# The Extension of Distributions on Manifolds, a Microlocal Approach 

Nguyen Viet Dang

#### Abstract

Let $M$ be a smooth manifold, $I \subset M$ a closed embedded submanifold of $M$ and $U$ an open subset of $M$. In this paper, we find conditions using a geometric notion of scaling for $t \in \mathcal{D}^{\prime}(U \backslash I)$ to admit an extension in $\mathcal{D}^{\prime}(U)$. We give microlocal conditions on $t$ which allow to control the wave front set of the extension generalizing a previous result of Brunetti-Fredenhagen. Furthermore, we show that there is a subspace of extendible distributions for which the wave front of the extension is minimal which has applications for the renormalization of quantum field theory on curved spacetimes.

## 1. Introduction

From the early days of quantum field theory, it has been known $[3,16,17]$ that QFT calculations are plagued with infinities arising from the integration of divergent Feynman amplitudes in momentum space. The recipe devised to subtract these divergences is called the renormalization algorithm [9]. When one generalizes QFT to curved Lorentzian spacetimes [2,22,53], a simple observation is that both the conventional axiomatic approach to quantum field theory following Wightman's axioms [52] or the usual textbook approach based on the representation of Feynman amplitudes in momentum space completely break down for the obvious reasons that there is no Fourier transform on curved spacetime and the spacetime is no longer Lorentz invariant. This motivates to look at the renormalization problem of Feynman amplitudes from the point of view of the position space and this problem was solved in the seminal work of Brunetti and Fredenhagen [5]. The starting point of [5] was to follow one of the very first approach to QFT due to Stueckelberg and his collaborators (D. Rivier, T.A. Green, A. Petermann), which is based on the concept of causality.

The ideas of Stueckelberg were first understood and developed by Bogoliubov and his school ([3]) and then by Epstein-Glaser ([18,19]) (on flat

[^0]spacetime). In these approaches, one works directly in position space and the renormalization is formulated as a problem of extension of distributions. Somehow, this point of view based on the S-matrix formulation of QFT was almost completely forgotten by people working on QFT at the exception of some works [38-40, 46,50,51]. However, in 1996, a student of Wightman, M. Radzikowski revived the subject. In his thesis [36,37, 47], he used microlocal analysis for the first time in this context and introduced the concept of microlocal spectrum condition, a condition on the wave front set of the distributional two-point function which represents the quantum states of positive energy (named Hadamard states) on curved spacetimes [23-26,54]. In 2000, in a breakthrough paper, Brunetti and Fredenhagen were able to generalize the Epstein-Glaser theory on curved spacetimes by relying on the fundamental contribution of Radzikowski. These results were further extended in some exciting recent works $[15,28,30-33,41,45]$ where the formalism of algebraic QFT now includes the treatment of gauge theories like Yang-Mills fields [29,55] and also incorporates the Batalin Vilkovisky formalism [20,21] to perturbatively quantize gravitation $[6,7,48]$.

All the above works rely on a formalism for renormalization theory which consists in a recursive procedure of extension of products of distributions representing Feynman amplitudes on configuration space. More precisely, if we denote by $\Delta_{F}$ the Feynman propagator which is a fundamental solution of the Klein Gordon operator $\square+m^{2}$ with a specific wave front set, then a Feynman amplitude will be a product of the form $\prod_{1<i \leq j<n} \Delta_{F}^{n_{i j}}\left(x_{i}, x_{j}\right)$; this product of distribution is well defined on the configuration space $M^{n}$ minus all diagonals $x_{i}=x_{j}$ since all the wave front sets are transverse and renormalization consists in extending the above product on the whole configuration space $M^{n}$ in a way which is compatible with the physical axiom of causality. The central technical ingredient of the recursive procedure is to control the wave front set and the microlocal scaling degree of the renormalized products in such a way that we can construct all Feynman amplitudes on all configuration spaces $M^{n}$ by induction on $n \in \mathbb{N}$. In the present paper, which is an outgrowth of [12], our goal is to build some scale spaces of distributions on manifolds, study their intrinsic property and then discuss the operations of extension and renormalization of products relying on recent works on the functional analytic properties of the space $\mathcal{D}_{\Gamma}^{\prime}$ of distributions with given wave front set $[4,10,11]$. In the short note [14], we plan to use the results of the present paper and recent works on QFT propagators $[23-26,54]$ to study the singularity of the Feynman propagator $\Delta_{F}$ near diagonals. An interesting perspective for future investigations is to study how our renormalization preserves or breaks symmetries of distributions in the spirit of [1].

The following section is a detailed overview of our results and can be read independently from the rest.

### 1.1. Main Results of our Paper

In our work, we investigate the following problem which has simple formulation: we are given a manifold $M$ and a closed submanifold $I \subset M$. We have a
distribution $t$ defined on $M \backslash I$ and we would like to find under what reasonable conditions on $t$

1. we can construct an extension $\bar{t}$ of $t$ defined on the whole manifold $M$,
2. we can control the wave front set of the extension.

The first problem has been addressed in greater generality in [13] where we found necessary and sufficient conditions for a distribution $t \in \mathcal{D}^{\prime}(M \backslash I)$ where $I$ is a closed subset of $M$, to be extendible. However, our method, which uses distance functions, is only adapted to Euclidean QFT. Actually, for QFT on curved Lorentzian spacetimes, it is crucial to find estimates on the wave front set of the extension. This is what we do in the present paper which is focused entirely on the microlocal approach.

In general, the extension problem has no positive answer for a generic distribution $t$ in $\mathcal{D}^{\prime}(M \backslash I)$ unless $t$ has moderate growth when we approach the singular submanifold $I$. In the work of Yves Meyer [44] where the manifold $M$ is flat space $\mathbb{R}^{n}$ and $I=\{0\}$, the distributions having this property are called weakly homogeneous distributions. There is also a related notion of Steinmann scaling degree in the QFT literature [51]. A first difficulty is to extend the definition of Meyer to the case of manifolds. In order to generalize the definition of scaling to measure the growth of distributions, we introduce a class of vector fields called Euler vector fields associated to the submanifold $I$ :

Definition 1.1. Let $M$ be a smooth manifold, $I$ a submanifold of $M$ and $U$ some open subset of $M$. Set $\mathcal{I}(U)$ to be the ideal of functions vanishing on $I$ and $\mathcal{I}^{k}(U)$ its $k$-th power. A vector field $\rho$ locally defined on $U$ is called Euler if

$$
\begin{equation*}
\forall f \in \mathcal{I}(U), \rho f-f \in \mathcal{I}^{2}(U) \tag{1.1}
\end{equation*}
$$

The above definition is obviously intrinsic. In particular, when $M=$ $\mathbb{R}^{d}, I=\{0\}$ then $\rho=h^{j} \frac{\mathrm{~d}}{\mathrm{~d} h^{j}}$ is Euler.

In Sect. 2, the main properties of Euler vector fields are studied. They satisfy a property of diffeomorphism invariance
Theorem 1.2. Let $M, M^{\prime}$ be two smooth manifolds, $I \subset M, I^{\prime} \subset M^{\prime}$ smooth embedded submanifolds and $\Phi:=U \longmapsto U^{\prime}$ a local diffeomorphism such that $\Phi(I \cap U)=I^{\prime} \cap U^{\prime}$. Then for any Euler vector field $\rho$ defined on $U$, its pushforward $\Phi_{*} \rho$ by the diffeomorphism $\Phi$ is also an Euler vector field.

And that the flow generated by Euler vector fields is always locally conjugate.

Theorem 1.3. Let $\rho_{1}, \rho_{2}$ be two Euler vector fields defined in some neighbourhood of $p \in I$. Then there is some germ of diffeomorphism $\Phi$ at $p$ such that $\rho_{1}=\Phi_{*} \rho_{2}$.

In the sequel, once we are given an Euler vector field $\rho$, we will denote by $\left(e^{t \rho}\right)_{t}$ the one parameter group of diffeomorphisms generated by $\rho$ and we will be particularly interested by the one parameter group of scaling flows $\left(e^{\log \lambda \rho}\right)_{\lambda \in(0,1]}$ and the open subsets $U$ which are stable by the flow $\left(e^{\log \lambda \rho}\right)_{\lambda \in(0,1]}$ are called $\rho$ convex.

For every manifold $M$ and $I \subset M$ a closed embedded submanifold, we construct in Sect. 3 a collection of spaces $\left(E_{s, I}(U)\right)_{U}$, indexed by open subsets of $M$, of weakly homogeneous distributions of degree $s$ where $E_{s, I}(U) \subset \mathcal{D}^{\prime}(U)$, with the following properties:

1. $E_{s, I}$ satisfies a restriction property, if $V \subset U$ then the restriction of $E_{s, I}(U)$ on $V$ is $E_{s, I}(V)$ and satisfies the following gluing property, if $\cup_{i} V_{i}$ is an open cover of $U$ s.t. $\cup_{i} \operatorname{int}\left(\overline{V_{i}}\right)$ is a neighbourhood of $U$, then for $t \in \mathcal{D}^{\prime}\left(\cup_{i} V_{i}\right)$, $t \in E_{s, I}\left(V_{i}\right), \forall i \Longrightarrow t \in E_{s, I}(U)$.
2. $E_{s, I}$ has the important property of diffeomorphism invariance:

Theorem 1.4. Let $M, M^{\prime}$ be two smooth manifolds, $I \subset M, I^{\prime} \subset M^{\prime}$ smooth embedded submanifolds and $\Phi:=U \longmapsto U^{\prime}$ a local diffeomorphism such that $\Phi(I \cap U)=I^{\prime} \cap U^{\prime}$. Then $\Phi^{*} E_{s, I}\left(U^{\prime}\right)=E_{s, I}(U)$.
3. The following proposition gives a concrete characterization of elements in $E_{s, I}(U)$ for arbitrary open sets $U$ which could be used as a definition of $E_{s, I}(U)$ :

Proposition 1.5. $t$ belongs to the local space $E_{s, I}(U)$ if and only if for all $p \in \operatorname{int}(\bar{U}) \cap I$ there is some open chart $\psi: V_{p} \subset \operatorname{int}(\bar{U}) \mapsto \mathbb{R}^{n+d}, \psi(I) \subset$ $\mathbb{R}^{n} \times\{0\}$ where $\lambda^{-s}\left(\psi_{*} t\right)(x, \lambda h)$ is bounded in $\mathcal{D}^{\prime}\left(\psi\left(V_{p} \cap U\right)\right)$.

However, the property of diffeomorphism invariance implies that $E_{s, I}$ does not depend on the choice of Euler vector fields. In particular, in the flat case where $M=\mathbb{R}^{n+d}$ with coordinates $(x, h)=\left(x^{i}, h^{j}\right)_{1 \leq i \leq n, 1 \leq j \leq d}$ and $I=\{h=0\}, t \in E_{s, I}\left(\mathbb{R}^{n+d}\right)$ if $\left(\lambda^{-s} t(x, \lambda h)\right)_{\lambda \in(0,1]}$ is a bounded family of distributions in $\mathcal{D}^{\prime}(V)$ where $\bar{V}$ is some neighbourhood of $I$.
4. The collection $\left(E_{s, I}\right)_{s \in \mathbb{R}}$ is filtered, $s^{\prime} \geq s \Longrightarrow E_{s, I} \subset E_{s^{\prime}, I}$ and $E_{s, I}$ satisfies an extension property (Sect. refextthmsection):

Theorem 1.6. Let $U \subset M$ be some open set. If $t \in E_{s, I}(U \backslash I)$ then $t$ is extendible. Conversely, if $t \in \mathcal{D}^{\prime}(M)$, then for any bounded open set $U \subset M$, $t \in E_{s, I}(U)$ for some $s \in \mathbb{R}$.

Moreover,
Theorem 1.7. For all $s \in \mathbb{R}$, there is a linear map

$$
t \in E_{s, I}(U \backslash I) \longmapsto \bar{t} \in E_{s^{\prime}, I}(U)
$$

where $s^{\prime}=s$ if $s+d \notin-\mathbb{N}$ and $s^{\prime}<s$ otherwise.
Using diffeomorphism invariance and locality of $E_{s, I}$, the proof of the above property is a consequence of the microlocal extension Theorem 1.8 proved in the flat case. The space $E_{s, I}$ only takes into account the growth of distributions along the submanifold $I$ which is not enough for many applications, in particular in quantum field theory where we need to know the wave front set of the extension $\bar{t}$ since we must multiply distributions to define Feynman amplitudes. Therefore, we need to refine the definition of weakly homogeneous distributions, let us introduce the necessary definitions to state our theorem. We work in $\mathbb{R}^{n+d}$ with coordinates $(x, h)=\left(x^{i}, h^{j}\right)_{1 \leq i \leq n, 1 \leq j \leq d}$,
$I=\mathbb{R}^{n} \times\{0\}$ is the linear subspace $\{h=0\}$. We assume $U$ to be of the form $U_{1} \times U_{2}$ where $U_{1}$ (resp. $U_{2}$ ) is an open subset of $\mathbb{R}^{n}$ (resp. $\mathbb{R}^{d}$ ) s.t. $\lambda U_{2} \subset U_{2}, \forall \lambda \in(0,1]$.

We denote by $(x, h ; \xi, \eta)$ the coordinates in cotangent space $T^{*} U$, where $\xi$ (resp. $\eta$ ) is dual to $x$ (resp. $h$ ). $T^{\bullet} U$ denotes the cotangent space $T^{*} U$ minus the zero section $\underline{0}$. If $U$ is convex, then a set $\Gamma \subset T^{\bullet} U$ is stable by scaling if

$$
\begin{equation*}
\forall \lambda \in(0,1],\left(\left\{\left(x, \lambda^{-1} h ; \xi, \lambda \eta\right) ;(x, h ; \xi, \eta) \in \Gamma\right\} \cap T^{\bullet} U\right) \subset \Gamma . \tag{1.2}
\end{equation*}
$$

For $\Gamma$ a closed conic set in $T^{\bullet} U, \mathcal{D}_{\Gamma}^{\prime}(U)$ is the space of distributions in $\mathcal{D}^{\prime}(U)$ with wave front set in $\Gamma$. We endow $\mathcal{D}_{\Gamma}^{\prime}(U)$ with the normal topology which is generated by the continuous seminorms for the strong topology of $\mathcal{D}^{\prime}(U)$ and the seminorms

$$
\begin{equation*}
\|t\|_{N, V, \chi}=\sup _{\xi \in V}\left|(1+|\xi|)^{N} \widehat{t \chi}(\xi)\right| \tag{1.3}
\end{equation*}
$$

for all $N \in \mathbb{N}, \chi \in \mathcal{D}(U), V$ a closed cone in $\mathbb{R}^{n+d, *}$ such that $(\operatorname{supp} \chi \times V) \cap$ $\Gamma=\emptyset$.

For $U$ a convex set and $\Gamma \subset T^{\bullet} U$ a closed conic set stable by scaling, we denote by $E_{s}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$ the locally convex space of weakly homogeneous distributions of degree $s$ in $\mathcal{D}_{\Gamma}^{\prime}(U)$ defined as follows: $t \in E_{s}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$ if $\left(\lambda^{-s} t(x, \lambda h)\right)_{\lambda \in(0,1]}$ is a bounded family of distributions in $\mathcal{D}_{\Gamma}^{\prime}(U)$.

We denote by $N^{*}(I)$ the conormal bundle of $I$. The central result of our paper is a general extension theorem (Sect. 4.3) for distributions in flat space with control of the wave front set:
Theorem 1.8. Let $U \subset \mathbb{R}^{n+d}$ be of the form $U_{1} \times U_{2}$ where $U_{1}$ (resp. $U_{2}$ ) is an open subset of $\mathbb{R}^{n}\left(\right.$ resp. $\left.\mathbb{R}^{d}\right)$ s.t. $\lambda U_{2} \subset U_{2}, \forall \lambda \in(0,1]$ and $\Gamma$ some closed conic set in $T^{\bullet} U$. Set $\Xi=\{(x, 0 ; \xi, \eta) \mid(x, h ; \xi, 0) \in \Gamma\} \subset T_{I}^{*} U$. For all $s \in \mathbb{R}$ there exists a linear, bounded map $t \in E_{s}\left(\mathcal{D}_{\Gamma}^{\prime}(U \backslash I)\right) \longmapsto \bar{t} \in E_{s^{\prime}}\left(\mathcal{D}_{\Gamma \cup \Xi \cup N^{*}(I)}^{\prime}(U)\right)$, where $s^{\prime}=s$ if $s+d \notin-\mathbb{N}$ and $s^{\prime}<s$ otherwise.

An immediate corollary of the above theorem is the bound $W F(\bar{t}) \subset$ $\left(W F(t) \cup \Xi \cup N^{*}(I)\right)$ on the wave front of the extension. The central ingredients of the proof are as follows: a partition of unity formula which is a continuous analog of the Littlewood-Paley decomposition used by Meyer [44], to consider $(\lambda, x, h) \mapsto \lambda^{-s} t(x, \lambda h)$ as a distribution on the extended space $\mathbb{R} \times \mathbb{R}^{n+d}$ and a new integral formula for the extension which reduces the bounds on the wave front set as applications of the Theorems in Ref. [4].

A particular case of the above theorem was proved by Brunetti and Fredenhagen [5] when the closure $\bar{\Gamma}$ of $\Gamma$ over $I$ is contained in $N^{*}(I)$. In that case, one can choose an extension $\bar{t}$ such that $W F(\bar{t}) \subset W F(t) \cup N^{*}(I)$ and $\bar{t} \in E_{s^{\prime}}\left(\mathcal{D}_{\Gamma \cup N^{*}(I)}^{\prime}(U)\right)$. The important condition $\left(\bar{\Gamma} \cap T_{I}^{\bullet} M\right) \subset N^{*}(I)$, called conormal landing condition, is intrinsic and generalizes in a straightforward way to manifolds. It is a kind of microlocal regularity condition and ensures that the wave front set of the extension is minimal.

Motivated by this intrinsic geometric condition and the result of Theorem 1.8, we construct in Sect. 6 a subspace $E_{s, N^{*}(I)} \subset E_{s, I}$ which satisfies the following properties:

1. $E_{s, N^{*}(I)}$ satisfies the same restriction and gluing properties as $E_{s, I}$
2. $E_{s, N^{*}(I)}$ has the important property of diffeomorphism invariance:

Theorem 1.9. Let $M, M^{\prime}$ be two smooth manifolds, $I \subset M, I^{\prime} \subset M^{\prime}$ smooth embedded submanifolds and $\Phi:=U \longmapsto U^{\prime}$ a local diffeomorphism such that $\Phi(I \cap U)=I^{\prime} \cap U^{\prime}$. Then $\Phi^{*} E_{s, N^{*}(I)}\left(U^{\prime}\right)=E_{s, N^{*}(I)}(U)$.

A consequence of the above diffeomorphism invariance is that the definition of $E_{S, N^{*}(I)}$ does not depend on the choice of Euler vector fields.
3. The collection of spaces $\left(E_{s, N^{*}(I)}\right)_{s \in \mathbb{R}}$ is filtered, $s^{\prime} \geq s \Longrightarrow E_{s, N^{*}(I)} \subset$ $E_{s^{\prime}, N^{*}(I)}$
The subspace $E_{s, N^{*}(I)}$ satisfies an extension theorem (Sect. 7)
Theorem 1.10. Let $U \subset M$ be some open neighbourhood of I. If $t \in E_{s, N^{*}(I)}$ $(U \backslash I)$ then there exists an extension $\bar{t}$ with $W F(\bar{t}) \subset W F(t) \cup N^{*}(I)$ and $\bar{t} \in E_{s^{\prime}, N^{*}(I)}(U)$, where $s^{\prime}=s$ if $s+d \notin-\mathbb{N}$ and $s^{\prime}<s$ otherwise.

The main interest of this subspace is that the wave front set $W F(\bar{t})$ of the extension $\bar{t}$ is minimal in the sense we only add the conormal $N^{*}(I)$ to $W F(t)$. Then in Sect. 8, we present an application of the above theorem to renormalize products of distributions, we denote by $E_{s}^{\rho}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$ the space of distributions $t$ s.t. the family $\left(\lambda^{-s} e^{\log \lambda \rho *} t\right)_{\lambda \in(0,1]}$ is bounded in $\mathcal{D}_{\Gamma}^{\prime}(U)$ for some $\rho$-convex set $U$ and some cone $\Gamma$ stable by scaling:

Theorem 1.11. Let $\rho$ be some Euler vector field, $U$ some neighbourhood of $I$, $\left(\Gamma_{1}, \Gamma_{2}\right)$ two cones in $T^{\bullet}(U \backslash I)$ which satisfy the conormal landing condition and $\Gamma_{1} \cap-\Gamma_{2}=\emptyset$. Set $\Gamma=\left(\Gamma_{1}+\Gamma_{2}\right) \cup \Gamma_{1} \cup \Gamma_{2}$. If $\Gamma_{1}+\Gamma_{2}$ satisfies the conormal landing condition then there exists a bilinear map $\mathcal{R}$ satisfying the following properties:

- $\mathcal{R}:\left(u_{1}, u_{2}\right) \in E_{s_{1}}^{\rho}\left(\mathcal{D}_{\Gamma_{1}}^{\prime}(U \backslash I)\right) \times E_{s_{2}}^{\rho}\left(\mathcal{D}_{\Gamma_{2}}^{\prime}(U \backslash I)\right) \mapsto \mathcal{R}\left(u_{1} u_{2}\right)$ $\in E_{s, N^{*}(I)}(U), \forall s<s_{1}+s_{2}$
- $\mathcal{R}\left(u_{1} u_{2}\right)=u_{1} u_{2}$ on $U \backslash I$
- $\mathcal{R}\left(u_{1} u_{2}\right) \in \mathcal{D}_{\Gamma \cup N^{*}(I)}^{\prime}(U)$.

The above actually means that $\mathcal{R}\left(u_{1} u_{2}\right) \in \mathcal{D}_{\Gamma \cup N^{*}(I)}^{\prime}(U)$ is a distributional extension of the Hörmander product $u_{1} u_{2} \in \mathcal{D}_{\Gamma}^{\prime}(U \backslash I)$.

In Sect. 9, we study the renormalization ambiguities which aim to classify the various extensions we constructed.

