CONCLUSIONS: The handoff instrument was used in the minority of encounters while the EMR was consulted to make a clinical decision. This suggests that in the presence of an EMR, a physical handoff instrument is less important. The physical instrument will ideally contain essential information, such as patient identification, code status, tasks to be performed, and may be substantially shorter than the current idealized form. This new model would need trial and validation to determine effectiveness. Given the paucity of notes written despite the frequent occurrence of medications being prescribed, more education may be necessary to demonstrate the use of documentation as a part of communication among care teams. It will be necessary to examine in more detail the activities of nighttime physicians to understand what an ideal handoff actually is and how to best support the advancement of safe and effective care in the hospital after hours.

WHAT AN EMR REVEALS ABOUT WORK HOURS FOR PRIMARY CARE PROVIDERS Maura J. McGuire[1,2]; Gene E. Green[3,2]; Steven J. Kravet[3,2]. [1]Johns Hopkins Community Physicians, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Johns Hopkins Community Physicians, Baltimore, MD. (Tracking ID #1639550)

BACKGROUND: There is an increasing shortage of primary care providers, and a perception of long work hours may be a barrier to careers in primary care. Most data on work-hours comes from self-reports. Time-stamp reports from electronic medical record systems (EMRs) provide an objective way to measure and compare physician work hours.

METHODS: Our group is an academically affiliated, multispecialty group practice with more than 35 practices and 220 PCPs caring for 220,000 patients. We have used an integrated EMR since 2007 for nearly all clinical work, and logged-in time mirrors work time for primary care specialties. The system tracks logged-in time and logs users off after 5 min of inactivity. In response to concerns about workload expressed by our practice teams, we obtained a report of hours logged over a 24 month period in 2010 and 2011. Work time was estimated by counting logged-in hours. Total annual hours were summed, and normalized for the provider's average full time equivalent (FTE) over the year. We collected subjective data on self-reported work hours and perceived difficulty of work in separately administered surveys.

RESULTS: Results for 128 PCPs who spent >50 % of their professional time in clinic are shown in Table 1; providers with significant hospital or management responsibilities were excluded because these activates would not be proportionately captured in the hours log. Assuming a 48-week work-year, general internists worked 59.6 h per week per FTE (range 39 to 113), family physicians 52.6 (35 to 123), med-peds physicians (44.2 to 67.8) and pediatricians 48.4 (39 to 65). Internal medicine hours were significantly greater than pediatrics and family practice hours ($P<0.05$). However, internists saw significantly fewer visits ($P<0.05$) and trended towards fewer RVUs ($P>0.05$). Self-reported weekly hours (Table 2) reflected these trends, although self-reported hours were less than EMR hours. There was no significant difference in hours worked in 2010 and 2011 for any specialty, despite subjective perceptions of "working harder than last year" by 67 % of the group in 2011.

CONCLUSIONS: Despite some limitations, our EMR data provides an objective report of provider work hours and allows us to compare hours vs. productivity for different primary care specialties in our practices. This supports concerns that workload for primary care physicians is significant, even in optimized practices with team-based care like ours. Internists worked the most hours but earned less RVUs, suggesting they incur a high level of uncompensated work relative to other specialties. EMR hours logged by several PCPs were excessive (> 100 per week) raising concerns about safety and quality-of-life. Evaluation of personality, panel case mix and quality of care in association with hours worked may suggest strategies to address variance among PCPs.

Comparison of EMR-Work Hours by Specialty

Specialty	Count	RVU/yr	Visits/yr	EMR Hours per FTE/yr	EMR Hours /yr	P value*
Internal medicine	53	3509	3110	2862	59.6	index group
FamilyPractice	48	3918	3867	2517	52.4	<0.05
Med-Peds	6	4602	4236	2574	53.6	0.354
Pediatrics	21	3984	4551	2324	48.4	<0.05

*Compared to internal medicine index group

Table 2: Self-Reported Hours

Specialty	Hours worked/week	Desired
Internal medicine	54.6	42.9
Family Practice	45.9	44.9
Med-Peds	47.9	45.8
Pediatrics	45.5	40.6

WHAT HAVE YOU DONE FOR ME LATELY: AN EXAMINATION OF PATIENTS' TRUST IN PHYSICIAN OVER TIME Howard S. Gordon[1,2]; Marvella Ford[3]; Oksana Pugach[2]. [1]Veterans Affairs Medical Center, Chicago, IL; [2]University of Illinois at Chicago, Chicago, IL; [3]Medical University of South Carolina, Charleston, SC. (Tracking ID #1623990)

BACKGROUND: Patients' trust in physician is an important aspect of successful patient-physician relationships. Yet few studies have examined the development of trust in physician over time.

METHODS: Patients age 18 or older were treated for an exacerbation of heart failure at one of two Veterans Affairs hospitals. Demographic and visit data were collected at pre- and post-visit interviews using self-report questionnaires during a 6 month follow-up period. Measures included patients rating of trust in their physician (5 item scale, scored on a range from 1 to 100 points) with higher values representing higher trust in physician. Patients rated physicians' supportiveness and informativeness and rated their own self-efficacy to communicate and perceived discrimination in health care. A total of 150 subjects with 523 measurements of trust in physician were used to examine change in trust over time and to examine the association of trust with demographic and visit variables. We used bivariate mixed-effect models to account for repeated measures of trust. We modeled change in trust over time with a multivariable mixed-effects model to account for repeated measures and control for potential covariates.

RESULTS: Patient reported mean (SD) trust scores were 81.1 (17.7), 87.8 (16.5), 84.0 (18.0), and 88.1 (17.8) points before, and after visit 1, and before, and after visit 2, respectively. Patients' mean age was 60 (8.8) years, 65 % of patients were black, 41 % reported income above $20,000, 65 % were from the southern study site, and 59 % saw the same doctor at the two study visits. The mean (SD) time between the two visits was 108 (67.2) days. Race was not significantly associated with trust ($P=0.59$). Patients who perceived discrimination in health care reported a non-significant 5.0 points lower trust ($P=0.15$). Patients who reported that the doctor was more supportive and was more informative reported higher trust (0.6 and 0.5 points, $p<.0001$, respectively). Patients who reported higher self efficacy to communicate and a belief in alternative medicine had 0.4 points ($P<.0001$) and 0.1 points ($P=0.002$) higher doctor trust, respectively. To control for multiple confounders and to model change in trust over time, data were analyzed with a mixed-effects linear model. Pre-visit trust was not statistically different between visits ($P=0.15$). Similarly, post-visit trust did not differ between visits ($P=0.90$). Compared to pre-visit trust, post-visit trust was 5.46 points ($p<.0001$) higher across two visits, after adjusting for other covariates. Post-visit trust was not lower for patients

who were black, reported low income, discrimination, or changed physicians between the two visits ($P>0.05$). Post-visit trust was higher for patients rating physicians as more supportive, holistic, and informative ($P<.01$).
CONCLUSIONS: Patients reported trust in physician improved from before to after a visit, but the gain in trust was not maintained when measured prior to the next visit. Trust was not associated with race or perceived discrimination in health care, but was associated with patients' ratings of doctors' supportiveness and informativeness. This study was small and was limited to patients who kept follow-up visits and results may not generalize to all patients. Longer durations of observation may be needed to examine the development and persistence of trust in physician over time; nonetheless, our results suggest that physicians can earn trust at each visit.

WHAT IS CARE COORDINATION? AN OBSERVATIONAL STUDY OF PRIMARY CARE PHYSICIANS Erin R. McNeely[1]; Timothy P. Stablein[3,4]; Denise L. Anthony[3,4]; Brooke Herndon[1,2]. [1]Dartmouth-Hitchcock Medical Center, Lebanon, NH; [2]Dartmouth College, Hanover, NH; [3]Dartmouth College, Hanover, NH; [4]Dartmouth College, Hanover, NH. (Tracking ID #1636261)

BACKGROUND: Care coordination is widely considered a hallmark of high quality care and is associated with improved patient outcomes. Despite its' importance, the definition of care coordination remains vague and is used to refer to a wide variety of functions. Without a clear definition, it is difficult to measure and reward this critical activity. We set out to identify the specific activities that primary care physicians perform in order to coordinate their patients' care with the goal of helping to refine the operational definition of care coordination.
METHODS: We conducted an observational study of 12 primary care physicians (PCPs) working in a multi-specialty group practice with 3 geographic sites in New Hampshire. We selected our sample purposely to include a distribution by specialty (6 Family Medicine physicians and 6 General Internists) and gender (4 male and 8 female). A trained observer spent one full day with each physician and manually recorded all of the work PCPs performed outside of face-to-face office visits. For each PCP we recorded the number of incoming and outgoing communications and whether they were conducted in-person, by phone or electronically. Further, we collected qualitative information on the content of each communication and the role it played in patient care. We calculated descriptive summary statistics using Stata 11.0.
RESULTS: The 12 PCPs in our study conducted a total of 1,144 communications outside of face-to-face visits, and the number per PCP per day ranged from 25 to 227. The number of incoming and outgoing communications was nearly equal (47 % and 53 % respectively). Slightly under half of all communications were conducted electronically with 25 % conducted in writing, 9 % in person, and 4 % by phone. Approximately one third of the communication conducted by PCPs outside of face-to-face visits was dedicated to coordinating patient care. These communications involved reviewing consultations by specialists, reviewing and interpreting test results, communicating the significance of consultations and test results with patients, delegating follow-up work to others, and formulating plans of care with patients and other providers.
CONCLUSIONS: Consistent with prior work, the primary care physicians in our sample conducted a large volume of work outside of face-to-face office visits. Approximately one third of this work was dedicated to coordination of patient care. There was substantial variation in the amount and type of care coordination performed by each provider. Further work is needed to determine whether the patterns observed in this study are consistent across other populations in order to develop a clear operational definition of care coordination as performed by primary care physicians.

WHAT IS TAUGHT, WHAT IS CAUGHT: ANALYSIS OF MESSAGES DELIVERED AND RECEIVED DURING TEACHING ROUNDS WITH AN EMPHASIS ON PATIENT SAFETY MESSAGES Diane L. Levine; Srinivasa Reddy Kamatam; Prateek Lohia; Nagaratna Sarvadevabatla; Mohan B. Palla. Wayne State University, Detroit, MI. (Tracking ID #1641951)

BACKGROUND: Formal curricula have been developed to teach patient safety. However, a significant amount of teaching occurs at the point of care. A PubMed review identified no literature related to teaching patient safety during daily rounds. Our objective was to study the nature and frequency of patient safety messages delivered on rounds and compare with other traditional topics such as Evidence based Medicine (EBM), teaching physical examination (PE), providing feedback and discussions of professionalism, as well as, newer topics such as cost effectiveness. In addition, we were interested in identifying the nature and frequency of messages received by residents and students on rounds.
METHODS: This was an IRB approved prospective cohort study conducted on the Internal Medicine teaching services at Detroit Receiving Hospital. Informed consent was obtained from all participants. During the first week of the study the attending physician carried a pocket digital recording device with a microphone during rounds to record all teaching and acclimate and decrease the impact of recording on teaching. During the second week of recording (active study period), attending physicians were asked immediately after rounds to reflect on their teaching and estimate and document (on coded cards) the number of teaching messages in 6 pre-specified domains including cost effectiveness, EBM, feedback, patient safety, professionalism, and teaching PE. Residents and students were likewise asked to reflect, estimate, and document the number of teaching messages in each domain. Team members did not discuss teaching messages and all cards were collected before the rounding team disbanded. Recordings were downloaded and transcribed. Patient and participant identifying information was removed. One way analysis of variance was used to compare differences in messages delivered by attending physicians and those received by residents and students. Post hoc tests helped to identify significant differences between groups.
RESULTS: Five attending physicians documented delivery of 156 messages during the active study week for an average of 6.25 messages per rounding session. Attending physicians delivered a variable number of messages in each domain and documented delivering messages related to EBM most frequently and professionalism least frequently. Twelve residents received an average of 10.29 messages per rounding session; 7 students received an average of 17.53. Patient safety messages (28, 17.9 %) were second only to EBM (40, 25.6 %) in total number of messages delivered. The average number of patient safety messages delivered per rounding session was 1.08. Residents perceived 1.99 safety messages and medical students 3.35. Students perceived more messages than attending physicians delivered in 3 domains including patient safety ($p=0.036$), feedback ($p=0.000$), and cost effectiveness ($p=0.037$). A trend for significance was noted for EBM ($p=0.056$). Difference between residents' and students' perception regarding feedback messages was also significant ($p=0.004$); students perceived more messages than residents.
CONCLUSIONS: Rounds are an effective way to teach patient safety. Residents and students were able to recall patient safety messages taught by attending physicians at the point of care. In fact, they perceived more messages than attending physicians recalled teaching. Qualitative analysis of recorded audiotapes will allow for better understanding of the nature of patient safety messages taught on rounds.

WHEN GUIDELINES COLLIDE: ADHERENCE TO USPSTF RECOMMENDATIONS FOR SCREENING MAMMOGRAPHY AMONG PRIMARY CARE SPECIALTIES Jennifer Corbelli; Melissa McNeil. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1642011)

BACKGROUND: In 2009, USPSTF guidelines for breast cancer screening changed significantly. New guidelines recommended biennial mammography in women starting at age 50. Conversely, ACS and ACOG continued to recommend yearly mammography starting at age 40. This new lack of consensus garnered significant attention in the media, and caused confusion and concern among patients and providers. The extent to which providers have implemented new USPSTF recommendations for breast cancer screening is unknown. The primary aim of this study is to examine and compare current attitudes and practices of internists, family physicians,

and gynecologists with respect to screening mammography, in view of new USPSTF guidelines.

METHODS: We conducted a cross-sectional study at a large academic medical center. Both resident and attending physicians in three primary care specialties (internal medicine, family medicine and gynecology) were electronically surveyed. Our survey was adopted with permission from National Survey of Primary Care Physicians' Cancer Screening Recommendations and Practices. Survey items assessed respondents' breast cancer screening practices in women of different ages and breast cancer risks. We used descriptive statistics to generate response distribution for each survey item. We used Chi-square tests to compare survey responses across specialties.

RESULTS: Our overall response rate was 55 % (316/575). An overall majority of providers in internal medicine (65 %), family medicine (64 %), and gynecology (92 %) recommended breast cancer screening starting at age 40 (p-value<0.001) vs. age 50. Similarly, a majority of providers in internal medicine (77 %), family medicine (74 %), and gynecology (98 %) recommended annual (vs. biennial) mammograms (p=0.003). Gynecologists were significant more likely than both internists and family physicians to recommend initial mammography at age 40 vs. age 50 (p=<0.0001) and to recommend yearly vs. biennial mammography (p=0.0003). .

CONCLUSIONS: USPSTF guidelines for screening mammography have not been embraced by primary care providers across various specialties. This finding is most pronounced among gynecologists, who are significantly more likely than internists and family physicians to both initiate screening mammography at age 40 vs. age 50, and to screen annually vs. biennially. The extent to which these findings may be driven by patient vs. provider preference is an area for further research. These results suggest that unless further data on the risks and benefits of screening mammography becomes available, disparate practice patterns among specialties and individual providers are likely to continue. Breast cancer screening is an area of profound significance to patients and their advocates: in light of current clinical uncertainty, the importance of individualized risk-assessment and shared patient/provider decision-making is paramount.

