\tau+\frac{\varepsilon}{2}}, v \gamma_{*\tau} \gamma_{\tau+\frac{\varepsilon}{2}} \rangle - \langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle + \langle \gamma_{*\tau} g_{\tau+\frac{\varepsilon}{2}}, v \gamma_{*\tau} g_{\tau+\frac{\varepsilon}{2}} \rangle] \\ \delta\mathcal{W}_2(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) &= \frac{\varepsilon}{2} \sum_{\tau \in \varepsilon\mathbb{Z} \cap [0, \delta)} [\langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle - \langle \gamma_{*\tau+\frac{\varepsilon}{2}} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau+\frac{\varepsilon}{2}} \gamma_{\tau+\varepsilon} \rangle \\ &\quad - \langle g_{*\tau} \gamma_{\tau+\varepsilon}, v g_{*\tau} \gamma_{\tau+\varepsilon} \rangle + \langle g_{*\tau+\frac{\varepsilon}{2}} \gamma_{\tau+\varepsilon}, v g_{*\tau+\frac{\varepsilon}{2}} \gamma_{\tau+\varepsilon} \rangle] \end{aligned}$$

We estimate $\delta\mathcal{W}_1$. The term of $\delta\mathcal{W}_1$ with index τ is

$$\begin{aligned} &[\langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle - \left\langle \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) \gamma_{\tau+\varepsilon} \right\rangle \\ &\quad - \langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle + \left\langle \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) g_{\tau+\varepsilon}, v \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) g_{\tau+\varepsilon} \right\rangle] \end{aligned}$$

since, by Lemma E.14, (5.30), (5.19) and Remark E.19,

$$\gamma_{\tau+\frac{\varepsilon}{2}} = j\left(\frac{\varepsilon}{2}\right) \gamma_{\tau+\varepsilon} \quad g_{\tau+\frac{\varepsilon}{2}} = j\left(\frac{\varepsilon}{2}\right) g_{\tau+\varepsilon}$$

We again apply Corollary G.3 with the Γ_i^j 's and $\tilde{\Gamma}_i^j$'s of (5.38). This time we use part (iii) with

$$A_1 = \tilde{A}_1 = A_3 = \tilde{A}_3 = \mathbf{1} \quad A_2 = A_4 = \mathfrak{h} \quad \tilde{A}_2 = \tilde{A}_4 = j\left(\frac{\varepsilon}{2}\right)$$

as coefficients for the substitution. The Corollary, with $L = \Lambda$, d replaced by $4md$, $d' = d_\Omega$ and $\delta = \frac{m}{2}d$, gives

$$\begin{aligned} &\left\| \langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle - \left\langle \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) \gamma_{\tau+\varepsilon} \right\rangle \right. \\ &\quad \left. - \langle \gamma_{*\tau} g_{\tau+\varepsilon}, v \gamma_{*\tau} g_{\tau+\varepsilon} \rangle + \left\langle \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) g_{\tau+\varepsilon}, v \gamma_{*\tau} j\left(\frac{\varepsilon}{2}\right) g_{\tau+\varepsilon} \right\rangle \right\|_{\text{fluct}} \\ &\leq 16 \|v\| \sigma'_\delta a_\delta (\sigma' a)^3 \end{aligned}$$

where, by Lemma 3.21,

$$\begin{aligned} a &\leq \max \left\{ \|\mathbf{1}\|, \|j\left(\frac{\varepsilon}{2}\right)\| \right\} \leq e^{K_j \frac{\varepsilon}{2}} \\ a_\delta &\leq \|j\left(\frac{\varepsilon}{2}\right) - \mathfrak{h}\| = K_j \frac{\varepsilon}{2} e^{K_j \frac{\varepsilon}{2}} \end{aligned}$$

Thus

$$\begin{aligned} \|\delta\mathcal{W}_1\|_{\text{fluct}} &\leq \frac{\varepsilon}{2} \frac{\delta}{\varepsilon} 16 \|v\| \sigma'_\delta a_\delta (\sigma' a)^3 \\ &\leq \varepsilon \delta K_j e^{2K_j \varepsilon} 4 \|v\| \sigma'_\delta \sigma'^3 \leq 2^{23} e^{6K_j} \varepsilon \delta \|v\| \text{rR}_+^3 \end{aligned}$$

since the right hand side of (5.39) is a bound on $4 \|v\| \sigma'_\delta \sigma'^3$. The bounds on $\delta\mathcal{W}_1$ and the two corresponding terms of $\delta\mathcal{V}_2(\varepsilon) - \delta\mathcal{V}_2\left(\frac{\varepsilon}{2}\right)$ are the same. \square

The Structure of the Fluctuation Integrand

Proposition 5.14. *The function $f_{\mathfrak{S}}(\alpha_*, \beta; \vec{\rho}; z_*, z)$ of (5.8) that appears in Lemma 5.4 and the function $\tilde{f}_{\mathfrak{S}}$ of (5.9) can be written in the form*

$$\begin{aligned} f_{\mathfrak{S}}(\alpha_*, \beta; \vec{\rho}; z_*, z) &= -Q_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) + \mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \\ &\quad + \mathcal{F}_l(\alpha_*, \beta; \vec{\rho}; z) + \mathcal{F}_r(\alpha_*, \beta; \vec{\rho}; z_*) + \mathcal{D}^{(1)}(\alpha_*, \beta; \vec{\rho}) + \mathcal{L}'_{\mathfrak{S}}(\alpha_*, \beta; \vec{\rho}) \end{aligned}$$

and

$$\tilde{f}_{\mathfrak{S}} = -Q_{\mathfrak{S}} + \mathcal{V}_{\mathfrak{S}}\left(\frac{\varepsilon}{2}; \dots\right) + \tilde{\mathcal{F}}_l + \tilde{\mathcal{F}}_r + \tilde{\mathcal{D}}^{(1)} + \tilde{\mathcal{L}}'_{\mathfrak{S}}$$

respectively, with history complete analytic functions $\mathcal{F}_l, \mathcal{F}_r, \mathcal{D}^{(1)}, \mathcal{L}'_{\mathfrak{S}}, \tilde{\mathcal{F}}_l, \tilde{\mathcal{F}}_r, \tilde{\mathcal{D}}^{(1)}, \tilde{\mathcal{L}}'_{\mathfrak{S}}$ that have the following properties.

(i) $\mathcal{F}_l(\alpha_*, \beta; \vec{\rho}; 0) = \mathcal{F}_r(\alpha_*, \beta; \vec{\rho}; 0) = 0$ and

$$\begin{aligned} \|\mathcal{F}_l\|_{\text{fluct}} &\leq K_V \delta \mathfrak{v} r R_+^3 + 2^8 \left(e^{-mc(\delta)} \|\mathcal{D}_1\|_{\mathfrak{S}_1} + \left\| \mathcal{D}_1 \Big|_{\Omega_1} \right\|_{\mathfrak{S}_1} \right) \\ \|\mathcal{F}_r\|_{\text{fluct}} &\leq K_V \delta \mathfrak{v} r R_+^3 + 2^8 \left(e^{-mc(\delta)} \|\mathcal{D}_2\|_{\mathfrak{S}_2} + \left\| \mathcal{D}_2 \Big|_{\Omega_2} \right\|_{\mathfrak{S}_2} \right) \end{aligned}$$

Similarly, $\tilde{\mathcal{F}}_l(\alpha_*, \beta; \vec{\rho}; 0) = \tilde{\mathcal{F}}_r(\alpha_*, \beta; \vec{\rho}; 0) = 0$ and

$$\begin{aligned} \|\tilde{\mathcal{F}}_l\|_{\text{fluct}} &\leq K_V \delta \mathfrak{v} r R_+^3 + 2^8 \left(e^{-mc(\delta)} \|\tilde{\mathcal{D}}_1\|_{\mathfrak{S}_1} + \left\| \tilde{\mathcal{D}}_1 \Big|_{\Omega_1} \right\|_{\mathfrak{S}_1} \right) \\ \|\tilde{\mathcal{F}}_r\|_{\text{fluct}} &\leq K_V \delta \mathfrak{v} r R_+^3 + 2^8 \left(e^{-mc(\delta)} \|\tilde{\mathcal{D}}_2\|_{\mathfrak{S}_2} + \left\| \tilde{\mathcal{D}}_2 \Big|_{\Omega_2} \right\|_{\mathfrak{S}_2} \right) \end{aligned}$$

Furthermore

$$\begin{aligned} \|\mathcal{F}_l - \tilde{\mathcal{F}}_l\|_{\text{fluct}} &\leq K_V \varepsilon \delta \mathfrak{v} r R_+^3 + 2^8 \left(e^{-mc(\delta)} \left\| \mathcal{D}_1 - \tilde{\mathcal{D}}_1 \right\|_{\mathfrak{S}_1} + \left\| (\mathcal{D}_1 - \tilde{\mathcal{D}}_1) \Big|_{\Omega_1} \right\|_{\mathfrak{S}_1} \right) \\ \|\mathcal{F}_r - \tilde{\mathcal{F}}_r\|_{\text{fluct}} &\leq K_V \varepsilon \delta \mathfrak{v} r R_+^3 + 2^8 \left(e^{-mc(\delta)} \left\| \mathcal{D}_2 - \tilde{\mathcal{D}}_2 \right\|_{\mathfrak{S}_2} + \left\| (\mathcal{D}_2 - \tilde{\mathcal{D}}_2) \Big|_{\Omega_2} \right\|_{\mathfrak{S}_2} \right) \end{aligned}$$

(ii) $\mathcal{D}^{(1)} \Big|_{\Omega^c} = \tilde{\mathcal{D}}^{(1)} \Big|_{\Omega^c} = 0$ and

$$\begin{aligned} \|\mathcal{D}^{(1)}\|_{\mathfrak{S}} &\leq K_V (2\delta \mathfrak{v}) r_+ R_+^3 + 2^8 e^{-mc(\delta)} \Sigma_{\mathcal{D}} + 2^8 \Sigma_{\mathcal{D}}^{(SF)} \\ \|\tilde{\mathcal{D}}^{(1)}\|_{\mathfrak{S}} &\leq K_V (2\delta \mathfrak{v}) r_+ R_+^3 + 2^8 e^{-mc(\delta)} \tilde{\Sigma}_{\mathcal{D}} + 2^8 \tilde{\Sigma}_{\mathcal{D}}^{(SF)} \end{aligned}$$

where

$$\begin{aligned} \Sigma_{\mathcal{D}} &= \|\mathcal{D}_1\|_{\mathfrak{S}_1} + \|\mathcal{D}_2\|_{\mathfrak{S}_2} & \Sigma_{\mathcal{D}}^{(SF)} &= \left\| \mathcal{D}_1 \Big|_{\Omega_1} \right\|_{\mathfrak{S}_1} + \left\| \mathcal{D}_2 \Big|_{\Omega_2} \right\|_{\mathfrak{S}_2} \\ \tilde{\Sigma}_{\mathcal{D}} &= \|\tilde{\mathcal{D}}_1\|_{\mathfrak{S}_1} + \|\tilde{\mathcal{D}}_2\|_{\mathfrak{S}_2} & \tilde{\Sigma}_{\mathcal{D}}^{(SF)} &= \left\| \tilde{\mathcal{D}}_1 \Big|_{\Omega_1} \right\|_{\mathfrak{S}_1} + \left\| \tilde{\mathcal{D}}_2 \Big|_{\Omega_2} \right\|_{\mathfrak{S}_2} \end{aligned}$$

Furthermore

$$\|\mathcal{D}^{(1)} - \tilde{\mathcal{D}}^{(1)}\|_{\mathfrak{S}} \leq K_V \varepsilon \delta \mathfrak{v} r R_+^3 + 2^8 e^{-mc(\delta)} \Delta_{\mathcal{D}} + 2^8 \Delta_{\mathcal{D}}^{(SF)}$$

where

$$\begin{aligned}\Delta_{\mathcal{D}} &= \|\mathcal{D}_1 - \tilde{\mathcal{D}}_1\|_{\mathfrak{S}_1} + \|\mathcal{D}_2 - \tilde{\mathcal{D}}_2\|_{\mathfrak{S}_2} \\ \Delta_{\mathcal{D}}^{(SF)} &= \left\| (\mathcal{D}_1 - \tilde{\mathcal{D}}_1) \Big|_{\Omega_1} \right\|_{\mathfrak{S}_1} + \left\| (\mathcal{D}_2 - \tilde{\mathcal{D}}_2) \Big|_{\Omega_2} \right\|_{\mathfrak{S}_2}\end{aligned}$$

(iii) $\mathcal{L}'_{\mathfrak{S}} \Big|_{\Omega^c} = \mathcal{L}'_{\mathfrak{S}}$ and $\tilde{\mathcal{L}}'_{\mathfrak{S}} \Big|_{\Omega^c} = \tilde{\mathcal{L}}'_{\mathfrak{S}}$ and

$$\begin{aligned}\|\mathcal{L}'_{\mathfrak{S}}\|_{\mathfrak{S}} &\leq K_{\mathcal{V}} (2\delta \mathfrak{v}) r_+ R_+^3 + 2^8 \Sigma_{\mathcal{D}} \\ \|\tilde{\mathcal{L}}'_{\mathfrak{S}}\|_{\mathfrak{S}} &\leq K_{\mathcal{V}} (2\delta \mathfrak{v}) r_+ R_+^3 + 2^8 \tilde{\Sigma}_{\mathcal{D}}\end{aligned}$$

and

$$\left\| \mathcal{L}'_{\mathfrak{S}} - \tilde{\mathcal{L}}'_{\mathfrak{S}} \right\|_{\mathfrak{S}} \leq K_{\mathcal{V}} \varepsilon \delta \mathfrak{v} r R_+^3 + 2^8 \Delta_{\mathcal{D}}$$

Proof. We set

$$\begin{aligned}\mathcal{F}_l(\alpha_*, \beta; \vec{p}; z) &= -[\langle \Omega j_{\mathfrak{c}}(\delta) \alpha_*, z \rangle + Q_{\mathfrak{S}_1}(\alpha_*, z; \vec{\alpha}_{*l}, 0)] + \mathcal{V}_l(\varepsilon; \alpha_*, \beta; \vec{p}; z) \\ &\quad + \mathcal{D}_1(\alpha_*, z + z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{p}_l) - \tilde{\mathcal{D}}_1(\alpha_*, z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{p}_l) \\ \mathcal{F}_r(\alpha_*, \beta; \vec{p}; z_*) &= -[\langle z_*, \Omega j_{\mathfrak{c}}(\delta) \beta \rangle + Q_{\mathfrak{S}_2}(z_*, \beta; 0, \vec{\alpha}_r)] + \mathcal{V}_r(\varepsilon; \alpha_*, \beta; \vec{p}; z_*) \\ &\quad + \mathcal{D}_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{p}_r) - \tilde{\mathcal{D}}_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{p}_r) \\ \mathcal{D}'(\alpha_*, \beta; \vec{p}) &= \delta Q(\alpha_*, \beta; \vec{p}) + \delta \mathcal{V}(\varepsilon; \alpha_*, \beta; \vec{p}) \\ &\quad + \mathcal{D}_1(\alpha_*, z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) + \mathcal{D}_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r)\end{aligned}$$

and

$$\mathcal{L}'_{\mathfrak{S}} = \mathcal{D}' \Big|_{\Omega^c}, \quad \mathcal{D}^{(1)} = \mathcal{D}' - \mathcal{L}'_{\mathfrak{S}}$$

The fact that $f_{\mathfrak{S}} = -Q_{\mathfrak{S}} + \mathcal{V}_{\mathfrak{S}} + \mathcal{F}_l + \mathcal{F}_r + \mathcal{D}^{(1)} + \mathcal{L}'_{\mathfrak{S}}$ is immediate from Remark 5.5 and (5.29). Similarly, we set

$$\begin{aligned}\tilde{\mathcal{F}}_l(\alpha_*, \beta; \vec{p}; z) &= -[\langle \Omega j_{\mathfrak{c}}(\delta) \alpha_*, z \rangle + Q_{\mathfrak{S}_1}(\alpha_*, z; \vec{\alpha}_{*l}, 0)] + \mathcal{V}_l\left(\frac{\varepsilon}{2}; \alpha_*, \beta; \vec{p}; z\right) \\ &\quad + \tilde{\mathcal{D}}_1(\alpha_*, z + z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{p}_l) - \tilde{\mathcal{D}}_1(\alpha_*, z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{p}_l) \\ \tilde{\mathcal{F}}_r(\alpha_*, \beta; \vec{p}; z_*) &= -[\langle z_*, \Omega j_{\mathfrak{c}}(\delta) \beta \rangle + Q_{\mathfrak{S}_2}(z_*, \beta; 0, \vec{\alpha}_r)] + \mathcal{V}_r\left(\frac{\varepsilon}{2}; \alpha_*, \beta; \vec{p}; z_*\right) \\ &\quad + \tilde{\mathcal{D}}_2(z_* + z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{p}_r) - \tilde{\mathcal{D}}_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{p}_r) \\ \tilde{\mathcal{D}}'(\alpha_*, \beta; \vec{p}) &= \delta Q(\alpha_*, \beta; \vec{p}) + \widetilde{\delta \mathcal{V}}\left(\frac{\varepsilon}{2}; \alpha_*, \beta; \vec{p}\right) \\ &\quad + \tilde{\mathcal{D}}_1(\alpha_*, z_\delta + \alpha_{\delta}^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) + \tilde{\mathcal{D}}_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r)\end{aligned}$$

and $\tilde{\mathcal{L}}'_{\mathfrak{S}} = \tilde{\mathcal{D}}' \Big|_{\Omega^c}$, $\tilde{\mathcal{D}}^{(1)} = \tilde{\mathcal{D}}' - \tilde{\mathcal{L}}'_{\mathfrak{S}}$.

(i) By Propositions 5.12(i), 5.13(i) and Lemma 5.10, with $g_1 = \mathcal{D}_1$,

$$\begin{aligned}\|\mathcal{F}_l\|_{\text{fluct}} &\leq K_Q \left[e^{-\text{mc}(\delta)} + \delta r R_+ e^{-\text{m} \mathfrak{c}} \right] + K_{\mathcal{V}} \delta \|v\| r R_+^3 \\ &\quad + 2^8 \left(e^{-\text{mc}(\delta)} \|\mathcal{D}_1\|_{\mathfrak{S}_1} + \left\| \mathcal{D}_1 \Big|_{\Omega_1} \right\|_{\mathfrak{S}_1} \right) \\ &\leq K_{\mathcal{V}} \delta r R_+^3 \mathfrak{v} + 2^8 \left(e^{-\text{mc}(\delta)} \|\mathcal{D}_1\|_{\mathfrak{S}_1} + \left\| \mathcal{D}_1 \Big|_{\Omega_1} \right\|_{\mathfrak{S}_1} \right)\end{aligned}$$

by (F.4b), (F.4c) and the hypothesis that $\|v\| \leq \frac{v}{2}$. Also, by construction,

$$\begin{aligned}\mathcal{F}_l - \tilde{\mathcal{F}}_l &= \mathcal{V}_l(\varepsilon; \alpha_*, \beta; \vec{p}; z) - \mathcal{V}_l\left(\frac{\varepsilon}{2}; \alpha_*, \beta; \vec{p}; z\right) \\ &\quad + (\mathcal{D}_1 - \tilde{\mathcal{D}}_1)(\alpha_*, z + z_\delta + \alpha_\delta^{\text{cr}}; \vec{p}_l) - (\mathcal{D}_1 - \tilde{\mathcal{D}}_1)(\alpha_*, z_\delta + \alpha_\delta^{\text{cr}}; \vec{p}_l)\end{aligned}$$

By Proposition 5.13(i) and Lemma 5.10, with $g_1 = \mathcal{D}_1 - \tilde{\mathcal{D}}_1$,

$$\|\mathcal{F}_l - \tilde{\mathcal{F}}_l\|_{\text{fluct}} \leq K_V \varepsilon \delta v r R_+^3 + 2^8 \left(e^{-m\epsilon(\delta)} \left\| \mathcal{D}_1 - \tilde{\mathcal{D}}_1 \right\|_{\mathfrak{S}_1} + \left\| (\mathcal{D}_1 - \tilde{\mathcal{D}}_1)|_{\Omega_1} \right\|_{\mathfrak{S}_1} \right)$$

$\mathcal{D}^{(1)}$ and $\mathcal{L}'_{\mathfrak{S}}$ are constructed so that $\mathcal{D}^{(1)}|_{\Omega^c} = 0$ and $\mathcal{L}'_{\mathfrak{S}} = \mathcal{L}'_{\mathfrak{S}}|_{\Omega^c}$. Also

$$\begin{aligned}\mathcal{D}^{(1)} &= \delta Q - \delta Q|_{\Omega^c} + \delta \mathcal{V} - \delta \mathcal{V}|_{\Omega^c} + \mathcal{D}_1(\alpha_*, z_\delta + \alpha_\delta^{\text{cr}}; \cdot) - \mathcal{D}_1(\alpha_*, z_\delta + \alpha_\delta^{\text{cr}}; \cdot)|_{\Omega^c} \\ &\quad + \mathcal{D}_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \cdot) - \mathcal{D}_2(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \cdot)|_{\Omega^c}\end{aligned}$$

Therefore, by Propositions 5.12(ii), 5.13(ii) and Lemma 5.10

$$\begin{aligned}\|\mathcal{D}^{(1)}\|_{\mathfrak{S}} &\leq K_Q \left[e^{-\frac{1}{4}m\epsilon(\delta)} + \delta r R_+ e^{-m\epsilon} \right] + K_V \delta \|v\| r R_+^3 \\ &\quad + 2^8 \left(e^{-m\epsilon(\delta)} (\|\mathcal{D}_1\|_{\mathfrak{S}_1} + \|\mathcal{D}_2\|_{\mathfrak{S}_2}) + \left(\left\| \mathcal{D}_1|_{\Omega_1} \right\|_{\mathfrak{S}_1} + \left\| \mathcal{D}_2|_{\Omega_2} \right\|_{\mathfrak{S}_2} \right) \right) \\ &\leq K_V 2\delta r_+ R_+^3 v + 2^8 \left(e^{-m\epsilon(\delta)} \Sigma_{\mathcal{D}} + \Sigma_{\mathcal{D}}^{(SF)} \right)\end{aligned}$$

by (F.3b), (F.4b), (F.4c). Also

$$\begin{aligned}\mathcal{D}^{(1)} - \tilde{\mathcal{D}}^{(1)} &= \left(\delta \mathcal{V} - \widetilde{\delta \mathcal{V}} \right) - \left(\delta \mathcal{V} - \widetilde{\delta \mathcal{V}} \right)|_{\Omega^c} \\ &\quad + (\mathcal{D}_1 - \tilde{\mathcal{D}}_1)(\alpha_*, z_\delta + \alpha_\delta^{\text{cr}}; \cdot) - (\mathcal{D}_1 - \tilde{\mathcal{D}}_1)(\alpha_*, z_\delta + \alpha_\delta^{\text{cr}}; \cdot)|_{\Omega^c} \\ &\quad + (\mathcal{D}_2 - \tilde{\mathcal{D}}_2)(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \cdot) - (\mathcal{D}_2 - \tilde{\mathcal{D}}_2)(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \cdot)|_{\Omega^c}\end{aligned}$$

Therefore, the desired estimate on $\|\mathcal{D}^{(1)} - \tilde{\mathcal{D}}^{(1)}\|_{\mathfrak{S}}$ follows from Proposition 5.13.ii and Lemma 5.10.

By Propositions 5.12(ii), 5.13(ii) and Lemma 5.10

$$\begin{aligned}\|\mathcal{L}'_{\mathfrak{S}}\|_{\mathfrak{S}} &= \left\| \mathcal{D}'|_{\Omega^c} \right\|_{\mathfrak{S}} \\ &\leq K_Q \left[e^{-\frac{1}{4}m\epsilon(\delta)} + \delta r R_+ e^{-m\epsilon} \right] + K_V \delta \|v\| r R_+^3 + 2^8 \|\mathcal{D}_1\|_{\mathfrak{S}_1} + 2^8 \|\mathcal{D}_2\|_{\mathfrak{S}_2} \\ &\leq K_V 2\delta r_+ R_+^3 v + 2^8 \Sigma_{\mathcal{D}}\end{aligned}$$

by (F.3b), (F.4b), (F.4c). Furthermore,

$$\begin{aligned}\mathcal{D}' - \tilde{\mathcal{D}}' &= \delta \mathcal{V} - \widetilde{\delta \mathcal{V}} + (\mathcal{D}_1 - \tilde{\mathcal{D}}_1)(\alpha_*, z_\delta + \alpha_\delta^{\text{cr}}; \vec{\alpha}_{*l}, \vec{\alpha}_l) \\ &\quad + (\mathcal{D}_2 - \tilde{\mathcal{D}}_2)(z_{*\delta} + \alpha_{*\delta}^{\text{cr}}, \beta; \vec{\alpha}_{*r}, \vec{\alpha}_r)\end{aligned}$$

The desired bound on $\|\mathcal{L}'_{\mathfrak{S}} - \tilde{\mathcal{L}}'_{\mathfrak{S}}\|_{\mathfrak{S}}$ now follows from Proposition 5.13(ii) and Lemma 5.10. \square

5.5. The Fluctuation Integral: Proofs of Theorems 3.26 and 3.28

Recall from Lemma 5.4 that

$$I(\alpha^*, \beta) = \sum_{\substack{\text{hierarchies} \\ \text{for scale } 2\delta \\ (\mathfrak{S}_1, \mathfrak{S}_2) \prec \mathfrak{S}}} I_{(\mathfrak{S}; \alpha^*, \beta)} b_1(\alpha^*, \alpha_\delta, \vec{\rho}_l) b_2(\alpha_\delta^*, \beta, \vec{\rho}_r) \chi_{2\delta}(\Omega_{\mathfrak{S}}; \alpha, \beta) \\ \times \mathcal{Z}_\delta^{2|\Omega_{\mathfrak{S}}|} \int d\mu_{\Omega_{\mathfrak{S}}, r}(z^*, z) e^{f_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}; z^*, z)} \Big|_{\substack{z_{*\delta}(\mathbf{x}) = z_\delta(\mathbf{x})^* \\ \text{for } \mathbf{x} \in \Lambda_{\mathfrak{S}} \setminus R}}$$

In this section, we perform the fluctuation integral to give the proofs of Theorems 3.26 and 3.28.

For each hierarchy \mathfrak{S} preceded by \mathfrak{S}_1 and \mathfrak{S}_2 , by Proposition 5.14 and Lemma 2.7,

$$\begin{aligned} & \mathcal{Z}_\delta^{2|\Omega_{\mathfrak{S}}|} \int d\mu_{\Omega_{\mathfrak{S}}, r}(z^*, z) e^{f_{\mathfrak{S}}(\alpha^*, \beta; \vec{\rho}; z^*, z)} \\ &= e^{-Q_{\mathfrak{S}} + \mathcal{V}_{\mathfrak{S}} + \mathcal{D}^{(1)} + \mathcal{L}'_{\mathfrak{S}}} \mathcal{Z}_\delta^{2|\Omega_{\mathfrak{S}}|} \int d\mu_{\Omega_{\mathfrak{S}}, r}(z^*, z) e^{\mathcal{F}_l(\alpha_*, \beta; \vec{\rho}; z) + \mathcal{F}_r(\alpha_*, \beta; \vec{\rho}; z^*)} \\ &= e^{-Q_{\mathfrak{S}} + \mathcal{V}_{\mathfrak{S}} + \mathcal{D}^{(1)} + \mathcal{L}'_{\mathfrak{S}}} \mathcal{Z}_{2\delta}^{|\Omega_{\mathfrak{S}}|} \frac{\int d\mu_{\Omega_{\mathfrak{S}}, r}(z^*, z) e^{\mathcal{F}_l(\alpha_*, \beta; \vec{\rho}; z) + \mathcal{F}_r(\alpha_*, \beta; \vec{\rho}; z^*)}}{\int d\mu_{\Omega_{\mathfrak{S}}, r}(z^*, z)} \end{aligned}$$

By Proposition 5.14.i and the hypotheses of Theorem 3.26,

$$\begin{aligned} \|\mathcal{F}_l + \mathcal{F}_r\|_{\text{fluct}} &\leq 2K_V \delta \mathfrak{v} r R_+^3 + 2^8 e^{-mc(\delta)} \Sigma_{\mathcal{D}} + 2^8 \Sigma_{\mathcal{D}}^{(SF)} \\ &\leq \frac{1}{40} \end{aligned} \quad (5.40)$$

by (F.4c) and (F.6a). So we can apply Theorem (3.14) with $w = w_{\text{fluct}}$ and $f = \mathcal{F}_l + \mathcal{F}_r$. It gives the existence of a function $\mathcal{D}^{(2)}(\alpha_*, \beta; \vec{\rho})$ such that

$$\frac{\int d\mu_{\Omega_{\mathfrak{S}}, r}(z^*, z) e^{\mathcal{F}_l(\alpha_*, \beta; \vec{\rho}; z) + \mathcal{F}_r(\alpha_*, \beta; \vec{\rho}; z^*)}}{\int d\mu_{\Omega_{\mathfrak{S}}, r}(z^*, z)} = e^{\mathcal{D}^{(2)}(\alpha_*, \beta; \vec{\rho})} \quad (5.41)$$

since $\mathcal{F}_l(0, 0; \vec{0}; z) = \mathcal{F}_r(0, 0; \vec{0}; z^*) = 0$. The estimate (3.5) in Theorem 3.14 applies and

$$\begin{aligned} \|\mathcal{D}^{(2)}\|_{\mathfrak{S}} &= \|\mathcal{D}^{(2)}\|_{\text{fluct}} \leq 1600 (\|\mathcal{F}_l + \mathcal{F}_r\|_{\text{fluct}})^2 \\ &\leq 40 \left(2K_V \delta \mathfrak{v} r R_+^3 + 2^8 e^{-mc(\delta)} \Sigma_{\mathcal{D}} + 2^8 \Sigma_{\mathcal{D}}^{(SF)} \right) \end{aligned} \quad (5.42)$$

by (5.40). As $[\mathcal{F}_l + \mathcal{F}_r] \Big|_{\Omega^c} = 0$, also $\mathcal{D}^{(2)} \Big|_{\Omega^c} = 0$. We set

$$\mathcal{D}_{\mathfrak{S}} = \mathcal{D}^{(1)} + \mathcal{D}^{(2)}$$

By Proposition 5.14(ii) and (5.42)

$$\|\mathcal{D}_{\mathfrak{S}}\|_{\mathfrak{S}} \leq 2^7 K_V (2\delta) r R_+^3 \mathfrak{v} + 2^{14} e^{-mc(\delta)} \Sigma_{\mathcal{D}} + 2^{14} \Sigma_{\mathcal{D}}^{(SF)}$$

By Corollary 5.7,

$$\mathcal{D}_{\mathfrak{S}} \Big|_{\Omega} = \bar{\mathfrak{R}}_{\Omega; \delta} (V_{\Omega, \delta}(\varepsilon; \cdot); \mathcal{D}_1(\cdot; 0) \Big|_{\Omega}, \mathcal{D}_2(\cdot; 0) \Big|_{\Omega})$$

The desired bound on $\mathcal{L}'_{\mathfrak{S}}$ was proven in Proposition 5.14. Since $K_D \geq 2^8 K_V$ and $K_L \geq 2K_V$ the proof of Theorem 3.26 is now complete.

We now move on to the proof of Theorem 3.28. The functions $\tilde{\mathcal{D}}^{(2)}$ and $\tilde{\mathcal{D}}_{\mathfrak{S}}$ are constructed as above and obey the corresponding estimates. By Proposition 5.14(i) and the hypotheses of Theorem 3.28,

$$\begin{aligned} \|(\mathcal{F}_l + \mathcal{F}_r) - (\tilde{\mathcal{F}}_l + \tilde{\mathcal{F}}_r)\|_{\text{fluct}} &\leq 2K_{\mathcal{V}} \varepsilon \delta r \mathfrak{v} R_+^3 + 2^8 e^{-m\mathfrak{c}(\delta)} \Delta_{\mathcal{D}} + 2^8 \Delta_{\mathcal{D}}^{(SF)} \\ &\leq \frac{1}{2^8} \end{aligned} \quad (5.43)$$

by (F.4c) and (F.6a). We apply [4, Corollary III.6] with $f = \mathcal{F}_l + \mathcal{F}_r$ and $f' = \tilde{\mathcal{F}}_l + \tilde{\mathcal{F}}_r$. Since

$$\|\mathcal{F}_l + \mathcal{F}_r\|_{\text{fluct}} + \|(\mathcal{F}_l + \mathcal{F}_r) - (\tilde{\mathcal{F}}_l + \tilde{\mathcal{F}}_r)\|_{\text{fluct}} \leq \frac{1}{40} + \frac{1}{2^8} \leq \frac{1}{34}$$

it shows that

$$\|\mathcal{D}^{(2)} - \tilde{\mathcal{D}}^{(2)}\|_{\mathfrak{S}} \leq 4(34) \left(2K_{\mathcal{V}} \varepsilon \delta \mathfrak{v} r R_+^3 + 2^8 e^{-m\mathfrak{c}(\delta)} \Delta_{\mathcal{D}} + 2^8 \Delta_{\mathcal{D}}^{(SF)} \right)$$

We combine this with the estimate of Proposition 5.14(ii) to give

$$\begin{aligned} \|\mathcal{D}_{\mathfrak{S}} - \tilde{\mathcal{D}}_{\mathfrak{S}}\|_{\mathfrak{S}} &\leq [(4)(34)(2) + 1] K_{\mathcal{V}} \varepsilon \delta \mathfrak{v} r R_+^3 + [(4)(34) + 1] 2^8 \left(e^{-m\mathfrak{c}(\delta)} \Delta_{\mathcal{D}} + \Delta_{\mathcal{D}}^{(SF)} \right) \\ &\leq 2^9 K_{\mathcal{V}} \varepsilon (2\delta \mathfrak{v}) r_+ R_+^3 + 2^{16} e^{-m\mathfrak{c}(\delta)} \Delta_{\mathcal{D}} + 2^{16} \Delta_{\mathcal{D}}^{(SF)} \end{aligned}$$

The desired bound on $\|\mathcal{L}'_{\mathfrak{S}} - \tilde{\mathcal{L}}'_{\mathfrak{S}}\|_{\mathfrak{S}}$ was proven in Proposition 5.14(iii). Since $K_D \geq 2^{10} K_{\mathcal{V}}$ and $K_L \geq 2K_{\mathcal{V}}$ the proof of Theorem 3.28 is now complete too. \square

6. Large Field Bounds

In this section, we prove the large field bounds stated in Propositions 3.36, 3.37 and 3.38 and Lemma 3.40. Fix a $0 < \delta \leq \Theta$ and an integer $m \geq 0$ and set $\varepsilon = 2^{-m}\delta$, as in Theorem 3.35. We shall assume that ε is small enough that $|e^{\varepsilon\mu} - 1| \leq \frac{1}{8}$. For notational compactness, we set

$$R_n = R(2^n \varepsilon) \quad R'_n = R'(2^n \varepsilon) \quad r_n = r(2^n \varepsilon) \quad \mathfrak{c}_n = \mathfrak{c}(2^n \varepsilon)$$

as well as $\chi_n(\Omega; \alpha, \beta) = \chi_{2^n \varepsilon}(\Omega; \alpha, \beta)$ and $F_n(\Omega_0) = F_{2^n \varepsilon}(\Omega_0)$.

Fix a hierarchy \mathfrak{S} for scale $\delta = 2^m \varepsilon$ with depth at most m . For a decimation interval $\mathcal{J} \subset [0, \delta]$, write $\Omega(\mathcal{J}) = \Omega_{\mathfrak{S}}(\mathcal{J})$ and $\Lambda(\mathcal{J}) = \Lambda_{\mathfrak{S}}(\mathcal{J})$. Similarly, $\Gamma_{*\mathfrak{S}}(\tau; \alpha^*, \vec{\alpha}^*) = \Gamma_*(\tau; \alpha^*, \vec{\alpha}^*)$, $\Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) = \Gamma(\tau; \vec{\alpha}, \beta)$ and $\Omega = \Omega_{\mathfrak{S}}([0, \delta])$, $\Lambda = \Lambda_{\mathfrak{S}}([0, \delta])$. Recall that, for each decimation interval $\mathcal{J} = [t_-, t_+] \subset [0, \delta]$, with midpoint t , $\mathcal{J}^- = [t_-, t]$ and $\mathcal{J}^+ = [t, t_+]$. Also recall, from Notation 2.5, that $\Lambda_0 = \Lambda_{\delta} = \emptyset$ and, for each $\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)$, $\Lambda_{\tau} = \Lambda(\mathcal{J}_{\tau}) = \Lambda([\tau - 2^{-\mathfrak{d}(\tau)}\delta, \tau + 2^{-\mathfrak{d}(\tau)}\delta])$, where \mathcal{J}_{τ} is the unique decimation interval centred on τ and the decimation index $\mathfrak{d}(\tau)$ is the smallest integer $k \geq 0$ such that $\tau \in \frac{\delta}{2^k} \mathbb{Z}$.

We shall consistently use the notation

$$\gamma_{*\tau} = \begin{cases} \alpha^* & \text{if } \tau = 0 \\ \Gamma_*(\tau; \alpha^*, \vec{\alpha}^*) & \text{if } \tau \in (0, \delta) \\ \beta^* & \text{if } \tau = \delta \end{cases} \quad \gamma_\tau = \begin{cases} \alpha & \text{if } \tau = 0 \\ \Gamma(\tau; \vec{\alpha}, \beta) & \text{if } \tau \in (0, \delta) \\ \beta & \text{if } \tau = \delta \end{cases} \quad (6.1)$$

Using this notation

$$\begin{aligned} & - \left[\frac{1}{2} \|\alpha\|^2 + Q_{\mathfrak{S}}(\alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) + \frac{1}{2} \|\beta\|^2 \right] \\ &= \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \left[-\frac{1}{2} \langle \gamma_{*\tau}, \gamma_\tau \rangle + \langle \gamma_{*\tau}, j(\varepsilon) \gamma_{\tau+\varepsilon} \rangle - \frac{1}{2} \langle \gamma_{*\tau+\varepsilon}, \gamma_{\tau+\varepsilon} \rangle \right] \end{aligned} \quad (6.2)$$

and

$$\mathcal{V}_{\mathfrak{S}}(\varepsilon; \alpha^*, \beta; \vec{\alpha}^*, \vec{\alpha}) = -\varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle \quad (6.3)$$

Throughout this section, we assume that the field α_τ is compatible with \mathfrak{S} in the sense of Definition E.1, as is the case in the domain of the integral operator $\mathcal{I}_{(\mathfrak{S}, \varepsilon; \alpha^*, \beta)}$. In particular,

$$|\alpha_\tau(\mathbf{x})| \leq \min\{\kappa_\tau(\mathbf{x}), \kappa_{*\tau}(\mathbf{x})\} \quad |\alpha(\mathbf{x})| \leq \kappa_{*0}(\mathbf{x}) \quad |\beta(\mathbf{x})| \leq \kappa_\delta(\mathbf{x}) \quad (6.4)$$

for all $\tau \in \varepsilon \mathbb{Z} \cap (0, \delta)$ and $\mathbf{x} \in X$. We also assume that $\mathfrak{h} \equiv 1$, as we did in Sect. 3.7 and, in particular, in Theorem 3.35.

In Propositions 3.36 and 3.37, we introduced restricted large fields regions $\tilde{P}_\alpha(\mathcal{J}), \dots, \tilde{Q}(\mathcal{J})$. The reason for introducing these smaller large field sets is the following. When we are decimating at time t , the centre of \mathcal{J} , we need to extract a small factor for certain points in $\Lambda(\mathcal{J})^c$ that are not in $\Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c$. Small factors were already extracted from the latter regions in previous decimation steps. Each time we extract a small factor associated with a point \mathbf{x} we will distribute it amongst all nearby points \mathbf{y} . As a result, when we are decimating at time t , it is not necessary to extract small factors from points that are within a distance $2\mathfrak{c}(|\mathcal{J}^\pm|)$ of $\Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c$. So, for example, $\tilde{P}_\alpha(\mathcal{J})$ consists of those points of $P_\alpha(\mathcal{J})$ whose distance from $\Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c$ is greater than $2\mathfrak{c}(|\mathcal{J}^\pm|)$.

Remark 6.1. For each decimation interval $\mathcal{J} = [t_-, t_+]$,

$$\begin{aligned} \tilde{P}_\alpha(\mathcal{J}) &= \left\{ \mathbf{x} \in \Omega_0(\mathcal{J}) \mid \begin{array}{l} |\alpha_{t_-}(\mathbf{x})| > R(|\mathcal{J}|), \\ d(\mathbf{x}, \Lambda(\mathcal{J})) > \mathfrak{c}(\frac{1}{2}|\mathcal{J}|) \\ d(\mathbf{x}, \Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c) > 2\mathfrak{c}(\frac{1}{2}|\mathcal{J}|) \end{array} \right\} \\ \tilde{P}_\beta(\mathcal{J}) &= \left\{ \mathbf{x} \in \Omega_0(\mathcal{J}) \mid \begin{array}{l} |\alpha_{t_+}(\mathbf{x})| > R(|\mathcal{J}|), \\ d(b, \Lambda(\mathcal{J})) > \mathfrak{c}(\frac{1}{2}|\mathcal{J}|) \\ d(b, \Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c) > 2\mathfrak{c}(\frac{1}{2}|\mathcal{J}|) \end{array} \right\} \end{aligned}$$

$$\begin{aligned}\tilde{P}'_\alpha(\mathcal{J}) &= \left\{ b \in \Omega_0(\mathcal{J})^* \mid \begin{array}{l} |(\nabla \alpha_{t-})(b)| > R'(|\mathcal{J}|), \\ d(b, \Lambda(\mathcal{J})) > c(\frac{1}{2}|\mathcal{J}|) \\ d(b, \Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c) > 2c(\frac{1}{2}|\mathcal{J}|) \end{array} \right\}, \\ \tilde{P}'_\beta(\mathcal{J}) &= \left\{ b \in \Omega_0(\mathcal{J})^* \mid \begin{array}{l} |(\nabla \alpha_{t+})(b)| > R'(|\mathcal{J}|), \\ d(b, \Lambda(\mathcal{J})) > c(\frac{1}{2}|\mathcal{J}|) \\ d(b, \Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c) > 2c(\frac{1}{2}|\mathcal{J}|) \end{array} \right\}, \\ \tilde{Q}(\mathcal{J}) &= \left\{ \mathbf{x} \in \Omega_0(\mathcal{J})^* \mid \begin{array}{l} |\alpha_{t+}(\mathbf{x}) - \alpha_{t-}(\mathbf{x})| > r(|\mathcal{J}|), \\ d(\mathbf{x}, \Lambda(\mathcal{J})) > c(\frac{1}{2}|\mathcal{J}|) \\ d(\mathbf{x}, \Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c) > 2c(\frac{1}{2}|\mathcal{J}|) \end{array} \right\}\end{aligned}$$

where $\Omega_0(\mathcal{J}) = \Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+)$.

6.1. Extracting Small Factors from the Quadratic Form

In this subsection, we prove Proposition 3.36. The main ingredient is

Lemma 6.2. Set $j(\varepsilon) = e^{-\varepsilon\mu} j(\varepsilon) = e^{-\varepsilon h}$ and $c_{j,\varepsilon} = \|\mathbb{1} - j(\varepsilon)\|$. Assume that $c_{j,\varepsilon} \leq \frac{1}{9}$. Then

$$\begin{aligned}&\operatorname{Re} \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \left[-\frac{1}{2} \langle \gamma_{*\tau}, \gamma_\tau \rangle + \langle \gamma_{*\tau}, j(\varepsilon) \gamma_{\tau+\varepsilon} \rangle - \frac{1}{2} \langle \gamma_{*\tau+\varepsilon}, \gamma_{\tau+\varepsilon} \rangle \right] \\&\leq -\frac{1}{4} \left\{ \sum_{\tau \in [0, \delta)} \frac{1}{2} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c}^2 + \sum_{\tau \in (0, \delta]} \langle \gamma_\tau^*, [\mathbb{1} - j(\varepsilon)] \gamma_\tau \rangle \right. \\&\quad \left. + \sum_{\tau \in [0, \delta)} \langle \gamma_{*\tau}^*, [\mathbb{1} - j(\varepsilon)] \gamma_{*\tau} \rangle \right\} \\&\quad + \frac{1}{2} \sum_{\tau \in (0, \delta)} |\langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon) \gamma_{\tau+\varepsilon}) \rangle| \\&\quad + \frac{1}{2} \sum_{\tau \in (0, \delta)} |\langle \gamma_\tau - \gamma_{*\tau}^*, \Lambda_\tau (\gamma_{*\tau} - j(\varepsilon) \gamma_{*\tau-\varepsilon}) \rangle| \\&\quad + \frac{1}{2} \sum_{\tau \in (0, \delta)} \|\Lambda_\tau^c (\gamma_{*\tau}^* - \gamma_\tau)\|^2 + |e^{\varepsilon\mu} - 1| \sum_{\tau \in [0, \delta]} [\|\gamma_\tau\|^2 + \|\gamma_{*\tau}\|^2]\end{aligned}$$

where, for each subset $S \subset X$, $\|u\|_S^2 = \sum_{\mathbf{x} \in S} |u(\mathbf{x})|^2 = \langle Su^*, Su \rangle$.

Proof. Recall that $\|\alpha\|^* = \langle \alpha^*, \alpha \rangle$ and $\gamma_{*0} = \gamma_0^*$, $\gamma_{*\delta} = \gamma_\delta^*$ so that $\langle \gamma_{*0}, \gamma_0 \rangle = \|\gamma_0\|^2 = \|\gamma_{*0}\|^2$ and $\langle \gamma_{*\delta}, \gamma_\delta \rangle = \|\gamma_\delta\|^2$. The real part of

$$\begin{aligned}&\sum_{\tau \in [0, \delta)} \left[-\frac{1}{2} \langle \gamma_{*\tau}, \gamma_\tau \rangle + \langle \gamma_{*\tau}, j(\varepsilon) \gamma_{\tau+\varepsilon} \rangle - \frac{1}{2} \langle \gamma_{*\tau+\varepsilon}, \gamma_{\tau+\varepsilon} \rangle \right] \\&= -\frac{1}{2} \|\gamma_0\|^2 - \sum_{\tau \in (0, \delta)} \langle \gamma_{*\tau}, \gamma_\tau \rangle - \frac{1}{2} \|\gamma_\delta\|^2 + \sum_{\tau \in [0, \delta)} \langle \gamma_{*\tau}, j(\varepsilon) \gamma_{\tau+\varepsilon} \rangle\end{aligned}$$

$$\begin{aligned}
&= -\frac{1}{2}\|\gamma_0\|^2 - \sum_{\tau \in (0, \delta)} \langle \gamma_{*\tau}, \gamma_\tau \rangle - \frac{1}{2}\|\gamma_\delta\|^2 + \sum_{\tau \in [0, \delta)} \langle \gamma_{*\tau}, \gamma_{\tau+\varepsilon} \rangle \\
&\quad - \sum_{\tau \in [0, \delta)} \langle \gamma_{*\tau}, [\mathbb{1} - j(\varepsilon)]\gamma_{\tau+\varepsilon} \rangle \\
&= \sum_{\tau \in (0, \delta)} \left[\frac{1}{2}\|\gamma_{*\tau}^*\|^2 - \langle \gamma_{*\tau}, \gamma_\tau \rangle + \frac{1}{2}\|\gamma_\tau\|^2 \right] \\
&\quad + \sum_{\tau \in [0, \delta)} \left[-\frac{1}{2}\|\gamma_{*\tau}^*\|^2 + \langle \gamma_{*\tau}, \gamma_{\tau+\varepsilon} \rangle - \frac{1}{2}\|\gamma_{\tau+\varepsilon}\|^2 \right] \\
&\quad - \sum_{\tau \in [0, \delta)} \langle \gamma_{*\tau}, [\mathbb{1} - j(\varepsilon)]\gamma_{\tau+\varepsilon} \rangle
\end{aligned}$$

is

$$\begin{aligned}
&\operatorname{Re} \sum_{\tau \in [0, \delta)} \left[-\frac{1}{2} \langle \gamma_{*\tau}, \gamma_\tau \rangle + \langle \gamma_{*\tau}, j(\varepsilon)\gamma_{\tau+\varepsilon} \rangle - \frac{1}{2} \langle \gamma_{*\tau+\varepsilon}, \gamma_{\tau+\varepsilon} \rangle \right] \\
&= \frac{1}{2} \sum_{\tau \in (0, \delta)} \|\gamma_{*\tau}^* - \gamma_\tau\|^2 - \frac{1}{2} \sum_{\tau \in [0, \delta)} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|^2 \\
&\quad - \sum_{\tau \in [0, \delta)} \operatorname{Re} \langle \gamma_{*\tau}, [\mathbb{1} - j(\varepsilon)]\gamma_{\tau+\varepsilon} \rangle \\
&= \sum_{\tau \in [0, \delta)} \left\{ \frac{1}{2}\|\gamma_{*\tau}^* - \gamma_\tau\|^2 - \frac{1}{2}\|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|^2 - \operatorname{Re} \langle \gamma_{*\tau}, [\mathbb{1} - j(\varepsilon)]\gamma_{\tau+\varepsilon} \rangle \right\}
\end{aligned}$$

because $\|\alpha - \beta\|^2 = \|\alpha\|^2 + \|\beta\|^2 - 2\operatorname{Re} \langle \alpha^*, \beta \rangle$. Now

$$\begin{aligned}
&\|\gamma_{*\tau}^* - \gamma_\tau\|_{\Lambda_\tau}^2 - \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau}^2 \\
&= \|\Lambda_\tau \gamma_{*\tau}^* - \Lambda_\tau j(\varepsilon)\gamma_{\tau+\varepsilon} - \Lambda_\tau (\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon})\|^2 - \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau}^2 \\
&= \|\Lambda_\tau \gamma_{*\tau}^* - \Lambda_\tau j(\varepsilon)\gamma_{\tau+\varepsilon}\|^2 - \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau}^2 \\
&\quad + \|\Lambda_\tau (\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon})\|^2 - 2\operatorname{Re} \langle \gamma_{*\tau} - j(\varepsilon)\gamma_{\tau+\varepsilon}^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon}) \rangle \\
&= \|\Lambda_\tau (\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}) + \Lambda_\tau [\mathbb{1} - j(\varepsilon)]\gamma_{\tau+\varepsilon}\|^2 - \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau}^2 \\
&\quad + \|\Lambda_\tau (\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon})\|^2 - 2\operatorname{Re} \langle \gamma_{*\tau} - j(\varepsilon)\gamma_{\tau+\varepsilon}^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon}) \rangle \\
&= 2\operatorname{Re} \langle \Lambda_\tau (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*), [\mathbb{1} - j(\varepsilon)]\gamma_{\tau+\varepsilon} \rangle + \|\Lambda_\tau [\mathbb{1} - j(\varepsilon)]\gamma_{\tau+\varepsilon}\|^2 \\
&\quad + \|\Lambda_\tau (\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon})\|^2 \\
&\quad - 2\operatorname{Re} \langle \gamma_{*\tau} - \gamma_\tau^* + \gamma_\tau^* - j(\varepsilon)\gamma_{\tau+\varepsilon}^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon}) \rangle \\
&= 2\operatorname{Re} \langle \Lambda_\tau (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*), [\mathbb{1} - j(\varepsilon)]\gamma_{\tau+\varepsilon} \rangle + \|\Lambda_\tau [\mathbb{1} - j(\varepsilon)]\gamma_{\tau+\varepsilon}\|^2 \\
&\quad - \|\Lambda_\tau (\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon})\|^2 - 2\operatorname{Re} \langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon}) \rangle
\end{aligned}$$

so that

$$\frac{1}{2}\|\gamma_{*\tau}^* - \gamma_\tau\|^2 - \frac{1}{2}\|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|^2 - \operatorname{Re} \langle \gamma_{*\tau}, [\mathbb{1} - j(\varepsilon)]\gamma_{\tau+\varepsilon} \rangle$$

$$\begin{aligned}
&= -\frac{1}{2} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c}^2 - \operatorname{Re} \langle \Lambda_\tau \gamma_{\tau+\varepsilon}^* + \Lambda_\tau^c \gamma_{*\tau}, [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle \\
&\quad + \frac{1}{2} \|\Lambda_\tau [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon}\|^2 \\
&\quad - \frac{1}{2} \|\Lambda_\tau (\gamma_\tau - j(\varepsilon) \gamma_{\tau+\varepsilon})\|^2 - \operatorname{Re} \langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon) \gamma_{\tau+\varepsilon}) \rangle \\
&\quad + \frac{1}{2} \|\gamma_{*\tau}^* - \gamma_\tau\|_{\Lambda_\tau^c}^2 \\
&= -\frac{1}{2} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c}^2 - \langle \gamma_{\tau+\varepsilon}^*, [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle - \frac{1}{2} \|\gamma_\tau - j(\varepsilon) \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau}^2 \\
&\quad - \operatorname{Re} \langle \Lambda_\tau^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*), [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle + \frac{1}{2} \|\Lambda_\tau [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon}\|^2 \\
&\quad - \operatorname{Re} \langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon) \gamma_{\tau+\varepsilon}) \rangle + \frac{1}{2} \|\gamma_{*\tau}^* - \gamma_\tau\|_{\Lambda_\tau^c}^2 \\
&= -\frac{1}{2} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c}^2 - e^{\varepsilon\mu} \langle \gamma_{\tau+\varepsilon}^*, [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle \\
&\quad - e^{\varepsilon\mu} \operatorname{Re} \langle \Lambda_\tau^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*), [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle + \frac{1}{2} \|\Lambda_\tau [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon}\|^2 \\
&\quad + (e^{\varepsilon\mu} - 1) \|\gamma_{\tau+\varepsilon}\|^2 + (e^{\varepsilon\mu} - 1) \operatorname{Re} \langle \Lambda_\tau^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*), \gamma_{\tau+\varepsilon} \rangle \\
&\quad - \frac{1}{2} \|\gamma_\tau - j(\varepsilon) \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau}^2 - \operatorname{Re} \langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon) \gamma_{\tau+\varepsilon}) \rangle \\
&\quad + \frac{1}{2} \|\gamma_{*\tau}^* - \gamma_\tau\|_{\Lambda_\tau^c}^2
\end{aligned}$$

Using Cauchy–Schwarz and $|AB| \leq \frac{1}{2}(A^2 + B^2)$,

$$\begin{aligned}
&|\langle \Lambda_\tau^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*), [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle| \\
&\leq \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c} \|\mathbb{1} - j(\varepsilon)\|^{1/2} \left\| [\mathbb{1} - j(\varepsilon)]^{1/2} \gamma_{\tau+\varepsilon} \right\| \\
&\leq \sqrt{c_{j,\varepsilon}} \frac{1}{2} \left(\|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c}^2 + \langle \gamma_{\tau+\varepsilon}^*, [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle \right) \\
&|(e^{\varepsilon\mu} - 1) \operatorname{Re} \langle \Lambda_\tau^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*), \gamma_{\tau+\varepsilon} \rangle| \\
&\leq \frac{1}{2} |e^{\varepsilon\mu} - 1| \left(\|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c}^2 + \|\gamma_{\tau+\varepsilon}\|^2 \right) \\
&\frac{1}{2} \|\Lambda_\tau [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon}\|^2 \\
&\leq \|[\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon}\|^2 + \|[j(\varepsilon) - j(\varepsilon)] \gamma_{\tau+\varepsilon}\|^2 \\
&\leq \|\mathbb{1} - j(\varepsilon)\| \left\| [\mathbb{1} - j(\varepsilon)]^{\frac{1}{2}} \gamma_{\tau+\varepsilon} \right\|^2 + [e^{\varepsilon\mu} - 1]^2 \|\mathbb{1} - j(\varepsilon)\| \|\gamma_{\tau+\varepsilon}\|^2 \\
&\leq c_{j,\varepsilon} \langle \gamma_{\tau+\varepsilon}^*, [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle + [e^{\varepsilon\mu} - 1]^2 \|\gamma_{\tau+\varepsilon}\|^2
\end{aligned}$$

Thus we have

$$\operatorname{Re} \sum_{\tau \in [0, \delta)} \left[-\frac{1}{2} \langle \gamma_{*\tau}, \gamma_\tau \rangle + \langle \gamma_{*\tau}, j(\varepsilon) \gamma_{\tau+\varepsilon} \rangle - \frac{1}{2} \langle \gamma_{*\tau+\varepsilon}, \gamma_{\tau+\varepsilon} \rangle \right]$$

$$\begin{aligned}
&\leq - \sum_{\tau \in [0, \delta)} \frac{1}{2} (1 - e^{\varepsilon\mu} \sqrt{c_{j,\varepsilon}} - |e^{\varepsilon\mu} - 1|) \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c}^2 \\
&\quad - \sum_{\tau \in [0, \delta)} \left(e^{\varepsilon\mu} - \frac{1}{2} e^{\varepsilon\mu} \sqrt{c_{j,\varepsilon}} - c_{j,\varepsilon} \right) \langle \gamma_{*\tau+\varepsilon}^*, [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle \\
&\quad + \sum_{\tau \in [0, \delta)} \left(\frac{3}{2} |e^{\varepsilon\mu} - 1| + [e^{\varepsilon\mu} - 1]^2 \right) \|\gamma_{\tau+\varepsilon}\|^2 \\
&\quad - \sum_{\tau \in [0, \delta)} \frac{1}{2} \|\gamma_\tau - j(\varepsilon) \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau}^2 - \sum_{\tau \in [0, \delta)} \operatorname{Re} \langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon) \gamma_{\tau+\varepsilon}) \rangle \\
&\quad + \frac{1}{2} \sum_{\tau \in [0, \delta)} \|\gamma_{*\tau}^* - \gamma_\tau\|_{\Lambda_\tau^c}^2
\end{aligned}$$

and hence, since $1 - e^{\varepsilon\mu} \sqrt{c_{j,\varepsilon}} - |e^{\varepsilon\mu} - 1| \geq \frac{1}{2}$ and $e^{\varepsilon\mu} - \frac{1}{2} e^{\varepsilon\mu} \sqrt{c_{j,\varepsilon}} - c_{j,\varepsilon} \geq \frac{1}{2}$,

$$\begin{aligned}
&\operatorname{Re} \sum_{\tau \in [0, \delta)} \left[-\frac{1}{2} \langle \gamma_{*\tau}, \gamma_\tau \rangle + \langle \gamma_{*\tau}, j(\varepsilon) \gamma_{\tau+\varepsilon} \rangle - \frac{1}{2} \langle \gamma_{*\tau+\varepsilon}^*, [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle \right] \\
&\leq - \sum_{\tau \in [0, \delta)} \left\{ \frac{1}{4} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c}^2 + \frac{1}{2} \langle \gamma_{*\tau+\varepsilon}^*, [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle \right\} \\
&\quad - \sum_{\tau \in (0, \delta)} \operatorname{Re} \langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon) \gamma_{\tau+\varepsilon}) \rangle + 2 |e^{\varepsilon\mu} - 1| \sum_{\tau \in [0, \delta]} \|\gamma_\tau\|^2 \\
&\quad + \frac{1}{2} \sum_{\tau \in (0, \delta)} \|\gamma_{*\tau}^* - \gamma_\tau\|_{\Lambda_\tau^c}^2
\end{aligned}$$

The bound

$$\begin{aligned}
&\operatorname{Re} \sum_{\tau \in [0, \delta)} \left[-\frac{1}{2} \langle \gamma_{*\tau}, \gamma_\tau \rangle + \langle \gamma_{*\tau}, j(\varepsilon) \gamma_{\tau+\varepsilon} \rangle - \frac{1}{2} \langle \gamma_{*\tau+\varepsilon}^*, [\mathbb{1} - j(\varepsilon)] \gamma_{\tau+\varepsilon} \rangle \right] \\
&\leq - \sum_{\tau \in (0, \delta)} \left\{ \frac{1}{4} \|\gamma_{*\tau-\varepsilon}^* - \gamma_\tau\|_{\Lambda_\tau^c}^2 + \frac{1}{2} \langle \gamma_{*\tau-\varepsilon}^*, [\mathbb{1} - j(\varepsilon)] \gamma_{*\tau-\varepsilon} \rangle \right\} \\
&\quad - \sum_{\tau \in (0, \delta)} \operatorname{Re} \langle \Lambda_\tau (\gamma_{*\tau} - j(\varepsilon) \gamma_{*\tau-\varepsilon}), \gamma_\tau - \gamma_{*\tau}^* \rangle \\
&\quad + 2 |e^{\varepsilon\mu} - 1| \sum_{\tau \in [0, \delta]} \|\gamma_{*\tau}\|^2 \\
&\quad + \frac{1}{2} \sum_{\tau \in (0, \delta)} \|\gamma_{*\tau}^* - \gamma_\tau\|_{\Lambda_\tau^c}^2
\end{aligned}$$

is proven similarly. Taking the average of these two bounds and using

$$\frac{1}{8} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c}^2 + \frac{1}{8} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_{\tau+\varepsilon}^c}^2 \geq \frac{1}{8} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c}^2$$

gives the bound of the Lemma. \square

The first line of the right hand side of the conclusion of Lemma 6.2, consists of terms that are invariably negative. The first can be thought of as a time derivative term and the other two as space derivative terms. These three terms are responsible for the contributions $r(|\mathcal{J}|)^2 \{ |\tilde{Q}(\mathcal{J})| + |\tilde{P}_\alpha(\mathcal{J})| + |\tilde{P}_\beta(\mathcal{J})| \}$ to Proposition 3.36. See (6.8) a,b,c.