## 2. Scaling on Manifolds

Introduction. To solve the extension problem for distributions on manifolds, we define in 1.1 a class of Euler vector fields which scale transversally to a given fixed submanifold $I \subset M$. In this section, we discuss the most important properties of this class of vector fields and their flows.

Example. If $M=\mathbb{R}^{n+d}$ and $I$ is the vector subspace which is the zero locus $\left\{h^{j}=0\right\}$ of the collection of coordinate functions $\left(h^{j}\right)_{j}$, then $h^{j} \partial_{h^{j}}$ is Euler.

Indeed, by application of Hadamard's lemma, if $f \in \mathcal{I}$ then $f=h^{j} H_{j}$ where the $H_{j}$ are smooth functions, which implies $\rho f=f+h^{i} h^{j} \partial_{h^{j}} H_{i} \Longrightarrow \rho f-f=$ $h^{i} h^{j} \partial_{h^{j}} H_{i} \in \mathcal{I}^{2}$.

Euler vector fields satisfy the following nice properties:

- Given $I$, the set of global Euler vector fields defined on some open neighbourhood of $I$ is nonempty.
- For any local Euler vector field $\left.\rho\right|_{U}$, for any open set $V \subset U$ there is an Euler vector field $\rho^{\prime}$ defined on a global neighbourhood of $I$ such that $\left.\rho^{\prime}\right|_{V}=\left.\rho\right|_{V}$.

Proof. These two properties result from the fact that one can glue together Euler vector fields by a partition of unity subordinated to some cover of some neighbourhood $N$ of $I$. By paracompactness of $M$, we can pick an arbitrary locally finite open cover $\cup_{a \in A} V_{a}$ of $M$ by open sets $V_{a}$, define the subset $J \subset A$ such that for each $a \in J, V_{a} \cap I \neq \emptyset$, there is a local chart $(x, h): V_{a} \mapsto \mathbb{R}^{n+d}$ where the image of $I$ by the local chart is the subspace $\left\{h^{j}=0\right\}$. For such charts which have non empty overlaps with $I$, we can define an Euler vector field $\left.\rho\right|_{V_{a}}$; it suffices to consider the vector field $\rho=h^{j} \partial_{h^{j}}$ in each local chart $V_{a}, a \in J$ and by the example 2 this is Euler. The vector fields $\rho_{a}=\left.\rho\right|_{V_{a}}$ do not necessarily coincide on the overlaps $V_{a} \cap V_{b}$. However, for any partition of unity $\left(\alpha_{a}\right)_{a}$ subordinated to $\left(V_{a}\right)_{a}$, the vector field $\rho$ defined by the formula

$$
\begin{equation*}
\rho=\sum_{a \in J} \alpha_{a} \rho_{a} \tag{2.1}
\end{equation*}
$$

is Euler since $\forall f \in \mathcal{I}(U), \rho f-f=\sum_{a \in J} \alpha_{a} \rho_{a} f-\sum_{a \in A} \alpha_{a} f=\sum_{a \in J}$ $\alpha_{a}\left(\rho_{a} f-f\right)-\sum_{a \in A \backslash J} \alpha_{a} f \in \mathcal{I}^{2}(U)$ since every $\alpha_{a}$ for $a \in A \backslash J$ vanishes on some neighbourhood of $I$.

We can find the general form of all possible Euler vector fields $\rho$ in arbitrary coordinate system $(x, h)$ where $I=\{h=0\}$.

Lemma 2.1. $\left.\rho\right|_{U}$ is Euler if and only if for all $p \in I \cap U$, in any arbitrary local chart $(x, h)$ centered at $p$ where $I=\{h=0\}, \rho$ has the standard form

$$
\begin{equation*}
\rho=h^{j} \frac{\partial}{\partial h^{j}}+h^{i} A_{i}^{j}(x, h) \frac{\partial}{\partial x^{j}}+h^{i} h^{j} B_{i j}^{k}(x, h) \frac{\partial}{\partial h^{k}} \tag{2.2}
\end{equation*}
$$

where $A, B$ are smooth functions of $(x, h)$.
Proof. The proof is straightforward by noticing that

$$
\begin{align*}
& \forall j, \rho h^{j}-h^{j}=o\left(\|h\|^{2}\right)  \tag{2.3}\\
& \forall(i, j),\left(\rho x^{i} h^{j}\right)-x^{i} h^{j}=o\left(\|h\|^{2}\right) \tag{2.4}
\end{align*}
$$

from the definition of $\rho$ being an Euler vector field.

### 2.1. The Diffeomorphism Invariance of Euler Vector Fields

The class of Euler vector fields enjoys many interesting properties, the first being diffeomorphism invariance. Let $G$ be the pseudogroup of local diffeomorphisms of $M$ (i.e. an element $\Phi$ in $G$ is defined over an open set $U \subset M$ and maps it diffeomorphically to an open set $\Phi(U) \subset M)$ such that $\forall p \in$ $I \cap U, \forall \Phi \in G, \Phi(p) \in I$. From the introduction, let us recall the statement of Theorem 1.2:

Theorem 2.2. Let $M, M^{\prime}$ be two smooth manifolds, $I \subset M, I^{\prime} \subset M^{\prime}$ smooth embedded submanifolds and $\Phi:=U \longmapsto U^{\prime}$ an element of $G$ such that $\Phi(I \cap$ $U)=I^{\prime} \cap U^{\prime}$. Then for any Euler vector field $\rho$ defined on $U$ the push-forward $\Phi_{*} \rho$ is Euler.

Proof. It suffices to establish that for all Euler vector field $\rho$, for all $\Phi \in G, \Phi_{*} \rho$ is Euler. In the sequel, we shall identify vector fields $X$ on any manifold with the Lie derivative $L_{X}$ which is an operator acting on functions of the given manifold. The identity $\forall f \in C^{\infty}(U),\left(\Phi_{*} \rho\right) f=\Phi^{-1 *}\left(\rho\left(\Phi^{*} f\right)\right)$ holds true, it follows from the well-known functorial identity $\Phi_{*}(\rho f)=\left(\Phi_{*} \rho\right)\left(\Phi_{*} f\right)$ [42, Proposition 2.80 p. 93]. Now if we choose $f$ to be an arbitrary function in $\mathcal{I}$ then we get

$$
\begin{equation*}
\forall \Phi \in G, \forall f \in \mathcal{I},\left(\Phi_{*} \rho\right) f-f=\Phi^{-1 *}\left(\rho\left(\Phi^{*} f\right)-\left(\Phi^{*} f\right)\right) \tag{2.5}
\end{equation*}
$$

Since $\Phi(I) \subset I$, we have actually $\Phi^{*} f \in \mathcal{I}$; hence $\left(\rho\left(\Phi^{*} f\right)-\left(\Phi^{*} f\right)\right) \in \mathcal{I}^{2}$ and we deduce that

$$
\Phi^{-1 *}\left(\rho\left(\Phi^{*} f\right)-\left(\Phi^{*} f\right)\right) \in \Phi^{-1 *} \mathcal{I}^{2}=\mathcal{I}^{2}
$$

### 2.2. Local Conjugations of Scalings

We work at the level of germs, a germ of Euler vector field at $p$ is some Euler vector field defined on some neighbourhood of $p$. A germ of diffeomorphism (resp. smooth family of germs) at $p$ fixing $p$ is some smooth map $\Phi \in C^{\infty}(U, M)$ (resp. $\left.\Phi \in C^{\infty}([0,1] \times U, M)\right)$ where $U$ is some neighbourhood of $p$, such that there is a coordinate chart $\left(x^{i}, h^{j}\right)_{1 \leq i \leq n, 1 \leq j \leq d}: U \mapsto \mathbb{R}^{n+d}$ where $I \cap U=$ $\left\{h^{j}=0,1 \leq j \leq d\right\}$ and $\left|\operatorname{det} d_{x, h} \Phi\right|>0\left(\right.$ resp. $\left.\inf _{\lambda \in[0,1]}\left|\operatorname{det} d_{x, h} \Phi(., \lambda)\right|>0\right)$ on $U$. On the one hand, we saw that the class of Euler vector fields is invariant by the action of the pseudogroup $G$ of local diffeomorphisms preserving $I$; on the other hand we will prove that for any two germs of Euler vector fields $\rho_{1}, \rho_{2}$ at $p$, there is a germ of diffeomorphism $\Psi$ at $p$ such that $\Psi_{*} \rho_{1}=\rho_{2}$.

Denote by $S(\lambda)=e^{\log \lambda \rho}$ the scaling operator defined by the Euler $\rho$; $S(\lambda)$ satisfies the identity $S\left(\lambda_{1}\right) \circ S\left(\lambda_{2}\right)=S\left(\lambda_{1} \lambda_{2}\right)$.

Proposition 2.3. Let p in $I$, $\left(\rho_{1}, \rho_{2}\right)$ be two germs of Euler vector fields at $p$ and $S_{a}(\lambda)=e^{\log \lambda \rho_{a}}, a=1,2$ the corresponding scalings. Then there is a smooth family $(\Phi(\lambda))_{\lambda \in[0,1]}$ of germs of diffeomorphisms at $p$ such that

$$
S_{2}(\lambda)=S_{1}(\lambda) \circ \Phi(\lambda)
$$

Proof. We use a local chart $(x, h): U \mapsto \mathbb{R}^{n+d}$ centered at $p$, where $I=\{h=$ $0\}$. We set $\rho=h^{j} \partial_{h^{j}}$ which generates the flow $S(\lambda)=e^{\log \lambda \rho}$ and we construct two germs of diffeomorphisms $\Phi_{a}(\lambda), a=1,2$ at $p$ such that

$$
\begin{equation*}
\forall \lambda \in(0,1], \Phi_{a}(\lambda)=S_{a}^{-1}(\lambda) \circ S(\lambda), a=1,2 \tag{2.6}
\end{equation*}
$$

Then the germ of diffeomorphism $\Phi(\lambda)=\Phi_{1}(\lambda) \circ \Phi_{2}^{-1}(\lambda)$ is a solution of our problem.

Let us construct $\Phi_{a}(\lambda)$ as a solution of the differential equation obtained by differentiating 2.6 :

$$
\begin{equation*}
\lambda \frac{\partial}{\partial \lambda} \Phi_{a}(\lambda)=\left(\rho-S^{-1}(\lambda)_{*} \rho_{a}\right)\left(\Phi_{a}(\lambda)\right) \text { with } \Phi_{a}(1)=I d \tag{2.7}
\end{equation*}
$$

Let $f$ be a smooth function and $X$ a vector field; then the push-forward of $f X$ by a diffeomorphism $\Phi$ is

$$
\begin{equation*}
\Phi_{*}(f X)=\left(\Phi_{*} f\right)\left(\Phi_{*} X\right) \tag{2.8}
\end{equation*}
$$

We use the general form (2.2) for Euler vector fields:

$$
\rho_{a}=h^{j} \frac{\partial}{\partial h^{j}}+h^{i} A_{i}^{j}(x, h) \frac{\partial}{\partial x^{j}}+h^{i} h^{j} B_{i j}^{k}(x, h) \frac{\partial}{\partial h^{k}}
$$

hence we apply formula (2.8)

$$
\begin{aligned}
S^{-1}(\lambda)_{*} \rho_{a} & =\lambda h^{j} \lambda^{-1} \partial_{h^{j}}+\lambda h^{i} A_{i}^{j}(x, \lambda h) \frac{\partial}{\partial x^{j}}+\lambda^{2} h^{i} h^{j} B_{i j}^{k}(x, \lambda h) \lambda^{-1} \frac{\partial}{\partial h^{k}} \\
& =h^{j} \partial_{h^{j}}+\lambda h^{i} A_{i}^{j}(x, \lambda h) \frac{\partial}{\partial x^{j}}+\lambda h^{i} h^{j} B_{i j}^{k}(x, \lambda h) \frac{\partial}{\partial h^{k}} \\
\Longrightarrow \rho-S_{*}^{-1}(\lambda) \rho_{a} & =-\lambda\left(h^{i} A_{i}^{j}(x, \lambda h) \frac{\partial}{\partial x^{j}}+h^{i} h^{j} B_{i j}^{k}(x, \lambda h) \frac{\partial}{\partial h^{k}}\right) .
\end{aligned}
$$

If we define the vector field $X(\lambda)=-\left(h^{i} A_{i}^{j}(x, \lambda h) \frac{\partial}{\partial x^{j}}+h^{i} h^{j} B_{i j}^{k}(x, \lambda h) \frac{\partial}{\partial h^{k}}\right)$, then

$$
\begin{equation*}
\frac{\partial \Phi_{a}}{\partial \lambda}(\lambda)=X\left(\lambda, \Phi_{a}(\lambda)\right) \text { with } \Phi_{a}(1)=I d \tag{2.9}
\end{equation*}
$$

$\Phi_{a}(\lambda)$ satisfies a non autonomous ODE where the vector field $X(\lambda,$.$) depends$ smoothly on $(\lambda, x, h)$. Note that for all $\lambda \in[0,1]$, the vector field $X(\lambda)$ vanishes at $p$; therefore, by choosing some sufficiently small open neighbourhood $U$ of $p$, there is a smooth map $\Phi(\lambda, p)$ which integrates the differential equation (2.9) on the interval $[0,1]$.

Keeping the notations and assumptions of the above proposition, we give a simple proof of Theorem 1.3 which states that Euler vector fields are always locally conjugate:
Theorem 2.4. Let $\rho_{1}, \rho_{2}$ be two germs of Euler vector fields at $p \in I$. Then there is a germ of diffeomorphism $\Psi$ at $p$ such that $\rho_{1}=\Psi_{*} \rho_{2}$.

Proof. To prove the above claim, it suffices to construct $\Psi$ in such a way that $S_{1}(\lambda)=\Psi \circ S_{2}(\lambda) \circ \Psi^{-1}$ where $S_{a}(\lambda)=e^{\log \lambda \rho_{a}}, a=(1,2)$. In local coordinates $\left(x^{i}, h^{j}\right)_{i j}$ around $p$ where $I=\{h=0\}$, let $\rho=h^{j} \partial_{h^{j}}$ be some Euler vector field (canonically associated to the choice of coordinates),
$S(\lambda)=e^{\log \lambda \rho}$ the corresponding scaling and $\Phi_{a}(\lambda)$ the family of diffeomorphisms $\Phi_{a}(\lambda)=S^{-1}(\lambda) \circ S_{a}(\lambda)$ which has a smooth limit $\Psi_{a}=\Phi_{a}(0)$ when $\lambda \rightarrow 0$ by Proposition 2.3. Start from the identity

$$
\begin{aligned}
\Phi_{a}(\lambda) \circ S(\mu) & =\left(S_{a}^{-1}(\lambda) \circ S(\lambda)\right) \circ S(\mu)=S_{a}^{-1}(\lambda) \circ S(\lambda \mu) \\
& =S_{a}(\mu) \circ S_{a}^{-1}(\lambda \mu) \circ S(\lambda \mu)=S_{a}(\mu) \circ \Phi_{a}(\lambda \mu)
\end{aligned}
$$

Hence $\forall(\lambda, \mu), \Phi_{a}(\lambda) \circ S(\mu)=S_{a}(\mu) \circ \Phi_{a}(\lambda \mu) \Longrightarrow \Phi_{a}(0) \circ S(\mu)=S_{a}(\mu) \circ \Phi_{a}(0)$ at the limit when $\lambda \rightarrow 0$ where the limit makes sense because $\Phi_{a}$ is smooth in $\lambda$ at 0 . Hence we find that $S_{1}(\lambda)=\Psi_{1} \circ \Psi_{2}^{-1} \circ S_{2}(\lambda) \circ \Psi_{2} \circ \Psi_{1}^{-1}$ and the germ of diffeomorphism $\Psi=\Psi_{1} \circ \Psi_{2}^{-1}$ solves our problem.

## 3. The Space $\boldsymbol{E}_{s, I}(\boldsymbol{U})$

In this section, $I$ is a closely embedded submanifold of $M$ and we use Euler vector fields to scale distributions along $I$ and to define scale spaces of distributions. First a set $U$ is called $\rho$-convex if $U$ is stable by the flow $\left(e^{-t \rho}\right)_{t>0}$. We give a definition of weakly homogeneous distributions on manifolds but this definition is $\rho$ dependent:
Definition 3.1. Let $U$ be a $\rho$-convex open set. The set $E_{s}^{\rho}(U)$ is defined as the set of distributions $t \in \mathcal{D}^{\prime}(U)$ such that

$$
\forall \varphi \in \mathcal{D}(U), \exists C, \sup _{\lambda \in(0,1]}\left|\left\langle\lambda^{-s} t_{\lambda}, \varphi\right\rangle\right| \leq C
$$

We next define the space $E_{s, p}^{\rho}$ of distributions which are locally weakly homogeneous of degree $s$ at $p \in I$.
Definition 3.2. A distribution $t$ belongs to $E_{s, p}^{\rho}$ if there exists an open $\rho$-convex set $U \subset M$ such that $\bar{U}$ is a neighbourhood of $p$ and such that $t \in E_{s}^{\rho}(U)$.
A key locality theorem. The next Theorem proves a crucial result that if $t$ is locally $E_{s, p}^{\rho}$ for some Euler vector field $\rho$ then it is locally $E_{s, p}^{\rho}$ for all Euler vector fields $\rho$.
Theorem 3.3. Let $p \in I$; if $t$ belongs to $E_{s, p}^{\rho}$ for some Euler vector field $\rho$, then it is so for any other Euler vector field.
Proof. It suffices to prove the equality $E_{s, p}^{\rho_{1}}=E_{s, p}^{\rho_{2}}$ for any pair $\rho_{1}, \rho_{2}$ of Euler vector fields at $p$. Recall there is a smooth family of germs $\{\Phi(\lambda)\}_{\lambda \in[0,1]}$ satisfying $\Phi(\lambda)=S_{1}^{-1}(\lambda) \circ S_{2}(\lambda)$ where $\left(S_{a}(\lambda)=e^{\log \lambda \rho_{a}}\right)_{a \in\{1,2\}}$, by Proposition 2.3. Then $\lambda^{-s} S_{2}(\lambda)^{*} t=\lambda^{-s} \Phi(\lambda)^{*}\left(S_{1}(\lambda)^{*} t\right)$ is a bounded family of distributions in $\mathcal{D}^{\prime}(V)$ for some neighbourhood $V$ of $p$ implies that $\lambda^{-s}\left(S_{1}(\lambda)^{*} t\right)$ is also a bounded family of distribution in $\mathcal{D}^{\prime}\left(V^{\prime}\right)$ for some smaller neighbourhood $V^{\prime}$ of $p$.

A comment on the statement of the theorem, first the definition that $U$ is $\rho$-convex is $\forall p \in U, \forall \lambda \in(0,1], S(\lambda, p) \in U$. Therefore, the fact that $\lambda>0$ in the definition allows $U$ to have empty intersection with $I$. The previous theorem allows to give a definition of the spaces of distributions $E_{s, p}$ and $E_{s, I}(U)$ which makes no mention of the choice of Euler vector field:

Definition 3.4. A distribution $t$ belongs to $E_{s, p}$ if $t$ belongs to $E_{s, p}^{\rho}$ for some $\rho$. We define $E_{s, I}(U)$ as the space of all distributions $t \in \mathcal{D}^{\prime}(U)$ such that $t \in E_{s, p}^{\rho}, \forall p \in I \cap \operatorname{int}(\bar{U})$.

An equivalent definition of the space $E_{s, I}(U)$ is the following: $t$ belongs to the local space $E_{s, I}(U)$ if and only if for all $p \in I \cap \operatorname{int}(\bar{U})$, there is some open chart $\psi: V_{p} \mapsto \mathbb{R}^{n+d}, \psi(I) \subset \mathbb{R}^{n} \times\{0\}$ where $\lambda^{-s}\left(\psi_{*} t\right)(x, \lambda h)$ is bounded in $\mathcal{D}^{\prime}\left(\psi\left(V_{p} \cap U\right)\right)$.

It is immediate that $E_{s, I}$ satisfies the restriction property: if $V \subset U$ then $p \in \operatorname{int}(\bar{V}) \cap I \Longrightarrow p \in \operatorname{int}(\bar{U}) \cap I$ and, therefore, the restriction of $E_{s, I}(U)$ on $V$ is $E_{s, I}(V)$.

A consequence of Theorem 3.3 is the following property of $E_{s, I}$ under gluings:

Theorem 3.5. $E_{s, I}$ satisfies the following gluing property: if $\cup_{i} V_{i}$ is an open cover of $U$ s.t. $\cup_{i}$ int $\left(\overline{V_{i}}\right)$ is a neighbourhood of $U$ then for $t \in \mathcal{D}^{\prime}\left(\cup V_{i}\right), t \in$ $E_{s, I}\left(V_{i}\right), \forall i \Longrightarrow t \in E_{s, I}(U)$

Proof. It suffices to prove that $t \in E_{s, p}(U)$ for all $p \in \operatorname{int}(\bar{U}) \cap I$. Let $p \in$ $\operatorname{int}(\bar{U}) \cap I$; then obviously $p \in \cup_{i} \operatorname{int}\left(\overline{V_{i}}\right)$ since $\cup_{i} \operatorname{int}\left(\overline{V_{i}}\right)$ is a neighbourhood of $U$. Then by definition of $t \in E_{s, p}\left(V_{i}\right)$, there is some neighbourhood $V_{p}$ of $p$ s.t. $V_{p} \subset \operatorname{int}\left(\overline{V_{i}}\right)$ for some $i$ and $\lambda^{-s} e^{\log \lambda \rho *} t$ is bounded in $\mathcal{D}^{\prime}\left(V_{p} \cap V_{i}\right)$ which implies in particular that $\lambda^{-s} e^{\log \lambda \rho *} t$ is bounded in $\mathcal{D}^{\prime}\left(\tilde{V}_{p} \cap U\right)$ where $\tilde{V}_{p}=V_{p} \cap \operatorname{int}(\bar{U})$ is a neighbourhood of $p$ in $\operatorname{int}(\bar{U})$; therefore $t \in E_{s, p}(U)$.