WHEN PHYSICIANS AND PATIENTS DISAGREE: CLINICAL EXPERIENCE AS A DETERMINANT OF PHYSICIANS' WILLINGNESS TO COMPLY WITH THE REQUESTS OF PATIENTS AT THE END OF LIFE John M. Thomas[1,2]; John R. O'Leary[3]; Terri Fried[4,5]. [1]VA Connecticut Healthcare System, West Haven, CT; [2]Yale University School of Medicine, New Haven, CT; [3]Yale University School of Medicine, New Haven, CT; [4]Yale University School of Medicine, New Haven, CT; [5]VA Connecticut Healthcare System, West Haven, CT. (Tracking ID #1637126)

BACKGROUND: Although increasing attention has been paid to patient autonomy in the United States over the past few decades, research characterizing physicians' attitudes in the care of patients at the end of life suggests that physicians are often unwilling to comply with the requests of decisionally capable patients. Little is known about the effects of clinical experience on physicians' willingness to comply with the requests of decisionally capable patients at the end of life.

METHODS: We surveyed attendings and residents about their willingness to honor the requests of the same decisionally capable elderly patient in 5 scenarios involving different requests regarding end-of-life treatment, including requests to withhold life-sustaining treatment, to withdraw life-sustaining treatment, to give dangerously high doses of narcotics, to prescribe a lethal amount of sleeping pills, and to give a lethal injection in its current illegal state. We asked physicians to state whether they would comply with each request, to recall whether they had ever been asked by a patient to perform each request, and to cite factors influencing their willingness to perform each request. Finally, we asked physicians whether they would be willing to give a lethal injection if it were legal.

RESULTS: Respondents included 191 attendings and 240 residents (58 % response rate). While a large majority of both attendings (92–100 %) and residents (71–94 %) were willing to comply with each of the requests to withhold intubation, to extubate, and to give high doses of narcotics, a significantly larger proportion of attendings versus residents were willing to comply with each of these requests. There were no significant differences in the small proportions of attendings (1–3 %) and residents (4–5 %) willing to prescribe a lethal amount of sleeping pills and to give a lethal injection in its current illegal state. A significantly larger proportion of residents (32 %) versus attendings (19 %) were willing to give a lethal injection if legal. After adjusting for sociodemographic factors, attending status was independently associated with increased willingness to extubate (AOR=3.0, 95 % CI=1.6–5.7) and with decreased willingness to give a lethal injection if legal (AOR=0.5, 95 % CI=0.3–0.8). When attendings were asked directly about influences on their willingness to extubate and to give high doses of narcotics, most cited reasons related to their clinical experiences, and when asked about influences on their willingness to prescribe a lethal amount of sleeping pills and to give a lethal injection, most attendings cited the existence of other palliative options as well as legal and moral concerns.

CONCLUSIONS: Training level was an important determinant of physicians' willingness to perform multiple patient requests at the end of life, and sociodemographic differences between attendings and residents did not account for these differences. Our findings suggest the role of clinical experience as influencing physicians' attitudes towards performing the requests of decisionally capable patients at the end of life.

WHERE YOU LIVE SUGGESTS HOW WELL YOU ADHERE: A NATIONAL COHORT OF PATIENTS BEGINNING STATIN THERAPY Andrew M. Davis[1]; Dima Qato[3]; Michael S. Taitel[2]; Jenny Jiang[2]; Elbert S. Huang[1]. [1]University of Chicago, Chicago, IL; [2]Walgreens, Deerfield, IL; [3]University of Illinois College of Pharmacy, Chicago, IL. (Tracking ID #1642292)

BACKGROUND: Non-adherence to cardiovascular medications is associated with worse health and economic outcomes. A metric of medication adherence has been added to national CMS quality monitoring. Medication adherence is consistently lower among minorities, and is thought to be an important contributor to poorer risk factor control and higher cardiovascular morbidity and mortality in these populations. Studies of adherence typically are limited geographically and focus on insured populations. To our knowledge, no national studies have explored the association of neighborhood racial composition and medication adherence, data that could inform the design of local neighborhood and retail pharmacy programs in chronic disease management, as well as co-pay policies.

METHODS: The study assessed patients in the national Walgreens database who began statin therapy for the first time during the first quarter of 2012. Individual patient adherence was defined as 'patient days on therapy' (PDOT) out of 180 days, dated from the initial prescription fill. Patients were linked to neighborhoods using their home addresses, with block group specific racial and socioeconomic variables from the 2010 U.S. census linked to each neighborhood. A typical block group (BG) has 1500 residents, five-fold finer than the zip code or census tract level. There were 332,193 patients with valid home addresses, and full plan and co-pay data existed for 328,130. Mean age was 60.2, and 49.5 % were female. A generalized linear model for repeated measures quantified the association between patient statin adherence at 6 months and neighborhood racial composition, adjusting for individual factors of age, gender, payer (Medicaid, Medicare, private insurance, cash), co-pay amount, use of 30-day vs. 90-day refill, and mental health prescription use, as well as the neighborhood characteristics of urban vs. rural location, educational attainment (% with college degree), and median household income.

RESULTS: The study cohort closely matched U.S. census distributions. As block groups became more racially or ethnically homogeneous, even controlling for multiple confounders, strong clinically significant (10–14 day) negative associations were seen in statin adherence for blacks and Hispanics. There was a strong inverse positive association for whites (13 days). No effect was seen for Asians (data not shown).

CONCLUSIONS: Clinically important disparities in statin adherence are associated with neighborhood racial and ethnic homogeneity, even

controlling for age, co-pay, payer, and basic socioeconomic factors. Awareness and monitoring of national and local adherence patterns, and exploration of their relation to various neighborhood characteristics can inform pharmacy and neighborhood-based programs designed to improve adherence. This innovative approach also calls attention to the equity of national quality metrics for medication adherence.

WOMEN VETERANS AND COMPREHENSIVE CARE: CHALLENGES FOR DESIGNATED WOMEN'S HEALTH PCP'S Alicia A. Bergman. Roudebush VAMC, Indianapolis, IN. (Tracking ID #1639673)

BACKGROUND: A key aspect of VA's plan for improving care for women veterans is to establish a national model of comprehensive and integrated clinical primary care. Using this approach, a single designated women's health primary care provider (PCP) in the same location sees patients for not only primary care issues, but also gender-specific care. Although it is ultimately expected to be the predominant model of care for women veterans at every VA site, on a local level at the Indianapolis Roudebush VA Medical Center, there have been difficulties with rolling out the one-provider model. The goal of this qualitative study was to identify barriers and facilitators encountered by PCPs to providing comprehensive women's health care services.
METHODS: In-depth interviews were conducted with 15 of the 36 designated women's health PCPs across five primary care clinics at the Roudebush VA Medical Center in Indianapolis, IN. Purposive and snowball sampling techniques were used to identify PCPs, aiming for diversity in sex, experience, length of VA service, and practicing site/service.
RESULTS: Qualitative thematic analysis of the interviews revealed six major barriers: 1) space and structure; 2) time; 3) support staff; 4) comfort level; 5) education; and 6) scheduling/logistics. Problems with space and structure pertained to not having a sufficient number of rooms to conduct pap and pelvic exams, an awkward layout of the available rooms, and a lack of privacy. As for time, 30 min was not perceived as sufficient to address primary care needs, chronic pain, mental health, and military sexual trauma issues, along with gender-specific care. For pap and pelvic exams in particular, time is needed to search for equipment, a female chaperone, and to wait for the patient to get undressed and dressed. Moreover, according to some PCPs, women veterans are more communicative than male veterans. Another barrier discussed by PCPs was difficulty in finding support staff to assist, (i.e., insufficient numbers of support staff), lack of support staff knowledge and/or comfort assisting, with some refusing to assist. Comfort level was also a barrier for PCPs, based on perceived patient discomfort with gender-specific care due to military sexual trauma, perceived patient discomfort when the patient-provider relationship is new, and finally, perceptions by male PCPs that women veterans prefer female PCPs. Education and Training were discussed as barriers by several PCPs insofar as they were not given sufficient educational resources to keep their skills up, and they did not know what training was required and what was optional. Finally, the barrier of scheduling and logistics pertained to the inability, as discussed by several PCPs, to plan ahead for pap smear and pelvic exam appointments.
CONCLUSIONS: Gaining in-depth knowledge about PCPs' struggles in one VA medical center with moving to the one-provider model, can help to shed light on potential challenges faced by PCPs across other sites. Specific strategies are outlined that can potentially inform wider implementation efforts as well as serve as a brainstorming platform from which new work flow process solutions can emerge.

WOMEN'S EXPERIENCES WITH ISOTRETINOIN RISK REDUCTION COUNSELING Carly Werner[1]; Melissa Papic[2]; Noel Prevost[3]; Laura Ferris[3]; E. Bimla Schwarz[1,2]. [1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh, Pittsburgh, PA. (Tracking ID #1638424)

BACKGROUND: Isotretinoin is an important treatment for debilitating skin disease, such as scarring acne. Because pregnancies exposed to isotretinoin are at increased risk of severe birth defects, use of isotretinoin is restricted to those registered with the iPLEDGE program. In an effort to reduce risk of isotretinoin-induced birth defects, this program includes educational materials for both patients and clinicians and requires female patients to undergo monthly serum pregnancy tests. Unfortunately, these restrictions have created gender-based disparities in isotretinoin treatment without significantly reducing rates of isotretinoin-exposed pregnancies.
METHODS: To explore women's experiences with the counseling they received about isotretinoin and risk reduction while participating in the iPLEDGE program, we conducted structured interviews with 16 women who had used isotretinoin for severe skin disease. Content analysis was performed using a grounded theory approach by two independent coders; discrepancies were resolved by consensus with the assistance of a third author when necessary.
RESULTS: Interviewees ranged in age from 17 to 34 years; 12 participants were White, 2 were Hispanic, 1 was Black, and 1 was Asian. None had become pregnant while using isotretinoin. Participating women clearly understood that isotretinoin increases risk of birth defects. Most described the counseling they had received prior to initiating isotretinoin treatment as "scary" and anxiety provoking. Women had less understanding of how they could most effectively protect themselves from becoming pregnant while taking isotretinoin. For many participants, iPLEDGE was their first introduction to contraception; few reported other formal instruction on contraception. Few received counseling on contraceptives other than "the pill." In particular, women had limited knowledge of highly effective reversible contraceptives such as the subdermal implant or intrauterine contraception. Few remembered being encouraged to speak with a family planning specialist prior to using isotretinoin, rather, most recalled being advised to either take an oral contraceptive or continue whatever contraceptive strategy they had previously employed. Women cited multiple influences on their contraceptive choices including discussions with friends and family, their physicians, the internet, and the media; however, some women expressed concerns about the accuracy of the information available from each of these sources. Most participants were surprised to learn that reversible contraceptives exist that are significantly more effective than the pill and upset that "no one ever told me" about these options. Women expressed interest in a brief overview of available contraceptives that would highlight the relative effectiveness and safety of available contraceptives. Women preferred a single-page summary and web-based resources to more comprehensive printed materials.
CONCLUSIONS: The iPLEDGE program increases women's anxiety about using isotretinoin. Offering women considering treatment with isotretinoin additional information on intrauterine and subdermal contraceptives may enable more women to successfully protect themselves from the medication-induced birth defects they fear.

IPAD-BASED PATIENT EDUCATION AND DATA COLLECTION FOR COLORECTAL CANCER SCREENING David P. Miller[1]; Nancy M. Denizard-Thompson[1]; James L. Wofford[1]; Don Babcock[2]; Kathryn E. Weaver[3]; Larry D. Case[2]; John Spangler[4]; Michael Pignone[5]. [1]Wake Forest School of Medicine, Winston-Salem, NC; [2]Wake Forest School of Medicine, Winston-Salem, NC; [3]Wake Forest School of Medicine, Winston-Salem, NC; [4]Wake Forest School of Medicine, Winston-Salem, NC; [5]University of North Carolina School of Medicine, Chapel Hill, NC. (Tracking ID #1637140)

BACKGROUND: Health care providers often report they lack time to counsel patients about preventive health topics. To reduce the burden on busy clinicians, many health care systems use educational brochures or websites. However, these strategies may not be effective for the one-third of Americans with low health literacy skills or for those who lack internet access. New methods are needed to improve patient education in the office while minimizing additional time demands on busy clinical staff. A system that could collect relevant health information from patients could offer additional time savings. We sought to determine the feasibility of using an iPad to both collect health information from patients and deliver an educational message about colorectal cancer (CRC) screening.
METHODS: We pilot tested a novel iPad program about CRC screening in a convenience sample of English-speaking patients, aged 50–74 years, from two primary care clinics affiliated with an academic medical center (one serving primarily low-income/underinsured patients and the other serving primarily hospital employees and families). A research assistant invited patients to participate while they were waiting for their physician in the clinic exam room. The program consisted of a brief 16-item baseline survey, a 5 min educational video, and a 17-item post-program survey. We designed the iPad program for a mixed literacy audience with minimal prior computer experience. Only one question was displayed on the screen at a time, possible answers were placed in large intuitive buttons, and all survey questions and responses were read aloud by a narrator unless the patient chose to turn this feature off. Patients' health literacy level was assessed using the previously validated item, "how confidant are you filling out medical forms by yourself?" Patient knowledge of CRC screening was assessed with 5 items in the baseline survey and repeated in the post-program survey.
RESULTS: All 40 participants who enrolled in the study completed the iPad program. Participants had a mean age of 60 years (range 51–72), 68 % were female, 70 % were white, and 20 % had limited health literacy. The vast majority of participants (90 %) completed the iPad program with 1 episode of assistance or less (28 of 32 adequate literacy patients, and 8 of 8 limited literacy patients). After watching the iPad program, CRC knowledge scores increased significantly for both limited and adequate literacy patients. At baseline, only 55 % of participants answered at least 4 of the 5 knowledge questions correctly compared with 90 % of participants on the post-program survey ($p<0.001$). Over 80 % of both limited and adequate literacy participants stated they preferred the iPad video to a brochure (88 % and 81 % respectively). All 40 participants (100 %) stated the survey questions were easy to read, and 37 (93 %) stated the survey buttons were easy to touch.
CONCLUSIONS: This novel iPad CRC screening program designed for a mixed literacy audience with limited computer skills was well accepted by patients. Regardless of literacy level, the vast majority of participants preferred the iPad program over traditional patient education brochures. Future research should investigate ways mobile technology can enhance patient education in the medical office.