The terms on the other two lines are all positive. The terms on the second line will be controlled using the “smallness” of $\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon}$ and $\gamma_{*\tau} - j(\varepsilon)\gamma_{*\tau-\varepsilon}$. See Lemma E.17. The first term on the third line is controlled in Proposition E.11(ii), using the smallness of $\gamma_{*\tau}^* - \gamma_\tau$. The small field part of the second term in the third line is bounded in the following lemma and gives the small field regulator $\text{Reg}_{SF}^{(2)}(\Omega; \alpha, \beta)$ in Proposition 3.36. The large field part is left explicitly in Proposition 3.36. In the proof of Theorem 3.35, it is canceled by quartic contributions.

Lemma 6.3.

$$|e^{\varepsilon\mu} - 1| \sum_{\tau \in [0, \delta]} [\|\gamma_\tau\|_\Omega^2 + \|\gamma_{*\tau}\|_\Omega^2] \leq K_{\text{reg}} \delta |\mu| [\|\alpha\|_\Omega^2 + \|\beta\|_\Omega^2] + \frac{1}{16} |\Omega^c|$$

with the K_{reg} of Definition 2.17.

Proof. Write, using the notation of Definition E.3,

$$\sum_{\tau \in (0, \delta)} \|\gamma_\tau\|_\Omega^2 = \sum_{\substack{\tau \in (0, \delta) \\ \tau_1, \tau_2 \in \mathcal{T}_r(\tau, \delta)}} \sum_{\mathbf{x} \in \Omega} \overline{(\Gamma_\tau^{\tau_1} \alpha_{\tau_1})(\mathbf{x})} (\Gamma_\tau^{\tau_2} \alpha_{\tau_2})(\mathbf{x})$$

We bound the terms with $(\tau_1, \tau_2) \neq (\delta, \delta)$ using

$$\begin{aligned} & \left| \sum_{\substack{\tau \in (0, \delta) \\ \tau_1, \tau_2 \in \mathcal{T}_r(\tau, \delta) \\ (\tau_1, \tau_2) \neq (\delta, \delta)}} \sum_{\mathbf{x} \in \Omega} \overline{(\Gamma_\tau^{\tau_1} \alpha_{\tau_1})(\mathbf{x})} (\Gamma_\tau^{\tau_2} \alpha_{\tau_2})(\mathbf{x}) \right| \\ & \leq \sum_{\substack{\tau \in (0, \delta) \\ \tau_1, \tau_2 \in \mathcal{T}_r(\tau, \delta) \\ (\tau_1, \tau_2) \neq (\delta, \delta)}} \sum_{\substack{\mathbf{x} \in \Omega \\ \mathbf{y} \in \Lambda_{\tau_1}^c, \mathbf{z} \in \Lambda_{\tau_2}^c}} |\Gamma_\tau^{\tau_1}(\mathbf{x}, \mathbf{y})| \kappa_{\tau_1}(\mathbf{y}) |\Gamma_\tau^{\tau_2}(\mathbf{x}, \mathbf{z})| \kappa_{\tau_2}(\mathbf{z}) \\ & \leq \sum_{\substack{\tau \in (0, \delta) \\ \tau_1, \tau_2 \in \mathcal{T}_r(\tau, \delta) \\ (\tau_1, \tau_2) \neq (\delta, \delta)}} N_0 \left(\Gamma_\tau^{\tau_1}; e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{\tau_1} \right) N_0 \left(\Gamma_\tau^{\tau_2}; e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{\tau_2} \right) \\ & \quad \times \min \{ |\Lambda_{\tau_1}^c|, |\Lambda_{\tau_2}^c| \} \\ & \leq |\Omega^c| \sum_{\tau \in (0, \delta)} \left[\sum_{\tau' \in (0, \delta)} N_0 \left(\Gamma_\tau^{\tau'}; e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{\tau'} \right) \right]^2 \\ & \leq \frac{\delta}{\varepsilon} |\Omega^c| (16e^{K_j} R(\delta))^2 \quad \text{by Lemma E.13} \end{aligned}$$

and we bound the term with $\tau_1 = \tau_2 = \delta$ using

$$\begin{aligned}
& \sum_{\tau \in (0, \delta)} \sum_{\mathbf{x} \in \Omega} \overline{(\Gamma_\tau^\delta \alpha_\delta)(\mathbf{x})} (\Gamma_\tau^\delta \alpha_\delta)(\mathbf{x}) \\
&= \sum_{\tau \in (0, \delta)} \sum_{\substack{\mathbf{x} \in \Omega \\ \mathbf{y}, \mathbf{z} \in X}} \overline{\Gamma_\tau^\delta(\mathbf{x}, \mathbf{y}) \beta(\mathbf{y})} \Gamma_\tau^\delta(\mathbf{x}, \mathbf{z}) \beta(\mathbf{z}) \\
&\leq \sum_{\tau \in (0, \delta)} \sum_{\mathbf{x}, \mathbf{y}, \mathbf{z} \in \Omega} \overline{\Gamma_\tau^\delta(\mathbf{x}, \mathbf{y}) \beta(\mathbf{y})} \Gamma_\tau^\delta(\mathbf{x}, \mathbf{z}) \beta(\mathbf{z}) + 2|\Omega^c| \\
&\quad \times \sum_{\tau \in (0, \delta)} N_0 \left(\Gamma_\tau^\delta; e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_\delta \right)^2 \\
&\leq \sum_{\tau \in (0, \delta)} N_0 \left(\Gamma_\tau^\delta; 1, 1 \right)^2 \|\beta\|_\Omega^2 + 2|\Omega^c| \sum_{\tau \in (0, \delta)} N_0 \left(\Gamma_\tau^\delta; e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_\delta \right)^2 \\
&\leq \frac{\delta}{\varepsilon} e^{2K_j} \|\beta\|_\Omega^2 + 2 \frac{\delta}{\varepsilon} |\Omega^c| (16e^{K_j} R(\delta))^2
\end{aligned}$$

We used that the operator on $L^2(\Omega)$ with kernel $\Gamma_\tau^\delta(\mathbf{x}, \mathbf{y})$ has norm at most $N_0(\Gamma_\tau^\delta; 1, 1)$.

We have also used that $|e^{\varepsilon\mu} - 1| \leq \frac{1}{8}$. Consequently $|e^{\varepsilon\mu} - 1| \leq 2\varepsilon|\mu|$ and, all together,

$$\begin{aligned}
& |e^{\varepsilon\mu} - 1| \sum_{\tau \in [0, \delta]} [\|\gamma_\tau\|_\Omega^2 + \|\gamma_{*\tau}\|_\Omega^2] \\
&\leq |e^{\varepsilon\mu} - 1| \left\{ 2\|\alpha\|_\Omega^2 + 2\|\beta\|_\Omega^2 + \frac{\delta}{\varepsilon} e^{2K_j} \|\alpha\|_\Omega^2 + \frac{\delta}{\varepsilon} e^{2K_j} \|\beta\|_\Omega^2 \right. \\
&\quad \left. + 6 \frac{\delta}{\varepsilon} |\Omega^c| (16e^{K_j} R(\delta))^2 \right\} \\
&\leq (4 + 2e^{2K_j}) \delta |\mu| [\|\alpha\|_\Omega^2 + \|\beta\|_\Omega^2] + 2^{12} e^{2K_j} \delta |\mu| R(\delta)^2 |\Omega^c|
\end{aligned}$$

By Hypothesis F.7.i, (2.19) and (2.17),

$$2^{12} e^{2K_j} \delta |\mu| R(\delta)^2 = 2^{12} e^{2K_j} K_\mu \delta^{1-2e_R-2e_r} \mathfrak{b}^{e_\mu-2e_R-2e_r} \leq \frac{1}{16}$$

The claim now follows from Remark D.3. \square

Proof of Proposition 3.36. Define, for each $t \in (0, \delta) \cap \varepsilon\mathbb{Z}$,

$$B_t = \Lambda(\mathcal{J}_t)^c \cap \Lambda(\mathcal{J}_t^-) \cap \Lambda(\mathcal{J}_t^+) \tag{6.5}$$

Observe that, for all $t \in (0, \delta) \cap \varepsilon\mathbb{Z}$,

$$\begin{aligned}
& \text{supp } \tilde{P}'_\alpha(\mathcal{J}_t) \subset B_t \\
& \text{supp } \tilde{P}'_\beta(\mathcal{J}_t) \subset B_t \\
& \tilde{Q}(\mathcal{J}_t) \subset B_t \\
& B_t \cap B_{t'} = \emptyset \quad \text{for all } t \neq t' \in \mathcal{J}_t^\circ
\end{aligned} \tag{6.6}$$

where $\mathcal{J}_t^\circ = \mathcal{J}_t \setminus \{t \pm \frac{1}{2}|\mathcal{J}_t|\}$ is the interior of the interval \mathcal{J}_t . To see the last line, observe that if t' is strictly between t and $t \pm \frac{1}{2}|\mathcal{J}_t|$, then $\Lambda(\mathcal{J}_t^\pm) \subset \Lambda_{t'}$ so that $B_t \subset \Lambda(\mathcal{J}_t^\pm)$ cannot intersect $B_{t'} \subset \Lambda_{t'}^c$.

Now fix any $0 \leq p, p' < m$. Suppose that $t, t' \in \varepsilon\mathbb{Z} \cap (0, \delta]$ have $\mathfrak{d}(t) = p$, $\mathfrak{d}(t') = p'$ and $t \neq t'$ and suppose that $B_t \cap B_{t'} \neq \emptyset$. We claim that

$$\begin{aligned} \{\tau \in \varepsilon\mathbb{Z} \mid \tau \in \mathcal{J}_t^-, \tau \neq t\} \cap \{\tau \in \varepsilon\mathbb{Z} \mid \tau \in \mathcal{J}_{t'}^-, \tau \neq t'\} &= \emptyset \\ \{\tau \in \varepsilon\mathbb{Z} \mid \tau \in \mathcal{J}_t^+, \tau \neq t\} \cap \{\tau \in \varepsilon\mathbb{Z} \mid \tau \in \mathcal{J}_{t'}^+, \tau \neq t'\} &= \emptyset \end{aligned} \quad (6.7)$$

To see the upper claim, first consider $p = p'$, so that $|\mathcal{J}_t^\pm| = |\mathcal{J}_{t'}^\pm| = \frac{1}{2^p}\delta$. Then either $t = t'$ or (6.7) is satisfied. So, without loss of generality, we may assume that $p < p'$ so that $|\mathcal{J}_{t'}^-| < |\mathcal{J}_t^-|$. If the upper claim of (6.7) is to be violated, then it is necessary that t' be in the interior of \mathcal{J}_t^- . But then (6.6) provides the contradiction that $B_t \cap B_{t'} = \emptyset$.

By Lemma D.4,

$$\begin{aligned} \sum_{\tau \in (0, \delta]} \langle \gamma_\tau^*, [\mathbb{1} - \mathfrak{j}(\varepsilon)]\gamma_\tau \rangle &= \sum_{\tau \in (0, \delta]} \left\langle \gamma_\tau^*, [\mathbb{1} - e^{-\varepsilon \nabla^* \mathcal{H} \nabla}] \gamma_\tau \right\rangle \geq c_{\mathcal{H}} e^{-4^{\text{DC}} \mathcal{H}} \sum_{\tau \in (0, \delta]} \varepsilon \|\nabla \gamma_\tau\|^2 \\ &= c_{\mathcal{H}} e^{-4^{\text{DC}} \mathcal{H}} \sum_{b \in X^*} \sum_{\tau \in (0, \delta]} \varepsilon |\nabla \gamma_\tau(b)|^2 \end{aligned}$$

Applying (6.7),

$$\begin{aligned} \sum_{\tau \in (0, \delta]} \langle \gamma_\tau^*, [\mathbb{1} - \mathfrak{j}(\varepsilon)]\gamma_\tau \rangle &\geq c_{\mathcal{H}} e^{-4^{\text{DC}} \mathcal{H}} \sum_{b \in X^*} \sum_{\substack{t \in (0, \delta] \\ \text{supp } b \subset B_t}} \sum_{\tau=t+\varepsilon}^{t+|\mathcal{J}_t^+|} \varepsilon |\nabla \gamma_\tau(b)|^2 \\ &= c_{\mathcal{H}} e^{-4^{\text{DC}} \mathcal{H}} \sum_{t \in (0, \delta)} \sum_{\tau=t+\varepsilon}^{t+|\mathcal{J}_t^+|} \sum_{\substack{b \in X^* \\ \text{supp } b \subset B_t}} \varepsilon |\nabla \gamma_\tau(b)|^2 \\ &\geq c_{\mathcal{H}} e^{-4^{\text{DC}} \mathcal{H}} \sum_{t \in (0, \delta)} \frac{1}{8} |\mathcal{J}_t| R'(|\mathcal{J}_t|)^2 \left| \tilde{P}'_\beta(\mathcal{J}_t) \right| \end{aligned} \quad (6.8a)$$

by Lemma E.12(ii). Similarly

$$\begin{aligned} \sum_{\tau \in [0, \delta)} \langle \gamma_{*\tau}^*, [\mathbb{1} - \mathfrak{j}(\varepsilon)]\gamma_{*\tau} \rangle &\geq c_{\mathcal{H}} e^{-4^{\text{DC}} \mathcal{H}} \sum_{t \in (0, \delta)} \sum_{\tau=t-|\mathcal{J}_t^-|}^{t-\varepsilon} \sum_{\substack{b \in X^* \\ \text{supp } b \subset B_t}} \varepsilon |\nabla \gamma_{*\tau}(b)|^2 \\ &\geq c_{\mathcal{H}} e^{-4^{\text{DC}} \mathcal{H}} \sum_{t \in (0, \delta)} \frac{1}{8} |\mathcal{J}_t| R'(|\mathcal{J}_t|)^2 \left| \tilde{P}'_\alpha(\mathcal{J}_t) \right| \end{aligned} \quad (6.8b)$$

and

$$\begin{aligned}
& \sum_{\tau \in [0, \delta)} 2 \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c}^2 \\
& \geq \sum_{\tau \in (0, \delta)} \left\{ \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c}^2 + \|\gamma_{*\tau-\varepsilon}^* - \gamma_\tau\|_{\Lambda_{\tau-\varepsilon}^c \cup \Lambda_\tau^c}^2 \right\} \\
& = \sum_{t \in (0, \delta)} \left\{ \|\gamma_{*t}^* - \gamma_{t+\varepsilon}\|_{\Lambda_t^c \cup \Lambda_{t+\varepsilon}^c}^2 + \|\gamma_{*t-\varepsilon}^* - \gamma_t\|_{\Lambda_{t-\varepsilon}^c \cup \Lambda_t^c}^2 \right\} \\
& \geq \sum_{t \in (0, \delta)} \left\{ \|\gamma_{*t}^* - \gamma_{t+\varepsilon}\|_{\tilde{Q}(\mathcal{J}_t)}^2 + \|\gamma_{*t-\varepsilon}^* - \gamma_t\|_{\tilde{Q}(\mathcal{J}_t)}^2 \right\} \\
& \geq \sum_{t \in (0, \delta)} \frac{1}{32} r(|\mathcal{J}_t|)^2 |\tilde{Q}(\mathcal{J}_t)| \tag{6.8c}
\end{aligned}$$

Hence, by Lemmas 6.2 and E.17 and Proposition E.11(ii),

$$\begin{aligned}
& \operatorname{Re} \sum_{\tau \in [0, \delta)} \left[-\frac{1}{2} \langle \gamma_{*\tau}, \gamma_\tau \rangle + \langle \gamma_{*\tau}, j(\varepsilon) \gamma_{\tau+\varepsilon} \rangle - \frac{1}{2} \langle \gamma_{*\tau+\varepsilon}, \gamma_{\tau+\varepsilon} \rangle \right] \\
& \leq -\frac{1}{4} \left\{ \sum_{\tau \in [0, \delta)} \frac{1}{2} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c}^2 + \sum_{\tau \in (0, \delta)} \langle \gamma_\tau^*, [\mathbb{1} - j(\varepsilon)] \gamma_\tau \rangle \right. \\
& \quad \left. + \sum_{\tau \in [0, \delta)} \langle \gamma_{*\tau}^*, [\mathbb{1} - j(\varepsilon)] \gamma_{*\tau} \rangle \right\} \\
& \quad + \sum_{\tau \in (0, \delta)} e^{-2m\epsilon(\frac{1}{2}|\mathcal{J}_\tau|)} |\Lambda_\tau^c| + |e^{\varepsilon\mu} - 1| \sum_{\tau \in [0, \delta]} [\|\gamma_\tau\|^2 + \|\gamma_{*\tau}\|^2] \\
& \leq -\frac{1}{16} \sum_{\tau \in [0, \delta)} \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c}^2 - K_{L2} \\
& \quad \times \sum_{t \in (0, \delta)} \left\{ r(|\mathcal{J}_t|)^2 |\tilde{Q}(\mathcal{J}_t)| + |\mathcal{J}_t| R'(\mathcal{J}_t)^2 |\tilde{P}'_\alpha(\mathcal{J}_t)| + |\mathcal{J}_t| R'(\mathcal{J}_t)^2 |\tilde{P}'_\beta(\mathcal{J}_t)| \right\} \\
& \quad + \sum_{\tau \in (0, \delta)} e^{-2m\epsilon(\frac{1}{2}|\mathcal{J}_\tau|)} |\Lambda_\tau^c| + |e^{\varepsilon\mu} - 1| \sum_{\tau \in [0, \delta]} [\|\gamma_\tau\|^2 + \|\gamma_{*\tau}\|^2]
\end{aligned}$$

where $K_{L2} = \frac{1}{32} \min\{c_{\mathcal{H}} e^{-4DC_{\mathcal{H}}}, \frac{1}{32}\}$ with $c_{\mathcal{H}}$ and $C_{\mathcal{H}}$ being the smallest and largest eigenvalues of \mathcal{H} , respectively. The claim follows from (F.4c), (F.7a), (F.7b) and Lemma 6.3. \square

6.2. Extracting Small Factors from the Quartic Form

In this section, we prove Proposition 3.37. Recall that

$$\mathcal{V}_{\mathfrak{S}} = -\varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \langle \gamma_{*\tau} \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle$$

If we could replace $\gamma_{*\tau}$ by γ_τ^* and $\gamma_{\tau+\varepsilon}$ by γ_τ , we would have

$$\begin{aligned} -\varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} \langle \gamma_\tau^* \gamma_\tau, v \gamma_\tau^* \gamma_\tau \rangle &\leq -\varepsilon \sum_{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta)} v_1 \|\gamma_\tau\|_{L^4(X)}^2 \\ &= -\varepsilon v_1 \sum_{\substack{\tau \in \varepsilon \mathbb{Z} \cap [0, \delta) \\ \mathbf{x} \in X}} |\gamma_\tau(\mathbf{x})|^4 \end{aligned}$$

which is very negative when some \mathbf{x} 's are in large field regions. The following lemma expresses the error introduced by such a replacement as a sum of two terms, $\tilde{\mathcal{E}}_{4,\mathfrak{S}}$ and $\hat{\mathcal{V}}_{\mathfrak{S}}$. The first, $\tilde{\mathcal{E}}_{4,\mathfrak{S}}$ is a pure small field contribution, which will be bounded by the “small field regulator” $\text{Reg}_{SF}^{(4)}$. See Lemma 6.7. The second, $\hat{\mathcal{V}}_{\mathfrak{S}}$, is a large field contribution and is bounded by the two terms in the third line of the right hand side in Proposition 3.37.

Lemma 6.4.

$$\begin{aligned} \mathcal{V}_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) &= -\frac{1}{2} \sum_{\tau \in [0, \delta)} \varepsilon \langle \gamma_{*\tau}^* \gamma_{*\tau}, v \gamma_{*\tau}^* \gamma_{*\tau} \rangle - \frac{1}{2} \sum_{\tau \in (0, \delta]} \varepsilon \langle \gamma_\tau^* \gamma_\tau, v \gamma_\tau^* \gamma_\tau \rangle \\ &\quad + \tilde{\mathcal{E}}_{4,\mathfrak{S}}(\alpha, \beta) + \hat{\mathcal{V}}_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \end{aligned}$$

where $\hat{\mathcal{V}}_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$ is defined in (6.14) and bounded in Lemma 6.6 and $\tilde{\mathcal{E}}_{4,\mathfrak{S}}(\alpha, \beta)$ is defined in (6.12) and bounded in Lemma 6.7. The first two terms on the right hand side are bounded in Lemma 6.5.

Proof. We start with the difference

$$\mathcal{V}_{\mathfrak{S}} - \left[-\frac{1}{2} \sum_{\tau \in [0, \delta)} \varepsilon \langle \gamma_{*\tau}^* \gamma_{*\tau}, v \gamma_{*\tau}^* \gamma_{*\tau} \rangle - \frac{1}{2} \sum_{\tau \in (0, \delta]} \varepsilon \langle \gamma_\tau^* \gamma_\tau, v \gamma_\tau^* \gamma_\tau \rangle \right]$$

between $\mathcal{V}_{\mathfrak{S}}$ and the expressions which are manifestly large and negative in the large field region. (See Lemma 6.5). From this, we successively pull off four controllable pieces, $\hat{\mathcal{V}}_{1,\mathfrak{S}}, \dots, \hat{\mathcal{V}}_{4,\mathfrak{S}}$, leaving the small field contribution $\tilde{\mathcal{E}}_{4,\mathfrak{S}}(\alpha, \beta)$. The first step is

$$\begin{aligned} \mathcal{V}_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) &+ \frac{1}{2} \sum_{\tau \in [0, \delta)} \varepsilon \langle \gamma_{*\tau}^* \gamma_{*\tau}, v \gamma_{*\tau}^* \gamma_{*\tau} \rangle + \frac{1}{2} \sum_{\tau \in (0, \delta]} \varepsilon \langle \gamma_\tau^* \gamma_\tau, v \gamma_\tau^* \gamma_\tau \rangle \\ &= -\frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \{ \langle \gamma_{*\tau}(\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*), v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle + \langle \gamma_{*\tau} \gamma_{*\tau}^*, v \gamma_{*\tau} (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*) \rangle \} \\ &\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \{ \langle (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle \\ &\quad + \langle \gamma_{\tau+\varepsilon}^* \gamma_{\tau+\varepsilon}, v (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon} \rangle \} \\ &= \mathcal{V}'_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) + \hat{\mathcal{V}}_{1,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \end{aligned}$$

where

$$\begin{aligned}
& \mathcal{V}'_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \\
&= -\frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \left\{ \langle \Lambda \gamma_{*\tau} (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*), v \Lambda \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle \right. \\
&\quad + \langle \Lambda \gamma_{*\tau} \gamma_{*\tau}^*, v \Lambda \gamma_{*\tau} (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*) \rangle \} \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \left\{ \langle \Lambda (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \Lambda \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle \right. \\
&\quad \left. + \langle \Lambda \gamma_{\tau+\varepsilon}^* \gamma_{\tau+\varepsilon}, v \Lambda (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon} \rangle \right\}
\end{aligned}$$

and

$$\begin{aligned}
& \widehat{\mathcal{V}}_{1, \mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \\
&= -\frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \left\{ \langle \Lambda^c \gamma_{*\tau} (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*), v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle \right. \\
&\quad + \langle \gamma_{*\tau} \gamma_{*\tau}^*, v \Lambda^c \gamma_{*\tau} (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*) \rangle \} \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \left\{ \langle \Lambda^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle \right. \\
&\quad + \langle \gamma_{\tau+\varepsilon}^* \gamma_{\tau+\varepsilon}, v \Lambda^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon} \rangle \} \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \left\{ \langle \Lambda \gamma_{*\tau} (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*), v \Lambda^c \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle \right. \\
&\quad + \langle \Lambda^c \gamma_{*\tau} \gamma_{*\tau}^*, v \Lambda \gamma_{*\tau} (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*) \rangle \} \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \left\{ \langle \Lambda (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \Lambda^c \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle \right. \\
&\quad + \langle \Lambda^c \gamma_{\tau+\varepsilon}^* \gamma_{\tau+\varepsilon}, v \Lambda (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon} \rangle \} \tag{6.9}
\end{aligned}$$

Next write

$$\mathcal{V}'_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) = \mathcal{V}''_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) + \widehat{\mathcal{V}}_{2, \mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$$

where, in the notation of Definition 2.9 and Lemma E.4(i),

$$\begin{aligned}
\mathcal{V}''_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) &= -\frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \langle \Lambda (\Gamma_{*\tau}^0 \alpha^*) (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*), v \Lambda (\Gamma_{*\tau}^0 \alpha^*) (\Gamma_{\tau+\varepsilon}^\delta \beta) \rangle \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \langle \Lambda (\Gamma_{*\tau}^0 \alpha^*) (\Gamma_{*\tau}^0 \alpha), v \Lambda (\Gamma_{*\tau}^0 \alpha^*) (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*) \rangle \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \langle \Lambda (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) (\Gamma_{\tau+\varepsilon}^\delta \beta), v \Lambda (\Gamma_{*\tau}^0 \alpha^*) (\Gamma_{\tau+\varepsilon}^\delta \beta) \rangle \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \langle \Lambda (\Gamma_{\tau+\varepsilon}^\delta \beta^*) (\Gamma_{\tau+\varepsilon}^\delta \beta), v \Lambda (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) (\Gamma_{\tau+\varepsilon}^\delta \beta) \rangle
\end{aligned}$$

and, using the notation of Definition E.3,

$$\begin{aligned}
& \hat{\mathcal{V}}_{2,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \\
&= -\frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \sum_{\substack{\tau_1, \tau_2 \in \mathcal{T}_l(\tau, \delta) \\ \tau_3 \in \mathcal{T}_r(\tau + \varepsilon, \delta) \\ (\tau_1, \tau_2, \tau_3) \neq (0, 0, \delta)}} \langle \Lambda(\Gamma_{*\tau}^{\tau_1} \alpha_{\tau_1}^*) (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*), v \Lambda(\Gamma_{*\tau}^{\tau_2} \alpha_{\tau_2}^*) (\Gamma_{\tau+\varepsilon}^{\tau_3} \alpha_{\tau_3}) \rangle \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \sum_{\substack{\tau_1, \tau_2, \tau_3 \in \mathcal{T}_l(\tau, \delta) \\ (\tau_1, \tau_2, \tau_3) \neq (0, 0, 0)}} \langle \Lambda(\Gamma_{*\tau}^{\tau_1} \alpha_{\tau_1}^*) (\Gamma_{*\tau}^{\tau_2} \alpha_{\tau_2}), v \Lambda(\Gamma_{*\tau}^{\tau_3} \alpha_{\tau_3}^*) (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*) \rangle \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \sum_{\substack{\tau_1, \tau_2 \in \mathcal{T}_r(\tau + \varepsilon, \delta) \\ \tau_3 \in \mathcal{T}_l(\tau, \delta) \\ (\tau_1, \tau_2, \tau_3) \neq (\delta, \delta, 0)}} \langle \Lambda(\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) (\Gamma_{\tau+\varepsilon}^{\tau_1} \alpha_{\tau_1}), v \Lambda(\Gamma_{*\tau}^{\tau_2} \alpha_{\tau_2}^*) (\Gamma_{\tau+\varepsilon}^{\tau_3} \alpha_{\tau_3}) \rangle \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \sum_{\substack{\tau_1, \tau_2, \tau_3 \in \mathcal{T}_r(\tau + \varepsilon, \delta) \\ (\tau_1, \tau_2, \tau_3) \neq (\delta, \delta, \delta)}} \langle \Lambda(\Gamma_{\tau+\varepsilon}^{\tau_1} \alpha_{\tau_1}^*) (\Gamma_{\tau+\varepsilon}^{\tau_2} \alpha_{\tau_2}), v \Lambda(\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) (\Gamma_{\tau+\varepsilon}^{\tau_3} \alpha_{\tau_3}) \rangle
\end{aligned} \tag{6.10}$$

Next write

$$\mathcal{V}_{\mathfrak{S}}''(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) = \mathcal{V}_{\mathfrak{S}}'''(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) + \hat{\mathcal{V}}_{3,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$$

where

$$\begin{aligned}
& \mathcal{V}_{\mathfrak{S}}'''(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \\
&= -\frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \langle \Lambda(\Gamma_{*\tau}^0 \Omega \alpha^*) (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*), v \Lambda(\Gamma_{*\tau}^0 \Omega \alpha^*) (\Gamma_{\tau+\varepsilon}^\delta \Omega \beta) \rangle \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \langle \Lambda(\Gamma_{*\tau}^0 \Omega \alpha^*) (\Gamma_{*\tau}^0 \Omega \alpha), v \Lambda(\Gamma_{*\tau}^0 \Omega \alpha^*) (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*) \rangle \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \langle \Lambda(\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) (\Gamma_{\tau+\varepsilon}^\delta \Omega \beta), v \Lambda(\Gamma_{*\tau}^0 \Omega \alpha^*) (\Gamma_{\tau+\varepsilon}^\delta \Omega \beta) \rangle \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \langle \Lambda(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta^*) (\Gamma_{\tau+\varepsilon}^\delta \Omega \beta), v \Lambda(\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) (\Gamma_{\tau+\varepsilon}^\delta \Omega \beta) \rangle
\end{aligned}$$

and, using $\Omega^{(0)} = \Omega$ and $\Omega^{(1)} = \Omega^c$,

$$\begin{aligned}
& \hat{\mathcal{V}}_{3,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \\
&= -\frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \sum_{\substack{i,j,k \in \{0,1\} \\ (i,j,k) \neq (0,0,0)}} \left\langle \Lambda\left(\Gamma_{*\tau}^0 \Omega^{(i)} \alpha^*\right) (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*), \right. \\
&\quad \times v \Lambda\left(\Gamma_{*\tau}^0 \Omega^{(j)} \alpha^*\right) \left(\Gamma_{\tau+\varepsilon}^\delta \Omega^{(k)} \beta\right) \rangle \\
&\quad - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \sum_{\substack{i,j,k \in \{0,1\} \\ (i,j,k) \neq (0,0,0)}} \left\langle \Lambda\left(\Gamma_{*\tau}^0 \Omega^{(i)} \alpha^*\right) \left(\Gamma_{*\tau}^0 \Omega^{(j)} \alpha\right), \right. \\
&\quad \times v \Lambda\left(\Gamma_{*\tau}^0 \Omega^{(k)} \beta\right) \left.\right\rangle
\end{aligned}$$

$$\begin{aligned}
& \times v \Lambda \left(\Gamma_{*\tau}^0 \Omega^{(k)} \alpha^* \right) (\gamma_{\tau+\varepsilon} - \gamma_{*\tau}^*) \Big\rangle \\
& - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \sum_{\substack{i,j,k \in \{0,1\} \\ (i,j,k) \neq (0,0,0)}} \Big\langle \Lambda (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \left(\Gamma_{\tau+\varepsilon}^\delta \Omega^{(i)} \beta \right), \\
& \quad \times v \Lambda \left(\Gamma_{*\tau}^0 \Omega^{(j)} \alpha^* \right) \left(\Gamma_{\tau+\varepsilon}^\delta \Omega^{(k)} \beta \right) \Big\rangle \\
& - \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \sum_{\substack{i,j,k \in \{0,1\} \\ (i,j,k) \neq (0,0,0)}} \Big\langle \Lambda \left(\Gamma_{\tau+\varepsilon}^\delta \Omega^{(i)} \beta^* \right) \left(\Gamma_{\tau+\varepsilon}^\delta \Omega^{(j)} \beta \right), \\
& \quad \times v \Lambda (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \left(\Gamma_{\tau+\varepsilon}^\delta \Omega^{(k)} \beta \right) \Big\rangle \tag{6.11}
\end{aligned}$$

Finally substitute, in $\mathcal{V}_{\mathfrak{S}}'''(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$,

$$\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon} = \tilde{\gamma}_{\tau, \varepsilon} + \tilde{\gamma}_{\tau, \varepsilon}^{(1)} + \tilde{\gamma}_{\tau, \varepsilon}^{(2)}$$

where

$$\tilde{\gamma}_{\tau, \varepsilon} = j(\tau) \tilde{\Omega} \alpha - j(\delta - \tau - \varepsilon) \tilde{\Omega} \beta \quad \tilde{\gamma}_{\tau, \varepsilon}^{(1)} = \gamma_{*\tau}^* - \gamma_{\tau+\varepsilon} - \tilde{\gamma}_{\tau, \varepsilon} \quad \tilde{\gamma}_{\tau, \varepsilon}^{(2)} = \tilde{\gamma}_{\tau, \varepsilon} - \tilde{\tilde{\gamma}}_{\tau, \varepsilon}$$

where $\tilde{\Omega}$ the set of all point in X that are within a distance $\mathbf{c}(\delta)$ of Ω and $\tilde{\gamma}_{\tau, \varepsilon}$ was defined in Corollary E.9, and write

$$\mathcal{V}_{\mathfrak{S}}'''(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) = \tilde{\mathcal{E}}_{4, \mathfrak{S}}(\alpha, \beta) + \hat{\mathcal{V}}_{4, \mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$$

where

$$\begin{aligned}
\tilde{\mathcal{E}}_{4, \mathfrak{S}}(\alpha, \beta) &= \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \Big\langle \Lambda \left(\Gamma_{*\tau}^0 \Omega \alpha^* \right) \tilde{\gamma}_{\tau, \varepsilon}, v \Lambda \left(\Gamma_{*\tau}^0 \Omega \alpha^* \right) \left(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta \right) \Big\rangle \\
&+ \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \Big\langle \Lambda \left(\Gamma_{*\tau}^0 \Omega \alpha^* \right) \left(\Gamma_{*\tau}^0 \Omega \alpha \right), v \Lambda \left(\Gamma_{*\tau}^0 \Omega \alpha^* \right) \tilde{\gamma}_{\tau, \varepsilon} \Big\rangle \\
&- \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \Big\langle \Lambda \tilde{\gamma}_{\tau, \varepsilon}^* \left(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta \right), v \Lambda \left(\Gamma_{*\tau}^0 \Omega \alpha^* \right) \left(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta \right) \Big\rangle \\
&- \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \Big\langle \Lambda \left(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta^* \right) \left(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta \right), v \Lambda \tilde{\gamma}_{\tau, \varepsilon}^* \left(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta \right) \Big\rangle \tag{6.12}
\end{aligned}$$

and

$$\begin{aligned}
& \hat{\mathcal{V}}_{4, \mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \\
&= \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \Big\langle \Lambda \left(\Gamma_{*\tau}^0 \Omega \alpha^* \right) (\tilde{\gamma}_{\tau, \varepsilon}^{(1)} + \tilde{\gamma}_{\tau, \varepsilon}^{(2)}), v \Lambda \left(\Gamma_{*\tau}^0 \Omega \alpha^* \right) \left(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta \right) \Big\rangle \\
&+ \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \Big\langle \Lambda \left(\Gamma_{*\tau}^0 \Omega \alpha^* \right) \left(\Gamma_{*\tau}^0 \Omega \alpha \right), v \Lambda \left(\Gamma_{*\tau}^0 \Omega \alpha^* \right) (\tilde{\gamma}_{\tau, \varepsilon}^{(1)} + \tilde{\gamma}_{\tau, \varepsilon}^{(2)}) \Big\rangle \\
&- \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \Big\langle \Lambda \left(\tilde{\gamma}_{\tau, \varepsilon}^{(1)} + \tilde{\gamma}_{\tau, \varepsilon}^{(2)} \right)^* \left(\Gamma_{\tau+\varepsilon}^\delta \beta \right), v \Lambda \left(\Gamma_{*\tau}^0 \Omega \alpha^* \right) \left(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta \right) \Big\rangle \\
&- \frac{\varepsilon}{2} \sum_{\tau \in [0, \delta)} \Big\langle \Lambda \left(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta^* \right) \left(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta \right), v \Lambda \left(\tilde{\gamma}_{\tau, \varepsilon}^{(1)} + \tilde{\gamma}_{\tau, \varepsilon}^{(2)} \right)^* \left(\Gamma_{\tau+\varepsilon}^\delta \Omega \beta \right) \Big\rangle \tag{6.13}
\end{aligned}$$

Of course

$$\widehat{\mathcal{V}}_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) = \sum_{i=1}^4 \widehat{\mathcal{V}}_{i,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \quad (6.14)$$

□

Lemma 6.5. *We have*

$$\begin{aligned} \sum_{\tau \in (0, \delta]} \varepsilon \langle \gamma_{\tau}^* \gamma_{\tau}, v \gamma_{\tau}^* \gamma_{\tau} \rangle &\geq 4C_L \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \delta]}} r(|\mathcal{J}|)^2 \# \tilde{P}_{\beta}(\mathcal{J}) \\ \sum_{\tau \in [0, \delta)} \varepsilon \langle \gamma_{*\tau}^* \gamma_{*\tau}, v \gamma_{*\tau}^* \gamma_{*\tau} \rangle &\geq 4C_L \sum_{\substack{\text{decimation} \\ \text{intervals} \\ \mathcal{J} \subset [0, \delta]}} r(|\mathcal{J}|)^2 \# \tilde{P}_{\alpha}(\mathcal{J}) \end{aligned}$$

with the C_L of Lemma F.5.

Proof. We again use, for each $t \in (0, \delta) \cap \varepsilon \mathbb{Z}$, the notation

$$B_t = \Lambda(\mathcal{J}_t)^c \cap \Lambda(\mathcal{J}_t^-) \cap \Lambda(\mathcal{J}_t^+)$$

of (6.5). Since v is repulsive, its smallest eigenvalue $v_1 > 0$, so that

$$\begin{aligned} \sum_{\tau \in (0, \delta]} \varepsilon \langle \gamma_{\tau}^* \gamma_{\tau}, v \gamma_{\tau}^* \gamma_{\tau} \rangle &\geq \varepsilon v_1 \sum_{\tau \in (0, \delta]} \|\gamma_{\tau}^* \gamma_{\tau}\|^2 = \sum_{\mathbf{x} \in X} \sum_{\tau \in (0, \delta]} \varepsilon v_1 |\gamma_{\tau}(\mathbf{x})|^4 \\ &\geq \sum_{\mathbf{x} \in X} \sum_{\substack{t \in (0, \delta) \\ \mathbf{x} \in B_t}} \sum_{\tau=t+\varepsilon}^{t+|\mathcal{J}_t^+|} \varepsilon v_1 |\gamma_{\tau}(\mathbf{x})|^4 \quad \text{by (6.7)} \\ &= \sum_{t \in (0, \delta)} \sum_{\tau=t+\varepsilon}^{t+|\mathcal{J}_t^+|} \sum_{\mathbf{x} \in B_t} \varepsilon v_1 |\gamma_{\tau}(\mathbf{x})|^4 \\ &\geq \frac{1}{16} \sum_{t \in (0, \delta)} |\mathcal{J}_t^+| v_1 R(|\mathcal{J}_t|)^4 \# \tilde{P}_{\beta}(\mathcal{J}_t) \quad \text{by Lemma E.12(v)} \end{aligned}$$

Similarly

$$\sum_{\tau \in [0, \delta)} \varepsilon \langle \gamma_{*\tau}^* \gamma_{*\tau}, v \gamma_{*\tau}^* \gamma_{*\tau} \rangle \geq \frac{1}{16} \sum_{t \in (0, \delta)} |\mathcal{J}_t^-| v_1 R(|\mathcal{J}_t|)^4 \# \tilde{P}_{\alpha}(\mathcal{J}_t)$$

By Hypothesis 2.14, $\frac{1}{16} |\mathcal{J}_t^{\pm}| v_1 \geq \frac{c_v}{16} |\mathcal{J}_t^{\pm}| \|v\| \geq \frac{c_v}{64} |\mathcal{J}_t^{\pm}| \mathfrak{v}$, and the claim now follows from (F.7c). □

Lemma 6.6. *Recall that $\widehat{\mathcal{V}}_{1,\mathfrak{S}}$, $\widehat{\mathcal{V}}_{2,\mathfrak{S}}$, $\widehat{\mathcal{V}}_{3,\mathfrak{S}}$ and $\widehat{\mathcal{V}}_{4,\mathfrak{S}}$ were defined in (6.9), (6.10), (6.11) and (6.13) respectively.*

$$\begin{aligned}
\left| \widehat{\mathcal{V}}_{1,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \right| &\leq \sum_{\tau \in [0, \delta)} 2^{19} e^{3K_j} \varepsilon \mathfrak{v} R(\varepsilon)^3 \| \gamma_{*\tau}^* - \gamma_{\tau+\varepsilon} \|_{\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c}^2 \\
&\quad + \sum_{\tau \in (0, \delta)} (2^{21} e^{3K_j} \varepsilon \mathfrak{v} R(\varepsilon)^3 \\
&\quad + 2^{28} e^{4K_j} |\mathcal{J}_\tau| \mathfrak{v} r(|\mathcal{J}_\tau|) R(|\mathcal{J}_\tau|)^3) |\Lambda_\tau^c| \\
\left| \widehat{\mathcal{V}}_{2,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \right| &\leq 2^{17} e^{4K_j} \delta \mathfrak{v} r(\delta) R(\delta)^3 |\Lambda^c| \\
\left| \widehat{\mathcal{V}}_{3,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha}) \right| &\leq 2^{17} e^{4K_j} \delta \mathfrak{v} r(\delta) R(\delta)^3 |\Omega^c| \\

&\leq \sum_{\tau' \in (0, \delta)} 2^{26} e^{4K_j} |\mathcal{J}_{\tau'}| \mathfrak{v} r(|\mathcal{J}_{\tau'}|) R(|\mathcal{J}_{\tau'}|)^3 |\Lambda_{\tau'}^c| \tag{6.16}
\end{aligned}$$

and

$$\begin{aligned}
\varepsilon \sum_{\tau \in [0, \delta)} &| \langle \Lambda (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \Lambda^c \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle | \leq 2^{14} e^{4K_j} \delta \mathfrak{v} r(\delta) R(\delta)^3 |\Lambda_{\frac{\delta}{2}}^c| \\
&\tag{6.17}
\end{aligned}$$

and

$$\begin{aligned}
\varepsilon \sum_{\tau \in [0, \delta)} &\sum_{\substack{\tau_1, \tau_2 \in \mathcal{T}_r(\tau+\varepsilon, \delta) \\ \tau_3 \in \mathcal{T}_l(\tau, \delta) \\ (\tau_1, \tau_2, \tau_3) \neq (\delta, \delta, 0)}} | \langle \Lambda (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) (\Gamma_{\tau+\varepsilon}^{\tau_1} \alpha_{\tau_1}), v \Lambda (\Gamma_{*\tau}^{\tau_3} \alpha_{\tau_3}^*) (\Gamma_{\tau+\varepsilon}^{\tau_2} \alpha_{\tau_2}) \rangle | \\
&\leq 2^{16} e^{4K_j} \delta \mathfrak{v} r(\delta) R(\delta)^3 |\Lambda^c| \tag{6.18}
\end{aligned}$$

and

$$\begin{aligned}
\varepsilon \sum_{\tau \in [0, \delta)} &| \langle \Lambda |\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*| (\Gamma_{\tau+\varepsilon}^\delta \Omega^c |\beta|), v \Lambda (\Gamma_{*\tau}^0 |\alpha|) (\Gamma_{\tau+\varepsilon}^\delta |\beta|) \rangle | \\
&\leq 2^{14} e^{4K_j} \delta \mathfrak{v} r(\delta) R(\delta)^3 |\Omega^c| \tag{6.19}
\end{aligned}$$

and

$$\begin{aligned} \varepsilon \sum_{\tau \in [0, \delta)} & \left| \left\langle \Lambda(\Gamma_{*\tau}^0 \Omega \alpha^*) \tilde{\gamma}_{\tau, \varepsilon}^{(1)}, v \Lambda(\Gamma_{*\tau}^0 \Omega \alpha^*) (\Gamma_{\tau+\varepsilon}^\delta \Omega \beta) \right\rangle \right| \\ & \leq 2^{14} e^{4K_j} \delta \mathfrak{v} r(\delta) R(\delta)^3 |\Lambda^c| \end{aligned} \quad (6.20)$$

and

$$\varepsilon \sum_{\tau \in [0, \delta)} \left| \left\langle \Lambda(\Gamma_{*\tau}^0 \Omega \alpha^*) \tilde{\gamma}_{\tau, \varepsilon}^{(2)}, v \Lambda(\Gamma_{*\tau}^0 \Omega \alpha^*) (\Gamma_{\tau+\varepsilon}^\delta \Omega \beta) \right\rangle \right| \leq \frac{1}{8} e^{-2m\mathfrak{c}(\delta)} \delta \mathfrak{v} |\tilde{\Omega}^c| \quad (6.21)$$

Four copies of (minor variants of) $\frac{1}{2}[(6.15)+(6.16)]$ bounds the first two lines of the definition of $\widehat{\mathcal{V}}_{1,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$ in (6.9). Four copies of (minor variants of) $\frac{1}{2}(6.17)$ bounds the last two lines of the definition of $\widehat{\mathcal{V}}_{1,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$ in (6.9). Four copies of (minor variants of) $\frac{1}{2}(6.18)$ bounds $\widehat{\mathcal{V}}_{2,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$, which was defined in (6.10). Twelve copies of (minor variants of) $\frac{1}{2}(6.19)$ bounds $\widehat{\mathcal{V}}_{3,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$, which was defined in (6.11). Four copies of (minor variants of) $\frac{1}{2}[(6.20)+(6.21)]$ bounds $\widehat{\mathcal{V}}_{4,\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$, which was defined in (6.13).

Proof of (6.15). By Proposition E.11(i,ii) with $\mathcal{J} = \mathcal{J}_\tau$, and (6.4),

$$|\gamma_\tau(\mathbf{y})|, |\gamma_{*\tau}(\mathbf{y})| \leq 2^6 e^{K_j} R(\varepsilon) \quad \text{for all } \mathbf{y} \in X$$

for all $\tau \in \varepsilon \mathbb{Z} \cap [0, \delta]$. Hence, since $\sum_{\mathbf{y} \in X} |v(\mathbf{x}, \mathbf{y})| \leq \mathfrak{v}$,

$$\begin{aligned} \varepsilon \sum_{\tau \in [0, \delta)} & \left| \left\langle \Lambda^c(\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c)(\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \right\rangle \right| \\ & \leq \sum_{\substack{\tau \in [0, \delta) \\ \mathbf{x} \in (\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c) \cap \Lambda^c}} \varepsilon \mathfrak{v} 2^{18} e^{3K_j} R(\varepsilon)^3 |\gamma_{*\tau}^*(\mathbf{x}) - \gamma_{\tau+\varepsilon}(\mathbf{x})| \\ & \leq \sum_{\substack{\tau \in [0, \delta) \\ \mathbf{x} \in (\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c) \cap \Lambda^c}} 2^{18} e^{3K_j} \varepsilon \mathfrak{v} R(\varepsilon)^3 \left\{ |\gamma_{*\tau}^*(\mathbf{x}) - \gamma_{\tau+\varepsilon}(\mathbf{x})|^2 + 1 \right\} \\ & \leq \sum_{\tau \in [0, \delta)} 2^{18} e^{3K_j} \varepsilon \mathfrak{v} R(\varepsilon)^3 \left\{ \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c}^2 + |\Lambda_\tau^c \cap \Lambda_{\frac{\delta}{2}}^c| + |\Lambda_{\tau+\varepsilon}^c \cap \Lambda_{\frac{\delta}{2}}^c| \right\} \\ & \leq \sum_{\tau \in [0, \delta)} 2^{18} e^{3K_j} \varepsilon \mathfrak{v} R(\varepsilon)^3 \|\gamma_{*\tau}^* - \gamma_{\tau+\varepsilon}\|_{\Lambda_\tau^c \cup \Lambda_{\tau+\varepsilon}^c}^2 + \sum_{\tau \in (0, \delta)} 2^{20} e^{3K_j} \varepsilon \mathfrak{v} R(\varepsilon)^3 |\Lambda_\tau^c| \end{aligned}$$

□

Proof of (6.16). We actually prove that

$$\begin{aligned} \varepsilon \sum_{\substack{\tau \in [0, \delta) \\ \tau \in 2\varepsilon \mathbb{Z}}} & \left| \left\langle \Lambda^c \Lambda_\tau \Lambda_{\tau+\varepsilon} (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \right\rangle \right| \\ & \leq \sum_{\tau' \in (0, \delta)} 2^{25} e^{4K_j} |\mathcal{J}_{\tau'}| \mathfrak{v} r(|\mathcal{J}_{\tau'}|) R(|\mathcal{J}_{\tau'}|)^3 |\Lambda_{\tau'}^c| \end{aligned} \quad (6.22a)$$

The proof that

$$\begin{aligned}
& \varepsilon \sum_{\substack{\tau \in [0, \delta) \\ \tau \in \varepsilon \mathbb{Z} \setminus 2\varepsilon \mathbb{Z}}} |\langle \Lambda^c \Lambda_\tau \Lambda_{\tau+\varepsilon} (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\
&= \varepsilon \sum_{\substack{\tau \in (0, \delta] \\ \tau \in 2\varepsilon \mathbb{Z}}} |\langle \Lambda^c \Lambda_\tau \Lambda_{\tau-\varepsilon} (\gamma_{*\tau-\varepsilon} - \gamma_\tau^*) \gamma_\tau, v \gamma_{*\tau-\varepsilon} \gamma_\tau \rangle| \\
&\leq \sum_{\tau' \in (0, \delta)} 2^{25} e^{4K_j} |\mathcal{J}_{\tau'}| \mathfrak{r}(|\mathcal{J}_{\tau'}|) R(|\mathcal{J}_{\tau'}|)^3 |\Lambda_{\tau'}^c| \tag{6.22b}
\end{aligned}$$

is similar.

Now for (6.22a). For any $\tau \in 2\varepsilon \mathbb{Z} \cap (0, \delta)$, we necessarily have $\mathcal{J}_{\tau+\varepsilon} = [\tau, \tau + 2\varepsilon] \subset \mathcal{J}_\tau$, so that $\Lambda_{\tau+\varepsilon} \supset \Lambda_\tau$. Hence, by Lemma E.4(ii), and recalling that $\Lambda_0 = \emptyset$,

$$\begin{aligned}
& \varepsilon \sum_{\tau \in 2\varepsilon \mathbb{Z} \cap [0, \delta)} |\langle \Lambda^c \Lambda_\tau \Lambda_{\tau+\varepsilon} (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\
&= \varepsilon \sum_{\tau \in 2\varepsilon \mathbb{Z} \cap [0, \delta)} |\langle \Lambda^c \Lambda_\tau (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\
&\leq \varepsilon \sum_{\tau \in 2\varepsilon \mathbb{Z} \cap (0, \delta)} \sum_{\substack{\tau_r \in \mathcal{T}_r(\tau, \delta) \\ \tau_l \in \mathcal{T}_l(\tau, \delta)}} \\
&\quad \times |\langle \Lambda^c \Lambda_{\pi(\tau_r)} \Lambda_{\tau_r}^c \Lambda_{\sigma(\tau_l)} \Lambda_{\tau_l}^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\
&\leq \varepsilon \sum_{\tau \in 2\varepsilon \mathbb{Z} \cap (0, \delta)} \sum_{[\tau_r, \tau_l] \in \mathcal{T}_{lr}(\tau, \delta)} \\
&\quad \times |\langle \Lambda^c \Lambda([\tau_l, \tau_r]) \Lambda_{\tau_r}^c \Lambda_{\tau_l}^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle|
\end{aligned}$$

where $\mathcal{T}_{lr}(\tau, \delta)$ is the set of all decimation intervals (in the sense of Notation 2.2) $[\tau_l, \tau_r]$ with $\tau_l \in \mathcal{T}_l(\tau, \delta)$, $\tau_r \in \mathcal{T}_r(\tau, \delta)$ and $\Lambda_{\pi(\tau_r)} \cap \Lambda_{\tau_r}^c \cap \Lambda_{\sigma(\tau_l)} \cap \Lambda_{\tau_l}^c \neq \emptyset$. If $[\tau_l, \tau_r] \in \mathcal{T}_{lr}(\tau, \delta)$, then $\tau \in (\tau_l, \tau_r)$ so, given any decimation interval $[\tau_l, \tau_r]$, the number of $\tau \in 2\varepsilon \mathbb{Z} \cap (0, \delta)$ with $[\tau_l, \tau_r] \in \mathcal{T}_{lr}(\tau)$ is less than $\frac{\tau_r - \tau_l}{2\varepsilon}$ and

$$\begin{aligned}
& \varepsilon \sum_{\substack{\tau \in 2\varepsilon \mathbb{Z} \cap (0, \delta) \\ [\tau_l, \tau_r] \in \mathcal{T}_{lr}(\tau, \delta)}} |\langle \Lambda^c \Lambda([\tau_l, \tau_r]) \Lambda_{\tau_l}^c \Lambda_{\tau_r}^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\
&\leq \frac{\tau_r - \tau_l}{2} \sup_{\substack{\tau \in 2\varepsilon \mathbb{Z} \cap (0, \delta) \\ [\tau_l, \tau_r] \in \mathcal{T}_{lr}(\tau, \delta)}} |\langle \Lambda^c \Lambda([\tau_l, \tau_r]) \Lambda_{\tau_l}^c \Lambda_{\tau_r}^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle|
\end{aligned}$$

We now fix any decimation interval $[\tau_l, \tau_r]$ and any $\tau \in 2\varepsilon \mathbb{Z} \cap (0, \delta)$ for which $[\tau_l, \tau_r] \in \mathcal{T}_{lr}(\tau, \delta)$ and bound

$$\begin{aligned}
& \frac{\tau_r - \tau_l}{2} |\langle \Lambda^c \Lambda([\tau_l, \tau_r]) \Lambda_{\tau_l}^c \Lambda_{\tau_r}^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\
&\leq \frac{\tau_r - \tau_l}{2} |\Lambda^c \cap \Lambda_{\tau_l}^c \cap \Lambda_{\tau_r}^c| (4e^{K_j} + 3)r(\tau_r - \tau_l)
\end{aligned}$$

$$\begin{aligned}
& \times \sup_{\mathbf{x} \in \Lambda([\tau_l, \tau_r])} \sum_{\mathbf{y} \in X} |\gamma_{\tau+\varepsilon}(\mathbf{x}) v(\mathbf{x}, \mathbf{y}) \gamma_{*\tau}(\mathbf{y}) \gamma_{\tau+\varepsilon}(\mathbf{y})| \\
& \leq \frac{\tau_r - \tau_l}{2} |\Lambda^c \cap \Lambda_{\tau_l}^c \cap \Lambda_{\tau_r}^c| (4e^{K_j} + 3) r(\tau_r - \tau_l) \|v\| \\
& \quad \times \left[\sum_{\tau' \in (0, \delta]} N_0 \left(\Gamma_{\tau+\varepsilon}^{\tau'}(\mathfrak{S}); e^{\frac{m}{2} d(\mathbf{x}, \Lambda([\tau_l, \tau_r]))}, \kappa_{\tau'} \right) \right]^2 \\
& \quad \times \left[\sum_{\tau' \in [0, \delta)} N_0 \left(\Gamma_{*\tau}^{\tau'}(\mathfrak{S}); e^{\frac{m}{2} d(\mathbf{x}, \Lambda([\tau_l, \tau_r]))}, \kappa_{*\tau'} \right) \right]
\end{aligned}$$

by Corollary E.9(b). Since τ is in the interior of $[\tau_l, \tau_r]$ and $\tau + \varepsilon$ is its neighbour and has $\mathfrak{d}(\tau + \varepsilon) = m > \mathfrak{d}(\tau_r)$, $\tau + \varepsilon$ is also in the interior of $[\tau_l, \tau_r]$. Hence by Lemma E.13,

$$\begin{aligned}
& \frac{\tau_r - \tau_l}{2} |\langle \Lambda^c \Lambda([\tau_l, \tau_r]) \Lambda_{\tau_l}^c \Lambda_{\tau_r}^c (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\
& \leq \frac{\tau_r - \tau_l}{2} |\Lambda^c \cap \Lambda_{\tau_l}^c \cap \Lambda_{\tau_r}^c| (4e^{K_j} + 3) r(\tau_r - \tau_l) \|v\| 40^3 e^{3K_j} R(\tau_r - \tau_l)^3 \\
& \leq 2^{20} e^{4K_j} (\tau_r - \tau_l) \mathfrak{v} r(\tau_r - \tau_l) R(\tau_r - \tau_l)^3 |\Lambda^c \cap \Lambda_{\tau_l}^c \cap \Lambda_{\tau_r}^c|
\end{aligned}$$

and

$$\begin{aligned}
& \varepsilon \sum_{\tau \in \varepsilon 2\mathbb{Z} \cap [0, \delta)} |\langle \Lambda^c \Lambda_\tau \Lambda_{\tau+\varepsilon} (\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\
& \leq \sum_{\substack{\text{decimation} \\ \text{intervals} \\ [\tau_l, \tau_r]}} 2^{20} e^{4K_j} (\tau_r - \tau_l) \mathfrak{v} r(\tau_r - \tau_l) R(\tau_r - \tau_l)^3 |\Lambda^c \cap \Lambda_{\tau_l}^c \cap \Lambda_{\tau_r}^c| \\
& \leq \sum_{\tau' \in \varepsilon \mathbb{Z} \cap (0, \delta)} 2^{25} e^{4K_j} |\mathcal{J}_{\tau'}| \mathfrak{v} r(|\mathcal{J}_{\tau'}|) R(|\mathcal{J}_{\tau'}|)^3 |\Lambda_{\tau'}^c|
\end{aligned}$$

For the last inequality, each decimation interval $[\tau_l, \tau_r]$ was assigned to a $\tau' \in \varepsilon \mathbb{Z} \cap (0, \delta)$ by

- o if $[\tau_l, \tau_r] = [0, \delta]$, the assigned τ' is $\frac{\delta}{2}$.
- o if $[\tau_l, \tau_r] \neq [0, \delta]$, then $[\tau_l, \tau_r]$ is an interval of length $\frac{1}{2^p} \delta$ for some scale $1 \leq p < m$. In this case τ' is assigned to the unique end point, τ_l or τ_r , whose decimation index is p .