We prove Theorem 1.4 which claims that $E_{s, I}(U)$ satisfies a property of diffeomorphism invariance:

Theorem 3.6. Let $I$ (resp. $I^{\prime}$ ) be a closed embedded submanifold of $M$ (resp. $\left.M^{\prime}\right), U \subset M$ (resp. $U^{\prime} \subset M^{\prime}$ ) open and $\Phi: U^{\prime} \mapsto U$ a diffeomorphism s.t. $\Phi\left(U^{\prime} \cap I^{\prime}\right)=I \cap U$. Then $\Phi^{*} E_{s, I}(U)=E_{s, I^{\prime}}\left(U^{\prime}\right)$.

Proof. By Theorem 3.5, we can localize the proof at all points $p \in \operatorname{int}(\bar{U}) \cap I$. Let $p \in \operatorname{int}(\bar{U}) \cap I$, then $t \in E_{s, I}(U)$ implies by definition that $t \in E_{s, p}^{\rho}$ for some $\rho$ which means that

$$
\begin{aligned}
& \lambda^{-s} e^{\log \lambda \rho *} t \text { bounded in } \mathcal{D}^{\prime}(V), \operatorname{int}(\bar{V}) \text { neighbourhood of } p \\
& \quad \Leftrightarrow \lambda^{-s} \Phi^{*} e^{\log \lambda \rho *} \Phi^{-1 *}\left(\Phi^{*} t\right) \text { bounded in } \mathcal{D}^{\prime}\left(\Phi^{-1}(V)\right)
\end{aligned}
$$

because the pull-back by a diffeomorphism is bounded from $\mathcal{D}^{\prime}(V)$ to $\mathcal{D}^{\prime}\left(\Phi^{-1}(V)\right)[4$, Prop 6.1],

$$
\Leftrightarrow \lambda^{-s} e^{\log \lambda\left(\Phi_{*}^{-1} \rho\right) *}\left(\Phi^{*} t\right) \text { bounded in } \mathcal{D}^{\prime}\left(\Phi^{-1}(V)\right)
$$

where the vector field $\Phi_{*}^{-1} \rho$ is a germ of Euler field near $p$ by Theorem 1.2. Therefore, $\Phi^{*} t$ is in $E_{s, p^{\prime}}^{\Phi_{*}^{-1} \rho}$ where $p^{\prime}=\Phi^{-1}(p)$ and repeating the proof for all $p \in \operatorname{int}(\bar{U}) \cap I$ yields the claim.

## 4. The Extension Problem on Flat Space

Formulation of the problem. We work in $\mathbb{R}^{n+d}$ with coordinates $(x, h) ; I=$ $\mathbb{R}^{n} \times\{0\}$ is the linear subspace $\{h=0\}$. In the sequel, unless it is specified otherwise, we will always assume that we work with open sets $U$ of the form $U_{1} \times U_{2}$ where $U_{1}$ (resp. $U_{2}$ ) is an open subset of $\mathbb{R}^{n}$ (resp. $\mathbb{R}^{d}$ ) s.t. $\lambda U_{2} \subset$ $U_{2}, \forall \lambda \in(0,1]$ in particular such $U$ is convex meaning that

$$
\begin{equation*}
(x, h) \in U \Longrightarrow \forall \lambda \in(0,1],(x, \lambda h) \in U \tag{4.1}
\end{equation*}
$$

We reformulate the extension problem on flat space.
Problem. We are given a convex open set $U \subset \mathbb{R}^{n+d}$ and $I=\mathbb{R}^{n} \times\{0\}$. We have a distribution $t \in \mathcal{D}^{\prime}(U \backslash I)$ and we would like to find under what reasonable conditions on $t$ one can construct an extension $\bar{t} \in \mathcal{D}^{\prime}(U)$.

### 4.1. Construction of a Formal Extension

In this subsection, we construct a candidate for the formal extension.
Defining a smooth partition of unity. A partition of unity will provide us with some family of smooth functions supported in $\mathbb{R}^{n+d} \backslash I$ approximating the constant function $1 \in C^{\infty}\left(\mathbb{R}^{n+d} \backslash I\right)$.
Definition 4.1. A smooth partition of unity is a function $\Psi \in C^{\infty}((0, \infty)$, $\left.\mathbb{R}^{n+d} \backslash I\right)$ such that $\forall \Lambda \in(0, \infty), \Psi_{\Lambda}=0$ in some neighbourhood of $I$ and $\Psi_{\Lambda} \underset{\Lambda \rightarrow \infty}{\rightarrow} 1$ for the Fréchet topology of $C^{\infty}\left(\mathbb{R}^{n+d} \backslash I\right)$.

Motivated by the above definition, we choose a function $\chi$ such that $\chi=1$ in a neighbourhood of $I$ and the projection $\pi: \mathbb{R}^{n} \times \mathbb{R}^{d} \longmapsto \mathbb{R}^{n} \times\{0\}$ is proper on the support of $\chi$. This implies $\chi$ satisfies the following constraint: for all compact set $K \subset \mathbb{R}^{n}, \exists(a, b) \in \mathbb{R}^{2}$ such that $b>a>0$ and $\left.\chi\right|_{\left(K \times \mathbb{R}^{d}\right) \cap\{|h| \leq a\}}=$ $1,\left.\chi\right|_{\left(K \times \mathbb{R}^{d}\right) \cap\{|h| \geq b\}}=0$. We set $\Psi(\Lambda, x, h)=1-\chi(x, \Lambda h)$ and it is a simple exercise to verify that this defines a partition of unity of $\mathbb{R}^{n+d} \backslash I$.

## A candidate for the extension.

Proposition 4.2. Let $U$ be an open set of $\mathbb{R}^{n+d}$; if $t \in \mathcal{D}^{\prime}(U \backslash I)$, then for any smooth partition of unity $\Psi_{\Lambda}$

$$
\begin{equation*}
t=\lim _{\Lambda \rightarrow+\infty} t \Psi_{\Lambda} \tag{4.2}
\end{equation*}
$$

as a distribution on $U \backslash I$.
From the above proposition, we deduce that if $\lim _{\Lambda \rightarrow+\infty} t \Psi_{\Lambda}$ converges in $\mathcal{D}^{\prime}(U)$ the limit defines an extension of $t$. So this raises the question that for all test function $\varphi \in \mathcal{D}(U)$, does the limit $\lim _{\Lambda \rightarrow+\infty}\left\langle t, \Psi_{\Lambda} \varphi\right\rangle$ exist ? To study this question, we introduce a continuous decomposition of our partition of unity formula

$$
\begin{aligned}
1-\chi(x, \Lambda h) & =1-\chi(x, h)+\chi(x, h)-\chi(x, \Lambda h) \\
& =\int_{\Lambda^{-1}}^{1} \frac{d \lambda}{\lambda} \lambda \frac{d}{d \lambda}\left[\chi\left(x, \lambda^{-1} h\right)\right]+1-\chi(x, h) \\
& =\int_{\Lambda^{-1}}^{1} \frac{d \lambda}{\lambda}(-\rho \chi)\left(x, \lambda^{-1} h\right)+1-\chi(x, h),
\end{aligned}
$$

where $\rho$ is the Euler vector field $\sum_{j=1}^{d} h^{j} \frac{\partial}{\partial h^{j}}$ which scales transversally to $I=\left\{h^{j}=0,1 \leq j \leq d\right\}$. In the sequel, we will write $\rho=h \frac{\partial}{\partial h}$ for brevity. Set $\psi=-\rho \chi$ and define the scaling by a factor $\lambda \in(0,1]$ :

$$
\psi_{\lambda}(x, h)=\psi(x, \lambda h)
$$

In these notations, the partition of unity formula simply writes

$$
\begin{equation*}
\chi-\chi_{\Lambda}=\int_{\Lambda^{-1}}^{1} \frac{d \lambda}{\lambda} \psi_{\lambda^{-1}} \tag{4.3}
\end{equation*}
$$

In the sequel, instead of studying the limit $\Lambda \rightarrow \infty$, we will set $\varepsilon^{-1}=\Lambda$ and study instead the limit $\varepsilon \rightarrow 0$. We will also denote by $\pi$ the projection $(x, h) \in \mathbb{R}^{n} \times \mathbb{R}^{d} \longmapsto x \in \mathbb{R}^{n}$ and $\chi$ will always designate a smooth function such that $\chi=1$ in some neighbourhood of $I$ and $\pi$ is proper on supp $\chi$. In what follows, we will study the behaviour of

$$
\begin{equation*}
t\left(1-\chi_{\varepsilon^{-1}}\right)=\int_{\varepsilon}^{1} \frac{d \lambda}{\lambda} t \psi_{\lambda^{-1}}+t(1-\chi) \tag{4.4}
\end{equation*}
$$

when $\varepsilon \rightarrow 0$.

### 4.2. The Extension Theorems

4.2.1. Some Definitions and Notations. Let us introduce the terminology needed to state our theorems. Let $U \subset \mathbb{R}^{n+d}$ be an open set, we denote by $(x, h ; \xi, \eta)$ the coordinates in cotangent space $T^{*} U$, where $\xi$ (resp. $\eta$ ) is dual to $x$ (resp. h). $T^{\bullet} U$ denotes the cotangent space $T^{*} U$ minus the zero section $\underline{0}$.

A set $\Gamma \subset T^{\bullet} U$ is stable by scaling if

$$
\begin{equation*}
\forall \lambda \in(0,1],\left(\left\{\left(x, \lambda^{-1} h ; \xi, \lambda \eta\right) ;(x, h ; \xi, \eta) \in \Gamma\right\} \cap T^{\bullet} U\right) \subset \Gamma \tag{4.5}
\end{equation*}
$$

Concisely, if we denote by $\Phi_{\lambda}^{*} \Gamma$ the pull-back of $\Gamma$ by $\Phi_{\lambda}$ [4], we require that $\forall \lambda \in(0,1],\left(\Phi_{\lambda}^{*} \Gamma \cap T^{\bullet} U\right) \subset \Gamma$. We also denote by $T_{I}^{*} \mathbb{R}^{n+d}$ the restriction of $T^{*} \mathbb{R}^{n+d}$ on $I$ and $N^{*}(I)$ the conormal bundle of $I$. As we explained in the introduction, the extension theorem has no positive solution for arbitrary distributions in $U \backslash I$. However, if we impose that the distribution has "moderate growth" in terms of scaling then we will be able to solve it. The scaling of distributions is defined by duality

$$
\begin{aligned}
\forall \varphi \in \mathcal{D}(U),\left\langle t_{\lambda}, \varphi\right\rangle & =\lambda^{-d}\left\langle t, \varphi_{\lambda^{-1}}\right\rangle \\
\text { where } \varphi_{\lambda^{-1}} & =\varphi\left(x, \lambda^{-1} h\right)
\end{aligned}
$$

In the sequel, for a given open set $U$, a compact set $K \subset U$, we will denote by $\left(\pi_{m, K}\right)_{m \in \mathbb{N}}$ the collection of continuous seminorms on the Fréchet space $\mathcal{D}_{K}(U)$ of test functions supported on $K$ defined as

$$
\forall \varphi \in \mathcal{D}_{K}(U), \pi_{m, K}(\varphi)=\sup _{|\alpha| \leq m, x \in K}\left|\partial^{\alpha} \varphi(x)\right|
$$

Weakly homogeneous distributions in $\mathcal{D}_{\Gamma}^{\prime}$. Let us formalize the notion of distribution having nice behaviour under scaling by defining the main space of distributions for which the extension problem has a positive answer.

For any cone $\Lambda \subset T^{\bullet} U$, we denote by $\mathcal{E}_{\Lambda}^{\prime}(U)$ the vector space of distributions compactly supported in $U$ whose wave front set is contained in $\Lambda$. Using the recent work $[10,6.3]$, we can characterize bounded sets in $\mathcal{D}_{\Gamma}^{\prime}$ by duality pairing. A set $B \subset \mathcal{D}_{\Gamma}^{\prime}(U)$ is bounded if for every $v \in \mathcal{E}_{\Lambda}^{\prime}(U)$ where $\Lambda$ is an open cone s.t. $\Lambda \cap-\Gamma=\emptyset$, we have

$$
\sup _{t \in B}|\langle t, v\rangle|<+\infty
$$

Definition 4.3. Let $\Gamma \subset T^{\bullet} U$ be a closed conic set stable by scaling. A distribution $t$ is weakly homogeneous of degree $s$ in $\mathcal{D}_{\Gamma}^{\prime}(U)$, if for all distributions $v \in \mathcal{E}_{\Lambda}^{\prime}(U)$ where $\Lambda=-\Gamma^{c}$,

$$
\sup _{\lambda \in[0,1]}\left|\left\langle\lambda^{-s} t_{\lambda}, v\right\rangle\right|<+\infty
$$

We denote this space by $E_{s}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$ and we endow it with the locally convex topology generated by the seminorms

$$
P_{B}(t)=\sup _{\lambda \in[0,1], v \in B}\left|\left\langle\lambda^{-s} t_{\lambda}, v\right\rangle\right|
$$

for $B$ equicontinuous [4, lemma 6.3] in $\mathcal{E}_{\Lambda}^{\prime}$.
We recover the definition of Yves Meyer in the particular case where $\Gamma=T^{\bullet} \mathbb{R}^{n+d}$ in which case $\mathcal{D}_{\Gamma}^{\prime}=\mathcal{D}^{\prime}$.

A key conceptual step in our approach is to think of $\lambda^{-s} t(x, \lambda h)$ as a distribution of the three variables $(\lambda, x, h)$. Let us define the map

$$
\begin{equation*}
\Phi:(\lambda, x, h) \in \mathbb{R} \times \mathbb{R}^{n+d} \longmapsto(x, \lambda h) \in \mathbb{R}^{n+d} \tag{4.6}
\end{equation*}
$$

Theorem 4.4. Let $s \in \mathbb{R}$ s.t. $s+d>0, \Gamma \subset T^{\bullet} U$ be a closed conic set stable by scaling. If $t \in \mathcal{D}^{\prime}(U \backslash I)$ is weakly homogeneous of degree $s$ in $\mathcal{D}_{\Gamma}^{\prime}(U \backslash I)$, then $\bar{t}=\lim _{\varepsilon \rightarrow 0} t\left(1-\chi_{\varepsilon^{-1}}\right)$ is a well-defined extension of $t$ and $W F(\bar{t}) \subset$ $W F(t) \cup N^{*}(I) \cup \Xi$ where

$$
\Xi=\left\{(x, 0 ; \xi, \eta) \mid \exists(x, h ; \xi, 0) \in \Gamma \cap T_{\text {supp } \psi}^{*} U\right\}
$$

Before we prove the theorem, let us show why the set $W F(t) \cup N^{*}(I) \cup \Xi$ is a closed conic set. Recall that $U=U_{1} \times U_{2} \subset \mathbb{R}^{n} \times \mathbb{R}^{d}$ where $\lambda U_{2} \subset U_{2}, \forall \lambda \in$ $(0,1]$. We may assume w.l.o.g that $U_{2}$ contains a set of the form $\{0<|h| \leq \varepsilon\}$. There is nothing to prove over $U \backslash I$ since $W F(t)$ is closed in $T^{\bullet}(U \backslash I)$; therefore we study the closure of $W F(t) \cup N^{*}(I) \cup \Xi$ in $T_{I}^{*} U$. Let $(x, 0 ; \xi, \eta)$ be in its closure $\overline{W F(t) \cup N^{*}(I) \cup \Xi}$. If $\xi=0$ then $(x, 0 ; 0, \eta) \in N^{*}(I)$. Otherwise, $\xi \neq 0$; there is a sequence $\left(x_{n}, h_{n} ; \xi_{n}, \eta_{n}\right) \rightarrow(x, 0 ; \xi, \eta)$ where $\left(x_{n}, h_{n} ; \xi_{n}, \eta_{n}\right) \in$ $W F(t)$ and $h_{n} \rightarrow 0$. But since $W F(t) \subset \Gamma$ and since $\Gamma$ is scale invariant, then $\left(x_{n}, \varepsilon \frac{h_{n}}{\left|h_{n}\right|} ; \xi_{n}, \varepsilon^{-1}\left|h_{n}\right| \eta_{n}\right) \in \Gamma$. By compactness of the unit sphere, we can extract a convergent subsequence for $\varepsilon \frac{h_{n}}{\left|h_{n}\right|}$ and the limit $(x, h ; \xi, 0)$ is in $\Gamma$. Therefore, by definition of $\Xi$, we will have $(x, 0 ; \xi, \eta) \in \Xi$ and this implies that $W F(t) \cup N^{*}(I) \cup \Xi$ is closed.

Proof. We have to establish the convergence of $t\left(1-\chi_{\varepsilon^{-1}}\right)$ in $\mathcal{D}_{\Lambda}^{\prime}(U)$ when $\varepsilon \rightarrow 0$ for $\Lambda=W F(t) \cup N^{*}(I) \cup \Xi$. Our proof is divided into three parts: in the first, we prove that the limit exists in $\mathcal{D}^{\prime}(U)$ with arguments similar to [44] but in our setting of continuous partition of unity. Then in the second part, we derive a new integral formula for $t\left(1-\chi_{\varepsilon^{-1}}\right)$, and we shall use the integral formula to show that the family $\left(t\left(1-\chi_{\varepsilon^{-1}}\right)\right)_{\varepsilon}$ is bounded in $\mathcal{D}_{\Lambda}^{\prime}(U)$ using the behaviour of the WF under the fundamental operations on distributions [4]. Then $\lim _{\varepsilon \rightarrow 0} t\left(\chi-\chi_{\varepsilon}\right)$ converges in $\mathcal{D}^{\prime}(U)$ and is bounded in $\mathcal{D}_{\Lambda}^{\prime}(U)$ implying that $\lim _{\varepsilon \rightarrow 0} t\left(\chi-\chi_{\varepsilon}\right)$ converges in $\mathcal{D}_{\Lambda}^{\prime}(U)$.

Step 1. We prove that $\lim _{\varepsilon \rightarrow 0} t\left(1-\chi_{\varepsilon^{-1}}\right)$ exists in $\mathcal{D}^{\prime}(U)$ when $\varepsilon \rightarrow 0$. Let us give a different analytical expression using the partition of unity formula,

$$
t\left(1-\chi_{\varepsilon^{-1}}\right)=\int_{\varepsilon}^{1} \frac{d \lambda}{\lambda} t \psi_{\lambda^{-1}}+t(1-\chi)
$$

Therefore,

$$
\begin{equation*}
\left\langle t\left(\chi-\chi_{\varepsilon^{-1}}\right), \varphi\right\rangle=\int_{\varepsilon}^{1} d \lambda \lambda^{s+d-1}\left\langle\left(\lambda^{-s} t_{\lambda}\right) \psi, \varphi_{\lambda}\right\rangle \tag{4.7}
\end{equation*}
$$

It follows that the r.h.s of 4.7 has a limit when $\varepsilon \rightarrow 0$ since $\lambda^{s+d-1}$ is integrable on $[0,1]$. It remains to prove that the limit is a distribution. $\left(\lambda^{-s} t_{\lambda}\right)_{\lambda \in(0,1]}$ is bounded in $\mathcal{D}^{\prime}(U \backslash I)$; therefore for all compact subset $K \subset U \backslash I$

$$
\exists C_{K}, \forall \varphi \in \mathcal{D}_{K}(U), \sup _{\lambda \in(0,1]}\left|\left\langle\lambda^{-s} t_{\lambda}, \varphi\right\rangle\right| \leq C_{K} \pi_{m, K}(\varphi)
$$

For all compact subset $K^{\prime} \subset \mathbb{R}^{n+d}$ and for all $\varphi \in \mathcal{D}_{K^{\prime}}(U)$, the family $\left(\psi \varphi_{\lambda}\right)_{\lambda}$ has fixed compact support which does not meet $I$ and is bounded in $\mathcal{D}_{K}(U \backslash I)$ for some compact set $K$ :

$$
\forall \lambda \in(0,1], \pi_{m, K}\left(\psi \varphi_{\lambda}\right) \leq C_{2} \pi_{m, K^{\prime}}(\varphi)
$$

The two above bounds easily imply that

$$
\begin{aligned}
\forall \varphi \in \mathcal{D}_{K^{\prime}}(U), \sup _{\lambda \in(0,1]}\left|\left\langle\lambda^{-s} t_{\lambda}, \psi \varphi_{\lambda}\right\rangle\right| & \leq C_{K} C_{2} \pi_{m, K^{\prime}}(\varphi) \\
\Longrightarrow\left|\left\langle t\left(\chi-\chi_{\varepsilon^{-1}}\right), \varphi\right\rangle\right| & \leq\left|\int_{\varepsilon}^{1} d \lambda \lambda^{s+d-1}\left\langle\left(\lambda^{-s} t_{\lambda}\right) \psi, \varphi_{\lambda}\right\rangle\right| \\
& \leq \frac{1-\varepsilon^{s+d}}{s+d} C_{K} C_{2} \pi_{m, K^{\prime}}(\varphi) \\
\Longrightarrow \lim _{\varepsilon \rightarrow 0}\left|\left\langle t\left(\chi-\chi_{\varepsilon^{-1}}\right), \varphi\right\rangle\right| & \leq \frac{C_{K} C_{2} \pi_{m, K^{\prime}}(\varphi)}{s+d}
\end{aligned}
$$

The above bound means that $\lim _{\varepsilon \rightarrow 0} t\left(\chi-\chi_{\varepsilon^{-1}}\right)$ is well defined in $\mathcal{D}^{\prime}(U)$. But the difficult point is to control the wave front set of the limit over the subspace $I=\{h=0\}$.