"FRIENDING" PHYSICAL ACTIVITY: RESULTS FROM THE SOCIAL NETWORKING FOR ACTIVITY PROMOTION WITH CELL PHONES (SNAP-C) STUDY Jennifer Kraschnewski[1]; Liza S. Rovniak[1]; Daniel R. George[2]; Erica Francis[1]; Christopher Sciamanna[1]. [1]Penn State Hershey Medical Center, Hershey, PA; [2]Penn State Hershey Medical Center, Hershey, PA. (Tracking ID #1641461)

BACKGROUND: Programs designed to help sedentary adults increase their physical activity (PA) are often effective in the short-term, but these effects are rarely maintained. Technology-based physical activity programs, such as those using cell phones, may help expand social networks that could support maintenance of PA. However, little research has explored how to engineer social networks to increase opportunities for PA. This study aims to explore the efficacy of using cell phones to engineer social networks using Facebook to provide long-term support for active lifestyles.
METHODS: Study Design - We conducted a randomized controlled trial to evaluate the effectiveness of a cell-phone based intervention to promote PA relative to an attention control group (emphasizing good nutrition). Study Participants - 87 participants were age and gender-matched prior to randomization to either an eight-week physical activity group or the control group. Inclusion criteria were: ages 25–64, sedentary, English-speaking, able to participate in moderate-intensity physical activity, ownership of a smart phone, and home computer with Internet access. Exclusion criteria were: body mass index greater than 39.9, consumption of 5 or more drinks of alcohol/day, current pregnancy, and living outside of the preselected study neighborhoods. Intervention - The physical activity intervention consisted of cell phone-based messaging and access to a cell phone-based Facebook private group site focused on PA. The attention control group consisted of similar procedures focused on good nutrition. Following randomization, participants attended a single introductory face-to-face meeting for their respective group to obtain an orientation to the program activities and meet fellow participants. Assessments—In-person assessments of outcomes were conducted at baseline and post-program (8 weeks). Objective measures included body mass index, waist circumference and blood pressure. Participants self-reported physical activity and nutrition using validated measures. Statistical Analysis—ANCOVA was used to compare study groups, adjusted for baseline values on outcome measures.
RESULTS: Most participants were women, white, middle-aged, and obese. No significant differences were observed between groups at baseline, suggesting successful random assignment. 88 % of participants completed the post-program assessment. PA group participants had a significant increase in PA when compared to control participants, including 85.2 MET (Metabolic Equivalent of Task)-minutes/week more of leisure-time activity ($P<0.03$). Participants in the PA group also had a statistically significant ($P<0.006$) decrease in waist circumference of 2.1 cm (3.62, 0.62) from baseline. Further, participants were actively engaged in the study's website. Almost two-thirds of participants engaged in discussion on the study's Facebook page at least every other week. The program received excellent reviews, with almost all participants (92 %) stating that they would recommend the program to other people.
CONCLUSIONS: We demonstrated the feasibility and initial efficacy of a cell phone-based intervention using Facebook to engineer social networks to improve engagement in PA. Future studies are necessary to determine the longer-term effects of this intervention on PA and objective measures of health.

"I'M GOING TO KILL HIV." PERSPECTIVES OF AFRICAN AMERICAN WOMEN IN THE DEEP SOUTH ON ANTIRETROVIRAL THERAPY ADHERENCE. Margaret R. DeMoss[1]; Loida Bonney[1]; Jennifer Grant[1]; Judith Barker[2]; Robin Klein[1]. [1]Emory School of Medicine, Atlanta, GA; [2]University of California, San Francisco, San Francisco, CA. (Tracking ID #1634428)

BACKGROUND: Despite evidence of stabilization in some areas of the US, HIV infection in black women is a growing epidemic in the Deep South. Although efforts to care for this population are in process, racial and gender disparities in morbidity and mortality exist due to a variety of factors including suboptimal adherence to highly active antiretroviral therapy (HAART). Using a phenomenological approach to qualitative inquiry, we sought to investigate aspects influencing adherence in an urban setting.
METHODS: We conducted a qualitative study of the factors influencing HAART adherence among black women with HIV/AIDS in an urban setting in the Deep South. Women were identified for participation by telephone or formal letter using an electronic medical record review of a public hospital system in Atlanta, Georgia, screened for eligibility, and then invited to participate by telephone or letter. Inclusion criteria specified women who had been aware of their HIV status for at least 2 years and had been linked to care previously. Individuals then underwent single face-to-face confidential in-depth semi-structured interviews about their HIV. Participants were asked about their racial, gender, and socioeconomic identities and how these affected treatment of their HIV. In addition, questions were directed to include experiences with racism, sexism, prior or current substance abuse, criminal activity, romantic relationships, and

experiences with the health care system and HAART. Two researchers independently reviewed the interview transcripts searching for commentaries which offered insight into how participants interpret their lives. Commentaries were collapsed into themes and codes.
RESULTS: One hundred eleven black women were identified during the initial chart review and seventy-eight were eligible to participate. Largely, there was no response to recruitment attempts. Data from the first twelve to enroll and successfully complete the interview process were analyzed. Most of the women were on HAART therapy at the time of interview and expressed knowledge of the role of HAART in management of their HIV disease. They stated it would keep them from getting sick and keep them alive, but it was unclear if they fully realized this when they were first started on HAART. They cited several reasons for not taking or stopping the medicines including wanting to avoid side effects, being in denial, and not feeling normal when taking HAART. Overall, three themes had effects on HAART adherence; (1) sentinel events (such as a near death from opportunistic infection) lead to changes in perspective and motivated women to adhere to HAART, (2) recognition that one had the personal strength necessary for adherence to therapy also motivated women to adhere, and (3) relationships with healthcare providers, especially trust issues, impacted adherence both positively and negatively.
CONCLUSIONS: These findings suggest that HAART adherence is a complex issue among urban black women with HIV in the Deep South. Those caring for this patient population need to recognize the influence of sentinel events, personal strength, and healthcare relationships as opportunities to improve adherence.

"THE WORST IS WHEN WE'RE WORKING AT ODDS": PCP PERSPECTIVES ON BARRIERS TO REPATRIATING PATIENTS FROM SPECIALTY TO PRIMARY CARE Jennifer J. Monacelli; Sara Ackerman; Nathaniel Gleason; Chanda Ho; Michael Wang; Don Collado; Ralph Gonzales. UC San Francisco, San Francisco, CA. (Tracking ID #1640467)

BACKGROUND: Improving care coordination and communication between primary care providers (PCPs) and specialists is a central principle of the Patient Centered Medical Home Neighborhood. Little is known about how PCPs and specialists decide if ongoing specialty follow-up care is needed for a given patient. In a separate abstract, we report survey results showing discordance between specialists and PCPs when asked to identify patients under their mutual care whose condition could be managed exclusively by the PCP. Here we report results of interviews with PCPs in which possible reasons for this discordance, including barriers to patient "repatriation" to the PCP, were explored. We identify several themes that provide insight into the complex reasons for fragmented care and key areas for improvement.
METHODS: Specialists (n=59) in 5 academic medicine subspecialty practices (cardiology, endocrinology, gastroenterology, pulmonology, and rheumatology) completed a 4-item, self-administered survey following each patient visit (n=104–173 surveys per specialty). PCPs with patients captured in the survey received a similar survey. 20 PCPs with ≥4 patients (from a total of 30 eligible PCPs) were randomly selected to participate in a semi-structured interview following completion of the survey, and 16 PCPs obliged. The interview elicited explanations of discordance in specialist and PCP responses to the survey question: "Could this diagnosis be managed exclusively by the PCP?" Five members of the study team performed independent analysis of interview notes and transcripts, followed by group discussions to reach consensus on key themes.
RESULTS: For cases in which the PCP was amenable to patient repatriation, but the specialist was not, explanations included: scope of PCP expertise (e.g. specialist underestimation of PCPs' ability to manage certain conditions); differences in clinical judgment (e.g. PCPs report being less aggressive than specialists in managing certain conditions); specialty follow-up "culture" (e.g. automatic scheduling of follow-up visits and absence of a common understanding of when and how to repatriate patients); and perceived financial gains derived from specialty follow-up visits. In addition, long-term, satisfying patient-specialist relationships were emphasized as both a benefit to the patient and a barrier to repatriation. For cases in which the specialist supported repatriation and the PCP did not, explanations included: scope of PCP expertise (e.g. specialist overestimation of PCPs' ability to manage certain conditions); competing time demands (e.g. PCPs report difficulties managing patients with multiple complex comorbidities within given time constraints); limited patient access to PCP for follow-up care; and PCP desire for specialist co-management of patients (e.g. for patients whose condition defies diagnosis). Patient preferences and provider liability concerns were identified as barriers to repatriation under both types of discordance.
CONCLUSIONS: These findings highlight complex forces that may impact the duration of follow-up care with a specialist, including clinical, procedural, financial, social, and cultural factors. Reducing barriers to repatriation for appropriate patients could decrease health care costs, alleviate access issues in specialty care, and simplify care coordination between physicians. Future studies should include specialty perspectives on discordance issues.

"THEY DON'T UNDERSTAND IT." PERCEIVED IGNORANCE AS A DETERRENT TO DISCLOSURE OF HIV STATUS IN A SAMPLE OF BLACK WOMEN IN THE SOUTH Kara Leverette[1]; Loida Bonney[1,2]; Jennifer Grant[1]; Judith C. Barker[3,2]. [1]Emory Univerisity, Atlanta, GA; [2]Center for AIDS Prevention Studies, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA. (Tracking ID #1639413)

BACKGROUND: Unlike several other demographic groups nationwide, Black women in the South have increasing rates of HIV infection and disproportionately high rates of adverse HIV-related outcomes. Effective care for HIV requires regular attendance at an HIV medical care provider who prescribes highly active anti-retroviral therapy (HAART), and adherence to that therapy. Both of these aspects of care have been a challenge for Black women in the South. Serostatus disclosure has been linked with higher levels of adherence and associated with improved sense of social wellbeing among HIV-positive individuals, but negative experiences related to disclosure have also been reported. Motivators for HIV status non-disclosure has been previously reported, however, to our knowledge, motivators among Black women in the urban South have not been studied in-depth. This study investigated Southern Black women's perspectives on motivators for serostatus non-disclosure from a phenomenological perspective.
METHODS: We identified women from a chart review of an electronic medical record of an HIV primary care clinic in Atlanta, Georgia. Women were recruited for participation by telephone call or formal letter. Twelve in-depth open-ended face-to-face 45–60 min interviews with HIV-positive Black women were conducted and audio-recorded. Inclusion criteria specified that women had been aware of their HIV serostatus for at least 2 years and had been linked to HIV care. Women were asked to give narratives about their experiences with HIV including, but not limited to learning about their diagnosis, and disclosing of serostatus. They were asked to describe the attitudes of their family, friends, acquaintances and community at large toward HIV positive people; to whom they have disclosed as well as time to disclosure. Transcribed narratives were examined thematically, coded and qualitatively analyzed.
RESULTS: One hundred eleven Black women were identified by record review. Contact was attempted with 78 who screened eligible to participate. There was a high rate of non-response. Data from the first 12 to enroll and successfully complete the interview were analyzed. Respondents ranged from 23 to 68 years of age, had been diagnosed an average of 19 years, and, at the time of the interview were all actively engaged in HIV care. In 8/12 (67 %) of interviews, perceived ignorance about HIV among family members, acquaintances, and others encountered in the women's communities emerged as a major motivator for non-disclosure. Women feared mistreatment and stigmatization from those whom they believed had limited HIV literacy. Several women discussed negative experiences where those with perceived limited HIV literacy mishandled the disclosed HIV

status. It was common for these black women to limit disclosure following unpleasant experiences. Women who had not disclosed limited social support.

CONCLUSIONS: Anticipation of negative experiences with others around HIV disclosure can motivate women not to disclose, and thus to limit their social support for improved adherence with HIV medical care appointments and HAART therapy. Understanding the perceptions of Southern black women surrounding disclosure and their communities can inform efforts to increase community HIV literacy and can potentially reduce the psychosocial burden of the HIV diagnosis among Black women to improve adherence and ultimately improve outcomes.

"I'M NOT SWEATING MY HAIR OUT": OVERCOMING PHYSICAL ACTIVITY BARRIERS IN AFRICAN AMERICAN WOMEN

Amy G. Huebschmann[1]; Lucille C. Johnson[2]; Andrea L. Dunn3. [1]University of Colorado School of Medicine, Aurora, CO; [2]The Center for African American Health, Denver, CO; [3]Klein Buendel, Inc., Golden, CO. (Tracking ID #1637219)

BACKGROUND: Only 36 % of U.S. African American (AA) women meet the Healthy People 2010 physical activity objectives compared to 50 % of Caucasian women. Lower rates may be related to cultural barriers, including the costs and time required to restyle hair after exercise—a reported barrier in one-third of AA women. To inform future interventions, a key qualitative segment of this mixed-methods study sought to identify both hairstyle-related and non-hairstyle-related physical activity barriers and facilitators in AA women.

METHODS: The study was co-developed by a community health and academic investigator with input from key stakeholders. To date, we have completed four of 8 planned focus groups with AA women in the Denver area. Focus groups were stratified by age (30–49 years; 50–75 years) and physical activity levels (<60 min/week vs. ≥60 min/week), and led by trained AA female facilitators. Data codes for hairstyle-related facilitators and barriers were developed from phrases of similar meaning in an iterative coding scheme.

RESULTS: Thirty AA women have participated. The major hairstyle-related barriers and facilitators involved perspiration. Specific barriers were the time burden to restyle hair after perspiring and the cost burden from needing more hairstyle products and more hair salon visits due to regular aerobic exercise. However, certain hairstyles facilitated activity because perspiration has minimal effects on them (e.g., "Before I got my 'locks' [hairstyle], I was like I'm not sweating my hair out"). Other hairstyle-related facilitators were: high self-efficacy to restyle hair after perspiration; reducing exercise intensity to avoid sweating, and choosing "my health over my hair". These themes were reported across all strata of age and activity. The major non-hairstyle-related barriers were: lack of time, lack of motivation ("laziness"), and health concerns such as arthritis pain with activity. The major non-hairstyle-related facilitators were: an exercise partner/group, enjoyable activities (e.g., walking, dance classes), and specific motivations to do regular physical activity, such as "being healthy", to relieve stress, or to set a good example for children and/or grandchildren.

CONCLUSIONS: AA women whose hairstyle is affected by perspiration may avoid physical activity because of the financial and time burden associated with restyling their hair. Future interventions that provide group physical activity options and that build self-efficacy to restyle hair after perspiration may allow more regular aerobic exercise for AA women.

CLINICAL VIGNETTES

"TIPS" FOR AVOIDING CAVERNOUS SINUS THROMBOSIS

Jenna Kay; Dustin T. Smith. Emory University, Atlanta, GA. (Tracking ID #1594567)

LEARNING OBJECTIVE 1: Recognize the signs and symptoms of cerebral venous and sinus thrombosis (CVST) and obtain appropriate, timely imaging to initiate early treatment.

LEARNING OBJECTIVE 2: Counsel patients on ear hygiene and the risks associated with the use of cotton swabs.

CASE: A 45-year-old man with no medical history presented for evaluation with 2 weeks of left eye swelling, double vision, headaches, and right-sided neck pain. Review of systems was notable for fever and night sweats. On physical exam, he was febrile and tachycardic to 119. He had severe left-sided chemosis with restricted gaze and swelling of the right neck. His vision and retinal exam were normal. His WBC count was 27,000 cells/mm3. CT of the head showed left-sided proptosis, soft tissue swelling, mastoiditis, and thickening of the right platysma muscle. Empiric vancomycin and piperacillin-tazobactim were started. The following day, the patient's eye swelling increased and his vision deteriorated. CT angiography of the head showed left cavernous and dural sinus thrombosis and right internal jugular vein thrombosis. A heparin infusion was started. Piperacillin-tazobactam was discontinued and ceftriaxone and metronidazole were initiated. Over the next 48 h, the patient's vision improved. His fever and leukocytosis resolved. Otoscopic exam of the left ear revealed purulent material and tips of cotton swabs in the tympanic membrane. Upon questioning, the patient remembered using cotton swabs to clean his ears in the past. Blood cultures grew Actinomyces naeslundii and meyeri. He received antibiotics for 6 weeks and warfarin for 3 months. He was counseled on ear hygiene and the risks associated with the use of cotton swabs. The patient experienced a full recovery apart from a persistent left abducens palsy.