At most $3 \leq 2^2$ intervals are assigned to each τ' and, for each decimation interval,

$$(\tau_r - \tau_l) \mathfrak{v} r(\tau_r - \tau_l) R(\tau_r - \tau_l)^3 |\Lambda^c \cap \Lambda_{\tau_l}^c \cap \Lambda_{\tau_r}^c| \leq 2^3 |\mathcal{J}_{\tau'}| \mathfrak{v} r(|\mathcal{J}_{\tau'}|) R(|\mathcal{J}_{\tau'}|)^3 |\Lambda_{\tau'}^c|$$

□

Proof of (6.17).

$$\begin{aligned}
& \varepsilon \sum_{\tau \in [0, \delta)} |\langle \Lambda(\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \Lambda^c \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\
& \leq \max_{\tau \in [0, \delta)} \delta |\langle \Lambda(\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) \gamma_{\tau+\varepsilon}, v \Lambda^c \gamma_{*\tau} \gamma_{\tau+\varepsilon} \rangle| \\
& \leq \max_{\tau \in [0, \delta)} \delta |\Lambda^c| \sup_{\mathbf{y} \in \Lambda^c} \sum_{\mathbf{x} \in \Lambda} |(\gamma_{*\tau}(\mathbf{x}) - \gamma_{\tau+\varepsilon}^*(\mathbf{x})) \gamma_{\tau+\varepsilon}(\mathbf{x}) v(\mathbf{x}, \mathbf{y}) \gamma_{*\tau}(\mathbf{y}) \gamma_{\tau+\varepsilon}(\mathbf{y})| \\
& \leq \max_{\tau \in [0, \delta)} \delta |\Lambda^c| (4e^{K_j} + 3) r(\delta) \|v\| \left[\sum_{\tau' \in (0, \delta]} N_0 \left(\Gamma_{\tau+\varepsilon}^{\tau'}(\mathfrak{S}); e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{\tau'} \right) \right]^2 \\
& \quad \times \left[\sum_{\tau' \in [0, \delta)} N_0 \left(\Gamma_{*\tau}^{\tau'}(\mathfrak{S}); e^{\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{*\tau'} \right) \right] \\
& \leq \delta (4e^{K_j} + 3) r(\delta) \frac{\mathfrak{v}}{2} (2^4 e^{K_j} R(\delta))^3 |\Lambda^c| \\
& \leq 2^{14} e^{4K_j} \delta \mathfrak{v} r(\delta) R(\delta)^3 |\Lambda^c|
\end{aligned}$$

by Corollary E.9(b) and Lemma E.13 (When $\tau + \varepsilon = \delta$, use $\Gamma_\delta^\delta(\mathfrak{S}) = \mathbb{1}$ and $\Gamma_\delta^{\tau'}(\mathfrak{S}) = 0$ for $\tau' \in (0, \delta)$, and when $\tau = 0$, use $\Gamma_{*0}^0(\mathfrak{S}) = \mathbb{1}$ and $\Gamma_{*0}^{\tau'}(\mathfrak{S}) = 0$ for $\tau' \in (0, \delta)$. In both cases, apply Lemma B.1). \square

Proof of (6.18). We are to sum over (τ_1, τ_2, τ_3) excluding $(\delta, \delta, 0)$. We treat the case $\tau_3 \neq 0$. The other cases are similar.

$$\begin{aligned}
& \varepsilon \sum_{\tau \in [0, \delta)} \sum_{\substack{\tau_1, \tau_2 \in \mathcal{T}_r(\tau + \varepsilon, \delta) \\ \tau_3 \in \mathcal{T}_l(\tau, \delta) \setminus \{0\}}} |\langle \Lambda(\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) (\Gamma_{\tau+\varepsilon}^{\tau_1} \alpha_{\tau_1}), v \Lambda (\Gamma_{*\tau}^{\tau_3} \alpha_{\tau_3}^*) (\Gamma_{\tau+\varepsilon}^{\tau_2} \alpha_{\tau_2}) \rangle| \\
& \leq \max_{\tau \in [0, \delta)} \delta \sum_{\substack{\tau_1, \tau_2 \in \mathcal{T}_r(\tau + \varepsilon, \delta) \\ \tau_3 \in \mathcal{T}_l(\tau, \delta) \setminus \{0\}}} |\langle \Lambda(\gamma_{*\tau} - \gamma_{\tau+\varepsilon}^*) (\Gamma_{\tau+\varepsilon}^{\tau_1} \alpha_{\tau_1}), v \Lambda (\Gamma_{*\tau}^{\tau_3} \alpha_{\tau_3}^*) (\Gamma_{\tau+\varepsilon}^{\tau_2} \alpha_{\tau_2}) \rangle| \\
& \leq \max_{\tau \in [0, \delta)} \delta \sum_{\substack{\tau_1, \tau_2 \in \mathcal{T}_r(\tau + \varepsilon, \delta) \\ \tau_3 \in \mathcal{T}_l(\tau, \delta) \setminus \{0\}}} \sum_{\substack{\mathbf{x}, \mathbf{y} \in \Lambda \\ \mathbf{z} \in \Lambda_{\tau_3}^c}} (4e^{K_j} + 3) r(\delta) |(\Gamma_{\tau+\varepsilon}^{\tau_1} \alpha_{\tau_1})(\mathbf{x})| |v(\mathbf{x}, \mathbf{y})| \\

\end{aligned}$$

by Lemma E.13, followed by (F.6b). \square

Lemma 6.7.

$$|\tilde{\mathcal{E}}_{4,\mathfrak{S}}(\alpha, \beta)| \leq \text{Reg}_{SF}^{(4)}(\alpha, \beta)$$

with the $\tilde{\mathcal{E}}_{4,\mathfrak{S}}(\alpha, \beta)$ defined in (6.12) and the $\text{Reg}_{SF}^{(4)}(\Omega; \alpha, \beta)$ and K_{reg} of Definition 2.17.

Proof. Applying that

$$\langle f, vg \rangle \leq \|v\| \|f\|_{L^2(X)} \|g\|_{L^2(X)}$$

and that

$$\begin{aligned}
\|fg\|_{L^2(X)} &\leq \left\| e^{-5m d(\mathbf{x}, \Omega)} f \right\|_{L^4(X)} \left\| e^{5m d(\mathbf{x}, \Omega)} g \right\|_{L^4(X)} \\
&\leq \left\| e^{5m d(\mathbf{x}, \Omega)} f \right\|_{L^4(X)} \left\| e^{5m d(\mathbf{x}, \Omega)} g \right\|_{L^4(X)}
\end{aligned}$$

we have

$$\begin{aligned}
|\tilde{\mathcal{E}}_{4,\mathfrak{S}}(\alpha, \beta)| &\leq 2\delta \max_{\tau \in [0, \delta]} \|v\| \left\| e^{-5m d(\mathbf{x}, \Omega)} \tilde{\gamma}_{\tau, \varepsilon} \right\|_{L^4(X)} \\
&\quad \times \max \left\{ \left\| e^{5m d(\mathbf{x}, \Omega)} \Gamma_{*\tau}^0 \Omega \alpha^* \right\|_{L^4(X)}^3, \left\| e^{5m d(\mathbf{x}, \Omega)} \Gamma_{\tau+\varepsilon}^\delta \Omega \beta \right\|_{L^4(X)}^3 \right\}
\end{aligned}$$

Next use the fact [8, Theorem 9.5.1] that, for any function $A : X \times X \rightarrow \mathbb{C}$, the norm of the operator $f \in L^4(X) \mapsto (Af)(\mathbf{x}) = \sum_{\mathbf{y} \in X} A(\mathbf{x}, \mathbf{y})f(\mathbf{y}) \in L^4(X)$ is bounded by

$$\max \left\{ \max_{\mathbf{x} \in X} \sum_{\mathbf{y} \in X} |A(\mathbf{x}, \mathbf{y})|, \max_{\mathbf{y} \in X} \sum_{\mathbf{x} \in X} |A(\mathbf{x}, \mathbf{y})| \right\}$$

and the trivial observation that, for $\mathbf{y} \in \Omega$, $|e^{5m d(\mathbf{x}, \Omega)} A(\mathbf{x}, \mathbf{y})| \leq |e^{5m d(\mathbf{x}, \mathbf{y})} A(\mathbf{x}, \mathbf{y})|$. Consequently

$$\begin{aligned}
\left\| e^{5m d(\mathbf{x}, \Omega)} \Gamma_{*\tau}^0 \Omega \alpha^* \right\|_{L^4(X)} &\leq \|\Gamma_{*\tau}^0\| \|\alpha\|_{L^4(\Omega)} \leq e^{K_j \delta} \|\alpha\|_{L^4(\Omega)} \\
\left\| e^{5m d(\mathbf{x}, \Omega)} \Gamma_{\tau+\varepsilon}^\delta \Omega \beta \right\|_{L^4(X)} &\leq \|\Gamma_{\tau+\varepsilon}^\delta\| \|\beta\|_{L^4(\Omega)} \leq e^{K_j \delta} \|\beta\|_{L^4(\Omega)}
\end{aligned}$$

To bound $\|e^{-5m d(\mathbf{x}, \Omega)} \tilde{\gamma}_{\tau, \varepsilon}\|_{L^4(X)}$, write

$$\tilde{\gamma}_{\tau, \varepsilon} = \tilde{\Omega}(\alpha - \beta) + (j(\tau) - 1) \tilde{\Omega} \alpha - (j(\delta - \tau - \varepsilon) - 1) \tilde{\Omega} \beta$$

Set

$$\begin{aligned}\mathcal{B}^{(0)} &= \left\{ b = (\mathbf{u}, \mathbf{v}) \in \tilde{\Omega}^* \mid \mathbf{u}, \mathbf{v} \in \tilde{\Omega} \right\} \\ \mathcal{B}_{b1} &= \left\{ b = (\mathbf{u}, \mathbf{v}) \in \tilde{\Omega}^* \mid \mathbf{u} \in \tilde{\Omega}, \mathbf{v} \in \tilde{\Omega}^c \right\} \\ \mathcal{B}_{b2} &= \left\{ b = (\mathbf{u}, \mathbf{v}) \in \tilde{\Omega}^* \mid \mathbf{u} \in \tilde{\Omega}^c, \mathbf{v} \in \tilde{\Omega} \right\}\end{aligned}$$

and write

$$e^{\mu\tau} \int_0^\tau d\tau' \left(\left[e^{-\tau' \nabla^* \mathcal{H} \nabla} \nabla^* \mathcal{H} \nabla \right] \tilde{\Omega} \alpha \right) (\mathbf{x}) = a_1(\mathbf{x}) + a_2(\mathbf{x}) + a_3(\mathbf{x})$$

with

$$\begin{aligned}a_1(\mathbf{x}) &= \sum_{\substack{\mathbf{z} \in X \\ b \in \mathcal{B}^{(0)}}} e^{\mu\tau} \int_0^\tau d\tau' e^{-\tau' \nabla^* \mathcal{H} \nabla} (\mathbf{x}, \mathbf{z}) (\nabla^* \mathcal{H})(\mathbf{z}, b) (\nabla \alpha)(b) \\ a_2(\mathbf{x}) &= \sum_{\substack{\mathbf{z} \in X \\ b = (\mathbf{u}, \mathbf{v}) \in \mathcal{B}_{b1}}} e^{\mu\tau} \int_0^\tau d\tau' e^{-\tau' \nabla^* \mathcal{H} \nabla} (\mathbf{x}, \mathbf{z}) (\nabla^* \mathcal{H})(\mathbf{z}, b) \{-\alpha(\mathbf{u})\} \\ a_3(\mathbf{x}) &= \sum_{\substack{\mathbf{z} \in X \\ b = (\mathbf{u}, \mathbf{v}) \in \mathcal{B}_{b2}}} e^{\mu\tau} \int_0^\tau d\tau' e^{-\tau' \nabla^* \mathcal{H} \nabla} (\mathbf{x}, \mathbf{z}) (\nabla^* \mathcal{H})(\mathbf{z}, b) \{\alpha(\mathbf{v})\}\end{aligned}$$

By (D.4)

$$\left\| (1 - e^{\mu\tau}) \tilde{\Omega} \alpha \right\|_{L^4(X)} \leq |\mu| \delta e^{K'_j} \|\alpha\|_{L^4(\tilde{\Omega})}$$

By (D.3), and the corresponding bounds with the sup over the right argument and the sum over the left argument,

$$\begin{aligned}\|a_1\|_{L^4(X)} &\leq \delta K'_j e^{K'_j} \|\nabla \alpha\|_{L^4(\tilde{\Omega}^*)} \\ \|e^{-5md(\mathbf{x}, \Omega)} a_2\|_{L^4(X)} &\leq e^{-5md(\Omega, \tilde{\Omega}^c)} \delta K'_j e^{K'_j} \|\alpha\|_{L^4(\tilde{\Omega})} \\ \|e^{-5md(\mathbf{x}, \Omega)} a_3\|_{L^4(X)} &\leq e^{-5md(\Omega, \tilde{\Omega}^c)} \delta K'_j e^{K'_j} \|\alpha\|_{L^4(\tilde{\Omega})}\end{aligned}$$

All together, using (D.2),

$$\begin{aligned}\|e^{-5md(\mathbf{x}, \Omega)} \tilde{\gamma}\|_{L^4(X)} &\leq \|\alpha - \beta\|_{L^4(X)} \\ &\quad + 2K'_j e^{K'_j} \left\{ \delta \left[\mu + e^{-5md(\Omega, \tilde{\Omega}^c)} \right] \left[\|\alpha\|_{L^4(\tilde{\Omega})} + \|\beta\|_{L^4(\tilde{\Omega})} \right] \right. \\ &\quad \left. + \delta \left[\|\nabla \alpha\|_{L^4(\tilde{\Omega}^*)} + \|\nabla \beta\|_{L^4(\tilde{\Omega}^*)} \right] \right\}\end{aligned}$$

and

$$\begin{aligned} \left| \tilde{\mathcal{E}}_{4,\mathfrak{S}}(\alpha, \beta) \right| &\leq \delta \mathfrak{v} 2K'_j e^{3K_j + K'_j} \max \left\{ \|\alpha\|_{L^4(\Omega)}^3, \|\beta\|_{L^4(\Omega)}^3 \right\} \\ &\quad \times \left\{ \|\alpha - \beta\|_{L^4(X)} + \delta \left[\mu + e^{-5\mathfrak{m}\mathfrak{c}(\delta)} \right] \left[\|\alpha\|_{L^4(\tilde{\Omega})} + \|\beta\|_{L^4(\tilde{\Omega})} \right] \right. \\ &\quad \left. + \delta \left[\|\nabla \alpha\|_{L^4(\tilde{\Omega}^*)} + \|\nabla \beta\|_{L^4(\tilde{\Omega}^*)} \right] \right\} \end{aligned}$$

The lemma now follows by Remark D.3. \square

Proof of Proposition 3.37. It suffices to apply Lemmas 6.4, 6.5, 6.6 and 6.7 and the observations, from (F.6a), that

$$\begin{aligned} 2^{19} e^{3K_j} \varepsilon \mathfrak{v} R(\varepsilon)^3 &\leq \frac{1}{16} \\ 2^{21} e^{3K_j} \varepsilon \mathfrak{v} R(\varepsilon)^3 + (2^{28} e^{4K_j} + 2^{19} e^{4K_j}) |\mathcal{J}| \mathfrak{v} r(|\mathcal{J}|) R(|\mathcal{J}|)^3 &\leq \frac{1}{8} \end{aligned}$$

\square

Remark 6.8. Since Proposition 3.37 is an upper bound, rather than an equality, the specific choice of $\text{Reg}_{SF}^{(4)}(\alpha, \beta)$ that we have made is far from the only possibility. We have chosen it to be relatively simple.

6.3. Extracting Small Factors from the Stokes' Cylinder

Proof of Proposition 3.38. In this section we prove the required bounds involving the Stokes' cylinder $C_s(\mathbf{x}; \alpha^*, \beta)$ introduced in Definition 2.8. For simplicity of notation, write

$$r = r(s) \quad R = R(s) \quad R' = R'(s) \quad r_+ = r(2s) \quad R_+ = R(2s) \quad R'_+ = R'(2s)$$

and

$$\Omega_1 = \Omega(\mathcal{J}^-) \quad \Omega_2 = \Omega(\mathcal{J}^+) \quad \Omega_0 = \Omega_1 \cap \Omega_2 \quad \Lambda = \Lambda(\mathcal{J}) \quad P_\alpha = P_\alpha(\mathcal{J}) \quad \dots$$

As pointed out in Definition 2.8, we may choose for this cylinder any two real dimensional surface in

$$\{(z_*, z) \in \mathbb{C}^2 \mid |z_*|, |z| < R\}$$

whose boundary is the union of the circle $\{(z_*, z) \in \mathbb{C}^2 \mid z_*^* = z, |z| = r\}$ and the curve bounding

$$D = \left\{ (z_*, z) \in \mathbb{C}^2 \mid |z_* - \sigma_*| \leq r, |z - \sigma| \leq r, z - z_*^* = \rho \right\}$$

where

$$\begin{aligned} \sigma &= ([\mathbb{1} - j_{\mathfrak{c}}(s)]\beta)(\mathbf{x}) \\ \sigma_* &= ([\mathbb{1} - j_{\mathfrak{c}}(s)]\alpha^*)(\mathbf{x}) \\ \rho &= (j_{\mathfrak{c}}(s)[\alpha - \beta])(\mathbf{x}) \end{aligned}$$

For the estimates, we make the special choice suggested by [5, Example A.2]. We introduce the interpolating set $\mathcal{B} = \bigcup_{0 \leq t \leq 1} D_t$ where

$$D_t = \{(z_*, z) \in \mathbb{C}^2 \mid |z_* - t\sigma_*| \leq r, |z - t\sigma| \leq r, z - z_*^* = t\rho\}$$

Set $C_s(\mathbf{x}; \alpha^*, \beta) = \bigcup_{0 < t < 1} \partial D_t$. Obviously, $C_s(\mathbf{x}; \alpha^*, \beta)$ has the required boundary.

We start by proving

$$\begin{aligned} |\sigma_*|, |\sigma| &\leq se^{2K'_j s} ([|\mu| + e^{-5mc}] R_+ + R'_+) \leq r \\ |\rho| &\leq r_+ + |\sigma| + |\sigma_*| \end{aligned} \quad (6.23)$$

For the first bound, by Corollary D.2,

$$\begin{aligned} |\sigma_*| &= |([1 - j_c(s)]\alpha^*)(\mathbf{x})| \\ &\leq sK'_j e^{K'_j s} \left([|\mu| + e^{-5mc}] \max_{\substack{\mathbf{y} \in X \\ d(\mathbf{x}, \mathbf{y}) \leq c}} |\alpha(\mathbf{y})| + \max_{\substack{b \in X^* \\ d(\mathbf{x}, b) \leq c}} |\nabla \alpha(b)| \right) \\ &\leq se^{2K'_j s} ([|\mu| + e^{-5mc}] R_+ + R'_+) \leq r \end{aligned}$$

The second inequality follows from the observations that $|\alpha(\mathbf{y})| \leq R_+$ for all \mathbf{y} within a distance c of Λ and $|\nabla \alpha(b)| \leq R'_+$ for all bonds b within a distance c of Λ . When $\mathbf{y} \in \Lambda$, this is enforced by the characteristic function $\chi_{2s}(\Lambda; \alpha, \beta)$. When \mathbf{y} is not in Λ , but is within a distance c of Λ , this is enforced by the factor of $\chi_{R_+}(\Omega_0 \setminus (P_\alpha \cup \Lambda), \alpha)$ in the characteristic function $\chi_{\mathfrak{A},s}(\Omega_1, \Omega_2; \alpha, \phi, \beta)$. (Recall that $d(\Lambda, P_\alpha \cup \Omega_0^c) > c(s) > c$, by (F.4a).) When $b \in \Lambda^*$, this is enforced by the characteristic function $\chi_{2s}(\Lambda; \alpha, \beta)$. When b is not in Λ^* , but is within a distance c of Λ , this is enforced by the factor of $\chi_{R'_+}(\Omega_0^* \setminus (P'_\alpha \cup \Lambda^*), \nabla \alpha)$ in the characteristic function $\chi_{\mathfrak{A},s}(\Omega_1, \Omega_2; \alpha, \phi, \beta)$. The third inequality follows immediately from (F.7d).

For the bound on ρ observe

$$|\rho| \leq |\beta(\mathbf{x}) - \alpha(\mathbf{x})| + |([1 - j_c(s)][\beta - \alpha])(\mathbf{x})| \leq r_+ + |\sigma_*| + |\sigma|$$

Since $C_s(\mathbf{x}; \alpha^*, \beta) \subset \bigcup_{0 \leq t \leq 1} D_t$, part (i) follows from (6.23) and (F.3f). By [5, Remark A.3], on $C_s(\mathbf{x}; \alpha^*, \beta)$,

$$\begin{aligned} \operatorname{Re}(z_* z) &\geq \frac{1}{2} (r^2 - |\rho|^2) - r (|\sigma| + |\sigma_*|) \\ &\geq \frac{1}{2} (r^2 - r_+^2) - \left(r_+ + \frac{|\sigma| + |\sigma_*|}{2} + r \right) (|\sigma| + |\sigma_*|) \\ &\geq \frac{1}{2} (r - r_+) (r + r_+) - 3r (|\sigma| + |\sigma_*|) \\ &\geq \frac{3}{4} r (r - r_+) - 6rs e^{2K'_j} ([|\mu| + e^{-5mc}] R_+ + R'_+) \\ &\geq C_L r^2 \end{aligned} \quad (6.24)$$

The second and third inequality follow from (6.23), the fourth inequality from (F.3b) and (6.23) and the last from (F.7d).

By [5, Remark A.3], the area of $C_s(\mathbf{x}; \alpha^*, \beta)$ is bounded by

$$8\pi r (|\sigma| + |\sigma_*| + |\rho|) \leq 40\pi r^2$$

□

6.4. Relative Sizes of Large Field Sets

In this subsection, we prove Lemma 3.40, which is used in the proof of Theorem 3.35. As in the part of the proof of Theorem 3.35 where Lemma 3.40 is used, we fix a hierarchy for scale $\delta = 2^n \varepsilon$. By way of preparation, we have

Lemma 6.9. *Let \mathcal{J} be a decimation interval of length $2^p \varepsilon$, for some $0 \leq p \leq n$, and $\mathbf{x} \in \Omega(\mathcal{J})^c$. Then there is a decimation interval $\mathcal{J}' \subset \mathcal{J}$, of length $2^q \varepsilon$, with $1 \leq q \leq p$, such that*

$$\begin{aligned} d\left(\mathbf{x}, \tilde{Q}(\mathcal{J}') \cup \text{supp } \tilde{P}'_\alpha(\mathcal{J}') \cup \text{supp } \tilde{P}'_\beta(\mathcal{J}') \cup \tilde{P}_\alpha(\mathcal{J}') \cup \tilde{P}_\beta(\mathcal{J}') \cup R(\mathcal{J}')\right) \\ \leq 4 \sum_{k=q-1}^{p-1} \mathfrak{c}(2^k \varepsilon) \end{aligned}$$

Proof. The proof is by induction on p . If $p = 0$, then $\Omega(\mathcal{J})^c = \emptyset$ and the statement is vacuous. Assume that the statement is satisfied for some $p \geq 0$. Let \mathcal{J} be a decimation interval of length $2^{p+1} \varepsilon$ and $\mathbf{x} \in \Omega(\mathcal{J})^c$. By Definition 2.4, there is a point $\mathbf{y}_1 \in \Omega(\mathcal{J}^-)^c \cup \Omega(\mathcal{J}^+)^c \cup P_\alpha(\mathcal{J}) \cup P_\beta(\mathcal{J}) \cup \text{supp } P'_\alpha(\mathcal{J}) \cup \text{supp } P'_\beta(\mathcal{J}) \cup Q(\mathcal{J}) \cup R(\mathcal{J})$ such that $d(\mathbf{x}, \mathbf{y}_1) \leq \mathfrak{c}(2^p \varepsilon)$.

- If $\mathbf{y}_1 \in \Omega(\mathcal{J}^-)^c \cup \Omega(\mathcal{J}^+)^c$, then by the induction hypothesis, there is a decimation interval \mathcal{J}' of length $2^q \varepsilon$, with $1 \leq q \leq p$, that is contained either in \mathcal{J}^- or \mathcal{J}^+ , such that

$$d\left(\mathbf{y}_1, \tilde{Q}(\mathcal{J}') \cup \cdots \cup \tilde{P}_\beta(\mathcal{J}') \cup R(\mathcal{J}')\right) \leq 4 \sum_{k=q-1}^{p-1} \mathfrak{c}(2^k \varepsilon)$$

As $d(\mathbf{x}, \mathbf{y}_1) \leq \mathfrak{c}(2^p \varepsilon)$, we are finished.

- If $\mathbf{y}_1 \in \tilde{P}_\alpha(\mathcal{J}) \cup \tilde{P}_\beta(\mathcal{J}) \cup \text{supp } \tilde{P}'_\alpha(\mathcal{J}) \cup \text{supp } \tilde{P}'_\beta(\mathcal{J}) \cup \tilde{Q}(\mathcal{J}) \cup R(\mathcal{J})$, we set $\mathcal{J}' = \mathcal{J}$ and are finished.
- If $\mathbf{y}_1 \in \mathcal{X}(\mathcal{J}) \setminus \tilde{\mathcal{X}}(\mathcal{J})$, for some $\mathcal{X} \in \{P_\alpha, P_\beta, \text{supp } P'_\alpha, \text{supp } P'_\beta, Q\}$, then there is a $\mathbf{y}_2 \in \Lambda(\mathcal{J}^-)^c \cup \Lambda(\mathcal{J}^+)^c \subset \Omega(\mathcal{J}^-)^c \cup \Omega(\mathcal{J}^+)^c$ with $d(\mathbf{y}_1, \mathbf{y}_2) \leq 2\mathfrak{c}(2^p \varepsilon) + 1 \leq 3\mathfrak{c}(2^p \varepsilon)$. By the induction hypothesis, there is a decimation interval \mathcal{J}' of length $2^q \varepsilon$, with $1 \leq q \leq p$, that is contained either in \mathcal{J}^- or \mathcal{J}^+ , such that

$$d\left(\mathbf{y}_2, \tilde{Q}(\mathcal{J}') \cup \cdots \cup \tilde{P}_\beta(\mathcal{J}') \cup R(\mathcal{J}')\right) \leq 4 \sum_{k=q-1}^{p-1} \mathfrak{c}(2^k \varepsilon)$$

As $d(\mathbf{x}, \mathbf{y}_2) \leq 4\mathfrak{c}(2^p \varepsilon)$, we are finished. \square

Proof of Lemma 3.40. By Lemma 6.9, for each decimation interval \mathcal{J} of length $2^p \varepsilon$, with $1 \leq p \leq n$,

$$\begin{aligned} |\Omega(\mathcal{J})^c| &\leq \sum_{q=1}^p \sum_{\substack{\text{decimation} \\ \text{intervals } \mathcal{J}' \subset \mathcal{J} \\ \text{of length } 2^q \varepsilon}} \left\{ \text{volume of ball of radius } \mathfrak{c}(2^q \varepsilon) \right\} \left\{ |\tilde{Q}(\mathcal{J}')| + |\tilde{P}'_\alpha(\mathcal{J}')| \right. \\ &\quad \left. + |\tilde{P}'_\beta(\mathcal{J}')| + |\tilde{P}_\alpha(\mathcal{J}')| + |\tilde{P}_\beta(\mathcal{J}')| + |\mathcal{R}(\mathcal{J}')| \right\} \end{aligned}$$

Since, for each $q \leq p$, any decimation interval \mathcal{J}' of length $2^q \varepsilon$ is contained in a unique decimation interval of length $2^p \varepsilon$,

$$\begin{aligned} & \sum_{p=1}^n \sum_{\substack{\text{decimation} \\ \text{intervals } \mathcal{J} \\ \text{of length } 2^p \varepsilon}} (\ell(2^p \varepsilon) + 1) |\Omega(\mathcal{J})^c| \\ & \leq \sum_{q=1}^n \sum_{\substack{\text{decimation} \\ \text{intervals } \mathcal{J}' \\ \text{of length } 2^q \varepsilon}} \left\{ |\tilde{Q}(\mathcal{J}')| + \dots + |\mathcal{R}(\mathcal{J}')| \right\} \\ & \quad \times \sum_{p=q}^n (\ell(2^p \varepsilon) + 1) \left\{ \text{volume of ball of radius } \sum_{k=q-1}^{p-1} c(2^k \varepsilon) \right\} \\ & \leq \sum_{q=1}^n \sum_{\substack{\text{decimation} \\ \text{intervals } \mathcal{J}' \\ \text{of length } 2^q \varepsilon}} C_{Lr}(2^q \varepsilon)^2 \left\{ |\tilde{Q}(\mathcal{J}')| + \dots + |\mathcal{R}(\mathcal{J}')| \right\} \end{aligned}$$

by (F.7e). \square

Appendix A. Large/Small Field Characteristic Functions

The representation of the effective density given in Theorem 2.16 involves the “large field integral operator” introduced in Definition 2.8. In part (i) of this definition we associate to a hierarchy \mathfrak{S} and a decimation interval \mathcal{J} an integral operator $\mathcal{I}_{(\mathcal{J}; \alpha^*, \beta)}$. Its definition involves a characteristic function $\chi_{\mathcal{J}}(\alpha, \alpha_\tau, \beta) = \chi_{\mathcal{J}, \mathfrak{S}}(\alpha, \alpha_\tau, \beta)$ implementing large and small field conditions. Here, we are going to define this characteristic function.

For this definition, we use the notation that, for $0 < r < R$, $z \in \mathbb{C}$, any set Y and any complex valued function f on Y

$$\chi_r(z) = \begin{cases} 1 & \text{if } |z| \leq r \\ 0 & \text{otherwise} \end{cases} \quad \chi_{r,R}(t) = \begin{cases} 1 & \text{if } r \leq |z| \leq R \\ 0 & \text{otherwise} \end{cases}$$

and

$$\chi_r(Y, f) = \prod_{x \in Y} \chi_r(f(x)) \quad \chi_{r,R}(Y, f) = \prod_{x \in Y} \chi_{r,R}(f(x))$$

As pointed out in the leadup to Definition 3.2, the data associated to an interval in a hierarchy naturally split into two parts, the “first kind” of natural large/small field conditions and the “second kind” associated to the stationary phase construction. The following definition collects the conditions of the “first kind” that arise in Lemma A.3, below.

Definition A.1. Let $\Omega_1, \Omega_2 \subset X$, $\delta > 0$ and let $\mathfrak{A} = (\Lambda, P_\alpha, P_\beta, P'_\alpha, P'_\beta, Q) \in F_\delta(\Omega_1 \cap \Omega_2)$ be a choice of “small/large field sets of the first kind” as in Definition 3.2. The characteristic function for the small/large field sets of the first kind is

$$\chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta) = \chi^{(1)}(\Omega_1, \Omega_2; \alpha, \phi, \beta) \chi_{\mathfrak{A}}^{(2)}(\alpha, \beta) \chi_{\mathfrak{A}}^{(3)}(\alpha, \phi, \beta)$$

where

$$\begin{aligned} \chi^{(1)}(\Omega_1, \Omega_2; \alpha, \phi, \beta) \\ = \chi_{R(\delta)}(\Omega_1 \setminus \Omega_0, \alpha) \chi_{R(\delta)}(\Omega_2 \setminus \Omega_0, \beta) \chi_{R(\delta)}((\Omega_1 \cup \Omega_2) \setminus \Omega_0, \phi) \\ \chi_{R'(\delta)}(\Omega_1^* \setminus \Omega_0^*, \nabla \alpha) \chi_{R'(\delta)}(\Omega_2^* \setminus \Omega_0^*, \nabla \beta) \chi_{R'(\delta)}((\Omega_1^* \cup \Omega_2^*) \setminus \Omega_0^*, \nabla \phi) \\ \chi_{r(\delta)}(\Omega_1^* \setminus \Omega_0^*, \alpha - \phi) \chi_{r(\delta)}(\Omega_2^* \setminus \Omega_0^*, \phi - \beta) \end{aligned}$$

and

$$\begin{aligned} \chi_{\mathfrak{A}}^{(2)}(\alpha, \beta) = \chi_{R(2\delta)}(\Omega_0 \setminus (P_\alpha \cup \Lambda), \alpha) & \quad \chi_{R(2\delta), R(\delta)}(P_\alpha, \alpha) \\ \chi_{R(2\delta)}(\Omega_0 \setminus (P_\beta \cup \Lambda), \beta) & \quad \chi_{R(2\delta), R(\delta)}(P_\beta, \beta) \\ \chi_{R'(2\delta)}(\Omega_0^* \setminus (P'_\alpha \cup \Lambda^*), \nabla \alpha) & \quad \chi_{R'(2\delta), R'(\delta)}(P'_\alpha, \nabla \alpha) \\ \chi_{R'(2\delta)}(\Omega_0^* \setminus (P'_\beta \cup \Lambda^*), \nabla \beta) & \quad \chi_{R'(2\delta), R'(\delta)}(P'_\beta, \nabla \beta) \\ \chi_{r(2\delta)}(\Omega_0^* \setminus (Q \cup \Lambda^*), \alpha - \beta) & \quad \chi_{r(2\delta), \infty}(Q, \alpha - \beta) \end{aligned}$$

and

$$\begin{aligned} \chi_{\mathfrak{A}}^{(3)}(\alpha, \phi, \beta) = \chi_{R(\delta)}(\Omega_0 \setminus \Lambda, \phi) \chi_{R'(\delta)}(\Omega_0^* \setminus \Lambda^*, \nabla \phi) \\ \chi_{r(\delta)}(\Omega_0^* \setminus \Lambda, \alpha - \phi) \chi_{r(\delta)}(\Omega_0^* \setminus \Lambda, \phi - \beta) \end{aligned}$$

with $\Omega_0 = \Omega_1 \cap \Omega_2$.

If \mathfrak{A} is part of the data associated to a decimation interval of length 2δ in a hierarchy \mathfrak{S} , and $\Omega_1 = \Omega(\mathcal{J}^-)$, $\Omega_2 = \Omega(\mathcal{J}^+)$, then

- $\chi^{(1)}$ imposes the “old” small field conditions on α , β and ϕ in $(\Omega(\mathcal{J}^-) \cup \Omega(\mathcal{J}^+)) \setminus (\Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+))$
- $\chi_{\mathfrak{A}}^{(2)}$ imposes the “new” small and large field conditions on α and β in the region $(\Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+)) \setminus \Lambda(\mathcal{J})$, the complement of the “small field region of the first kind” for \mathcal{J} in the previous “small field regions”
- $\chi_{\mathfrak{A}}^{(3)}$ imposes small field conditions on ϕ in $(\Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+)) \setminus \Lambda(\mathcal{J})$

Observe that $\chi_{\mathfrak{A}, \delta}$ does not depend on the values of the fields on the set Λ . For the small/large field conditions of the second kind, we use (as in Theorem 2.16) the characteristic function $\chi_\delta(Y; \alpha, \beta)$ (defined for $\delta > 0$, a subset $Y \subset X$ and fields α, β) which takes the value one if

- $|\alpha(\mathbf{x})|, |\beta(\mathbf{x})| \leq R(\delta)$ for all $\mathbf{x} \in Y$ and
- $|\nabla \alpha(b)|, |\nabla \beta(b)| \leq R'(\delta)$ for all bonds b on X that have at least one end in Y and
- $|\alpha(\mathbf{x}) - \beta(\mathbf{x})| \leq r(\delta)$ for all \mathbf{x} within a distance one of Y

and which takes the value zero otherwise.

Definition A.2. Let \mathfrak{S} be a hierarchy in the sense of Definition 2.4, and let \mathcal{J} be a decimation interval for \mathfrak{S} of scale $2t$. Define

$$\chi_{\mathcal{J}}(\alpha, \phi, \beta) = \chi_{\mathfrak{A}, t}(\Omega(\mathcal{J}^-), \Omega(\mathcal{J}^+); \alpha, \phi, \beta) \chi_{2t}(\Lambda(\mathcal{J}) \setminus \Omega(\mathcal{J}); \alpha, \beta)$$

where

$$\mathfrak{A} = (\Lambda(\mathcal{J}), P_\alpha(\mathcal{J}), P_\beta(\mathcal{J}), P'_\alpha(\mathcal{J}), P'_\beta(\mathcal{J}), Q(\mathcal{J})) \in F_\delta(\Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+))$$

The second factor imposes the small field conditions in the difference between the small field regions of “the first and the second” kind for \mathcal{J} .

Lemma A.3. Let $\Omega_1, \Omega_2 \subset X$ and $\delta > 0$. Then

$$\begin{aligned} & \chi_\delta(\Omega_1; \alpha, \phi) \chi_\delta(\Omega_2; \phi, \beta) \\ &= \sum_{\mathfrak{A} \in F_\delta(\Omega_1 \cap \Omega_2)} \chi_{2\delta}(\Lambda_{\mathfrak{A}}; \alpha, \beta) \chi_{r(\delta)}(\Lambda_{\mathfrak{A}}, \alpha - \phi) \\ & \quad \times \chi_{r(\delta)}(\Lambda_{\mathfrak{A}}, \phi - \beta) \chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta) \end{aligned}$$

Proof. Again set $\Omega_0 = \Omega_1 \cap \Omega_2$. By definition,

$$\begin{aligned} & \chi_\delta(\Omega_1; \alpha, \phi) \chi_\delta(\Omega_2; \phi, \beta) \\ &= \chi_{R(\delta)}(\Omega_1, \alpha) \chi_{R(\delta)}(\Omega_1, \phi) & \chi_{R(\delta)}(\Omega_2, \phi) \chi_{R(\delta)}(\Omega_2, \beta) \\ & \quad \chi_{R'(\delta)}(\Omega_1^*, \nabla \alpha) \chi_{R'(\delta)}(\Omega_1^*, \nabla \phi) & \chi_{R'(\delta)}(\Omega_2^*, \nabla \phi) \chi_{R'(\delta)}(\Omega_2^*, \nabla \beta) \\ & \quad \chi_{r(\delta)}(\Omega_1^*, \alpha - \phi) & \chi_{r(\delta)}(\Omega_2^*, \phi - \beta) \\ &= \chi^{(1)}(\Omega_1, \Omega_2; \alpha, \phi, \beta) \cdot \chi_{R(\delta)}(\Omega_0, \alpha) & \chi_{R(\delta)}(\Omega_0, \beta) \chi_{R'(\delta)}(\Omega_0^*, \nabla \alpha) \\ & \quad \cdot \chi_{R(\delta)}(\Omega_0, \phi) \chi_{R'(\delta)}(\Omega_0^*, \nabla \phi) & \chi_{r(\delta)}(\Omega_0^*, \alpha - \phi) \chi_{r(\delta)}(\Omega_0^*, \phi - \beta) \\ & \hspace{10cm} \text{(A.1)} \end{aligned}$$

The first factor, $\chi^{(1)}(\Omega_1, \Omega_2; \alpha, \phi, \beta)$, in (A.1) was defined in Definition A.1, and involves only fields at points of $(\Omega_1^* \cup \Omega_2^*) \setminus \Omega_0$. The next four factors involve only the external fields α and β at points $\mathbf{x} \in \Omega_0^*$. To introduce the more restrictive small field conditions of scale 2δ , we expand

$$\begin{aligned} \chi_{R(\delta)}(\Omega_0, \alpha) &= \prod_{\mathbf{x} \in \Omega_0} [\chi_{R(2\delta)}(\alpha(\mathbf{x})) + \chi_{R(2\delta), R(\delta)}(\alpha(\mathbf{x}))] \\ &= \sum_{P_\alpha \subset \Omega_0} \chi_{R(2\delta)}(\Omega_0 \setminus P_\alpha, \alpha) \chi_{R(2\delta), R(\delta)}(P_\alpha, \alpha) \\ \chi_{R(\delta)}(\Omega_0, \beta) &= \sum_{P_\beta \subset \Omega_0} \chi_{R(2\delta)}(\Omega_0 \setminus P_\beta, \beta) \chi_{R(2\delta), R(\delta)}(P_\beta, \beta) \\ \chi_{R'(\delta)}(\Omega_0^*, \nabla \alpha) &= \sum_{P'_\alpha \subset \Omega_0^*} \chi_{R'(2\delta)}(\Omega_0^* \setminus P'_\alpha, \nabla \alpha) \chi_{R'(2\delta), R'(\delta)}(P'_\alpha, \nabla \alpha) \\ \chi_{R'(\delta)}(\Omega_0^*, \nabla \beta) &= \sum_{P'_\beta \subset \Omega_0^*} \chi_{R'(2\delta)}(\Omega_0^* \setminus P'_\beta, \nabla \beta) \chi_{R'(2\delta), R'(\delta)}(P'_\beta, \nabla \beta) \\ 1 &= \sum_{Q \subset \Omega_0^*} \chi_{r(2\delta)}(\Omega_0^* \setminus Q, \alpha - \beta) \chi_{r(2\delta), \infty}(Q, \alpha - \beta) \end{aligned}$$

and get, for the product of the four factors in (A.1) that depend only on the external fields on Ω_0^* ,

$$\begin{aligned} & \chi_{R(\delta)}(\Omega_0, \alpha) \chi_{R(\delta)}(\Omega_0, \beta) \chi_{R'(\delta)}(\Omega_0^*, \nabla \alpha) \chi_{R'(\delta)}(\Omega_0^*, \nabla \beta) \\ &= \sum_{(\Lambda, P_\alpha, P_\beta, P'_\alpha, P'_\beta, Q) \in F_\delta(\Omega_0)} \chi_{R(2\delta)}(\Omega_0 \setminus P_\alpha, \alpha) \chi_{R(2\delta), R(\delta)}(P_\alpha, \alpha) \\ & \quad \chi_{R(2\delta)}(\Omega_0 \setminus P_\beta, \beta) \chi_{R(2\delta), R(\delta)}(P_\beta, \beta) \\ & \quad \chi_{R'(2\delta)}(\Omega_0^* \setminus P'_\alpha, \nabla \alpha) \chi_{R'(2\delta), R'(\delta)}(P'_\alpha, \nabla \alpha) \end{aligned}$$

$$\begin{aligned}
& \chi_{R'(2\delta)}(\Omega_0^* \setminus P'_\beta, \nabla \beta) \quad \chi_{R'(2\delta), R'(\delta)}(P'_\beta, \nabla \beta) \\
& \chi_{r(2\delta)}(\Omega_0^* \setminus Q, \alpha - \beta) \quad \chi_{r(2\delta), \infty}(Q, \alpha - \beta) \\
= & \sum_{\mathfrak{A} \in F_\delta(\Omega_0)} \chi_{\mathfrak{A}}^{(2)}(\alpha, \beta) \chi_{2\delta}(\Lambda_{\mathfrak{A}}; \alpha, \beta)
\end{aligned} \tag{A.2}$$

For each $\mathfrak{A} = (\Lambda, P_\alpha, P_\beta, P'_\alpha, P'_\beta, Q) \in F_\delta(\Omega_0)$ we write the last four factors of (A.1)

$$\begin{aligned}
& \chi_{R(\delta)}(\Omega_0, \phi) \quad \chi_{R'(\delta)}(\Omega_0^*, \nabla \phi) \quad \chi_{r(\delta)}(\Omega_0^*, \alpha - \phi) \quad \chi_{r(\delta)}(\Omega_0^*, \phi - \beta) \\
& = \chi_{\mathfrak{A}}^{(3)}(\alpha, \phi, \beta) \cdot \chi_{R(\delta)}(\Lambda, \phi) \quad \chi_{R'(\delta)}(\Lambda^*, \nabla \phi) \quad \chi_{r(\delta)}(\Lambda^*, \alpha - \phi) \\
& \quad \times \chi_{r(\delta)}(\Lambda^*, \phi - \beta)
\end{aligned} \tag{A.3}$$

Inserting (A.2) and (A.3) into (A.1) we get

$$\begin{aligned}
& \chi_\delta(\Omega_1; \alpha, \phi) \quad \chi_\delta(\Omega_2; \phi, \beta) = \sum_{\mathfrak{A} \in \mathcal{A}} \chi_{2\delta}(\Lambda_{\mathfrak{A}}; \alpha, \beta) \quad \chi_{r(\delta)}(\Lambda_{\mathfrak{A}}^*, \alpha - \phi) \\
& \quad \chi_{r(\delta)}(\Lambda_{\mathfrak{A}}^*, \phi - \beta) \quad \chi_{R(\delta)}(\Lambda_{\mathfrak{A}}, \phi) \quad \chi_{R'(\delta)}(\Lambda_{\mathfrak{A}}^*, \nabla \phi) \quad \chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta)
\end{aligned} \tag{A.4}$$

In Lemma A.5 below we show that

$$\begin{aligned}
& \chi_{2\delta}(\Lambda; \alpha, \beta) \quad \chi_{R(\delta)}(\Lambda, \phi) \quad \chi_{R'(\delta)}(\Lambda^*, \nabla \phi) \quad \chi_{r(\delta)}(\Lambda^*, \alpha - \phi) \quad \chi_{r(\delta)}(\Lambda^*, \phi - \beta) \\
& = \chi_{2\delta}(\Lambda; \alpha, \beta) \quad \chi_{r(\delta)}(\Lambda^*, \alpha - \phi) \quad \chi_{r(\delta)}(\Lambda^*, \phi - \beta)
\end{aligned}$$

If we insert this into (A.4) we get

$$\begin{aligned}
& \chi_\delta(\Omega_1; \alpha, \phi) \quad \chi_\delta(\Omega_2; \phi, \beta) \\
& = \sum_{\mathfrak{A} \in \mathcal{A}} \chi_{2\delta}(\Lambda_{\mathfrak{A}}; \alpha, \beta) \quad \chi_{r(\delta)}(\Lambda_{\mathfrak{A}}^*, \alpha - \phi) \quad \chi_{r(\delta)}(\Lambda_{\mathfrak{A}}^*, \phi - \beta) \\
& \quad \times \chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta) \\
& = \sum_{\mathfrak{A} \in \mathcal{A}} \chi_{2\delta}(\Lambda_{\mathfrak{A}}; \alpha, \beta) \quad \chi_{r(\delta)}(\Lambda_{\mathfrak{A}}, \alpha - \phi) \quad \chi_{r(\delta)}(\Lambda_{\mathfrak{A}}, \phi - \beta) \\
& \quad \times \chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta)
\end{aligned}$$

We were free to drop the factors $\chi_{r(\delta)}(\Lambda_{\mathfrak{A}}^* \setminus \Lambda_{\mathfrak{A}}, \alpha - \phi) \chi_{r(\delta)}(\Lambda_{\mathfrak{A}}^* \setminus \Lambda_{\mathfrak{A}}, \phi - \beta)$ from the term $\chi_{r(\delta)}(\Lambda_{\mathfrak{A}}^*, \alpha - \phi) \chi_{r(\delta)}(\Lambda_{\mathfrak{A}}^*, \phi - \beta)$ because they also appear in $\chi_{\mathfrak{A}, \delta}(\Omega_1, \Omega_2; \alpha, \phi, \beta)$. \square

Lemma A.4. *Let \mathfrak{S} be a hierarchy for scale 2δ . Set $\varepsilon = 2^{-\text{depth}(\mathfrak{S})}(2\delta)$.*

- (a) *Let \mathcal{J} be a decimation interval centred on τ . If $|\alpha_\tau(\mathbf{x})| > R(\varepsilon)$, for some $\mathbf{x} \in X \setminus \Lambda(\mathcal{J})$, then*

$$\prod_{\substack{\text{decimation intervals} \\ \tilde{\mathcal{J}} = [\tau_l, \tau_r] \subset \mathcal{J}}} \chi_{\tilde{\mathcal{J}}}(\alpha_{\tau_l}, \alpha_{\tau_c}, \alpha_{\tau_r}) = 0$$

where $\tau_c = \frac{\tau_l + \tau_r}{2}$.

(b) If $|\alpha_\delta(\mathbf{x})| > R(\varepsilon)$, for some $\mathbf{x} \in X \setminus \Lambda_{\mathfrak{S}}$, then

$$\chi_{\mathfrak{A}, \delta}(\Omega([0, \delta]), \Omega([\delta, 2\delta]); \alpha, \alpha_\delta, \beta) \prod_{\substack{\text{decimation intervals} \\ \tilde{\mathcal{J}} = [\tau_l, \tau_r] \subset [0, 2\delta]}} \chi_{\tilde{\mathcal{J}}}(\alpha_{\tau_l}, \alpha_{\tau_c}, \alpha_{\tau_r}) = 0$$

where $\mathfrak{A} = (\Lambda_{\mathfrak{S}}, P_\alpha([0, 2\delta])), \dots, Q([0, 2\delta]))$, $\tau_c = \frac{\tau_l + \tau_r}{2}$.

Proof. We prove part (a). In the event that $\mathbf{x} \in (\Omega(\mathcal{J}^-) \cup \Omega(\mathcal{J}^+)) \setminus \Lambda(\mathcal{J})$, the factor $\chi_{\mathcal{J}}(\alpha_{\tau_l}, \alpha_\tau, \alpha_{\tau_r})$ vanishes

- o when $\mathbf{x} \in (\Omega(\mathcal{J}^-) \cup \Omega(\mathcal{J}^+)) \setminus (\Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+))$ because of the $\chi_{R(\delta)}(\Omega_1 \cup \Omega_2) \setminus \Omega_0, \phi)$ in $\chi^{(1)}(\Omega_1, \Omega_2; \alpha, \phi, \beta)$, with $\Omega_1 = \Omega(\mathcal{J}^-)$, $\Omega_2 = \Omega(\mathcal{J}^+)$, $\Omega_0 = \Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+)$, $\delta = \frac{1}{2}|\mathcal{J}|$, $\phi = \alpha_\tau$
- o when $\mathbf{x} \in (\Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+)) \setminus \Lambda(\mathcal{J})$ because of the factor $\chi_{R(\delta)}(\Omega_0 \setminus \Lambda, \phi)$ in $\chi_{\mathfrak{A}}^{(3)}(\alpha, \phi, \beta)$, with $\Omega_0 = \Omega(\mathcal{J}^-) \cap \Omega(\mathcal{J}^+)$, $\Lambda = \Lambda(\mathcal{J})$, $\delta = \frac{1}{2}|\mathcal{J}|$, $\phi = \alpha_\tau$
Observe that, in these two cases $\Lambda(\mathcal{J}) \neq X$, so that we necessarily have $\delta \geq \varepsilon$. In the event that $\mathbf{x} \in X \setminus (\Omega(\mathcal{J}^-) \cup \Omega(\mathcal{J}^+))$, there is a unique decimation interval $\tilde{\mathcal{J}} = [\tau_l, \tau_r] \subset \mathcal{J}$ having $\tau_r = \tau$ with $\mathbf{x} \in \Omega(\tilde{\mathcal{J}}^+) \setminus \Omega(\tilde{\mathcal{J}})$. In this case, the factor $\chi_{\tilde{\mathcal{J}}}(\alpha_{\tau_l}, \alpha_{\tau_c}, \alpha_{\tau_r})$ vanishes
- o when $\mathbf{x} \in \Omega(\tilde{\mathcal{J}}^+) \setminus (\Omega(\tilde{\mathcal{J}}^-) \cap \Omega(\tilde{\mathcal{J}}^+))$ because of the factor $\chi_{R(\delta)}(\Omega_2 \setminus \Omega_0, \beta)$ in $\chi^{(1)}(\Omega_1, \Omega_2; \alpha, \phi, \beta)$, with $\Omega_2 = \Omega(\tilde{\mathcal{J}}^+)$, $\Omega_0 = \Omega(\tilde{\mathcal{J}}^-) \cap \Omega(\tilde{\mathcal{J}}^+)$, $\delta = \frac{1}{2}|\tilde{\mathcal{J}}|$, $\beta = \alpha_\tau$
- o when $\mathbf{x} \in (\Omega(\tilde{\mathcal{J}}^-) \cap \Omega(\tilde{\mathcal{J}}^+)) \setminus \Lambda(\tilde{\mathcal{J}})$ because of the factors $\chi_{R(2\delta)}(\Omega_0 \setminus (P_\beta \cup \Lambda), \beta)$ and $\chi_{R(2\delta), R(\delta)}(P_\beta, \beta)$ in $\chi_{\mathfrak{A}}^{(2)}(\alpha, \beta)$, with $\Omega_0 = \Omega(\tilde{\mathcal{J}}^-) \cap \Omega(\tilde{\mathcal{J}}^+)$, $P_\beta = P_\beta(\tilde{\mathcal{J}})$, $\Lambda = \Lambda(\tilde{\mathcal{J}})$, $\delta = \frac{1}{2}|\tilde{\mathcal{J}}|$, $\beta = \alpha_\tau$
- o when $\mathbf{x} \in \Lambda(\tilde{\mathcal{J}}) \setminus \Omega(\tilde{\mathcal{J}})$ because of the factor $\chi_{2t}(\Lambda(\mathcal{J}) \setminus \Omega(\mathcal{J}); \alpha, \beta)$ in the $\chi_{\mathcal{J}}(\alpha, \phi, \beta)$ of Definition A.2, with \mathcal{J} replaced by $\tilde{\mathcal{J}}$, $2t = |\tilde{\mathcal{J}}|$, $\beta = \alpha_\tau$.

Observe that, in these three cases $\Omega(\tilde{\mathcal{J}}) \neq X$, so that we necessarily have $t, \delta \geq \varepsilon$. \square

Lemma A.5. Let $\delta > 0$ be sufficiently small and $\Lambda \subset \Omega_0$. Assume that

$$\begin{aligned} |\alpha|_\Lambda, |\beta|_\Lambda &\leq R(2\delta) & |\nabla \alpha|_{\Lambda^*}, |\nabla \beta|_{\Lambda^*} &\leq R'(2\delta) \\ |\alpha - \phi|_{\Lambda^*} &\leq r(\delta) & |\phi - \beta|_{\Lambda^*} &\leq r(\delta) \end{aligned}$$

Then

$$|\phi|_\Lambda \leq R(\delta), \quad |\nabla \phi|_{\Lambda^*} \leq R'(\delta)$$

Proof. It follows from our assumptions that

$$|\nabla \phi - \nabla \alpha|_{\Lambda^*} \leq \|\nabla\| |\phi - \alpha|_{\Lambda^*} \leq \|\nabla\| r(\delta)$$

where $\|\nabla\|$ is the operator norm of the gradient. Consequently, by (F.3d,e),

$$|\phi|_\Lambda \leq R(2\delta) + r(\delta) \leq R(\delta)$$

and

$$|\nabla \phi|_{\Lambda^*} \leq R'(2\delta) + \|\nabla\| r(\delta) \leq R'(\delta)$$

\square

Appendix B. Bounds on Weight Factors

Lemma B.1. Let \mathfrak{S} be a hierarchy for scale δ and $\varepsilon = 2^{-n}\delta$ with $n \geq \text{depth}(\mathfrak{S})$. Let $\tau \in \varepsilon\mathbb{Z} \cap [0, \delta]$ and $\tau' \in \varepsilon\mathbb{Z} \cap (0, \delta)$.