Step 2 We just proved that $\lim _{\varepsilon \rightarrow 0} t\left(\chi-\chi_{\varepsilon}\right)$ converges in $\mathcal{D}^{\prime}(U)$. In order to control the WF of the limit, it suffices to prove that the family $t\left(\chi-\chi_{\varepsilon}\right)_{\varepsilon}$ is bounded in $\mathcal{D}_{\Lambda}^{\prime}(U), \Lambda=W F(t) \cup N^{*}(I) \cup \Xi$. We propose a simple method
which consists in giving a new integral formula for the identity 4.7. We double the space $\mathbb{R}^{n+d}$ and transform the formula $\int_{\varepsilon}^{1} \frac{d \lambda}{\lambda} \lambda^{s+d}\left\langle\left(\lambda^{-s} t_{\lambda}\right) \psi, \varphi_{\lambda}\right\rangle$ into an integral formula on $\mathbb{R} \times \mathbb{R}^{n+d} \times \mathbb{R}^{n+d}$. We work in $\mathbb{R} \times \mathbb{R}^{n+d} \times \mathbb{R}^{n+d}$ with coordinates $\left(\lambda, x, h, x^{\prime}, h^{\prime}\right)$. We denote by $\delta \in \mathcal{D}^{\prime}\left(\mathbb{R}^{n+d}\right)$ the delta distribution supported at $(0,0) \in \mathbb{R}^{n+d}$ and $\delta_{\Delta}(.,$.$) the delta distribution supported by the$ diagonal $\Delta \subset \mathbb{R}^{n+d} \times \mathbb{R}^{n+d}$ where we have the relation $\delta_{\Delta}\left((x, h),\left(x^{\prime}, h^{\prime}\right)\right)=$ $\delta\left(x-x^{\prime}, h-h^{\prime}\right)$. Thus $\left\langle t\left(\chi-\chi_{\varepsilon^{-1}}\right), \varphi\right\rangle$

$$
\begin{aligned}
= & \int_{\varepsilon}^{1} \frac{d \lambda}{\lambda} \lambda^{s+d}\left\langle\left(\lambda^{-s} t_{\lambda}\right) \psi, \varphi_{\lambda}\right\rangle \\
= & \int_{\mathbb{R}^{n+d}} d x^{\prime} d h^{\prime} \int_{\mathbb{R} \times \mathbb{R}^{n+d}} \frac{d \lambda}{\lambda} d x d h 1_{[\varepsilon, 1]}(\lambda) \lambda^{s+d} \lambda^{-s} t(x, \lambda h) \\
& \times \psi(x, h) \delta\left(x-x^{\prime}, \lambda h-h^{\prime}\right) \varphi\left(x^{\prime}, h^{\prime}\right) .
\end{aligned}
$$

Finally, we end up with the integral formula:

$$
\begin{align*}
& t\left(\chi-\chi_{\varepsilon^{-1}}\right)\left(x^{\prime}, h^{\prime}\right) \\
& =\int_{\mathbb{R} \times \mathbb{R}^{n+d}} d \lambda d x d h 1_{[\varepsilon, 1]}(\lambda) \lambda^{s+d-1} \lambda^{-s} t(x, \lambda h) \psi(x, h) \delta\left(x-x^{\prime}, \lambda h-h^{\prime}\right) . \tag{4.8}
\end{align*}
$$

It suffices to estimate $\Lambda$ over $I$ since we already know that the family $t\left(\chi-\chi_{\varepsilon^{-1}}\right)_{\varepsilon}$ is bounded in $\mathcal{D}_{W F(t)}^{\prime}(U \backslash I)$, i.e. $\Lambda \cap T^{*}(U \backslash I)=W F(t)$. We want to calculate the WF of the r.h.s of (4.8) in $T_{I}^{*} U$.

1. decompose the r.h.s of (4.8) in two blocks

$$
\underbrace{1_{[\varepsilon, 1]}(\lambda) \lambda^{s+d-1} \lambda^{-s} t(x, \lambda h) \psi(x, h)}_{B_{1, \varepsilon}} \underbrace{\delta\left(x-x^{\prime}, \lambda h-h^{\prime}\right)}
$$

2. $1_{[\varepsilon, 1]}(\lambda) \lambda^{s+d-1} \in L^{1}(\mathbb{R})$ and $t \in E_{s}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$; hence by Lemma 10.3 proved in appendix, the block $\left(B_{1, \varepsilon}=1_{[\varepsilon, 1]}(\lambda) \lambda^{s+d-1} \lambda^{-s} t(x, \lambda h) \psi(x, h)\right)_{\varepsilon}$ is a bounded family in $\mathcal{D}_{V}^{\prime}(\mathbb{R} \times U)$ when $\varepsilon \in(0,1]$ and where

$$
V=\left\{\left.\left(\begin{array}{l}
\lambda ; \widehat{\lambda}  \tag{4.9}\\
x ; \widehat{\xi} \\
h ; \widehat{\eta}
\end{array}\right) \right\rvert\,\binom{ x ; \widehat{\xi}}{h ; \widehat{\eta}} \in \Gamma \cup \underline{0},(x, h) \in \operatorname{supp} \psi\right\} .
$$

We evaluate the wave front set of the family of products of distributions $\left(B_{1, \varepsilon}(\lambda, x, h) \delta\left(x-x^{\prime}, \lambda h-h^{\prime}\right)\right)_{\varepsilon}$ in $T^{*}\left(\mathbb{R} \times U \times \mathbb{R}^{n+d}\right)$ using the functional properties of the Hörmander product [4, Theorem 7.1]. We start with the wave front set of the various distributions involved in formula (4.8); the family $B_{1, \varepsilon}(\lambda, x, h) \otimes 1\left(x^{\prime}, h^{\prime}\right)$ is bounded in $\mathcal{D}_{\Lambda_{1}}^{\prime}\left(\mathbb{R} \times \mathbb{R}^{n+d} \times \mathbb{R}^{n+d}\right)$, where

$$
\Lambda_{1}=\left\{\left.\left(\begin{array}{c}
\lambda ; \widehat{\lambda} \\
x ; \widehat{\xi} \\
h ; \widehat{\eta} \\
x^{\prime} ; 0 \\
h^{\prime} ; 0
\end{array}\right) \right\rvert\,\binom{ x ; \widehat{\xi}}{h ; \widehat{\eta}} \in \Gamma \cup \underline{0},(x, h) \in \operatorname{supp} \psi\right\}
$$

$W F\left(\delta_{\Delta}(\Phi,).\right) \subset \Lambda_{2}$

$$
=\left\{\left.\left(\begin{array}{cc}
\lambda ; & -\langle h, \eta\rangle \\
x ; & -\xi \\
h ; & -\lambda \eta \\
x^{\prime} ; & \xi \\
h^{\prime} ; & \eta
\end{array}\right) \right\rvert\,(x, \lambda h)=\left(x^{\prime}, h^{\prime}\right) \text { and }(\xi, \eta) \neq(0,0)\right\}
$$

Note that $\Lambda_{1} \cap-\Lambda_{2}=\emptyset$ which implies by hypocontinuity of the Hörmander product [4, Theorem 7.1] that the products $\left(B_{1, \varepsilon}(\lambda, x, h) \delta\left(x-x^{\prime}, \lambda h-h^{\prime}\right)\right)_{\varepsilon}$ are bounded in $\mathcal{D}_{\Lambda_{1}+\Lambda_{2} \cup \Lambda_{1} \cup \Lambda_{2}}^{\prime}$.

The projection

$$
\pi_{3}:=\left(\lambda, x, h, x^{\prime}, h^{\prime}\right) \longmapsto\left(x^{\prime}, h^{\prime}\right)
$$

is proper on the support of $u$; therefore the push-forward of $B_{1, \varepsilon}(\lambda, x, h) \delta(x-$ $\left.x^{\prime}, \lambda h-h^{\prime}\right)$ by $\pi_{3}$, which equals the integral $\int_{\mathbb{R} \times U} d \lambda d x d h B_{1, \varepsilon}(\lambda, x, h) \delta(x-$ $\left.x^{\prime}, \lambda h-h^{\prime}\right)$, exists in the distributional sense. By continuity hence boundedness of the push-forward [4, Theorem 7.3], we find that the family $\left(t\left(\chi-\chi_{\varepsilon^{-1}}\right)\right)_{\varepsilon}$ is bounded in $\mathcal{D}_{\Lambda}^{\prime}$ where

$$
\begin{equation*}
\left(\Lambda \cap T_{I}^{*} U\right) \subset \pi_{3 *}\left(\left(\Lambda_{1}+\Lambda_{2}\right) \cup \Lambda_{1} \cup \Lambda_{2}\right) \cap T_{I}^{*} U \tag{4.10}
\end{equation*}
$$

We study the closed conic set $\pi_{3 *}\left(\Lambda_{1}+\Lambda_{2}\right) \cap T_{I}^{*} U$ : an element $\left(x^{\prime}, 0 ; \xi, \eta\right)$ belongs to $\pi_{3 *}\left(\Lambda_{1}+\Lambda_{2}\right)$ if and only if the system of equations

$$
\left\{\begin{array}{c}
\widehat{\lambda}-\langle h, \eta\rangle=0 \\
\widehat{\xi}-\xi=0 \\
\widehat{\eta}-\lambda \eta=0
\end{array} \text { s.t. }(x, \lambda h)=\left(x^{\prime}, 0\right),(x, h) \in \operatorname{supp} \psi,\binom{x ; \widehat{\xi}}{h ; \widehat{\eta}} \in \Gamma \cup \underline{0}\right\}
$$

has a solution. Note that the three conditions $\left\{\begin{array}{c}(x, h) \in \operatorname{supp} \psi \\ (x, \lambda h)=\left(x^{\prime}, 0\right) \\ \widehat{\eta}-\lambda \eta=0\end{array}\right\}$ imply that $|h| \neq 0, \lambda=0, \widehat{\eta}=0$. Therefore,

$$
\begin{aligned}
& \left(x^{\prime}, 0 ; \xi, \eta\right) \in \pi_{3 *}\left(\Lambda_{1}+\Lambda_{2}\right) \\
& \Leftrightarrow\left\{\binom{x ; \xi}{h ; 0} \in \Gamma \cup \underline{0},(x, h) \in \operatorname{supp} \psi\right\} \\
& \Leftrightarrow \pi_{3 *}\left(\Lambda_{1}+\Lambda_{2}\right) \cap T_{I}^{*} U \subset \Xi
\end{aligned}
$$

It is immediate that $\pi_{3 *} \Lambda_{1}=\emptyset$; finally

$$
\begin{aligned}
& \binom{x^{\prime} ; \xi}{0 ; \eta} \in \pi_{3 *} \Lambda_{2} \cap T_{I}^{*} U \\
& \Leftrightarrow\left\{\begin{array}{c}
\langle h, \eta\rangle=0 \\
\xi=0 \\
\lambda \eta=0
\end{array}\right\} \text { for }(x, \lambda h)=\left(x^{\prime}, 0\right),(x, h) \in \operatorname{supp} \psi \\
& \Longrightarrow \xi=0 \Longrightarrow \pi_{3 *} \Lambda_{2} \cap T_{I}^{*} U \subset N^{*}(I)
\end{aligned}
$$

Finally, we can summarize the bounds that we obtained

$$
\begin{equation*}
\Lambda \cap T_{I}^{*} \mathbb{R}^{n+d} \subset \Xi \cup N^{*}(I) \tag{4.11}
\end{equation*}
$$

which establishes the claim of our theorem.

Now we prove that under the assumptions of Theorem 4.4, the extension $\bar{t}$ constructed is weakly homogeneous of degree $s$ in $\mathcal{D}_{\Gamma \cup N^{*}(I) \cup \Xi}^{\prime}(U)$.

Theorem 4.5. Let $s \in \mathbb{R}$ s.t. $s+d>0, \Gamma \subset T^{\bullet} U$ be a closed conic set stable by scaling. Then the extension $\bar{t}=\lim _{\varepsilon \rightarrow 0} t\left(1-\chi_{\varepsilon^{-1}}\right)$ is in $E_{s}\left(\mathcal{D}_{\Xi \cup \Gamma \cup N^{*}(I)}^{\prime}(U)\right)$ for $\Xi=\{(x, 0 ; \xi, \eta) \mid(x, h) \in \operatorname{supp} \psi, \quad(x, h ; \xi, 0) \in \Gamma\}$.

Proof. For all test function $\varphi$, we study the family $\left(\left\langle\mu^{-s} \bar{t}_{\mu}, \varphi\right\rangle\right)_{\mu \in(0,1]}$. But since $\bar{t}=\lim _{\varepsilon \rightarrow 0} t\left(1-\chi_{\varepsilon^{-1}}\right)$, it suffices to study the family $\mu^{-s}\left(t\left(1-\chi_{\varepsilon^{-1}}\right)\right)_{\varepsilon, \mu}$ for $\varepsilon \leq \mu$.

A simple calculation using variable changes gives

$$
\begin{aligned}
\forall 0 & <\varepsilon \leq \mu \leq 1, \mu^{-s}\left\langle\left(t\left(1-\chi_{\varepsilon^{-1}}\right)\right)_{\mu}, \varphi\right\rangle \\
& =\int_{\varepsilon}^{1} \frac{d \lambda}{\lambda} \mu^{-s-d}\left\langle t \psi_{\lambda^{-1}}, \varphi_{\mu^{-1}}\right\rangle+\left\langle\mu^{-s} t_{\mu}\left(1-\chi_{\mu}\right), \varphi\right\rangle \\
& =\int_{\varepsilon}^{1} \frac{d \lambda}{\lambda}\left(\frac{\lambda}{\mu}\right)^{s+d}\left\langle\lambda^{-s} t_{\lambda} \psi, \varphi_{\frac{\lambda}{\mu}}\right\rangle+\left\langle\mu^{-s} t_{\mu}\left(1-\chi_{\mu}\right), \varphi\right\rangle \\
& =\int_{\frac{\varepsilon}{\mu}}^{\frac{1}{\mu}} \frac{d \lambda}{\lambda} \lambda^{s+d}\left\langle(\lambda \mu)^{-s} t_{\lambda \mu} \psi, \varphi_{\lambda}\right\rangle+\left\langle\mu^{-s} t_{\mu}\left(1-\chi_{\mu}\right), \varphi\right\rangle .
\end{aligned}
$$

First, note that the family $\left(\mu^{-s} t_{\mu}\right)_{\mu \in(0,1]}$ is bounded in $\mathcal{D}_{\Gamma}^{\prime}(U \backslash I)$ and $\left(1-\chi_{\mu}\right) \rightarrow 0$ when $\mu \rightarrow 0$; therefore, the family $\left(\mu^{-s} t_{\mu}\left(1-\chi_{\mu}\right)\right)_{\mu \in(0,1]}$ is bounded.

The next thing we show is that the integral $\int_{\frac{\varepsilon}{\mu}}^{\frac{1}{\mu}} \frac{d \lambda}{\lambda} \lambda^{s+d}\left\langle(\lambda \mu)^{-s} t_{\lambda \mu} \psi, \varphi_{\lambda}\right\rangle$ does not blow up because its integrand vanishes when $\lambda$ is large enough. Let $K$ be a compact subset of $\mathbb{R}^{n+d}$.

$$
\begin{aligned}
\varphi \in \mathcal{D}_{K}(U) & \Longrightarrow \exists R>0 \text { s.t. } \operatorname{supp} \varphi \subset\{|h| \leq R\} \\
& \Longrightarrow \operatorname{supp} \varphi_{\lambda} \subset\left\{|h| \leq \lambda^{-1} R\right\}
\end{aligned}
$$

Recall that $\pi$ was the projection $\pi:=(x, h) \in \mathbb{R}^{n+d} \mapsto x \in \mathbb{R}^{n}$.

$$
\begin{aligned}
& \pi \text { is proper on supp } \psi \text { and } \pi(\operatorname{supp} \varphi) \subset \mathbb{R}^{n} \text { compact } \\
& \left.\Longrightarrow \operatorname{supp} t_{\lambda \mu} \psi\right|_{\left(K \times \mathbb{R}^{d}\right) \cap U} \subset\{a \leq|h| \leq b\} \text { for } 0<a<b \\
& \Longrightarrow\left\{\lambda \geq \frac{R}{a} \Longrightarrow\left\langle t_{\lambda \mu} \psi, \varphi_{\lambda}\right\rangle=0\right\} \\
& \Longrightarrow \forall \mu \in(0,1], \varepsilon \leq \mu, \\
& \int_{\frac{\varepsilon}{\mu}}^{\frac{1}{\mu}} \frac{d \lambda}{\lambda} \lambda^{s+d}\left\langle(\lambda \mu)^{-s} t_{\lambda \mu} \psi, \varphi_{\lambda}\right\rangle \\
& =\int_{0}^{+\infty} \frac{d \lambda}{\lambda} 1_{\left\{\frac{\varepsilon}{\mu} \leq \frac{R}{a}\right\}}(\lambda) \lambda^{s+d}\left\langle(\lambda \mu)^{-s} t_{\lambda \mu} \psi, \varphi_{\lambda}\right\rangle .
\end{aligned}
$$

For all $t$, we define $t^{\mu}(x, h)=\mu^{-s} t(x, \mu h)$ and we consider the family of distributions $B=\left(t^{\mu}\right)_{\mu \in(0,1]}$ which is bounded in $E_{s}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$. Therefore, the result of Lemma (10.3) implies that the family

$$
\left(1_{\left\{\frac{\varepsilon}{\mu} \leq \frac{R}{a}\right\}}(\lambda) \lambda^{s+d-1} \lambda^{-s} t^{\mu}(x, \lambda h) \psi(x, h)\right)_{0<\varepsilon \leq \mu \leq 1}
$$

is bounded in $\mathcal{D}_{\Lambda}^{\prime}\left(\left[0, \frac{R}{a}\right] \times(U \backslash I)\right)$, for $\Lambda=\left\{(\lambda, x, h ; \tau, \xi, \eta) \in \dot{T}^{*}\left(\left[0, \frac{R}{a}\right] \times\right.\right.$ $(U \backslash I)) \mid(x, h) \in \operatorname{supp} \psi,(x, h ; \xi, \eta) \in \Gamma \cup \underline{0}\}$. Therefore, we can repeat the proof of Theorem 4.4 for the family

$$
\int_{\mathbb{R} \times \mathbb{R}^{n+d}} d \lambda d x d h 1_{\left\{\frac{\varepsilon}{\mu} \leq \frac{R}{a}\right\}}(\lambda) \lambda^{s+d-1} \lambda^{-s} t^{\mu}(x, \lambda h) \psi(x, h) \delta_{\Delta}(\Phi(\lambda, x, h), .(4.12)
$$

Using the fact that

1. the Hörmander product of $1_{\left\{\frac{\varepsilon}{\mu} \leq \frac{R}{a}\right\}}(\lambda) \lambda^{s+d-1} \lambda^{-s} t^{\mu}(x, \lambda h) \psi(x, h)$ with $\delta_{\Delta}(\Phi(\lambda, x, h),$.$) is hypocontinuous [4, Thm 7.1]$
2. the push-forward of $1_{\left\{\frac{\varepsilon}{\mu} \leq \frac{R}{a}\right\}}(\lambda) \lambda^{s+d-1} \lambda^{-s} t^{\mu}(x, \lambda h) \psi(x, h) \delta_{\Delta}(\Phi(),.$.$) by$ the projection $\pi_{3}$ is continuous in the normal topology and hence bounded [4, Thm 7.3];
we obtain the desired result.
4.2.2. Optimality of the Wave Front Set of the Extension. We show with an example how our technique gives an optimal bound for the wave front set of the extension of distributions in a situation where the assumptions of the results of Brunetti-Fredenhagen [5, Lemma 6.1] are not satisfied.
The wave front set of an example of extension not handled by BrunettiFredenhagen's method. We work in $T^{*} \mathbb{R}^{3}$ with variables $\left(x_{1}, x_{2}, h ; \xi_{1}, \xi_{2}, \eta\right)$ and $I$ is the plane $\left(\mathbb{R}^{2} \times\{0\}\right)=\{h=0\}$. Let $f \in C^{\infty}(\mathbb{R} \backslash\{0\}) \cap L^{\infty}(\mathbb{R}), f>0$ which is nonsmooth at the origin and let us consider the function $f\left(x_{1}\right)$ as a distribution in the vector space $\mathbb{R}^{3} \backslash I$. Then we prove the following claim:

Proposition 4.6. Let $\chi \in C^{\infty}(\mathbb{R})$ be a smooth function s.t. $\chi(h)=1$ when $h \leq 1$ and $\chi(h)=0$ when $h \geq 2$. Then the family of distributions $f\left(x_{1}\right)\left(\chi\left(\varepsilon^{-1} h\right)-\right.$ $\chi(h))_{\varepsilon}$ converges to $f\left(x_{1}\right)$ when $\varepsilon \rightarrow 0$ in $\mathcal{D}_{V}^{\prime}$ where $V=N^{*}\left(\left\{x_{1}=0\right\}\right) \cup$ $N^{*} I \cup\left(N^{*}\left(\left\{x_{1}=0\right\}\right)+N^{*} I\right)$.

In fact, for all $\varepsilon>0$, the wave front set of the distribution $f\left(x_{1}\right)\left(\chi\left(\varepsilon^{-1} h\right)\right.$ $-\chi(h))$ is in $N^{*}\left(\left\{x_{1}=0\right\}\right)$; therefore, it does not satisfy the assumption that the closure of $W F\left(f\left(x_{1}\right)\left(\chi\left(\varepsilon^{-1} h\right)-\chi(h)\right)\right)$ should be contained in the conormal $N^{*}(I)$ which is an important assumption of Theorem 6.9 in the paper [5] of Brunetti Fredenhagen.

Proof. Let $V$ be the smallest closed conic set such that the family $f\left(x_{1}\right)$ $\left(\chi\left(\varepsilon^{-1} h\right)-\chi(h)\right)_{\varepsilon \in(0,1]}$ is bounded in $\mathcal{D}_{V}^{\prime}$. It is obvious that outside $\{h=0\}$ the cone $V$ equals $N^{*}\left(\left\{x_{1}=0\right\}\right)$. It suffices to calculate $V$ over $\{h=0\}$.

To estimate $V$ over $\{h=0\}$, there are two cases to study: $x_{1}=0$ and $x_{1} \neq 0$ ( $x_{2}$ is arbitrary). We start with the case $x_{1} \neq 0$. Let $\varphi$ be a test function:

$$
\begin{aligned}
\mathcal{F} & \left(f\left(x_{1}\right) \varphi\left(x_{1}, x_{2}\right)\left(\chi\left(\varepsilon^{-1} h\right)-\chi(h)\right)\right) \\
& \left.=\widehat{f \varphi}\left(\xi_{1}, \xi_{2}\right)\left(\chi \widehat{\left(\varepsilon^{-1} .\right.}\right)(\eta)-\widehat{\chi}(\eta)\right) \\
& =\widehat{f \varphi}\left(\xi_{1}, \xi_{2}\right)(\varepsilon \widehat{\chi}(\varepsilon \eta)-\widehat{\chi}(\eta))
\end{aligned}
$$

Since $\widehat{\chi} \neq 0$ and is even analytic, we have $\forall R>0, \sup _{|\eta| \geq R}|\widehat{\chi}(\eta)|=C(R)>0$. This gives us the estimate

$$
\begin{aligned}
\forall R>0, \sup _{\eta}(1+|\eta|)^{N} \varepsilon|\widehat{\chi}(\varepsilon \eta)| & \geq\left(1+\frac{R}{\varepsilon}\right)^{N} \varepsilon C(R) \\
& \geq \varepsilon^{-N+1} R^{N} C(R) \rightarrow_{\varepsilon \rightarrow 0} \infty
\end{aligned}
$$

This implies that $\left(\chi\left(\varepsilon^{-1}.\right)-\chi\right)$ is bounded in $\mathcal{D}_{N^{*}(I)}^{\prime}$; therefore using the fact that $f>0$, we find that $V$ corresponds with the conormal $N^{*}(I)$ of $I$ as long as $f$ is smooth hence outside $x_{1}=0$.