DISCUSSION: Cerebral venous and sinus thrombosis (CVST) is an uncommon condition that is becoming more frequently recognized with the availability of MRI. Seventy-five percent of patients are women. Most patients have thrombosis in more than one area of the cerebral drainage system. Headache is the most common symptom. Other signs/symptoms include evidence of intracranial hypertension (vomiting, papilloedema, visual disturbances), neurologic deficits, seizures, and coma. Infectious cavernous sinus thrombosis, as in this patient, classically causes headache, fever, and eye symptoms. Patients with severe papilloedema may develop permanent vision deficits without treatment. Importantly, head CT is normal in up to 30 % of cases. Brain MRI is the most sensitive exam for identifying occlusions with CT venography as an alternate modality. Predisposing factors include malignancy, prothrombic states, pregnancy, infection, inflammatory disease, and trauma. In this patient, otitis media after cotton swab-induced injury and foreign body retention led to septic thrombophlebitis, and no additional work-up for malignancy or prothrombotic state was pursued. Treatment consists of reversing the underlying cause if possible, controlling seizures and intracranial hypertension if present, and initiating anticoagulation, although the optimal duration of therapy is unknown. If detected early, most patients make a complete recovery.

"TYPE-1" PRESENTATION

Junwa Kunimatsu; Riri Watanabe; Atsuto Yoshizawa. National Center for Global Health and Medicine Hospital, Tokyo, Japan. (Tracking ID #1635759)

LEARNING OBJECTIVE 1: Recognize that clinicians should consider adult T-cell leukemia/lymphoma(ATLL) when a patient from the endemic area of HTLV-1 presents a rapidly progressive lymphadenopathy and/or hepatosplenomegaly.

LEARNING OBJECTIVE 2: Recognize that, even if symptomatic, a patient with undiagnosed ATLL may not know his or her own HTLV-1 status.

CASE: A 40-year-old Japanese man presented with a month history of red eyes, polydipsia, and polyarticular pain. No weight change, ophthalmalgia, and visual disturbance was reported. He saw an ophthalmologist 3 weeks before the current evaluation, and conjunctivitis was diagnosed but his eyes were not improved. He had not traveled abroad recently. He lived with his family in Tokyo. He smoked tobacco, but did not use alcohol or illicit drugs. On examination, vital signs were normal. Bilateral conjunctivas were congested. The neck was supple. No cutaneous lesion was noted. The joints showed no swelling. The examination was otherwise normal. Platelet count was 115,000/mm3. Lactate dehydrogenase was 472 mg/dl. The

electrolytes, creatinine, albumin, and liver enzymes were normal. Although the patient denied any recent sexual contact with a high-risk person and had not had episode of diarrheal disease, persistent conjunctivitis and polyarthralgia led us to consider a "Reiter-like" condition; i.e., reactive arthritis. We prescribed NSAIDs for his joint pain. Two weeks later, the patient additionally reported fever and night sweat. Newly-onset cervical lymphadenopathy and splenomegaly were noted. CT and FDG-PET scan revealed multiple enlarged lymph nodes in the neck, supraclavicular fossae, and mediastinum bilaterally, with highly uptakes of FDG. Lymph node biopsy showed a mature T-cell lymphoma. Later, HTLV-1 was detected from blood sample. Consequently, we reached the diagnosis of adult T-cell leukemia-lymphoma(ATLL).
DISCUSSION: ATLL is geographically clustered, with prevalence in southwestern Japan(mainly on Okinawa and Kyushu), the Caribbean, West Africa, southern America, and Australia. The clinical presentation and disease course vary remarkably; some patients have an indolent, asymptomatic course for years, but the majority of patients present with rapidly progressive manifestations, as seen in this case. In regard to clinical reasoning, the clinical presentation of our case contained some pitfalls in retrospect. Firstly, no hypercalcemia is evident despite of marked dipsia. Hypercalsemia is a important clue in diagnosing symptomatic ATLL. We reasoned excess polydipsia can mask even an overt hypercalcemia. Secondly, the patient had not known his own HTLV-1 status, and had no family history of HTLV-1 associated diseases. Although we took his history of birthplace: Miyazaki prefecture(Kyusyu region), we did not consider ATLL on the first evaluation. Lastly, the patient is relatively young for ATLL, while the median age at onset of ATLL is 50 to 60 years. In general, a combination of arthritis and conjunctivitis in sexually active, young patientsleads clinicians to think of reactive arthritis. We speculated that his red eyes were a nonspecific conjunctivitis, although ATLL is associated with uveitis. The clinical features of this patient's acute illness, which included rapid enlargement of lymph nodes and spleen, are consistent with a disease progression of ATLL. Clinicians should consider an early phase of symptomatic ATLL when a patient from the endemic area of HTLV-1 presents a rapidly progressive lymphadenopathy and/or hepatosplenomegaly.

"UNBREAK MY HEART": TAKOTSUBO'S CARDIOMYOPATHY AND MOBITZ II BLOCK Peter-Trung Phan; Shivtej Kaushal. Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #1622851)

LEARNING OBJECTIVE 1: Recognize that Takotsubo's cardiomyopathy is a disease that should be included on the differential for a presentation of acute coronary syndrome and that its prognosis is generally favorable.
LEARNING OBJECTIVE 2: Understand that second degree heart block can be caused by Takotsubo cardiomyopathy
CASE: A 65 year-old female with hypothyroidism and depression presented to the hospital for an elective ganglion cyst removal and incidentally was found to be in 2:1 atrioventricular (AV) block on telemetry. She subsequently was admitted to the hospital and upon further evaluation, had been having symptoms of syncope, fatigue, and palpitations for 1 month. Her electrocardiograms showed the aforementioned 2:1 AV block, but also alternating right and left bundle branch blocks. Electrolytes and thyroid stimulating hormone were normal, and chest radiograph did not show any abnormalities. She was not on any medications that would cause AV block. Her echocardiogram showed a left ventricular ejection fraction (LVEF) of 40–45 %, no significant valvular abnormalities, and akinesis of the anteroseptal and anterior walls. Her initial troponin was negative, but progressively became elevated to eight times normal levels. The patient underwent temporary transvenous cardiac pacing and coronary artery catheterization. Her cardiac catheterization showed a right-dominant system with an 80 % stenosis of the ostial segment of the right coronary artery. However, the left ventriculogram showed hyperdynamic basal segments, mid and distal segment ballooning and akinesis, consistent with Takotsubo cardiomyopathy. The patient was prescribed a beta-blocker, statin, and angiotensin converting enzyme inhibitor and had a cardiac resynchronization therapy pacing (CRT-P) device implanted. She did well throughout her hospitalization and continues to follow in clinic.
DISCUSSION: Takotsubo cardiomyopathy mimics a myocardial infarction in its symptoms, electrocardiographic findings, and cardiac biomarkers. However, it is rare, occurring once in every 5000 hospitalizations. It is usually associated with emotional stress and has a predilection for elderly women. In Takotsubo cardiomyopathy, patients can develop pulmonary edema and other complications of heart failure with an in-hospital mortality from 1 % to 8 %. Patients who survive the acute episode will have normalization of their LVEF within 4 weeks. One of the proposed mechanisms of this pathology involves catecholamine toxicity and a localization of beta-adrenergic receptors in the apex. Without treatment, the condition is self-limited with a recurrence of 10 %. Also, it has been reported that only 5 % of Takotsubo cardiomyopathies are complicated with AV block and even fewer are treated with CRT-P. We present a case that may give us further insight on the pathophysiology of Takotsubo cardiomyopathy and demonstrate a differential for patients presenting with acute coronary syndrome that has a favorable prognosis.

5-AMINOSALICYLIC ACID INDUCED AGRANULOCYTOSIS Ahmet A. Oktay; Fritzie S. Albarillo; Dima Dandachi; Samaneh Dowlatshahi; Laura Raftery. Saint Francis Hospital, Evanston, IL. (Tracking ID #1635473)

LEARNING OBJECTIVE 1: Increasing the awareness of a serious adverse effect of 5-Aminosalicylic Acid (5-ASA); agranulocytosis.
LEARNING OBJECTIVE 2: Recognizing the general features of the diagnosis and management of drug-induced agranulocytosis.
CASE: A 74 year-old male patient, who lived independently, was brought to the ED after he was found lying on the floor of his apartment. He was awake but confused and not able to provide a reliable history. Information was obtained from medical records. He had a PMH of hypertension, type-2 diabetes mellitus, coronary artery disease, systolic CHF and Crohn's disease. He had no past surgical history or known drug allergies. His medications included aspirin, budesonide, docusate, omeprazole, niacin, metoprolol, lisinopril, isosorbide mononitrate, gabapentin, rosuvastatin and 5-ASA which was started 2 months back when Crohn's disease was diagnosed with colonoscopy and biopsy. He had remote history of cigarette smoking but no history of alcohol or illegal drug abuse. On physical exam; his temperature was 100.9 °F, BP was 93/48 mmHg and heart rate was 98 beats/minute. He appeared sick. Mild wheezing was auscultated on both lungs. Abdomen was distended with diffuse tenderness. Initial CBC showed: hemoglobin, 9.9 mg/dL; WBC count, 500/μL (neutrophils 0 %, lymphocytes 88 %, monocytes 12 %); and platelet count, 90.000/μL. His CBC was within normal limits (except hemoglobin: 11.3 mg/dL) 2 months prior. Initial imaging studies showed bilateral interstitial edema on chest X-Ray and focal narrowing of transverse colon on CT-abdomen/pelvis. He was admitted to the ICU with neutropenic fever. 5-ASA was discontinued. After blood cultures were obtained, he was started on broad-spectrum IV antibiotics and granulocyte colony-stimulating factor (G-CSF). Bone marrow aspiration and biopsy were performed and revealed maturation arrest with no bands, neutrophils, myelocytes, and metamyelocytes identified. His blood culture grew Klebsiella pneumoniae. Agranulocytosis persisted for 8 days despite G-CSF; his absolute neutrophil count (ANC) began recovering (ANC: 180/μL) on day 8 and by day 9, it was 4600/μL. He was discharged to a nursing home after 4 weeks of hospital stay.
DISCUSSION: Neutropenia is defined by ANC <1500/μL; agranulocytosis generally refers to the absence of granulocytes in the peripheral blood. Drugs and infection are two important causes of acquired neutropenia. Sulfasalazine, which contains 5-ASA linked to a sulfapyridine moiety, has been associated with both neutropenia and agranulocytosis. 5-ASA, a first-line therapy for inflammatory bowel disease, does not have the sulfa moiety thought to be responsible for neutropenia. However, in post marketing surveillance 5-ASA has been implicated as a cause of agranulocytosis; which is not widely known. In our patient detection of agranulocytosis 2 months after the start of 5-ASA, supports our suspicion of drug toxicity. We speculate that the agranulocytosis preceded the K.pneumoniae, a colonizer of the alimentary

canal, and that prompt antibiotic therapy was crucial in his surviving sepsis. We think patients who are on 5-ASA should be informed about and monitored for the potential side effects including neutropenia and/or agranulocytosis which can be fatal.

62 YEAR-OLD MAN WITH COUGH, HEMOPTYSIS AND A PULMONARY MASS Aisha Siddiqi; Tushar A. Tuliani; Kevin Belgrave; Donald P. Levine; Diane L. Levine. Wayne State University, Detroit, MI. (Tracking ID #1642030)

LEARNING OBJECTIVE 1: Recognize the importance of making a histologic diagnosis for all masses
LEARNING OBJECTIVE 2: Diagnose a rare cause of an upper lobe mass
CASE: A 62 year old man presented with a chief complaint of cough and hemoptysis. The patient had been in his usual state of health until 1 year prior to admission (PTA) when he developed progressive right-sided pleuritic pain associated with unintentional weight loss. One month prior to admission he developed a cough, which was productive of thick and bloody sputum occurring multiple times a day. He denied any fever or chills. Past medical history was significant for tuberculosis in the 1980s requiring a prolonged course of treatment (2 years; records not available). Family history was negative for cancer. Social history was significant for a 30 pack-years of cigarette smoking and alcohol abuse. On admission, the patient appeared cachectic. He was tachypneic. Physical exam was remarkable for increased tactile vocal fremitus and decreased breath sounds in the right upper lung field anteriorly. Chest radiography revealed a well-circumscribed right upper lobe mass with the appearance of an aspergilloma. Sputum smear and culture were negative for acid-fast bacilli and fungal elements. A serum aspergillus galactomannan antigen was negative. CT scan of the thorax showed areas of calcification and necrotic tissue with a cavitation surrounded by scarring. A CT-guided biopsy demonstrated tumor cells positive for vimentin, smooth muscle actin and CD 99. A bone scan revealed no primary bone sarcoma, but showed invasion into the upper anterolateral right ribs. The patient was referred to oncology.
DISCUSSION: The patient's history of tuberculosis and scarring, characteristic findings on chest radiography and history of hemoptysis were highly suggestive of aspergilloma. However, the negative aspergillus galactomannan antigen was inconsistent with this diagnosis prompting biopsy of the mass. The positive CD 99 immunohistochemistry supported a diagnosis of Ewing's Sarcoma (ES)/ Primitive Neuroectodermal Tumor (PNET). Primary extra-osseous Ewing's Sarcoma of pulmonary origin is exceedingly rare and is unassociated with traditional risk factors for lung cancer such as smoking or exposure to chemicals/dusts. Mutation of chromosome 22 is highly characteristic. To date, only 11 cases have been reported. In addition, unlike primary osseous Ewing's Sarcoma, nearly all cases (10) have been reported in adults. Primary localized Ewing's Sarcoma of the bone has a median survival of 100 months. In contrast, localized extra-osseous Ewing's Sarcoma has a poor prognosis with a median survival of 15 months. Although chemotherapy responsive, treatment only improves survival by 1 year. This case highlights the importance of making a histologic diagnosis. Treatment for aspergilloma would have delayed diagnosis and potentially compromised this patient's opportunity for response to chemotherapy. Also, making the diagnosis of primary pulmonary Ewing's Sarcoma allows for appropriate end of life discussions and planning.