(i)

$$\sup_{\substack{\mathbf{x}, \mathbf{y} \in X \\ \kappa_{*\tau}(\mathbf{y}) < \infty}} e^{-\frac{m}{3}d(\mathbf{x}, \mathbf{y})} \frac{\kappa_{*\tau}(\mathbf{y})}{\kappa_{*\tau}(\mathbf{x})} \leq 2, \quad \sup_{\substack{\mathbf{x}, \mathbf{y} \in X \\ \kappa_\tau(\mathbf{y}) < \infty}} e^{-\frac{m}{3}d(\mathbf{x}, \mathbf{y})} \frac{\kappa_\tau(\mathbf{y})}{\kappa_\tau(\mathbf{x})} \leq 2$$

(ii) Let $0 \leq k \leq n$ and set

$$\begin{aligned} \mathcal{J}_{*k} &= \begin{cases} [\tau', \tau' + 2^{-k}\delta] & \text{if } k \geq \mathfrak{d}(\tau') \\ \text{the unique decimation interval} \\ \text{of length } 2^{-k}\delta \text{ that contains } \tau' & \text{if } k < \mathfrak{d}(\tau') \end{cases} \\ \mathcal{J}_k &= \begin{cases} [\tau' - 2^{-k}\delta, \tau'] & \text{if } k \geq \mathfrak{d}(\tau') \\ \text{the unique decimation interval} \\ \text{of length } 2^{-k}\delta \text{ that contains } \tau' & \text{if } k < \mathfrak{d}(\tau') \end{cases} \end{aligned}$$

Then

$$\begin{aligned} \kappa_{*\tau'}(\mathbf{y}) &\leq 4e^{\frac{m}{3}d(\mathbf{y}, \Lambda(\mathcal{J}_{*k}))} R(2^{-k}\delta) \quad \text{and} \\ \kappa_{\tau'}(\mathbf{y}) &\leq 4e^{\frac{m}{3}d(\mathbf{y}, \Lambda(\mathcal{J}_k))} R(2^{-k}\delta) \quad \text{for all } \mathbf{y} \in \Lambda_{\tau'}^c \end{aligned}$$

The $\kappa_{*\tau'}(\mathbf{y})$ bound also applies when $\tau' = 0$ if we take $\mathfrak{d}(0) = 0$ and $\Lambda_0 = \emptyset$. The $\kappa_{\tau'}(\mathbf{y})$ bound also applies when $\tau' = \delta$ if we take $\Lambda_\delta = \emptyset$.

Proof. (i) We prove the first inequality. Let $\mathbf{x}, \mathbf{y} \in X$. It suffices to consider the case that $\kappa_{*\tau}(\mathbf{x})$ and $\kappa_{*\tau}(\mathbf{y})$ are both finite. Let $\mathcal{J} = [\tau, \tau + 2^k\varepsilon]$ and $\mathcal{J}'' = [\tau, \tau + 2^\ell\varepsilon]$ be the maximal decimation intervals with τ as left endpoint such that $\mathbf{x} \in \Lambda(\mathcal{J})$, $\mathbf{y} \in \Lambda(\mathcal{J}'')$. Then $\kappa_{*\tau}(\mathbf{x}) = R(2^k\varepsilon)$ and $\kappa_{*\tau}(\mathbf{y}) = R(2^\ell\varepsilon)$ if $\tau \neq 0$ and $\kappa_{*\tau}(\mathbf{x}) = 2R(2^k\varepsilon)$ and $\kappa_{*\tau}(\mathbf{y}) = 2R(2^\ell\varepsilon)$ if $\tau = 0$. If $k \leq \ell + 1$ then $\frac{\kappa_{*\tau}(\mathbf{y})}{\kappa_{*\tau}(\mathbf{x})} = \frac{R(2^\ell\varepsilon)}{R(2^k\varepsilon)} \leq \frac{R(2^\ell\varepsilon)}{R(2^{\ell+1}\varepsilon)} \leq 2$ by (F.3a). If $k > \ell + 1$, then $\mathbf{x} \in \Lambda(\mathcal{J})$, while $\mathbf{y} \in \Lambda(\mathcal{J}')^c$ for $\mathcal{J}' = [\tau, \tau + 2^{\ell+1}\varepsilon] \subsetneq \mathcal{J}$. Hence, in this case, we have $\frac{\kappa_{*\tau}(\mathbf{y})}{\kappa_{*\tau}(\mathbf{x})} = \frac{R(2^\ell\varepsilon)}{R(2^k\varepsilon)} \leq e^{\frac{m}{3}d(\mathbf{x}, \mathbf{y})}$ by (F.5).

(ii) Again, we prove the first inequality. Let $\mathcal{J}'' = [\tau', \tau' + t]$ be the maximal decimation interval with τ' as left hand end point such that $\mathbf{y} \in \Lambda(\mathcal{J}'')$. We automatically have $t \geq \varepsilon$, since $\Lambda([\tau', \tau' + \varepsilon]) = X$, and $t \leq \frac{\delta}{2^{\mathfrak{d}(\tau')}}$, since no decimation interval having τ' as an endpoint has length longer than $\frac{\delta}{2^{\mathfrak{d}(\tau')}}$. By definition, $\kappa_{*\tau'}(\mathbf{y}) = R(t)$ if $\tau' \neq 0$ and $\kappa_{*\tau'}(\mathbf{y}) = 2R(t)$ if $\tau' = 0$. The desired bound is trivial if $2^{-k}\delta \leq 2t$, so assume that $2^{-k}\delta > 2t$. Set

$$\mathcal{J}' = \begin{cases} [\tau', \tau' + 2t] & \text{if } t < \frac{\delta}{2^{\mathfrak{d}(\tau')}} \\ [\tau' - t, \tau' + t] = \mathcal{J}_{\tau'} & \text{if } t = \frac{\delta}{2^{\mathfrak{d}(\tau')}} \end{cases}$$

Then $\mathbf{y} \in \Lambda(\mathcal{J}')^c$ and $\mathcal{J}' \subsetneq \mathcal{J}_{*k}$, so that

$$\kappa_{*\tau'}(\mathbf{y}) \leq 2R(t) \leq 2e^{\frac{m}{3}d(\mathbf{x}, \mathbf{y})} R(2^{-k}\delta)$$

for all $\mathbf{x} \in \Lambda(\mathcal{J}_{*k})$, by (F.5). \square

Appendix C. Normalization Constants

In this appendix, we prove

Lemma C.1. *There is a unique function $\delta \in (0, 1) \rightarrow \mathcal{Z}_\delta \in (0, 1)$ that obeys*

$$\mathcal{Z}_{2\delta} = \mathcal{Z}_\delta^2 \int_{|z| \leq r(\delta)} \frac{dz^* \wedge dz}{2\pi i} e^{-|z|^2} \quad \lim_{\delta \rightarrow 0+} \frac{1}{\delta} \log \mathcal{Z}_\delta = 0$$

Furthermore,

$$|\ln \mathcal{Z}_\delta| \leq e^{-r(\delta)^2}$$

Proof. Define, for all $0 < \delta < 1$,

$$i(\delta) = \frac{1}{2\delta} \log \int_{|z| \leq r(\delta)} \frac{dz^* \wedge dz}{2\pi i} e^{-|z|^2}$$

and observe that $i(\delta) < 0$. The condition relating $\mathcal{Z}_{2\delta}$ to \mathcal{Z}_δ is equivalent to

$$\frac{1}{2\delta} \log \mathcal{Z}_{2\delta} = \frac{1}{\delta} \log \mathcal{Z}_\delta + i(\delta)$$

Iterating gives

$$\frac{1}{\delta} \log \mathcal{Z}_\delta = \frac{1}{2^{-n}\delta} \log \mathcal{Z}_{2^{-n}\delta} + \sum_{\ell=1}^n i(2^{-\ell}\delta)$$

Existence and uniqueness will follow from convergence of the series $\sum_{\ell=1}^{\infty} i(2^{-\ell}\delta)$, which we now prove.

Since

$$\begin{aligned} \int_{|z| \leq r(\delta)} \frac{dz^* \wedge dz}{2\pi i} e^{-|z|^2} &= 1 - \int_{|(x,y)| \geq r(\delta)} \frac{dx dy}{\pi} e^{-(x^2+y^2)} \\ &= 1 - \frac{1}{\pi} \int_{r(\delta)}^{\infty} dr \int_0^{2\pi} d\theta r e^{-r^2} = 1 - \int_{r(\delta)^2}^{\infty} ds e^{-s} \\ &= 1 - e^{-r(\delta)^2} \end{aligned}$$

and $|\ln(1-x)| \leq \frac{|x|}{1-|x|} \leq 2|x|$ for all $|x| \leq \frac{1}{2}$, we have $|i(\delta)| \leq \frac{1}{\delta} e^{-r(\delta)^2}$. Hence the series

$$\delta e^{r(\delta)^2} \sum_{\ell=1}^{\infty} |i(2^{-\ell}\delta)| \leq \sum_{\ell=1}^{\infty} 2^\ell e^{-(r(2^{-\ell}\delta)^2 - r(\delta)^2)}$$

By (F.7d),

$$\begin{aligned} r(2^{-\ell}\delta)^2 - r(\delta)^2 &= \sum_{p=1}^{\ell} (r(2^{-p}\delta)^2 - r(2^{-p+1}\delta)^2) \\ &\geq \sum_{p=1}^{\ell} r(2^{-p}\delta) (r(2^{-p}\delta) - r(2^{-p+1}\delta)) \end{aligned}$$

$$\geq \sum_{p=1}^{\ell} 3 L(2^{-p}\delta) \geq 3\ell$$

so the series

$$\delta e^{r(\delta)^2} \sum_{\ell=1}^{\infty} |i(2^{-\ell}\delta)| \leq \sum_{\ell=1}^{\infty} 2^{\ell} e^{-3\ell} = \frac{2/e^3}{1 - 2/e^3} \leq 1$$

does indeed converge and

$$\log \mathcal{Z}_{\delta} = \delta \sum_{\ell=1}^{\infty} i(2^{-\ell}\delta) = \sum_{\ell=1}^{\infty} 2^{\ell-1} \log \int_{|z| \leq r(2^{-\ell}\delta)} \frac{dz^* \wedge dz}{2\pi i} e^{-|z|^2}$$

is bounded in absolute value by $e^{-r(\delta)^2}$. \square

Appendix D. Bounds on the Propagator

Throughout this appendix we assume that $\hbar \equiv 1$. Then Recall that $X = \mathbb{Z}^D / L\mathbb{Z}^D$. In (2.16), we assumed that the one-particle operator $h = \nabla^* \mathcal{H} \nabla$ where $\mathcal{H} : L^2(X^*) \rightarrow L^2(X^*)$ is a translation invariant, self-adjoint operator all of whose eigenvalues lie between $c_{\mathcal{H}} > 0$ and $C_{\mathcal{H}} > 0$ and for which

$$D_{\mathcal{H}} = \sum_{\substack{\mathbf{x} \in X \\ 1 \leq i, j \leq D}} e^{6md(\mathbf{x}, 0)} |\mathcal{H}(b_i(0), b_j(\mathbf{x}))| < \infty$$

Here, for each $1 \leq i \leq D$ and $\mathbf{x} \in X$, $b_i(\mathbf{x}) = (\mathbf{x}, \mathbf{x} + e_i)$ denotes the bond with base point \mathbf{x} and direction e_i . Under this hypothesis, the kernel of h is

$$h(\mathbf{x}, \mathbf{y}) = \sum_{1 \leq i, j \leq D} [\mathcal{H}(b_i(\mathbf{x} - e_i), b_j(\mathbf{y} - e_j)) - \mathcal{H}(b_i(\mathbf{x} - e_i), b_j(\mathbf{y})) - \mathcal{H}(b_i(\mathbf{x}), b_j(\mathbf{y} - e_j)) + \mathcal{H}(b_i(\mathbf{x}), b_j(\mathbf{y}))]$$

The norm $\|\|h\|\| \leq \mathcal{N}_{6m}(h; 1, 1) \leq 4e^{12m} D_{\mathcal{H}}$ and the constant $K_j = \mathcal{N}_{6m}(h - \mu; 1, 1)$ of Lemma 3.21 obeys

$$K_j \leq 4e^{12m} D_{\mathcal{H}} + |\mu| \quad (D.1)$$

Furthermore, we have the following bounds.

Lemma D.1. Set $K'_j = \max\{|\mu| + 4D_{\mathcal{H}} e^{10m}, 1\}$. Let $S \subset X$ and $A : L^2(X) \rightarrow L^2(X)$. For all $\tau \geq 0$ and $\mathbf{x} \in X$,

$$\begin{aligned} & |A([\mathbf{1} - j(\tau)]S\alpha)(\mathbf{x})| \\ & \leq \tau K'_j e^{K'_j \tau} \|A\| \left([|\mu| + e^{-5md(\mathbf{x}, S^c)}] \max_{\mathbf{y} \in S} |\alpha(\mathbf{y})| + \max_{b \in S^*} |\nabla \alpha(b)| \right) \end{aligned}$$

For all $\tau \geq 0$ and $S' \subset X$,

$$\begin{aligned} & \sum_{\mathbf{x} \in S'} |A([\mathbf{1} - j(\tau)]S\alpha)(\mathbf{x})| \\ & \leq \tau K'_j e^{K'_j \tau} \|A\| \left([|\mu| + e^{-5md(S', S^c)}] \max_{\mathbf{y} \in S} |\alpha(\mathbf{y})| + \max_{b \in S^*} |\nabla \alpha(b)| \right) |S| \end{aligned}$$

Proof. Write

$$\begin{aligned} & ([\mathbb{1} - j(\tau)]S\alpha)(\mathbf{y}) \\ &= (1 - e^{\mu\tau}) S\alpha(\mathbf{y}) + e^{\mu\tau} \left([\mathbb{1} - e^{-\tau\nabla^*\mathcal{H}\nabla}] S\alpha \right) (\mathbf{y}) \\ &= (1 - e^{\mu\tau}) S\alpha(\mathbf{y}) + e^{\mu\tau} \int_0^\tau d\tau' \left(\left[e^{-\tau'\nabla^*\mathcal{H}\nabla} \nabla^* \mathcal{H} \nabla \right] S\alpha \right) (\mathbf{y}) \end{aligned} \quad (\text{D.2})$$

As above

$$\begin{aligned} \sum_{\mathbf{z} \in X} e^{5md(\mathbf{x}, \mathbf{z})} \left| \left(A e^{-\tau'\nabla^*\mathcal{H}\nabla} \right) (\mathbf{x}, \mathbf{z}) \right| &\leq e^{4\tau'D_{\mathcal{H}}e^{10m}} \|A\| \\ \sup_{\mathbf{z} \in X} \sum_{b \in X^*} e^{5m[d(\mathbf{z}, b)+1]} |(\nabla^*\mathcal{H})(\mathbf{z}, b)| &\leq 2D_{\mathcal{H}}e^{10m} \end{aligned} \quad (\text{D.3})$$

For any bond $b = (\mathbf{y}, \mathbf{y}')$

$$\begin{aligned} \nabla(S\alpha)(b) &= S(\mathbf{y}')\alpha(\mathbf{y}') - S(\mathbf{y})\alpha(\mathbf{y}) \\ &= [S(\mathbf{y}') - S(\mathbf{y})]\alpha(\mathbf{y}') + S(\mathbf{y})[\alpha(\mathbf{y}') - \alpha(\mathbf{y})] \\ &= \alpha(\mathbf{y}')(\nabla S)(b) + S(\mathbf{y})(\nabla\alpha)(b) \end{aligned}$$

The second term is nonzero only for $\mathbf{y} \in S$ and hence for $b \in S^*$. The first term is bounded in magnitude by $|\alpha(\mathbf{y}')|$ and is nonzero only if b connects a point of S to a point of S^c . In this case, possibly replacing b by $-b$, we can always arrange that \mathbf{y}' is in S .

The part of $(A[\mathbb{1} - j(\tau)]S\alpha)(\mathbf{x})$ in which the last ∇ of (D.2), multiplied on the left by A , acts on α is bounded by

$$e^{\mu\tau} \tau \|A\| e^{4\tau D_{\mathcal{H}}e^{10m}} 2D_{\mathcal{H}}e^{10m} \max_{b \in S^*} |\nabla\alpha(b)| \leq \tau K'_j e^{K'_j \tau} \|A\| \max_{b \in S^*} |\nabla\alpha(b)|$$

The part in which the last ∇ of (D.2) acts on the characteristic function is bounded by

$$\begin{aligned} & e^{\mu\tau} \tau \|A\| e^{4\tau D_{\mathcal{H}}e^{10m}} 2D_{\mathcal{H}}e^{10m} e^{-5md(\mathbf{x}, S^c)} \max_{\substack{\mathbf{y}' \in S \\ d(\mathbf{y}', S^c) \leq 1}} |\alpha(\mathbf{y}')| \\ & \leq \tau K'_j e^{K'_j \tau} \|A\| e^{-5md(\mathbf{x}, S^c)} \max_{\mathbf{y} \in S} |\alpha(\mathbf{y})| \end{aligned}$$

The first bound now follows from

$$|1 - e^{\mu\tau}| \leq |\mu| \tau e^{|\mu|\tau} \leq |\mu| \tau e^{K'_j \tau} \quad (\text{D.4})$$

The proof of the second bound is similar. \square

Corollary D.2. *Let $\mathfrak{c}' > 0$ and recall, from (3.2), that*

$$j_{\mathfrak{c}'}(\tau)(\mathbf{x}, \mathbf{y}) = \begin{cases} j(\tau)(\mathbf{x}, \mathbf{y}) & \text{if } d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c}' \\ 0 & \text{otherwise} \end{cases}$$

For all $\tau \geq 0$ and $\mathbf{x} \in X$,

$$|([1 - j_{\epsilon'}(\tau)]\alpha)(\mathbf{x})| \leq \tau K'_j e^{K'_j \tau} \left(\left[|\mu| + e^{-5m\epsilon'} \right] \max_{\substack{\mathbf{y} \in X \\ d(\mathbf{x}, \mathbf{y}) \leq \epsilon'}} |\alpha(\mathbf{y})| + \max_{\substack{b \in X^* \\ d(\mathbf{x}, b) \leq \epsilon'}} |\nabla \alpha(b)| \right)$$

Proof. Just apply the previous lemma with A being the identity operator and S the set of points $\mathbf{y} \in X$ that are within a distance ϵ' of \mathbf{x} . \square

Remark D.3. Recall, from 2.17, that $K_{\text{reg}} = 2^9 \exp\{20e^{12m_D} D_{\mathcal{H}}\}$. In Lemmas 6.3 and 6.7, we used

$$4 + 2e^{2K_j} \leq 4 + 2e^2 \exp\{4e^{12m_D} D_{\mathcal{H}}\} \leq 2^5 \exp\{4e^{12m_D} D_{\mathcal{H}}\} \leq K_{\text{reg}}$$

and

$$2K'_j e^{3K_j + K'_j} \leq 2e^{3K_j + 2K'_j} \leq 2e^5 \exp\{20D e^{12m_D} D_{\mathcal{H}}\} \leq K_{\text{reg}}$$

Here, we have used that $|\mu| \leq 1$.

Lemma D.4. For all $\alpha \in L^2(X)$ and all $0 \leq \varepsilon \leq 1$,

$$c_{\mathcal{H}} e^{-4D C_{\mathcal{H}}} \varepsilon \|\nabla \alpha\|^2 \leq \langle \alpha^*, [1 - e^{-\varepsilon \nabla^* \mathcal{H} \nabla}] \alpha \rangle \leq C_{\mathcal{H}} \varepsilon \|\nabla \alpha\|^2$$

Proof. We have

$$1 - e^{-\varepsilon \nabla^* \mathcal{H} \nabla} = - \int_0^1 dt \frac{d}{dt} e^{-\varepsilon t \nabla^* \mathcal{H} \nabla} = \int_0^1 dt \varepsilon \nabla^* \mathcal{H} \nabla e^{-\varepsilon t \nabla^* \mathcal{H} \nabla}$$

Since $e^{-\varepsilon t \nabla^* \mathcal{H} \nabla}$ commutes with $\varepsilon \nabla^* \mathcal{H} \nabla$ and all of the eigenvalues of $e^{-\varepsilon t \nabla^* \mathcal{H} \nabla}$ lie between $e^{-\varepsilon t C_{\mathcal{H}} \|\nabla\|^2} \geq e^{-4\varepsilon t D C_{\mathcal{H}}}$ and one

$$\begin{aligned} \langle \alpha^*, [1 - e^{-\varepsilon \nabla^* \mathcal{H} \nabla}] \alpha \rangle &\geq \int_0^1 dt \varepsilon e^{-4\varepsilon t D C_{\mathcal{H}}} \langle \alpha^*, \nabla^* \mathcal{H} \nabla \alpha \rangle \\ &\geq \varepsilon e^{-4\varepsilon D C_{\mathcal{H}}} \langle \alpha, \nabla^* \mathcal{H} \nabla \alpha \rangle \\ &\geq c_{\mathcal{H}} \varepsilon e^{-4\varepsilon D C_{\mathcal{H}}} \|\nabla \alpha\|^2 \end{aligned}$$

Similarly,

$$\langle \alpha^*, [1 - e^{-\varepsilon \nabla^* \mathcal{H} \nabla}] \alpha \rangle \leq \int_0^1 dt \varepsilon \langle \alpha^*, \nabla^* \mathcal{H} \nabla \alpha \rangle \leq C_{\mathcal{H}} \varepsilon \|\nabla \alpha\|^2$$

\square

Appendix E. Bounds on the Background Field

In this appendix we provide both pointwise and norm bounds on the background field as well as comparisons between the background field and the

original field α_τ . Throughout Sects. E.1–E.4 of the appendix, we fix a hierarchy \mathfrak{S} for scale δ and write

$$\gamma_{*\tau} = \begin{cases} \alpha^* & \text{if } \tau = 0 \\ \Gamma_{*\mathfrak{S}}(\tau; \alpha_*, \vec{\alpha}_*) & \text{if } \tau \in (0, \delta) \\ \beta^* & \text{if } \tau = \delta \end{cases} \quad \gamma_\tau = \begin{cases} \alpha & \text{if } \tau = 0 \\ \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) & \text{if } \tau \in (0, \delta) \\ \beta & \text{if } \tau = \delta \end{cases}$$

We also fix an integer $n \geq \text{depth}\mathfrak{S}$ and set $\varepsilon = 2^{-n}\delta$. Recall, from Notation 2.2, that, for each decimation point $\tau \in \cap(0, \delta)$,

- the decimation index, $\mathfrak{d}(\tau)$, of τ is determined by $\tau \in \frac{\delta}{2^{\mathfrak{d}(\tau)}}\mathbb{Z} \setminus \frac{2\delta}{2^{\mathfrak{d}(\tau)}}\mathbb{Z}$. By convention, we also set $\mathfrak{d}(0) = \mathfrak{d}(\delta) = 0$ and, if τ is not a decimation point, $\mathfrak{d}(\tau) = \infty$.
- $\mathcal{J}_\tau = [\tau - \frac{\delta}{2^{\mathfrak{d}(\tau)}}, \tau + \frac{\delta}{2^{\mathfrak{d}(\tau)}}]$, $\mathcal{J}_\tau^- = [\tau - \frac{\delta}{2^{\mathfrak{d}(\tau)}}, \tau]$ and $\mathcal{J}_\tau^+ = [\tau, \tau + \frac{\delta}{2^{\mathfrak{d}(\tau)}}]$
- $\Lambda_\tau = \Lambda([\tau - \frac{\delta}{2^{\mathfrak{d}(\tau)}}, \tau + \frac{\delta}{2^{\mathfrak{d}(\tau)}}])$. By convention, we also set $\Lambda_0 = \Lambda_\delta = \emptyset$, and, if τ is not a decimation point, $\Lambda_\tau^c = \emptyset$.
- In this appendix, we use $\varepsilon_\tau = \frac{\delta}{2^{\mathfrak{d}(\tau)}} = \frac{1}{2}|\mathcal{J}_\tau| = |\mathcal{J}_\tau^-| = |\mathcal{J}_\tau^+|$ to denote the lattice spacing of the coarsest lattice $\frac{\delta}{2^\kappa}\mathbb{Z}$ that contains τ . By convention, we set $\varepsilon_0 = \varepsilon_\delta = \delta$.

In Sect. E.5, we fix a hierarchy \mathfrak{S} for scale 2δ . We further assume, throughout this appendix, that the field α_τ is compatible with \mathfrak{S} in the following sense. (In the integral operator $\mathcal{I}_{\mathfrak{S}}$, the field α_τ is compatible with \mathfrak{S} .)

Definition E.1. A field configuration $\alpha_\tau(\mathbf{x})$ is said to be compatible with the hierarchy \mathfrak{S} if, for each decimation interval $[\tau_-, \tau_+]$,

$$\begin{aligned} |\alpha_{\tau_-}(\mathbf{x})|, |\alpha_{\tau_+}(\mathbf{x})| &\leq R(\tau_+ - \tau_-) \text{ for all } \mathbf{x} \in \Lambda([\tau_-, \tau_+]) \\ |\nabla \alpha_{\tau_-}(b)|, |\nabla \alpha_{\tau_+}(b)| &\leq R'(\tau_+ - \tau_-) \text{ for all } b \in \Lambda([\tau_-, \tau_+])^* \\ |\alpha_{\tau_+}(\mathbf{x}) - \alpha_{\tau_-}(\mathbf{x})| &\leq r(\tau_+ - \tau_-) \text{ for all } \mathbf{x} \in \Lambda([\tau_-, \tau_+])^* \end{aligned}$$

where we recall that, for each $S \subset X$, S^* is the set of bonds with at least one end in S and S^* is the set of points in X that are connected to some point of S by some bond.

Remark E.2. Compatibility implies

$$|\alpha_\tau(\mathbf{x})| \leq \min\{\kappa_\tau(\mathbf{x}), \kappa_{*\tau}(\mathbf{x})\} \quad |\alpha(\mathbf{x})| \leq \kappa_{*0}(\mathbf{x}) \quad |\beta(\mathbf{x})| \leq \kappa_\delta(\mathbf{x})$$

for all $\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)$ and $\mathbf{x} \in X$.

E.1. Additional Descriptions

We now rewrite the definition, Definition 2.9, of the background field (still with $j(t)$ being interpreted as the \mathfrak{h} -operator of (3.1)) in a way that makes more clear which coefficients $\Gamma_\tau^{\tau'}(\mathfrak{S})$, $\Gamma_\tau^{\tau'}(\mathfrak{S})$ are nonzero. The coefficients $\Gamma_{*\tau}^{\tau'}(\mathfrak{S}) = \Gamma_{*\tau}^{\tau'}$ and $\Gamma_\tau^{\tau'}(\mathfrak{S}) = \Gamma_\tau^{\tau'}$ were defined as follows. For $\tau \in (0, \delta)$,

- For $\tau = \tau'$,

$$\Gamma_{*\tau}^\tau = \Gamma_\tau^\tau = \Lambda_\tau^c$$

- For $\tau \neq \tau'$, $\Gamma_{*\tau}^{\tau'} = 0$ unless $\tau > \tau'$ and $[\tau', \tau]$ is strictly contained in a decimation interval with τ' as its left endpoint. If \mathcal{J} is the smallest such decimation interval and δ' its length, then

$$\Gamma_{*\tau}^{\tau'} = j\left(\tau - \tau' - \frac{\delta'}{2}\right) \Lambda(\mathcal{J}) j\left(\frac{\delta'}{2}\right) \Lambda_{\tau'}^c,$$

- Similarly for $\tau \neq \tau'$, $\Gamma_{\tau}^{\tau'} = 0$ unless $\tau < \tau'$ and $[\tau, \tau']$ is strictly contained in a decimation interval with τ' as its right endpoint. If \mathcal{J} is the smallest such interval and δ' its length, then

$$\Gamma_{\tau}^{\tau'} = j\left(\tau' - \tau - \frac{\delta'}{2}\right) \Lambda(\mathcal{J}) j\left(\frac{\delta'}{2}\right) \Lambda_{\tau'}^c$$

Observe that if \mathcal{J} is a decimation interval, with τ' as right hand endpoint and which contains τ in its interior, then $\mathfrak{d}(\tau) > \mathfrak{d}(\tau')$ and τ' is the smallest element of $\varepsilon_{\tau'}\mathbb{Z}$ that is above τ . Also observe that if $\mathfrak{d}(\tau') > n$, then $\Lambda_{\tau'}^c = \emptyset$ so that $\Gamma_{*\tau}^{\tau'} = \Gamma_{\tau}^{\tau'} = 0$.

Definition E.3. For each $\tau \in (0, \delta)$, set

$$\begin{aligned} \mathcal{T}_r(\tau, \delta) &= \left\{ \tau' \in (\tau, \delta] \cap \varepsilon\mathbb{Z} \mid \mathfrak{d}(\tau') < \mathfrak{d}(\tau), \tau' = \min \left\{ \tau'' \in \varepsilon_{\tau'}\mathbb{Z} \mid \tau'' > \tau \right\} \right\} \\ \mathcal{T}_l(\tau, \delta) &= \left\{ \tau' \in [0, \tau) \cap \varepsilon\mathbb{Z} \mid \mathfrak{d}(\tau') < \mathfrak{d}(\tau), \tau' = \max \left\{ \tau'' \in \varepsilon_{\tau'}\mathbb{Z} \mid \tau'' < \tau \right\} \right\} \end{aligned}$$

The figure below provides an example. In it, $\varepsilon = 1$, $n = 5$ so that $\delta = 32\varepsilon$, $\tau = 14\varepsilon$ so that $\mathfrak{d}(\tau) = 4$, $\varepsilon_{\tau} = 2\varepsilon$, $\mathcal{T}_r(\tau, \delta) = \{16\varepsilon, 32\varepsilon\}$ and $\mathcal{T}_l(\tau, \delta) = \{12\varepsilon, 8\varepsilon, 0\}$.

As $\delta \in \mathcal{T}_r(\tau, \delta)$ and $0 \in \mathcal{T}_l(\tau, \delta)$ both $\mathcal{T}_r(\tau, \delta)$ and $\mathcal{T}_l(\tau, \delta)$ are always nonempty. When τ and δ are clear from the context, we drop them from the notation. Also, for each $\tau' \in \mathcal{T}_r$, let $\pi(\tau')$ denote the predecessor element of τ' in \mathcal{T}_r , which is the largest element of \mathcal{T}_r that is strictly smaller than τ' . When τ' is the smallest element of \mathcal{T}_r , set $\pi(\tau') = \tau$. Similarly, for each $\tau' \in \mathcal{T}_l$, let $\sigma(\tau')$ be the successor element of τ' , which is the smallest element of \mathcal{T}_l that is strictly larger than τ' . When τ' is the largest element of \mathcal{T}_l , $\sigma(\tau') = \tau$.

Lemma E.4. Let $\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)$.

(i)

$$\begin{aligned} \gamma_{\tau} &= \Lambda_{\tau}^c \alpha_{\tau} + \sum_{\tau' \in \mathcal{T}_r(\tau, \delta)} j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')} j(\tau' - \pi(\tau')) \Lambda_{\tau'}^c \alpha_{\tau'} \\ \gamma_{*\tau} &= \Lambda_{\tau}^c \alpha_{\tau}^* + \sum_{\tau' \in \mathcal{T}_l(\tau, \delta)} j(\tau - \sigma(\tau')) \Lambda_{\sigma(\tau')} j(\sigma(\tau') - \tau') \Lambda_{\tau'}^c \alpha_{\tau'}^* \end{aligned}$$

(ii)

$$\Lambda_{\tau} = \bigcup_{\tau' \in \mathcal{T}_r} \Lambda_{\pi(\tau')} \cap \Lambda_{\tau'}^c, \quad \Lambda_{\tau} = \bigcup_{\tau' \in \mathcal{T}_l} \Lambda_{\sigma(\tau')} \cap \Lambda_{\tau'}^c$$

provides two partitions of Λ_τ into disjoint subsets. Let $\tau_r \in \mathcal{T}_r$ and $\tau_l \in \mathcal{T}_l$. Then we have $\sigma(\tau_l) - \varepsilon_{\sigma(\tau_l)} = \tau_l$ and $\pi(\tau_r) + \varepsilon_{\pi(\tau_r)} = \tau_r$. If

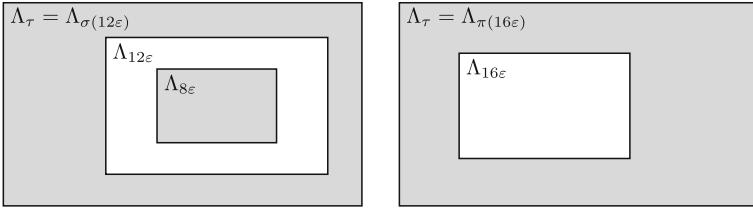

$$\Lambda_{\pi(\tau_r)} \cap \Lambda_{\tau_r}^c \cap \Lambda_{\sigma(\tau_l)} \cap \Lambda_{\tau_l}^c \neq \emptyset$$

then $[\tau_l, \tau_r]$ is a decimation interval of length $\min\{\varepsilon_{\tau_l}, \varepsilon_{\tau_r}\}$ and

$$\Lambda_{\pi(\tau_r)} \Lambda_{\tau_r}^c \Lambda_{\sigma(\tau_l)} \Lambda_{\tau_l}^c = \Lambda([\tau_l, \tau_r]) \Lambda_{\tau_l}^c \Lambda_{\tau_r}^c$$

as well.

In the figures below, the partitions of Λ_τ , stated in Lemma E.4(ii), are illustrated for the example inside Definition E.3.

In the proof of Lemma E.4 we need

Remark E.5. (i) If $\tau', \tilde{\tau}' \in \mathcal{T}_r(\tau, \delta)$ and $\tau' < \tilde{\tau}'$ then $\mathfrak{d}(\tau') > \mathfrak{d}(\tilde{\tau}')$.

If $\tau', \tilde{\tau}' \in \mathcal{T}_l(\tau, \delta)$ and $\tau' < \tilde{\tau}'$ then $\mathfrak{d}(\tau') < \mathfrak{d}(\tilde{\tau}')$.

For each $0 < \mathfrak{d} < \mathfrak{d}(\tau)$ there is exactly one $\tau' \in \mathcal{T}_l(\tau, \delta) \cup \mathcal{T}_r(\tau, \delta)$ with $\mathfrak{d}(\tau') = \mathfrak{d}$.

(ii) If $\tau', \tilde{\tau}' \in \mathcal{T}_l(\tau, \delta) \cup \mathcal{T}_r(\tau, \delta)$ and $\mathfrak{d}(\tau') > \mathfrak{d}(\tilde{\tau}')$, then

$$\Lambda_{\tilde{\tau}'} \subset \Lambda_{\tau'} \subset \Lambda_\tau$$

Proof. (i) Let $\tau' < \tilde{\tau}'$ both be in $\mathcal{T}_r(\tau, \delta)$ and suppose that $\mathfrak{d}(\tau') \leq \mathfrak{d}(\tilde{\tau}')$. Then both τ' and $\tilde{\tau}'$ are in $\varepsilon_{\tilde{\tau}'}\mathbb{Z}$ and $\tilde{\tau}'$ cannot be the element of $\varepsilon_{\tilde{\tau}'}\mathbb{Z}$ closest to τ , which is a contradiction.

Let $\tau' \in \mathcal{T}_l(\tau, \delta) \setminus \{0\}$ and $\tilde{\tau}' \in \mathcal{T}_r(\tau, \delta) \setminus \{\delta\}$ and suppose that $\mathfrak{d}(\tau') = \mathfrak{d}(\tilde{\tau}')$. Then $[\tau' - \varepsilon_{\tau'}, \tau' + \varepsilon_{\tau'}]$ and $[\tilde{\tau}' - \varepsilon_{\tilde{\tau}'}, \tilde{\tau}' + \varepsilon_{\tilde{\tau}'}]$ are both decimation intervals of length $2\varepsilon_{\tau'}$ and both contain τ in their interiors. So they must be identical. That's impossible since $\tau' < \tau < \tilde{\tau}'$ forces $\tau' \neq \tilde{\tau}'$.

Let $0 \leq \mathfrak{d} < \mathfrak{d}(\tau)$. There is exactly one decimation interval of length $\frac{\delta}{2^\mathfrak{d}}$ that contains τ . Call it $[\tau', \tilde{\tau}']$. If $\mathfrak{d} > 0$, then exactly one of $\tau', \tilde{\tau}'$ has decimation index \mathfrak{d} . If $\mathfrak{d} = 0$, then both of $\tau', \tilde{\tau}'$ have decimation index \mathfrak{d} . If $\mathfrak{d}(\tau') = \mathfrak{d}$, then $\tau' \in \mathcal{T}_l$. If $\mathfrak{d}(\tilde{\tau}') = \mathfrak{d}$, then $\tilde{\tau}' \in \mathcal{T}_r$.

(ii) All of $[\tau - \varepsilon_\tau, \tau + \varepsilon_\tau]$, $[\tau' - \varepsilon_{\tau'}, \tau' + \varepsilon_{\tau'}]$ and $[\tilde{\tau}' - \varepsilon_{\tilde{\tau}'}, \tilde{\tau}' + \varepsilon_{\tilde{\tau}'}]$ are decimation intervals that contain τ in their interiors. Since $\mathfrak{d}(\tau) > \mathfrak{d}(\tau') > \mathfrak{d}(\tilde{\tau}')$, the first is contained in the second, which, in turn is contained in the third. Consequently,

$$\Lambda([\tilde{\tau}' - \varepsilon_{\tilde{\tau}'}, \tilde{\tau}' + \varepsilon_{\tilde{\tau}'}]) \subset \Lambda([\tau' - \varepsilon_{\tau'}, \tau' + \varepsilon_{\tau'}]) \subset \Lambda([\tau - \varepsilon_\tau, \tau + \varepsilon_\tau])$$

(If $\mathfrak{d}(\tilde{\tau}') = 0$, drop consideration of $[\tilde{\tau}' - \varepsilon_{\tilde{\tau}'}, \tilde{\tau}' + \varepsilon_{\tilde{\tau}'}]$ and use that $\Lambda_{\tilde{\tau}'} = \emptyset$). \square

Proof of Lemma E.4. (i) We give the proof for γ_τ . We have already observed that $\Gamma_\tau^{\tau'}$ may be nonzero only for $\tau' = \tau$ or $\tau' \in \mathcal{T}_r$.

Now fix any $\tau' \in \mathcal{T}_r$. Then $[\tau, \tau']$ is strictly contained in a decimation interval with τ' as its right endpoint, namely $[\tau' - \varepsilon_{\tau'}, \tau']$. Denote by \mathcal{J} the smallest such interval and by δ' its length, so that

$$\Gamma_\tau^{\tau'} = j \left(\tau' - \tau - \frac{\delta'}{2} \right) \Lambda([\tau' - \delta', \tau']) j \left(\frac{\delta'}{2} \right) \Lambda_{\tau'}^c$$

If $\tau' - \frac{\delta'}{2} = \tau$, then all elements of (τ, τ') have decimation index strictly larger than $\mathfrak{d}(\tau)$ and τ' is the smallest element of \mathcal{T}_r .

If $\tau' - \frac{\delta'}{2} > \tau$, then τ is contained in the interior of the decimation interval $[\tau' - \delta', \tau' - \frac{\delta'}{2}]$ so that $\tau' - \frac{\delta'}{2}$ is the smallest element of $\frac{\delta'}{2}\mathbb{Z}$ above τ . As $\tau' - \frac{\delta'}{2}$ has the same decimation index as $\frac{\delta'}{2}$, we have $\tau' - \frac{\delta'}{2} \in \mathcal{T}_r$. All elements of $(\tau' - \frac{\delta'}{2}, \tau')$ have decimation index strictly larger than that of $\frac{\delta'}{2}$, and so cannot be in \mathcal{T}_r (because $\tau' - \frac{\delta'}{2}$ has smaller decimation index and is closer to τ), we have $\pi(\tau') = \tau' - \frac{\delta'}{2}$. In both cases, $\Lambda([\tau' - \delta', \tau']) = \Lambda_{\pi(\tau')}$ so that

$$\Gamma_\tau^{\tau'} = j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')} j(\tau' - \pi(\tau')) \Lambda_{\tau'}^c$$

as desired.

If $\tau' - \frac{\delta'}{2} < \tau$, then $[\tau' - \frac{\delta'}{2}, \tau']$ is a decimation interval that contains τ in its interior, contradicting the assumption that $[\tau' - \delta', \tau']$ is the shortest such decimation interval.

The proof for $\gamma_{*\tau}$ is similar.

(ii) Observe that $\Lambda_{\tau'} \subset \Lambda_{\pi(\tau')}$ for all $\tau' \in \mathcal{T}_r$ and $\Lambda_{\tau'} \subset \Lambda_{\sigma(\tau')}$ for all $\tau' \in \mathcal{T}_l$ and that $\tau' = \delta \in \mathcal{T}_r$ has $\Lambda_\delta^c = X$ and $\tau' = 0 \in \mathcal{T}_l$ has $\Lambda_0^c = X$. Consequently

$$\Lambda_\tau = \bigcup_{\tau' \in \mathcal{T}_r} \Lambda_{\pi(\tau')} \cap \Lambda_{\tau'}^c, \quad \Lambda_\tau = \bigcup_{\tau' \in \mathcal{T}_l} \Lambda_{\sigma(\tau')} \cap \Lambda_{\tau'}^c$$

provides two partitions of Λ_τ into disjoint subsets.

We have already shown, in part (i), that $\pi(\tau_r) + \frac{\delta}{2^{\mathfrak{d}(\pi(\tau_r))}} = \tau_r$ for all $\tau_r \in \mathcal{T}_r$.

Now fix any $\tau_r \in \mathcal{T}_r$ and $\tau_l \in \mathcal{T}_l$ and assume that

$$\mathbf{x} \in \Lambda_{\pi(\tau_r)} \cap \Lambda_{\tau_r}^c \cap \Lambda_{\sigma(\tau_l)} \cap \Lambda_{\tau_l}^c \neq \emptyset$$

Write, as in part (i),

$$\pi(\tau_r) = \tau_r - \frac{1}{2}\delta'_r \quad \sigma(\tau_l) = \tau_l + \frac{1}{2}\delta'_l$$

Both

$$\begin{aligned} \left[\pi(\tau_r) - \frac{1}{2}\delta'_r, \pi(\tau_r) + \frac{1}{2}\delta'_r \right] &= [\tau_r - \delta'_r, \tau_r] \\ \left[\sigma(\tau_l) - \frac{1}{2}\delta'_l, \sigma(\tau_l) + \frac{1}{2}\delta'_l \right] &= [\tau_l, \tau_l + \delta'_l] \end{aligned}$$

are decimation intervals that contain τ in their interiors. Hence one must be contained in the other. Say that $\delta'_r \leq \delta'_l$ so that the first is contained in the second and $\Lambda_{\sigma(\tau_l)} \subset \Lambda_{\pi(\tau_r)}$. To prove the claim, it suffices to show that $\tau_l + \delta'_l = \tau_r$ —i.e. that the right hand ends of the two intervals coincide—since then $[\tau_l, \tau_r]$ is a decimation interval and $\Lambda([\tau_l, \tau_r]) = \Lambda_{\sigma(\tau_l)} \subset \Lambda_{\pi(\tau_r)}$.

Suppose that they do not coincide. That is,

$$\sigma(\tau_l) - \frac{1}{2}\delta'_l \leq \pi(\tau_r) - \frac{1}{2}\delta'_r < \pi(\tau_r) + \frac{1}{2}\delta'_r < \sigma(\tau_l) + \frac{1}{2}\delta'_l$$

or equivalently,

$$\tau_l \leq \tau_r - \delta'_r < \tau < \tau_r < \tau_l + \delta'_l$$

Since $\tau_r \in (\tau_l, \tau_l + \delta'_l)$, we have $\mathcal{J}_{\tau_r} \subset [\tau_l, \tau_l + \delta'_l]$ leading to the contradiction

$$\Lambda_{\tau_r}^c \cap \Lambda_{\sigma(\tau_l)} = \Lambda(\mathcal{J}_{\tau_r})^c \cap \Lambda([\tau_l, \tau_l + \delta'_l]) = \emptyset$$

The argument that the left hand ends of the intervals coincide when $\delta'_r \geq \delta'_l$ is similar. \square

E.2. Comparison to the Case “ $j(\tau) = \mathfrak{h}$ ”

Recall, from (2.16), that $j(\tau) = e^{-\tau(h-\mu)}$ with $h = \nabla^* \mathcal{H} \nabla$ where $\mathcal{H} : L^2(X^*) \rightarrow L^2(X^*)$ is a translation invariant, self-adjoint operator all of whose eigenvalues lie between $c_{\mathcal{H}} > 0$ and $C_{\mathcal{H}} > 0$ and for which

$$D_{\mathcal{H}} = \sum_{\substack{\mathbf{x} \in X \\ 1 \leq i, j \leq d}} e^{6md(\mathbf{x}, 0)} |\mathcal{H}(b_i(0), b_j(\mathbf{x}))| < \infty$$

Here, for each $1 \leq i \leq d$ and $\mathbf{x} \in X$, $b_i(\mathbf{x}) = (\mathbf{x}, \mathbf{x} + e_i)$ denotes the bond with base point \mathbf{x} and direction e_i .

If $j(\tau)$ were the $j(0) = \mathfrak{h}$, the background field would reduce to

Definition E.6. Define, for each $0 < \tau < \delta$,

$$\begin{aligned} \hat{\gamma}_{*\tau} &= \Lambda_{\tau}^c \alpha_{\tau}^* + \sum_{\tau' \in \mathcal{T}_l(\tau, \delta)} \Lambda_{\sigma(\tau')} \Lambda_{\tau'}^c \mathfrak{h} \alpha_{\tau'}^* \\ \hat{\gamma}_{\tau} &= \Lambda_{\tau}^c \alpha_{\tau} + \sum_{\tau' \in \mathcal{T}_r(\tau, \delta)} \Lambda_{\pi(\tau')} \Lambda_{\tau'}^c \mathfrak{h} \alpha_{\tau'} \end{aligned}$$

We now prove some bounds on the difference between $\gamma_{*(\tau)}$ and $\hat{\gamma}_{*(\tau)}$ and derive some consequences of the bounds.

Proposition E.7. Assume that $\mathfrak{h} \equiv 1$. Let $0 < \tau < \delta$. If $\mathbf{x} \in \Lambda_{\tau}^c$, then

$$|\gamma_{*\tau}(\mathbf{x}) - \hat{\gamma}_{*\tau}(\mathbf{x})|, |\gamma_{\tau}(\mathbf{x}) - \hat{\gamma}_{\tau}(\mathbf{x})| \leq \frac{1}{2} e^{-m\mathfrak{c}(\varepsilon_{\tau})}$$

If \mathcal{J} is a decimation interval that contains τ and $\mathbf{x} \in \Lambda(\mathcal{J})$, then

$$|\gamma_{*\tau}(\mathbf{x}) - \hat{\gamma}_{*\tau}(\mathbf{x})|, |\gamma_{\tau}(\mathbf{x}) - \hat{\gamma}_{\tau}(\mathbf{x})| \leq (2e^{K_j} + 1) \ r(|\mathcal{J}|)$$

The proof of this proposition uses¹⁶

Lemma E.8. Let $0 < \tau < \delta$ and $\mathcal{T}_r = \{\tau_1 < \tau_2 < \dots < \tau_p = \delta\}$.

¹⁶ In Lemma E.8, we do not assume that \mathfrak{h} is identically one.

(a) If $\mathbf{x} \in \Lambda_\tau^c$, then

$$\gamma_\tau(\mathbf{x}) = \alpha_\tau(\mathbf{x}) + E_a(\tau, \mathbf{x}) \text{ with } |E_a(\tau, \mathbf{x})| \leq \frac{1}{2}e^{-mc(\varepsilon_\tau)}$$

If $\mathbf{x} \in \Lambda_{\tau_{\ell-1}} \cap \Lambda_{\tau_\ell}^c$, for some $1 \leq \ell \leq p$ (with the convention that $\tau_0 = \tau$), then

(b) when $d(\mathbf{x}, \Lambda_{\tau_\ell}) \geq \frac{1}{2}\mathfrak{c}(\varepsilon_{\tau_\ell})$ (automatic for $\ell = p$) and $d(\mathbf{x}, \Lambda_{\tau_{\ell-1}}^c) \geq \frac{1}{2}\mathfrak{c}(2\varepsilon_{\tau_{\ell-1}})$,

$$\gamma_\tau(\mathbf{x}) = \mathfrak{h}\alpha_{\tau_\ell}(\mathbf{x}) + ([j(\tau_\ell - \tau) - \mathfrak{h}] \Lambda_{\tau_{\ell-1}} \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell})(\mathbf{x}) + E_b(\tau, \mathbf{x})$$

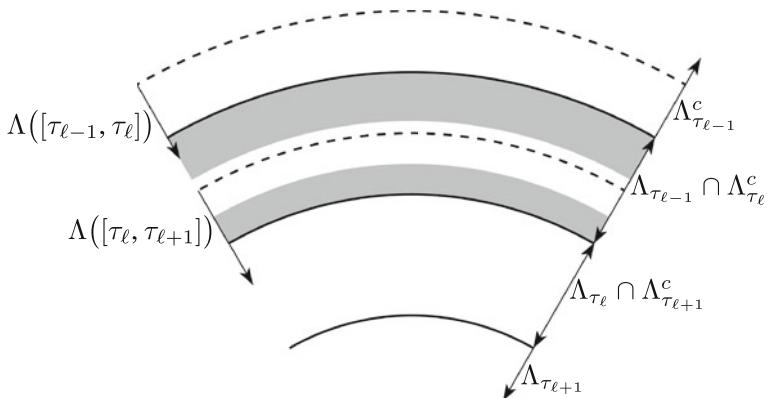

with $|E_b(\tau, \mathbf{x})| \leq 2e^{-mc(\varepsilon_{\tau_\ell})}$

(c) when $d(\mathbf{x}, \Lambda_{\tau_{\ell-1}}^c) \leq \frac{1}{2}\mathfrak{c}(2\varepsilon_{\tau_{\ell-1}})$

$$\begin{aligned} \gamma_\tau(\mathbf{x}) &= \mathfrak{h}\alpha_{\tau_\ell}(\mathbf{x}) - \left(j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c \Lambda([\tau_{\ell-1}, \tau_\ell]) [\alpha_{\tau_\ell} - \alpha_{\tau_{\ell-1}}] \right)(\mathbf{x}) \\ &\quad + \left(\left\{ [j(\tau_\ell - \tau) - \mathfrak{h}] - j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c [j(\tau_\ell - \tau_{\ell-1}) - \mathfrak{h}] \right\} \right. \\ &\quad \times \Lambda([\tau_{\ell-1}, \tau_\ell]) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \Big) (\mathbf{x}) \\ &\quad + E_c(\tau, \mathbf{x}) \text{ with } |E_c(\tau, \mathbf{x})| \leq 2e^{-mc(\varepsilon_{\tau_\ell})} \end{aligned}$$

(d) when $\ell < p$ and $d(\mathbf{x}, \Lambda_{\tau_\ell}) \leq \frac{1}{2}\mathfrak{c}(\varepsilon_{\tau_\ell})$

$$\begin{aligned} \gamma_\tau(\mathbf{x}) &= \mathfrak{h}\alpha_{\tau_\ell}(\mathbf{x}) + ([j(\tau_\ell - \tau) - \mathfrak{h}] \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_\ell}^c [\alpha_{\tau_\ell} - \alpha_{\tau_{\ell+1}}])(\mathbf{x}) \\ &\quad + \left(\{ [j(\tau_\ell - \tau) - \mathfrak{h}] + j(\tau_\ell - \tau) \Lambda_{\tau_\ell} [j(\tau_{\ell+1} - \tau_\ell) - \mathfrak{h}] \} \Lambda([\tau_\ell, \tau_{\ell+1}]) \right. \\ &\quad \times \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}} \Big) (\mathbf{x}) \\ &\quad + E_d(\tau, \mathbf{x}) \text{ with } |E_d(\tau, \mathbf{x})| \leq 2e^{-mc(\varepsilon_{\tau_\ell})} \end{aligned}$$

For \mathbf{x} running over $\Lambda = \Lambda([0, \delta])$, we also have that

- (e) if $0 < \tau < \frac{\delta}{2}$, then

$$\begin{aligned}\gamma_{*\tau}(\mathbf{x}) &= (j(\tau)\alpha^*)(\mathbf{x}) + E_{*e}(\mathbf{x}) \\ \gamma_\tau(\mathbf{x}) &= \left(j(\delta-\tau)\Lambda\left(\left[\frac{\delta}{2}, \delta\right]\right) \beta - j\left(\frac{\delta}{2}-\tau\right)\Lambda^c[j\left(\frac{\delta}{2}\right)-\mathfrak{h}]\Lambda\left(\left[\frac{\delta}{2}, \delta\right]\right)\beta \right)(\mathbf{x}) \\ &\quad + \left(j\left(\frac{\delta}{2}-\tau\right)\Lambda^c\Lambda\left(\left[\frac{\delta}{2}, \delta\right]\right)[\alpha_{\frac{\delta}{2}}-\beta] \right)(\mathbf{x}) + E_e(\mathbf{x})\end{aligned}$$

with $\sum_{\mathbf{x} \in \Lambda} |E_{*e}(\mathbf{x})| \leq e^{-mc(\delta)}|\Lambda^c|$ and $\sum_{\mathbf{x} \in \Lambda} |E_e(\mathbf{x})| \leq e^{-mc(\delta)}|\Lambda^c|$

- (f) if $\tau = \frac{\delta}{2}$, then

$$\begin{aligned}\gamma_{*\tau}(\mathbf{x}) &= (j(\tau)\alpha^*)(\mathbf{x}) + E_{*f}(\mathbf{x}) \\ \gamma_\tau(\mathbf{x}) &= (j(\delta-\tau)\beta)(\mathbf{x}) + E_f(\mathbf{x})\end{aligned}$$

with $\sum_{\mathbf{x} \in \Lambda} |E_{*f}(\mathbf{x})| \leq e^{-mc(\delta)}|\Lambda^c|$ and $\sum_{\mathbf{x} \in \Lambda} |E_f(\mathbf{x})| \leq e^{-mc(\delta)}|\Lambda^c|$

- (g) if $\frac{\delta}{2} < \tau < \delta$, then

$$\begin{aligned}\gamma_{*\tau}(\mathbf{x}) &= \left(j(\tau)\Lambda\left(\left[0, \frac{\delta}{2}\right]\right)\alpha^* - j\left(\tau-\frac{\delta}{2}\right)\Lambda^c[j\left(\frac{\delta}{2}\right)-\mathfrak{h}]\Lambda\left(\left[0, \frac{\delta}{2}\right]\right)\alpha^* \right)(\mathbf{x}) \\ &\quad + \left(j\left(\tau-\frac{\delta}{2}\right)\Lambda^c\Lambda\left(\left[0, \frac{\delta}{2}\right]\right)[\alpha_{\frac{\delta}{2}}^*-\alpha^*] \right)(\mathbf{x}) + E_{*g}(\mathbf{x}) \\ \gamma_\tau(\mathbf{x}) &= (j(\delta-\tau)\beta)(\mathbf{x}) + E_g(\mathbf{x})\end{aligned}$$

with $\sum_{\mathbf{x} \in \Lambda} |E_{*g}(\mathbf{x})| \leq e^{-mc(\delta)}|\Lambda^c|$ and $\sum_{\mathbf{x} \in \Lambda} |E_g(\mathbf{x})| \leq e^{-mc(\delta)}|\Lambda^c|$

Proof. Recall from Lemma E.4 that

$$\gamma_\tau = \Lambda_\tau^c \alpha_\tau + \sum_{k=1}^p j(\tau_{k-1} - \tau) \Lambda_{\tau_{k-1}} j(\tau_k - \tau_{k-1}) \Lambda_{\tau_k}^c \alpha_{\tau_k} \quad (\text{E.1})$$

For each $1 \leq k \leq p$,

$$\begin{aligned}& |(j(\tau_{k-1} - \tau) \Lambda_{\tau_{k-1}} j(\tau_k - \tau_{k-1}) \Lambda_{\tau_k}^c \alpha_{\tau_k})(\mathbf{x})| \\ & \leq N_0(\chi_{\{\mathbf{x}\}} j(\tau_{k-1} - \tau) \Lambda_{\tau_{k-1}} j(\tau_k - \tau_{k-1}) \Lambda_{\tau_k}^c ; 1, \kappa_{\tau_k}) \\ & \leq 4R(2\varepsilon_{\tau_{k'}}) e^{-\frac{9}{2}m \max\{d(\mathbf{x}, \Lambda_{\tau_{k-1}}), d(\mathbf{x}, \Lambda_{\tau_k}^c)\}} \|j(\tau_{k-1} - \tau)\| \|j(\tau_k - \tau_{k-1})\| \\ & \leq 4e^{K_j} R(\varepsilon_{\tau_{k'}}) e^{-\frac{9}{2}m \max\{d(\mathbf{x}, \Lambda_{\tau_{k-1}}), d(\mathbf{x}, \Lambda_{\tau_k}^c)\}} \quad (\text{E.2})\end{aligned}$$

where $\chi_{\{\mathbf{x}\}}$ is the characteristic function of the set $\{\mathbf{x}\}$ and k' is the maximum of $k-1$ and the largest ℓ' with $\mathbf{x} \in \Lambda_{\tau_{\ell'}}$. If $\mathbf{x} \in \Lambda_\tau^c$, then $k' = k-1$. For the second inequality we used Lemma G.5(ii) with

- o L_1 being the single point set $\{\mathbf{x}\}$, $L_2 = \Lambda_{\tau_{k-1}} = \Lambda([\tau_k - 2\varepsilon_{\tau_{k-1}}, \tau_k])$, $L_3 = \Lambda_{\tau_k}^c$,
- o with d replaced by 0, $\delta_1 = 0$, $\delta_2 = \frac{m}{3}d$, $\delta = \frac{9}{2}md$, $\tilde{d} = 5md$,
- o $O_2 = \Lambda_{\tau_{k'}}$, $\kappa = \kappa_{\tau_k}$ and $R = 4R(2\varepsilon_{\tau_{k'}})$. This choice of R is justified by Lemma B.1.ii.