We conclude by studying the case where $x_{1}=0$. Since $f$ is singular at $x_{1}=0$ and that $s s(f)=\{0\}=\pi_{T^{*} \mathbb{R} \mapsto \mathbb{R}}(W F(f))$, the wave front set of $f$ in the fiber $T_{0}^{*} \mathbb{R}$ over $x_{1}=0$ is non-empty and we deduce there is a function $\varphi$ of the two variables $\left(x_{1}, x_{2}\right)$ such that $\widehat{f \varphi}\left(\xi_{1}, \xi_{2}\right)$ has slow decrease in the direction $\left(\xi_{1}, 0\right)$. The Fourier transform of $f \varphi\left(\chi\left(\varepsilon^{-1}\right.\right.$.) - $\left.\chi\right)$ w.r.t $\left(x_{1}, x_{2}, h\right)$ equals $\left.\widehat{f \varphi}\left(\xi_{1}, \xi_{2}\right)\left(\widehat{\chi\left(\varepsilon^{-1}\right.}\right)(\eta)-\widehat{\chi}(\eta)\right)$ from which one easily concludes that $\left\{\left(0, x_{2}, 0 ; \xi_{1}, 0, \eta\right)\right\}=N^{*}(I)+N^{*}\left(\left\{x_{1}=0\right\}\right) \subset V$.

The singular case. In the next part, we will deal with the singular case where $-m-1<s+d \leq-m, m \in \mathbb{N}$. Instead of calculating the pairing $\left\langle t\left(\chi-\chi_{\varepsilon^{-1}}\right), \varphi\right\rangle$, we will subtract from $\varphi$ its Taylor polynomial in the $h$ variable to a sufficient order; therefore, we will pair $t\left(\chi-\chi_{\varepsilon^{-1}}\right)$ with the Taylor remainder $I_{m} \varphi$ defined by

$$
\begin{equation*}
I_{m} \varphi(x, h)=\frac{1}{m!} \sum_{|\alpha|=m+1} h^{\alpha} \int_{0}^{1}(1-t)^{m}\left(\partial_{h}^{\alpha} \varphi\right)(x, t h) d t \tag{4.13}
\end{equation*}
$$

Then we will study the existence of the limit:

$$
\begin{equation*}
\langle\bar{t}, \varphi\rangle=\lim _{\varepsilon \rightarrow 0}\left\langle t\left(\chi-\chi_{\varepsilon^{-1}}\right), I_{m} \varphi\right\rangle+\langle t(1-\chi), \varphi\rangle \tag{4.14}
\end{equation*}
$$

First, observe that if the support of $\varphi$ does not meet $I$, then $\varphi$ equals its Taylor remainder $I_{m} \varphi$ since $\varphi$ vanishes at infinite order on the subspace $I$ and formula 4.14 is well defined and coincides with $\langle t, \varphi\rangle$. Therefore if $\bar{t}$ were defined, it would be an extension of $t$.

Theorem 4.7. Let $s \in \mathbb{R}$ s.t. $-m-1<s+d \leq-m, m \in \mathbb{N}, U \subset \mathbb{R}^{n+d}$ be a convex set and $\Gamma \subset T^{\bullet} U$ be a closed conic set stable by scaling. If $t \in \mathcal{D}^{\prime}(U \backslash I)$ is weakly homogeneous of degree $s$ in $\mathcal{D}_{\Gamma}^{\prime}(U \backslash I)$, then formula (4.14) defines an extension $\bar{t}$ of $t$ and $W F(\bar{t}) \subset W F(t) \cup N^{*}(I) \cup \Xi$ where

$$
\Xi=\{(x, 0 ; \xi, \eta) \mid(x, h) \in \operatorname{supp} \psi, \quad(x, h ; \xi, 0) \in \Gamma\}
$$

Proof. Before we state our theorem, let us describe the central new ingredient of our proof. In appendix, we will study the Schwartz kernel of the operator $I_{m} \in \mathcal{D}^{\prime}\left(\mathbb{R}^{n+d} \times \mathbb{R}^{n+d}\right)$ realizing the projection on the Taylor remainder. We work in $\mathbb{R}^{n+d} \times \mathbb{R}^{n+d}$ with coordinates $\left(x, h, x^{\prime}, h^{\prime}\right)$ and we note $I_{m}\left((x, h),\left(x^{\prime}, h^{\prime}\right)\right)$ this Schwartz kernel.

Step 1 The distribution $I_{m}(.,$.$) plays the same role in the proof of The-$ orem 4.7 as $\delta_{\Delta}(.,$.$) in the proof of Theorem 4.4$ and we prove in appendix (Lemma 10.1) that

$$
\begin{align*}
I_{m}(., .) & =\sum_{|\alpha|=m+1} h^{\alpha} R_{\alpha}(., .) \text { where } \forall \alpha, R_{\alpha}(., .) \in \mathcal{D}^{\prime}\left(\mathbb{R}^{n+d} \times \mathbb{R}^{n+d}\right)  \tag{4.15}\\
& W F\left(R_{\alpha}(., .)\right) \subset\{(x, h, x, t h ; \xi, t \eta,-\xi,-\eta) \mid t \in[0,1],(\xi, \eta) \neq(0,0)\} \tag{4.16}
\end{align*}
$$

Step 2 Let $\varphi \in \mathcal{D}(U)$ be a test function; we have to establish the convergence of the formula

$$
\left\langle t\left(\chi-\chi_{\varepsilon^{-1}}\right), I_{m}(\varphi)\right\rangle+\langle t(1-\chi), \varphi\rangle
$$

when $\varepsilon \rightarrow 0$. As in the proof of Theorem 4.4, we use the partition of unity to derive an equivalent formula for $\lim _{\varepsilon \rightarrow 0}\left\langle t\left(\chi-\chi_{\varepsilon^{-1}}\right), I_{m}(\varphi)\right\rangle$ in terms of the family $\lambda^{-s} t_{\lambda}$ :

$$
\begin{align*}
& \lim _{\varepsilon \rightarrow 0}\left\langle t\left(\chi-\chi_{\varepsilon^{-1}}\right), I_{m}(\varphi)\right\rangle \\
& \quad=\int_{0}^{1} \frac{d \lambda}{\lambda} \lambda^{s+d+m+1}\left\langle\left(\lambda^{-s} t_{\lambda}\right) \psi, \sum_{|\alpha|=m+1} h^{\alpha} R_{\alpha}(\varphi)_{\lambda}\right\rangle \tag{4.17}
\end{align*}
$$

where $R_{\alpha}(\varphi)_{\lambda}(x, h)=\frac{1}{m!} \int_{0}^{1}(1-t)^{m} \partial_{h}^{\alpha} \varphi(x, t \lambda h) d t$ and the r.h.s. of (4.17) is absolutely convergent since $s+d+m+1>0$. It remains to prove that the limit when $\varepsilon \rightarrow 0$ is a well-defined distribution. The proof is similar to the proof in Theorem 4.4 except that we should use the fact that the seminorms of $\psi \sum_{|\alpha|=m+1} h^{\alpha} R_{\alpha}(\varphi)_{\lambda}$ are controlled by the seminorms of $\varphi$ by Taylor's formula for the integral remainder.

Step 3 We are reduced to prove the boundedness of the family of distributions parametrized by $\varepsilon \in(0,1]$

$$
\begin{aligned}
& t\left(\chi-\chi_{\varepsilon^{-1}}\right) I_{m}\left(x^{\prime}, h^{\prime}\right) \\
& \quad=\int_{\mathbb{R} \times \mathbb{R}^{n+d}} d \lambda d x d h 1_{[\varepsilon, 1]}(\lambda) \lambda^{s+d+m} \lambda^{-s} t(x, \lambda h) \psi(x, h) \lambda^{-m-1} I_{m}\left((x, \lambda h),\left(x^{\prime}, h^{\prime}\right)\right)
\end{aligned}
$$

in $\mathcal{D}_{\Lambda}^{\prime}$ where $\Lambda=W F(t) \cup \Xi \cup N^{*}(I)$.
We can repeat exactly the same proof as for Theorem 4.4 using parallel notations. Set $B_{1, \varepsilon}(\lambda, x, h)=1_{[\varepsilon, 1]}(\lambda) \lambda^{s+d+m} \lambda^{-s} t(x, \lambda h) \psi(x, h)$ then by Lemma 10.3, the family $\left(B_{1, \varepsilon}(\lambda, x, h) \otimes 1\left(x^{\prime}, h^{\prime}\right)\right)_{\varepsilon \in(0,1]}$ is bounded in $\mathcal{D}_{\Lambda_{1}}^{\prime}(U \times$ $U \times \mathbb{R}$ ) where

$$
\Lambda_{1}=\left\{\left.\left(\begin{array}{c}
\lambda ; \widehat{\lambda} \\
x ; \widehat{\xi} \\
h ; \widehat{\eta} \\
x^{\prime} ; 0 \\
h^{\prime} ; 0
\end{array}\right) \right\rvert\,\binom{ x ; \widehat{\xi}}{h ; \widehat{\eta}} \in \Gamma \cup \underline{0},(x, h) \in \operatorname{supp} \psi\right\}
$$

Equation 4.15 together with the pull-back theorem of Hörmander implies

$$
\begin{aligned}
& W F\left(\lambda^{-m-1} I_{m}(\Phi, .)\right) \\
& \qquad \subset \Lambda_{2}=\left\{\left.\left(\begin{array}{cc}
\lambda ;-\langle h, \eta\rangle \\
x ; & -\xi \\
h ; & -t \eta \\
x^{\prime} ; & \xi \\
h^{\prime} ; & \eta
\end{array}\right) \right\rvert\,(x, t h)=\left(x^{\prime}, h^{\prime}\right), t \in[0, \lambda],(\xi, \eta) \neq(0,0)\right\} .
\end{aligned}
$$

Note that $\Lambda_{1} \cap-\Lambda_{2}=\emptyset$ implies that the family of products

$$
\left(B_{1, \varepsilon}(\lambda, x, h) \lambda^{-m-1} I_{m}\left((x, \lambda h),\left(x^{\prime}, h^{\prime}\right)\right)\right)_{\varepsilon}
$$

is bounded in $\mathcal{D}_{\Lambda_{1}+\Lambda_{2} \cup \Lambda_{1} \cup \Lambda_{2}}^{\prime}$ by hypocontinuity of the Hörmander product [4, Thm 7.1]. As in the proof of proposition 4.4, we have $t\left(\chi-\chi_{\varepsilon^{-1}}\right) I_{m}=$ $\pi_{3}\left(B_{1, \varepsilon} \lambda^{-m-1} I_{m}\left(\Phi,\left(x^{\prime}, h^{\prime}\right)\right)\right)$; therefore, in order to conclude, it suffices to control the family $\left(\pi_{3 *}\left(B_{1, \varepsilon} \lambda^{-m-1} I_{m}\left(\Phi,\left(x^{\prime}, h^{\prime}\right)\right)\right)\right)_{\varepsilon}$ in $\mathcal{D}_{\Lambda}^{\prime}$ where $\Lambda=W F(t)$ $\cup \Xi \cup N^{*}(I)$, using continuity of the push-forward [4, Theorem 7.3], we have the following estimate:

$$
\begin{equation*}
\left(\Lambda \cap T_{I}^{*} U\right) \subset \pi_{3 *}\left(\Lambda_{1}+\Lambda_{2} \cup \Lambda_{1} \cup \Lambda_{2}\right) \cap T_{I}^{*} U \tag{4.18}
\end{equation*}
$$

We study the closed conic set $\pi_{3 *}\left(\Lambda_{1}+\Lambda_{2}\right) \cap T_{I}^{*} U$ : an element $\left(x^{\prime}, 0 ; \xi, \eta\right)$ belongs to $\pi_{3 *}\left(\Lambda_{1}+\Lambda_{2}\right)$ if and only if the system of equations

$$
\begin{gathered}
\left(\begin{array}{c}
\widehat{\lambda}-\langle h, \eta\rangle=0 \\
\widehat{\xi}-\xi=0 \\
\widehat{\eta}-t \eta=0
\end{array}\right) \text { s.t. } \exists t \in[0, \lambda] \text { s.t. }(x, t h)=\left(x^{\prime}, 0\right), \\
(x, h) \in \operatorname{supp} \psi,\binom{x ; \widehat{\xi}}{h ; \widehat{\eta}} \in \Gamma \cup \underline{0}
\end{gathered}
$$

has a solution. Note that $\left\{\begin{array}{c}(x, h) \in \operatorname{supp} \psi \\ (x, t h)=\left(x^{\prime}, 0\right) \\ \widehat{\eta}-t \eta=0\end{array}\right\} \Rightarrow|h| \neq 0, t=0, \widehat{\eta}=0$. Therefore,

$$
\begin{aligned}
& \left(x^{\prime}, 0 ; \xi, \eta\right) \in \pi_{3 *}\left(\Lambda_{1}+\Lambda_{2}\right) \\
& \quad \Leftrightarrow\left\{\binom{x ; \xi}{h ; 0} \in \Gamma \cup \underline{0},(x, h) \in \operatorname{supp} \psi\right\} \\
& \quad \Leftrightarrow \pi_{3 *}\left(\Lambda_{1}+\Lambda_{2}\right) \cap T_{I}^{*} U \subset \Xi .
\end{aligned}
$$

It is immediate that $\pi_{3 *} \Lambda_{1}=\emptyset$; finally

$$
\begin{aligned}
& \binom{x^{\prime} ; \xi}{0} \in \pi_{3 *} \Lambda_{2} \cap T_{I}^{*} U \\
& \quad \Leftrightarrow\left\{\begin{array}{c}
\langle h, \eta\rangle=0 \\
\xi=0 \\
t \eta=0
\end{array}\right\} \text { for }(x, t h)=\left(x^{\prime}, 0\right), t \in[0, \lambda],(x, h) \in \operatorname{supp} \psi \\
& \quad \Longrightarrow \xi=0 \Longrightarrow \pi_{3 *} \Lambda_{2} \cap T_{I}^{*} U \subset N^{*}(I)
\end{aligned}
$$

Finally, we can summarize the bounds that we obtained:

$$
\begin{equation*}
\Lambda \cap T_{I}^{*} \mathbb{R}^{n+d} \subset \Xi \cup N^{*}(I) \tag{4.19}
\end{equation*}
$$

which establishes the claim of our theorem.
We want to show that our extension is weakly homogeneous in $\mathcal{D}_{\Gamma}^{\prime}$.
Proposition 4.8. Under the assumptions of proposition (4.7), if $s$ is not an integer then the extension map $t \in E_{s}\left(\mathcal{D}_{\Gamma}^{\prime}(U \backslash I)\right) \longmapsto \bar{t} \in E_{S}\left(\mathcal{D}_{\Gamma \cup N^{*}(I) \cup \Xi}^{\prime}(U)\right)$ is bounded.

Proposition 4.9. Under the assumptions of proposition (4.7), if $s+d$ is a non positive integer, then

- the extension map $t \in E_{s}\left(\mathcal{D}_{\Gamma}^{\prime}(U \backslash I)\right) \longmapsto \bar{t} \in E_{s^{\prime}}\left(\mathcal{D}_{\Gamma \cup N^{*}(I) \cup \Xi}^{\prime}(U)\right)$, $\forall s^{\prime}<s$ is bounded,
- the family of distributions $\lambda^{-s}(\log \lambda)^{-1} \bar{t}_{\lambda}$ is bounded in $\mathcal{D}_{\Gamma \cup N^{*}(I) \cup \Xi}^{\prime}(U)$.

Proof. Choose a test function $\varphi$. To check the homogeneity of the renormalized integral is a little tricky since we have to take the scaling of counterterms into account. When we scale the test function $\varphi$ we should scale simultaneously the Taylor polynomial $\left(P_{m} \varphi\right)_{\lambda}$ and the remainder $\left(I_{m} \varphi\right)_{\lambda}$ :

$$
\varphi_{\lambda}=\left(P_{m} \varphi\right)_{\lambda}+\left(I_{m} \varphi\right)_{\lambda}=P_{m} \varphi_{\lambda}+I_{m} \varphi_{\lambda}
$$

We want to know to which scale space $E_{S^{\prime}}\left(\mathcal{D}_{\Gamma \cup N^{*}(I)}^{\prime}\right)$ the distribution $\bar{t}$ belongs:

$$
\begin{aligned}
\mu^{-s^{\prime}}\left\langle\bar{t}_{\mu}, \varphi\right\rangle & =\mu^{-s^{\prime}} \int_{0}^{1} \frac{d \lambda}{\lambda} \mu^{-d}\left\langle t \psi_{\lambda^{-1}},\left(I_{m} \varphi\right)_{\mu^{-1}}\right\rangle \\
& =\mu^{-s^{\prime}} \int_{0}^{1} \frac{d \lambda}{\lambda} \lambda^{d} \mu^{-d}\left\langle t_{\lambda} \psi,\left(I_{m} \varphi\right)_{\lambda \mu^{-1}}\right\rangle
\end{aligned}
$$

For the moment, we find that

$$
\mu^{-s^{\prime}}\left\langle\bar{t}_{\mu}, \varphi\right\rangle=\mu^{s-s^{\prime}} \int_{0}^{1} \frac{d \lambda}{\lambda}\left(\frac{\lambda}{\mu}\right)^{s+d}\left\langle\left(\lambda^{-s} t_{\lambda}\right) \psi,\left(I_{m} \varphi\right)_{\frac{\lambda}{\mu}}\right\rangle
$$

The test function $\varphi$ is supported in $\{|h| \leq R\}$; therefore, $\varphi_{\frac{\lambda}{\mu}}$ is supported on $|h| \leq \frac{\mu R}{\lambda}$ thus when $\frac{R \mu}{\lambda} \leq a \Leftrightarrow \frac{R \mu}{a} \leq \lambda$, the support of $\varphi_{\frac{\lambda}{\mu}}$ does not meet the support of $\lambda^{-s} t_{\lambda} \psi$ because $\psi$ is supported on $a \leq|h|$, whereas the polynomial part $P_{m} \varphi$ is supported everywhere since it is a Taylor polynomial. Consequently, we must split the scaled distribution $\mu^{-s} \bar{t}_{\mu}=I_{1}^{\mu}+I_{2}^{\mu}$ in two parts, where:

$$
\begin{aligned}
&\left\langle I_{1}^{\mu}, \varphi\right\rangle=\int_{0}^{\frac{R \mu}{a}} \frac{d \lambda}{\lambda}\left(\frac{\lambda}{\mu}\right)^{s+d}\left\langle\left(\lambda^{-s} t_{\lambda}\right) \psi,\left(I_{m} \varphi\right)_{\frac{\lambda}{\mu}}\right\rangle \\
&=\int_{0}^{\frac{R \mu}{a}} \frac{d \lambda}{\lambda}\left(\frac{\lambda}{\mu}\right)^{(d+s+m+1)}\left\langle\left(\lambda^{-s} t_{\lambda}\right) \psi, \sum_{|\alpha|=m+1} h^{\alpha} R_{\alpha, \frac{\lambda}{\mu}}\right\rangle \\
&\left\langle I_{2}^{\mu}, \varphi\right\rangle=\int_{\frac{R \mu}{a}}^{1} \frac{d \lambda}{\lambda}\left(\frac{\lambda}{\mu}\right)^{s+d} \quad\left\langle\lambda^{-s} t_{\lambda}, \varphi_{\frac{\lambda}{\mu}}-\left(P_{m} \varphi\right)_{\frac{\lambda}{\mu}}\right\rangle \\
& \text { no contribution of } \varphi_{\frac{\lambda}{\mu}} \text { since } \frac{R \mu}{a} \leq \lambda
\end{aligned}
$$

We make a simple variable change for $I_{1}^{\mu}$ :

$$
\left\langle I_{1}^{\mu}, \varphi\right\rangle=\int_{0}^{\frac{R}{a}} \frac{d \lambda}{\lambda} \lambda^{(d+s+m+1)}\left\langle(\lambda \mu)^{-s} t_{\lambda \mu} \psi, \sum_{|\alpha|=m+1} h^{\alpha} R_{\alpha, \lambda}\right\rangle ;
$$

then following the proof of proposition 4.4, we note that

$$
\begin{align*}
I_{1}^{\mu}= & \int_{\mathbb{R} \times \mathbb{R}^{n+d}} d \lambda d x d h \lambda^{s+d+m} \lambda^{-s} \Phi^{*}\left(\mu^{-s} t_{\mu}\right)(\lambda, x, h) 1_{\left[0, \frac{R}{a}\right]} \\
& \times \psi(x, h) \lambda^{-m-1} I_{m}(\Phi(.), .) . \tag{4.20}
\end{align*}
$$

Therefore, we can repeat the proof of proposition 4.7 for the bounded family $\left(\mu^{-s} t_{\mu}\right)_{\mu}$ in $\mathcal{D}_{\Gamma}^{\prime}(U)$ and we deduce that $\left(I_{1}^{\mu}\right)_{\mu}$ is bounded in $\mathcal{D}_{\Lambda}^{\prime}$ where $\Lambda=$ $\Gamma \cup N^{*}(I) \cup \Xi$.