A 20 YEAR OLD MAN WITH FEVER, DIZZINESS AND CONFUSION…; DR. GEETA LAUD, DR. DIVYA KAUSHIK, ALEXANDER RITTER MSIV. MONTEFIORE MEDICAL CENTER, BRONX, NY. Divya Kaushik; Alexander Ritter; Geeta Laud. Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1643205)

LEARNING OBJECTIVE 1: Recognize the clinical presentation, EEG and MRI findings of viral encephalitis.
LEARNING OBJECTIVE 2: 2. Emphasize the importance of immediate treatment with anti-viral medication and possible indications for adjunctive treatment with dexamethasone.
CASE: A 20 year-old man presented with 1 day of headaches, confusion, vomiting and dizziness. On exam, he was febrile to 102 with marked pallor, dryness, delusions, and severe drowsiness. There were no focal neurological deficits. Treatment with Cefepime, Vancomycin and Acyclovir was begun. The initial CSF analysis revealed WBC 51, RBC 4, Lymphocytes 97, Glucose 62, protein 24 and ultimately returned positive for HSV by PCR. Antibiotics were discontinued and the patient was maintained on IV Acyclovir. During the first week of hospitalization, the patient was severely symptomatic with unrelenting fevers, photophobia, severe headache, dizziness, disorientation, ataxia, and delusions. MRI of the brain revealed an acute corpus collosum infarct, and signal abnormalities in the medial temporal lobes. The EEG revealed epileptiform activity with temporal spikes. On repeat MRI, after 8 days on acyclovir, there was increased diffuse inflammation and brain stem edema. A four-day course of Dexamethasone, 10 mg IV daily, was initiated. The patient became afebrile within 6 h and his dizziness, ataxia, confusion, and headaches improved. He completed a 28-day course of Acyclovir and a negative HSV PCR was confirmed on repeat lumbar puncture. A third MRI revealed a resolved corpus infarct. The patient symptomatically improved and remained afebrile but had persistent short term memory loss.
DISCUSSION: HSV encephalitis is a devastating disease, which accounts for approximately 10 % of cases of encephalitis in the United States. Even with appropriate treatment and early intervention, the prognosis is guarded. Almost two thirds of treated patients will have a post-encephalitic syndrome comprised of varying degrees of neuropsychiatric behavioral abnormalities such as, Kluver-Bucy Syndrome (loss of normal anger and fear responses, and sexual disinhibition), anterograde amnesia, and motor, speech, and seizure disorders. With treatment the mortality rate at 6 months is approximately 15 % and severe disability is approximately 20 %. Our patient exhibited another clinical feature of HSV encephalitis, a corpus collosum infarct. The finding is thought to represent a transient signal abnormality theoretically caused by an overwhelming cytokine-mediated response to the virus, as opposed to true infarct. Although our patient received appropriate and timely treatment with Acyclovir, his symptoms and MRI findings initially persisted without much improvement. This prompted a discussion of steroids as an adjunctive treatment. A literature search for evidence to support the use of steroids in HSV encephalitis yielded a retrospective, non-randomized, multivariate regression study of 45 patients from Nihon University Department of Medicine in Japan (2005). This study showed that steroid treatment in HSV encephalitis reduced severe post-encephalitic complications and death. The significant improvement of this patient supported the use of corticosteroids in this disease.

A 36 YEAR OLD GENTLEMAN WITH SHORTNESS OF BREATH: A RARE "SINUS" PROBLEM Navya Nambudiri[2]; Vinod E. Nambudiri[1,2]; Nabil Shafi[2]; Jayashri Aragam[2]. [1]Brigham and Women's Hospital/Harvard Medical School, Brookline, MA; [2]Veterans Affairs Medical Center West Roxbury, West Roxbury, MA. (Tracking ID #1638895)

LEARNING OBJECTIVE 1: Recognize structural abnormalities of the heart are important differential diagnoses for an acute presentation of congestive heart failure.
LEARNING OBJECTIVE 2: Diagnose ruptured sinus of Valsalva aneurysms as presenting with dyspnea on exertion, chest pain, and a new onset continuous murmur.
CASE: A 36-year-old male presented with dyspnea on exertion for 3 weeks. His symptoms began after a high-intensity workout. The dyspnea worsened intermittently and was associated with a squeezing sensation, more noticeable with ambulation. Review of systems was notable for orthopnea, a 15-pound weight gain over 3 weeks, and a gurgling sound heard while lying supine. Review of systems was negative for fevers,

chills, close sick contacts, and lower extremity edema. Past medical history was notable for tricuspid regurgitation and hypertension. He took no medications at home. His father had hypertension and hyperlipidemia, and his mother had systemic lupus erythematosus. There was no family history of sudden cardiac death. Physical exam findings included a JVP up to the level of the ear, bibasilar crackles, a palpable liver 4 cm below the costal margin, and bilateral ankle edema. A 3/6 systolic ejection murmur was appreciated throughout the precordium, loudest at the left lower sternal border and axilla, which was not augmented with handgrip. S1 and S2 were preserved and the PMI was non-displaced. A right ventricular heave was noted. Chest x-ray showed pulmonary edema. EKG showed normal sinus rhythm without ST or T-wave abnormalities. Transthoracic echocardiogram showed preserved ejection faction and a non-coronary sinus of Valsalva aneurysm with continuous left-to-right shunt into the right atrium due to aneurysmal rupture, confirmed on CT-Angiography and transesophageal echocardiography.
DISCUSSION: Sinus of Valsalva aneurysms are rare cardiac structural abnormalities. They may be found on the right, noncoronary, or left sinuses of Valsalva, with right sinus aneurysms as the most common (70–90 %). Men are more commonly affected than women, and there are reports of higher rates in Asian countries compared to Western populations. They may be congenital or acquired. Common associated heart structural anomalies are ventricular septal defects or bicuspid aortic valves. Sinus of Valsalva aneurysms are often asymptomatic if unruptured. They may be seen on transthoracic echocardiography, transesophageal echocardiograpy, CT-angiography, or cardiac MRI. Rupture of sinus of Valsalva aneurysms is most common in the third or fourth decade of life. Ruptured sinus of Valsalva aneurysms may become symptomatic with a clinical presentation of sudden hemodynamic collapse or a more gradual presentation of heart failure due to aortic-cardiac shunting, as was seen in our patient. The patient underwent repair of the ruptured sinus of Valsalva aneurysm with a bovine pericardial patch without surgical or post-surgical complications. He was started on metoprolol, aspirin, and lisinopril and continued to do well at 3 months follow-up.

A BAD CONNECTION RESOLVED: PATIENT SURVIVES AORTOENTERIC FISTULA Mahmuda Islam; Adnanul Karim; Jingdong Su; Aiman Shokr; Roger D. Smalligan. Texas Tech University Health Sciences Center, Amarillo, TX. (Tracking ID #1635940)

LEARNING OBJECTIVE 1: Recognize clinical features of aortoenteric fistulas.
LEARNING OBJECTIVE 2: Diagnose aortoenteric fistulas in patients with occult clinical features.
CASE: A 64-year-old male presented with 2 days of melena, crampy epigastric pain and dyspepsia. He had a past medical history of HTN, COPD and substance abuse. He smoked 2 packs per day and drinks 5–6 beers/day. Family history was positive for premature CAD. On physical examination BP 170/60 and pulse was 80. He had mild epigastric tenderness and a palpable pulsatile mass was noted with the remainder of exam normal. Labs were normal except for mild anemia. GI was consulted and EGD was negative. The patient's pain and melena persisted so a repeat EGD was performed which showed bleeding from a duodenal ulcer that was missed on first pass. A CT of the abdomen without contrast showed an infrarenal abdominal aortic aneurysm (AAA) of 5.3×5.1 cm with duodenum draped over the anterior aspect of the aneurysm with indistinctness and irregular inflammatory appearance between the aorta and the duodenal wall. The patient was underwent surgical repair of the duodenal ulcer-AAA and required axillary-femoral and femoro-femoral bypasses in the process. Post-operative course was complicated by Strep. viridens infection at the surgical sites which was treated with ceftriaxone and rifampin. The patient developed delirium tremens as well and required prolonged mechanical ventilation, tracheostomy and PEG tube placement. He weaned eventually and was able to be transferred to a rehab hospital.
DISCUSSION: Aortoenteric fistulas (AEF) are rare but life threatening, occuring in 0.3–2 % of open AAA repairs. Development of primary, spontaneous AEF usually results from the AAA eroding into the 3rd or 4th portion of the duodenum as was seen in our patient. Eighty-five percent are atherosclerotic, 8 % mycotic, and 1 % due to media necrosis. Secondary AEF occurs in the setting of prosthetic aortic valve surgery when a pseudoaneurysm develops at the suture line of AAA repair or by direct mechanical effects of scarring between bowel and suture line. Risk factors for AEF therefore include AAA repair, prosthetic aortic grafts, aortic stent placement, radiation, infection of graft, PUD, diverticular disease, tumor and trauma. Patients typically present like our patient with upper GI bleeding, crampy abdominal pain and a pulsatile mass. Lower GI bleeding is occasionally seen and catastrophic bleeding can occur with any AEF. EGD and abdominal CT are crucial to making the diagnosis and MRI with contrast is not frequently used. This case is an important reminder to internists of the importance of considering aortoenteric fistulas in the differential of patients with acute GI bleeding, especially if the above risk factors are present, principally a history of AAA.

A BELLY FULL OF JELLY Ashwin Sridharan; Marcus A. Bachhuber; Patrick Hourani. Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1635264)

LEARNING OBJECTIVE 1: Identify the differential diagnosis of ascites without portal hypertension
LEARNING OBJECTIVE 2: Understand the pathophysiology and clinical presentation of pseudomyxoma peritonei
CASE: A 61 year-old man presented with several years of progressive abdominal and lower extremity swelling. The swelling had become profound in the past several weeks and he could barely ambulate. He denied a history of liver, cardiac, or kidney disease, or any drug use, transfusions, high-risk sexual behavior, or recent travel. The patient's abdomen was markedly distended with ascites and a right-sided inguinal hernia was noted. He had 3+ pitting lower extremity edema to the thigh. No peripheral stigmata of liver disease or chronic alcohol use were found. His cardiac exam was normal with a normal jugular venous pressure. Laboratory studies revealed a serum albumin of 2.9 g/dL, with normal serum aspartate and alanine aminotransferases, alkaline phosphatase, creatinine, urinalysis, and coagulation studies. Studies for viral hepatitis were negative. Diagnostic paracentesis revealed yellow, thick, mucinous ascites with 411 leukocytes/mm3, 14 % polymorphonucleocytes. The serum albumin-ascites gradient was 0.9 g/dL, indicating that portal hypertension was not likely present. Bacterial and mycobacterial cultures were negative. Fluid cytology and peritoneal biopsy were unremarkable. Computed tomography of the abdomen and pelvis with intravenous contrast revealed massive loculated ascites with small calcifications along septations. No masses or lymphadenopathy were noted. As the ascites was not likely due to hepatic, cardiac, renal, pancreatic, or infectious etiology, a mucin-producing neoplasm (pseudomyxoma peritonei) was suspected. Exploratory laparoscopy was performed. Fifteen liters of mucinous ascites were drained and a 38×20×11 cm mass originating from the appendix was discovered. A right hemicolectomy with end ileostomy was performed. Pathology revealed appendiceal mucinous adenocarcinoma. The patient declined chemotherapy. He remains alive 2 years after initial presentation.
DISCUSSION: Ascites related to portal hypertension is commonly encountered by the internist, but cases without portal hypertension present a diagnostic challenge. Processes leading to ascites without portal hypertension include local or metastatic peritoneal carcinomatosis (most common), tuberculosis, pancreatitis, bile ascites, and chylous ascites from lymphatic system leakage. Pseudomyxoma peritonei is a rare cause of ascites characterized by diffuse collection of gelatinous material from mucin-producing implants on peritoneal surfaces. Mucin-producing tissue can be either adenoma, termed disseminated peritoneal adenomucinosis, or adenocarcinoma, termed peritoneal mucinous carcinomatosis. Typically these neoplasms arise in the appendix. Peritoneal spread is thought to occur when an appendiceal neoplasm occludes the lumen of the appendix and ruptures it, seeding the peritoneum with mucin-producing cells. The abdomen slowly accumulates this mucinous ascites over months to years, leading to increased abdominal girth or a new inguinal hernia, the two most common presenting complaints of this condition. Computed tomography findings are often non-specific, but abdominal septations with calcifications raise the suspicion of this disease. In conclusion, the presence of ascites

without portal hypertension should prompt a broad differential diagnosis, and appendiceal tumors should be considered in cases of mucinous ascites.

A BLOODY BEAST HIDING IN THE CHEST Salman J. Bandeali; Vu Hoang; Lee Lu. Baylor College of Medicine, Houston, TX. (Tracking ID #1643313)

LEARNING OBJECTIVE 1: Report a rare cause of massive hemoptysis from uterine cancer metastases.
LEARNING OBJECTIVE 2: Realize endometrial cancer may recur even after a total abdominal hysterectomy.
CASE: A 67-year-old Caucasian female presented with complaint of having coughed up a cup of bright red blood after multiple bouts of vigorous coughing. Over the past 3 months, patient developed a dry cough which did not resolve with anti-histamines and cough suppressant. She was diagnosedwith reactive airway disease and prescribed bronchodilators but to no avail. She denied any fever, chills, night sweats, travel, and sick contacts but endorsed a 9 lbs weight loss in past 6 months. Her past medical history was significant for endometrial cancer 12 years ago treated with total abdominal hysterectomy, bilateral salpingo-oophorectomy, and pelvic lymph node dissection. She had been disease free since then and had been discharged from gynecology clinic 7 years ago. During exam, the patientstarted coughing bright red blood with clots (1000 mL in 10 min). She became tachypneic (24/min) with accessory muscle use, tachycardic (110/min), and hypoxic. She was immediately intubated with a double lumen endobronchial blocker tube.An emergent IR-guided embolization was attempted;however, no active bleeding site could be identified except for a prominent right bronchial artery in which a coil was deployed. Pulmonary circulation was normal. The patient however did not stop bleeding and required multiple blood transfusions. Thoracic surgery was consulted, and sheunderwent right sided lobectomy. Pathology revealedpulmonary metastases from recurrent uterine adenocarcinoma. The patient tolerated the surgery well and was discharged with oncology follow up for chemotherapy.
DISCUSSION: Almost 100 % of recurrence of uterine cancer occurs within 3 years after treatment. Our patient was 12 years without evidence of disease. Surveillance is usually based on regular follow-ups and evaluation via history and physical exam. Recurrence sites include vaginal/pelvic (50 %) and distant metastases in the abdomen or lungs (50 %). Massive hemoptysis is defined as expectoration of 600 mL blood in 24 h. It constitutes only 5 % of all hemoptysis cases;however, it is a medical emergency and is associated with significant mortality and morbidity. The most common causes of hemoptysis include tuberculosis, lung cancer, and bronchiectasis. To our knowledge, this is the first case of recurrent uterine cancer presenting as massive hemoptysis from pulmonary metastases. The co-existence of massive hemoptysis and malignancy has been shown to have a mortality rate of 80 %. Hence, even in the absence of uterus and after 12 years "free" of disease, endometrial cancer can recur and present with massive hemoptysis due to pulmonary metastases.