(a) First consider the case that $\mathbf{x} \in \Lambda_\tau^c$ (which forces $\tau \in \varepsilon\mathbb{Z}$). Then, the $k = 1$ term in (E.1) vanishes so that

$$\begin{aligned}
& |\gamma_\tau(\mathbf{x}) - \alpha_\tau(\mathbf{x})| \\
&= \left| \sum_{k=2}^p (j(\tau_{k-1} - \tau) \Lambda_{\tau_{k-1}} j(\tau_k - \tau_{k-1}) \Lambda_{\tau_k}^c \alpha_{\tau_k})(\mathbf{x}) \right| \\
&\leq \sum_{k=2}^p 4e^{K_j} R(\varepsilon_{\tau_{k-1}}) e^{-\frac{9}{2}md(\mathbf{x}, \Lambda_{\tau_{k-1}})} \\
&\leq \sum_{k=2}^p 4e^{K_j} R(\varepsilon_{\tau_{k-1}}) e^{-\frac{9}{2}mc(2\varepsilon_\tau)} \quad (\text{put } \ell = 1 \text{ in the figure below}) \\
&\leq \sum_{k=2}^p \frac{1}{4} e^{-4mc(2\varepsilon_\tau)} \quad \text{by (F.6b)} \\
&\leq \frac{1}{4} e^{-2mc(2\varepsilon_\tau)} \sum_{k=2}^p e^{-2mc(2\varepsilon_{\tau_{k-1}})} \\
&\leq \frac{1}{2} e^{-mc(\varepsilon_\tau)} \quad \text{by (F.4a,d)}
\end{aligned}$$

(b, c, d) Now we consider the case $\mathbf{x} \in \Lambda_{\tau_{\ell-1}} \cap \Lambda_{\tau_\ell}^c$ with $1 \leq \ell \leq p$. In particular, $\mathbf{x} \in \Lambda_\tau$. Set

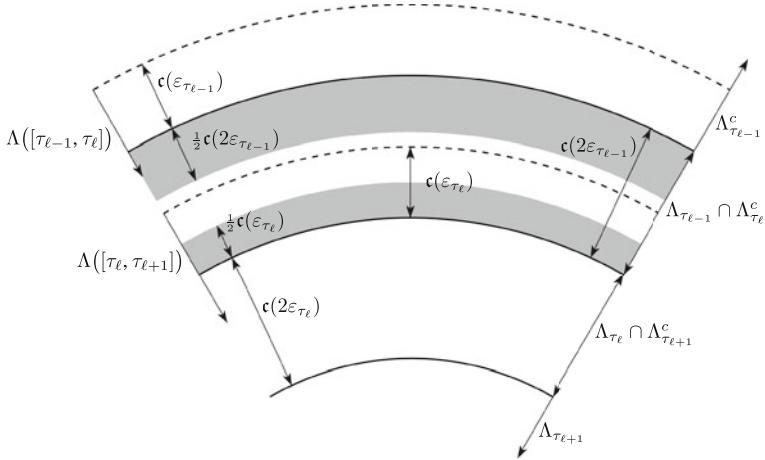

$$K = \begin{cases} \{\ell\} & \text{in case (b)} \\ \{\ell, \ell-1\} & \text{in case (c)} \\ \{\ell, \ell+1\} & \text{in case (d)} \end{cases}$$

As in the last paragraph

$$\left| \gamma_\tau(\mathbf{x}) - \sum_{k \in K} j(\tau_{k-1} - \tau) \Lambda_{\tau_{k-1}} j(\tau_k - \tau_{k-1}) \Lambda_{\tau_k}^c \alpha_{\tau_k} \right| \leq e^{-mc(\varepsilon_{\tau_\ell})}$$

In case (b), when $d(\mathbf{x}, \Lambda_{\tau_{\ell-1}}^c) \geq \frac{1}{2}c(2\varepsilon_{\tau_{\ell-1}})$ and $d(\mathbf{x}, \Lambda_{\tau_\ell}) \geq \frac{1}{2}c(\varepsilon_{\tau_\ell})$, we write the $k = \ell$ term as

$$\begin{aligned}
& j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}} j(\tau_\ell - \tau_{\ell-1}) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \\
&= j(\tau_\ell - \tau) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} - j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c j(\tau_\ell - \tau_{\ell-1}) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \\
&= \Lambda_{\tau_{\ell-1}} \Lambda_{\tau_\ell}^c \mathfrak{h} \alpha_{\tau_\ell} + [j(\tau_\ell - \tau) - \mathfrak{h}] \Lambda_{\tau_{\ell-1}} \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \\
&\quad + j(\tau_\ell - \tau) \Lambda_{\tau_{\ell-1}}^c \alpha_{\tau_\ell} - j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c j(\tau_\ell - \tau_{\ell-1}) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell}
\end{aligned}$$

and bound, as in (E.2),

$$\begin{aligned}
 & \left| \left(j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c j(\tau_\ell - \tau_{\ell-1}) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \right) (\mathbf{x}) \right| \\
 & \leq 4e^{K_j} R(2\varepsilon_{\tau_{\ell-1}}) e^{-\frac{9}{4}m\mathfrak{c}(2\varepsilon_{\tau_{\ell-1}})} \\
 & \leq \frac{1}{4} e^{-m\mathfrak{c}(\varepsilon_{\tau_{\ell-1}})} \\
 & \left| \left(j(\tau_\ell - \tau) \Lambda_{\tau_{\ell-1}}^c \alpha_{\tau_\ell} \right) (\mathbf{x}) \right| \leq \frac{1}{4} e^{-m\mathfrak{c}(\varepsilon_{\tau_{\ell-1}})}
 \end{aligned}$$

For case (c), when $d(\mathbf{x}, \Lambda_{\tau_{\ell-1}}^c) \leq \frac{1}{2}\mathfrak{c}(2\varepsilon_{\tau_{\ell-1}})$ and hence $d(\mathbf{x}, \Lambda_{\tau_\ell}) \geq \frac{1}{2}\mathfrak{c}(2\varepsilon_{\tau_{\ell-1}})$, we first observe that

$$\Lambda_{\tau_\ell} \Subset \Lambda_{\tau_{\ell-1}} = \Lambda([\tau_{\ell-1} - \varepsilon_{\tau_{\ell-1}}, \tau_\ell]) \Subset \Lambda([\tau_{\ell-1}, \tau_\ell])$$

Here the symbol $A \Subset B$ signifies that A is a proper subset of B unless $B = X$. So the $k = \ell$ term is

$$\begin{aligned}
 & j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}} j(\tau_\ell - \tau_{\ell-1}) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \\
 & = j(\tau_\ell - \tau) \Lambda([\tau_{\ell-1}, \tau_\ell]) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \\
 & \quad - j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c j(\tau_\ell - \tau_{\ell-1}) \Lambda([\tau_{\ell-1}, \tau_\ell]) \\
 & \quad \times \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} + j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}} j(\tau_\ell - \tau_{\ell-1}) \Lambda([\tau_{\ell-1}, \tau_\ell])^c \alpha_{\tau_\ell} \\
 & = \Lambda([\tau_{\ell-1}, \tau_\ell]) \Lambda_{\tau_\ell}^c \mathfrak{h} \alpha_{\tau_\ell} - j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c \Lambda([\tau_{\ell-1}, \tau_\ell]) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \\
 & \quad + \left\{ [j(\tau_\ell - \tau) - \mathfrak{h}] - j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c [j(\tau_\ell - \tau_{\ell-1}) - \mathfrak{h}] \right\} \Lambda([\tau_{\ell-1}, \tau_\ell]) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \\
 & \quad + j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}} j(\tau_\ell - \tau_{\ell-1}) \Lambda([\tau_{\ell-1}, \tau_\ell])^c \alpha_{\tau_\ell}
 \end{aligned}$$

and the $k = \ell - 1$ term, which is only present when $\ell \geq 2$, is

$$\begin{aligned}
 & j(\tau_{\ell-2} - \tau) \Lambda_{\tau_{\ell-2}} j(\tau_{\ell-1} - \tau_{\ell-2}) \Lambda_{\tau_{\ell-1}}^c \alpha_{\tau_{\ell-1}} \\
 & = j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c \Lambda([\tau_{\ell-1}, \tau_\ell]) \alpha_{\tau_{\ell-1}} \\
 & \quad - j(\tau_{\ell-2} - \tau) \Lambda_{\tau_{\ell-2}}^c j(\tau_{\ell-1} - \tau_{\ell-2}) \Lambda_{\tau_{\ell-1}}^c \Lambda([\tau_{\ell-1}, \tau_\ell]) \alpha_{\tau_{\ell-1}} \\
 & \quad + j(\tau_{\ell-2} - \tau) \Lambda_{\tau_{\ell-2}} j(\tau_{\ell-1} - \tau_{\ell-2}) \Lambda([\tau_{\ell-1}, \tau_\ell])^c \alpha_{\tau_{\ell-1}}
 \end{aligned}$$

As in (E.2),

$$\begin{aligned} |(j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}} j(\tau_\ell - \tau_{\ell-1}) \Lambda([\tau_{\ell-1}, \tau_\ell])^c \alpha_{\tau_\ell})(\mathbf{x})| &\leq \frac{1}{4} e^{-4mc(\varepsilon_{\tau_{\ell-1}})} \\ |(j(\tau_{\ell-2} - \tau) \Lambda_{\tau_{\ell-2}}^c j(\tau_{\ell-1} - \tau_{\ell-2}) \Lambda_{\tau_{\ell-1}}^c \Lambda([\tau_{\ell-1}, \tau_\ell]) \alpha_{\tau_{\ell-1}})(\mathbf{x})| &\leq \frac{1}{4} e^{-2mc(\varepsilon_{\tau_{\ell-2}})} \\ |(j(\tau_{\ell-2} - \tau) \Lambda_{\tau_{\ell-2}} j(\tau_{\ell-1} - \tau_{\ell-2}) \Lambda([\tau_{\ell-1}, \tau_\ell])^c \alpha_{\tau_{\ell-1}})(\mathbf{x})| &\leq \frac{1}{4} e^{-4mc(\varepsilon_{\tau_{\ell-1}})} \end{aligned}$$

Adding the representations of the $k = \ell$ and $k = \ell - 1$ terms and using the fact that $\Lambda_{\tau_{\ell-1}}^c \Lambda_{\tau_\ell}^c = \Lambda_{\tau_{\ell-1}}^c$, we see that—up to an error of at most $2e^{-mc(\varepsilon_{\tau_\ell})}$

$$\begin{aligned} \gamma_\tau(\mathbf{x}) &= \mathfrak{h} \alpha_{\tau_\ell}(\mathbf{x}) - \left(j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c \Lambda([\tau_{\ell-1}, \tau_\ell]) [\alpha_{\tau_\ell} - \alpha_{\tau_{\ell-1}}] \right) (\mathbf{x}) \\ &\quad + \left(\left\{ [j(\tau_\ell - \tau) - \mathfrak{h}] - j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c [j(\tau_\ell - \tau_{\ell-1}) - \mathfrak{h}] \right\} \right. \\ &\quad \left. \times \Lambda([\tau_{\ell-1}, \tau_\ell]) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \right) (\mathbf{x}) \end{aligned}$$

(When $\ell = 1$, $(j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c \Lambda([\tau_{\ell-1}, \tau_\ell]))(\mathbf{x}) = 0$, since $\mathbf{x} \in \Lambda_{\tau_\ell}$.)

For case (d), when $\ell < p$ and $d(\mathbf{x}, \Lambda_{\tau_\ell}) \leq \frac{1}{2}\mathfrak{c}(\varepsilon_{\tau_\ell})$ so that $d(\mathbf{x}, \Lambda_{\tau_{\ell-1}}^c) \geq \frac{1}{2}\mathfrak{c}(2\varepsilon_{\tau_{\ell-1}})$, we first observe that $\mathbf{x} \in \Lambda([\tau_\ell, \tau_{\ell+1}])$ and that

$$\Lambda_{\tau_{\ell+1}} \Subset \Lambda_{\tau_\ell} = \Lambda([\tau_\ell - \varepsilon_{\tau_\ell}, \tau_{\ell+1}]) \Subset \Lambda([\tau_\ell, \tau_{\ell+1}])$$

So the $k = \ell$ term is

$$\begin{aligned} &j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}} j(\tau_\ell - \tau_{\ell-1}) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \\ &= j(\tau_\ell - \tau) \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} + j(\tau_\ell - \tau) \Lambda([\tau_\ell, \tau_{\ell+1}])^c \alpha_{\tau_\ell} \\ &\quad - j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c j(\tau_\ell - \tau_{\ell-1}) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} \end{aligned}$$

and the $k = \ell + 1$ term is

$$\begin{aligned} &j(\tau_\ell - \tau) \Lambda_{\tau_\ell} j(\tau_{\ell+1} - \tau_\ell) \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}} \\ &= j(\tau_\ell - \tau) \Lambda_{\tau_\ell} \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}} \\ &\quad + j(\tau_\ell - \tau) \Lambda_{\tau_\ell} (j(\tau_{\ell+1} - \tau_\ell) - \mathfrak{h}) \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}} \\ &\quad + j(\tau_\ell - \tau) \Lambda_{\tau_\ell} j(\tau_{\ell+1} - \tau_\ell) \Lambda([\tau_\ell, \tau_{\ell+1}])^c \alpha_{\tau_{\ell+1}} \end{aligned}$$

As in (E.2)

$$\begin{aligned} |(j(\tau_\ell - \tau) \Lambda([\tau_\ell, \tau_{\ell+1}])^c \alpha_{\tau_\ell})(\mathbf{x})| &\leq \frac{1}{4} e^{-2mc(\varepsilon_{\tau_\ell})} \\ |(j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c j(\tau_\ell - \tau_{\ell-1}) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell})(\mathbf{x})| &\leq \frac{1}{4} e^{-mc(\varepsilon_{\tau_{\ell-1}})} \\ |(j(\tau_\ell - \tau) \Lambda_{\tau_\ell} j(\tau_{\ell+1} - \tau_\ell) \Lambda([\tau_\ell, \tau_{\ell+1}])^c \alpha_{\tau_{\ell+1}})(\mathbf{x})| &\leq \frac{1}{4} e^{-2mc(\varepsilon_{\tau_\ell})} \end{aligned}$$

Adding the representations of the $k = \ell$ and $k = \ell + 1$ terms and using the fact that $\Lambda_{\tau_\ell}^c \Lambda_{\tau_{\ell+1}}^c = \Lambda_{\tau_\ell}^c$, we see that—up to an error at \mathbf{x} of at most $2e^{-mc(\varepsilon_{\tau_\ell})}$

$$\begin{aligned} \gamma_\tau &= j(\tau_\ell - \tau) \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell} + j(\tau_\ell - \tau) \Lambda_{\tau_\ell} \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}} \\ &\quad + j(\tau_\ell - \tau) \Lambda_{\tau_\ell} (j(\tau_{\ell+1} - \tau_\ell) - \mathfrak{h}) \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}} \end{aligned}$$

$$= j(\tau_\ell - \tau) \left[\Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}} + \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_\ell}^c [\alpha_{\tau_\ell} - \alpha_{\tau_{\ell+1}}] \right] \\ + j(\tau_\ell - \tau) \Lambda_{\tau_\ell} (j(\tau_{\ell+1} - \tau_\ell) - \mathfrak{h}) \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}}$$

Writing, in the first term, $j(\tau_\ell - \tau) = \mathfrak{h} + [j(\tau_\ell - \tau) - \mathfrak{h}]$ and evaluating at \mathbf{x} , we have

$$\gamma_\tau(\mathbf{x}) = \mathfrak{h} \alpha_{\tau_\ell}(\mathbf{x}) + \left([j(\tau_\ell - \tau) - \mathfrak{h}] \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}} \right) (\mathbf{x}) \\ + \left([j(\tau_\ell - \tau) - \mathfrak{h}] \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_\ell}^c [\alpha_{\tau_\ell} - \alpha_{\tau_{\ell+1}}] \right) (\mathbf{x}) \\ + \left(j(\tau_\ell - \tau) \Lambda_{\tau_\ell} [j(\tau_{\ell+1} - \tau_\ell) - \mathfrak{h}] \Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}} \right) (\mathbf{x})$$

up to an error of at most $2e^{-mc(\varepsilon_{\tau_\ell})}$. (e, f, g) We give the proof for $\gamma_{*\tau}$. Recall from Lemma E.4(i), that, on Λ ,

$$\gamma_{*\tau}^* = \sum_{\tau' \in \mathcal{T}_l(\tau, \delta)} j(\tau - \sigma(\tau')) \Lambda_{\sigma(\tau')} j(\sigma(\tau') - \tau') \Lambda_{\tau'}^c \alpha_{\tau'}$$

As in (E.2), if $0 < \tau < \delta$ (otherwise $\mathcal{T}_l(\tau, \delta)$ is empty),

$$\sum_{\substack{\mathbf{x} \in \Lambda \\ \tau' \in \mathcal{T}_l(\tau, \delta) \setminus \{0, \frac{\delta}{2}\}}} \left| (j(\tau - \sigma(\tau')) \Lambda_{\sigma(\tau')} j(\sigma(\tau') - \tau') \Lambda_{\tau'}^c \alpha_{\tau'}) (\mathbf{x}) \right| \\ \leq \sum_{\substack{\tau' \in \mathcal{T}_l(\tau, \delta) \\ \tau' \neq 0, \frac{\delta}{2}}} N_0 (\Lambda j(\tau - \sigma(\tau')) \Lambda_{\sigma(\tau')} j(\sigma(\tau') - \tau') \Lambda_{\tau'}^c ; 1, \kappa_{*\tau'}) |\Lambda_{\tau'}^c| \\ \leq \sum_{\substack{\tau' \in \mathcal{T}_l(\tau, \delta) \\ \tau' \neq 0, \frac{\delta}{2}}} 4e^{K_j} R(\delta) e^{-\frac{9}{2}md(\Lambda, \Lambda_{\tau'}^c)} |\Lambda^c| \\ \leq \sum_{\tau' \in \mathcal{T}_l(\tau, \delta) \setminus \{0\}} 4e^{K_j} R(\delta) e^{-\frac{9}{2}mc(2\varepsilon_{\tau'})} |\Lambda^c| \\ \leq \sum_{\tau' \in \mathcal{T}_l(\tau, \delta) \setminus \{0\}} \frac{1}{4} e^{-4mc(2\varepsilon_{\tau'})} |\Lambda^c| \quad \text{by (F.6b)} \\ \leq \frac{1}{4} e^{-mc(\delta)} |\Lambda^c| \quad \text{by (F.4d)}$$

Case $0 < \tau \leq \frac{\delta}{2}$: In this case $\tau' = \frac{\delta}{2} \notin \mathcal{T}_l(\tau, \delta)$ and the $\tau' = 0 \in \mathcal{T}_l(\tau, \delta)$ contribution to $\gamma_{*\tau}^*$ is

$$j(\tau - \sigma(0)) \Lambda_{\sigma(0)} j(\sigma(0)) \alpha = j(\tau) \alpha - j(\tau - \sigma(0)) \Lambda_{\sigma(0)}^c j(\sigma(0)) \alpha$$

For $\tau = \frac{\delta}{2}$, $\sigma(0) = \tau$ and the second term vanishes on Λ . For $0 < \tau < \frac{\delta}{2}$, by Lemma B.1(i),

$$\sum_{\mathbf{x} \in \Lambda} \left| (j(\tau - \sigma(0)) \Lambda_{\sigma(0)}^c j(\sigma(0)) \alpha) (\mathbf{x}) \right| \\ \leq \sum_{\substack{\mathbf{x} \in \Lambda, \mathbf{z} \in X \\ \mathbf{y} \in \Lambda_{\sigma(0)}^c}} |j(\tau - \sigma(0))(\mathbf{x}, \mathbf{y})| |j(\sigma(0))(\mathbf{y}, \mathbf{z})| \kappa_{*0}(\mathbf{z})$$

$$\begin{aligned}
&\leq 4R(\delta) e^{-\frac{9}{2}md(\Lambda, \Lambda_{\sigma(0)}^c)} \\
&\quad \times \sum_{\substack{\mathbf{x} \in \Lambda, \mathbf{z} \in X \\ \mathbf{y} \in \Lambda_{\sigma(0)}^c}} |j(\tau - \sigma(0))(\mathbf{x}, \mathbf{y})| e^{\frac{9}{2}md(\mathbf{x}, \mathbf{y})} |j(\sigma(0))(\mathbf{y}, \mathbf{z})| e^{\frac{1}{3}md(\mathbf{x}, \mathbf{z})} \\
&\leq 4R(\delta) e^{-\frac{9}{2}md(\Lambda, \Lambda_{\sigma(0)}^c)} \left| \Lambda_{\sigma(0)}^c \right| \ ||| j(\tau - \sigma(0)) ||| \ ||| j(\sigma(0)) ||| \\
&\leq 4e^{K_j} R(\delta) e^{-\frac{9}{2}mc(\delta/2)} \left| \Lambda_{\sigma(0)}^c \right| \text{ since } \tau < \frac{\delta}{2}, \text{ so that } \sigma(0) < \frac{\delta}{2} \text{ and } \varepsilon_{\sigma(0)} \leq \frac{\delta}{4} \\
&\leq \frac{1}{4} e^{-4mc(\delta)} |\Lambda^c| \text{ by (F.6b)} \tag{E.3}
\end{aligned}$$

Case $\frac{\delta}{2} < \tau < \delta$: In this case $\tau' = \frac{\delta}{2} \in \mathcal{I}_l(\tau, \delta)$. The $\tau' = 0$ term is

$$\begin{aligned}
&j(\tau - \sigma(0)) \Lambda_{\sigma(0)} j(\sigma(0)) \alpha = j\left(\tau - \frac{\delta}{2}\right) \Lambda j\left(\frac{\delta}{2}\right) \alpha \\
&= j(\tau) \Lambda\left(\left[0, \frac{\delta}{2}\right]\right) \alpha - j\left(\tau - \frac{\delta}{2}\right) \Lambda^c j\left(\frac{\delta}{2}\right) \Lambda\left(\left[0, \frac{\delta}{2}\right]\right) \alpha \\
&\quad + j\left(\tau - \frac{\delta}{2}\right) \Lambda j\left(\frac{\delta}{2}\right) \Lambda\left(\left[0, \frac{\delta}{2}\right]\right)^c \alpha \\
&= j(\tau) \Lambda\left(\left[0, \frac{\delta}{2}\right]\right) \alpha - j\left(\tau - \frac{\delta}{2}\right) \Lambda^c [j\left(\frac{\delta}{2}\right) - \mathfrak{h}] \Lambda\left(\left[0, \frac{\delta}{2}\right]\right) \alpha \\
&\quad - j\left(\tau - \frac{\delta}{2}\right) \Lambda^c \Lambda\left(\left[0, \frac{\delta}{2}\right]\right) \alpha \\
&\quad + j\left(\tau - \frac{\delta}{2}\right) \Lambda j\left(\frac{\delta}{2}\right) \Lambda\left(\left[0, \frac{\delta}{2}\right]\right)^c \alpha
\end{aligned}$$

and the $\tau' = \frac{\delta}{2}$ term is

$$\begin{aligned}
&j\left(\tau - \sigma\left(\frac{\delta}{2}\right)\right) \Lambda_{\sigma(\frac{\delta}{2})} j\left(\sigma\left(\frac{\delta}{2}\right) - \frac{\delta}{2}\right) \Lambda_{\frac{\delta}{2}}^c \alpha_{\frac{\delta}{2}} \\
&= j\left(\tau - \frac{\delta}{2}\right) \Lambda^c \Lambda\left(\left[0, \frac{\delta}{2}\right]\right) \alpha_{\frac{\delta}{2}} \\
&\quad - j\left(\tau - \sigma\left(\frac{\delta}{2}\right)\right) \Lambda_{\sigma(\frac{\delta}{2})}^c j\left(\sigma\left(\frac{\delta}{2}\right) - \frac{\delta}{2}\right) \Lambda^c \Lambda\left(\left[0, \frac{\delta}{2}\right]\right) \alpha_{\frac{\delta}{2}} \\
&\quad + j\left(\tau - \sigma\left(\frac{\delta}{2}\right)\right) \Lambda_{\sigma(\frac{\delta}{2})} j\left(\sigma\left(\frac{\delta}{2}\right) - \frac{\delta}{2}\right) \Lambda\left(\left[0, \frac{\delta}{2}\right]\right)^c \alpha_{\frac{\delta}{2}}
\end{aligned}$$

As in (E.3),

$$\begin{aligned}
&\sum_{\mathbf{x} \in \Lambda} \left| \left(j\left(\tau - \frac{\delta}{2}\right) \Lambda j\left(\frac{\delta}{2}\right) \Lambda\left(\left[0, \frac{\delta}{2}\right]\right)^c \alpha \right) (\mathbf{x}) \right| \leq \frac{1}{4} e^{-4mc(\delta/2)} |\Lambda^c| \\
&\sum_{\mathbf{x} \in \Lambda} \left| \left(j\left(\tau - \sigma\left(\frac{\delta}{2}\right)\right) \Lambda_{\sigma(\frac{\delta}{2})}^c j\left(\sigma\left(\frac{\delta}{2}\right) - \frac{\delta}{2}\right) \Lambda^c \Lambda\left(\left[0, \frac{\delta}{2}\right]\right) \alpha_{\frac{\delta}{2}} \right) (\mathbf{x}) \right| \\
&\leq \frac{1}{8} e^{-4mc(\delta/2)} |\Lambda^c|
\end{aligned}$$

$$\begin{aligned} & \sum_{\mathbf{x} \in \Lambda} \left| \left(j \left(\tau - \sigma \left(\frac{\delta}{2} \right) \right) \Lambda_{\sigma(\frac{\delta}{2})} j \left(\sigma \left(\frac{\delta}{2} \right) - \frac{\delta}{2} \right) \Lambda \left(\left[0, \frac{\delta}{2} \right] \right)^c \alpha_{\frac{\delta}{2}} \right) (\mathbf{x}) \right| \\ & \leq \frac{1}{8} e^{-4mc(\delta/2)} |\Lambda^c| \end{aligned}$$

□

Proof of Proposition E.7. For $\mathbf{x} \in \Lambda_\tau^c$, $\hat{\gamma}_\tau(\mathbf{x}) = \alpha_\tau(\mathbf{x})$ and $\hat{\gamma}_{*\tau} = \alpha_\tau(\mathbf{x})^*$ and the desired bound follows immediately from Lemma E.8 and its analog for $\gamma_{*\tau}$. For the rest of the proof we restrict to $\mathbf{x} \in \Lambda_\tau$.

We prove the bound on $|\gamma_\tau(\mathbf{x}) - \hat{\gamma}_\tau(\mathbf{x})|$. The bound on $|\gamma_{*\tau}(\mathbf{x}) - \hat{\gamma}_{*\tau}(\mathbf{x})|$ is proven similarly. Write $\mathcal{T}_r = \{\tau_1 < \tau_2 < \dots < \tau_p = \delta\}$ and fix any $1 \leq \ell \leq p$, any decimation interval \mathcal{J} containing τ and any $\mathbf{x} \in \Lambda_{\tau_{\ell-1}} \cap \Lambda_{\tau_\ell}^c \cap \Lambda(\mathcal{J})$. Note that $\Lambda_{\tau_\ell}^c \cap \Lambda(\mathcal{J})$ is empty unless $|\mathcal{J}| \leq \varepsilon_{\tau_\ell}$ and that $2e^{-mc(\varepsilon_{\tau_\ell})} \leq \frac{1}{8} \leq \frac{1}{8}r(|\mathcal{J}|)$ by (F.4c).

For case (b) of Lemma E.8, it suffices to bound

$$\begin{aligned} & |([j(\tau_\ell - \tau) - 1] \Lambda_{\tau_{\ell-1}} \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell})(\mathbf{x})| \\ & \leq (\tau_\ell - \tau) K'_j e^{K'_j} \left([|\mu| + e^{-5md(\mathbf{x}, \Lambda_{\tau_{\ell-1}}^c \cup \Lambda_{\tau_\ell})}] \max_{\mathbf{y} \in \Lambda_{\tau_{\ell-1}}} |\alpha_{\tau_\ell}(\mathbf{y})| + \max_{b \in \Lambda_{\tau_{\ell-1}}^*} |\nabla \alpha_{\tau_\ell}(b)| \right) \\ & \leq 2\varepsilon_{\tau_{\ell-1}} K'_j e^{K'_j} \left([|\mu| + e^{-\frac{5}{2}mc(\varepsilon_{\tau_\ell})}] R(2\varepsilon_{\tau_{\ell-1}}) + R'(2\varepsilon_{\tau_{\ell-1}}) \right) \\ & \leq \varepsilon_{\tau_\ell} K'_j e^{K'_j} ([|\mu| + e^{-mc}] R(\varepsilon_{\tau_\ell}) + R'(\varepsilon_{\tau_\ell})) \quad \text{by (F.3a,e), (F.4a)} \\ & \leq \frac{1}{32} r(\varepsilon_{\tau_\ell}) \leq \frac{1}{32} r(|\mathcal{J}|) \quad \text{by (F.6c), (F.3b)} \end{aligned}$$

In the first inequality, we used Lemma D.1. In the second inequality we used that both τ and τ_ℓ are in $[\tau_{\ell-1} - \varepsilon_{\tau_{\ell-1}}, \tau_{\ell-1} + \varepsilon_{\tau_{\ell-1}}]$ to bound $\tau_\ell - \tau$ by $2\varepsilon_{\tau_{\ell-1}}$. In the third inequality we repeatedly used $tR^{(\ell)}(t) \leq 2tR^{(\ell)}(2t)$, which gives $tR^{(\ell)}(t) \leq (2^\ell t) R^{(\ell)}(2^\ell t)$ for all $\ell \in \mathbb{N}$.

For case (c), we use the bounds

$$\begin{aligned} & |([j(\tau_\ell - \tau) - 1] \Lambda([\tau_{\ell-1}, \tau_\ell]) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell})(\mathbf{x})| \leq \frac{1}{16} r(|\mathcal{J}|) \\ & |([j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c [j(\tau_\ell - \tau_{\ell-1}) - 1] \Lambda([\tau_{\ell-1}, \tau_\ell]) \Lambda_{\tau_\ell}^c \alpha_{\tau_\ell})(\mathbf{x})| \leq \frac{1}{32} r(|\mathcal{J}|) \end{aligned}$$

which are proven as above, together with

$$\begin{aligned} & |([j(\tau_{\ell-1} - \tau) \Lambda_{\tau_{\ell-1}}^c \Lambda([\tau_{\ell-1}, \tau_\ell]) [\alpha_{\tau_\ell} - \alpha_{\tau_{\ell-1}}])(\mathbf{x})| \\ & \leq e^{-md(\Lambda(\mathcal{J}), \Lambda_{\tau_{\ell-1}}^c)} \|j(\tau_{\ell-1} - \tau)\| \sup_{\mathbf{y} \in \Lambda_{\tau_{\ell-1}}^c \cap \Lambda([\tau_{\ell-1}, \tau_\ell])} |\alpha_{\tau_\ell}(\mathbf{y}) - \alpha_{\tau_{\ell-1}}(\mathbf{y})| \\ & \leq e^{-md(\Lambda(\mathcal{J}), \Lambda_{\tau_{\ell-1}}^c)} e^{K_j} r(\varepsilon_{\tau_{\ell-1}}) \\ & \leq e^{K_j} \begin{cases} r(\varepsilon_{\tau_{\ell-1}}) \leq 2r(|\mathcal{J}|) & \text{if } |\mathcal{J}| \leq 2\varepsilon_{\tau_{\ell-1}} \\ e^{-mc(2\varepsilon_{\tau_{\ell-1}})} r(\varepsilon_{\tau_{\ell-1}}) \leq 2\varepsilon_{\tau_{\ell-1}} \mathfrak{r}(\varepsilon_{\tau_{\ell-1}}) \leq 1 \leq r(|\mathcal{J}|) & \text{if } |\mathcal{J}| > 2\varepsilon_{\tau_{\ell-1}} \end{cases} \end{aligned}$$

by (F.3b), (F.4c) and (F.6a). For case (d) of Lemma E.8, it suffices to bound

$$\begin{aligned} & \left| ([j(\tau_\ell - \tau) - 1]\Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_\ell}^c [\alpha_{\tau_\ell} - \alpha_{\tau_{\ell+1}}])(\mathbf{x}) \right| \leq e^{K_j} r(\varepsilon_{\tau_\ell}) \\ & \left| \left([j(\tau_\ell - \tau) - 1]\Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}} \right)(\mathbf{x}) \right| \leq \frac{1}{32} r(\varepsilon_{\tau_\ell}) \\ & \left| \left(j(\tau_\ell - \tau) \Lambda_{\tau_\ell} [j(\tau_{\ell+1} - \tau_\ell) - 1]\Lambda([\tau_\ell, \tau_{\ell+1}]) \Lambda_{\tau_{\ell+1}}^c \alpha_{\tau_{\ell+1}} \right)(\mathbf{x}) \right| \leq \frac{1}{32} r(\varepsilon_{\tau_\ell}) \end{aligned}$$

since, as we have observed, $|\mathcal{J}| \leq \varepsilon_{\tau_\ell}$. These bounds are proven as above. \square

Corollary E.9. Assume that $\mathfrak{h} \equiv 1$.

(a) Let $0 < \tau < \delta$. If $\mathbf{x} \in \Lambda_\tau^c$, then

$$|\gamma_{*\tau}(\mathbf{x}) - \gamma_\tau(\mathbf{x})^*| \leq e^{-mc(\varepsilon_\tau)}$$

Let \mathcal{J} be a decimation interval of that contains τ . If $\mathbf{x} \in \Lambda(\mathcal{J})$, then

$$|\gamma_{*\tau}(\mathbf{x}) - \gamma_\tau(\mathbf{x})^*| \leq (4e^{K_j} + 3) r(|\mathcal{J}|)$$

(b) Let $0 < \tau < \delta$. If $\tau \in 2\varepsilon\mathbb{Z}$ and $\mathbf{x} \in \Lambda(\mathcal{J})$, then

$$\begin{aligned} |\gamma_{*\tau}(\mathbf{x}) - \gamma_{\tau \pm \varepsilon}(\mathbf{x})^*| &\leq (4e^{K_j} + 3) r(|\mathcal{J}|) \\ |\gamma_\tau(\mathbf{x}) - \gamma_{*\tau \pm \varepsilon}(\mathbf{x})^*| &\leq (4e^{K_j} + 3) r(|\mathcal{J}|) \end{aligned}$$

If $\tau \pm \varepsilon \in \{0, \delta\}$ and $\mathbf{x} \in \Lambda(\mathcal{J})$, then

$$\begin{aligned} |\gamma_{*\tau}(\mathbf{x}) - \gamma_{\tau \pm \varepsilon}(\mathbf{x})^*| &\leq 2(e^{K_j} + 1) r(|\mathcal{J}|) \\ |\gamma_\tau(\mathbf{x}) - \gamma_{*\tau \pm \varepsilon}(\mathbf{x})^*| &\leq 2(e^{K_j} + 1) r(|\mathcal{J}|) \end{aligned}$$

(c) Let $0 \leq \tau < \delta$ and set

$$\tilde{\gamma}_{\tau, \varepsilon} = \begin{cases} j(\tau)\alpha - j(\delta - \tau - \varepsilon)\Lambda([\frac{\delta}{2}, \delta])\beta & \text{if } 0 \leq \tau < \frac{\delta}{2} - \varepsilon \\ j(\tau)\alpha - j(\delta - \tau - \varepsilon)\beta & \text{if } \tau = \frac{\delta}{2} - \varepsilon, \frac{\delta}{2} \\ j(\tau)\Lambda([0, \frac{\delta}{2}])\alpha - j(\delta - \tau - \varepsilon)\beta & \text{if } \frac{\delta}{2} < \tau < \delta \end{cases}$$

and

$$\tilde{\tilde{\gamma}}_{\tau, \varepsilon} = j(\tau)\tilde{\Omega}\alpha - j(\delta - \tau - \varepsilon)\tilde{\Omega}\beta$$

where $\tilde{\Omega}$ the set of all point in X that are within a distance $\mathfrak{c}(\delta)$ of $\Omega([0, \delta])$. Then

$$\sum_{\mathbf{x} \in \Lambda} |\gamma_{*\tau}(\mathbf{x})^* - \gamma_{\tau+\varepsilon}(\mathbf{x}) - \tilde{\gamma}_{\tau, \varepsilon}(\mathbf{x})| \leq 3e^{K_j} r(\delta) |\Lambda^c|$$

and

$$\sum_{\mathbf{x} \in \Lambda} e^{-4md(\mathbf{x}, \Omega)} |\tilde{\gamma}_{\tau, \varepsilon}(\mathbf{x}) - \tilde{\tilde{\gamma}}_{\tau, \varepsilon}(\mathbf{x})| \leq \frac{1}{8} e^{-3mc(\delta)} |\tilde{\Omega}^c|$$

Proof. (a) The result for $\mathbf{x} \in \Lambda_\tau^c$ follows immediately from Proposition E.7, so we restrict to $\mathbf{x} \in \Lambda_\tau$ for the rest of the proof.

To prove the bound on $|\gamma_{*\tau}(\mathbf{x}) - \gamma_\tau(\mathbf{x})^*|$ it suffices to prove that $|\hat{\gamma}_{*\tau}(\mathbf{x}) - \hat{\gamma}_\tau(\mathbf{x})^*| \leq r(|\mathcal{J}|)$, which we now proceed to do. By Definition E.6 and Lemma E.4.ii, for $\mathbf{x} \in \Lambda(\mathcal{J}) \subset \Lambda_\tau$,

$$\hat{\gamma}_{*\tau}(\mathbf{x}) - \hat{\gamma}_\tau(\mathbf{x})^* = \sum_{\substack{\tau_r \in \mathcal{T}_r(\tau, \delta) \\ \tau_l \in \mathcal{T}_l(\tau, \delta)}} \Lambda_{\pi(\tau_r)}(\mathbf{x}) \Lambda_{\tau_r}^c(\mathbf{x}) \Lambda_{\sigma(\tau_l)}(\mathbf{x}) \Lambda_{\tau_l}^c(\mathbf{x}) [\alpha_{\tau_l}(\mathbf{x})^* - \alpha_{\tau_r}(\mathbf{x})^*]$$

and furthermore, since $\bigcup_{\substack{\tau_r \in \mathcal{T}_r \\ \tau_l \in \mathcal{T}_l}} \Lambda_{\pi(\tau_r)} \cap \Lambda_{\tau_r}^c \cap \Lambda_{\sigma(\tau_l)} \cap \Lambda_{\tau_l}^c$ is a partition of Λ_τ into disjoint subsets, at most one term in this sum is nonzero and it is

$$\Lambda([\tau_l, \tau_r])(\mathbf{x}) \Lambda_{\tau_l}^c(\mathbf{x}) \Lambda_{\tau_r}^c(\mathbf{x}) [\alpha_{\tau_l}(\mathbf{x})^* - \alpha_{\tau_r}(\mathbf{x})^*]$$

This term is bounded by $r(\tau_r - \tau_l)$. If $|\mathcal{J}| > \tau_r - \tau_l$, then at least one of τ_l, τ_r must be in the interior of \mathcal{J} . If, for example, τ_l is in the interior of \mathcal{J} , then $[\tau_l - \varepsilon_{\tau_l}, \tau_l + \varepsilon_{\tau_l}] \subset \mathcal{J}$ so that $\Lambda(\mathcal{J}) \subset \Lambda_{\tau_l}$ and our one potentially nonzero term is in fact zero for all $\mathbf{x} \in \Lambda(\mathcal{J})$. Hence the one possibly nonzero term is bounded by $r(|\mathcal{J}|)$.

(b) To prove the bound on $|\gamma_{*\tau}(\mathbf{x}) - \gamma_{\tau \pm \varepsilon}(\mathbf{x})^*|$ in the case that $\tau \in 2\varepsilon\mathbb{Z}$, we prove that $|\hat{\gamma}_{*\tau}(\mathbf{x}) - \hat{\gamma}_{\tau \pm \varepsilon}(\mathbf{x})^*| \leq r(|\mathcal{J}|)$. Again, by Definition E.6 and Lemma E.4(ii), for $\mathbf{x} \in \Lambda(\mathcal{J}) \subset \Lambda_\tau \subset \Lambda_{\tau \pm \varepsilon}$,

$$\begin{aligned} \hat{\gamma}_{*\tau}(\mathbf{x}) - \hat{\gamma}_{\tau \pm \varepsilon}(\mathbf{x})^* &= \sum_{\substack{\tau_r \in \mathcal{T}_r(\tau \pm \varepsilon, \delta) \\ \tau_l \in \mathcal{T}_l(\tau, \delta)}} \Lambda_{\pi(\tau_r)}(\mathbf{x}) \Lambda_{\tau_r}^c(\mathbf{x}) \Lambda_{\sigma(\tau_l)}(\mathbf{x}) \Lambda_{\tau_l}^c(\mathbf{x}) [\alpha_{\tau_l}(\mathbf{x})^* - \alpha_{\tau_r}(\mathbf{x})^*] \end{aligned}$$

- o If $\tau_r \in \mathcal{T}_r(\tau \pm \varepsilon, \delta)$ happens to have $\varepsilon_{\tau_r} < \varepsilon_\tau$, then, Λ_{τ_r} has τ as an end point and is properly contained in $[\tau - \varepsilon_\tau, \tau + \varepsilon_\tau]$. Hence $\Lambda_\tau \subset \Lambda_{\tau_r}$ and $\Lambda_{\tau_r}^c \Lambda_{\sigma(\tau_l)} = 0$ for all $\tau_l \in \mathcal{T}_l(\tau, \delta)$.
- o No $\tau_r \in \mathcal{T}_r(\tau + \varepsilon, \delta)$ can have $\varepsilon_{\tau_r} = \varepsilon_\tau$, because the first element of $\varepsilon_{\tau_r}\mathbb{Z} = \varepsilon_\tau\mathbb{Z}$ above $\tau + \varepsilon$ is $\tau + \varepsilon_\tau$, which does not satisfy $\varepsilon_{\tau+\varepsilon_\tau} = \varepsilon_\tau$.
- o If $\tau_r \in \mathcal{T}_r(\tau - \varepsilon, \delta)$ happens to have $\varepsilon_{\tau_r} = \varepsilon_\tau$, then $\tau_r = \tau$ and $\Lambda_{\tau_r}^c \Lambda_{\sigma(\tau_l)} = \Lambda_\tau^c \Lambda_{\sigma(\tau_l)} = 0$ for all $\tau_l \in \mathcal{T}_l(\tau, \delta)$.
- o If $\tau_r \in \mathcal{T}_r(\tau \pm \varepsilon, \delta)$ happens to have $\varepsilon_{\tau_r} > \varepsilon_\tau$, then, because $\tau \pm \varepsilon$ is a nearest neighbour of τ and is in $\varepsilon\mathbb{Z} \setminus 2\varepsilon\mathbb{Z}$, it is necessary that $\tau_r > \tau$ and indeed τ_r is the smallest element of $\varepsilon_{\tau_r}\mathbb{Z}$ above τ too so that $\tau_r \in \mathcal{T}_r(\tau, \delta)$ too. Conversely, every $\tau_r \in \mathcal{T}_r(\tau, \delta)$ is also in $\mathcal{T}_r(\tau \pm \varepsilon, \delta)$. Denote by $\pi'(\tau_r)$ and $\pi(\tau_r)$ the predecessor elements of τ_r in $\mathcal{T}_r(\tau \pm \varepsilon, \delta)$ and $\mathcal{T}_r(\tau, \delta)$ respectively. If $\varepsilon_{\pi'(\tau_r)} \geq \varepsilon_{\pi(\tau_r)}$, then $\pi'(\tau_r) = \pi(\tau_r)$. If $\varepsilon_{\pi'(\tau_r)} < \varepsilon_{\pi(\tau_r)}$, then $\pi(\tau_r) = \tau$ and $\Lambda_{\pi'(\tau_r)}(\mathbf{x}) = \Lambda_{\pi(\tau_r)}(\mathbf{x}) = 1$.

Hence, once again,

$$\begin{aligned} \hat{\gamma}_{*\tau}(\mathbf{x}) - \hat{\gamma}_{\tau \pm \varepsilon}(\mathbf{x})^* &= \sum_{\substack{\tau_r \in \mathcal{T}_r(\tau, \delta) \\ \tau_l \in \mathcal{T}_l(\tau, \delta)}} \Lambda_{\pi(\tau_r)}(\mathbf{x}) \Lambda_{\tau_r}^c(\mathbf{x}) \Lambda_{\sigma(\tau_l)}(\mathbf{x}) \Lambda_{\tau_l}^c(\mathbf{x}) [\alpha_{\tau_l}(\mathbf{x})^* - \alpha_{\tau_r}(\mathbf{x})^*] \\ &= \hat{\gamma}_{*\tau}(\mathbf{x}) - \hat{\gamma}_\tau(\mathbf{x})^* \end{aligned}$$

and the desired result follows from $|\hat{\gamma}_{*\tau}(\mathbf{x}) - \hat{\gamma}_\tau(\mathbf{x})^*| \leq r(|\mathcal{J}|)$.

Finally, we prove the bound on $|\gamma_{*\tau}(\mathbf{x}) - \gamma_{\tau \pm \varepsilon}(\mathbf{x})^*|$ in the case that $\tau \pm \varepsilon \in \{0, \delta\}$. In this case, either $\tau = \varepsilon$ so that $\gamma_{\tau \pm \varepsilon}(\mathbf{x})^* = \alpha_0(\mathbf{x})^* \equiv \alpha(\mathbf{x})^*$ or $\tau = \delta - \varepsilon$ so that $\gamma_{\tau \pm \varepsilon}(\mathbf{x})^* = \alpha_\delta(\mathbf{x})^* \equiv \beta(\mathbf{x})^*$. We prove that $|\hat{\gamma}_{*\tau}(\mathbf{x}) - \alpha_{\tau \pm \varepsilon}(\mathbf{x})^*| \leq r(|\mathcal{J}|)$. Again, by Definition E.6 and Lemma E.4(ii), for $\mathbf{x} \in \Lambda(\mathcal{J}) \subset \Lambda_\tau$,

$$\hat{\gamma}_{*\tau}(\mathbf{x}) - \hat{\gamma}_{\tau \pm \varepsilon}(\mathbf{x})^* = \sum_{\tau_l \in \mathcal{T}_l(\tau, \delta)} \Lambda_{\sigma(\tau_l)}(\mathbf{x}) \Lambda_{\tau_l}^c(\mathbf{x}) [\alpha_{\tau_l}(\mathbf{x})^* - \alpha_{\tau \pm \varepsilon}(\mathbf{x})^*]$$

In the case that $\tau = \varepsilon$, $\mathcal{T}_l(\tau, \delta)$ contains exactly one element, namely $\tau_l = 0 = \tau \pm \varepsilon$, and the right hand side is exactly zero. In the case that $\tau = \delta - \varepsilon$, $\mathcal{T}_l(\tau, \delta) = \{\delta - 2^j \varepsilon \mid 1 \leq j \leq n\}$ so that

$$\begin{aligned} \hat{\gamma}_{*\tau}(\mathbf{x}) - \hat{\gamma}_{\tau \pm \varepsilon}(\mathbf{x})^* &= \sum_{j=1}^n \Lambda_{\delta - 2^{j-1} \varepsilon}(\mathbf{x}) \Lambda_{\delta - 2^j \varepsilon}^c(\mathbf{x}) [\alpha_{\delta - 2^j \varepsilon}(\mathbf{x})^* - \alpha_\delta(\mathbf{x})^*] \\ &= \sum_{j=1}^n \Lambda([\delta - 2^j \varepsilon, \delta])(\mathbf{x}) \Lambda_{\delta - 2^j \varepsilon}^c(\mathbf{x}) [\alpha_{\delta - 2^j \varepsilon}(\mathbf{x})^* - \alpha_\delta(\mathbf{x})^*] \end{aligned}$$

Since $\bigcup_{j=1}^n \Lambda_{\delta - 2^{j-1} \varepsilon} \Lambda_{\delta - 2^j \varepsilon}^c$ is a partition of $\Lambda_{\delta - \varepsilon} = \Lambda_\tau$ into disjoint subsets, at most one term in this sum is nonzero. If this term is the j th, it is bounded by $r(2^j \varepsilon)$. If $|\mathcal{J}| > 2^j \varepsilon$, then $\Lambda(\mathcal{J}) \subset \Lambda_{\delta - 2^j \varepsilon}$ and our one potentially nonzero term is in fact zero for all $\mathbf{x} \in \Lambda(\mathcal{J})$. Hence the one possibly nonzero term is bounded by $r(|\mathcal{J}|)$.

(c, first bound) It suffices to combine parts (e), (f) and (g) of Lemma E.8 with the bounds

$$\begin{aligned} &\sum_{\mathbf{x} \in \Lambda} \left| \left(j \left(\frac{\delta}{2} - \tau - \varepsilon \right) \Lambda^c \Lambda \left(\left[\frac{\delta}{2}, \delta \right] \right) [\alpha_{\frac{\delta}{2}} - \beta] \right) (\mathbf{x}) \right| \\ &\leq \sum_{\substack{\mathbf{x} \in \Lambda \\ \mathbf{y} \in \Lambda^c \Lambda \left(\left[\frac{\delta}{2}, \delta \right] \right)}} \left| j \left(\frac{\delta}{2} - \tau - \varepsilon \right) (\mathbf{x}, \mathbf{y}) \right| \left| [\alpha_{\frac{\delta}{2}} - \beta](\mathbf{y}) \right| \\ &\leq \sum_{\substack{\mathbf{x} \in \Lambda \\ \mathbf{y} \in \Lambda^c \Lambda \left(\left[\frac{\delta}{2}, \delta \right] \right)}} \left| j \left(\frac{\delta}{2} - \tau - \varepsilon \right) (\mathbf{x}, \mathbf{y}) \right| r \left(\frac{\delta}{2} \right) \\ &\leq \|j \left(\frac{\delta}{2} - \tau - \varepsilon \right)\| |\Lambda^c| r \left(\frac{\delta}{2} \right) \leq 2e^{K_j} r(\delta) |\Lambda^c| \end{aligned}$$

and, using Lemma D.1,

$$\begin{aligned} &\sum_{\mathbf{x} \in \Lambda} \left| \left(j \left(\frac{\delta}{2} - \tau - \varepsilon \right) \Lambda^c [j \left(\frac{\delta}{2} \right) - \mathbb{1}] \Lambda \left(\left[\frac{\delta}{2}, \delta \right] \right) \beta \right) (\mathbf{x}) \right| \\ &\leq \sum_{\substack{\mathbf{x} \in \Lambda \\ \mathbf{y} \in \Lambda^c}} \left| j \left(\frac{\delta}{2} - \tau - \varepsilon \right) (\mathbf{x}, \mathbf{y}) \right| \left| \left\{ j \left(\frac{\delta}{2} \right) - \mathbb{1} \right\} \Lambda \left(\left[\frac{\delta}{2}, \delta \right] \right) \beta \right| (\mathbf{y}) \end{aligned}$$

$$\begin{aligned}
&\leq \sum_{\substack{\mathbf{x} \in \Lambda \\ \mathbf{y} \in \Lambda^c}} \left| j\left(\frac{\delta}{2} - \tau - \varepsilon\right)(\mathbf{x}, \mathbf{y}) \right| e^{5md(\mathbf{x}, \mathbf{y})} \frac{\delta}{2} K'_j e^{K'_j \frac{\delta}{2}} e^{-5md(\Lambda, \mathbf{y})} \\
&\quad \times \left(\left[|\mu| + e^{-5md(\mathbf{y}, \Lambda([\frac{\delta}{2}, \delta])^c)} \right] \max_{\mathbf{z} \in \Lambda([\frac{\delta}{2}, \delta])} |\beta(\mathbf{z})| + \max_{b \in \Lambda([\frac{\delta}{2}, \delta])^*} |\nabla \beta(b)| \right) \\
&\leq \|j\left(\frac{\delta}{2} - \tau - \varepsilon\right)\| \|\Lambda^c\| \frac{\delta}{2} e^{2K'_j} \left(\left[|\mu| + e^{-5md(\Lambda, \Lambda([\frac{\delta}{2}, \delta])^c)} \right] R\left(\frac{\delta}{2}\right) \right. \\
&\quad \left. + R'\left(\frac{\delta}{2}\right) \right) \\
&\leq \frac{\delta}{2} e^{K_j} e^{2K'_j} \left(\left[|\mu| + e^{-5mc(\delta/2)} \right] R\left(\frac{\delta}{2}\right) + R'\left(\frac{\delta}{2}\right) \right) |\Lambda^c| \\
&\leq \frac{1}{32} r\left(\frac{\delta}{2}\right) |\Lambda^c| \leq \frac{1}{16} r(\delta) |\Lambda^c| \quad \text{by (F.4a), (F.6c), (F.3b)}
\end{aligned}$$

when $0 \leq \tau < \frac{\delta}{2} - \varepsilon$ and the similar bounds

$$\begin{aligned}
\sum_{\mathbf{x} \in \Lambda} \left| \left(j\left(\tau - \frac{\delta}{2}\right) \Lambda^c \Lambda \left(\left[0, \frac{\delta}{2} \right] \right) [\alpha_{\frac{\delta}{2}} - \alpha] \right) (\mathbf{x}) \right| &\leq 2e^{K_j} r(\delta) |\Lambda^c| \\
\sum_{\mathbf{x} \in \Lambda} \left| \left(j\left(\tau - \frac{\delta}{2}\right) \Lambda^c \left[j\left(\frac{\delta}{2}\right) - 1 \right] \Lambda \left(\left[0, \frac{\delta}{2} \right] \right) \alpha \right) (\mathbf{x}) \right| &\leq \frac{1}{16} r(\delta) |\Lambda^c|
\end{aligned}$$

when $\frac{\delta}{2} < \tau < \delta$. We have used the compatibility assumption of Definition E.1. Since $(2e^{K_j} + 2e^{-mc(\delta)} + \frac{1}{16}) r(\delta) |\Lambda^c| \leq 3e^{K_j} r(\delta) |\Lambda^c|$, by (F.4c), the desired results follow.

(c, second bound) We have

$$\tilde{\gamma}_{\tau, \varepsilon} - \tilde{\tilde{\gamma}}_{\tau, \varepsilon} = \begin{cases} j(\tau) \tilde{\Omega}^c \alpha - j(\delta - \tau - \varepsilon) \tilde{\Omega}^c \Lambda \left(\left[\frac{\delta}{2}, \delta \right] \right) \beta & \text{if } 0 \leq \tau < \frac{\delta}{2} - \varepsilon \\ j(\tau) \tilde{\Omega}^c \alpha - j(\delta - \tau - \varepsilon) \tilde{\Omega}^c \beta & \text{if } \tau = \frac{\delta}{2} - \varepsilon, \frac{\delta}{2} \\ j(\tau) \tilde{\Omega}^c \Lambda \left(\left[0, \frac{\delta}{2} \right] \right) \alpha - j(\delta - \tau - \varepsilon) \tilde{\Omega}^c \beta & \text{if } \frac{\delta}{2} < \tau < \delta \end{cases}$$

All terms are bounded in the same way. For example, by Lemma B.1(i) and Definition 2.13,

$$\begin{aligned}
&\sum_{\mathbf{x} \in \Lambda} e^{-4md(\mathbf{x}, \Omega)} \left| \left(j(\tau) \tilde{\Omega}^c \alpha \right) (\mathbf{x}) \right| \\
&\leq \sum_{\substack{\mathbf{x} \in \Lambda \\ \mathbf{y} \in \tilde{\Omega}^c}} e^{-4md(\mathbf{x}, \Omega)} |j(\tau)(\mathbf{x}, \mathbf{y})| \kappa_{*0}(\mathbf{y}) \\
&\leq 4R(\delta) \sum_{\substack{\mathbf{x} \in \Lambda \\ \mathbf{y} \in \tilde{\Omega}^c}} |j(\tau)(\mathbf{x}, \mathbf{y})| e^{\frac{m}{3}d(\mathbf{x}, \mathbf{y})} e^{4md(\mathbf{x}, \mathbf{y})} e^{-4md(\mathbf{y}, \Omega)} \\
&\leq 4 \|j(\tau)\| e^{-4md(\Omega, \tilde{\Omega}^c)} R(\delta) |\tilde{\Omega}^c|
\end{aligned}$$

$$\begin{aligned} &\leq 4e^{K_j} e^{-4m\mathfrak{c}(\delta)} R(\delta) |\tilde{\Omega}^c| \\ &\leq \frac{1}{16} e^{-3m\mathfrak{c}(\delta)} |\tilde{\Omega}^c| \quad \text{by (F.6b)} \end{aligned}$$

□

Lemma E.10. Assume that $\mathfrak{h} \equiv 1$.

(i) Let $t \in \varepsilon\mathbb{Z} \cap (0, \delta)$ and $\mathbf{x} \in \Lambda_t^c$ with

$$d(\mathbf{x}, \Lambda_t) \geq \mathfrak{c}(\varepsilon_t) \quad d(\mathbf{x}, \Lambda([t - \varepsilon_t, t])^c) \geq \mathfrak{c}(\varepsilon_t) \quad d(\mathbf{x}, \Lambda([t, t + \varepsilon_t])^c) \geq \mathfrak{c}(\varepsilon_t)$$

(If $t \notin 2\varepsilon\mathbb{Z}$, then $\Lambda([t - \varepsilon_t, t])^c = \Lambda([t - \varepsilon_t, t])^c = \emptyset$ and the conditions $d(\mathbf{x}, \Lambda([t - \varepsilon_t, t])^c) \geq \mathfrak{c}(\varepsilon_t)$ and $d(\mathbf{x}, \Lambda([t, t + \varepsilon_t])^c) \geq \mathfrak{c}(\varepsilon_t)$ are vacuous.) Then

$$\begin{aligned} |\gamma_\tau(\mathbf{x}) - (j(t + \varepsilon_t - \tau) B_{\mathbf{x}, \varepsilon_t} \Lambda_{t+\varepsilon_t}^c \alpha_{t+\varepsilon_t})(\mathbf{x})| &\leq e^{-m\mathfrak{c}(\varepsilon_t)} & \text{if } t < \tau \leq t + \varepsilon_t \\ |\gamma_\tau(\mathbf{x}) - (j(t - \tau) B_{\mathbf{x}, \varepsilon_t} \Lambda_t^c \alpha_t)(\mathbf{x})| &\leq e^{-m\mathfrak{c}(\varepsilon_t)} & \text{if } t - \varepsilon_t < \tau \leq t \\ |\gamma_{*\tau}(\mathbf{x}) - (j(\tau - t) B_{\mathbf{x}, \varepsilon_t} \Lambda_t^c \alpha_t^*)(\mathbf{x})| &\leq e^{-m\mathfrak{c}(\varepsilon_t)} & \text{if } t \leq \tau < t + \varepsilon_t \\ |\gamma_{*\tau}(\mathbf{x}) - (j(\tau - t + \varepsilon_t) B_{\mathbf{x}, \varepsilon_t} \Lambda_{t-\varepsilon_t}^c \alpha_{t-\varepsilon_t}^*)(\mathbf{x})| &\leq e^{-m\mathfrak{c}(\varepsilon_t)} & \text{if } t - \varepsilon_t \leq \tau < t \end{aligned}$$

for any set

$$B_{\mathbf{x}, \varepsilon_t} \supset \{\mathbf{y} \in X \mid d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c}(\varepsilon_t)\}$$

(ii) Let $\mathbf{x} \in X$ obey $d(\mathbf{x}, \Lambda([0, \delta])^c) \geq \mathfrak{c}(\delta)$. Then

$$\begin{aligned} |\gamma_\tau(\mathbf{x}) - (j(\delta - \tau) B_{\mathbf{x}, \delta} \beta)(\mathbf{x})| &\leq e^{-m\mathfrak{c}(\delta)} & \text{if } 0 < \tau < \delta \\ |\gamma_{*\tau}(\mathbf{x}) - (j(\tau) B_{\mathbf{x}, \delta} \alpha^*)(\mathbf{x})| &\leq e^{-m\mathfrak{c}(\delta)} & \text{if } 0 < \tau < \delta \end{aligned}$$

for any set

$$B_{\mathbf{x}, \delta} \supset \{\mathbf{y} \in T \mid d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c}(\delta)\}$$

Proof. (i) We prove the first bound. The proofs of the other three bounds are very similar. Fix any $\tau \in \varepsilon\mathbb{Z}$ obeying $t < \tau \leq t + \varepsilon_t$. By Definition 2.9, $\gamma_\tau(\mathbf{x}) = \sum_{\tau' \geq \tau} (\Gamma_\tau^{\tau'} \alpha_{\tau'})(\mathbf{x})$. Fix any $\tau \leq \tau' \leq \delta$ with $\Gamma_\tau^{\tau'} \neq 0$. By Lemma E.4.i, $\tau' \in \{\tau\} \cup \mathcal{T}_r(\tau, \delta)$. Set

$$\begin{aligned} L_x &= \{\mathbf{x} \in X \mid d(\mathbf{x}, \Lambda_t) \geq \mathfrak{c}(\varepsilon_t), d(\mathbf{x}, \Lambda([t - \varepsilon_t, t])^c) \geq \mathfrak{c}(\varepsilon_t), \\ &\quad d(\mathbf{x}, \Lambda([t, t + \varepsilon_t])^c) \geq \mathfrak{c}(\varepsilon_t)\} \end{aligned}$$

when $t \in 2\varepsilon\mathbb{Z}$ and $L_x = \{\mathbf{x} \in X \mid d(\mathbf{x}, \Lambda_t) \geq \mathfrak{c}(\varepsilon)\}$ when $t \notin 2\varepsilon\mathbb{Z}$.