Notice that in the second term $I_{2}^{\mu}$ only the counterterm $P_{m} \varphi$ contributes

$$
\begin{aligned}
I_{2}^{\mu} & =\int_{\frac{R \mu}{a}}^{1} \frac{d \lambda}{\lambda}\left(\frac{\lambda}{\mu}\right)^{s+d}\left\langle\lambda^{-s} t_{\lambda} \psi,-\left(P_{m} \varphi\right)_{\frac{\lambda}{\mu}}\right\rangle \\
& =\int_{\frac{R \mu}{a}}^{1} \frac{d \lambda}{\lambda}\left\langle\lambda^{-s} t_{\lambda} \psi,-\sum_{|\alpha| \leq m}\left(\frac{\lambda}{\mu}\right)^{s+d+|\alpha|} \frac{h^{\alpha}}{\alpha!} \pi^{*}\left(i^{*} \partial_{h}^{\alpha} \varphi\right)\right\rangle
\end{aligned}
$$

We reformulate $I_{2}^{\mu}$ as

$$
\begin{aligned}
& -\int_{\mathbb{R} \times \mathbb{R}^{n+d}} \frac{d \lambda}{\lambda} d x d h \lambda^{-s} \Phi^{*} t(\lambda, x, h) 1_{\left[\frac{R \mu}{a}, 1\right]} \psi(x, h) \\
& \quad \times \sum_{|\alpha| \leq m}\left(\frac{\lambda}{\mu}\right)^{s+d+|\alpha|} \frac{h^{\alpha}}{\alpha!} \pi^{*}\left(i^{*} \partial_{h}^{\alpha} \delta_{\Delta}(., .)\right)
\end{aligned}
$$

Then notice that by assumption $s+d \leq-m$ and $|\alpha|$ ranges from 0 to $m$ which implies that we always have $s+d+|\alpha| \leq 0$.

If $s+d<m$ then for all $\alpha$ such that $0 \leq|\alpha| \leq m$ we have the inequality $s+d+|\alpha|<0$; hence the family of functions $1_{\left[\frac{R \mu}{a}, 1\right]}\left(\frac{\lambda}{\mu}\right)^{s+d+|\alpha|} \lambda^{-1}$ is integrable w.r.t the variable $\lambda$ uniformly in the parameter $\mu$ since

$$
\left\|1_{\left[\frac{R \mu}{a}, 1\right]}\left(\frac{\lambda}{\mu}\right)^{s+d+|\alpha|} \lambda^{-1}\right\|_{L^{1}(\mathbb{R})}=\frac{1}{|s+d+|\alpha||} \underbrace{\left.\left(\frac{1}{\mu}\right)^{s+d+|\alpha|}-\left(\frac{R}{a}\right)^{s+d+|\alpha|} \right\rvert\,}_{\text {no blow up when } \mu \rightarrow 0}
$$

Therefore, the family $\left(\lambda^{-s-1} \Phi^{*} t(\lambda, x, h) 1_{\left[\frac{R \mu}{\alpha}, 1\right]} \psi(x, h)\left(\frac{\lambda}{\mu}\right)^{s+d+|\alpha|} \frac{h^{\alpha}}{\alpha!}\right)_{\mu \in(0,1)}$ is bounded in $\mathcal{D}_{V}^{\prime}$ where $V=\left\{(\lambda, x, h ; \tau, \xi, \eta) \in \dot{T}^{*}\left(\mathbb{R} \times \mathbb{R}^{n+d}\right) ; \lambda \in[0,1]\right.$, $(x, h ; \xi, \eta) \in \Gamma \cup \underline{0}\}$ by Proposition 10.3 and we can repeat the proof of proposition 4.7 where the Schwartz kernel $I_{m}(\Phi(),.$.$) should be replaced with$ the distribution $\pi^{*}\left(i^{*} \partial_{h}^{\alpha} \delta_{\Delta}(.,).\right)$ whose wave front set is calculated in Lemma 10.2 in appendix; the proof of Proposition 4.7 still applies in our case since $W F\left(\pi^{*}\left(i^{*} \partial_{h}^{\alpha} \delta_{\Delta}(.,).\right)\right) \subset W F\left(I_{m}(\Phi(),.).\right)$. However if $s+d+m=0$ then for $|\alpha|=m$, we find that the family of functions

$$
\left(1_{\left[\frac{R \mu}{a}, 1\right]}\left(\frac{\lambda}{\mu}\right)^{s+d+|\alpha|} \lambda^{-1}=\lambda^{-1} 1_{\left[\frac{R \mu}{a}, 1\right]}\right)_{\mu \in(0,1]}
$$

is no longer bounded in the $L_{\lambda}^{1}([0,1])$ for $\mu \in(0,1]$, but exhibits a logarithmic divergence:

$$
\forall \mu \in(0,1],\left\|1_{\left[\frac{R \mu}{a}, 1\right]} \lambda^{-1}\right\|_{L^{1}(\mathbb{R})}=\log \left(\frac{R \mu}{a}\right) \leq \log \mu+\log \left(\frac{R}{a}\right)
$$

Then it is easy to conclude that $(\log \lambda)^{-1} \lambda^{-s} \bar{t}_{\lambda}$ is bounded in $\mathcal{D}_{\Xi \cup N^{*}(I) \cup \Gamma}^{\prime}(U)$.

### 4.3. The General Extension in the Flat Case

For the sequel, we recall that $\chi \in C^{\infty}\left(\mathbb{R}^{n+d}\right)$ is our partition of unity used to construct the extension and $\psi=-h \frac{d \chi}{d h}$.

Theorem 4.10. Let $s \in \mathbb{R}, \Gamma \subset T^{\bullet} U$ be a closed conic set stable by scaling. If $t \in \mathcal{D}^{\prime}(U \backslash I)$ is weakly homogeneous of degree $s$ in $\mathcal{D}_{\Gamma}^{\prime}(U \backslash I)$, then

1. there is an extension $\bar{t} \in \mathcal{D}^{\prime}(U)$ of $t$, where

$$
\begin{aligned}
W F(\bar{t}) & \subset W F(t) \cup N^{*}(I) \cup \Xi \\
\Xi & =\{(x, 0 ; \xi, \eta) \mid(x, h) \in \operatorname{supp} \psi,(x, h ; \xi, 0) \in \Gamma\}
\end{aligned}
$$

2. $\bar{t}$ is in $E_{s, \Gamma \cup \Xi \cup N^{*}(I)}(U)$ if $-s-d \notin \mathbb{N}$ and $\bar{t} \in E_{s^{\prime}, \Gamma \cup \Xi \cup N^{*}(I)}(U), \forall s^{\prime}<s$ otherwise.

We give here the proof of an important particular case of the above theorem:

Theorem 4.11. Under the assumptions of the above theorem if $\left(\bar{\Gamma} \cap T_{I}^{\bullet} U\right) \subset$ $N^{*}(I)$ then

1. there is an extension $\bar{t} \in \mathcal{D}^{\prime}(U)$ of $t$, where

$$
W F(\bar{t}) \subset W F(t) \cup N^{*}(I)
$$

2. $\bar{t}$ is in $E_{s, \Gamma \cup N^{*}(I)}(U)$ if $-s-d \notin \mathbb{N}$ and $\bar{t} \in E_{s^{\prime}, \Gamma \cup N^{*}(I)}(U), \forall s^{\prime}<s$ otherwise.

Proof. The proof proceeds in two steps. First, we show that there exists a neighbourhood $V$ of $I=\{h=0\}$ such that $\forall(x, h ; \xi, \eta) \in T^{\bullet} V \cap \Gamma, \eta \neq 0$. In the second part, we explain that by carefully choosing $\chi$ in such a way that supp $\chi \subset V$, the subset $\Xi$ will be empty.

Step 1, we prove that for all compact set $K$ there is some neighbourhood $V$ of $I$ such that $\Gamma \cap T_{K \cap V}^{\bullet} U$ does not meet the set $\{(x, h ; \xi, 0) \mid \xi \neq 0\}$. Then it follows immediately by a covering argument that there exists a neighbourhood $V$ of $I=\{h=0\}$ such that $\forall(x, h ; \xi, \eta) \in T^{\bullet} V \cap \Gamma, \eta \neq 0$. By contradiction assume there is some compact set $K$ such that for all $V_{n}=\left\{|h| \leq n^{-1}\right\}$, there is some $\left(x_{n}, h_{n} ; \xi_{n}, 0\right) \in\left(T_{K \cap V_{n}}^{\bullet} U\right) \cap \Gamma$. By extracting a convergent subsequence one easily concludes that there would be a sequence $\left(x_{n}, h_{n} ; \xi_{n}, 0\right) \rightarrow$ $(x, 0 ; \xi, 0) \in \Gamma$, a contradiction !

Step 2 We choose a function $\chi$ which equals 1 in some neighbourhood of $I$ and $\chi$ is supported in $V$. Therefore, the function $\psi=-\rho \chi$ is supported in $V$. But the set $\Gamma \cap T_{V}^{*} U$ does not meet the set $\{(x, h ; \xi, 0) \mid \xi \neq 0\}$; therefore, the set $\Xi=\{(x, 0 ; \xi, \eta) \mid(x, h) \in \operatorname{supp} \psi(x, h ; \xi, 0) \in \Gamma\}$ is empty and the conclusion follows.

## 5. The Extension Theorem for $\boldsymbol{E}_{\boldsymbol{s}, \boldsymbol{I}}$

We are now ready to prove Theorem 1.7 and some part of the claim of Theorem 1.6:

Theorem 5.1. Let $U$ be an open neighbourhood of $I \subset M$, if $t \in E_{s, I}(U \backslash I)$; then there exists an extension $\bar{t}$ in $E_{s^{\prime}, I}(U)$ where $s^{\prime}=s$ if $-s-d \notin \mathbb{N}$ and $s^{\prime}<s$ otherwise.

Proof. $t \in E_{s, I}(U \backslash I)$ implies that for all $p \in I$, there is some open chart $\psi: V_{p} \subset U \mapsto \mathbb{R}^{n+d}, \psi(I) \subset \mathbb{R}^{n} \times\{0\}$ where $\lambda^{-s}\left(\psi_{*} t\right)(x, \lambda h)$ is bounded in $\mathcal{D}^{\prime}\left(\psi\left(V_{p} \backslash I\right)\right)$. Moreover, we must choose $V_{p}$ in such a way that its image $U=$
$\psi\left(V_{p}\right) \subset \mathbb{R}^{n+d}$ is of the form $U_{1} \times U_{2}$ where $U_{1} \subset \mathbb{R}^{n}, U_{2} \subset \mathbb{R}^{d}$ and the open set $U_{2}$ has the following property : $\lambda U_{2} \subset U_{2}, \forall \lambda \in[0,1]$. The collection of open sets $\left(V_{p}\right)_{p \in I}$ forms an open cover of $I$; consider a locally finite subcover $\cup_{a \in A} V_{a}$ and denote by $\left(\psi_{a}\right)_{a \in A}$ the corresponding charts. For every $a \in A$, Theorem 4.10 yields an extension $\overline{\psi_{a *} t}$ of $\psi_{a *} t$ in $E_{s^{\prime}, I}\left(\psi_{a}\left(V_{a}\right)\right)$ and by diffeomorphism invariance of $E_{s^{\prime}, I}$ (Theorem 1.4), the element $\psi_{a}^{*} \overline{\psi_{a *} t}$ belongs to $E_{s^{\prime}, I}\left(V_{a}\right)$. Choose a partition of unity $\left(\varphi_{a}\right)_{a}$ subordinated to the open cover $\cup_{a \in A} V_{a}$; then an extension of $t$ reads $\sum_{a \in A} \varphi_{a} \psi_{a}^{*} \overline{\psi_{a *} t}+\left(1-\sum_{a \in A} \varphi_{a}\right) t$ and belongs to $E_{s^{\prime}, I}(U)$ by the gluing property for $E_{s^{\prime}, I}$.

### 5.1. A Converse Result

Before we move on, let us prove a converse theorem, namely that given any distribution $t \in \mathcal{D}^{\prime}\left(\mathbb{R}^{n+d}\right)$, for all relatively compact subset $U$, we can find $s_{0} \in \mathbb{R}$ such that for all $s \leq s_{0}, t \in E_{s, I}(U)$; this means morally that any distribution has "finite scaling degree" along an arbitrary vector subspace. We also have the property that $\forall s_{1} \leq s_{2}, t \in E_{s_{2}, I} \Longrightarrow t \in E_{s_{1}, I}$. This means that the spaces $E_{s, I}$ are filtered. We work in $\mathbb{R}^{n+d}$ where $I=\mathbb{R}^{n} \times\{0\}$ and $\rho=h^{j} \frac{\partial}{\partial h^{j}}$ :
Proposition 5.2. Let $U$ be a relatively compact convex open set and $t \in \mathcal{D}^{\prime}\left(\mathbb{R}^{n+d}\right)$. If $t$ is of order $k$ on $U$, then $t \in E_{s, I}(U)$ for all $s \leq d+k$, where $d$ is the codimension of $I \subset \mathbb{R}^{n+d}$. In particular any compactly supported distribution is in $E_{s, I}\left(\mathbb{R}^{n+d}\right)$ for some $s$.
Proof. First note that if a function $\varphi \in \mathcal{D}(U)$, then the family of scaled functions $\left(\varphi_{\lambda^{-1}}\right)_{\lambda \in(0,1]}$ has support contained in a compact set $K=\{(x, \lambda h) \mid(x, h) \in$ $\operatorname{supp} \varphi, \lambda \in(0,1]\}$. We recall that for any distribution $t$, there exists $k, C_{K}$ such that

$$
\begin{aligned}
& \forall \varphi \in \mathcal{D}_{K}(U),|\langle t, \varphi\rangle| \leq C_{K} \pi_{K, k}(\varphi) \\
& \qquad\left|\left\langle t_{\lambda}, \varphi\right\rangle\right|=\left|\lambda^{-d}\left\langle t, \varphi_{\lambda-1}\right\rangle\right| \leq C_{K} \lambda^{-d} \pi_{K, k}\left(\varphi_{\lambda^{-1}}\right) \leq C_{K} \lambda^{-d-k} \pi_{K, k}(\varphi) .
\end{aligned}
$$

So we find that $\lambda^{d+k}\left\langle t_{\lambda}, \varphi\right\rangle$ is bounded which yields the conclusion.
Then Theorem 1.6 follows from Proposition 5.2 and the diffeomorphism invariance of $E_{s, I}$.

## 6. The Subspace $\boldsymbol{E}_{s, N^{*}(I)}(\boldsymbol{U})$

It is a central assumption of our extension theorems that the family $\left(\lambda^{-s} t_{\lambda}\right)_{\lambda}$ is bounded in $\mathcal{D}_{\Gamma}^{\prime}$ and we found that in the particular case where $\left.\bar{\Gamma}\right|_{I} \subset N^{*}(I)$ the wave front set of the extension is minimal, i.e.

$$
\begin{equation*}
W F(\bar{t}) \subset W F(t) \cup N^{*}(I) \tag{6.1}
\end{equation*}
$$

In this section, we generalize the previous situation to manifolds. We define a subspace $E_{s, N^{*}(I)}$ of $E_{s}$ which contains distributions $t$ such that their extension $\bar{t}$ satisfies $W F(\bar{t}) \subset W F(t) \cup N^{*}(I)$.

### 6.1. The Conormal Landing Condition

Definition 6.1. Let $U$ be an open neighbourhood of $I$. A closed conic set $\Gamma \subset$ $T^{\bullet}(U \backslash I)$ (resp. $\Gamma \subset T^{\bullet} U$ ) is said to satisfy the conormal landing condition if $\left(\bar{\Gamma} \cap T_{I}^{\bullet} U\right) \subset N^{*} I\left(\right.$ resp. $\left.\left(\Gamma \cap T_{I}^{\bullet} U\right) \subset N^{*} I\right)$, where $\bar{\Gamma}$ is the closure of $\Gamma$ in $T^{\bullet} U$.

The conormal landing condition which concerns the closure of $\Gamma$ over $T_{I}^{*} U$ is clearly intrinsic and does not depend on chosen coordinates. The following is a stability result for sets which satisfy the conormal landing condition:
Lemma 6.2. Let $U$ be some open neighbourhood of $I, \Gamma \subset T^{\bullet}(U \backslash I)$, and $\Phi \in$ $C^{\infty}([0,1] \times U, U)$ be such that $\Phi(\lambda,$.$) is a germ of diffeomorphism along I$, $\left.\Phi(\lambda,)\right|_{I$.$} is the identity map for all \lambda \in(0,1]$ and

$$
\forall(x, h ; \xi, \eta) \in N^{*}(I),\left(\Phi_{\lambda}^{-1}(x, h) ;(\xi, \eta) \circ d \Phi_{\lambda}\right)=(x, h ; \xi, \eta) .
$$

If $\Gamma$ satisfies the conormal landing condition then the cone $\Gamma^{\prime}$ defined as

$$
\begin{equation*}
\Gamma^{\prime}=\underset{\lambda \in(0,1]}{\cup} \Phi(\lambda)^{*} \Gamma \tag{6.2}
\end{equation*}
$$

also does.
In the terminology of Lemma 10.5 in appendix, the condition of the above Lemma means that the cotangent lift $T^{*} \Phi(\lambda,$.$) restricted to N^{*}(I)$ acts as the identity map.

Proof. Let $(x, 0 ; \xi, \eta)$ be in the closure of $\Gamma^{\prime}$; then there exists a sequence $\left(\lambda_{n}, x_{n}, h_{n} ; \xi_{n}, \eta_{n}\right)_{n}$ such that $\left(\Phi_{\lambda_{n}}^{-1}\left(x_{n}, h_{n}\right) ;\left(\xi_{n}, \eta_{n}\right) \circ d \Phi_{\lambda_{n}}\right) \rightarrow(x, 0 ; \xi, \eta)$. By compactness of $[0,1]$, we can always extract a subsequence so that $\lambda_{n} \rightarrow$ $\lambda_{0} \in[0,1]$. Then necessarily $\left(\Phi_{\lambda_{0}}^{-1}\left(x_{n}, h_{n}\right) ;\left(\xi_{n}, \eta_{n}\right) \circ d \Phi_{\lambda_{0}}\right) \rightarrow(x, 0 ; \xi, \eta)$ which implies that $\left(x_{n}, h_{n} ; \xi_{n}, \eta_{n}\right) \rightarrow\left(\Phi_{\lambda_{0}}(x, 0) ;(\xi, \eta) \circ d \Phi_{\lambda_{0}}^{-1}\right)=(x, 0 ; \xi, \eta)$ since the cotangent lift $\left.T^{*} \Phi\left(\lambda_{0},.\right)\right|_{N^{*}(I)}$ is the identity map and $T^{*} \Phi\left(\lambda_{0},.\right) \mid$ is a diffeomorphism.

### 6.2. Construction of $\boldsymbol{E}_{s, N^{*}(I)}$

We keep the notations of the above subsection. We give a preliminary definition of the space $E_{s}^{\rho}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$ for $\rho$-convex open sets $U$ and a given closed cone $\Gamma \subset T^{\bullet} U$ which depends on the choice of $\rho$.
Definition 6.3. Let $U$ be a $\rho$ convex set and $\Gamma \subset T^{\bullet} U$ be a closed cone; then $E_{s}^{\rho}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$ is defined as the space of distribution $t$ such that the family $\left(\lambda^{-s} e^{\log \lambda \rho *} t\right)_{\lambda \in(0,1]}$ is bounded in $\mathcal{D}_{\Gamma}^{\prime}(U)$.

We next define a localized version of the above space around an element $p \in I$.
Definition 6.4. $t$ belongs to $E_{s, N^{*}(I), p}^{\rho}$ if there exists a $\rho$-convex open set $U$ s.t. $\bar{U}$ is a neighbourhood of $p$ and $t \in E_{s}^{\rho}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$ for some $\Gamma \subset T^{\bullet} U$ which satisfies the conormal landing condition.
Theorem 6.5. Let $t \in \mathcal{D}^{\prime}(M \backslash I)$ and $p \in I$. If $t$ belongs to $E_{s, N^{*}(I), p}^{\rho}$ for some Euler vector field $\rho$ then it is so for any Euler vector field.

Proof. Let $\rho_{1}, \rho_{2}$ be two Euler vector fields and $t$ belongs to $E_{s, N *(I), p}^{\rho_{1}}$. It suffices to establish that the family $\left(\lambda^{-s} e^{\log \lambda \rho_{2} *} t\right)_{\lambda}$ is bounded in $\mathcal{D}_{\Gamma_{2}}^{\prime}\left(V_{p}^{\prime} \backslash I\right)$ for some neighbourhood $V_{p}^{\prime}$ of $p$ and $\Gamma_{2}$ satisfying the conormal landing condition. We use Proposition 2.3 which states that locally there exists a smooth family of germs of diffeomorphisms $\Phi(\lambda): V_{p} \mapsto M$ such that $\forall \lambda \in[0,1], \Phi(\lambda)(p)=p$ and $\Phi(\lambda)$ relates the two scalings:

$$
e^{\log \lambda \rho_{2} *}=\Phi(\lambda)^{*} e^{\log \lambda \rho_{1} *}
$$

Assume that $V_{p}$ is chosen small enough so that $\lambda^{-s} e^{\log \lambda \rho_{1} *} t$ is bounded in $\mathcal{D}_{\Gamma_{1}}^{\prime}\left(V_{p} \backslash I\right)$; then by [4, Theorem 6.9], we deduce that the family

$$
\left(\Phi(\lambda)^{*}\left(\lambda^{-s} e^{\log \lambda \rho_{1} *} t\right)\right)_{\lambda}=\left(\lambda^{-s} e^{\log \lambda \rho_{2} *} t\right)_{\lambda}
$$

is in fact bounded in $\mathcal{D}_{\Gamma_{2}}^{\prime}\left(V_{p}^{\prime} \backslash I\right)$ for some smaller neighbourhood $V_{p}^{\prime}$ of $p$ and with $\Gamma_{2}$ given by the following equation:

$$
\Gamma_{2}=\bigcup_{\lambda \in[0,1]} \Phi(\lambda)^{*} \Gamma_{1}
$$

By Lemma 10.6 proved in appendix, the family $\Phi(\lambda)$ satisfies

$$
\forall(x, h ; \xi, \eta) \in N^{*}(I),\left(\Phi_{\lambda}^{-1}(x, y) ;(\xi, \eta) \circ d \Phi_{\lambda}\right)=(x, h ; \xi, \eta)
$$

which implies by Lemma 6.2 that $\Gamma_{2}$ satisfies the conormal landing condition concluding our proof.