A BROKEN HEART AND A BROKEN BACK: THE DIAGNOSTIC CHALLENGE OF BACK PAIN Christopher D. Velez; Jason A. Korcak. Montefiore Medical Center, Bronx, NY. (Tracking ID #1643089)

LEARNING OBJECTIVE 1: Identify the clinical features of the serious causes of back pain.
LEARNING OBJECTIVE 2: Recognize the association between pyogenic vertebral osteomyelitis and infectious endocarditis.
CASE: A 54-year-old man with no past medical history presented with back pain for 1 month, as well as fever for 3 days. After presenting with less severe symptoms 1 week earlier, the patient returned with the worst back pain of his life. He denied a history of similar symptoms, trauma, recent procedures, including dental work, and intravenous drug use. The patient was from Albania, but had been living in the US for several decades. He had a fever of 102 ° F, poor dentition, a normal cardiac exam, marked mid-thoracic paraspinal tenderness, and a normal neurologic exam. The white blood cell count was 8.2 k/μL, the erythrocyte sedimentation rate was 79 mm/hr, and the C-reactive protein was 10.1 mg/dL. Blood cultures rapidly grew Streptococcus oralis in all four bottles. Transesophageal echocardiography showed moderate mitral valve regurgitation and a mobile 8 mm vegetation on the anterior leaflet of the mitral valve consistent with infectious endocarditis. MRI of the spine demonstrated abnormal bone marrow signal at the level of the T5 and T6 vertebrae consistent with osteomyelitis and diskitis, as well as an adjacent left paraspinal phlegmon.
DISCUSSION: Back pain presents a diagnostic challenge for the internist. While back pain is the fifth most common reason for all physician visits, there is no clear etiology found in over 80 % of cases. Although patients often receive a diagnosis of nonspecific musculoskeletal injury, several key warning signs necessitate consideration of a broader differential diagnosis. Progressively worsening back pain, unremitting pain, or signs of systemic illness, including unexplained fever or weight loss, should raise concern for infection, malignancy, or inflammatory disease. Focal neurologic findings, such as the radicular pain of disc herniation or saddle anesthesia in cauda equina syndrome, should also prompt a more extensive work-up. In addition, back pain may represent referred pain from other conditions, including aortic dissection and diseases of the pelvic and abdominal viscera, such as pancreatitis. In our case, the severity of the back pain, fever, and elevated inflammatory markers were important warning signs. The patient's back pain arose from hematogenous spread of S. oralis to the paraspinal region of the thoracic vertebrae in the setting of native valve endocarditis. Approximately 30 % of patients diagnosed with pyogenic vertebral osteomyelitis also have concomitant infective endocarditis. This relationship highlights the diagnostic challenge of back pain. While back pain is a common complaint with a typically benign etiology, internists must be aware of the clinical signs and symptoms that may indicate more serious causes.

A CASE REPORT OF DIZZINESS FROM AN OROPHARYNGEAL CANCER Takeomi Nakamura; Christine Kwan. Teine Keijinkai Hospital, Sapporo, Japan. (Tracking ID #1642584)

LEARNING OBJECTIVE 1: To recognize that dizziness may be caused by bradycardia from carotid sinus hypersensitivity syndrome from orpharyngeal cancers.
LEARNING OBJECTIVE 2: To use carotid sinus massage as a method to assess dizziness.
CASE: A 44 year-old Japanese man with no significant past medical history presents with acute onset dizziness described as spinning of everything around him. It continued for past hour. He also reported that he has sometimes felt shortness of breath and palpitations be-fore admission. He denied other constitutional symptoms as fever, weight change, or fatigue. He also denied neurological symptoms as syncope, speech changes, asymmetrical weakness, or head changes including vision and hearing. His wife reported that he snores loudly while sleeping but no orthopnea or PND. He has no medication or any allergies. He smokes 1 pack/day x20years. He does not drink. His occupation is a truck driver. His family history is unremarkable. Physical examination shows blood pressure of 120/71 mmHg, pulse of 48 beats /minute, respiratory rate of 20/minute, O2 Saturation of 98 %, and temperature of 37.5c. Head and neck exam reveals erythematous, swollen tonsils and right cervical lymphadenopathy at 5×5 cm, nontender, hard, and fixed with recurrence of dizziness and nausea with palpitation along with concurrent telementry's showing bradycardia to 40 beats/minute, junctional rhythm with retrograde atrial waves in all leads, and sinus pause of 2 s. Neurological exam is within normal limits. The rest of the examination is unremarkable. Laboratory testing, including complete blood counts and chemistry, is within normal limits. Head magnetic resonance imaging reveals a right oropharyngeal mass concerning for a malignancy. Biopsy results show malignant tumor with cervical node involvement. The patient is then started on chemotherapy and radiotherapy with gradual improvement of the dizziness.
DISCUSSION: Hypersensitivity of the afferent or efferent limbs of the carotid sinus reflex arc result in vagal activation and/or sympathetic

inhibition, leading to bradycardia and/or vasodilation may also be called carotid sinus syndrome or carotid sinus syncope. While the patient does not present with syncope, he has pre-syncopal symptoms of dizziness. In patients with an unknown cause of syncope, carotid sinus massage can help diagnose carotid sinus hypersensitivity syndrome in more than 25 % of cases. Of course, the massage should not be performed on those with a carotid bruit or transient ischemic attack/stroke in the past three As a matter of fact, the pathophysiology of carotid sinus syndrome secondary to head and neck malignancy is not well understood. Local pathologic conditions adjacent to the carotid sinus such as enlarged lymph nodes, operation scars, and mechanical pressure by a mass on carotid sinus or by actual invasion of the carotid sinus, sinus nerve or glosso-pharyngeal nerve by tumor have been postulated to produce carotid sinus syndrome. In our presented case, the cancer involved cervical lymph node and they produced sustained compression on the carotid sinus resulting in carotid sinus syndrome. After starting chemoradiation, the patient was followed for 7 months without dizziness or any other related symptoms. We can recognize that dizziness may be caused by bradycardia from carotid sinus hypersensitivity syndrome from orpharyngeal cancers with cervical node in-volvement.

A CASE OF CHRONIC, LOCALIZED LYMPHADENOPATHY Tanya Gupta; Karen Levy; Sophia M. Li; Neil J. Farber. University of California—San Diego, School of Medicine, La Jolla, CA. (Tracking ID #1622993)

LEARNING OBJECTIVE 1: Recognize the differential diagnosis of lymphadenopathy
LEARNING OBJECTIVE 2: Recognize clinical and pathologic features of angiomyomatous hamartoma
CASE: The cause of isolated lymphadenopathy without accompanying clinical symptoms can be challenging to approach given the large number of possible etiologies. As discussed in this vignette, developing a differential based on the extent of lymphadenopathy (localized vs. generalized) and chronicity may help narrow the approach. The patient is a 67 year old male with history of bullous pemphigoid presenting with worsening peripheral edema. Bilateral lower extremity edema and inguinal lymphadenopathy began shortly after initiating prednisone for treatment of pemphigoid. Prednisone was tapered after 3 months and mycophenolate was subsequently initiated for 1 month, at which time the edema significantly worsened causing balance problems and 10 pound weight gain. He denied fever, chills, dyspnea, cough, chest pain. Of note, patient had history of exposure to raw milk and to a sibling with tuberculosis, but no exposure to wild animals. On physical exam, patient was well appearing with vitals within normal limits. Exam was only remarkable for 3+ pitting edema of bilateral lower extremities, edema of genitals, and significant bilateral inguinal lymphadenopathy. Lymphadenopathy was not appreciated in the neck. Routine CBC and BMP were within normal limits, ALT 37, AST 48, total protein 5.7, and albumin 3.5. Patient had a quantiferon negative test. CT abdomen and pelvis revealed large calcified mesenteric node 3.2×2.5 cm and enlarged bilateral inguinal nodes with central necrosis. Approximately 7 months after onset of lymphadenopathy, inguinal excisional biopsy revealed vascular and smooth muscle proliferation suggestive of angiomyomatous hamartoma.
DISCUSSION: As an isolated physical exam finding, lymphadenopathy can have an extensive number of causes. Thus, qualifying the patient's lymphadenopathy as chronic and localized helps narrow the initial differential to infectious causes, such as tuberculosis, lymphogranuloma venereum, brucellosis, and tularemia; auto-immune causes, such as sarcoid; and tumors such as angiomyolipoma, lymphoma, Kaposi's sarcoma, and metastasis. In this case, the ultimate diagnosis of angiomyomatous hamartoma came from its classic pathologic findings on biopsy. Angiomyomatous hamartoma is a benign cause of inguinal lymphadenopathy in which normal lymph node architecture is replaced with smooth muscle cells, adipose cells, and vessels extending from the hilum to the surface of the node. Since it was first described in 1992, a total of 18 other cases have been reported. Most of these cases involved inguinal nodes, with the exception of a few involving femoral nodes, one involving popliteal nodes, and one in cervical nodes. The pathogenesis remains unclear, though it has most recently been thought to be prompted by impaired lymphatic flow. Mycophenolate use has been associated with lymphoproliferative disorders and sarcoidosis, which raises the question of a possible association with development of angiomyomatous hamartoma in this patient. Additionally, bullous pemphigoid has been noted in patients with lymphoma, raising the question of a possible association of pemphigoid with angiomyomatous hamartoma as well. Because this disorder is benign, chemotherapy and radiation are not required. Rather, surgical excision of nodes restores lymphatic flow and leads to resolution of edema without recurrence.

A CASE OF CRYPTOSPORIDIAL DIARRHEA IN AN IMMUNE-COMPETENT ADULT Naba R. Mainali; Patrick Quinlan; Anene Ukaigwe; Shailaja Amirishetty. Reading Health System, West Reading, PA. (Tracking ID #1621816)

LEARNING OBJECTIVE 1: To recognize the clinical presentation and diagnosis of cryptosporidial diarrhea.
LEARNING OBJECTIVE 2: To describe the management of cryptosporidial diarrhea in an immune-competent patient.
CASE: Diarrhea caused by Cryptosporidium is most commonly seen in patients with HIV/AIDS or other immuno-compromised conditions like Diabetes Mellitus, patients on high dose of steroids or immuno-suppressants. The organism is a parasite that infects gastrointestinal epithelium producing potentially life threatening diarrhea in AIDS but usually self-limited diarrhea in immune-competent hosts. Here in, we present an interesting case of persistent diarrhea caused by Cryptosporidium in an immune-competent adult requiring treatment with nitazoxanide. A 43-year-old female presented to the Emergency Department complaining of diarrhea, abdominal discomfort and nausea for the last 10 days. To begin with, she had diarrhea, vomiting, nausea and low grade fever. After 3 days, she stopped vomiting and became afebrile. However, she continued to have diarrhea and nausea. She went to local medical center and was treated with normal saline and antiemetics with the provisional diagnosis of viral gastroenteritis and was sent home. She had minimal relief but again continued to have the similar symptoms with loss of appetite and weight loss. On the 10th day, she decided to come to our hospital for the further evaluation. She denied fever, chills, abdominal pain, and burning micturition at the time of presentation. She denied any history of allergy, unusual food intake, sick contacts, bloody stools, HIV risk behavior and travel to other countries. Physical exam revealed blood pressure of 90/68 mm Hg and heart rate of 88/min with slightly dry oral mucosa without lymphadenopathy and rashes. Abdominal exam showed mildly tender abdomen with hyperactive bowel sounds. Heart, lungs and neurological examination were essentially normal. Laboratory findings revealed normal CBC, sodium 141 meq/L, potassium 3.1 meq/L, magnesium 1.3 meq/dL, bicarbonate 28 meq/L, blood urea nitrogen (BUN) 7 meq/L, creatinine 0.75 mg/dL. CT scan of the abdomen and pelvis revealed gas and fluid distended colon with wall thickening. Colonoscopy showed only mild proctitis. Rota virus antigen, Giardia antigen, Clostridium difficile toxin, HIV 1/2 antibodies were all negative. Stool culture for Cryptosporidium was found to be positive. She was treated with normal saline, electrolyte replacement and nitazoxanide 500 mg orally twice daily for total of 3 days. She became completely symptom free on the fifth day of starting treatment. She was then discharged to home without any medications. She was asymptomatic on 1 month follow up visit.
DISCUSSION: In immunocompetent hosts, Cryptosporidium can cause acute or persistent diarrhea associated with low grade fever, nausea, vomiting and weight loss. Confirmatory diagnosis of cryptosporidiosis requires microscopical detection of the parasite in tissues or body fluids. The easiest and quickest method of detecting oocysts is modified acid-fast staining of the organism on microscopical examination of the stool. Cryptosporidiosis in immune-competent hosts is usually self-limiting and no specific treatment is required as compared to highly active anti-retroviral treatment and/or antiparasitic agents in patients with AIDS. Nitazoxanide reduces the load of parasites and currently a treatment of choice for cryptosporidiosis in immunocompetent individuals if not self-limited.

A CASE OF HYPOXIA IN A TEENAGER Priti Dangayach; Nainesh Shah; Achilia Morrow. Baylor College of Medicine, Houston, TX. (Tracking ID #1601482)

LEARNING OBJECTIVE 1: Recognize the association between cigarette smoking and acute eosinophilic pneumonia.
LEARNING OBJECTIVE 2: Recognize the clinical features of AEP, a potentially life threatening yet fully reversible disease
CASE: An 18-year-old Caucasian female presented to the emergency room with nausea, vomiting, and non-bloody diarrhea associated with fevers, chills, and epigastric pain. She noted an outbreak of food poisoning at the shelter where she lives. Her medical history included depression and anxiety. On review of systems, she noted a mild cough minimally productive of yellow sputum for the past month after initiating smoking several cigarettes daily. She denied shortness of breath, hemoptysis, and chest pain. She had no known allergies and denied use of alcohol, drugs, or new medications. On examination, her temperature was 103 F, heart rate 130–140 beats/minute, normotensive, with a respiratory rate of 35 with an oxygen saturation of 85 % on room air. Her oxygen saturation improved to 95 % with 3 L of supplemental oxygen by nasal cannula. She had course breath sounds with diminished air movement in bilateral lung fields. ABG showed pH 7.43, PCO2 24.3, P02 149 on 3 L O2. Her WBC count was 26,200 uL with a differential of 90 % neutrophils, 5 % lymphocytes, 4 % monocytes, and 1 % eosinophils. A chest x-ray showed moderate bibasilar reticulonodular opacities. An abdominal CT scan was performed for her abdominal symptoms, which incidentally noted diffuse groundglass opacities in the right middle lobe and lingula with bilateral intralobular septal thickening. To further investigate the findings, bronchoscopy with bronchoalveolar lavage (BAL) was performed. The cell count differential revealed marked eosinophilia (34 % eosinophils). Routine cultures, cytology, AFB stain and culture, ova and parasite exam, and hypersensitivity panel were negative. The diagnosis of acute eosinophilic pneumonia (AEP) was made with cigarette smoking as the etiology. She was initiated on 60 mg of oral prednisone daily and was educated on her "allergy" to cigarettes. Her chest x-ray, oxygen saturation, and tachypnea remarkably improved, and she was discharged from the hospital on room air with a three-week prednisone taper. After discharge, she resumed smoking. Within a week of doing so, she returned to the ED with symptoms of subcostal pain and cough. Her symptoms again improved with steroids.
DISCUSSION: Although this patient's presenting gastrointestinal symptoms are not classic for AEP, the findings of fever, hypoxemic respiratory failure, and BAL with greater than 25 % eosinophilia with significant response to corticosteroids are diagnostic of AEP. Literature suggests recent onset cigarette smoking is a trigger for this acute hypersensitivity reaction. Re-exposure to cigarette smoke helped confirm that this was the inciting agent for the patient's AEP. Without prompt treatment, this disease can progress to respiratory failure, necessitating mechanical ventilation. This case highlights the importance for physicians to recognize cigarette smoking as an inciting agent for acute eosinophilic pneumonia in order to recognize this potentially life threatening yet fully reversible disease.