Case 1: $\tau \leq \tau' < t + \varepsilon_t$. In this case $\varepsilon_{\tau'} < \varepsilon_t$, (as is true for all times in $(t, t + \varepsilon_t)$) so that any $\mathbf{x} \in L_x$ obeys

$$\mathbf{x} \in \Lambda([t, t + \varepsilon_t]) \subset \Lambda_{\tau'}$$

By our rules for constructing small field sets, either $\Lambda_{\tau'}^c = \emptyset$, or $\Lambda([t, t + \varepsilon_t]) = \Lambda_{\tau'}$ (in which case $\varepsilon_{\tau'} = \frac{1}{2}\varepsilon_t$ and the distance from \mathbf{x} to $\Lambda_{\tau'}^c$ is at least $\mathfrak{c}(\varepsilon_t) = \mathfrak{c}(2\varepsilon_{\tau'})$) or $d(\Lambda([t, t + \varepsilon_t]), \Lambda_{\tau'}^c) \geq \mathfrak{c}(2\varepsilon_{\tau'})$. So the distance from L_x to $\Lambda_{\tau'}^c$ is at least $\mathfrak{c}(2\varepsilon_{\tau'})$, unless $\Lambda_{\tau'}^c \equiv 0$. Therefore, for $\tau = \tau'$, $(\Gamma_\tau^{\tau'} \alpha_{\tau'})(\mathbf{x}) = 0$ and for $\tau < \tau'$,

$$\begin{aligned}
\left| \left(\Gamma_{\tau'}^{\tau'} \alpha_{\tau'} \right) (\mathbf{x}) \right| &= \left| \left(j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')} j(\tau' - \pi(\tau')) \Lambda_{\tau'}^c \alpha_{\tau'} \right) (\mathbf{x}) \right| \\
&\leq N_0 (L_x j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')} j(\tau' - \pi(\tau')) \Lambda_{\tau'}^c ; 1, \kappa_{\tau'}) \\
&\leq 4R(\varepsilon_t) e^{-4m\mathfrak{c}(2\varepsilon_{\tau'})} e^{K_j(\tau' - \tau)}
\end{aligned}$$

by Lemma G.5(ii) with $\kappa = \kappa_{\tau'}$, $R = 4R(\varepsilon_t)$, $L_1 = L_x \subset \Lambda([t, t + \varepsilon_t]) = O_2$, $L_2 = \Lambda_{\pi(\tau')}$ and $L_3 = \Lambda_{\tau'}^c$. For this and all other applications of the lemma in this proof, d is replaced by 0, $\delta_1 = 0$, $\delta_2 = \frac{m}{3}d$, $\delta = 4md$ and $\tilde{d} = 5md$.

Case 2: $\tau' > t + \varepsilon_t$. In this case $2\varepsilon_t < 2\varepsilon_{\pi(\tau')} \leq \varepsilon_{\tau'}$ (since all times $t' \in (\tau' - 2\varepsilon_{\pi(\tau')}, \tau')$, including $t + \varepsilon_t$ have $\varepsilon_{t'} < 2\varepsilon_{\pi(\tau')}$). Now $t - \varepsilon_t$ is the element of $2\varepsilon_t\mathbb{Z}$ below $t + \varepsilon_t$ that is nearest $t + \varepsilon_t$. As $\tau' - 2\varepsilon_{\pi(\tau')}$ is an element of $2\varepsilon_t\mathbb{Z}$ that is below $t + \varepsilon_t$, we have $\tau' - 2\varepsilon_{\pi(\tau')} \leq t - \varepsilon_t < t + \varepsilon_t < \tau'$. Hence $\Lambda_{\pi(\tau')} = \Lambda([\tau' - 2\varepsilon_{\pi(\tau')}, \tau']) \subset \Lambda_t$. So the distance from L_x to $\Lambda_{\pi(\tau')}$ is at least $\mathfrak{c}(\varepsilon_t)$. Therefore,

$$\begin{aligned}
\left| \left(\Gamma_{\tau'}^{\tau'} \alpha_{\tau'} \right) (\mathbf{x}) \right| &= \left| \left(j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')} j(\tau' - \pi(\tau')) \Lambda_{\tau'}^c \alpha_{\tau'} \right) (\mathbf{x}) \right| \\
&\leq N_0 (L_x j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')} j(\tau' - \pi(\tau')) \Lambda_{\tau'}^c ; 1, \kappa_{\tau'}) \\
&\leq 4R(2\varepsilon_{\pi(\tau')}) e^{-4m\mathfrak{c}(\varepsilon_t)} e^{K_j(\tau' - \tau)}
\end{aligned}$$

by Lemma G.5(ii) with $R = 4R(2\varepsilon_{\pi(\tau')})$, $L_1 = L_x$, $O_2 = L_2 = \Lambda_{\pi(\tau')}$ and $L_3 = \Lambda_{\tau'}^c$.

Case 3: $\tau' = t + \varepsilon_t$. If $\tau = t + \varepsilon_t$ too, then

$$\left(\Gamma_{\tau'}^{\tau'} \alpha_{\tau'} \right) (\mathbf{x}) = (\Lambda_{\tau'}^c \alpha_{\tau'}) (\mathbf{x}) = (j(t + \varepsilon_t - \tau) B_{\mathbf{x}, \varepsilon_t} \Lambda_{t+\varepsilon_t}^c \alpha_{t+\varepsilon_t}) (\mathbf{x})$$

In general $\varepsilon_{\tau'} \geq 2\varepsilon_{\pi(\tau')}$ and $\varepsilon_{\tau'} \geq 2\varepsilon_t$. Furthermore, since $t = \tau' - \varepsilon_t < \tau < \tau'$, we have $2\varepsilon_{\pi(\tau')} \leq \varepsilon_{\tau'}$. Hence $\Lambda([t, t + \varepsilon_t]) \subset \Lambda([\tau' - 2\varepsilon_{\pi(\tau')}, \tau']) = \Lambda_{\pi(\tau')}$. So the distance from \mathbf{x} to $\Lambda_{\pi(\tau')}^c$ is at least $\mathfrak{c}(\varepsilon_t)$. As well, by definition, the distance from \mathbf{x} to $B_{\mathbf{x}, \varepsilon_t}^c$ is at least $\mathfrak{c}(\varepsilon_t)$. Therefore, setting $L_1 = \{\mathbf{y} \in X \mid d(\mathbf{y}, \Lambda([t, t + \varepsilon_t]))^c \geq \mathfrak{c}(\varepsilon_t), d(\mathbf{y}, B_{\mathbf{x}, \varepsilon_t}^c) \geq \mathfrak{c}(\varepsilon_t)\}$,

$$\begin{aligned}
&\left| \left(\Gamma_{\tau'}^{\tau'} \alpha_{\tau'} \right) (\mathbf{x}) - (j(t + \varepsilon_t - \tau) B_{\mathbf{x}, \varepsilon_t} \Lambda_{t+\varepsilon_t}^c \alpha_{t+\varepsilon_t}) (\mathbf{x}) \right| \\
&= \left| \left(\{j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')} j(\tau' - \pi(\tau')) - j(\tau' - \tau) B_{\mathbf{x}, \varepsilon_t}\} \Lambda_{\tau'}^c \alpha_{\tau'} \right) (\mathbf{x}) \right| \\
&= \left| \left(\{j(\tau' - \tau) B_{\mathbf{x}, \varepsilon_t}^c - j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')}^c j(\tau' - \pi(\tau'))\} \Lambda_{\tau'}^c \alpha_{\tau'} \right) (\mathbf{x}) \right| \\
&\leq N_0 (L_1 j(\tau' - \tau) B_{\mathbf{x}, \varepsilon_t}^c \Lambda_{\tau'}^c ; 1, \kappa_{\tau'}) \\
&\quad + N_0 (L_1 j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')}^c j(\tau' - \pi(\tau')) \Lambda_{\tau'}^c ; 1, \kappa_{\tau'}) \\
&\leq 8R(\varepsilon_t) e^{-4m\mathfrak{c}(\varepsilon_t)} e^{K_j(\tau' - \tau)}
\end{aligned}$$

by Lemma G.5(ii) with $R = 4R(\varepsilon_t)$, $L_3 = \Lambda_{\tau'}^c$,

$$O_2 = \Lambda([\tau' - \varepsilon_t, \tau']) = \Lambda([t, t + \varepsilon_t]) \supset L_1$$

and L_2 being $B_{\mathbf{x}, \varepsilon_t}^c$ for the first bound and $\Lambda_{\pi(\tau')}^c$ for the second bound.

We have now shown that $|\gamma_{\tau}(\mathbf{x}) - (j(t + \varepsilon_t - \tau) B_{\mathbf{x}, \varepsilon_t} \Lambda_{t+\varepsilon_t}^c \alpha_{t+\varepsilon_t})(\mathbf{x})|$ is bounded by

$$\begin{aligned}
& \sum_{\tau' \in \{\tau\} \cup \mathcal{T}_r(\tau, \delta)} 8R(\varepsilon_t) e^{-4mc(\min\{\varepsilon_t, 2\varepsilon_{\tau'}\})} e^{K_j} \\
& \leq \sum_{\tau' \in \{\tau\} \cup \mathcal{T}_r(\tau, \delta)} \frac{1}{2} e^{-\frac{15}{4}mc(\min\{\varepsilon_t, 2\varepsilon_{\tau'}\})} \\
& \leq e^{-mc(\varepsilon_t)} \sum_{\tau' \in \{\tau\} \cup \mathcal{T}_r(\tau, \delta)} e^{-\frac{11}{8}mc(\varepsilon_{\tau'})} \leq e^{-mc(\varepsilon_t)} \sum_{\delta'=0}^n e^{-\frac{11}{8}mc(2^{\delta'})} \\
& \leq e^{-mc(\varepsilon_t)}
\end{aligned} \tag{E.4}$$

by (F.6b) and (F.4a,d).

(ii) We prove the first bound. The proof of the second bound is similar. Fix any $\tau \in \varepsilon\mathbb{Z}$ obeying $0 < \tau < \delta$. By definition $\gamma_\tau(\mathbf{x}) = \sum_{\tau' \geq \tau} (\Gamma_\tau^{\tau'} \alpha_{\tau'})(\mathbf{x})$. Fix any $\tau \leq \tau' \leq \delta$ with $\Gamma_\tau^{\tau'} \neq 0$. By Lemma E.4(i), $\tau' \in \{\tau\} \cup \mathcal{T}_r(\tau, \delta)$. Set

$$L_x = \{\mathbf{x} \in X \mid d(\mathbf{x}, \Lambda([0, \delta])^c) \geq c(\delta)\}$$

Case 1: $\tau \leq \tau' < \delta$. By our rules for constructing small field sets, either $\Lambda_{\tau'}^c = \emptyset$, or $\Lambda([0, \delta]) = \Lambda_{\tau'}$ (in which case $\varepsilon_{\tau'} = \frac{\delta}{2}$) or $d(\Lambda([0, \delta]), \Lambda_{\tau'}^c) \geq c(2\varepsilon_{\tau'})$. Consequently, if $\Lambda_{\tau'}^c \neq \emptyset$, the distance from L_x to $\Lambda_{\tau'}^c$ is at least $c(2\varepsilon_{\tau'})$. Therefore, for $\tau = \tau'$, $(\Gamma_\tau^{\tau'} \alpha_{\tau'})(\mathbf{x}) = 0$ and for $\tau < \tau'$,

$$\begin{aligned}
|(\Gamma_\tau^{\tau'} \alpha_{\tau'})(\mathbf{x})| &= |(j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')} j(\tau' - \pi(\tau')) \Lambda_{\tau'}^c \alpha_{\tau'})(\mathbf{x})| \\
&\leq N_0(L_x j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')} j(\tau' - \pi(\tau')) \Lambda_{\tau'}^c ; 1, \kappa_{\tau'}) \\
&\leq 4R(\delta) e^{-4mc(2\varepsilon_{\tau'})} e^{K_j(\tau' - \tau)}
\end{aligned}$$

by Lemma G.5(ii) with $\kappa = \kappa_{\tau'}$, $R = 4R(\delta)$, $O_2 = \Lambda([0, \delta]) \supset L_x = L_1$, $L_2 = \Lambda_{\pi(\tau')}$ and $L_3 = \Lambda_{\tau'}^c$.

Case 2: $\tau' = \delta$. As $\Lambda([0, \delta]) \subset \Lambda([\delta - 2\varepsilon_{\pi(\tau')}, \delta]) = \Lambda_{\pi(\tau')}$ the distance from L_x to $\Lambda_{\pi(\tau')}^c$ is at least $c(\delta)$. We are assuming that the distance from \mathbf{x} to $B_{\mathbf{x}, \delta}^c$ is also at least $c(\delta)$ so that, setting $L_1 = \{\mathbf{y} \in L_x \mid d(\mathbf{y}, B_{\mathbf{x}, \delta}^c) \geq c(\delta)\}$, we have

$$\begin{aligned}
& |(\Gamma_\tau^\delta \beta)(\mathbf{x}) - (j(\delta - \tau) B_{\mathbf{x}, \delta} \beta)(\mathbf{x})| \\
& = |(\{j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')} j(\tau' - \pi(\tau')) - j(\delta - \tau) B_{\mathbf{x}, \delta}\} \beta)(\mathbf{x})| \\
& = \left| \left(\left\{ j(\delta - \tau) B_{\mathbf{x}, \delta}^c - j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')}^c j(\tau' - \pi(\tau')) \right\} \beta \right) (\mathbf{x}) \right| \\
& \leq N_0(L_1 j(\delta - \tau) B_{\mathbf{x}, \delta}^c ; 1, \kappa_\delta) \\
& \quad + N_0(L_1 j(\pi(\tau') - \tau) \Lambda_{\pi(\tau')}^c j(\tau' - \pi(\tau')) ; 1, \kappa_\delta) \\
& \leq 8R(\delta) e^{-4mc(\delta)} e^{K_j(\delta - \tau)}
\end{aligned}$$

by Lemma G.5(ii) with $R = 4R(\delta)$, $L_3 = X$

$$O_2 = \Lambda([0, \delta]) \supset L_1$$

and L_2 being $B_{\mathbf{x}, \delta}^c$ for the first bound and $\Lambda_{\pi(\tau')}^c$ for the second bound.

The desired bound now follows from (E.4) with $\varepsilon_t = \delta$. \square

E.3. The Size of the Background Field

In this subsection, we show that the background fields $\gamma_{*\tau}(\mathbf{x})$, $\gamma_\tau(\mathbf{x})$ obey roughly the same bounds as the large and small field conditions impose on the integration variables $\alpha_\tau(\mathbf{x})$.

Proposition E.11. *Assume that $\mathfrak{h} \equiv 1$.*

- (i) *Let $\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)$ and \mathcal{J} be a decimation interval that contains τ in its interior. If $\mathbf{x} \in \Lambda(\mathcal{J})$, then*

$$|\gamma_{*\tau}(\mathbf{x})|, |\gamma_\tau(\mathbf{x})| \leq 40 e^{K_j} R(|\mathcal{J}|)$$

- (ii) *For all $\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)$ and $\mathbf{x} \in \Lambda_\tau^c$*

$$|\gamma_{*\tau}(\mathbf{x}) - \alpha_\tau(\mathbf{x})^*|, |\gamma_\tau(\mathbf{x}) - \alpha_\tau(\mathbf{x})| \leq \frac{1}{2} e^{-m \mathfrak{c}(\varepsilon_\tau)}$$

Proof. (i) The proof follows Lemma E.13, below.

(ii) follows immediately from Proposition E.7. \square

Lemma E.12. *Assume that $\mathfrak{h} \equiv 1$. Let $[t_-, t_+]$ be a decimation interval in $[0, \delta]$ with centre $t = \frac{1}{2}(t_+ + t_-)$. Recall that the sets $\tilde{P}'_\alpha(\mathcal{J})$, $\tilde{P}'_\beta(\mathcal{J})$, $\tilde{Q}(\mathcal{J})$ were defined in Proposition 3.36 and that the sets $\tilde{P}_\alpha(\mathcal{J})$, $\tilde{P}_\beta(\mathcal{J})$ were defined in Proposition 3.37.*

- (i) *If $b \in \tilde{P}'_\alpha([t_-, t_+])$, then*

$$|\nabla \gamma_{*\tau}(b)| \geq \frac{1}{2} R'(t_+ - t_-) \quad \text{for all } t_- \leq \tau < t$$

- (ii) *If $b \in \tilde{P}'_\beta([t_-, t_+])$, then*

$$|\nabla \gamma_\tau(b)| \geq \frac{1}{2} R'(t_+ - t_-) \quad \text{for all } t < \tau \leq t_+$$

- (iii) *If $\mathbf{x} \in \tilde{Q}([t_-, t_+])$, then*

$$|\gamma_{*\tau}(\mathbf{x})^* - \gamma_{t+\varepsilon}(\mathbf{x})| + |\gamma_{*\tau-\varepsilon}(\mathbf{x})^* - \gamma_t(\mathbf{x})| \geq \frac{1}{4} r(t_+ - t_-)$$

- (iv) *If $\mathbf{x} \in \tilde{P}_\alpha([t_-, t_+])$, then*

$$|\gamma_{*\tau}(\mathbf{x})| \geq \frac{1}{2} R(t_+ - t_-) \quad \text{for all } t_- \leq \tau < t$$

- (v) *If $\mathbf{x} \in \tilde{P}_\beta([t_-, t_+])$, then*

$$|\gamma_\tau(\mathbf{x})| \geq \frac{1}{2} R(t_+ - t_-) \quad \text{for all } t < \tau \leq t_+$$

Proof. Set $\mathfrak{c}_\pm = \mathfrak{c}(t - t_-) = \mathfrak{c}(t_+ - t)$ and

$$J_{\tau,\pm}(\mathbf{x}, \mathbf{y}) = j_{\mathfrak{c}_\pm}(\tau)(\mathbf{x}, \mathbf{y}) = \begin{cases} j(\tau)(\mathbf{x}, \mathbf{y}) & \text{if } d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c}_\pm \\ 0 & \text{otherwise} \end{cases}$$

Recall that $j(\tau) = e^{\tau\mu} e^{-\tau\nabla^* \mathcal{H} \nabla}$ with \mathcal{H} obeying (2.16).

(i), (ii) We give the proof for part (ii). The proof of part (i) is similar. Let $t < \tau \leq t_+$. As $b \in \tilde{P}'_\beta([t_-, t_+])$, both end points $\mathbf{x} \in b$ satisfy the hypotheses,

$$d(\mathbf{x}, \Lambda([t_-, t_+])) , d(\mathbf{x}, \Lambda([t_-, t])^c) , d(\mathbf{x}, \Lambda([t, t_+])^c) > \mathfrak{c}_\pm$$

of Lemma E.10(i). (Again, when $t_+ - t_- \leq 2\varepsilon$, $\Lambda([t_-, t]) = \Lambda([t, t_+]) = X$ and the conditions $d(\mathbf{x}, \Lambda([t_-, t])^c), d(\mathbf{x}, \Lambda([t, t_+])^c) > \mathfrak{c}_\pm$ are vacuous.) Furthermore, all points \mathbf{y} within a distance \mathfrak{c}_\pm of either end point $\mathbf{x} \in b$, are in $\Lambda_t^c \subset \Lambda_{t+}^c$. Hence, by Lemma E.10.i, with $B_{\mathbf{x}, \varepsilon_t} = \{\mathbf{y} \in X \mid d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c}_\pm\}$,

$$|\nabla (\gamma_\tau - (J_{t+ - \tau, \pm} \alpha_{t+})) (b)| \leq 2 \max_{\mathbf{x} \in b} |\gamma_\tau(\mathbf{x}) - (J_{t+ - \tau, \pm} \alpha_{t+})(\mathbf{x})| \leq 2e^{-m\mathfrak{c}_\pm}$$

Write $b = (\mathbf{x}, \mathbf{x} + e_i) = b_i(\mathbf{x})$. As $J_{t+ - \tau, \pm}$ is translation invariant

$$\begin{aligned} & \nabla ((J_{t+ - \tau, \pm} \alpha_{t+})) (b) \\ &= (J_{t+ - \tau, \pm} \alpha_{t+})(\mathbf{x} + e_i) - (J_{t+ - \tau, \pm} \alpha_{t+})(\mathbf{x}) \\ &= \sum_{\mathbf{y}} J_{t+ - \tau, \pm}(\mathbf{x} + e_i, \mathbf{y}) \alpha_{t+}(\mathbf{y}) - \sum_{\mathbf{y}} J_{t+ - \tau, \pm}(\mathbf{x}, \mathbf{y}) \alpha_{t+}(\mathbf{y}) \\ &= \sum_{\mathbf{y}} J_{t+ - \tau, \pm}(\mathbf{x}, \mathbf{y} - e_i) \alpha_{t+}(\mathbf{y}) - \sum_{\mathbf{y}} J_{t+ - \tau, \pm}(\mathbf{x}, \mathbf{y}) \alpha_{t+}(\mathbf{y}) \\ &= \sum_{\mathbf{y}} J_{t+ - \tau, \pm}(\mathbf{x}, \mathbf{y}) \alpha_{t+}(\mathbf{y} + e_i) - \sum_{\mathbf{y}} J_{t+ - \tau, \pm}(\mathbf{x}, \mathbf{y}) \alpha_{t+}(\mathbf{y}) \\ &= \sum_{\mathbf{y}} J_{t+ - \tau, \pm}(\mathbf{x}, \mathbf{y}) (\nabla \alpha_{t+})(b_i(\mathbf{y})) \end{aligned} \tag{E.5}$$

Since $b \in \tilde{P}'_\beta([t_-, t_+])$, we have $|\nabla \alpha_{t+}(b)| > R'(t_+ - t_-)$ and

$$\begin{aligned} |\nabla \gamma_\tau(b)| &= |(J_{t+ - \tau, \pm} \nabla \alpha_{t+})(b) + \nabla (\gamma_\tau - J_{t+ - \tau, \pm} \alpha_{t+})(b)| \\ &\geq |(J_{t+ - \tau, \pm} \nabla \alpha_{t+})(b)| - 2e^{-m\mathfrak{c}_\pm} \\ &\geq |\nabla \alpha_{t+}(b)| - |((\mathbb{1} - J_{t+ - \tau, \pm}) \nabla \alpha_{t+})(b)| - 2e^{-m\mathfrak{c}_\pm} \\ &\geq R'(t_+ - t_-) - |((\mathbb{1} - J_{t+ - \tau, \pm}) \nabla \alpha_{t+})(b)| - 2e^{-m\mathfrak{c}_\pm} \end{aligned}$$

where we are using $(J_{t+ - \tau, \pm} \nabla \alpha_{t+})(b)$ to refer to the last line of (E.5). By Lemma 3.21(ii),

$$\begin{aligned} & |((\mathbb{1} - J_{t+ - \tau, \pm}) \nabla \alpha_{t+})(b)| \\ &\leq \|\mathbb{1} - j(t_+ - \tau)\| \sup \{|\nabla \alpha_{t+}(b_i(\mathbf{y}))| \mid d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c}_\pm\} \\ &\leq (t_+ - t) K_j e^{K_j(t_+ - t)} \sup \{|\nabla \alpha_{t+}(b_i(\mathbf{y}))| \mid d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c}_\pm\} \end{aligned}$$

For all \mathbf{y} with $d(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c}_\pm$, $b_i(\mathbf{y})$ is necessarily in $\Lambda([t, t_+])^*$. Hence,

$$|\nabla \alpha_{t+}(b_i(\mathbf{y}))| \leq R'(t_+ - t)$$

so that

$$|((\mathbb{1} - J_{t+ - \tau, \pm}) \nabla \alpha_{t+})(b)| \leq K_j e^{K_j(t_+ - t)} (t_+ - t) R'(t_+ - t)$$

and

$$\begin{aligned} |\nabla \gamma_\tau(b)| &\geq R'(t_+ - t_-) - K_j e^{K_j(t_+ - t)} (t_+ - t) R'(t_+ - t) - 2e^{-m\mathfrak{c}_\pm} \\ &\geq \frac{1}{2} R'(t_+ - t_-) \end{aligned}$$

by (F.3e), (F.4c) and Hypothesis F.7(i).

(iii) Since $\mathbf{x} \in \tilde{Q}([t_-, t_+])$, we have $|\alpha_{t_+}(\mathbf{x}) - \alpha_{t_-}(\mathbf{x})| > r(t_+ - t_-)$. Hence at least one of $|\alpha_{t_+}(\mathbf{x}) - \alpha_t(\mathbf{x})|$, $|\alpha_t(\mathbf{x}) - \alpha_{t_-}(\mathbf{x})|$ must be at least $\frac{1}{2}r(t_+ - t_-)$. We prove that in the former case $|\gamma_{*t}(\mathbf{x})^* - \gamma_{t+\varepsilon}(\mathbf{x})| \geq \frac{1}{4}r(t_+ - t_-)$. The proof that in the latter case $|\gamma_{*t-\varepsilon}(\mathbf{x})^* - \gamma_t(\mathbf{x})| \geq \frac{1}{4}r(t_+ - t_-)$ is similar. So assume that $|\alpha_{t_+}(\mathbf{x}) - \alpha_t(\mathbf{x})| \geq \frac{1}{2}r(t_+ - t_-)$. As in the proof of part (ii), using the third and first bounds of Lemma E.10(i),

$$\begin{aligned} & |\gamma_{*t}(\mathbf{x})^* - \gamma_{t+\varepsilon}(\mathbf{x})| \\ &= |\alpha_t(\mathbf{x}) - \alpha_{t_+}(\mathbf{x}) + (\gamma_{*t}^* - \alpha_t)(\mathbf{x}) + (\mathbb{1} - J_{t_+ - t - \varepsilon, \pm}) \alpha_{t_+}(\mathbf{x}) \\ &\quad - (\gamma_{t+\varepsilon} - J_{t_+ - t - \varepsilon, \pm} \alpha_{t_+})(\mathbf{x})| \\ &\geq \frac{1}{2}r(t_+ - t_-) - |(\mathbb{1} - J_{t_+ - t - \varepsilon, \pm}) \alpha_{t_+}(\mathbf{x})| - 2e^{-mc\pm} \end{aligned}$$

since $\Lambda_{t_+} \subset \Lambda_t$ so that $d(\mathbf{x}, \Lambda_t) > c_\pm$ implies that $d(\mathbf{x}, \Lambda_{t_+}) > c_\pm$ too. By Lemma D.1 with $S = \{\mathbf{y} \in X \mid d(\mathbf{x}, \mathbf{y}) \leq c_\pm\}$

$$\begin{aligned} & |(\mathbb{1} - J_{t_+ - t - \varepsilon, \pm}) \alpha_{t_+}(\mathbf{x})| \\ &\leq (t_+ - t) K'_j e^{K'_j(t_+ - t)} \left([|\mu| + e^{-5mc\pm}] \max_{\mathbf{y} \in S} |\alpha_{t_+}(\mathbf{y})| + \max_{b \in S^*} |\nabla \alpha_{t_+}(b)| \right) \end{aligned}$$

Again, any \mathbf{y} within a distance c_\pm of $\mathbf{x} \in \tilde{Q}([t_-, t_+])$ is necessarily in $\Lambda([t, t_+])$. Hence

$$\max_{\mathbf{y} \in S} |\alpha_{t_+}(\mathbf{y})| \leq R(t_+ - t) \quad \max_{b \in S^*} |\nabla \alpha_{t_+}(b)| \leq R'(t_+ - t)$$

so that

$$\begin{aligned} & |(\mathbb{1} - J_{t_+ - t - \varepsilon, p}) \alpha_{\tau_+}(\mathbf{x})| \\ &\leq K'_j e^{K'_j(t_+ - t)} (t_+ - t) (|\mu|R(t_+ - t) + e^{-5mc\pm}R(t_+ - t) + R'(t_+ - t)) \\ &\leq \frac{1}{32}r(t_+ - t) \quad \text{by (F.6c) and (F.4a)} \end{aligned}$$

and

$$\begin{aligned} |\gamma_{*t}(\mathbf{x})^* - \gamma_{t+\varepsilon}(\mathbf{x})| &\geq \frac{1}{2}r(t_+ - t_-) - \frac{1}{32}r(t_+ - t) - 2e^{-mc\pm} \\ &\geq \frac{1}{4}r(t_+ - t_-) \quad \text{by (F.3b) and (F.4c)} \end{aligned}$$

(iv, v) We give the proof for part (v). The proof of part (iv) is similar. Let $t < \tau \leq t_+$. As $\mathbf{x} \in \tilde{P}_\beta([t_-, t_+])$, it satisfies the hypotheses

$$d(\mathbf{x}, \Lambda([t_-, t_+])) , d(\mathbf{x}, \Lambda([t_-, t])^c) , d(\mathbf{x}, \Lambda([t, t_+])^c) > c_\pm$$

of Lemma E.10(i) (again, when $t_+ - t_- \leq 2\varepsilon$, $\Lambda([t_-, t]) = \Lambda([t, t_+]) = X$ and the conditions $d(\mathbf{x}, \Lambda([t_-, t])^c) , d(\mathbf{x}, \Lambda([t, t_+])^c) > c_\pm$ are vacuous). As well, all points \mathbf{y} within a distance c_\pm of \mathbf{x} , are in $\Lambda_t^c \subset \Lambda_{t_+}^c$. Hence, by Lemma E.10.i, with $B_{\mathbf{x}, \varepsilon_t} = \{\mathbf{y} \in X \mid d(\mathbf{x}, \mathbf{y}) \leq c_\pm\}$,

$$|\gamma_\tau(\mathbf{x}) - (J_{t_+ - \tau, \pm} \alpha_{t_+})(\mathbf{x})| \leq e^{-mc\pm}$$

Since $\mathbf{x} \in \tilde{P}_\beta([t_-, t_+])$, we have $|\alpha_{t_+}(\mathbf{x})| > R(t_+ - t_-)$ and

$$\begin{aligned} |\gamma_\tau(\mathbf{x})| &= |(J_{t_+-\tau,\pm}\alpha_{t_+})(\mathbf{x}) + (\gamma_\tau - J_{t_+-\tau,\pm}\alpha_{t_+})(\mathbf{x})| \\ &\geq |(J_{t_+-\tau,\pm}\alpha_{t_+})(\mathbf{x})| - e^{-m\epsilon_\pm} \\ &\geq |\alpha_{t_+}(\mathbf{x})| - |((1 - J_{t_+-\tau,\pm})\alpha_{t_+})(\mathbf{x})| - e^{-m\epsilon_\pm} \\ &\geq R(t_+ - t_-) - |((1 - J_{t_+-\tau,\pm})\alpha_{t_+})(\mathbf{x})| - e^{-m\epsilon_\pm} \end{aligned}$$

By Corollary D.2,

$$\begin{aligned} &|((1 - J_{t_+-\tau,\pm})\alpha_{t_+})(\mathbf{x})| \\ &\leq (t_+ - t) K'_j e^{K'_j(t_+ - t)} \left([|\mu| + e^{-5m\epsilon_\pm}] \max_{\substack{\mathbf{y} \in X \\ d(\mathbf{x}, \mathbf{y}) \leq \epsilon_\pm}} |\alpha_{t_+}(\mathbf{y})| + \max_{\substack{b \in X^* \\ d(\mathbf{x}, b) \leq \epsilon_\pm}} |\nabla \alpha_{t_+}(b)| \right) \end{aligned}$$

All $\mathbf{y} \in X$ with $d(\mathbf{x}, \mathbf{y}) \leq \epsilon_\pm$, are necessarily in $\Lambda([t, t_+])$ and all bonds b with $d(\mathbf{x}, b) \leq \epsilon_\pm$, are necessarily in $\Lambda([t, t_+])^*$. Hence,

$$|\alpha_{t_+}(\mathbf{y})| \leq R(t_+ - t) \quad \text{and} \quad |\nabla \alpha_{t_+}(b)| \leq R'(t_+ - t)$$

so that, by (F.4a), (F.6c) and (F.3b),

$$\begin{aligned} &|((1 - J_{t_+-\tau,\pm})\alpha_{t_+})(\mathbf{x})| \\ &\leq K'_j e^{K'_j(t_+ - t)} \varepsilon(t_+ - t) ([|\mu| + e^{-5m\epsilon_\pm}] R(t_+ - t) + R'(t_+ - t)) \\ &\leq \frac{1}{16} r(t_+ - t_-) \end{aligned}$$

and, by (F.3d) and (F.4c),

$$|\gamma_\tau(b)| \geq R(t_+ - t_-) - \frac{1}{16} r(t_+ - t_-) - e^{-m\epsilon_\pm} \geq \frac{1}{2} R(t_+ - t_-)$$

□

Lemma E.13. *Let $\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)$ and \mathcal{J} be a decimation interval that contains τ in its interior. Then*

$$\begin{aligned} \sum_{\tau' \in [0, \delta]} \mathcal{N}_{4m} \left(\Gamma_{*\tau}' ; e^{\frac{m}{2} d(\mathbf{x}, \Lambda(\mathcal{J}))}, \kappa_{*\tau'} \right) &\leq \begin{cases} 40e^{K_j \tau} R(|\mathcal{J}|) & \text{if } \mathcal{J} \subsetneq [0, \delta] \\ 16e^{K_j \tau} R(\delta) & \text{if } \mathcal{J} = [0, \delta] \end{cases} \\ \sum_{\tau' \in (0, \delta]} \mathcal{N}_{4m} \left(\Gamma_\tau' ; e^{\frac{m}{2} d(\mathbf{x}, \Lambda(\mathcal{J}))}, \kappa_{\tau'} \right) &\leq \begin{cases} 40e^{K_j(\delta-\tau)} R(|\mathcal{J}|) & \text{if } \mathcal{J} \subsetneq [0, \delta] \\ 16e^{K_j(\delta-\tau)} R(\delta) & \text{if } \mathcal{J} = [0, \delta] \end{cases} \end{aligned}$$

Proof. We prove the first bound. The proof of the second is virtually identical. Write $\mathcal{J} = [\tau_-, \tau_+]$ and let $\tau_+ - \tau_- = \frac{1}{2^p} \delta$. We first consider the case that $\tau' \in \mathcal{T}_l(\tau, \delta)$ with $\mathfrak{d}(\sigma(\tau')) > p$. We claim that \mathcal{J} is exactly the decimation interval \mathcal{J}_{*p} of Lemma B.1.

- If $\mathfrak{d}(\tau') > p$, then, since τ' is the largest element of $\varepsilon_{\tau'}\mathbb{Z}$ below τ and τ_- is an element of $\varepsilon_{\tau'}\mathbb{Z}$ below τ , we have $\tau_- < \tau' < \tau < \tau_+$ so that \mathcal{J} the unique decimation interval of length $\frac{1}{2^p} \delta$ that contains τ' .

- If $\delta(\tau') \leq p < \delta(\sigma(\tau'))$, then $\tau_- < \sigma(\tau')$, since $\sigma(\tau')$ is the largest element of $\frac{\delta}{2^{\delta(\sigma(\tau'))}}\mathbb{Z}$ below τ . And $\tau_- \geq \tau'$, since τ_- is the largest element of $\frac{\delta}{2^p}\mathbb{Z}$ below τ . And it is impossible to have $\tau' < \tau_- < \sigma(\tau')$ since then τ_- would be in $\mathcal{T}_l(\tau, \delta)$ and $\sigma(\tau')$ would not be the successor of τ' . So $\tau_- = \tau'$ and $\mathcal{J} = [\tau', \tau' + \frac{\delta}{2^p}]$.

Consequently,

$$\begin{aligned}
& \mathcal{N}_{4m} \left(\Gamma_{*\tau}^{\tau'}; e^{\frac{m}{2} d(\mathbf{x}, \Lambda(\mathcal{J}))}, \kappa_{*\tau'} \right) \\
&= \mathcal{N}_{4m} \left(j(\tau - \sigma(\tau')) \Lambda_{\sigma(\tau')} j(\sigma(\tau') - \tau') \Lambda_{\tau'}^c; e^{\frac{m}{2} d(\mathbf{x}, \Lambda(\mathcal{J}))}, \kappa_{*\tau'} \right) \\
&\leq 4R(|\mathcal{J}|) e^{-\frac{m}{6} d(\Lambda(\mathcal{J}), \Lambda_{\tau'}^c)} \mathcal{N}_{5m} (j(\tau - \sigma(\tau')); 1, 1) \mathcal{N}_{5m} (j(\sigma(\tau') - \tau'); 1, 1) \\
&\leq 4R(|\mathcal{J}|) e^{-\frac{m}{6} d(\Lambda(\mathcal{J}), \Lambda_{\tau'}^c)} \|j(\tau - \sigma(\tau'))\| \|j(\sigma(\tau') - \tau')\| \\
&\leq 4e^{K_j(\tau - \tau')} R(|\mathcal{J}|) \begin{cases} e^{-\frac{m}{6} c(|\mathcal{J}_{\tau'}|)} & \text{if } |\mathcal{J}_{\tau'}| < |\mathcal{J}| \\ 1 & \text{otherwise} \end{cases} \tag{E.6}
\end{aligned}$$

For the first inequality we used Lemma G.5((i)c) with d replaced by $4md$,

$$\begin{aligned}
L_1 &= X, \quad L_2 = \Lambda_{\sigma(\tau')}, \quad L_3 = \Lambda_{\tau'}^c, \quad O_1 = O_2 = \Lambda(\mathcal{J}) \\
\delta_1 &= \frac{m}{2}d, \quad \delta_2 = \frac{m}{3}d, \quad \delta = \frac{m}{6}d, \quad \tilde{d} = 5md, \quad \kappa = \kappa_{*\tau'}, \quad R = 4R(|\mathcal{J}|)
\end{aligned}$$

and $D_O \geq \delta(L_3, O_1) = \frac{1}{6}md(\Lambda(\mathcal{J}), \Lambda_{\tau'}^c)$. (The hypothesis that $\kappa(\mathbf{x}) = \kappa_{*\tau'}(\mathbf{x}) \leq Re^{\delta_2(\mathbf{x}, O_2)} = 4R(|\mathcal{J}|)e^{\frac{m}{3}d(\mathbf{x}, \Lambda(\mathcal{J}))}$ for all $\mathbf{x} \in X$ is fulfilled by Lemma B.1(ii), since, as we observed above, \mathcal{J} is the decimation interval \mathcal{J}_{*p} of that Lemma). The last inequality follows from Lemma 3.21(i).

We next consider the case that $\tau' \in \mathcal{T}_l(\tau, \delta)$ with $p \geq \delta(\sigma(\tau'))$. In this case $\Lambda_{\sigma(\tau')} \subset \Lambda(\mathcal{J})$ and

$$\begin{aligned}
& \mathcal{N}_{4m} \left(\Gamma_{*\tau}^{\tau'}; e^{\frac{m}{2} d(\mathbf{x}, \Lambda(\mathcal{J}))}, \kappa_{*\tau'} \right) \\
&\leq \mathcal{N}_{4m} (j(\tau - \sigma(\tau')) \Lambda_{\sigma(\tau')} j(\sigma(\tau') - \tau') \Lambda_{\tau'}^c; 1, \kappa_{*\tau'}) \\
&\leq 4R(|\mathcal{J}_{\sigma(\tau')}|) \mathcal{N}_{5m} (j(\tau - \sigma(\tau')); 1, 1) \mathcal{N}_{5m} (j(\sigma(\tau') - \tau'); 1, 1) \\
&\leq 4R(|\mathcal{J}_{\sigma(\tau')}|) \|j(\tau - \sigma(\tau'))\| \|j(\sigma(\tau') - \tau')\| \\
&\leq 4e^{K_j(\tau - \tau')} R(|\mathcal{J}_{\sigma(\tau')}|) \tag{E.7}
\end{aligned}$$

by Lemma G.5(ii) with d replaced by $4md$,

$$\begin{aligned}
L_1 &= X, \quad L_2 = \Lambda_{\sigma(\tau')}, \quad L_3 = \Lambda_{\tau'}^c, \quad O_2 = \Lambda_{\sigma(\tau')} \\
\delta &= \delta_1 = 0, \quad \delta_2 = \frac{m}{3}d, \quad \tilde{d} = 5md, \quad \kappa = \kappa_{*\tau'}, \quad R = 4R(|\mathcal{J}_{\sigma(\tau')}|)
\end{aligned}$$

Finally, as $\Gamma_{*\tau}^{\tau'} = \Lambda_{\tau'}^c$,

$$\begin{aligned}
& \mathcal{N}_{4m} \left(\Gamma_{*\tau}^{\tau}; e^{m/2 d(\mathbf{x}, \Lambda(\mathcal{J}))}, \kappa_{*\tau} \right) = \mathcal{N}_{4m} \left(\Lambda_{\tau}^c; 1, \kappa_{*\tau} e^{-m/2 d(\mathbf{x}, \Lambda(\mathcal{J}))} \right) \\
&\leq 4R(|\mathcal{J}|) \mathcal{N}_{4m} (\Lambda_{\tau}^c; 1, 1) \\
&= 4R(|\mathcal{J}|) \tag{E.8}
\end{aligned}$$

Again we used Lemma B.1(ii).

Using (F.4d) to sum (E.6) over $\tau' \in \mathcal{T}_l(\tau, \delta)$ with $\mathfrak{d}(\tau') > p + 1$ (so that $|\mathcal{J}_{\tau'}| < |\mathcal{J}|$), using (E.6) up to twice more for the cases $\mathfrak{d}(\tau') = p + 1$ (so that $|\mathcal{J}_{\tau'}| = |\mathcal{J}|$), and $\mathfrak{d}(\tau') \leq p < \mathfrak{d}(\sigma(\tau'))$, using (F.3c) to sum (E.7) over $\tau' \in \mathcal{T}_l(\tau, \delta)$ with $\mathfrak{d}(\sigma(\tau')) \leq p$ and finally adding (E.8) gives the bound for $\mathcal{J} \subsetneq [0, \delta]$. When $\mathcal{J} = [0, \delta]$, the case $\mathfrak{d}(\sigma(\tau')) \leq p$ is absent. \square

Proof of Proposition E.11(i). For all $\mathbf{x} \in \Lambda(\mathcal{J})$

$$|\gamma_{*\tau}(\mathbf{x})| \leq \left| \sum_{\tau' \leq \tau} \left(\Gamma_{*\tau}^{\tau'} \alpha_{\tau'} \right) (\mathbf{x})^* \right| \leq \sum_{\tau' \leq \tau} \mathcal{N}_0 \left(\Gamma_{*\tau}^{\tau'}; e^{\frac{m}{2} d(\mathbf{x}, \Lambda(\mathcal{J}))}, \kappa_{*\tau'} \right)$$

by Remark E.2 and the assumption that $d(\mathbf{x}, \Lambda(\mathcal{J})) = 0$. Now just apply Lemma E.13. The proof of the bound on $\gamma_{\tau}(\mathbf{x})$ is similar. \square

E.4. Comparison of $\gamma_{\tau+\varepsilon}$ and $j(\varepsilon)\gamma_{\tau}$

Lemma E.14. (a) *Let $\tau, \tau' \in (0, \delta]$ and $t > 0$. If $[\tau - t, \tau] \cap \varepsilon\mathbb{Z} = \emptyset$, then*

$$\Gamma_{\tau-t}^{\tau'} = j(t) \Gamma_{\tau}^{\tau'} \quad \Gamma(\tau - t; \vec{\alpha}, \beta) = j(t) \Gamma(\tau; \vec{\alpha}, \beta)$$

(b) *Let $\tau, \tau' \in [0, \delta)$ and $t > 0$. If $(\tau, \tau+t] \cap \varepsilon\mathbb{Z} = \emptyset$, then*

$$\Gamma_{*\tau+t}^{\tau'} = j(t) \Gamma_{*\tau}^{\tau'} \quad \Gamma(\tau + t; \alpha_*, \vec{\alpha}_*) = j(t) \Gamma(\tau; \alpha_*, \vec{\alpha})$$

Proof. We prove part (a). It suffices to prove the τ' formula, since the other one follows from it. Since $\Lambda_{\tau'}^c = \emptyset$ for all τ' with $\mathfrak{d}(\tau') > n$, it suffices to consider $\tau' \in \varepsilon\mathbb{Z} \cap (0, \delta]$. If $\tau > \tau'$, then $\tau - t > \tau'$ too, so that $\Gamma_{\tau-t}^{\tau'} = \Gamma_{\tau}^{\tau'} = 0$. So it suffices to consider $\tau \leq \tau'$.

Case $\tau' - \tau \geq \varepsilon$: Let $[\tau' - \frac{\delta}{2^d}, \tau']$ be the shortest decimation interval with τ' as right hand end point that properly contains $[\tau, \tau']$. (If no such decimation interval exists, then $\Gamma_{\tau-t}^{\tau'} = \Gamma_{\tau}^{\tau'} = 0$.) Since $\tau' - \tau \geq \varepsilon$, we have $d \leq n$ and $\tau' - \frac{\delta}{2^d} \in \varepsilon\mathbb{Z}$. Hence $[\tau' - \frac{\delta}{2^d}, \tau']$ also properly contains $[\tau - t, \tau']$ and

$$\Gamma_{\tau}^{\tau'} = j \left(\tau' - \tau - \frac{\delta}{2^{d+1}} \right) \Lambda \left(\left[\tau' - \frac{\delta}{2^d}, \tau' \right] \right) j \left(\frac{\delta}{2^{d+1}} \right) \Lambda_{\tau'}^c$$

$$\Gamma_{\tau-t}^{\tau'} = j \left(\tau' - \tau + t - \frac{\delta}{2^{d+1}} \right) \Lambda \left(\left[\tau' - \frac{\delta}{2^d}, \tau' \right] \right) j \left(\frac{\delta}{2^{d+1}} \right) \Lambda_{\tau'}^c = j(t) \Gamma_{\tau}^{\tau'}$$

Case $0 \leq \tau' - \tau < \varepsilon$: In this case $\tau' - \tau + t < \varepsilon$ too, since otherwise $\tau' - \varepsilon$ would be an element of $\varepsilon\mathbb{Z}$ in $[\tau - t, \tau]$. Let \mathcal{J}_{τ} and $\mathcal{J}_{\tau-t}$ be the shortest decimation intervals with τ' as right hand end point that properly contain $[\tau, \tau']$ and $[\tau - t, \tau']$, respectively. Both are contained in $[\tau' - \varepsilon, \tau]$. Hence $\Lambda(\mathcal{J}_{\tau}) = \Lambda(\mathcal{J}_{\tau-t}) = X$ and

$$\Gamma_{\tau}^{\tau'} = j \left(\tau' - \tau - \frac{1}{2} |\mathcal{J}_{\tau}| \right) \Lambda(\mathcal{J}_{\tau}) j \left(\frac{1}{2} |\mathcal{J}_{\tau}| \right) \Lambda_{\tau'}^c = j(\tau' - \tau) \Lambda_{\tau}^c$$

$$\begin{aligned} \Gamma_{\tau-t}^{\tau'} &= j \left(\tau' - \tau + t - \frac{1}{2} |\mathcal{J}_{\tau-t}| \right) \Lambda(\mathcal{J}_{\tau-t}) j \left(\frac{1}{2} |\mathcal{J}_{\tau-t}| \right) \Lambda_{\tau'}^c = j(\tau' - \tau + t) \Lambda_{\tau}^c \\ &= j(t) \Gamma_{\tau}^{\tau'} \end{aligned}$$

\square

Lemma E.15. (i) Let $\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)$. If $\mathfrak{d}(\tau) = n$ (that is, $\tau \in \varepsilon\mathbb{Z} \setminus 2\varepsilon\mathbb{Z}$), then

$$\Lambda_\tau [\gamma_{*\tau} - j(\varepsilon)\gamma_{*\tau-\varepsilon}] = \Lambda_\tau [\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon}] = 0$$

If $0 < \mathfrak{d}(\tau) < n$ (that is, $\tau \in 2\varepsilon\mathbb{Z}$), then

$$\sum_{\tau' \in [0, \delta]} \mathcal{N}_{3m} \left(\Lambda_\tau [\Gamma_{*\tau}' - j(\varepsilon)\Gamma_{*\tau-\varepsilon}'] ; 1, \kappa_{*\tau'} \right) \leq e^{-m\mathfrak{c}(\varepsilon_\tau)}$$

$$\sum_{\tau' \in (0, \delta]} \mathcal{N}_{3m} \left(\Lambda_\tau [\Gamma_\tau' - j(\varepsilon)\Gamma_{\tau+\varepsilon}'] ; 1, \kappa_{\tau'} \right) \leq e^{-m\mathfrak{c}(\varepsilon_\tau)}$$

(ii) Let $O \subset \Omega_{\mathfrak{S}} = \Omega([0, \delta])$, $r > 0$ and define the weight factor

$$\lambda(\mathbf{x}) = \begin{cases} r & \text{if } \mathbf{x} \in O \\ \infty & \text{if } \mathbf{x} \notin O \end{cases}$$

Then

$$\sum_{\tau \in (0, \delta]} \mathcal{N}_{2m} \left([\Gamma_{*\tau}^0 - j(\varepsilon)\Gamma_{*\tau-\varepsilon}^0] O ; e^{-m d(\mathbf{x}, O)}, \lambda \right) \leq 4e^{K_j} r e^{-2m d(O, \Omega_{\mathfrak{S}}^c)}$$

$$\sum_{\tau \in [0, \delta)} \mathcal{N}_{2m} \left([\Gamma_\tau^\delta - j(\varepsilon)\Gamma_{\tau+\varepsilon}^\delta] O ; e^{-m d(\mathbf{x}, O)}, \lambda \right) \leq 4e^{K_j} r e^{-2m d(O, \Omega_{\mathfrak{S}}^c)}$$

Here we set $\Gamma_{*\delta}^0 = \Gamma_\delta^\delta = j(\delta)$ and $\Gamma_{*0}^0 = \Gamma_0^\delta = 1$.

Proof. (i) The vanishing when $\mathfrak{d}(\tau) = n$ is proven in Lemma E.16, below. Now assume that $0 < \mathfrak{d}(\tau) < n$ and write $\varepsilon_\tau = 2^\mathfrak{d}\varepsilon$. (That is, $\mathfrak{d} = n - \mathfrak{d}(\tau)$.) The same Lemma gives

$$\begin{aligned} & \sum_{\tau' \in [0, \delta]} \mathcal{N}_{3m} \left(\Lambda_\tau [\Gamma_{*\tau}' - j(\varepsilon)\Gamma_{*\tau-\varepsilon}'] ; 1, \kappa_{*\tau'} \right) \\ &= \mathcal{N}_{3m} \left(\Lambda_\tau j \left(\frac{1}{2} \varepsilon_\tau \right) \Lambda ([\tau - \varepsilon_\tau, \tau])^c j \left(\frac{1}{2} \varepsilon_\tau \right) \Lambda_{\tau-\varepsilon_\tau}^c ; 1, \kappa_{*\tau-\varepsilon_\tau} \right) \\ &+ \sum_{\ell=1}^{\mathfrak{d}-1} \mathcal{N}_{3m} \left(\Lambda_\tau j (2^{\ell-1}\varepsilon) \Lambda ([\tau - 2^\ell\varepsilon, \tau]) j (2^{\ell-1}\varepsilon) \Lambda_{\tau-2^\ell\varepsilon}^c ; 1, \kappa_{*\tau-2^\ell\varepsilon} \right) \\ &+ \mathcal{N}_{3m} \left(\Lambda_\tau j (\varepsilon) \Lambda_{\tau-\varepsilon_\tau}^c ; 1, \kappa_{*\tau-\varepsilon_\tau} \right) \end{aligned}$$

For each $1 \leq \ell \leq \mathfrak{d} - 1$, we apply Lemma G.5((i)a), with d replaced by $3md$,

$$L_1 = \Lambda_\tau, \quad L_2 = \Lambda ([\tau - 2^\ell\varepsilon, \tau]), \quad L_3 = \Lambda_{\tau-2^\ell\varepsilon}^c, \quad O_1 = X, \quad O_2 = \Lambda_\tau$$

$$\delta_1 = 0, \quad \delta_2 = \frac{m}{3}d, \quad \delta = \frac{3m}{2}d, \quad \tilde{d} = 5md, \quad \kappa = \kappa_{*\tau-2^\ell\varepsilon}, \quad R = 4R(2\varepsilon_\tau)$$

and $D_L \geq \frac{3}{2}m d(\Lambda_\tau, \Lambda_{\tau-2^\ell\varepsilon}^c) \geq \frac{3}{2}m\mathfrak{c}(2^{\ell+1}\varepsilon)$, to get

$$\begin{aligned} & \mathcal{N}_{3m} \left(\Lambda_\tau j (2^{\ell-1}\varepsilon) \Lambda ([\tau - \varepsilon_\ell, \tau]) j (2^{\ell-1}\varepsilon) \Lambda_{\tau-\varepsilon_\ell}^c ; 1, \kappa_{*\tau-\varepsilon_\ell} \right) \\ & \leq 4R(2\varepsilon_\tau) e^{-\frac{3}{2}md(\Lambda_\tau, \Lambda_{\tau-\varepsilon_\ell}^c)} \|j (2^{\ell-1}\varepsilon)\| \|j (2^{\ell-1}\varepsilon)\| \\ & \leq 4e^{K_j} 2^\ell\varepsilon R(2\varepsilon_\tau) e^{-\frac{3}{2}m\mathfrak{c}(2^{\ell+1}\varepsilon)} \leq \frac{1}{4} e^{-\frac{5}{4}m\mathfrak{c}(2^{\ell+1}\varepsilon)} \end{aligned}$$

by (F.6b).

For the last term, we again apply Lemma G.5(i(a)), this time with

$$\begin{aligned} L_1 &= \Lambda_\tau, & L_2 = L_3 &= \Lambda_{\tau-\varepsilon}^c, & O_1 &= X, & O_2 &= \Lambda_\tau \\ \delta_1 &= 0, & \delta_2 &= \frac{m}{3}d, & \delta &= \frac{3m}{2}d, & \tilde{\delta} &= 5md, & \kappa &= \kappa_{*\tau-\varepsilon}, & R &= 4R(2\varepsilon_\tau) \end{aligned}$$

and $D_L \geq \frac{3}{2}m d(\Lambda_\tau, \Lambda_{\tau-\varepsilon}^c) \geq \frac{3}{2}mc(2\varepsilon)$, to get

$$\mathcal{N}_{3m}(\Lambda_\tau j(\varepsilon) \Lambda_{\tau-\varepsilon}^c; 1, \kappa_{*\tau-\varepsilon}) \leq 4R(2\varepsilon_\tau) e^{K_j \varepsilon} e^{-\frac{3}{2}mc(2\varepsilon)} \leq \frac{1}{4} e^{-\frac{5}{4}mc(2\varepsilon)}$$

For the first term, the same Lemma gives

$$\begin{aligned} &\mathcal{N}_{3m}\left(\Lambda_\tau j\left(\frac{1}{2}\varepsilon_\tau\right) \Lambda([\tau - \varepsilon_\tau, \tau])^c j\left(\frac{1}{2}\varepsilon_\tau\right) \Lambda_{\tau-\varepsilon_\tau}^c; 1, \kappa_{*\tau-\varepsilon_\tau}\right) \\ &\leq 4R(2\varepsilon_\tau) e^{-\frac{3}{2}md(\Lambda_\tau, \Lambda([\tau - \varepsilon_\tau, \tau])^c)} \|j\left(\frac{1}{2}\varepsilon_\tau\right)\| \|j\left(\frac{1}{2}\varepsilon_\tau\right)\| \\ &\leq 4e^{K_j \varepsilon_\tau} R(2\varepsilon_\tau) e^{-\frac{3}{2}mc(\varepsilon_\tau)} \\ &\leq \frac{1}{4} e^{-\frac{5}{4}mc(\varepsilon_\tau)} \end{aligned}$$

Using (F.4d) to bound the sum over $1 < \ell < \mathfrak{d} - 1$ and adding the bounds on the first and last terms gives the desired bound for $\Lambda_\tau[\Gamma_{*\tau}^{\tau'} - j(\varepsilon)\Gamma_{*\tau-\varepsilon}^{\tau'}]$. The proof of the other bound is similar.