The previous theorem allows us to define spaces $E_{s, N^{*}(I), p}, E_{s, N^{*}(I)}$ with no mention of the choice of Euler vector field $\rho$ :

Definition 6.6. A distribution $t \in \mathcal{D}^{\prime}(U)$ belongs to $E_{s, N^{*}(I), p}(U)$ if $t \in E_{s, N^{*}(I), p}^{\rho}$ for some Euler vector field $\rho$. We define $E_{s, N^{*}(I)}(U)$ as the space of all distributions $t \in \mathcal{D}^{\prime}(U)$ such that $t \in E_{s, N^{*}(I), p}(U)$ for all $p \in I \cap \operatorname{int}(\bar{U})$.

It is immediate to deduce from Theorem 6.5 and definition 6.6 that $E_{s, N^{*}(I)}$ satisfies the same restriction and gluing properties as $E_{s, I}$.

We prove that $E_{s, N^{*}(I)}(U)$ satisfies a property of diffeomorphism invariance:

Theorem 6.7. Let $I$ (resp. $I^{\prime}$ ) be a closed embedded submanifold of $M$ (resp. $\left.M^{\prime}\right), U \subset M$ (resp. $U^{\prime} \subset M^{\prime}$ ) open and $\Phi: U^{\prime} \mapsto U$ a diffeomorphism s.t. $\Phi\left(U^{\prime} \cap I^{\prime}\right)=I \cap U$. Then $\Phi^{*} E_{s, N^{*}(I)}(U)=E_{s, N^{*}\left(I^{\prime}\right)}\left(U^{\prime}\right)$.

Proof. By Theorem 6.5, we can localize the proof at all points $p \in I \cap \operatorname{int}(\bar{U})$. Let $p \in I \cap \operatorname{int}(\bar{U})$; then $t \in E_{s, N^{*}(I)}(U)$ implies by definition that $t \in$ $E_{s}^{\rho}\left(\mathcal{D}_{\Gamma}^{\prime}(V)\right)$, where $\operatorname{int}(\bar{V})$ is a neighbourhood of $p$, some Euler $\rho$ and $\Gamma$ satisfying the conormal landing condition, which means that

$$
\begin{aligned}
& \lambda^{-s} e^{\log \lambda \rho *} t \text { bounded } \mathcal{D}_{\Gamma}^{\prime}(V) \\
& \quad \Leftrightarrow \lambda^{-s} \Phi^{*} e^{\log \lambda \rho *} \Phi^{-1 *}\left(\Phi^{*} t\right) \text { bounded in } \mathcal{D}_{\Phi^{*} \Gamma}^{\prime}\left(\Phi^{-1}(V)\right)
\end{aligned}
$$

because the pull-back by a diffeomorphism is a bounded map from $\mathcal{D}_{\Gamma}^{\prime}(V) \mapsto$ $\mathcal{D}_{\Phi * \Gamma}^{\prime}\left(\Phi^{-1}(V)\right)$,

$$
\Leftrightarrow \lambda^{-s} e^{\log \lambda\left(\Phi_{*}^{-1} \rho\right) *}\left(\Phi^{*} t\right) \text { bounded in } \mathcal{D}_{\Phi^{*} \Gamma}^{\prime}\left(\Phi^{-1}(V)\right)
$$

where the vector field $\Phi_{*}^{-1} \rho$ is Euler by Theorem 1.2. Therefore, $\Phi^{*} t$ is in $E_{s}^{\Phi_{*}^{-1} \rho}\left(\mathcal{D}_{\Phi^{*} \Gamma}^{\prime}\left(\Phi^{-1}(V)\right)\right)$ at $p^{\prime}=\Phi^{-1}(p)$, where $\Phi^{*} \Gamma$ also satisfies the conormal landing condition; hence $\Phi^{*} t$ is locally in $E_{s, N^{*}(I), p}$ at $p$ and repeating the proof for all $p \in I \cap \operatorname{int}(\bar{U})$ yields the claim.

## 7. The Extension Theorem for $\boldsymbol{E}_{s, N^{*}(I)}$

We are now ready to prove Theorem 1.10:
Theorem 7.1. Let $U \subset M$ be some open neighbourhood of $I$. If $t \in E_{s, N^{*}(I)}$ $(U \backslash I)$, then there exists an extension $\bar{t}$ with $W F(\bar{t}) \subset W F(t) \cup N^{*}(I)$ and $\bar{t} \in E_{s^{\prime}, N^{*}(I)}(U)$, where $s^{\prime}=s$ if $s+d \notin-\mathbb{N}$ and $s^{\prime}<s$ otherwise.

Proof. $t \in E_{s, N^{*}(I)}(U \backslash I)$ implies that for all $p \in I$, there is some open chart $\psi: V_{p} \subset U \mapsto \mathbb{R}^{n+d}, \psi(I) \subset \mathbb{R}^{n} \times\{0\}$ where $\lambda^{-s}\left(\psi_{*} t\right)(x, \lambda h)$ is bounded in $\mathcal{D}_{\Gamma}^{\prime}\left(\psi\left(V_{p} \backslash I\right)\right)$ for $\Gamma$ satisfying the conormal landing condition. Moreover, we must choose $V_{p}$ in such a way that its image $U=\psi\left(V_{p}\right) \subset \mathbb{R}^{n+d}$ is of the form $U_{1} \times U_{2}$ where $U_{1} \subset \mathbb{R}^{n}, U_{2} \subset \mathbb{R}^{d}$ and $\lambda U_{2} \subset U_{2}, \forall \lambda \in[0,1] . \cup_{p \in I} V_{p}$ forms an open cover of $I$, consider a locally finite subcover $\cup_{a \in A} V_{a}$ and denote by $\left(\psi_{a}\right)_{a \in A}$ the corresponding charts. For every $a \in A$, Theorem 4.10 yields an extension $\overline{\psi_{a *} t}$ of $\psi_{a *} t$ in $E_{s^{\prime}, N^{*}(I)}\left(\psi_{a}\left(V_{a}\right)\right)$ and by diffeomorphism invariance of $E_{s^{\prime}, N^{*}(I)}$ (Theorem 6.7), the element $\psi_{a}^{*} \overline{\psi_{a *}}$ belongs to $E_{s^{\prime}, N^{*}(I)}\left(V_{a}\right)$. Choose a partition of unity $\left(\varphi_{a}\right)_{a}$ subordinated to the open cover $\cup_{a \in A} V_{a}$; then an extension of $t$ reads $\sum_{a \in A} \varphi_{a} \psi_{a}^{*} \overline{\psi_{a *} t}+\left(1-\sum_{a \in A} \varphi_{a}\right) t$ and belongs to $E_{s^{\prime}, N^{*}(I)}(U)$ by the gluing property for $E_{s^{\prime}, N^{*}(I)}$.

## 8. Renormalized Products

In this section, we have a fixed Euler vector field $\rho$ and we scale only w.r.t. the flow generated by $\rho$. We can now prove our Theorem 1.11 which deals with the renormalization of certain products of distributions. We denote by $E_{s}^{\rho}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$ the space of distributions $t$ s.t. the family $\left(\lambda^{-s} e^{\log \lambda \rho *} t\right)_{\lambda \in(0,1]}$ is bounded in $\mathcal{D}_{\Gamma}^{\prime}(U)$ for some $\rho$-convex set $U$ and some cone $\Gamma$ stable by scaling:

Theorem 8.1. Let $\rho$ be some Euler vector field, $U$ some neighbourhood of $I$, $\left(\Gamma_{1}, \Gamma_{2}\right)$ two cones in $T^{\bullet}(U \backslash I)$ which satisfy the conormal landing condition and $\Gamma_{1} \cap-\Gamma_{2}=\emptyset$. Set $\Gamma=\left(\Gamma_{1}+\Gamma_{2}\right) \cup \Gamma_{1} \cup \Gamma_{2}$. If $\Gamma_{1}+\Gamma_{2}$ satisfies the conormal landing condition then there exists a bilinear map $\mathcal{R}$ satisfying the following properties:

- $\mathcal{R}:\left(u_{1}, u_{2}\right) \in E_{s_{1}}^{\rho}\left(\mathcal{D}_{\Gamma_{1}}^{\prime}(U \backslash I)\right) \times E_{s_{2}}^{\rho}\left(\mathcal{D}_{\Gamma_{2}}^{\prime}(U \backslash I)\right) \mapsto \mathcal{R}\left(u_{1} u_{2}\right) \in E_{s, N^{*}(I)}(U)$, $\forall s<s_{1}+s_{2}$
- $\mathcal{R}\left(u_{1} u_{2}\right)=u_{1} u_{2}$ on $U \backslash I$
- $\mathcal{R}\left(u_{1} u_{2}\right) \in \mathcal{D}_{\text {ГUN* }}^{\prime}(I)(U)$.

Proof. The families $\left(\lambda^{-s_{i}} e^{\log \lambda \rho *} u_{i}\right)_{\lambda \in(0,1]}$ are bounded in $\mathcal{D}_{\Gamma_{i}}^{\prime}(U \backslash I)$. By hypocontinuity of the Hörmander product [4, Theorem 7.1], the family

$$
\left(\lambda^{-s_{1}-s_{2}} e^{\log \lambda \rho *}\left(u_{1} u_{2}\right)\right)_{\lambda \in(0,1]}
$$

is bounded in $\mathcal{D}_{\Gamma}^{\prime}(U \backslash I), \Gamma$ still satisfies the conormal landing condition by assumption then it follows by Theorem 1.10 that $u_{1} u_{2}$ admits an extension $\mathcal{R}\left(u_{1} u_{2}\right)$ in $E_{s, N^{*}(I)}(U)$ and $\mathcal{R}\left(u_{1} u_{2}\right) \in \mathcal{D}_{\Gamma \cup N^{*}(I)}^{\prime}(U)$.

## 9. Renormalization Ambiguities

### 9.1. Removable Singularity Theorems

First, we would like to start this section by a simple removable singularity theorem in the spirit of [27, Theorems 5.2 and 6.1]. In a renormalization procedure, there is always an ambiguity which is the ambiguity of the extension of the distribution. Indeed, two extensions always differ by a distribution supported on $I$. The removable singularity theorem states that if $s+d>0$ and if we demand that $t \in E_{s, I}(U \backslash I)$ should extend to $\bar{t} \in E_{s, I}(U)$, then the extension is unique. Otherwise, if $-m-1<s+d \leq-m$, then we bound the transversal order of the ambiguity. We fix the coordinate system $\left(x^{i}, h^{j}\right)$ in $\mathbb{R}^{n+d}$ and $I=\{h=0\}$. The collection of coordinate functions $\left(h^{j}\right)_{1 \leq j \leq d}$ defines a canonical collection of transverse vector fields $\left(\partial_{h^{j}}\right)_{j}$. We denote by $\delta_{I}$ the unique distribution such that

$$
\begin{equation*}
\forall \varphi \in \mathcal{D}\left(\mathbb{R}^{n+d}\right),\left\langle\delta_{I}, \varphi\right\rangle=\int_{\mathbb{R}^{n}} \varphi(x, 0) d^{n} x . \tag{9.1}
\end{equation*}
$$

If $t \in \mathcal{D}^{\prime}\left(\mathbb{R}^{n+d}\right)$ with supp $t \subset I$, then by [49, Theorems 36,37 p. 101-102] or [34, Theorem 2.3.5] there exist unique distributions (once the system of transverse vector fields $\partial_{h^{j}}$ is fixed) $t_{\alpha} \in \mathcal{D}^{\prime}\left(\mathbb{R}^{n}\right)$, where each compact intersects supp $t_{\alpha}$ for a finite number of multi-indices $\alpha$, such that $t(x, h)=$ $\sum_{\alpha} t_{\alpha}(x) \partial_{h}^{\alpha} \delta_{I}(h)$ where the $\partial_{h}^{\alpha}$ are derivatives in the transverse directions.
Theorem 9.1. Let $t \in E_{s, I}(U \backslash I)$ and $\bar{t} \in E_{s^{\prime}, I}(U \backslash I)$ its extension given by Theorem (4.4) and Theorem (4.5) where $s^{\prime}=s$ when $-s-d \notin \mathbb{N}$ or $s^{\prime}<s$ otherwise. Then $\tilde{t}$ is an extension in $E_{s^{\prime}, I}(U)$ if and only if

$$
\begin{equation*}
\tilde{t}(x, h)=\bar{t}(x, h)+\sum_{\alpha \leq m} t_{\alpha}(x) \partial_{h}^{\alpha} \delta_{I}(h), \tag{9.2}
\end{equation*}
$$

where $m$ is the integer part of $-s-d$. In particular when $s+d>0$ the extension is unique.

Remark. when $-s-d$ is a nonnegative integer, the counterterm is in $E_{s, I}$ whereas the extension is in $E_{s^{\prime}, I}, \forall s^{\prime}<s$.

Proof. We scale an elementary distribution $\partial_{h}^{\alpha} \delta_{I}$ :

$$
\left\langle\left(\partial_{h}^{\alpha} \delta_{I}\right)_{\lambda}, \varphi\right\rangle=\lambda^{-d}\left\langle\partial_{h}^{\alpha} \delta_{I}, \varphi_{\lambda}-1\right\rangle=(-1)^{|\alpha|} \lambda^{-d-|\alpha|}\left\langle\partial_{h}^{\alpha} \delta_{I}, \varphi\right\rangle ;
$$

hence $\lambda^{-s}\left(\partial^{\alpha} \delta_{I}\right)_{\lambda}=\lambda^{-d-|\alpha|-s} \partial_{h}^{\alpha} \delta_{I}$ is bounded iff $d+s+|\alpha| \leq 0 \Longrightarrow d+$ $s \leq-|\alpha|$. When $s+d>0, \forall \alpha, \partial_{h}^{\alpha} \delta_{I} \notin E_{s, I}$; hence any two extensions in $E_{s, I}(U)$ cannot differ by a local counterterm of the form $\sum_{\alpha} t_{\alpha} \partial_{h}^{\alpha} \delta_{I}$. When $-m-1<d+s \leq-m$, then $\lambda^{-s}\left(\partial_{h}^{\alpha} \delta_{I}\right)_{\lambda}$ is bounded iff $s+d+|\alpha| \leq 0 \Leftrightarrow$ $-m \leq-|\alpha| \Leftrightarrow|\alpha| \leq m$. We deduce that $\partial_{h}^{\alpha} \delta_{I} \in E_{s, I}$ for all $\alpha \leq m$ which means that the scaling degree bounds the order $|\alpha|$ of the derivatives in the transverse directions. Assume there are two extensions in $E_{s, I}$, their difference is of the form $u=\sum_{\alpha} u_{\alpha} \partial_{h}^{\alpha} \delta_{I}$ by the structure theorem (36) p. 101 in [49] and is also in $E_{s, I}$ which means their difference equals $u=\sum_{|\alpha| \leq m} u_{\alpha} \partial_{h}^{\alpha} \delta_{I}$.

### 9.2. Counterterms on Manifolds and Conormal Distributions

What happens in the case of manifolds? From the point of view of L. Schwartz, the only thing to keep in mind is that a distribution supported on a submanifold $I$ is always well defined locally and the representation of this distribution is unique once we fix a system of coordinate functions $\left(h^{j}\right)_{j}$ which are transverse to $I$ [49, Theorem 37 p .102$]$. For any distribution $t_{\alpha} \in \mathcal{D}^{\prime}(I)$, if we denote by $i: I \hookrightarrow M$ the canonical embedding of $I$ in $M$ then $i_{*} t_{\alpha}$ is the push-forward of $t_{\alpha}$ in $M$ :

$$
\forall \varphi \in \mathcal{D}(M),\left\langle i_{*} t_{\alpha}, \varphi\right\rangle=\left\langle t_{\alpha}, \varphi \circ i\right\rangle
$$

The next lemma completes Theorem 9.1. Here the idea is that we add a constraint on the local counterterm $t$, namely that $W F(t)$ is contained in the conormal of $I$. Then we prove that the coefficients $t_{\alpha}$ appearing in the Schwartz representation (9.2) are in fact smooth functions.

Lemma 9.2. Let $t \in \mathcal{D}^{\prime}(M)$ such that $t$ is supported on $I$; then

1) $t$ has a unique decomposition as locally finite linear combinations of transversal derivatives of push-forward to $M$ of distributions $t_{\alpha}$ in $\mathcal{D}^{\prime}(I): t=$ $\sum_{\alpha} \partial_{h}^{\alpha}\left(i_{*} t_{\alpha}\right)$, and 2) $W F(t)$ is contained in the conormal of I if and only if $\forall \alpha, t_{\alpha}$ is smooth.

Proof. If $\left(t_{\alpha}\right)_{\alpha}$ are smooth then the wave front set of the push-forward $i_{*} t_{\alpha}$ is contained in the normal of the embedding $i$ denoted by $N_{i}$ [4, 2.3.1] which is nothing but the conormal bundle $N^{*}(I)$ [4, Example 2.9]. To prove the converse, in local coordinates, let

$$
t(x, h)=\sum_{\alpha} \partial_{h}^{\alpha}\left(t_{\alpha}(x) \delta_{I}(h)\right)=\sum_{\alpha} t_{\alpha}(x) \partial_{h}^{\alpha} \delta_{I}(h) .
$$

Assume $t_{\alpha}$ is not smooth then $W F\left(t_{\alpha}\right)$ would be non empty. Then $W F\left(t_{\alpha}\right)$ contains an element $\left(x_{0} ; \xi_{0}\right)$. Pick $\chi \in \mathcal{D}\left(R^{n}\right)$ such that $\chi\left(x_{0}\right) \neq 0$; then

$$
\mathcal{F}\left(t_{\alpha} \chi \partial_{h}^{\alpha} \delta_{I}\right)(\xi, \eta)=\widehat{t_{\alpha} \chi}(\xi)(-i \eta)^{\alpha}
$$

hence we find a codirection $\left(\lambda \xi_{0}, \lambda \eta\right), \xi_{0} \neq 0$ in which the product $\widehat{t_{\alpha} \chi} \widehat{\partial_{h}^{\alpha} \delta_{I}}$ is not rapidly decreasing; hence there is a point $(x, 0)$ such that $\left(x, 0 ; \xi_{0}, \eta_{0}\right) \in W F(t)[34$, Lemma 8.2.1] which is in contradiction with the fact that $W F(t) \subset N^{*}(I)=\{(x, 0,0, \eta) \mid \eta \neq 0\}$.

Combining with Theorem 9.1, we obtain the following:

Corollary 9.3. Let $t \in \mathcal{D}^{\prime}\left(\mathbb{R}^{n+d}\right)$ and supp $t \subset I$. If $W F(t) \subset N^{*}(I)$ and $t \in E_{s, N^{*}(I)}\left(\mathbb{R}^{n+d}\right),-m-1<s+d \leq-m$, then $t(x, h)=\sum_{\alpha} t_{\alpha}(x) \partial_{h}^{\alpha} \delta_{I}(h)$, where $\forall \alpha, t_{\alpha} \in C^{\infty}\left(\mathbb{R}^{n}\right)$ and $|\alpha| \leq m$.

Corollary 9.4. Let $M$ be a smooth manifold and I a closed embedded submanifold. For $-m-1<s+d \leq-m$, the space of distributions $t \in E_{s, N^{*}(I)}(M)$ such that supp $t \in I$ and $W F(t)$ is contained in the conormal of $I$ is a finitely generated module of rank $\frac{m+d!}{m!d!}$ over the ring $C^{\infty}(I)$.

Proof. In each local chart $(x, h)$ where $I=\{h=0\}, t=\sum_{\alpha} t_{\alpha}(x) \partial_{h}^{\alpha} \delta_{I}(h)$ where the length $|\alpha|$ is bounded by $m$ by the above corollary and $\forall \alpha, t_{\alpha} \in$ $C^{\infty}(I)$. This improves on the result given by the structure theorem of Laurent Schwartz since we now know that the $t_{\alpha}$ are smooth.

## Acknowledgements

We would like to thank Christian Brouder and Frédéric Hélein for their collaboration, many enlightening discussions and their support which results in the present paper. We also thank Yoann Dabrowski for his many advices concerning the functional analytic aspects of the space $\mathcal{D}_{\Gamma}^{\prime}$ and his deep influence on the way the author thinks about the extension problem. Finally we would like to thank the Labex CEMPI (ANR-11-LABX-0007-01) and the Laboratoire Paul Painlevé for excellent working conditions.