A CASE OF MULTIPLE MYELOMA INVOLVING THE THYROID GLAND Anthony P. Sertich; Nazrul Chowdhury; Steven Urban. Texas Tech University Health Sciences Center, Amarillo, TX. (Tracking ID #1631261)

LEARNING OBJECTIVE 1: Recognize that multiple myeloma can present with a thyroid mass.
LEARNING OBJECTIVE 2: Understand that biopsy of a thyroid mass is necessary in euthyroid patients with suspected malignancy.
CASE: A 61-year-old white female presented with a neck mass that had enlarged over 4 months coupled with an unintentional 10 pound weight loss. Her past medical history was pertinent for questionable monoclonal gammopathy of undetermined significance. Her physical exam was remarkable for a large, hard, and uneven thyroid mass that moved with deglutition. Cervical lymphadenopathy was absent. Complete blood count (CBC) showed a hemoglobin of 7.6 g/dL with a platelet count of 37,000. Peripheral smear showed Rouleaux formation. The creatinine was 1.2; total protein was 7.6, and the albumin 3.7. Serum calcium was 17 mg/dL. Urinalysis revealed 2+ proteinuria, but no urinary light chain was detected. Thyroid studies were normal. Serum lactate dehydrogenase was 1066 IU/L. The serum immunoglobulins were as follows: IgA- 23 mg/dL IgG-2300 mg/dL IgM- 28 mg/dL Serum protein electrophoresis (SPEP) and serum immunofixation confirmed monoclonality. The serum free light chain assay yielded IgG Kappa of 19.4 mg/L and Lambda as 0.3 mg/L, with a Kappa/Lambda ratio of 61 (abnormal <0.03 or >32). Computed tomography (CT) of the neck showed a 10×8×8 cm thyroid mass. Positron emission tomography (PET)/CT showed a high standardized uptake value (SUV) in the mass. Skeletal survey showed no osteolytic lesions, and magnetic resonance imaging (MRI) of the spine and pelvis showed no lytic lesions or spinal cord involvement. Biopsy of the mass showed diffuse infiltration with multiple clonal plasma cells, and biopsy of the bone marrow exhibited 90 % plasma cells with Kappa light chain, CD 138 positivity.
DISCUSSION: Multiple myeloma (MM) is a malignant plasma cell disorder of the bone marrow. Extramedullary involvement is uncommon, and thyroid involvement is extremely rare, with only three reported cases in the global literature. Although there are many case reports of solitary plasmacytomas involving the neck or thyroid cartilage, this case represents multiple myeloma presenting in the thyroid, with CD138-positive monoclonal plasma cells. It is important to differentiate between extramedullary MM and solitary plasmacytoma because of the stark contrast in prognosis between the two. Local radiotherapy leads to long-term clinical stability in at least 90 % of cases of solitary plasmacytoma, and unless complication warrants surgical intervention, the radiotherapy is sufficient for an average 10 year survival. However, MM carries with it a worse prognosis, especially in cases with extramedullary spread, thus identification of MM early can increase survival in those afflicted. This means a high clinical suspicion for those at risk (e.g., a history of MGUS) even if the classic vertebral presentation is not suspected. One should always consider unusual locations, such as the central nervous system, lungs, sphenoid sinus, orbit, ovaries, colon, liver/spleen, and thyroid, as potential extramedullary presentations of MM. If suspicion is high, urgent biopsy and laboratory analysis should be ordered to evaluate for MM. The difficulty arises in quantifying suspicion for those in primary care to ensure MM is caught early; we present a case that lays the foundation for establishing these guidelines.

A CASE OF TAKOTSUBO CARDIOMYOPATHY WITH ACQUIRED LONG QT INTERVAL AND HIGH DEFIBRILLATION THRESHOLD. Mahmoud Abdelghany[1]; Genevieve Brumberg[2]; Jan Nemec[3]. [1]Conemaugh Memorial Medical Center, Temple University, Johnstown, PA; [2]Conemaugh Memorial Medical Center, Temple University, Johnstown, PA; 3UPMC Heart and Vascular Institute, Pittsburgh, PA. (Tracking ID #1642876)

LEARNING OBJECTIVE 1: Patients who develop Takotsubo cardiomyopathy may have underlying channelopathy with a propensity to acquired long QT, higher DFT and long term risk of sudden death. Determining the correlation among these factors may better elucidate the mechanism of acquired arrhythmias and help in identifying high risk patients in an otherwise healthy population.
CASE: Introduction: Takotsubo Cardiomyopathy rarely presents with sudden death. Cases needed high DFT have been associated with low EF and dilated heart. Here we present a case of Takotsubo cardiomyopathy who failed cardioversion twice and needed above 25 J to converts during DFT testing although she had a normal EF and a non-dilated heart. Case:The patient is a 60 year old female who presented with sudden loss of consciousness after a stressful family event and was found to be in ventricular tachycardia. She required multiple defibrillations as well as antiarrhythmics during the initial resuscitation. Urgent cardiac catheteriza-

tion showed no significant coronary artery disease. Left ventriculography showed severe apical hypokinesia with ballooning consistent with Takotsubo cardiomyopathy. EF was 30 %. During the next several hours her QT interval prolonged dramatically to more than 700 milliseconds but subsequently normalized. Echocardiography 3 days later showed mitral valve prolapse with mild to moderate mitral regurgitation and improvement of EF to 50 %. Given initial presentation and multiple risk factors, the patient had a dual chamber implantable cardioverter defibrillator (ICD) placed. During DFT testing the patient failed two shocks at 25 joules but was successfully cardioverted at 30 joules after exclusion of the proximal coil.

DISCUSSION: Patients with Takotsubo cardiomyopathy may present with a dramatic abnormality of ventricular repolarization, including deep negative precordial T waves, QT interval prolongation and rarely torsades de pointes. The exact mechanism of repolarization abnormality is uncertain, but may be related to the effect of prolonged excessive β-adrenergic stimulation on myocardial Ca2+ handling or local ventricular edema. These same factors may explain the high DFT seen in our patient. Although sudden death is rare in Takotsubo, a patient presenting with cardiac arrest, transient left ventricular dysfunction, and dramatic repolarization abnormalities has clear risk for ventricular arrhythmia. Studies have shown up to 10 % recurrence rates for Takotsubo cardiomyopathy, placing this patient at risk for recurrent sudden death for which an implantable cardioverter defibrillator was placed.

A CURIOUS CASE OF RECURRENT RHABDOMYOLYSIS Benjamin Click; Thomas Radomski; Harish Jasti. University of Pittsburgh, Pittsburgh, PA. (Tracking ID #1641169)

LEARNING OBJECTIVE 1: Identify the differential diagnosis of recurrent rhabdomyolysis.

LEARNING OBJECTIVE 2: Describe a classic presentation and the treatment of McArdle disease in an adult.

CASE: A 20 year-old male was admitted to our hospital for management of recurrent rhabdomyolysis. His first episode occurred when working as a firefighter extinguishing a house fire. The second instance followed a series of short-distance sprints, and his current presentation occurred after direct trauma to his legs. Each episode was characterized by myalgias, followed by morning stiffness, and dark urine lasting several days. He also reported a life-long history of exercise intolerance with easy fatigability. He was diagnosed with diabetes mellitus 4 months prior to admission and was briefly treated with metformin, which was later discontinued in favor of insulin due to intolerance. He also experienced an episode of ventricular tachycardia at the age of 15 for which he underwent an ablation. His family history was notable for his mother and a maternal uncle with dermatomyositis and a maternal uncle with an undifferentiated myositis. The patient denied any alcohol, tobacco, or drug use. Physical exam revealed a tired-appearing young man in no acute distress. He was afebrile with normal vital signs. Cardiac, lung, abdominal and dermatologic exams were unremarkable. Musculoskeletal exam revealed 5/5 strength throughout, with no joint tenderness, swelling, or deformity. Labs revealed a CPK 78,465, LDH 2657, AST 492, ALT 272, Alk Phos 61, Tbili 0.9. A basic metabolic panel and CBC were unremarkable. A TSH was normal. CRP was 1.9. RF, ANA, and Anti-Jo-1 Abs were also negative. A cytogenetic analysis was ultimately performed, revealing mutations in two exons of the PYGM gene encoding the myophosphorylase enzyme. This was consistent with McArdle disease.

DISCUSSION: Rhabdomyolysis is a common clinical entity encountered by general internists. It is frequently caused by direct trauma, hyperthermia, infection, or exposure to toxins and drugs. When recurrent rhabdomyolysis is identified, it is important to investigate for underlying inflammatory and metabolic etiologies, such as dermatomyositis, polymyositis, and inclusion body myositis, in addition to the family of glycogen storage diseases. McArdle disease is a glycogen storage disease caused by mutations in the myophosphorylase enzyme. Patients often present as teenagers or young adults with exercise intolerance, fatigue, myalgias, muscle cramps, and myoglobinuria. Common diagnostic tools include muscle biopsy, electromyography, genetic testing, and forearm lactate exercise testing. Muscle biopsy shows focal decreased myophosphorylase activity on immunohistochemical staining. Electromyography demonstrates myotonic discharges, fibrillations, and positive waves. Genetic testing of the myophosphorylase gene reveals mutations in approximately 97 % of McArdle disease patients. Treatment of McArdle disease includes sucrose administration prior to dynamic exercise with low-impact warm up activity and a balanced diet of carbohydrates, protein, and fat. Other potentially beneficial therapies include creatinine and vitamin B6 supplementation. For our patient, given his family history and recurrent nature of rhabdomyolysis, further investigation of potential genetic disorders and inflammatory myopathies yielded a definitive diagnosis of McArdle disease.

A CUTE RASH Erin C. Contratto. University of Alabama Birmingham, Birmingham, AL. (Tracking ID #1642499)

LEARNING OBJECTIVE 1: Recognize the importance of evaluating past medical history and medication exposures in patients presenting with a rash.

LEARNING OBJECTIVE 2: Demonstrate the need for early skin biopsy in patients presenting with an atypical rash.

CASE: A 45-year-old white female presented with a 1 month history of erythematous nodules on her chest, abdomen and back. The nodules were not painful, nonpruritic and varied in size. The nodules appeared first at her oophorectomy scar and then spread to the remainder of her trunk. She denied any systemic symptoms or recent medication changes. Her past history was remarkable for ductal carcinoma in situ (DCIS) 2 years prior and genotype positive for Breast Cancer type 1 (BRCA1). She underwent bilateral mastectomy and prophylactic oophorectomy at the time of DCIS diagnosis and completed chemotherapy with doxorubicin and cyclophosphamide. Routine imaging 7 months prior to the appearance of the rash was negative for malignancy. Physical examination demonstrated several 0.5 to 5 cm firm, erythematous papules scattered over her chest, abdomen, back and bilateral upper and lower extremities. She had no lymphadenopathy or visceromegaly. Laboratory evaluation noted white blood cell count 6200/mL, hemoglobin 13.6 gm/dl, platelets 226,000/mL, and a normal differential. Punch biopsy revealed a dermal infiltrate of large cells with irregular nuclei, consistent with leukemia cutis. Bone marrow biopsy aspirate and flow cytometry were normal. She underwent induction chemotherapy for acute myelogenous leukemia with cytarabine and daunorubicin. Within 30 days her skin lesions faded completely. A repeat skin biopsy at 14 days and repeat bone marrow biopsy at 30 days were normal. The patient then received traditional consolidation chemotherapy for acute myelogenous leukemia, and had no evidence of recurrence for 6 months.

DISCUSSION: Leukemia cutis is a form of secondary extramedullary acute leukemia, defined by cutaneous infiltration of neoplastic leukocytes. Patients with leukemia cutis present with erythematous papules and nodules of varying sizes, affecting multiple body sites. Lesions can occur at prior sites of trauma, consistent with the Koebner phenomenon. Lesions are often asymptomatic, typically occur after the patient has a known diagnosis of leukemia, and are a poor prognostic sign. Diagnosis of leukemia cutis is confirmed by skin biopsy; thus, early skin biopsy is appropriate to rule out malignancy when evaluating patients with a persistent rash. Aleukemic leukemia cutis, a form of primary extramedullary leukemia, presents when dermatologic findings precede hematologic manifestations of leukemia. Despite the absence of bone marrow infiltrates, patients with aleukemic leukemia cutis, are considered to have acute leukemia. Risk factors for developing acute myelogenous leukemia and myelogenous leukemia cutis include prior exposure to tobacco smoke, petroleum products or chemotherapy, particularly exposure to alkylating agents such as cyclophosphamide. Due to the low incidence of disease, treatment methods for patients with aleukemic leukemia are not standardized. Several recent case reports have described relative success in treating extramedullary leukemia with standard chemotherapy regimens for acute myelogenous leukemia, in order to prevent further progression of disease.

A DIFFICULT DILEMMA: MANAGEMENT OF ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS IN THE SETTING OF CONCOMITANT INFECTION AND ALTERED MENTAL STATUS Michael Spagnola; Sara Wikstrom. George Washington University, Washington, DC. (Tracking ID #1643082)

LEARNING OBJECTIVE 1: Recognize the management dilemma in treating a patient with active systemic lupus erythematosus with a known infection
LEARNING OBJECTIVE 2: Recognize the broad differential for altered mental status in a patient with active systemic lupus erythematosus
CASE: A 48-year old woman presented to our hospital with fevers, fatigue, confusion and weight loss after a recent admission to an outside hospital where she was diagnosed with systemic lupus erythematosus (SLE) and treated with 3 days of high dose corticosteroids. On physical examination, she had a blunted affect and waxing and waning mental status. She had bilateral crackles in the lower lung fields and bilateral pitting lower extremity edema. Laboratory studies revealed an elevated ANA titer, low complement levels, nephrotic range proteinuria, severe hypoalbuminemia and acute kidney injury. A kidney biopsy was obtained and the patient was treated with high dose IV corticosteroids and cyclophosphamide for suspected lupus nephritis. The patient's mental status improved somewhat and her acute kidney injury resolved. Her respiratory status acutely worsened, requiring her intubation. A CT of the chest revealed a 1 cm abscess in the right upper lung and bilateral pleural effusions. The patient was initially started on broad spectrum antibiotics for presumed hospital acquired pneumonia, but was switched to four drug therapy for tuberculosis after her tracheal aspirate grew mycobacterium tuberculosis. The patient's IV corticosteroids were continued as she has symptoms and lab findings consistent with active SLE. The patient's mental status continued to deteriorate. She became increasingly disoriented, began confabulating and complaining of visual hallucinations. A CT head showed no acute findings and a MRI brain showed non-specific focal white matter disease in the bilateral frontal lobes. A lumbar puncture was negative for meningitis or encephalitis. At this point, the patient's family insisted that she be transitioned to oral corticosteroids as they were concerned for steroid-induced psychosis, despite the reservations of her medical team who believed that the IV corticosteroids were necessary in the setting of an active SLE flare. The patient subsequently developed tonic clonic seizures and was emergently treated with anti-epileptic drugs, IV corticosteroids and azathioprine for presumed lupus cerebritis. She had no further seizures and her altered mental status gradually resolved. Her corticosteroids were slowly tapered and the patient was discharged 5 weeks later with oral corticosteroids, azathioprine, tuberculosis treatment, and anti-epileptic drugs.
DISCUSSION: This case illustrates a management dilemma as the patient had active systemic lupus cerebritis which required treatment with corticosteroids. Her subsequent immunosuppression led to the development of a new infection. In this case, it was important to control her active SLE with corticosteroids and treat the active infection concomitantly. This case also demonstrates the wide differential diagnosis for altered mental status in a patient receiving treatment for active SLE. In this patient's case, the diagnosis of lupus cerebritis was reached only after an extensive workup for infectious, structural, medication-related and psychiatric causes for her altered mental status was obtained.