(ii) We prove the first bound. If $\tau \neq 2^\ell \varepsilon$ for all $\ell \in \{0, \dots, n\}$, then $\Gamma_{*\tau}^0 - j(\varepsilon)\Gamma_{*\tau-\varepsilon}^0 = 0$ by Remark 3.5.iv. If $\tau = 2^\ell \varepsilon$ for some $\ell \in \{1, \dots, n-1\}$, then

$$\begin{aligned} \Gamma_{*\tau}^0 - j(\varepsilon)\Gamma_{*\tau-\varepsilon}^0 &= \Lambda([0, 2^{\ell+1}\varepsilon]) j(2^\ell \varepsilon) - j(2^{\ell-1}\varepsilon) \Lambda([0, 2^\ell \varepsilon]) j(2^{\ell-1}\varepsilon) \\ &= -\Lambda([0, 2^{\ell+1}\varepsilon])^c j(2^\ell \varepsilon) + j(2^{\ell-1}\varepsilon) \Lambda([0, 2^\ell \varepsilon])^c j(2^{\ell-1}\varepsilon) \end{aligned}$$

Therefore,

$$\begin{aligned} &\mathcal{N}_{2m}\left([\Gamma_{*\tau}^0 - j(\varepsilon)\Gamma_{*\tau-\varepsilon}^0] O; e^{-m d(\mathbf{x}, O)}, \lambda\right) \\ &\leq \mathcal{N}_{2m}\left(\Lambda([0, 2^{\ell+1}\varepsilon])^c j(2^\ell \varepsilon) O; e^{-m d(\mathbf{x}, O)}, \lambda\right) \\ &\quad + \mathcal{N}_{2m}\left(j(2^{\ell-1}\varepsilon) \Lambda([0, 2^\ell \varepsilon])^c j(2^{\ell-1}\varepsilon) O; e^{-m d(\mathbf{x}, O)}, \lambda\right) \\ &\leq re^{-2md(O, \Lambda([0, 2^{\ell+1}\varepsilon])^c)} \|j(2^\ell \varepsilon)\| + re^{-2md(O, \Lambda([0, 2^\ell \varepsilon])^c)} \|j(2^{\ell-1}\varepsilon)\|^2 \\ &\leq 2re^{K_j 2^\ell \varepsilon} \begin{cases} e^{-2m[d(O, \Omega_{\mathfrak{S}}^c) + \mathfrak{c}(2^{\ell+1}\varepsilon)]} & \text{if } 1 \leq \ell \leq n-2 \\ e^{-2md(O, \Omega_{\mathfrak{S}}^c)} & \text{if } \ell = n-1 \end{cases} \end{aligned}$$

In the second inequality we applied Lemma G.5.ii with d replaced by $2md$,

$$\begin{aligned} L_1 &= X, & L_3 = O_1 = O_2 &= O, & \delta_1 &= md, & \delta_2 &= 0, \\ \delta &= 2md, & \tilde{\delta} &= 5md, & \kappa &= \lambda, & R &= r \end{aligned}$$

and

$$L_2 = \begin{cases} \Lambda([0, 2^{\ell+1}\varepsilon])^c & \text{for the first summand} \\ \Lambda([0, 2^\ell\varepsilon])^c & \text{for the second summand} \end{cases}$$

Similarly, for $\tau = \varepsilon$,

$$\begin{aligned} \mathcal{N}_{2m} & \left([\Gamma_{*\varepsilon}^0 - j(\varepsilon)\Gamma_{*0}^0] O ; e^{-m d(\mathbf{x}, O)}, \lambda \right) \\ &= \mathcal{N}_{2m} \left(\Lambda([0, 2\varepsilon])^c j(\varepsilon)O ; e^{-m d(\mathbf{x}, O)}, \lambda \right) \\ &\leq r e^{-2m[d(O, \Omega_{\mathfrak{S}}^c) + \mathfrak{c}(2\varepsilon)]} e^{K_j \varepsilon} \end{aligned}$$

and, for $\tau = \delta$,

$$\begin{aligned} \mathcal{N}_{2m} & \left([\Gamma_{*\delta}^0 - j(\varepsilon)\Gamma_{*\delta-\varepsilon}^0] O ; e^{-m d(\mathbf{x}, O)}, \lambda \right) \\ &= \mathcal{N}_{2m} \left(j\left(\frac{\delta}{2}\right) \Lambda_{\mathfrak{S}}^c j\left(\frac{\delta}{2}\right) O ; e^{-m d(\mathbf{x}, O)}, \lambda \right) \\ &\leq r e^{-2md(O, \Omega_{\mathfrak{S}}^c)} e^{K_j \delta} \end{aligned}$$

Summing up the last three bounds, using (F.4d), gives

$$\begin{aligned} \sum_{\tau \in (0, \delta]} \mathcal{N}_{2m} & \left([\Gamma_{*\tau}^0 - j(\varepsilon)\Gamma_{*\tau-\varepsilon}^0] O ; e^{-m d(\mathbf{x}, O)}, \lambda \right) \\ &\leq e^{K_j} r e^{-2m d(O, \Omega_{\mathfrak{S}}^c)} \left[\sum_{\ell=0}^{n-2} 2e^{-2m\mathfrak{c}(2^{\ell+1}\varepsilon)} + 2 + 1 \right] \\ &\leq e^{K_j} r e^{-2m d(O, \Omega_{\mathfrak{S}}^c)} \left[\sum_{\ell=0}^{n-2} \frac{1}{2^{\ell+1}\varepsilon} e^{-2m\mathfrak{c}(2^{\ell+1}\varepsilon)} + 2 + 1 \right] \\ &\leq 4e^{K_j} r e^{-2m d(O, \Omega_{\mathfrak{S}}^c)} \end{aligned}$$

which is the desired result. \square

Lemma E.16. *Let $\tau \in \varepsilon\mathbb{Z} \cap (0, \delta)$. Recall that $\varepsilon = 2^{-n}\delta$ with the integer $n \geq \text{depth } \mathfrak{S}$.*

- (i) *If $\mathfrak{d}(\tau) = n$ (that is, $\tau \in \varepsilon\mathbb{Z} \setminus 2\varepsilon\mathbb{Z}$), then $\Lambda_\tau(\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon}) = 0$.
If $0 < \mathfrak{d}(\tau) < n$ (that is, $\tau \in 2\varepsilon\mathbb{Z}$), then*

$$\begin{aligned} \Lambda_\tau(\gamma_\tau - j(\varepsilon)\gamma_{\tau+\varepsilon}) &= \Lambda_\tau \left\{ j\left(\frac{1}{2}\varepsilon_\tau\right) \Lambda([\tau, \tau + \varepsilon_\tau])^c j\left(\frac{1}{2}\varepsilon_\tau\right) \Lambda_{\tau+\varepsilon_\tau}^c \alpha_{\tau+\varepsilon_\tau} \right. \\ &\quad \left. - \sum_{\ell=1}^{n-\mathfrak{d}(\tau)-1} (2^{\ell-1}\varepsilon) \Lambda([\tau, \tau + 2^\ell\varepsilon]) j(2^{\ell-1}\varepsilon) \Lambda_{\tau+2^\ell\varepsilon}^c \alpha_{\tau+2^\ell\varepsilon} \right. \\ &\quad \left. - j(\varepsilon) \Lambda_{\tau+\varepsilon}^c \alpha_{\tau+\varepsilon} \right\} \end{aligned}$$

where, if $\tau = \delta - \varepsilon_\tau$, then $\alpha_{\tau+\varepsilon_\tau} = \beta$.

- (ii) *If $\mathfrak{d}(\tau) = n$ (that is, $\tau \in \varepsilon\mathbb{Z} \setminus 2\varepsilon\mathbb{Z}$), then $\Lambda_\tau(\gamma_{*\tau} - j(\varepsilon)\gamma_{*\tau-\varepsilon}) = 0$.
If $0 < \mathfrak{d}(\tau) < n$ (that is, $\tau \in 2\varepsilon\mathbb{Z}$), then*

$$\begin{aligned} \Lambda_\tau (\gamma_{*\tau} - j(\varepsilon) \gamma_{*\tau-\varepsilon}) &= \Lambda_\tau \left\{ j\left(\frac{1}{2}\varepsilon_\tau\right) \Lambda([\tau - \varepsilon_\tau, \tau])^c j\left(\frac{1}{2}\varepsilon_\tau\right) \Lambda_{\tau-\varepsilon_\tau}^c \alpha_{\tau-\varepsilon_\tau}^* \right. \\ &\quad - \sum_{\ell=1}^{n-\mathfrak{d}(\tau)-1} j\left(2^{\ell-1}\varepsilon\right) \Lambda\left([\tau - 2^\ell\varepsilon, \tau]\right) j\left(2^{\ell-1}\varepsilon\right) \\ &\quad \times \Lambda_{\tau-2^\ell\varepsilon}^c \alpha_{\tau-2^\ell\varepsilon}^* - j(\varepsilon) \Lambda_{\tau-\varepsilon}^c \alpha_{\tau-\varepsilon}^* \left. \right\} \end{aligned}$$

where, if $\tau = \varepsilon_\tau$, then $\alpha_{*\tau-\varepsilon_\tau} = \alpha^*$.

Proof. We give the proof for part (ii). The proof of part (i) is similar. For $\tau \in (\varepsilon, \delta)$ and $\tau' \in [0, \delta)$, directly from Definition 2.9,

$$\begin{aligned} \Lambda_\tau \Gamma_{*\tau}^{\tau'} &= \begin{cases} 0 & \text{if } \tau \notin (\tau', \tau' + \varepsilon_{\tau'}) \\ \Lambda_\tau j(\tau - \tau' - 2^{m-1}\varepsilon) \Lambda([\tau', \tau' + 2^m\varepsilon]) j(2^{m-1}\varepsilon) \Lambda_{\tau'}^c, & \text{if } \tau \in [\tau' + 2^{m-1}\varepsilon, \tau' + 2^m\varepsilon] \\ & \text{with } m \geq 1, 2^m\varepsilon \leq \varepsilon_{\tau'} \end{cases} \end{aligned}$$

(so that, in particular, $\Lambda_\tau \Gamma_{*\tau}^{\tau'} \neq 0$ only for $\varepsilon_\tau < \varepsilon_{\tau'}$) and

$$j(\varepsilon) \Gamma_{*\tau-\varepsilon}^{\tau'} = \begin{cases} 0 & \text{if } \tau \notin (\tau', \tau' + \varepsilon_{\tau'}) \\ j(\varepsilon) \Lambda_{\tau'}^c, & \text{if } \tau = \tau' + \varepsilon \\ j(\tau - \tau' - 2^{m'-1}\varepsilon) \Lambda([\tau', \tau' + 2^{m'}\varepsilon]) j(2^{m'-1}\varepsilon) \Lambda_{\tau'}^c, & \text{if } \tau \in (\tau' + 2^{m'-1}\varepsilon, \tau' + 2^{m'}\varepsilon) \\ & \text{with } m' \geq 1, 2^{m'}\varepsilon \leq \varepsilon_{\tau'} \end{cases}$$

(so that, in particular, $j(\varepsilon) \Gamma_{*\tau-\varepsilon}^{\tau'} \neq 0$ only for $\varepsilon_\tau < \varepsilon_{\tau'}$ or $\tau = \tau' + \varepsilon_{\tau'}$).

- o If $\tau = \tau' + \varepsilon$ with $\tau' \in \varepsilon\mathbb{Z} \setminus 2\varepsilon\mathbb{Z}$ so that $\varepsilon_{\tau'} = \varepsilon$, then

$$\Lambda_\tau \left\{ \Gamma_{*\tau}^{\tau'} - j(\varepsilon) \Gamma_{*\tau-\varepsilon}^{\tau'} \right\} = -\Lambda_\tau j(\varepsilon) \Lambda_{\tau'}^c,$$

This gives the last term in the statement, for the case $\tau \in 2\varepsilon\mathbb{Z}$.

- o If $\tau = \tau' + \varepsilon$ with $\varepsilon_{\tau'} > \varepsilon$, then $m = 1$ and

$$\Lambda_\tau \left\{ \Gamma_{*\tau}^{\tau'} - j(\varepsilon) \Gamma_{*\tau-\varepsilon}^{\tau'} \right\} = \Lambda_\tau \Lambda([\tau', \tau' + 2\varepsilon]) j(\varepsilon) \Lambda_{\tau'}^c - \Lambda_\tau j(\varepsilon) \Lambda_{\tau'}^c = 0$$

since $\Lambda_\tau = \Lambda([\tau', \tau' + 2\varepsilon])$. This (together with the last o) gives the $\mathfrak{d}(\tau) = n$ case in the statement.

- o If $\tau = \tau' + 2^k\varepsilon$ for some $k > 0$ with $2^k\varepsilon < \varepsilon_{\tau'}$, then $m = k+1$ and $m' = k$. As $\varepsilon_\tau = 2^k\varepsilon$, we have $\Lambda_\tau = \Lambda([\tau', \tau' + 2^{k+1}\varepsilon])$ and

$$\begin{aligned} \Lambda_\tau \left\{ \Gamma_{*\tau}^{\tau'} - j(\varepsilon) \Gamma_{*\tau-\varepsilon}^{\tau'} \right\} &= \Lambda([\tau', \tau' + 2^{k+1}\varepsilon]) \{ j(2^k\varepsilon) - j(2^{k-1}\varepsilon) \Lambda([\tau', \tau' + 2^k\varepsilon]) j(2^{k-1}\varepsilon) \} \Lambda_{\tau'}^c \\ &= \Lambda_\tau j(2^{k-1}\varepsilon) \Lambda([\tau', \tau' + 2^k\varepsilon])^c j(2^{k-1}\varepsilon) \Lambda_{\tau'}^c \end{aligned}$$

In this case $\varepsilon < 2^k\varepsilon = \varepsilon_\tau$. This gives the first term in the statement, for the case $\tau \in 2\varepsilon\mathbb{Z}$.

- o If $\tau = \tau' + \varepsilon_{\tau'}$, with $\varepsilon_{\tau'} > \varepsilon$, then $\Gamma_{*\tau}^{\tau'} = 0$ and $2^{m'}\varepsilon = \varepsilon_{\tau'}$ so that

$$\Lambda_{\tau} \left\{ \Gamma_{*\tau}^{\tau'} - j(\varepsilon) \Gamma_{*\tau-\varepsilon}^{\tau'} \right\} = -\Lambda_{\tau} j \left(\frac{1}{2} \varepsilon_{\tau'} \right) \Lambda([\tau', \tau' + \varepsilon_{\tau'}]) j \left(\frac{1}{2} \varepsilon_{\tau'} \right) \Lambda_{\tau'}^c$$

In this case $\varepsilon_{\tau} > \varepsilon_{\tau'}$. This gives the ℓ^{th} term in the statement, with ℓ determined by $2^{\ell}\varepsilon = \varepsilon_{\tau'}$, for the case $\tau \in 2\varepsilon\mathbb{Z}$.

- o If $\tau \in (\tau', \tau' + \varepsilon_{\tau'})$ but $\tau \neq \tau' + 2^k\varepsilon$ for all $k \geq 0$ with $2^k\varepsilon \leq \varepsilon_{\tau'}$, then $m = m' \geq 1$ with $2^m\varepsilon = 2^{m'}\varepsilon \leq \varepsilon_{\tau'}$ and $\Gamma_{*\tau}^{\tau'} = j(\varepsilon) \Gamma_{*\tau-\varepsilon}^{\tau'}$.

Finally, we consider $\tau = \varepsilon$. Then

$$\gamma_{*\varepsilon} = \Gamma_{*\varepsilon}^{\varepsilon} \alpha_{\varepsilon}^* + \Gamma_{*\varepsilon}^0 \alpha^* = \Lambda_{\varepsilon}^c \alpha_{\varepsilon}^* + \Lambda([0, 2\varepsilon]) j(\varepsilon) \alpha^*$$

so that

$$\Lambda_{\varepsilon} \gamma_{*\varepsilon} = \Lambda([0, 2\varepsilon]) j(\varepsilon) \alpha^* \quad \Lambda_{\varepsilon} j(\varepsilon) \gamma_{*0} = \Lambda([0, 2\varepsilon]) j(\varepsilon) \alpha^*$$

and

$$\Lambda_{\tau} (\gamma_{*\tau} - j(\varepsilon) \gamma_{*\tau-\varepsilon}) = 0$$

□

Lemma E.17. *Assume that $\mathfrak{h} \equiv 1$. Then*

$$\begin{aligned} \sum_{\tau \in (0, \delta)} |\langle \gamma_{*\tau} - \gamma_{\tau}^*, \Lambda_{\tau} (\gamma_{\tau} - j(\varepsilon) \gamma_{\tau+\varepsilon}) \rangle| &\leq \frac{1}{4} \sum_{\tau' \in (0, \delta)} e^{-mc(\varepsilon_{\tau'})} |\Lambda_{\tau'}^c| \\ \sum_{\tau \in (0, \delta)} |\langle \gamma_{\tau} - \gamma_{*\tau}^*, \Lambda_{\tau} (\gamma_{*\tau} - j(\varepsilon) \gamma_{*\tau-\varepsilon}) \rangle| &\leq \frac{1}{4} \sum_{\tau' \in (0, \delta)} e^{-mc(\varepsilon_{\tau'})} |\Lambda_{\tau'}^c| \end{aligned}$$

Proof. We prove the first bound. Write $\varepsilon_{\tau} = 2^{\mathfrak{d}}\varepsilon$. (That is, $\mathfrak{d} = n - \mathfrak{d}(\tau)$.) By Lemma E.16(i), for $\mathfrak{d} > 0$,

$$\begin{aligned} \Lambda_{\tau} (\gamma_{\tau} - j(\varepsilon) \gamma_{\tau+\varepsilon}) &= \Lambda_{\tau} \left\{ j \left(\frac{1}{2} \varepsilon_{\tau} \right) \Lambda([\tau, \tau + \varepsilon_{\tau}])^c j \left(\frac{1}{2} \varepsilon_{\tau} \right) \Lambda_{\tau+\varepsilon}^c \alpha_{\tau+\varepsilon_{\tau}} \right. \\ &\quad - \sum_{\ell=1}^{\mathfrak{d}-1} j(2^{\ell-1}\varepsilon) \Lambda([\tau, \tau + 2^{\ell}\varepsilon]) j(2^{\ell-1}\varepsilon) \Lambda_{\tau+2^{\ell}\varepsilon}^c \alpha_{\tau+2^{\ell}\varepsilon} \\ &\quad \left. - j(\varepsilon) \Lambda_{\tau+\varepsilon}^c \alpha_{\tau+\varepsilon} \right\} \end{aligned}$$

and, if $\mathfrak{d} = 0$, then $\Lambda_{\tau} (\gamma_{\tau} - j(\varepsilon) \gamma_{\tau+\varepsilon}) = 0$.

For most terms that result from inserting this into the left hand side of the first claim, we shall use the bound

$$\begin{aligned} |\langle \gamma_{*\tau} - \gamma_{\tau}^*, \Lambda_{\tau} A \Lambda_{\tau'}^c \alpha_{\tau'} \rangle| &\leq \sup_{\mathbf{y} \in \Lambda_{\tau}} |\gamma_{*\tau}(\mathbf{y}) - \gamma_{\tau}(\mathbf{y})^*| N_0(\Lambda_{\tau} A \Lambda_{\tau'}^c; 1, \kappa_{\tau'}) |\Lambda_{\tau'}^c| \\ &\leq 80 e^{K_j} R(2\varepsilon_{\tau}) N_0(\Lambda_{\tau} A \Lambda_{\tau'}^c; 1, \kappa_{\tau'}) |\Lambda_{\tau'}^c| \end{aligned}$$

by Proposition E.11(i). Using this bound, we have, for each $\tau \in (0, \delta)$ with $\tau \in 2\varepsilon\mathbb{Z}$ and each $1 \leq \ell \leq \mathfrak{d} - 1$,

$$\begin{aligned}
& |\langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau j(2^{\ell-1}\varepsilon) \Lambda([\tau, \tau + 2^\ell\varepsilon]) j(2^{\ell-1}\varepsilon) \Lambda_{\tau+2^\ell\varepsilon}^c \alpha_{\tau+2^\ell\varepsilon} \rangle| \\
& \leq 80 e^{K_j} R(2\varepsilon_\tau) N_0(\Lambda_\tau j(2^{\ell-1}\varepsilon) \Lambda([\tau, \tau + 2^\ell\varepsilon]) j(2^{\ell-1}\varepsilon) \\
& \quad \times \Lambda_{\tau+2^\ell\varepsilon}^c; 1, \kappa_{\tau+2^\ell\varepsilon}) |\Lambda_{\tau+2^\ell\varepsilon}^c| \\
& \leq 320 e^{K_j} R(2\varepsilon_\tau)^2 e^{K_j 2^\ell \varepsilon} e^{-4md(\Lambda_\tau, \Lambda_{\tau+2^\ell\varepsilon}^c)} |\Lambda_{\tau+2^\ell\varepsilon}^c| \\
& \leq 320 R(\varepsilon_\tau)^2 e^{2K_j} e^{-4mc(2^{\ell+1}\varepsilon)} |\Lambda_{\tau+2^\ell\varepsilon}^c| \\
& \leq \frac{1}{8} e^{-mc(2^\ell\varepsilon)} |\Lambda_{\tau+2^\ell\varepsilon}^c| \quad \text{by (F.4a) and (F.6b)}
\end{aligned}$$

by Lemma G.5(ii) with d replaced by 0, $\delta_1 = 0$, $\delta_2 = \frac{m}{3}d$, $\delta = 4md$, $\tilde{\delta} = 5md$, $\kappa = \kappa_{\tau+2^\ell\varepsilon}$, $R = 4R(2\varepsilon_\tau)$, $O_2 = \Lambda_\tau = L_1$, $L_2 = \Lambda([\tau, \tau + 2^\ell\varepsilon])$ and $L_3 = \Lambda_{\tau+2^\ell\varepsilon}^c$.

We also have, for each $\tau \in 2\varepsilon\mathbb{Z} \cap (0, \delta)$,

$$\begin{aligned}
& |\langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau j(\varepsilon) \Lambda_{\tau+\varepsilon}^c \alpha_{\tau+\varepsilon} \rangle| \\
& \leq 80 e^{K_j} R(2\varepsilon_\tau) N_0(\Lambda_\tau j(\varepsilon) \Lambda_{\tau+\varepsilon}^c; 1, \kappa_{\tau+\varepsilon}) |\Lambda_{\tau+\varepsilon}^c| \\
& \leq 320 e^{K_j} R(2\varepsilon_\tau)^2 e^{K_j \varepsilon} e^{-4mc(2\varepsilon)} |\Lambda_{\tau+\varepsilon}^c| \\
& \leq \frac{1}{8} e^{-mc(\varepsilon)} |\Lambda_{\tau+\varepsilon}^c|
\end{aligned}$$

by Lemma G.5(ii) with d replaced by 0, $\delta_1 = 0$, $\delta_2 = \frac{m}{3}d$, $\delta = 4md$, $\tilde{\delta} = 5md$, $\kappa = \kappa_{\tau+\varepsilon}$, $R = 4R(2\varepsilon_\tau)$, $O_2 = \Lambda_\tau = L_1 = L_2$ and $L_3 = \Lambda_{\tau+\varepsilon}^c$, followed by (F.4a) and (F.6b).

We still have the “ $\Lambda([\tau, \tau + \varepsilon_\tau])^c = \Lambda_{\tau+\frac{1}{2}\varepsilon_\tau}^c$ ” terms to deal with. For these, we use

$$\begin{aligned}
& \left| \left\langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau j\left(\frac{1}{2}\varepsilon_\tau\right) \Lambda_{\tau+\frac{1}{2}\varepsilon_\tau}^c j\left(\frac{1}{2}\varepsilon_\tau\right) \Lambda_{\tau+\varepsilon_\tau}^c \alpha_{\tau+\varepsilon_\tau} \right\rangle \right| \\
& \leq \sum_{\mathbf{x}, \mathbf{y}, \mathbf{z} \in X} |\gamma_{*\tau}(\mathbf{x}) - \gamma_\tau(\mathbf{x})^*| \Lambda_\tau(\mathbf{x}) j\left(\frac{1}{2}\varepsilon_\tau\right) (\mathbf{x}, \mathbf{y}) \Lambda_{\tau+\frac{1}{2}\varepsilon_\tau}^c(\mathbf{y}) j\left(\frac{1}{2}\varepsilon_\tau\right) (\mathbf{y}, \mathbf{z}) \\
& \quad \times \Lambda_{\tau+\varepsilon_\tau}^c(\mathbf{z}) |\alpha_{\tau+\varepsilon_\tau}(\mathbf{z})| \\
& \leq \sum_{\mathbf{x}, \mathbf{y}, \mathbf{z} \in X} 320 e^{K_j} R(\varepsilon_\tau)^2 e^{\frac{m}{3}d(\mathbf{x}, \mathbf{z})} \Lambda_\tau(\mathbf{x}) j\left(\frac{1}{2}\varepsilon_\tau\right) (\mathbf{x}, \mathbf{y}) \\
& \quad \times \Lambda_{\tau+\frac{1}{2}\varepsilon_\tau}^c(\mathbf{y}) j\left(\frac{1}{2}\varepsilon_\tau\right) (\mathbf{y}, \mathbf{z}) \Lambda_{\tau+\varepsilon_\tau}^c(\mathbf{z})
\end{aligned}$$

by Proposition E.11(i), and the fact, from Lemma B.1(ii), that

$$|\alpha_{\tau+\varepsilon_\tau}(\mathbf{z})| \leq \kappa_{\tau+\varepsilon_\tau}(\mathbf{z}) \leq 4R(\varepsilon_\tau) e^{\frac{m}{3}d(\mathbf{z}, \Lambda([\tau, \tau + \varepsilon_\tau]))} \leq 4R(\varepsilon_\tau) e^{\frac{m}{3}d(\mathbf{x}, \mathbf{z})}$$

when $\mathbf{x} \in \Lambda_\tau \subset \Lambda([\tau, \tau + \varepsilon_\tau])$. For all $\mathbf{x}, \mathbf{y}, \mathbf{z}$ for which the summand does not vanish,

$$\begin{aligned}
e^{\frac{m}{3}d(\mathbf{x}, \mathbf{z})} & \leq e^{-4md(\Lambda_\tau, \Lambda_{\tau+\frac{1}{2}\varepsilon_\tau}^c)} e^{4md(\mathbf{x}, \mathbf{y})} e^{\frac{m}{3}d(\mathbf{x}, \mathbf{z})} \\
& \leq e^{-4md(\Lambda_\tau, \Lambda_{\tau+\frac{1}{2}\varepsilon_\tau}^c)} e^{5md(\mathbf{x}, \mathbf{y})} e^{5md(\mathbf{y}, \mathbf{z})}
\end{aligned}$$

and we have

$$\begin{aligned}
& \left| \left\langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau j \left(\frac{1}{2} \varepsilon_\tau \right) \Lambda_{\tau + \frac{1}{2} \varepsilon_\tau}^c j \left(\frac{1}{2} \varepsilon_\tau \right) \Lambda_{\tau + \varepsilon_\tau}^c \alpha_{\tau + \varepsilon_\tau} \right\rangle \right| \\
& \leq \sum_{\mathbf{y} \in X} 320 e^{K_j} R(\varepsilon_\tau)^2 e^{-4m d(\Lambda_\tau, \Lambda_{\tau + \frac{1}{2} \varepsilon_\tau}^c)} \|j\left(\frac{1}{2} \varepsilon_\tau\right)\| \|\Lambda_{\tau + \frac{1}{2} \varepsilon_\tau}^c(\mathbf{y})\| \|j\left(\frac{1}{2} \varepsilon_\tau\right)\| \\
& \leq 320 e^{K_j} R(\varepsilon_\tau)^2 e^{K_j \varepsilon_\tau} e^{-4m c(\varepsilon_\tau)} \left| \Lambda_{\tau + \frac{1}{2} \varepsilon_\tau}^c \right| \\
& \leq \frac{1}{8} e^{-m c(\frac{1}{2} \varepsilon_\tau)} \left| \Lambda_{\tau + \frac{1}{2} \varepsilon_\tau}^c \right|
\end{aligned}$$

by (F.4a) and (F.6b). All together

$$\begin{aligned}
& \sum_{\tau \in (0, \delta)} |\langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon) \gamma_{\tau + \varepsilon}) \rangle| \\
& \leq \sum_{\tau \in 2\varepsilon \mathbb{Z} \cap (0, \delta)} \left\{ \frac{1}{8} e^{-m c(\frac{1}{2} \varepsilon_\tau)} \left| \Lambda_{\tau + \frac{1}{2} \varepsilon_\tau}^c \right| + \sum_{\ell=0}^{n-\mathfrak{d}(\tau)-1} \frac{1}{8} e^{-m c(2^\ell \varepsilon)} \left| \Lambda_{\tau + 2^\ell \varepsilon}^c \right| \right\} \\
& \leq \sum_{\tau' \in (0, \delta)} \frac{1}{8} e^{-m c(\varepsilon_{\tau'})} \left| \Lambda_{\tau'}^c \right| \left[\# \left\{ \tau \in (0, \delta) \mid \tau + \frac{1}{2} \varepsilon_\tau = \tau' \right\} \right. \\
& \quad \left. + \# \left\{ (\tau, \ell) \mid \tau \in (0, \delta), 0 \leq \ell \leq n - \mathfrak{d}(\tau) - 1, \tau + 2^\ell \varepsilon = \tau' \right\} \right]
\end{aligned}$$

Here, we have used that $\tau + 2^\ell \varepsilon \in (0, \delta)$ for all $\tau \in (0, \delta)$ and $\ell < n - \mathfrak{d}(\tau)$. On the other hand, given any $\tau' \in (0, \delta)$ there is at most one $\tau \in (0, \delta)$ with $\tau + \frac{1}{2} \varepsilon_\tau = \tau'$ (because it is necessary that $\frac{1}{2} \varepsilon_\tau = \varepsilon_{\tau'}$), and there is at most one pair (τ, ℓ) with $\tau \in (0, \delta)$, $0 \leq \ell \leq n - \mathfrak{d}(\tau) - 1$ and $\tau + 2^\ell \varepsilon = \tau'$ (because it is necessary that $2^\ell \varepsilon = \varepsilon_{\tau'}$). So we end up with

$$\sum_{\tau \in (0, \delta)} |\langle \gamma_{*\tau} - \gamma_\tau^*, \Lambda_\tau (\gamma_\tau - j(\varepsilon) \gamma_{\tau + \varepsilon}) \rangle| \leq \sum_{\tau' \in (0, \delta)} \frac{1}{4} e^{-m c(\varepsilon_{\tau'})} \left| \Lambda_{\tau'}^c \right|$$

□

E.5. Error Terms in the Recursive Construction

Now assume that \mathfrak{S} is a hierarchy for scale 2δ , preceded by hierarchies $(\mathfrak{S}_1, \mathfrak{S}_2)$ for scale δ . Let $\varepsilon = 2^{-n}\delta$ with $n \geq \max\{\text{depth}(\mathfrak{S}_1), \text{depth}(\mathfrak{S}_2)\}$. For simplicity we again write $\Lambda = \Lambda_{\mathfrak{S}}$. As in (5.19) we set

$$\begin{aligned}
\partial_{\mathfrak{c}} \Gamma_{*\tau} &= \begin{cases} 0 & \text{if } \tau \in [0, \delta) \text{ or } \tau = 2\delta \\ \Lambda j_\delta & \text{if } \tau = \delta \\ \partial \Gamma_{*\tau} + \Gamma_{*\tau-\delta}^0(\mathfrak{S}_2) \Lambda j_\delta & \text{if } \tau \in (\delta, 2\delta) \end{cases} \\
\partial_{\mathfrak{c}} \Gamma_\tau &= \begin{cases} \partial \Gamma_\tau + \Gamma_{*\tau}^\delta(\mathfrak{S}_1) \Lambda j_\delta & \text{if } \tau \in (0, \delta) \\ \Lambda j_\delta & \text{if } \tau = \delta \\ 0 & \text{if } \tau \in (\delta, 2\delta] \text{ or } \tau = 0 \end{cases}
\end{aligned}$$

with $j_\delta = j(\delta) - j_\epsilon(\delta)$ and, as in Proposition 3.6,

$$\begin{aligned}\partial\Gamma_{*\tau} &= j(\tau - \delta - 2^{m-1}\varepsilon)\Lambda([\delta, \delta + 2^m\varepsilon])^c j(2^{m-1}\varepsilon)\Lambda j(\delta) \\ &\quad \text{for } \tau \in [\delta + 2^{m-1}\varepsilon, \delta + 2^m\varepsilon] \\ \partial\Gamma_\tau &= j(\delta - 2^{m-1}\varepsilon - \tau)\Lambda([\delta - 2^m\varepsilon, \delta])^c j(2^{m-1}\varepsilon)\Lambda j(\delta) \\ &\quad \text{for } \tau \in (\delta - 2^m\varepsilon, \delta - 2^{m-1}\varepsilon]\end{aligned}$$

with $1 \leq m \leq n$.

Lemma E.18.

$$\begin{aligned}\mathcal{N}_{2m} \left(\partial_\epsilon \Gamma_{*\tau}; e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) &\leq 4e^{2K_j} R(2\delta) \left(\delta e^{-m\epsilon} + e^{-m\epsilon(\delta)} \right) \\ \mathcal{N}_{2m} \left(\partial_\epsilon \Gamma_\tau; e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{2\delta} \right) &\leq 4e^{2K_j} R(2\delta) \left(\delta e^{-m\epsilon} + e^{-m\epsilon(\delta)} \right)\end{aligned}$$

Proof. We prove the first bound.

In the case $\tau = \delta$ we use Remark G.4(i), Lemma B.1(i) and Lemma 3.21(iii) to see that

$$\begin{aligned}\mathcal{N}_{2m} \left(\partial_\epsilon \Gamma_{*\delta}; e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\ &= \mathcal{N}_{2m} \left(\Lambda j_\delta; e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) = \mathcal{N}_{2m} \left(\Lambda j_\delta; 1, \kappa_{*0} \right) \\ &\leq \|j_\delta\| 2R(2\delta) \sup_{\mathbf{x}, \mathbf{y} \in X} \left(e^{-md(\mathbf{x}, \mathbf{y})} \frac{\kappa_{*0}(\mathbf{y})}{\kappa_{*0}(\mathbf{x})} \right) \\ &\leq 4\delta K_j R(2\delta) e^{K_j \delta} e^{-m\epsilon}\end{aligned}$$

Now let $\tau \in (\delta, 2\delta)$. There is a unique $1 \leq m \leq n$ such that $\tau \in [\delta + 2^{m-1}\varepsilon, \delta + 2^m\varepsilon]$. We estimate $\mathcal{N}_{2m}(\partial\Gamma_{*\tau}; e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0})$ and $\mathcal{N}_{2m}(\Gamma_{*\tau-\delta}^0(\mathfrak{S}_2) \Lambda j_\delta; e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0})$ separately.

By [4, (IV.1)]

$$\begin{aligned}\mathcal{N}_{2m} \left(\partial\Gamma_{*\tau}; e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\ &= \mathcal{N}_{2m} \left(j(\tau - \delta - 2^{m-1}\varepsilon) \Lambda([\delta, \delta + 2^m\varepsilon])^c j(2^{m-1}\varepsilon) \Lambda j(\delta); e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\ &\leq \mathcal{N}_{2m} \left(j(\tau - \delta - 2^{m-1}\varepsilon); e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)} \right) \\ &\quad \times \mathcal{N}_{2m} \left(\Lambda([\delta, \delta + 2^m\varepsilon])^c j(2^{m-1}\varepsilon) \Lambda j(\delta); e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \tag{E.9}\end{aligned}$$

Using Remark G.4(i), we bound the first factor on the right hand side of (E.9) by

$$\begin{aligned}\mathcal{N}_{2m} \left(j(\tau - \delta - 2^{m-1}\varepsilon); e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}, e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)} \right) \\ &\leq \|j(\tau - \delta - 2^{m-1}\varepsilon)\| \sup_{\mathbf{x}, \mathbf{y} \in X} e^{-\frac{3}{2}md(\mathbf{x}, \mathbf{y})} \frac{e^{-\frac{3}{2}m d(\mathbf{y}, \Lambda)}}{e^{-\frac{3}{2}m d(\mathbf{x}, \Lambda)}} \\ &\leq e^{K_j(\tau - \delta - 2^{m-1}\varepsilon)}\end{aligned}$$

The second factor on the right hand side of (E.9) is bounded by

$$\begin{aligned} \mathcal{N}_{2m} & \left(\Lambda ([\delta, \delta + 2^m \varepsilon])^c j(2^{m-1} \varepsilon) \Lambda j(\delta); e^{-\frac{3}{2} m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\ & \leq 4R(2\delta) e^{-md(\Lambda, \Lambda([\delta, \delta + 2^m \varepsilon]))^c} \|j(2^{m-1} \varepsilon)\| \|j(\delta)\| \\ & \leq 4e^{K_j(\delta + 2^{m-1} \varepsilon)} R(2\delta) e^{-mc(2^m \varepsilon)} \end{aligned}$$

Here we used Lemma G.5(ii) with d replaced by $2md$ and

$$\begin{aligned} L_1 & = \Lambda ([\delta, \delta + 2^m \varepsilon])^c, \quad L_2 = \Lambda, \quad L_3 = X, \quad O_1 = O_2 = \Lambda \\ \delta_1 & = \frac{3m}{2}d, \quad \delta_2 = \frac{m}{3}d, \quad \delta = md, \quad \tilde{d} = 5md, \quad \kappa = \kappa_{*0}, \quad R = 4R(2\delta) \end{aligned}$$

Putting the last two estimates together we get

$$\mathcal{N}_{2m} \left(\partial \Gamma_{*\tau}; e^{-\frac{3}{2} m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \leq 4e^{2K_j \delta} R(2\delta) e^{-mc(2^m \varepsilon)} \leq 4e^{K_j} R(2\delta) e^{-mc(\delta)}$$

Similarly

$$\begin{aligned} & \mathcal{N}_{2m} \left(\Gamma_{*\tau-\delta}^0 (\mathfrak{S}_2) \Lambda j_\delta; e^{-\frac{3}{2} m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\ & = \mathcal{N}_{2m} \left(j(\tau - \delta - 2^{m-1} \varepsilon) \Lambda ([\delta, \delta + 2^m \varepsilon]) j(2^{m-1} \varepsilon) \Lambda j_\delta; e^{-\frac{3}{2} m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\ & \leq \mathcal{N}_{2m} \left(j(\tau - \delta - 2^{m-1} \varepsilon); e^{-\frac{3}{2} m d(\mathbf{x}, \Lambda)}, e^{-\frac{3}{2} m d(\mathbf{x}, \Lambda)} \right) \\ & \quad \times \mathcal{N}_{2m} \left(\Lambda ([\delta, \delta + 2^m \varepsilon]) j(2^{m-1} \varepsilon) \Lambda j_\delta; e^{-\frac{3}{2} m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\ & \leq e^{K_j(\tau - \delta - 2^{m-1} \varepsilon)} 4R(2\delta) \|j(2^{m-1} \varepsilon)\| \|j_\delta\| \leq 4e^{K_j \tau} R(2\delta) \delta K_j e^{-mc} \\ & \leq 4K_j e^{K_j} R(2\delta) \delta e^{-mc} \end{aligned}$$

□

Remark E.19. (a) Let $\tau \in (0, \delta]$ and $t > 0$. If $[\tau - t, \tau] \cap \varepsilon\mathbb{Z} = \emptyset$, then $\partial \Gamma_{\tau-t} = j(t) \partial \Gamma_\tau$.

(b) Let $\tau \in [0, \delta)$ and $t > 0$. If $(\tau, \tau + t] \cap \varepsilon\mathbb{Z} = \emptyset$, then $\partial \Gamma_{*\tau+t} = j(t) \partial \Gamma_{*\tau}$.

Proof. For all $\tau \in (0, \delta]$

$$\partial \Gamma_\tau \beta = \Gamma_{\mathfrak{S}}(\tau; \vec{\alpha}, \beta) - \Gamma_{\mathfrak{S}_1}(\tau; \vec{\alpha}_l, \Lambda_{\mathfrak{S}} j(\delta) \beta + \Lambda_{\mathfrak{S}}^c \alpha_\delta)$$

Apply Lemma E.14. □

Lemma E.20. Write $\partial_j \Gamma_{*\tau} = \partial_c \Gamma_{*\tau} - j(\varepsilon) \partial_c \Gamma_{*\tau-\varepsilon}$.

- (i) $\partial_j \Gamma_{*\tau} = 0$ if $\tau \in (0, 2\delta] \setminus \{\delta, \delta + \varepsilon, \delta + \varepsilon_1, \dots, \delta + \frac{\delta}{2}, 2\delta\}$
 Furthermore

$$\begin{aligned} \partial_j \Gamma_{*\delta} & = \Lambda j_\delta \\ \partial_j \Gamma_{*\delta+\varepsilon} & = \Lambda ([\delta, \delta + 2\varepsilon])^c j(\varepsilon) \Lambda j_\varepsilon(\delta) \\ \partial_j \Gamma_{*\delta+2^\ell \varepsilon} & = \Lambda ([\delta, \delta + 2^{\ell+1} \varepsilon])^c j(2^\ell \varepsilon) \Lambda j_\varepsilon(\delta) - j(2^{\ell-1} \varepsilon) \\ & \quad \times \Lambda ([\delta, \delta + 2^\ell \varepsilon])^c j(2^{\ell-1} \varepsilon) \Lambda j_\varepsilon(\delta) \quad \text{for } \ell = 1, \dots, n-1 \\ \partial_j \Gamma_{*2\delta} & = -j(\delta) \Lambda j_\delta - j\left(\frac{\delta}{2}\right) \Lambda ([\delta, 2\delta])^c j\left(\frac{\delta}{2}\right) \Lambda j_\varepsilon(\delta) \end{aligned}$$

(ii)

$$\sum_{\tau \in (\delta, 2\delta)} \mathcal{N}_{3m} \left(\partial_j \Gamma_{*\tau}; e^{-\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) + \mathcal{N}_{3m} \left(\partial_j \Gamma_{*2\delta} + j(\delta) \Lambda j_\delta; e^{-\frac{m}{2} d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \leq e^{-\frac{1}{2} m \mathfrak{c}(\delta)}$$

Proof. (i) If $\tau \in (\delta, 2\delta)$ and $m = \min \left\{ m' \mid \tau \in (\delta, \delta + 2^{m'} \varepsilon) \right\}$ then, by construction

$$\begin{aligned} \partial_{\mathfrak{c}} \Gamma_{*\tau} &= \partial \Gamma_{*\tau} + \Gamma_{*\tau-\delta}^0(\mathfrak{S}_2) \Lambda j_\delta \\ &= j(\tau - \delta - 2^{m-1} \varepsilon) \Lambda ([\delta, \delta + 2^m \varepsilon])^c j(2^{m-1} \varepsilon) \Lambda j(\delta) \\ &\quad + j(\tau - \delta - 2^{m-1} \varepsilon) \Lambda ([\delta, \delta + 2^m \varepsilon]) j(2^{m-1} \varepsilon) \Lambda j_\delta \\ &= j(\tau - \delta) \Lambda j(\delta) - j(\tau - \delta - 2^{m-1} \varepsilon) \Lambda ([\delta, \delta + 2^m \varepsilon]) j(2^{m-1} \varepsilon) \Lambda j(\delta) \\ &\quad + j(\tau - \delta - 2^{m-1} \varepsilon) \Lambda ([\delta, \delta + 2^m \varepsilon]) j(2^{m-1} \varepsilon) \Lambda j_\delta \\ &= j(\tau - \delta) \Lambda j(\delta) - j(\tau - \delta - 2^{m-1} \varepsilon) \Lambda ([\delta, \delta + 2^m \varepsilon]) j(2^{m-1} \varepsilon) \Lambda j_{\mathfrak{c}}(\delta) \end{aligned}$$

Consequently, if $\tau \in (\delta, 2\delta)$ is not of the form $\delta + 2^\ell \varepsilon$ for any $\ell = 0, \dots, n$, then $\partial_{\mathfrak{c}} \Gamma_{*\tau} - j(\varepsilon) \partial_{\mathfrak{c}} \Gamma_{*\tau-\varepsilon} = 0$. If $\tau = \delta + 2^\ell \varepsilon$ for some $\ell = 1, \dots, n-1$, then

$$\begin{aligned} \partial_{\mathfrak{c}} \Gamma_{*\tau} - j(\varepsilon) \partial_{\mathfrak{c}} \Gamma_{*\tau-\varepsilon} &= -\Lambda ([\delta, \delta + 2^{\ell+1} \varepsilon]) j(2^\ell \varepsilon) \Lambda j_{\mathfrak{c}}(\delta) \\ &\quad + j(2^{\ell-1} \varepsilon) \Lambda ([\delta, \delta + 2^\ell \varepsilon]) j(2^{\ell-1} \varepsilon) \Lambda j_{\mathfrak{c}}(\delta) \\ &= \Lambda ([\delta, \delta + 2^{\ell+1} \varepsilon])^c j(2^\ell \varepsilon) \Lambda j_{\mathfrak{c}}(\delta) \\ &\quad - j(2^{\ell-1} \varepsilon) \Lambda ([\delta, \delta + 2^\ell \varepsilon])^c j(2^{\ell-1} \varepsilon) \Lambda j_{\mathfrak{c}}(\delta) \end{aligned}$$

If $\tau \in (0, \delta)$, both $\partial_{\mathfrak{c}} \Gamma_{*\tau}$ and $j(\varepsilon) \partial_{\mathfrak{c}} \Gamma_{*\tau-\varepsilon}$ are zero.

For $\tau = \delta$, we have $\partial_{\mathfrak{c}} \Gamma_{*\delta} - j(\varepsilon) \partial_{\mathfrak{c}} \Gamma_{*\delta-\varepsilon} = \Lambda j_\delta$.

For $\tau = \delta + \varepsilon$,

$$\begin{aligned} \partial_{\mathfrak{c}} \Gamma_{*\delta+\varepsilon} - j(\varepsilon) \partial_{\mathfrak{c}} \Gamma_{*\delta} &= j(\varepsilon) \Lambda j(\delta) - \Lambda ([\delta, \delta + 2\varepsilon]) j(\varepsilon) \Lambda j_{\mathfrak{c}}(\delta) - j(\varepsilon) \Lambda j_\delta \\ &= \Lambda ([\delta, \delta + 2\varepsilon])^c j(\varepsilon) \Lambda j_{\mathfrak{c}}(\delta) \end{aligned}$$

For $\tau = 2\delta$,

$$\begin{aligned} \partial_{\mathfrak{c}} \Gamma_{*2\delta} - j(\varepsilon) \partial_{\mathfrak{c}} \Gamma_{*2\delta-\varepsilon} &= -j(\delta) \Lambda j(\delta) + j\left(\frac{\delta}{2}\right) \Lambda ([\delta, 2\delta]) j\left(\frac{\delta}{2}\right) \Lambda j_{\mathfrak{c}}(\delta) \\ &= -j(\delta) \Lambda j_\delta - j\left(\frac{\delta}{2}\right) \Lambda ([\delta, 2\delta])^c j\left(\frac{\delta}{2}\right) \Lambda j_{\mathfrak{c}}(\delta) \end{aligned}$$

(ii) By part (i),

$$\begin{aligned} \sum_{\tau \in (\delta, 2\delta)} \mathcal{N}_{3m} \left(\partial_j \Gamma_{*\tau}; e^{-\frac{1}{2} m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\ + \mathcal{N}_{3m} \left(\partial_j \Gamma_{*2\delta} + j(\delta) \Lambda j_\delta; e^{-\frac{1}{2} m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \end{aligned}$$

$$\begin{aligned}
&\leq \sum_{\ell=0}^{n-1} \mathcal{N}_{3m} \left(\Lambda \left([\delta, \delta + 2^{\ell+1}\varepsilon] \right)^c j(2^\ell\varepsilon) \Lambda j_c(\delta); e^{-\frac{1}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\
&+ \sum_{\ell=1}^n \mathcal{N}_{3m} \left(j(2^{\ell-1}\varepsilon) \Lambda \left([\delta, \delta + 2^\ell\varepsilon] \right)^c j(2^{\ell-1}\varepsilon) \Lambda j_c(\delta); e^{-\frac{1}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right)
\end{aligned} \tag{E.10}$$

To bound the terms of the first sum on the right hand side of (E.10), we use Lemma G.5.ii with d replaced by $3md$ and

$$\begin{aligned}
L_1 &= \Lambda \left([\delta, \delta + 2^{\ell+1}\varepsilon] \right)^c, \quad L_2 = \Lambda, \quad L_3 = X, \quad O_1 = O_2 = \Lambda \\
\delta_1 &= \frac{m}{2}d, \quad \delta_2 = \frac{m}{3}d, \quad \delta = md, \quad \tilde{d} = 5md, \quad \kappa = \kappa_{*0}, \quad R = 4R(2\delta)
\end{aligned}$$

to get

$$\begin{aligned}
&\mathcal{N}_{3m} \left(\Lambda \left([\delta, \delta + 2^{\ell+1}\varepsilon] \right)^c j(2^\ell\varepsilon) \Lambda j_c(\delta); e^{-\frac{1}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\
&\leq 4R(2\delta) e^{-md(\Lambda, \Lambda([\delta, \delta + 2^{\ell+1}\varepsilon]))} \|j(2^\ell\varepsilon)\| \|j_c(\delta)\| \\
&\leq 4e^{K_j(\delta+2^\ell\varepsilon)} R(2\delta) e^{-mc(2^{\ell+1}\varepsilon)}
\end{aligned} \tag{E.11}$$

To bound the terms of the second sum on the right hand side of (E.10), we use [4, (IV.1)] to see that

$$\begin{aligned}
&\mathcal{N}_{3m} \left(j(2^{\ell-1}\varepsilon) \Lambda \left([\delta, \delta + 2^\ell\varepsilon] \right)^c j(2^{\ell-1}\varepsilon) \Lambda j_c(\delta); e^{-\frac{1}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\
&\leq \mathcal{N}_{3m} \left(j(2^{\ell-1}\varepsilon); e^{-\frac{1}{2}m d(\mathbf{x}, \Lambda)}, e^{-\frac{1}{2}m d(\mathbf{x}, \Lambda)} \right) \\
&\times \mathcal{N}_{3m} \left(\Lambda \left([\delta, \delta + 2^\ell\varepsilon] \right)^c j(2^{\ell-1}\varepsilon) \Lambda j_c(\delta); e^{-\frac{1}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right)
\end{aligned}$$

Remark G.4(i) gives the bound

$$\begin{aligned}
&\mathcal{N}_{3m} \left(j(2^{\ell-1}\varepsilon); e^{-\frac{1}{2}m d(\mathbf{x}, \Lambda)}, e^{-\frac{1}{2}m d(\mathbf{x}, \Lambda)} \right) \\
&\leq \|j(2^{\ell-1}\varepsilon)\| \sup_{\mathbf{x}, \mathbf{y} \in X} e^{-\frac{1}{2}md(\mathbf{x}, \mathbf{y})} \frac{e^{-\frac{1}{2}m d(\mathbf{y}, \Lambda)}}{e^{-\frac{1}{2}m d(\mathbf{x}, \Lambda)}} \\
&\leq e^{K_j 2^{\ell-1}\varepsilon}
\end{aligned}$$

for the first factor on the right hand side. (E.11), with ℓ replaced by $\ell - 1$, shows that the second factor is bounded by $4e^{K_j(\delta+2^{\ell-1}\varepsilon)} R(2\delta) e^{-mc(2^\ell\varepsilon)}$. Consequently

$$\begin{aligned}
&\mathcal{N}_{3m} \left(j(2^{\ell-1}\varepsilon) \Lambda \left([\delta, \delta + 2^\ell\varepsilon] \right)^c j(2^{\ell-1}\varepsilon) \Lambda j_c(\delta); e^{-\frac{1}{2}m d(\mathbf{x}, \Lambda)}, \kappa_{*0} \right) \\
&\leq 4e^{K_j(\delta+2^\ell\varepsilon)} R(2\delta) e^{-mc(2^\ell\varepsilon)}
\end{aligned} \tag{E.12}$$

Inserting (E.11) and (E.12),

$$(E.10) \leq 4e^{K_j 2\delta} R(2\delta) \left\{ \sum_{\ell=0}^{n-1} e^{-mc(2^{\ell+1}\varepsilon)} + \sum_{\ell=1}^n e^{-mc(2^\ell\varepsilon)} \right\} \leq e^{-\frac{1}{2}mc(\delta)}$$

by (F.4d) and (F.6b). \square

Appendix F. Properties of the Various Constants

The model under consideration is determined by the kinetic energy $h = \nabla^* \mathcal{H} \nabla$, the two-body potential $2v(\mathbf{x}, \mathbf{y})$, the temperature $T > 0$, and the chemical potential μ . We are assuming that both \mathcal{H} and v are exponentially decaying. That is, there is a “mass” $m > 0$ such that

$$\begin{aligned} D_{\mathcal{H}} &= \sum_{\substack{\mathbf{x} \in X \\ 1 \leq i, j \leq d}} e^{6m d(\mathbf{x}, 0)} |\mathcal{H}(b_i(0), b_j(\mathbf{x}))| \\ \|v\| &= \sup_{\mathbf{x} \in X} \sum_{\mathbf{y} \in X} e^{5m d(\mathbf{x}, \mathbf{y})} |v(\mathbf{x}, \mathbf{y})| \end{aligned}$$

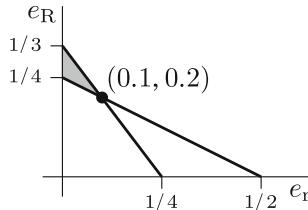

are finite. See (2.16) and (2.5). We have also assumed that there are constants $0 < c_{\mathcal{H}} < C_{\mathcal{H}}$ such that all of the eigenvalues of \mathcal{H} lie between $c_{\mathcal{H}}$ and $C_{\mathcal{H}}$. In Lemmas 3.21 and D.1, we introduced constants K_j, K'_j (depending only on $D_{\mathcal{H}}, m$ and μ) for bounds on the semigroup $j(t) = e^{-t(h-\mu)}$. Our bounds are uniform for two-body potentials lying in the annulus $\frac{1}{4}\mathfrak{v} \leq \|v\| \leq \frac{1}{2}\mathfrak{v}$ and for which the lowest eigenvalue obeys $v_1 \geq c_v \|v\|$. See Hypothesis 2.14. The constant $\mathfrak{v} > 0$ must be sufficiently small and the constant $c_v \in (0, 1)$ is arbitrary. The chemical potential μ is required to obey $|\mu| \leq \max\{K_\mu \mathfrak{v}^{e_\mu}, 1\}$ with strictly positive K_μ and $\frac{1}{2} < e_\mu \leq 1$.

For the bounds and the construction of the large field/small field decomposition, we introduced, in (2.17)–(2.20), the cutoff functions

$$\begin{aligned} r(t) &= \left(\frac{1}{t\mathfrak{v}}\right)^{e_r} & R(t) &= \left(\frac{1}{t\mathfrak{v}}\right)^{e_R} r(t) & R'(t) &= \left(\frac{1}{t}\right)^{e_{R'}} r(t) \\ \mathfrak{c} &= \log^2 \frac{1}{\mathfrak{v}} & \mathfrak{c}(t) &= \log^2 \frac{1}{t\mathfrak{v}} & \ell(t) &= \left(\frac{1}{t\mathfrak{v}}\right)^{e_\ell} \end{aligned} \tag{F.1}$$

with strictly positive exponents $e_r, e_R, e_{R'}$ and e_ℓ that obey

$$\begin{aligned} 3e_R + 4e_r &< 1 & 1 \leq 4e_R + 2e_r & 2(e_R + e_r) < e_\mu \leq 1 \\ e_{R'} + e_r &< 1 & \frac{1}{2} \leq e_{R'} & e_\ell < 2e_r \end{aligned} \tag{F.2}$$

Our main results Theorems 2.16 and 2.18 apply when \mathfrak{v} and the time interval length θ are sufficiently small. The precise restrictions are determined by a number of technical conditions that are specified in Hypothesis F.7 at the end of this appendix.

Clearly

$$R(2t) \leq R(t) \leq 2R(2t) \tag{F.3a}$$

$$r(2t) \leq r(t) \leq 2r(2t) \quad (\text{F.3b})$$

$$\sum_{n=1}^{\infty} R(2^n t) \leq 6R(t) \quad (\text{F.3c})$$

Lemma F.1. *There is a constant $t_{\max} > 0$, depending only on e_r , e_R and $e_{R'}$ such that, for all $0 < t \leq t_{\max}$ and $0 < v \leq 1$,*

$$R(2t) + r(t) < R(t) \quad (\text{F.3d})$$

$$R'(2t) + \|\nabla\| r(t) \leq R'(t) \leq 2R'(2t) \quad (\text{F.3e})$$

$$\frac{r(t)}{R(t)} \leq \frac{1}{2^{10}} \quad (\text{F.3f})$$

Proof. These all follow directly from the definitions (F.1) and conditions (F.2). \square

Lemma F.2. *There is a constant $0 < v_{\max} < 1$, depending only on m , such that, for all $0 < t < \frac{1}{2}$ and $0 < v \leq v_{\max}$,*

$$c < c(2t) < c(t) \leq 2c(2t) \quad (\text{F.4a})$$

$$e^{-m c} \leq v \quad (\text{F.4b})$$

$$e^{-\frac{1}{4}m c(t)} \leq \min \left\{ tv, \frac{1}{32} \right\} \quad (\text{F.4c})$$

$$\sum_{k=0}^{\infty} \frac{1}{2^{-k} t} e^{-\frac{1}{8} m c(2^{-k} t)} \leq 1 \quad (\text{F.4d})$$

Proof. Parts (F.5a–c) are obvious. For (F.4d),

$$\begin{aligned} \sum_{k=0}^{\infty} \frac{1}{2^{-k} t} e^{-\frac{1}{8} m c(2^{-k} t)} &= \sum_{k=0}^{\infty} e^{\log \frac{2^k}{t} - \frac{1}{8} m \log^2 \frac{2^k}{t v}} \\ &\leq \sum_{k=0}^{\infty} e^{\log \frac{2^k}{t} - 2 \log \frac{2^k}{t v}} \leq \sum_{k=0}^{\infty} e^{-\log \frac{2^k}{t v}} = \sum_{k=0}^{\infty} \frac{t v}{2^k} \\ &= 2t v \end{aligned}$$

For the first inequality we used $\frac{1}{8} m \log \frac{2}{v} \geq 2$ and for the second inequality we used $v \leq 1$. \square

Lemma F.3. *There are constants $t_{\max} > 0$ and $0 < v_{\max} < 1$, depending only on m , such that the following is true for all $0 < \delta \leq t_{\max}$ and $0 < v \leq v_{\max}$. Let \mathfrak{S} be a hierarchy for scale δ and let $\mathcal{J}' \subsetneq \mathcal{J}$ be decimation intervals for \mathfrak{S} , with lengths t' and t , respectively. For all $\mathbf{x} \in \Lambda(\mathcal{J})$ and $\mathbf{y} \in \Lambda(\mathcal{J}')^c$ we have*

$$R\left(\frac{t'}{2}\right) \leq e^{\frac{m}{3} d(\mathbf{x}, \mathbf{y})} R(t) \quad (\text{F.5})$$

Proof. Recall from (F.3a) that $R(t) \leq 2R(2t)$. So

$$R\left(\frac{t'}{2}\right) \leq \frac{2t}{t'} R(t)$$

and, by Definition 2.4,

$$d(\mathbf{x}, \mathbf{y}) \geq \mathfrak{c}(t') = \log^2 \frac{1}{t' \mathfrak{v}} = \left(\log \frac{2t}{t'} + \log \frac{1}{2t\mathfrak{v}} \right)^2 \geq 2 \log \frac{1}{2t\mathfrak{v}} \log \frac{2t}{t'} \geq \frac{3}{m} \log \frac{2t}{t'}$$

assuming $2 \log \frac{1}{2t\mathfrak{v}} \geq \frac{3}{m}$. \square

The next Proposition involves the constant $K_d = \sup_{\mathbf{y} \in X} \sum_{\mathbf{x} \in X} e^{-d(\mathbf{x}, \mathbf{y})} > 1$, which is a characteristic quantity of the spatial lattice X alone and was defined in the proof of Lemma 3.42.