## Appendix

Wave front set of the kernels of the operators $I_{m}, \boldsymbol{R}_{\alpha}$. In this part, we calculate the wave front set of the kernels of the operators $I_{m}, R_{\alpha}$ introduced in the proof of Theorem 4.7. Recall $I=\mathbb{R}^{n} \times\{0\}$ is the vector subspace $\{h=0\}$; we define the projection $\pi:(x, h) \in \mathbb{R}^{n+d} \longmapsto(x, 0) \in \mathbb{R}^{n} \times\{0\}$, the inclusion $i: \mathbb{R}^{n} \times\{0\} \hookrightarrow \mathbb{R}^{n+d}$ and the operator $I_{m}$ of projection on the Taylor remainder of degree $m$ :

$$
\begin{aligned}
I_{m} & :=\varphi \in C^{\infty}\left(\mathbb{R}^{n+d}\right) \longmapsto I_{m} \varphi=\varphi-P_{m} \varphi \in C^{\infty}\left(\mathbb{R}^{n+d}\right) \\
P_{m} \varphi & =\sum_{|\alpha| \leq m} \frac{h^{\alpha}}{\alpha!} \pi^{*}\left(i^{*} \partial_{h}^{\alpha} \varphi\right) \\
I_{m} \varphi & =\frac{1}{m!} \sum_{|\alpha|=m+1} h^{\alpha} \int_{0}^{1}(1-t)^{m}\left(\partial_{h}^{\alpha} \varphi\right)_{t} d t .
\end{aligned}
$$

We also introduce the operators $\left(R_{\alpha}\right)_{\{|\alpha|=m+1\}}$ :

$$
I_{m}=\sum_{|\alpha|=m+1} h^{\alpha} R_{\alpha}
$$

We next explain how to calculate the Schwartz kernels of $I_{m}, R_{\alpha}$ which are distributions in $\mathcal{D}^{\prime}\left(\mathbb{R}^{n+d} \times \mathbb{R}^{n+d}\right)$ and their wave front set. We double the space $\mathbb{R}^{n+d}$ and we work in $\mathbb{R}^{n+d} \times \mathbb{R}^{n+d}$ with coordinates $\left(x, h, x^{\prime}, h^{\prime}\right)$. We
denote by $\delta \in \mathcal{D}^{\prime}\left(\mathbb{R}^{n+d}\right)$ the delta distribution supported at $(0,0) \in \mathbb{R}^{n+d}$ and $\delta_{\Delta}(.,.) \in \mathcal{D}^{\prime}\left(\mathbb{R}^{n+d} \times \mathbb{R}^{n+d}\right)$ the delta distribution supported on the diagonal $\Delta$ in $\mathbb{R}^{n+d} \times \mathbb{R}^{n+d}$ where we have the relation $\delta_{\Delta}\left((x, h),\left(x^{\prime}, h^{\prime}\right)\right)=\delta\left(x-x^{\prime}, h-h^{\prime}\right)$. The Schwartz kernel of $I_{m}$ is the distribution defined as

$$
\begin{align*}
I_{m}(., .) & =\delta_{\Delta}(., .)-\sum_{|\alpha| \leq m} \frac{h^{\alpha}}{\alpha!} \pi^{*}\left(i^{*} \partial_{h}^{\alpha} \delta_{\Delta}(., .)\right)  \tag{10.1}\\
& =\frac{1}{m!} \sum_{|\alpha|=m+1} h^{\alpha} \int_{0}^{1}(1-t)^{m} \partial_{h}^{\alpha} \delta_{\Delta}(\Phi(t, .), .) d t \tag{10.2}
\end{align*}
$$

where $\Phi(t, x, h)=(x, t h)$. We also need to define Schwartz kernels $R_{\alpha}$ :

$$
\begin{aligned}
R_{\alpha}(., .) & =\frac{1}{m!} \int_{0}^{1}(1-t)^{m} \partial_{h}^{\alpha} \delta(\Phi(t, .), .) d t \\
\text { where } I_{m}(., .) & =\sum_{|\alpha|=m+1} h^{\alpha} R_{\alpha}(., .)
\end{aligned}
$$

Lemma 10.1. Let $I_{m}(.,$.$) and R_{\alpha}(.,$.$) be defined as above; then$

$$
\begin{equation*}
W F\left(R_{\alpha}(., .)\right) \subset\{(x, h, x, t h ; \xi, t \eta,-\xi,-\eta) \mid t \in[0,1],(\xi, \eta) \neq(0,0)\} \tag{10.3}
\end{equation*}
$$

and

$$
\begin{equation*}
W F\left(I_{m}(., .)\right) \subset\{(x, h, x, t h ; \xi, t \eta,-\xi,-\eta) \mid t \in[0,1],(\xi, \eta) \neq(0,0)\} \tag{10.4}
\end{equation*}
$$

Proof. Let us calculate $W F\left(I_{m}(.,).\right)$; the idea is to work in "extended space" $[0,1] \times \mathbb{R}^{n+d} \times \mathbb{R}^{n+d}$ with coordinates $\left(t, x, h, x^{\prime}, h^{\prime}\right)$. Consider the map
$\Phi:=\left(t, x, h, x^{\prime}, h^{\prime}\right) \in[0,1] \times \mathbb{R}^{n+d} \times \mathbb{R}^{n+d} \longmapsto\left(x, t h, x^{\prime}, h^{\prime}\right) \in \mathbb{R}^{n+d} \times \mathbb{R}^{n+d} ;$ then $\left(\Phi^{*} \delta\right)\left(t, x, h, x^{\prime}, h^{\prime}\right)=\delta\left((x, t h),\left(x^{\prime}, h^{\prime}\right)\right)$ and application of the pull-back theorem [4, Proposition 6.1] implies that

$$
\begin{align*}
& \left.W F\left(\Phi^{*} \partial_{h}^{\alpha} \delta(., .)\right)\right) \\
& \subset\left\{\left(t, x, h, x^{\prime}, h^{\prime} ; \tau, \xi, t \eta,-\xi,-\eta\right) \mid(x, t h)=\left(x^{\prime}, h^{\prime}\right)\right. \\
& \text { and } \tau=\langle h . \eta\rangle,(\xi, \eta) \neq(0,0)\} \text {. } \tag{10.5}
\end{align*}
$$

We also note that $m!R_{\alpha}$ is just the integral of $\left.f=1_{[0,1]}(1-t)^{m} \Phi^{*} \partial_{h}^{\alpha} \delta(.,).\right) d t$ over $[0,1]$; in other words, it is the push-forward of $f$ by the projection $\mathbf{p}$ : $\mathbb{R} \times \mathbb{R}^{2(n+d)} \mapsto \mathbb{R}^{2(n+d)}$. From the bound (10.5) on $\left.W F\left(\Phi^{*} \partial_{h}^{\alpha} \delta(.,).\right)\right)$ and the behaviour of wave front sets under product, we find the rough upper bound:
$W F(f) \subset \Xi=\left\{\left(t, x, h, x^{\prime}, h^{\prime} ; \tau, \xi, t \eta,-\xi,-\eta\right) \mid(x, t h)=\left(x^{\prime}, h^{\prime}\right),(\xi, \eta) \neq(0,0)\right\}$.
Finally, from the relation $\left.R_{\alpha}=\frac{\mathbf{p}_{*} f}{m!}, f=1_{[0,1]}(1-t)^{m} \Phi^{*} \partial_{h}^{\alpha} \delta(.,).\right) d t$ we find that

$$
\begin{aligned}
& W F\left(R_{\alpha}(., .)\right) \subset \mathbf{p}_{*} W F(f) \subset \mathbf{p}_{*} \Xi \\
\Longrightarrow & W F\left(R_{\alpha}(., .)\right) \subset\{(x, h, x, t h ; \xi, t \eta,-\xi,-\eta) \mid t \in[0,1],(\xi, \eta) \neq(0,0)\} .
\end{aligned}
$$

We also need the wave front set of the Schwartz kernel of the operator $\varphi \longmapsto P_{m} \varphi$ which projects $\varphi$ on its "Taylor polynomial":

$$
\begin{equation*}
\forall|\alpha| \leq m, W F\left(\pi^{*}\left(i^{*} \partial_{h}^{\alpha} \delta_{\Delta}(., .)\right)\right) \subset\{(x, h, x, 0 ; \xi, 0,-\xi,-\eta) \mid(\xi, \eta) \neq(0,0)\} \tag{10.6}
\end{equation*}
$$

Note the important fact that $W F\left(\pi^{*}\left(i^{*} \partial_{h}^{\alpha} \delta_{\Delta}(.,).\right)\right) \subset W F\left(I_{m}(.,).\right)$.
Lemma 10.2. Let $\delta_{\Delta}\left((x, h),\left(x^{\prime}, h^{\prime}\right)\right)$ be the delta function of the diagonal $\Delta \subset$ $\mathbb{R}^{n+d} \times \mathbb{R}^{n+d}, i: x \longmapsto(x, 0)$ the inclusion of $\mathbb{R}^{n}$ in $\mathbb{R}^{n+d}$ and $\pi$ the projection $(x, h) \in \mathbb{R}^{n+d} \longmapsto x \in \mathbb{R}^{n}$. The Schwartz kernel of the linear map $\varphi \longmapsto$ $\pi^{*}\left(i^{*} \partial_{h}^{\alpha} \varphi\right)$ is $\pi^{*}\left(i^{*} \partial_{h}^{\alpha} \delta_{\Delta}\right)$,

$$
\begin{equation*}
W F\left(\pi^{*}\left(i^{*} \partial_{h}^{\alpha} \delta_{\Delta}\right)\right) \subset\{(x, h, x, 0 ; \xi, 0,-\xi,-\eta) \mid(\xi, \eta) \neq(0,0)\} \tag{10.7}
\end{equation*}
$$

Proof. First, we have $W F\left(i^{*} \partial_{h}^{\alpha} \delta_{\Delta}\right) \subset\{(x, x, 0 ; \xi,-\xi,-\eta), \quad(\xi, \eta) \neq(0,0)\}$; then

$$
\begin{array}{rl}
W & F\left(\pi^{*}\left(i^{*} \partial_{h}^{\alpha} \delta_{\Delta}\right)\right) \\
\quad \subset\left\{\left(x, h, x^{\prime}, h^{\prime} ; \xi, 0, \xi^{\prime}, \eta^{\prime}\right) \mid\left(x, x^{\prime}, h^{\prime} ; \xi, \xi^{\prime}, \eta^{\prime}\right) \in W F\left(i^{*} \partial_{h}^{\alpha} \delta_{\Delta}\right)\right\} \\
\quad=\{(x, h, x, 0 ; \xi, 0,-\xi,-\eta) \mid(\xi, \eta) \neq(0,0)\} .
\end{array}
$$

Technical Lemma. In this part, we prove the main technical Lemma which is essential in the proof of the main Theorems of Section 4 and we follow its terminology and notations.

Lemma 10.3. Let $U \subset \mathbb{R}^{n+d}$ be a convex set, for $\varepsilon \geq 0,1_{[\varepsilon, 1]}$ is the indicator function of $[\varepsilon, 1]$. Set

$$
V=\left\{\left.\left(\begin{array}{l}
\lambda ; \widehat{\lambda}  \tag{10.8}\\
x ; \widehat{\xi} \\
h ; \widehat{\eta}
\end{array}\right) \right\rvert\,\binom{ x ; \widehat{\xi}}{h ; \widehat{\eta}} \in \Gamma \cup \underline{0},(x, h) \in \operatorname{supp} \psi\right\}
$$

Let $B$ be some bounded subset in $E_{s}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$. For all function $f \in L^{1}([0,1]) \cap$ $C^{\infty}(0,1)$, for all $t \in B$, the family $\left(f 1_{[\varepsilon, 1]} \lambda^{-s} \Phi^{*} t\right)_{\varepsilon \in[0,1], t \in B}$ is bounded in $\mathcal{D}_{V}^{\prime}(\mathbb{R} \times U)$.

Proof. We first prove that $\left(f 1_{[\varepsilon, 1]} \lambda^{-s} \Phi^{*} t\right)_{\varepsilon \in[0,1]}$ is weakly bounded in $\mathcal{D}^{\prime}(\mathbb{R} \times$ $U) . \lambda^{-s} t_{\lambda}$ is bounded in $\mathcal{D}^{\prime}(U)$; therefore by the uniform boundedness principle in Fréchet space [43],

$$
\begin{aligned}
& \forall K \subset U \text { compact, } \\
& \qquad \exists m \in \mathbb{N}, \exists C>0, \forall \varphi \in \mathcal{D}_{K}(U), \sup _{\lambda \in[0,1]}\left|\left\langle\lambda^{-s} t_{\lambda}, \varphi\right\rangle\right| \leq C \pi_{m, K}(\varphi) .
\end{aligned}
$$

If $t$ is in a bounded subset $B$ of $E_{s}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$, then one can choose the constant $C$ independent of $t \in B$. It follows easily that for all subset of the form $(\mathbb{R} \times K) \subset$ $(\mathbb{R} \times U)$ :
$\exists m \in \mathbb{N}, C \geq 0$, such that $\forall \varphi \in \mathcal{D}_{\mathbb{R} \times K}(\mathbb{R} \times U), \forall \varepsilon \geq 0$,

$$
\begin{aligned}
& \left|\int_{[\varepsilon, 1] \times \mathbb{R}^{n+d}} f(\lambda) \lambda^{-s} t(x, \lambda h) \varphi(\lambda, x, h) d \lambda d x d h\right| \\
& \leq\|f\|_{L^{1}([0,1])} \sup _{\lambda \in[0,1]}\left|\left\langle\lambda^{-s} t_{\lambda}, \varphi(\lambda, .)\right\rangle\right| \\
& \leq C\|f\|_{L^{1}([0,1])} \sup _{\lambda \in[0,1]} \pi_{m, K}(\varphi(\lambda, .)) \\
& \leq C\|f\|_{L^{1}([0,1])} \pi_{m,[0,1] \times K}(\varphi) .
\end{aligned}
$$

For all $(\lambda, x, h ; \tau, \xi, \eta) \notin V$, there is a conic set $W \subset \mathbb{R}^{n+d} \backslash\{0\}$, a test function $\varphi_{2} \in \mathcal{D}(U)$ such that $(x, h ; \xi, \eta) \in \operatorname{supp} \varphi_{2} \times W$ and $\left(\operatorname{supp} \varphi_{2} \times W\right) \cap$ $\Gamma=\emptyset$. Let $\varphi(\lambda, x, h)=\varphi_{1}(\lambda) \varphi_{2}(x, h)$ for some $\varphi_{1}, \varphi_{1}(\lambda) \neq 0$ in $\mathcal{D}(\mathbb{R})$ and we define a conic neighbourhood $W^{\prime}$ of $\left(\tau_{0}, \xi_{0}, \eta_{0}\right)$ as follows: $W^{\prime}=\{(\tau, \xi, \eta)| | \tau \mid \leq$ $\left.2 \frac{\left|\tau_{0}\right|}{\left|\xi_{0}\right|+\left|\eta_{0}\right|}(|\xi|+|\eta|),(\xi, \eta) \in W\right\}$. We find that $\forall(\tau, \xi, \eta) \in W^{\prime}$ :

$$
\begin{aligned}
& \left|\int_{\varepsilon}^{1} d \lambda f(\lambda)\left\langle\lambda^{-s} t_{\lambda}, \varphi_{2} e^{i(x . \xi+h . \eta)}\right\rangle \varphi_{1}(\lambda) e^{i \lambda . \tau}\right| \\
& =\left|\int_{\varepsilon}^{1} d \lambda \widehat{\lambda^{-s} t_{\lambda} \varphi_{2}}(\xi, \eta) f(\lambda) \varphi_{1}(\lambda) e^{i \lambda . \tau}\right| \\
& \leq\left\|\varphi_{1}\right\|_{L^{\infty}(\mathbb{R})}\|f\|_{L^{1}[0,1]}\left\|\lambda^{-s} t_{\lambda}\right\|_{N, W, \varphi_{2}}(1+|\xi|+|\eta|)^{-N} \\
& \leq C\left\|\varphi_{1}\right\|_{L^{\infty}(\mathbb{R})}\|f\|_{L^{1}[0,1]}\left\|\lambda^{-s} t_{\lambda}\right\|_{N, W, \varphi_{2}}(1+|\tau|+|\xi|+|\eta|)^{-N}
\end{aligned}
$$

where $C=\left(1+2 \frac{\left|\tau_{0}\right|}{\left|\xi_{0}\right|+\left|\eta_{0}\right|}\right)^{N}$. Therefore, $\forall(\lambda, x, h ; \tau, \xi, \eta) \notin \Lambda, \exists \chi \in \mathcal{D}(\mathbb{R} \times U)$ and a closed conic set $W^{\prime}$ such that $\chi(\lambda, x, h) \neq 0,\left(\operatorname{supp} \chi \times W^{\prime}\right) \cap \Lambda=\emptyset$ and the following estimate is satisfied:

$$
\begin{equation*}
\forall N, \exists C,\left\|f \lambda^{-s} \Phi^{*} t\right\|_{N, W^{\prime}, \chi} \leq C \sup _{\lambda \in[0,1]}\left\|\lambda^{-s} t_{\lambda}\right\|_{N, W, \varphi} \tag{10.9}
\end{equation*}
$$

for some continuous seminorm $\sup _{\lambda \in[0,1]}\left\|\lambda^{-s} t_{\lambda}\right\|_{N, W, \varphi}$ of $E_{s}\left(\mathcal{D}_{\Gamma}^{\prime}(U)\right)$ and where the constant $C$ does not depend on $t$.

It follows easily from the above that the family $\left(f 1_{[\varepsilon, 1]} \lambda^{-s} \Phi^{*} t\right)_{\varepsilon \in(0,1]}$ is bounded in $\mathcal{D}_{V}^{\prime}(\mathbb{R} \times U)$.

The symplectic geometry of the vector fields tangent to $I$ and of the diffeomorphisms leaving $I$ invariant. We will work at the infinitesimal level within the class $\mathfrak{g}$ of vector fields tangent to $I$ defined by Hörmander [35, Lemma (18.2.5)]. First recall their definition in coordinates $(x, h)$ where $I=\{h=0\}$ : the vector fields $X$ tangent to $I$ are of the form

$$
h^{j} a_{j}^{i}(x, h) \partial_{h^{i}}+b^{i}(x, h) \partial_{x^{i}}
$$

and they form an infinite dimensional Lie algebra denoted by $\mathfrak{g}$ which is a Lie subalgebra of $\operatorname{Vect}(M)$. Actually, these vector fields form a module over the ring $C^{\infty}(M)$ finitely generated by the vector fields $h^{i} \partial_{h^{j}}, \partial_{x^{i}}$. This module is naturally filtered by the vanishing order of the vector field on $I$.

Definition 10.4. Let $\mathcal{I}$ be the ideal of functions vanishing on $I$. For $k \in \mathbb{N}$, let $F_{k}$ be the submodule of vector fields tangent to $I$ defined as follows: $X \in F_{k}$ if $X \mathcal{I} \subset \mathcal{I}^{k+1}$.

This definition of the filtration is completely coordinate invariant. We also immediately have $F_{k+1} \subset F_{k}$. Note that $F_{0}=\mathfrak{g}$.
Cotangent lift of vector fields. We recall the following fact: any vector field $X \in \operatorname{Vect}(M)$ lifts functorially to a Hamiltonian vector field $X^{*} \in \operatorname{Vect}\left(T^{*} M\right)$ by the following procedure which is beautifully described in [8, p. 34]:

$$
\begin{aligned}
X & =a^{i} \frac{\partial}{\partial x^{i}}+b^{j} \frac{\partial}{\partial h^{j}} \in V e c t(M) \stackrel{\sigma}{\mapsto} \sigma(X)=a^{i} \xi_{i}+b^{j} \eta_{j} \in C^{\infty}\left(T^{*} M\right) \\
\mapsto X^{*} & =\{\sigma(X), .\}=a^{i} \frac{\partial}{\partial x^{i}}+b^{j} \frac{\partial}{\partial h^{j}}-\frac{\partial\left(a^{i} \xi_{i}+b^{j} \eta_{j}\right)}{\partial x^{i}} \frac{\partial}{\partial \xi_{i}}-\frac{\partial\left(a^{i} \xi_{i}+b^{j} \eta_{j}\right)}{\partial h^{j}} \frac{\partial}{\partial \eta_{j}},
\end{aligned}
$$

where $\{.,$.$\} is the Poisson bracket of T^{*} M$.
Lemma 10.5. Let $X$ be a vector field in $\mathfrak{g}$. If $X \in F_{1}$, then $X^{*}$ vanishes on the conormal $N^{*}(I)$ of $I$ and $N^{*}(I)$ is contained in the set of fixed points of the symplectomorphism $e^{X^{*}}$.
Proof. If $X \in F_{1}$, then $\sigma(X)=h^{j} h^{i} a_{j i}^{l}(x, h) \eta_{l}+h^{i} b_{i}^{l}(x, h) \xi_{l}$ where $a_{j i}^{l}, b_{i}^{l}$ are smooth functions on $T^{*} M$ by the Hadamard lemma. The symplectic gradient $X^{*}$ is given by the formula

$$
X^{*}=\frac{\partial \sigma(X)}{\partial \xi_{i}} \partial_{x^{i}}-\frac{\partial \sigma(X)}{\partial x^{i}} \partial_{\xi_{i}}+\frac{\partial \sigma(X)}{\partial \eta_{i}} \partial_{h^{i}}-\frac{\partial \sigma(X)}{\partial h^{i}} \partial_{\eta_{i}} ;
$$

thus $X^{*}=0$ when $\xi=0, h=0$ which means $X^{*}=0$ on the conormal $N^{*}(I)$.
Lemma 10.6. Let $\rho_{1}, \rho_{2}$ be two Euler vector fields and $\Phi(\lambda)=e^{-\log \lambda \rho_{1}} \circ e^{\log \lambda \rho_{2}}$. Then the cotangent lift $T^{*} \Phi(\lambda)$ restricted to $N^{*}(I)$ is the identity map:

$$
\left.T^{*} \Phi(\lambda)\right|_{N^{*}(I)}=\left.I d\right|_{N^{*}(I)}
$$

Proof. Let us set

$$
\begin{equation*}
\Phi(\lambda)=e^{-\log \lambda \rho_{1}} \circ e^{\log \lambda \rho_{2}} \tag{10.10}
\end{equation*}
$$

which is a family of diffeomorphisms which depends smoothly in $\lambda \in[0,1]$ according to 2.3. The proof is similar to the proof of proposition 2.3; $\Phi(\lambda)$ satisfies the differential equation:

$$
\begin{equation*}
\lambda \frac{d \Phi(\lambda)}{d \lambda}=e^{-\log \lambda \rho_{1}}\left(\rho_{2}-\rho_{1}\right) e^{\log \lambda \rho_{1}} \Phi(\lambda) \text { where } \Phi(1)=I d \tag{10.11}
\end{equation*}
$$

We reformulated this differential equation as

$$
\begin{equation*}
\frac{d \Phi(\lambda)}{d \lambda}=X(\lambda) \Phi(\lambda), \Phi(1)=I d \tag{10.12}
\end{equation*}
$$

where the vector field $X(\lambda)=\frac{1}{\lambda} e^{-\log \lambda \rho_{1}}\left(\rho_{2}-\rho_{1}\right) e^{\log \lambda \rho_{1}}$ depends smoothly in $\lambda \in[0,1]$. The cotangent lift $T^{*} \Phi_{\lambda}$ satisfies the differential equation

$$
\begin{equation*}
\frac{d T^{*} \Phi(\lambda)}{d \lambda}=X^{*}(\lambda) T^{*} \Phi(\lambda), T^{*} \Phi(1)=I d \tag{10.13}
\end{equation*}
$$

Notice that $\forall \lambda \in[0,1], X(\lambda) \in F_{1}$ which implies that for all $\lambda$ the lifted Hamiltonian vector field $X^{*}(\lambda)$ will vanish on $N^{*}(I)$ by the lemma (10.5). Since $T^{*} \Phi(1)=I d$ obviously fixes the conormal, this immediately implies that $\forall \lambda,\left.T^{*} \Phi(\lambda)\right|_{N^{*}(I)}=\left.I d\right|_{N^{*}(I)}$.