Lemma F.4. *There are constants $t_{\max} > 0$ and $\mathfrak{v}_{\max} > 0$ (depending only on $e_R, e_{R'}, e_r, e_\ell, K_d, K_\mu, K'_j$ and K_j), such that*

$$2^{48} K_d e^{6K_j} t \mathfrak{v} r(t) R(t)^3 < \frac{1}{40} \quad (\text{F.6a})$$

$$96 e^{K_j} R(t) e^{-\frac{1}{4} m \mathfrak{c}(t)} \leq 1 \quad (\text{F.6b})$$

$$e^{2K'_j+K_j} t \{ R'(t) + e^{-m \mathfrak{c}} R(t) + |\mu| R(t) \} \leq \frac{1}{32} r(t) \quad (\text{F.6c})$$

$$19 + 4D + 10 \log R(t) \leq \frac{1}{4} \ell(2t) \quad (\text{F.6d})$$

for all $0 < t \leq t_{\max}$ and $0 < \mathfrak{v} \leq \mathfrak{v}_{\max}$.

Proof. For (F.6a), just recall that $t \mathfrak{v} r(t) R(t)^3 = (t \mathfrak{v})^{1-3e_R-4e_r}$ and $3e_R+4e_r < 1$.

By (F.4c), $R(t) e^{-\frac{1}{4} m \mathfrak{c}(t)} \leq t \mathfrak{v} R(t) = (t \mathfrak{v})^{1-e_R-e_r}$ tends to zero as $t \mathfrak{v} \rightarrow 0$ and (F.6b) follows.

Since (F.4b)

$$\begin{aligned} & e^{2K'_j+K_j} t \{ R'(t) + e^{-m \mathfrak{c}} R(t) + |\mu| R(t) \} \\ & \leq e^{2K'_j+K_j} \{ t^{1-e_{R'}} + (t \mathfrak{v})^{1-e_R} + K_\mu t^{1-e_R} \mathfrak{v}^{e_\mu-e_R} \} r(t) \leq \frac{1}{32} r(t) \end{aligned}$$

and the constraint (F.6c) is satisfied if t is small enough.

The inequality (F.6d) is satisfied since the ratio between $\log R(t) = (e_R + e_r) \log \frac{1}{t \mathfrak{v}}$ and $\ell(2t) = (\frac{1}{2t \mathfrak{v}})^{e_\ell}$ converges to zero as $t \mathfrak{v}$ tends to zero. \square

As in the proof of Proposition 3.36, set $K_{L2} = \frac{1}{32} \min\{c_H e^{-4D C_H}, \frac{1}{32}\}$.

Lemma F.5. *There are constants¹⁷ C_L and t_{\max} such that, setting $L(t) = C_L r(t)^2$,*

$$\frac{1}{2} K_{L2} t R'(t)^2 \geq L(t) \quad (\text{F.7a})$$

$$K_{L2} r(t)^2 \geq L(t) \quad (\text{F.7b})$$

$$\frac{c_v}{512} t \mathfrak{v} R(t)^4 \geq L(t) \quad (\text{F.7c})$$

$$6e^{2K'_j} (t [|\mu| + e^{-5m \mathfrak{c}}] R(2t) + t R'(t)) \leq \frac{L(t)}{r(t)} \leq \frac{1}{3} (r(t) - r(2t)) \quad (\text{F.7d})$$

¹⁷ The constant C_L depends only on $c_H, C_H, c_v, e_{R'}$ and e_r . The constant t_{\max} depends only on $C_L, K'_j, K_\mu, e_\mu, e_R, e_r, e_\ell$.

$$2^{11} \sum_{p=q}^n \ell(2^p \varepsilon) \left(\sum_{k=q-1}^{p-1} \mathfrak{c}(2^k \varepsilon) \right)^3 \leq L(2^q \varepsilon) \quad (\text{F.7e})$$

for all $0 < t \leq t_{\max}$, $0 < \mathfrak{v} \leq \mathfrak{v}_{\max}$ (with the \mathfrak{v}_{\max} of Lemma F.2 and all $\varepsilon > 0$ and $n \in \mathbb{N}$ with $2^n \varepsilon \leq t_{\max}$.

Proof. Using (F.4b), the constraint (F.7d) will be satisfied if

$$\begin{aligned} & 6e^{2K'_j} (t^{1-e_{\text{R}}} [K_{\mu} \mathfrak{v}^{e_{\mu}-e_{\text{R}}} + \mathfrak{v}^{5-e_{\text{R}}}] + t^{1-e_{\text{R}'}}) r(t) \\ & \leq \frac{L(t)}{r(t)} = C_L r(t) \leq \frac{1}{3} (1 - \frac{1}{2^{e_{\text{r}}}}) r(t) \end{aligned}$$

As long as \mathfrak{v} is smaller than the \mathfrak{v}_{\max} of Lemma F.2 and t is small enough, we may choose $L(t)$ to be a small constant times $r(t)^2$. We may also choose this constant to be smaller than $\frac{1}{2} K_{L2}$ and $\frac{c_v}{512}$. Then constraints (F.8a,b,c) are also satisfied.

Observe that, for any $0 < 2t\mathfrak{v} \leq 1$ and real $b \geq 1$,

$$\begin{aligned} & \left(\log \frac{1}{t\mathfrak{v}} \right)^{b+1} \\ &= \left(\log 2 + \log \frac{1}{2t\mathfrak{v}} \right)^{b+1} \geq \left(\log \frac{1}{2t\mathfrak{v}} \right)^{b+1} + (b+1)(\log 2) \left(\log \frac{1}{2t\mathfrak{v}} \right)^b \\ &\geq \left(\log \frac{1}{2t\mathfrak{v}} \right)^{b+1} + \left(\log \frac{1}{2t\mathfrak{v}} \right)^b \end{aligned}$$

Iterating, we have, for all $\varepsilon > 0$ and $0 \leq m < n$ with $0 < 2^n \varepsilon \mathfrak{v} \leq 1$ and any real $b \geq 1$,

$$\begin{aligned} \left(\log \frac{1}{2^m \varepsilon \mathfrak{v}} \right)^{b+1} &\geq \left(\log \frac{1}{2^n \varepsilon \mathfrak{v}} \right)^{b+1} + \sum_{j=m+1}^n \left(\log \frac{1}{2^j \varepsilon \mathfrak{v}} \right)^b \\ &\implies \sum_{j=m}^n \left(\log \frac{1}{2^j \varepsilon \mathfrak{v}} \right)^b \leq 2 \left(\log \frac{1}{2^m \varepsilon \mathfrak{v}} \right)^{b+1} \end{aligned}$$

and hence

$$\begin{aligned} 2^{11} \sum_{p=q}^n \ell(2^p \varepsilon) \left(\sum_{k=q-1}^{p-1} \mathfrak{c}(2^k \varepsilon) \right)^3 &\leq 2^{14} \sum_{p=q}^n \ell(2^p \varepsilon) \left(\log \frac{1}{2^{q-1} \varepsilon \mathfrak{v}} \right)^9 \\ &\leq 2^{23} \left(\log \frac{1}{2^q \varepsilon \mathfrak{v}} \right)^9 \sum_{p=q}^n \ell(2^p \varepsilon) \end{aligned}$$

Since, for any $e_{\ell} > 0$,

$$\sum_{p=q}^n \left(\frac{1}{2^p \varepsilon \mathfrak{v}} \right)^{e_{\ell}} = \left(\frac{1}{\varepsilon \mathfrak{v}} \right)^{e_{\ell}} \sum_{p=q}^n \frac{1}{2^{pe_{\ell}}} = \frac{1}{1 - 2^{-e_{\ell}}} \left(\frac{1}{2^q \varepsilon \mathfrak{v}} \right)^{e_{\ell}}$$

the left hand side of (F.7e)

$$2^{11} \sum_{p=q}^n \ell(2^p \varepsilon) \left(\sum_{k=q-1}^{p-1} \mathfrak{c}(2^k \varepsilon) \right)^3 \leq \frac{2^{23}}{1 - 2^{-e_\ell}} \left(\log \frac{1}{2^q \varepsilon \mathfrak{v}} \right)^9 \left(\frac{1}{2^q \varepsilon \mathfrak{v}} \right)^{e_\ell}$$

is indeed smaller than $L(2^q \varepsilon) = C_L \left(\frac{1}{2^q \varepsilon \mathfrak{v}} \right)^{2e_r}$ if $e_\ell < 2e_r$ and $2^n \varepsilon \mathfrak{v}$ is small enough. \square

During the construction, we introduced the auxiliary constants

- o $K_R = 2^{12} K_j^2$ and $K_E = 2^{23}$ in Theorem 3.24,
- o $K_D = 2^{35} e^{6K_j}$ and $K_L = 2^{48} e^{6K_j}$ in Theorem 3.26,
- o $K_\Delta = 2^{40} e^{10K_j}$ in Theorem 3.27 and
- o $K_Q = 2^9 e^{2K_j}$ and $K_V = 2^{25} e^{6K_j}$ in Propositions 5.12 and 5.13, respectively.

Lemma F.6. *There is a constant $t_{\max} > 0$ (depending only on e_R , e_r and K_j), such that, for all $0 < t \leq t_{\max}$ and $0 < \mathfrak{v} \leq 1$, we have*

$$\left[\frac{e^{tK_j}}{2^{1-2e_r}} + \frac{K_j^2 e^{2K_j t}}{K_R} (2t\mathfrak{v})^{2e_r} + \left(\frac{\sqrt{K_R}}{2^{1-e_R-2e_r}} \frac{t e^{-mc}}{(t\mathfrak{v})^{e_R+2e_r}} + \frac{2^{5+e_r} K_j e^{K_j t}}{\sqrt{K_R}} \right)^2 \right] \leq 1 \quad (\text{F.8a})$$

$$\begin{aligned} & \frac{e^{2tK_j}}{2^{1-(2e_R+4e_r)}} + \frac{16K_j e^{8K_j t} e^{-mc}}{K_E r(2t)^2 R(2t)^2 \mathfrak{v}} + \frac{1}{K_E} 2^{51} (2t\mathfrak{v}) r(2t) R(2t)^3 \\ & + \frac{2^{10} e^{-\frac{1}{2} mc}}{K_E \mathfrak{v} R(2t)^2} + \frac{2^{20}}{K_E} \leq 1 \end{aligned} \quad (\text{F.8b})$$

$$2^{-2e_r} e^{2K_j} + 2^{28} (t\mathfrak{v}) r(t) R(t)^3 \leq 1 \quad (\text{F.8c})$$

Proof. (a) Since $e_r < \frac{1}{10}$,

$$\frac{e^{tK_j}}{2^{1-2e_r}} + \left(\frac{2^{5+e_r} K_j e^{K_j t}}{\sqrt{K_R}} \right)^2 \leq \left(\frac{1}{2^{1-2e_r}} + \frac{1}{2^{2-2e_r}} \right) e^{2K_j t} \leq \frac{7}{8} e^{2K_j t}$$

By (F.4b), all remaining contributions may be made arbitrarily small by choosing t_{\max} small enough.

(b) Since $1 - (2e_R + 4e_r) = 1 - (3e_R + 4e_r) + e_R > e_R \geq \frac{1}{5}$, by (2.17), we have

$$\frac{e^{2tK_j}}{2^{1-(2e_R+4e_r)}} + \frac{1}{K_E} 2^{51} (2t\mathfrak{v}) r(2t) R(2t)^3 + \frac{2^{20}}{K_E} \leq 1 - \frac{1}{2^8}$$

by (F.6a), if t is small enough. Using (F.4b) and (2.17), the remaining two terms can be made arbitrarily small.

(c) is obvious. \square

The precise smallness assumptions on θ and \mathfrak{v} in Theorems 2.16 and 2.18 are

- Hypothesis F.7.** (i) θ is smaller than $\frac{c_v}{2^{48}e^{6K_j}(1+K_\mu^3)}, \left(\frac{1-2^{-2(-3e_R-4e_r)}}{2^{17}e^{10K_j}}\right)^{\frac{1}{1-2e_R-4e_r}}$ and each of the t_{\max} 's of Lemmas F.1 to F.6.
(ii) \mathfrak{v} is smaller than $(\frac{1}{2^{12}e^{2K_j}})^{\frac{1}{1-2e_R-4e_r}}$ and each of the \mathfrak{v}_{\max} 's of Lemmas F.1 to F.5.

These are also all of the restrictions that we put on the constants Θ and \mathfrak{v}_0 of Theorems 3.24, 3.26 and Proposition 3.29.

Appendix G. Changes of Variables and Estimates of Operator Norms

The basic change of variables formula for the operator norms of Definition 3.18 is Proposition 3.19. It, and consequences of it, are proven in [4, §IV]. For the purposes of our construction, we need variants of these results for special situations, namely that the operators implementing the change of variables have restricted ranges or that the functions to which the change of variables is applied are polynomials. The first is treated in Proposition G.1 and the second in Lemma G.2 and Corollary G.3. Also, in Remark G.4 and Lemma G.5, we develop tools to bound the operator norms of Definition 3.18.

We work in the same abstract environment as in [4, §IV]. We are given weight factors $\kappa_1, \dots, \kappa_s$ on an abstract metric space X with metric d . We consider analytic functions $f(\alpha_1, \dots, \alpha_s; \mathfrak{h})$ of the complex fields $\alpha_1, \dots, \alpha_s$ and the additional “history” field \mathfrak{h} . Denote by w the weight system with metric d that associates the weight factor κ_j to the field α_j , and the constant weight factor 1 to the history field \mathfrak{h} (see Definition 3.12).

Proposition G.1. Let Γ_j , $1 \leq j \leq r$, be \mathfrak{h} -operators on \mathbb{C}^X . Let $\Lambda \subset X$ and, for each $1 \leq j \leq r$, Λ_j be either Λ or Λ^c . Set

$$\tilde{f}(\alpha_1, \dots, \alpha_{s-1}, \beta_1, \dots, \beta_r; \mathfrak{h}) = f\left(\alpha_1, \dots, \alpha_{s-1}, \sum_{j=1}^r \Lambda_j \Gamma_j \beta_j; \mathfrak{h}\right)$$

Furthermore let $\tilde{\kappa}_i$, $1 \leq i \leq s-1$ and λ_j , $1 \leq j \leq r$ be weight factors. Let \tilde{w} be the weight system with metric d that associates the weight factor $\tilde{\kappa}_i$ to the field α_i , for $1 \leq i \leq s-1$, the weight factor λ_j to the field β_j , for $1 \leq j \leq r$, and the constant weight factor 1 to the history field \mathfrak{h} . Assume that $\tilde{\kappa}_i(\mathbf{x}) \leq \kappa_i(\mathbf{x})$ for all $1 \leq i \leq s-1$ and $\mathbf{x} \in X$ and that there is a $\nu > 1$ such that

$$\sum_{\substack{1 \leq j \leq r \\ \Lambda_j = \Lambda}} N_d(\Lambda_j \Gamma_j; \kappa_s, \lambda_j) \leq \frac{1}{\nu} \quad \text{and} \quad \sum_{\substack{1 \leq j \leq r \\ \Lambda_j = \Lambda^c}} N_d(\Lambda_j \Gamma_j; \kappa_s, \lambda_j) \leq \frac{1}{\nu}$$

Then

$$\|\tilde{f}\|_{\tilde{w}} \leq C_\nu \|f\|_w \quad \text{with } C_\nu = \begin{cases} \frac{4\nu}{(e \ln \nu)^2} & \text{if } \nu \leq e \\ \frac{4}{\nu} & \text{if } e \leq \nu < 4 \\ 1 & \text{if } \nu \geq 4 \end{cases}$$

Proof. We introduce auxiliary fields $\{\beta'_j\}_{1 \leq j \leq r}$ and $\{\gamma_1, \gamma_2\}$ and define

$$f'(\alpha_1, \dots, \alpha_{s-1}, \gamma_1, \gamma_2; \mathfrak{h}) = f(\alpha_1, \dots, \alpha_{s-1}, \Lambda\gamma_1 + \Lambda^c\gamma_2; \mathfrak{h})$$

$$f''(\alpha_1, \dots, \alpha_{s-1}, \beta'_1, \dots, \beta'_r; \mathfrak{h}) = f' \left(\alpha_1, \dots, \alpha_{s-1}, \sum_{\substack{1 \leq j \leq r \\ \Lambda_j = \Lambda}} \beta'_j, \sum_{\substack{1 \leq j \leq r \\ \Lambda_j = \Lambda^c}} \beta'_j; \mathfrak{h} \right)$$

Then

$$\tilde{f}(\alpha_1, \dots, \alpha_{s-1}, \beta_1, \dots, \beta_r; \mathfrak{h}) = f''(\alpha_1, \dots, \alpha_{s-1}, \Lambda_1\Gamma_1\beta_1, \dots, \Lambda_r\Gamma_r\beta_r; \mathfrak{h})$$

Set, for each $1 \leq j \leq r$, $t_j = N_d(\Lambda_j\Gamma_j; \kappa_s, \lambda_j)$ and introduce the auxiliary weight system w' with metric d that associates the weight factor one to the history field,

- o the weight factor κ_i to the field α_i , for each $1 \leq i \leq s-1$,
- o the weight factor $\lambda'_j(\mathbf{x}) = t_j\kappa_s(\mathbf{x})$ to the field β'_j , for each $1 \leq j \leq r$, and
- o the weight factors $\kappa'_1(\mathbf{x}) = \sum_{\substack{1 \leq j \leq r \\ \Lambda_j = \Lambda}} t_j\kappa_s(\mathbf{x})$ and $\kappa'_2(\mathbf{x}) = \sum_{\substack{1 \leq j \leq r \\ \Lambda_j = \Lambda^c}} t_j\kappa_s(\mathbf{x})$, respectively, to the fields γ_1 and γ_2 .

By [4, Proposition IV.4],

$$\|\tilde{f}(\alpha_1, \dots, \alpha_{s-1}, \beta_1, \dots, \beta_r; \mathfrak{h})\|_{\bar{w}} \leq \|f''(\alpha_1, \dots, \alpha_{s-1}, \beta'_1, \dots, \beta'_r; \mathfrak{h})\|_{w'}$$

since

$$N_d(\Lambda_j\Gamma_j; \lambda'_j, \lambda_j) = N_d(\Lambda_j\Gamma_j; t_j\kappa_s, \lambda_j) = \frac{1}{t_j} N_d(\Lambda_j\Gamma_j; \kappa_s, \lambda_j) = 1$$

By [4, Lemma IV.5.i], applied twice,

$$\|f''(\alpha_1, \dots, \alpha_{s-1}, \beta'_1, \dots, \beta'_r; \mathfrak{h})\|_{w'} \leq \|f'(\alpha_1, \dots, \alpha_{s-1}, \gamma_1, \gamma_2; \mathfrak{h})\|_{w'}$$

since,

$$\sum_{\substack{1 \leq j \leq r \\ \Lambda_j = \Lambda}} \sup_{\mathbf{x}} \frac{\lambda'_j(\mathbf{x})}{\kappa'_1(\mathbf{x})} = \sum_{\substack{1 \leq j \leq r \\ \Lambda_j = \Lambda^c}} \sup_{\mathbf{x}} \frac{\lambda'_j(\mathbf{x})}{\kappa'_2(\mathbf{x})} = 1$$

By part (iii) of [4, Lemma IV.5], with r replaced by 2,

$$\|f'(\alpha_1, \dots, \alpha_{s-1}, \gamma_1, \gamma_2; \mathfrak{h})\|_{w'} \leq C_\nu \|f(\alpha_1, \dots, \alpha_s; \mathfrak{h})\|_w$$

since $C_\nu = C_{\nu,2}$ and

$$\sup_{\mathbf{x}} \frac{\kappa'_1(\mathbf{x})}{\kappa_s(\mathbf{x})} = \sum_{\substack{1 \leq j \leq r \\ \Lambda_j = \Lambda}} t_j \leq \frac{1}{\nu} \quad \text{and} \quad \sup_{\mathbf{x}} \frac{\kappa'_1(\mathbf{x})}{\kappa_s(\mathbf{x})} = \sum_{\substack{1 \leq j \leq r \\ \Lambda_j = \Lambda^c}} t_j \leq \frac{1}{\nu}$$

□

In Sect. 5, we use a refinement of [4, Proposition IV.4] for functions of low degree in the fields that exploits exponential decay of operators away from a given subset L of X . This estimate is contained in

Lemma G.2. Let A_1, \dots, A_s be \mathfrak{h} -operators on \mathbb{C}^X and let $\kappa'_1, \dots, \kappa'_s$ be weight factors. Furthermore, let $f(\alpha_1, \dots, \alpha_s; \mathfrak{h})$ be a polynomial in the fields $\alpha_1, \dots, \alpha_s$ and set

$$f'(\alpha_1, \dots, \alpha_s; \mathfrak{h}) = f(A_1\alpha_1, \dots, A_s\alpha_s; \mathfrak{h})$$

- (a) Assume that $f(\alpha_1, \dots, \alpha_s; \mathfrak{h})$ is homogeneous of degree d_j in α_j for each $1 \leq j \leq s$. Then

$$\|f'\|_{\tilde{w}} \leq \|f\|_w \prod_{j=1}^s N_d(A_j; \kappa_j, \kappa'_j)^{d_j}$$

where \tilde{w} is the weight system with metric d that associates the weight factor κ'_j to the field α_j and the constant weight factor 1 to the history field \mathfrak{h} .

- (b) Let $t_1, \dots, t_s \in \mathbb{R}$ with $t_1 + \dots + t_s \leq 0$. Also, Let d' and δ be metrics that obey

$$d \geq d' + \left(\sum_{\substack{i=1 \\ t_i \geq 0}}^s t_i \right) \delta$$

Denote by w' the weight system with metric d' that associates the weight factor κ'_j to the field α_j and the constant weight factor 1 to the history field \mathfrak{h} .

Assume that $f(\alpha_1, \dots, \alpha_s; \mathfrak{h})$ is homogeneous of degree one in each of the fields $\alpha_1, \dots, \alpha_s$. Then, for any subset L of X ,

$$\|f'\|_{w'} \leq \|f\|_w \prod_{j=1}^s N_{d'} \left(A_j; \kappa_j e^{t_j \delta(\mathbf{x}, L)}, \kappa'_j \right)$$

Proof. (a) follows from [4, Proposition IV.4] by scaling.

- (b) Denote by w_{aux} the weight system with metric d' that associates the weight factor $\kappa_j e^{t_j \delta(\mathbf{x}, L)}$ to the field α_j . We claim that

$$\|f\|_{w_{\text{aux}}} \leq \|f\|_w \tag{G.1}$$

The claim follows from (G.1), since, by part (a),

$$\|f'\|_{w'} \leq \|f\|_{w_{\text{aux}}} \prod_{j=1}^s N_{d'} \left(A_j; \kappa_j e^{t_j \delta(\mathbf{x}, L)}, \kappa'_j \right)$$

To prove (G.1) we may assume that there is $r \geq 0$ such that $t_1, \dots, t_r \geq 0$ and $t_{r+1}, \dots, t_s \leq 0$. By hypothesis, $\sum_{i=1}^r t_i \leq \sum_{j=r+1}^s (-t_j)$. Therefore there are $a_{ij} \geq 0$, $i = 1, \dots, r$, $j = r+1, \dots, s$ such that

$$t_i = \sum_{j=r+1}^s a_{ij} \quad \text{for } i = 1, \dots, r \tag{G.2}$$

$$(-t_j) \geq \sum_{i=1}^r a_{ij} \quad \text{for } j = r+1, \dots, s \tag{G.3}$$

Now fix $\mathbf{x}_1, \dots, \mathbf{x}_s \in X$, $\ell \geq 0$ and $\vec{\mathbf{z}} \in X^\ell$. Let T be a tree whose set of vertices contains $\mathbf{x}_1, \dots, \mathbf{x}_s, \mathbf{z}_1, \dots, \mathbf{z}_\ell$. Denote by $\text{length}_\delta(T)$ the length of T with respect to the metric δ . For each $1 \leq i, j \leq s$, the points \mathbf{x}_i and \mathbf{x}_j can be connected by a path in T . Therefore

$$\delta(\mathbf{x}_i, L) \leq \delta(\mathbf{x}_j, L) + \text{length}_\delta(T)$$

Consequently

$$\begin{aligned} & \sum_{i=1}^s t_i \delta(\mathbf{x}_i, L) \\ &= \sum_{i=1}^r \sum_{j=r+1}^s a_{ij} \delta(\mathbf{x}_i, L) + \sum_{i=r+1}^s t_i \delta(\mathbf{x}_i, L) \\ &\leq \sum_{i=1}^r \sum_{j=r+1}^s a_{ij} \delta(\mathbf{x}_j, L) + \sum_{i=1}^r \sum_{j=r+1}^s a_{ij} \text{length}_\delta(T) + \sum_{j=r+1}^s t_j \delta(\mathbf{x}_j, L) \\ &= \sum_{j=r+1}^s \left(t_j + \sum_{i=1}^r a_{ij} \right) \delta(\mathbf{x}_j, L) + \sum_{i=1}^r t_i \text{length}_\delta(T) \\ &\leq \left(\sum_{i=1}^r t_i \right) \text{length}_\delta(T) \end{aligned}$$

by (G.2). Therefore

$$\text{length}_{d'}(T) + \sum_{i=1}^s t_i \delta(\mathbf{x}_i, L) \leq \text{length}_d(T)$$

This holds for any tree T , whose set of vertices contains $\mathbf{x}_1, \dots, \mathbf{x}_s, \mathbf{z}_1, \dots, \mathbf{z}_\ell$, so that

$$\tau_{d'}(\mathbf{x}_1, \dots, \mathbf{x}_s, \vec{\mathbf{z}}) + \sum_{i=1}^s t_i \delta(\mathbf{x}_i, L) \leq \tau_d(\mathbf{x}_1, \dots, \mathbf{x}_s, \vec{\mathbf{z}})$$

If we expand

$$\begin{aligned} & f(\alpha_1, \dots, \alpha_s; \mathfrak{h}) \\ &= \sum_{\ell \geq 0} \sum_{\substack{\mathbf{x}_1, \dots, \mathbf{x}_\ell \in X \\ \vec{\mathbf{z}} \in X^\ell}} a_\ell(\mathbf{x}_1, \dots, \mathbf{x}_\ell; \vec{\mathbf{z}}) \alpha_1(\mathbf{x}_1) \cdots \alpha_s(\mathbf{x}_s) \mathfrak{h}(\mathbf{z}_1) \cdots \mathfrak{h}(\mathbf{z}_\ell) \end{aligned}$$

and apply Definition 3.12, we get (G.1) □

Corollary G.3. *Let $h(\gamma_1, \dots, \gamma_r; \mathfrak{h})$ be a multilinear form in the fields $\gamma_1, \dots, \gamma_r$. Furthermore, let*

$$\Gamma_i^j, \tilde{\Gamma}_i^j, A_j \text{ and } \tilde{A}_j$$

$(i = 1, \dots, r; j = 1, \dots, s)$ be \mathfrak{h} -operators on \mathbb{C}^X . Set

$$\begin{aligned} f_1(\alpha_1, \dots, \alpha_s; \mathfrak{h}) &= h \left(\sum_{j=1}^s \Gamma_1^j \alpha_j, \dots, \sum_{j=1}^s \Gamma_r^j \alpha_j; \mathfrak{h} \right) \\ f_2(\alpha_1, \dots, \alpha_s; \mathfrak{h}) &= h \left(\sum_{j=1}^s \Gamma_1^j \alpha_j, \dots, \sum_{j=1}^s \Gamma_r^j \alpha_j; \mathfrak{h} \right) \\ &\quad - h \left(\sum_{j=1}^s \tilde{\Gamma}_1^j \alpha_j, \dots, \sum_{j=1}^s \tilde{\Gamma}_r^j \alpha_j; \mathfrak{h} \right) \\ f_3(\alpha_1, \dots, \alpha_s; \mathfrak{h}) &= h \left(\sum_{j=1}^s A_1 \Gamma_1^j \alpha_j, \dots, \sum_{j=1}^s A_r \Gamma_r^j \alpha_j; \mathfrak{h} \right) \\ &\quad - h \left(\sum_{j=1}^s \tilde{A}_1 \Gamma_1^j \alpha_j, \dots, \sum_{j=1}^s \tilde{A}_r \Gamma_r^j \alpha_j; \mathfrak{h} \right) \\ &\quad - h \left(\sum_{j=1}^s A_1 \tilde{\Gamma}_1^j \alpha_j, \dots, \sum_{j=1}^s A_r \tilde{\Gamma}_r^j \alpha_j; \mathfrak{h} \right) \\ &\quad + h \left(\sum_{j=1}^s \tilde{A}_1 \tilde{\Gamma}_1^j \alpha_j, \dots, \sum_{j=1}^s \tilde{A}_r \tilde{\Gamma}_r^j \alpha_j; \mathfrak{h} \right) \end{aligned}$$

Let $\lambda_1, \dots, \lambda_r$ be weight factors. Let w' be the weight system with some metric d' that associates the weight factor κ_j to the field α_j ; and let w_λ be the weight system with metric d that associates the weight factor λ_i to the field γ_i . Let δ either be 0 or a metric which obeys

$$d \geq d' + (r-1)\delta$$

and let $L \subset X$. Then

- (i) $\|f_1\|_{w'} \leq \|h\|_{w_\lambda} \prod_{i=1}^r (\sum_{j=1}^s N_{d'}(\Gamma_i^j; \lambda_i e^{t_i \delta(\mathbf{x}, L)}, \kappa_j))$
where each t_i , $1 \leq i \leq r$, is either 1 or $-(r-1)$ and at least one of them is $-(r-1)$
- (ii) $\|f_2\|_{w'} \leq r \|h\|_{w_\lambda} \sigma_\delta \sigma^{r-1}$
where

$$\sigma = \max_{i=1, \dots, r} \max \left\{ \sum_{j=1}^s N_{d'}(\Gamma_i^j; \lambda_i e^{\delta(\mathbf{x}, L)}, \kappa_j), \sum_{j=1}^s N_{d'}(\tilde{\Gamma}_i^j; \lambda_i e^{\delta(\mathbf{x}, L)}, \kappa_j) \right\}$$

$$\sigma_\delta = \max_{i=1, \dots, r} \sum_{j=1}^s \frac{\kappa_j}{\lambda_i} \|\Gamma_i^j - \tilde{\Gamma}_i^j\|$$

- (iii) $\|f_3\|_{w'} \leq r^2 \|h\|_{w_\lambda} \sigma_\delta a_\delta (\sigma a)^{r-1}$

where

$$a = \max_{\substack{i=1,\dots,r \\ t=1,-(r-1)}} \max \left\{ N_{d'}(A_i; \lambda_i e^{t\delta(\mathbf{x}, L)}, \lambda_i e^{t\delta(\mathbf{x}, L)}), N_{d'}(\tilde{A}_i; \lambda_i e^{t\delta(\mathbf{x}, L)}, \lambda_i e^{t\delta(\mathbf{x}, L)}) \right\}$$

$$a_\delta = \max_{\substack{i=1,\dots,r \\ t=1,-(r-1)}} N_{d'}(A_i - \tilde{A}_i; \lambda_i e^{t\delta(\mathbf{x}, L)}, \lambda_i e^{t\delta(\mathbf{x}, L)})$$

Proof. (i) It suffices to prove that, for each choice of $1 \leq j_1, \dots, j_r \leq s$, the $\|\cdot\|_{w'}$ norm of $h(\Gamma_1^{j_1} \alpha_{j_1}, \dots, \Gamma_r^{j_r} \alpha_{j_r}; \mathfrak{h})$ is bounded by $\|h\|_{w_\lambda} \prod_{i=1}^r N_{d'}(\Gamma_i^{j_i}; \lambda_i e^{t_i \delta(\mathbf{x}, L)}, \kappa_{j_i})$. This follows from Lemma G.2(b) and [4, Lemma IV.5.ii] (when two or more of the j_i 's happen to be the same).

(ii) Write the telescoping sum

$$f_2(\alpha_1, \dots, \alpha_s) = h \left(\sum_{j=1}^s (\Gamma_1^j - \tilde{\Gamma}_1^j) \alpha_j, \sum_{j=1}^s \Gamma_2^j \alpha_j, \dots, \sum_{j=1}^s \Gamma_r^j \alpha_j \right)$$

$$+ h \left(\sum_{j=1}^s \tilde{\Gamma}_1^j \alpha_j, \sum_{j=1}^s (\Gamma_2^j - \tilde{\Gamma}_2^j) \alpha_j, \dots, \sum_{j=1}^s \Gamma_r^j \alpha_j \right)$$

$$+ \dots + h \left(\sum_{j=1}^s \tilde{\Gamma}_1^j \alpha_j, \sum_{j=1}^s \tilde{\Gamma}_2^j \alpha_j, \dots, \sum_{j=1}^s (\tilde{\Gamma}_r^j - \Gamma_r^j) \alpha_j \right)$$

and apply part (i) to each of the summands. For term number i_0 , which contains $\Gamma_{i_0}^j - \tilde{\Gamma}_{i_0}^j$, choose $t_{i_0} = -(r-1)$ and $t_i = 1$ for all $i \neq i_0$. (We have suppressed the argument \mathfrak{h} and will do so for the rest of the proof.)

(iii) Write the telescoping sum

$$f_3(\alpha_1, \dots, \alpha_s)$$

$$= h \left(\sum_{j=1}^s A_1(\Gamma_1^j - \tilde{\Gamma}_1^j) \alpha_j, \dots, \sum_{j=1}^s A_r \Gamma_r^j \alpha_j \right)$$

$$- h \left(\sum_{j=1}^s \tilde{A}_1(\Gamma_1^j - \tilde{\Gamma}_1^j) \alpha_j, \dots, \sum_{j=1}^s \tilde{A}_r \Gamma_r^j \alpha_j \right)$$

$$+ \dots + h \left(\sum_{j=1}^s A_1 \tilde{\Gamma}_1^j \alpha_j, \dots, \sum_{j=1}^s A_r (\tilde{\Gamma}_r^j - \Gamma_r^j) \alpha_j \right)$$

$$- h \left(\sum_{j=1}^s \tilde{A}_1 \tilde{\Gamma}_1^j \alpha_j, \dots, \sum_{j=1}^s \tilde{A}_r (\tilde{\Gamma}_r^j - \tilde{\Gamma}_r^j) \alpha_j \right)$$

We claim that the $\|\cdot\|_w$ norm of each of the r lines is bounded by $r \|h\|_{w_\lambda} \sigma_\delta a_\delta (\sigma a)^{r-1}$. We prove this for the first line. The proof for the other lines is similar.

We again write a telescoping sum

$$\begin{aligned}
& h \left(\sum_{j=1}^s A_1(\Gamma_1^j - \tilde{\Gamma}_1^j) \alpha_j, \dots, \sum_{j=1}^s A_r(\Gamma_r^j - \tilde{\Gamma}_r^j) \alpha_j \right) \\
& - h \left(\sum_{j=1}^s \tilde{A}_1(\Gamma_1^j - \tilde{\Gamma}_1^j) \alpha_j, \dots, \sum_{j=1}^s \tilde{A}_r(\Gamma_r^j - \tilde{\Gamma}_r^j) \alpha_j \right) \\
& = h \left(\sum_{j=1}^s (A_1 - \tilde{A}_1)(\Gamma_1^j - \tilde{\Gamma}_1^j) \alpha_j, \sum_{j=1}^s A_2 \Gamma_2^j \alpha_j, \dots, \sum_{j=1}^s A_r \Gamma_r^j \alpha_j \right) \\
& + h \left(\sum_{j=1}^s \tilde{A}_1(\Gamma_1^j - \tilde{\Gamma}_1^j) \alpha_j, \sum_{j=1}^s (A_2 - \tilde{A}_2) \Gamma_2^j \alpha_j, \dots, \sum_{j=1}^s A_r \Gamma_r^j \alpha_j \right) \\
& + \dots + h \left(\sum_{j=1}^s \tilde{A}_1(\Gamma_1^j - \tilde{\Gamma}_1^j) \alpha_j, \sum_{j=1}^s \tilde{A}_2(\Gamma_2^j - \tilde{\Gamma}_2^j) \alpha_j, \dots, \sum_{j=1}^s (A_r - \tilde{A}_r) \Gamma_r^j \alpha_j \right)
\end{aligned}$$

By the first bound, the $\|\cdot\|_w$ norm of the first term is bounded by

$$\begin{aligned}
& \|h\|_{w_\lambda} \left(\sum_{j=1}^s N_{d'} \left((A_1 - \tilde{A}_1)(\Gamma_1^j - \tilde{\Gamma}_1^j); \lambda_1 e^{-(r-1)\delta(\mathbf{x}, L)}, \kappa_j \right) \right) \\
& \times \prod_{i=2}^r \left(\sum_{j=1}^s N_{d'} \left(A_i \Gamma_i^j; \lambda_i e^{\delta(\mathbf{x}, L)}, \kappa_j \right) \right) \\
& \leq \|h\|_{w_\lambda} N_{d'}(A_1 - \tilde{A}_1; \lambda_1 e^{-(r-1)\delta(\mathbf{x}, L)}, \lambda_1 e^{-(r-1)\delta(\mathbf{x}, L)}) \\
& \times \left(\sum_{j=1}^s N_{d'}(\Gamma_1^j - \tilde{\Gamma}_1^j; \lambda_1 e^{-(r-1)\delta(\mathbf{x}, L)}, \kappa_j) \right) \\
& \times \prod_{i=2}^r \left(N_{d'}(A_i; \lambda_i e^{\delta(\mathbf{x}, L)}, \lambda_i e^{\delta(\mathbf{x}, L)}) \sum_{j=1}^s N_{d'}(\Gamma_i^j; \lambda_i e^{\delta(\mathbf{x}, L)}, \kappa_j) \right) \\
& \leq \|h\|_{w_\lambda} \left(a_\delta \sum_{j=1}^s N_{d'}(\Gamma_1^j - \tilde{\Gamma}_1^j; \lambda_1 e^{-(r-1)\delta(\mathbf{x}, L)}, \kappa_j) \right) \\
& \times \prod_{i=2}^r \left(\sum_{j=1}^s a N_{d'}(\Gamma_i^j; \lambda_i e^{\delta(\mathbf{x}, L)}, \kappa_j) \right) \\
& \leq \|h\|_{w_\lambda} \sigma_\delta a_\delta (\sigma a)^{r-1}
\end{aligned}$$

by [4, Remark IV.3.ii]. The norm of the second term is bounded by

$$\begin{aligned} \|h\|_{w_\lambda} & \left(\sum_{j=1}^s N_{d'} \left(\tilde{A}_1(\Gamma_1^j - \tilde{\Gamma}_1^j); \lambda_1 e^{-(r-1)\delta(\mathbf{x}, L)}, \kappa_j \right) \right) \\ & \times \left(\sum_{j=1}^s N_{d'} \left((A_2 - \tilde{A}_2)\Gamma_2^j; \lambda_2 e^{\delta(\mathbf{x}, L)}, \kappa_j \right) \right) \prod_{i=3}^r \left(\sum_{j=1}^s N_{d'} \left(A_i \Gamma_i^j; \lambda_i e^{\delta(\mathbf{x}, L)}, \kappa_j \right) \right) \\ & \leq \|h\|_{w_\lambda} (\sigma_\delta a)(\sigma a_\delta)(\sigma a)^{r-2} \end{aligned}$$

Similarly, one bounds the norms of each of the other $r-2$ terms by $\|h\|_{w_\lambda} \sigma_\delta a_\delta (\sigma a)^{r-1}$. \square

In order to apply Proposition 3.19, [4, Corollary IV.6] or Lemma G.2 we need techniques to estimate operator norms. They are given in Remark G.4 and Lemma G.5, below.

Remark G.4. Let A be an \mathfrak{h} -linear map from \mathbb{C}^X to \mathbb{C}^X . Let d_1, d_2 be metrics with $d_1 - d_2 \geq d$. Furthermore let κ, κ' be weight factors.

(i)

$$\begin{aligned} N_d(A; \kappa, \kappa') & \leq N_{d_1}(A; 1, 1) \left(\sup_{\substack{\mathbf{x}, \mathbf{y} \in X \\ A(\mathbf{x}, \mathbf{y}) \neq 0}} e^{-d_2(\mathbf{x}, \mathbf{y})} \frac{\kappa'(\mathbf{y})}{\kappa'(\mathbf{x})} \right) \left(\sup_{\substack{\mathbf{x} \in X \\ A(\mathbf{x}, \cdot) \neq 0}} \frac{\kappa'(\mathbf{x})}{\kappa(\mathbf{x})} \right) \\ N_d(A; \kappa, \kappa') & \leq N_{d_1}(A; 1, 1) \left(\sup_{\substack{\mathbf{x}, \mathbf{y} \in X \\ A(\mathbf{x}, \mathbf{y}) \neq 0}} e^{-d_2(\mathbf{x}, \mathbf{y})} \frac{\kappa(\mathbf{y})}{\kappa(\mathbf{x})} \right) \left(\sup_{\substack{\mathbf{y} \in X \\ A(\cdot, \mathbf{y}) \neq 0}} \frac{\kappa'(\mathbf{y})}{\kappa(\mathbf{y})} \right) \end{aligned}$$

(ii) Let $\mathfrak{c} > 0$ and define the \mathfrak{h} -linear operator $A_\mathfrak{c}$ by

$$A_\mathfrak{c}(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y}) = \begin{cases} A(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y}) & \text{if } d_2(\mathbf{x}, \mathbf{y}) \leq \mathfrak{c} \\ 0 & \text{if } d_2(\mathbf{x}, \mathbf{y}) > \mathfrak{c} \end{cases}$$

Then

$$N_d(A_\mathfrak{c} - A; \kappa, \kappa') \leq e^{-\mathfrak{c}} N_{d_1}(A; \kappa, \kappa')$$

(iii) Denote

$$K = \sup_{\substack{\mathbf{x}, \mathbf{y} \in X \\ A(\mathbf{x}; \cdot; \mathbf{y}) \neq 0}} \frac{\kappa'(\mathbf{y})}{\kappa(\mathbf{x})} e^{-d_2(\mathbf{x}, \mathbf{y})}$$

Then

$$N_d(A; \kappa, \kappa') \leq K N_{d_1}(A; 1, 1)$$

(iv) Let J be a linear operator on \mathbb{C}^X . Then

$$N_d(\exp(J); \kappa, \kappa) \leq e^{N_d(J; \kappa, \kappa)}$$

$$N_d(\exp(J) - \mathfrak{h}; \kappa, \kappa) \leq N_d(J; \kappa, \kappa) e^{N_d(J; \kappa, \kappa)}$$

Proof. To prove parts (i) and (ii), observe that, for all $\mathbf{x}, \mathbf{y} \in X$ and all $\vec{\mathbf{z}} \in X^{(1)}$

$$e^{\tau_d(\text{supp } (\mathbf{x}, \vec{\mathbf{z}}, \mathbf{y}))} |A(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y})| \frac{\kappa'(\mathbf{y})}{\kappa(\mathbf{x})} \leq e^{-d_2(\mathbf{x}, \mathbf{y})} e^{\tau_{d_1}(\text{supp } (\mathbf{x}, \vec{\mathbf{z}}, \mathbf{y}))} |A(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y})| \frac{\kappa'(\mathbf{y})}{\kappa(\mathbf{x})}$$

This immediately gives part (ii). The two inequalities of part (i) follow by writing

$$\frac{\kappa'(\mathbf{y})}{\kappa(\mathbf{x})} = \frac{\kappa'(\mathbf{y})}{\kappa'(\mathbf{x})} \cdot \frac{\kappa'(\mathbf{x})}{\kappa(\mathbf{x})} = \frac{\kappa(\mathbf{y})}{\kappa(\mathbf{x})} \cdot \frac{\kappa'(\mathbf{y})}{\kappa(\mathbf{y})}$$

Similarly, part (iii) follows from

$$\begin{aligned} e^{\tau_d(\text{supp } (\mathbf{x}, \vec{\mathbf{z}}, \mathbf{y}))} |A(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y})| \frac{\kappa'(\mathbf{y})}{\kappa(\mathbf{x})} &\leq K e^{d_2(\mathbf{x}, \mathbf{y})} e^{\tau_d(\text{supp } (\mathbf{x}, \vec{\mathbf{z}}, \mathbf{y}))} |A(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y})| \\ &\leq K e^{\tau_{d_1}(\text{supp } (\mathbf{x}, \vec{\mathbf{z}}, \mathbf{y}))} |A(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y})| \end{aligned}$$

Part (iv) follows from the expansion

$$\text{exph}(J) = e^{\bar{J}} = \mathfrak{h} + \sum_{\ell=1}^{\infty} \frac{1}{\ell!} \bar{J}^\ell$$

and [4, (IV.1)]. \square

In Appendix E, we use a more sophisticated

Lemma G.5. *Let*

- o $L_1, L_2, L_3, O_1, O_2 \subset X$
- o A_1, A_2 be \mathfrak{h} -linear operators on \mathbb{C}^X
- o $\delta_1, \delta_2, \delta, \tilde{d}$ metrics on X
- o $R > 0$ and κ a weight factor such that $\kappa(\mathbf{x}) \leq R e^{\delta_2(\mathbf{x}, O_2)}$ for all $\mathbf{x} \in L_3$.

Set

$$\begin{aligned} D_L &= \max \{ \delta(L_1, L_2), \delta(L_2, L_3), \delta(L_3, L_1) \} \\ D_O &= \max \{ D_L, \delta(L_1, O_1), \delta(L_2, O_1), \delta(L_3, O_1) \} \end{aligned}$$

(i) Assume that $d + \delta_2 + \delta \leq \tilde{d}$. If

- (a) $L_j \subset O_2$ for at least one $j \in \{1, 2, 3\}$ and $D = D_L$
or if

- (b) $L_j \subset O_2$ for at least one $j \in \{1, 2, 3\}$, $\delta_1 \geq \delta$ and $D = D_O$
or if

- (c) $O_1 \subset O_2$, $\delta_1 \geq \delta + \delta_2$ and $D = D_O$ then

$$\begin{aligned} N_d \left(L_1 A_1 L_2 A_2 L_3; e^{\delta_1(\mathbf{x}, O_1)}, \kappa \right) \\ \leq R e^{-D} N_{\tilde{d}}(L_1 A_1 L_2; 1, 1) N_{\tilde{d}}(L_2 A_2 L_3; 1, 1) \end{aligned}$$

(d) Assume that $d + \delta_1 + \delta_2 + \delta \leq \tilde{d}$ and that $L_i \subset O_1$, $L_j \subset O_2$ for some $1 \leq i, j \leq 3$. Then

$$\begin{aligned} N_d \left(L_1 A_1 L_2 A_2 L_3; e^{-\delta_1(\mathbf{x}, O_1)}, \kappa \right) \\ \leq R e^{-D_L} N_{\tilde{d}}(L_1 A_1 L_2; 1, 1) N_{\tilde{d}}(L_2 A_2 L_3; 1, 1) \end{aligned}$$

Proof. We may assume that $R = 1$ and that $\kappa(\mathbf{x}) = e^{\delta_2(\mathbf{x}, O_2)}$. We write the kernel of the operator $L_1 A_1 L_2 A_2 L_3$ as

$$(L_1 A_1 L_2 A_2 L_3)(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y}) = \sum_{\substack{\mathbf{u} \in L_2 \\ \vec{\mathbf{z}}_1, \vec{\mathbf{z}}_2 \in X^{(1)} \\ \vec{\mathbf{z}}_1 \circ (\mathbf{u}) \circ \vec{\mathbf{z}}_2 = \vec{\mathbf{z}}}} (L_1 A_1 L_2)(\mathbf{x}; \vec{\mathbf{z}}_1; \mathbf{u}) (L_2 A_2 L_3)(\mathbf{u}; \vec{\mathbf{z}}_2; \mathbf{y})$$

(i) Fix $\mathbf{x} \in L_1, \mathbf{u} \in L_2, \mathbf{y} \in L_3, \vec{\mathbf{z}}_1, \vec{\mathbf{z}}_2 \in X^{(1)}$. Then

$$\begin{aligned} & -\delta_1(\mathbf{x}, O_1) + \tau_d(\text{supp}(\mathbf{x}; \vec{\mathbf{z}}_1 \circ \mathbf{u} \circ \vec{\mathbf{z}}_2; \mathbf{y})) + \delta_2(\mathbf{y}, O_2) \\ & \leq \tau_d(\text{supp}(\mathbf{x}; \vec{\mathbf{z}}_1; \mathbf{u})) + \tau_d(\text{supp}(\mathbf{u}; \vec{\mathbf{z}}_2; \mathbf{y})) + \delta(\mathbf{x}, \mathbf{u}) + \delta(\mathbf{u}, \mathbf{y}) + \delta_2(\mathbf{y}, O_2) \\ & \quad -\delta_1(\mathbf{x}, O_1) - \delta(\mathbf{x}, \mathbf{u}) - \delta(\mathbf{u}, \mathbf{y}) \\ & \leq \tau_{\tilde{d}}(\text{supp}(\mathbf{x}; \vec{\mathbf{z}}_1; \mathbf{u})) + \tau_{\tilde{d}}(\text{supp}(\mathbf{u}; \vec{\mathbf{z}}_2; \mathbf{y})) - \delta_2(\mathbf{x}, \mathbf{u}) - \delta_2(\mathbf{u}, \mathbf{y}) + \delta_2(\mathbf{y}, O_2) \\ & \quad -\delta_1(\mathbf{x}, O_1) - \delta(\mathbf{x}, \mathbf{u}) - \delta(\mathbf{u}, \mathbf{y}) \end{aligned}$$

As $\mathbf{x} \in L_1, \mathbf{u} \in L_2, \mathbf{y} \in L_3$

$$\begin{aligned} & \delta(\mathbf{x}, \mathbf{u}) + \delta(\mathbf{u}, \mathbf{y}) \geq D_L \\ & \delta(\mathbf{x}, O_1) + \delta(\mathbf{x}, \mathbf{u}) + \delta(\mathbf{u}, \mathbf{y}) \geq D_O \end{aligned}$$

If $L_j \subset O_2$ for at least one $j \in \{1, 2, 3\}$ then

$$-\delta_2(\mathbf{x}, \mathbf{u}) - \delta_2(\mathbf{u}, \mathbf{y}) + \delta_2(\mathbf{y}, O_2) \leq 0$$

Therefore

$$\begin{aligned} & -\delta_2(\mathbf{x}, \mathbf{u}) - \delta_2(\mathbf{u}, \mathbf{y}) + \delta_2(\mathbf{y}, O_2) - \delta_1(\mathbf{x}, O_1) - \delta(\mathbf{x}, \mathbf{u}) - \delta(\mathbf{u}, \mathbf{y}) \\ & \leq \begin{cases} -D_L & \text{in case a)} \\ -D_O & \text{in case b)} \end{cases} \end{aligned}$$

In case (c), $\delta_1(\mathbf{x}, O_1) \geq \delta_2(\mathbf{x}, O_2) + \delta(\mathbf{x}, O_1)$ so that

$$\begin{aligned} & -\delta_2(\mathbf{x}, \mathbf{u}) - \delta_2(\mathbf{u}, \mathbf{y}) + \delta_2(\mathbf{y}, O_2) - \delta_1(\mathbf{x}, O_1) - \delta(\mathbf{x}, \mathbf{u}) - \delta(\mathbf{u}, \mathbf{y}) \\ & \leq -\delta_2(\mathbf{x}, \mathbf{u}) - \delta_2(\mathbf{u}, \mathbf{y}) + \delta_2(\mathbf{y}, O_2) - \delta_2(\mathbf{x}, O_2) - \delta(\mathbf{x}, O_1) - \delta(\mathbf{x}, \mathbf{u}) - \delta(\mathbf{u}, \mathbf{y}) \\ & \leq -D_O \end{aligned}$$

Consequently, in all three cases

$$\begin{aligned} & -\delta_1(\mathbf{x}, O_1) + \tau_d(\text{supp}(\mathbf{x}; \vec{\mathbf{z}}_1 \circ \mathbf{u} \circ \vec{\mathbf{z}}_2; \mathbf{y})) + \delta_2(\mathbf{y}, O_2) \\ & \leq -D + \tau_{\tilde{d}}(\text{supp}(\mathbf{x}; \vec{\mathbf{z}}_1; \mathbf{u})) + \tau_{\tilde{d}}(\text{supp}(\mathbf{u}; \vec{\mathbf{z}}_2; \mathbf{y})) \end{aligned}$$

so that

$$\begin{aligned} & e^{-\delta_1(\mathbf{x}, O_1)} e^{\tau_d(\text{supp}(\mathbf{x}; \vec{\mathbf{z}}_1 \circ \mathbf{u} \circ \vec{\mathbf{z}}_2; \mathbf{y}))} |(L_1 A_1 L_2)(\mathbf{x}; \vec{\mathbf{z}}_1; \mathbf{u}) (L_2 A_2 L_3)(\mathbf{u}; \vec{\mathbf{z}}_2; \mathbf{y})| \kappa(\mathbf{y}) \\ & \leq e^{-D} e^{\tau_{\tilde{d}}(\text{supp}(\mathbf{x}; \vec{\mathbf{z}}_1; \mathbf{u}))} |(L_1 A_1 L_2)(\mathbf{x}; \vec{\mathbf{z}}_1; \mathbf{u})| e^{\tau_{\tilde{d}}(\text{supp}(\mathbf{u}; \vec{\mathbf{z}}_2; \mathbf{y}))} \\ & \quad \times |(L_2 A_2 L_3)(\mathbf{u}; \vec{\mathbf{z}}_2; \mathbf{y})| \end{aligned}$$

If we define the auxiliary \mathfrak{h} -linear operators \tilde{A}_1 and \tilde{A}_2 by

$$\begin{aligned} \tilde{A}_1(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y}) &= e^{\tau_{\tilde{d}}(\text{supp}(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y}))} |A_1(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y})| \\ \tilde{A}_2(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y}) &= e^{\tau_{\tilde{d}}(\text{supp}(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y}))} |A_2(\mathbf{x}; \vec{\mathbf{z}}; \mathbf{y})| \end{aligned}$$

we now have, by [4, (IV.1)],

$$\begin{aligned} N_d \left(L_1 A_1 L_2 A_2 L_3 ; e^{\delta_1(\mathbf{x}, O_1)}, \kappa \right) &\leq R e^{-D} N_0 \left(L_1 \tilde{A}_1 L_2 \tilde{A}_2 L_3 ; 1, 1 \right) \\ &\leq R e^{-D} N_0 \left(L_1 \tilde{A}_1 L_2 ; 1, 1 \right) N_0 \left(L_2 \tilde{A}_2 L_3 ; 1, 1 \right) \\ &= R e^{-D} N_{\tilde{d}} \left(L_1 A_1 L_2 ; 1, 1 \right) N_{\tilde{d}} \left(L_2 A_2 L_3 ; 1, 1 \right) \end{aligned}$$

(ii) As in part (i), fix $\mathbf{x} \in L_1$, $\mathbf{u} \in L_2$, $\mathbf{y} \in L_3$, $\vec{\mathbf{z}}_1, \vec{\mathbf{z}}_2 \in X^{(1)}$ and bound

$$\begin{aligned} &\delta_1(\mathbf{x}, O_1) + \tau_d (\text{supp}(\mathbf{x}; \vec{\mathbf{z}}_1 \circ \mathbf{u} \circ \vec{\mathbf{z}}_2; \mathbf{y})) + \delta_2(\mathbf{y}, O_2) \\ &\leq \tau_d (\text{supp}(\mathbf{x}; \vec{\mathbf{z}}_1; \mathbf{u})) + \tau_d (\text{supp}(\mathbf{u}; \vec{\mathbf{z}}_2; \mathbf{y})) + \delta(\mathbf{x}, \mathbf{u}) + \delta(\mathbf{u}, \mathbf{y}) + \delta_1(\mathbf{x}, O_1) \\ &\quad + \delta_2(\mathbf{y}, O_2) - \delta(\mathbf{x}, \mathbf{u}) - \delta(\mathbf{u}, \mathbf{y}) \\ &\leq \tau_{\tilde{d}} (\text{supp}(\mathbf{x}; \vec{\mathbf{z}}_1; \mathbf{u})) + \tau_{\tilde{d}} (\text{supp}(\mathbf{u}; \vec{\mathbf{z}}_2; \mathbf{y})) - (\delta_1(\mathbf{x}, \mathbf{u}) + \delta_1(\mathbf{u}, \mathbf{y}) - \delta_1(\mathbf{x}, O_1)) \\ &\quad - (\delta_2(\mathbf{x}, \mathbf{u}) + \delta_2(\mathbf{u}, \mathbf{y}) - \delta_2(\mathbf{y}, O_2)) - (\delta(\mathbf{x}, \mathbf{u}) + \delta(\mathbf{u}, \mathbf{y})) \\ &\leq -D_L + \tau_{\tilde{d}} (\text{supp}(\mathbf{x}; \vec{\mathbf{z}}_1; \mathbf{u})) + \tau_{\tilde{d}} (\text{supp}(\mathbf{u}; \vec{\mathbf{z}}_2; \mathbf{y})) \end{aligned}$$

$V_{\Omega,\delta}(\varepsilon; \alpha_*, \beta)$	(2.1)	principal interaction
$V_{\Omega;\theta}(\alpha_*, \beta)$	$\lim_{m \rightarrow \infty} V_{\Omega;\theta}(2^{-m}\theta; \alpha_*, \beta)$	(2.4)
$\mathcal{V}_{\mathfrak{S}}(\alpha_*, \beta; \vec{\alpha}_*, \vec{\alpha})$	(2.11)	dominant quartic part
$v(\mathbf{x}, \mathbf{y})$	two-body potential	see Hypothesis 2.14
X	$\mathbb{Z}^D/L\mathbb{Z}^D$	space
Y^*	bonds with at least one end in Y	just before Notation 2.2
Y^*	points within distance one of Y	just before Notation 2.2
\mathcal{Z}_δ	Lemma 2.7	normalization constant