A FATAL RASH: IT'S ALWAYS LUPUS! Auras R. Atreya; Sonali Arora; Scott Halista; Thomas Higgins. Baystate Medical Center/Tufts University School of Medicine, Springfield, MA. (Tracking ID #1639107)

LEARNING OBJECTIVE 1: Recognize rheumatological conditions presenting primarily as skin disorders.
CASE: A 47 years old lady with no significant past medical history presented to the hospital with a skin rash that started just 1 month back but progressively worse over past 2 weeks. She had no previous dermatological history. What initially started as a 'few pimples' on the face, progressed to a significant rash that included the face (eyebrows, nose, chin and malar area and ears), chest back, fingertips, axillary and genital area. On examination, there was a widespread scaly, crusted eruption with perivaginal desquamation. There were certain areas that appeared purpuric and even hemorrhagic. Her pinnae appeared dark and necrosed and she presented due to increasing swelling and tenderness. There were few oral and genital ulcers. Purplish skin changes of the fingertips of both hands and toes in the absence of digital ulceration. She had tried over-the-counter calamine and bacitracin creams/lotions. She denied any constitutional symptoms, fevers, chills, nausea, vomiting, diarrhea, abdominal pain, weakness or new medications. Preliminary bloodwork was significant for anemia, leucopenia (2400/mm3), thrombocytopenia (48,000/mm3), elevated liver enzymes (AST 283 units/L and ALT 79 units/L) and CRP (4.7 mg/dL); ESR was normal. Complement levels were low (C3 55 mg/dL, C4 8 mg/dL) and infective work-up was negative. Dermatology and Rheumatology consults were obtained and a vasculitic process was considered as the primary differential given acuity of onset and widespread involvement; she was started on empirical steroids. Skin biopsy revealed erythrocytic extravasation with focally prominent perivascular infiltrate with nonspecific immunoperoxidase staining. Hospital course was complicated by acute hypoxic respiratory failure requiring intubation. CT chest showed diffuse bilateral ground-glass opacity and patchy areas of consolidation reflecting thought to be pneumonitis. A presumptive diagnosis of SLE was made, confirmed by a positive ANA titer. Plasmapheresis and Cyclophosphamide therapy was attempted, but the patient rapidly deteriorated with ARDS, ventilator-acquired pneumonia, septic shock and oliguric renal failure and died. Her family chose not to perform an autopsy. family chose not to perform an autopsy.
DISCUSSION: While SLE is best known as a multi-system disorder involving skin, joints, kidneys, hematological and immunological systems, patients presenting purely with dermatological involvement are less common. Classic skin lesions include malar rash, discoid rash, alopecia etc. What makes this case unique were crusty lesions with purplish digits suggesting a vasculitic process, which progressed with amazing alacrity to involve other organs. In the acute setting, immunosuppression with steroids, cyclophophamide/azathioprine/methotrexate and IVIG/plasmapheresis form the mainstay of treatment for serious SLE flares. Unfortunately, despite early recognition of this condition, these measures could not save our patient.

A GREAT MASQUERADER Christina M. Cruz; Yelena Averbukh. Montefiore Medical Center, Bronx, NY. (Tracking ID #1642474)

LEARNING OBJECTIVE 1: To recognize hemophagocytic lymphohistiocytosis as a potential mimicker of sepsis syndromes
LEARNING OBJECTIVE 2: To diagnose hemophagocytic lymphohistiocytosis
CASE: Twenty-six year-old woman with rheumatoid arthritis, on steroids, methotrexate and adalimumab (initiated 8 weeks prior to presentation), presenting with fever and rash. Fever developed 2 weeks before presentation, for which she was prescribed Trimethoprim/sulfamethoxazole for presumed urinary tract infection. Three days after starting antibiotics she developed diffuse itching followed by a diffuse, erythematous rash, which initially began on trunk and progressively spread to upper and lower extremities. Vital signs were significant for BP 90/50, HR 140 s, RR 40 and oxygen saturation of 80 % on room air. Other findings included bilateral rales in all lung fields, regular tachycardia without murmurs, and morbilliform rash on trunk, arms and thighs bilaterally, without desquamation or bulla. Serum chemistries were significant for hemoglobin 8.6, platelets 94 and WBC 2,700, AST 153, ALT 117, ferritin 11,700 ng/ml, triglycerides 343 mg/dl and fibrinogen 101 mg/dl. Chest radiograph revealed diffuse interstitial prominence. She was transferred to the intensive care unit for management of presumed septic shock where she required pressors and ventilator support. Extensive infectious workup was negative. Abdominal ultrasound revealed mild splenomegaly. Given the negative infectious workup and hyperferritinemia other etiologies were considered. She was diagnosed with hemophagocytic lymphohisticytosis. She was treated with a course of steroids with clinical improvement. Bone marrow

biopsy revealed normocellular marrow with trilineage hematopoiesis and no morphological evidence of hemophagocytic lymphohistiocytosis.
DISCUSSION: Hemophagocytic lymphohistiocytosis (HLH) is a rare, and often fatal, disorder of unregulated immune activation. The initial signs and symptoms can mimic common infections and sepsis syndromes, however the treatment differs. It is more commonly seen in children, but it is also recognized in adults. HLH can be familial or sporadic, and typically secondary to infection, malignancy or rheumatologic disease. The incidence in adults is unknown, in part secondary to the difficulty in recognizing HLH. In 2001, the Histiocyte Society published updated diagnostic criteria and since then these have served as the gold standard for diagnosis of HLH. These criteria include various genetic mutations or 5 of 8 of the following: fever, splenomegaly, cytopenias (affecting at least 2 of 3 lineages in the peripheral blood), hypertriglyceridemia and/or hypofibrinogenemia, hemophagocytosis in bone marrow, spleen, lymph nodes, or liver, low or absent NK-cell activity, ferritin >500 and elevated soluble CD25 (soluble interleukin-2 receptor). Moreover, ferritin concentrations >10,000 microg/liter were 90 % sensitive and 96 % specific for HLH, with very minimal overlap with sepsis, infections, and liver failure. Interestingly, hemophagocytosis is neither sensitive nor specific, with one, small case control study quoting a sensitivity of 83 % and specificity of 60 %; others show that it is not uncommon to have an initial negative bone marrow biopsy. Recognition and diagnosis of HLH are of utmost importance given it relatively high mortality with quotes of 2 month survival in those left untreated. Treatment usually involves immunosuppressive therapy with steroids and chemotherapeutic agents.

A GUT FEELING ABOUT A RASH Tanvir Haque. University of North Carolina, Chapel Hill, NC. (Tracking ID #1628101)

LEARNING OBJECTIVE 1: Recognize common signs, symptoms, and presentation of Henoch-Schönlein Purpura
LEARNING OBJECTIVE 2: Diagnose Henoch-Schönlein Purpura with gastrointestinal involvement
CASE: A 62 year old woman presented with 5 days of severe abdominal pain, joint pain, and rash. Abdominal pain was band-like, radiated across her upper abdomen and back, and associated with bilious emesis, but no hematemesis, melena or hematochezia. She has started no new medications except for Ibuprofen for her new joint pains. Her epigastrium was mildly tender, but without any peritoneal signs. She had a scattered, flat, erythematous, non-blanchable, macular rash involving her bilateral lower extremities, concentrated on the shins and plantar aspects of her feet. Additionally, she had tender swelling of her bilateral 2nd, 3rd and 4th metacarpophalangeal joints and wrists. Initial lab work revealed normal platelet, and white blood cell count, creatinine, urinalysis, lipase and transaminases. C Reactive Protein was mildly elevated at 8 mg/dL, Erythrocyte Sedimentation Rate was 5 mm/hr. Abdominal CT revealed diffuse wall thickening and mucosal enhancements of the second and third portions of the duodenum. Esophagogastroduodenoscopy, demonstrated severe duodenitis with evidence of severe bowel edema, ulcerations, and submucosal hemorrhage in the second and third part of the duodenum, with biopsy showing severe neutrophilic inflammation with erosion and hemorrhage. Within 48 h of presentation, her rash advanced to a raised, purpuric quality. Skin biopsy revealed neutrophilic inflammation involving adjacent blood vessels. Direct immunofluorescence revealed IgA and fibrinogen deposition in the walls of superficial dermal vessels, consistent with Henoch-Schonlein Purpura (HSP). Initiation of high dose corticosteroids led to gradual improvement of her rash, arthralgias and abdominal pain. She was discharged with a steroid taper and follow-up 3 months off steroids revealed resolution of all symptoms and normal kidney function.
DISCUSSION: The combination of abdominal pain, joint pain, and rash are commonly seen in general internal medicine. Vasculitis is an uncommon cause of the above symptoms, and HSP, while primarily a disease of children, is often more severe in adults, particularly with renal involvement. HSP vasculitis is an inflammatory process involving IgA-mediated immune complex deposition into vessel walls, which activates the complement system and promotes neutrophilic infiltration into blood vessels. Diagnosis, as it did in this case, is often times confirmed by tissue biopsy. This patient had a common presentation of the disease; however, it was striking that she first developed vasculitis in her bowel—a harbinger for later findings on her skin. Treatment regarding HSP can be controversial, however, it is widely held that immunosuppression with corticosteroids is key, especially in adults with evidence of renal compromise. This case illustrates a common presentation of adult HSP, but underscores the severity of possible gastrointestinal involvement, as well as the importance of early recognition to minimize complications and initiated early treatment.

A HIGH PRESSURE SITUATION: A RARE CAUSE OF HEADACHE IN A 37 YEAR-OLD MAN Jacqueline Chu; Dean Xerras. MGH, Boston, MA. (Tracking ID #1638630)

LEARNING OBJECTIVE 1: Recognize characteristics of intracranial hypertension in men
LEARNING OBJECTIVE 2: Diagnose idiopathic intracranial hypertension
CASE: A healthy 37 yo man presented to the ED with a sudden onset, sharp occipital headache after bending to pick up a cable. He suffered the worst headache of life and presented for evaluation. He was concerned of mild vision changes, citing a slight "tunnel" to his vision. He had photophobia, and nausea with one episode of vomiting. No fevers, history of trauma or fall. He had a 30 lb weight gain in the last 4 months; in the prior year he had intentionally lost 30 lbs via diet and exercise, but recent return to old habits allowed him to regain the weight. No significant headache history or family history of migraines, although his twin brother was just diagnosed with benign intracranial hypertension. He did not smoke, drank socially, and used marijuana occasionally. He took no medications. On examination, he was a well-nourished average-sized man with pupils equal and reactive to light and extraocular movements intact, with very slight reduced ability to abduct the R eye medially. He had normal strength, sensation and reflexes throughout. His headache was slightly worse when bending over and his gait was unaffected. A non-contrast CT of the head was normal, and a diagnostic lumbar puncture demonstrated an opening pressure of 45 cm H2O with closing pressure of 28. There was no xanthochromia nor were there abnormal cell counts or chemistries on the CSF. The patient was managed with acetazolamide and after 4 days a repeat LP had a normal opening pressure of 16 cm H2O. He was encouraged to exercise, lose weight, and continue his acetazolamide.
DISCUSSION: A relatively infrequent diagnosis in the general public, idiopathic intracranial hypertension is more rare still in men. Traditionally thought of as a diagnosis in obese women in their 20s–40s, IIH presents with different characteristics in men than women. Men with IIH most often come to attention because of visual changes and less likely from headache, although our case was an exception. Men present with worse visual acuity and reduced visual fields and were at higher likelihood of having severe visual loss. Though our patient was not obese, he had recently had a 30 lb weight gain. Of note, his twin brother had just been diagnosed with idiopathic intracrianial hypertension; a few case reports comment on twins presenting with the diagnosis, and in these cases patients have been diagnosed in the same year of age, with slightly lower mean age and weight. Early diagnosis of intracranial hypertension is important for protection of visual acuity and prevention of optic atrophy. Diagnosis requires a documentation of intracranial pressure > 20 cm H20, and negative radiographic imaging for space-occupying lesions with normal CSF chemistries and cell counts. Idiopathic intracranial hypertension requires exoneration of venous sinus thrombosis, uremia, endocrine disturbances or medication effects (tetracycline, OCP use, vitamin A toxicity) causing pseudotumor. Treatment with acetazolamide is a carbonic anhydrase inhibitor that reduces CSF formation and hence can be titrated up to control intracranial pressure; topiramate works similarly. During treatment careful monitoring by neuroophthalmology is important to monitor for papilledema and intervene via optic nerve fenestration or VP shunting if medical therapy fails.

A NEW FACIAL EXPRESSION TO BOTOX Aakash Aggarwal; Emerald Banas; Praveen Sampath; Ajoy Roy. SUNY Upstate Medical University, Syracuse, NY. (Tracking ID #1638099)

LEARNING OBJECTIVE 1: Present a rare case of anaphylaxis to Botox
CASE: A 47 year old African American male presented with complaints of dysphagia. As reported by the patient, he had a long standing history of endoscopically confirmed achalasia and already had had a surgical myotomy as well as a pneumatic dilation with temporary relief of symptoms but now had recurrence of symptoms. A barium swallow revealed no esophageal emptying while the patient was supine and a slow emptying while the patient was upright. During the endoscopy the patient was premedicated with Fentanyl 200 mcg IV and Midazolam 5 mg IV. Notably the patient had received both Fentanyl and Midazolam in previous endoscopies without any complications. During the procedure, 90 units of botulinum toxin(botox) was injected into the lower esophageal sphincter. Soon after the injection the patient's eyes and face started swelling up, Systolic blood pressure was in the 220's and patient was tachycardic in the 120's and his oxygen saturation dropped into the 70's. Intubation was attempted but was unsuccessful due to extreme vocal cord edema. An emergency cricothyroidotomy was performed and the patient was also given 100 mg of hydrocortisone IV and 50 mg of diphenhydramine IV and then shifted to the medical intensive care unit(MICU) after stabilization. In the MICU, the patient was ventilated using the cricothyroidotomy tube for 2 days and given IV dexamethasone. The cricothyroidotomy tube was taken out due to the risk of tracheal stenosis and endotracheal intubation was done. A day after the intubation, the patient was extubated successfully and transferred to the floor and discharged to home in stable condition the next day.
DISCUSSION: Botulinum toxin is a neurotoxin produced by the spore forming anaerobic bacillus, Clostridium botulinum. Its therapeutic use was first studied in the 1960s and was finally used in the 1980's. In 1993, Pasricha and colleagues demonstrated its use in achalasia. We present a rare case of anaphylactic reaction to botox. Anaphylaxis is defined as acute onset of an illness (minutes to several hours) involving the skin, mucosal tissue, or both and at least one of the following: A) Respiratory compromise B) Reduced blood pressure (BP) or associated symptoms and signs of end-organ dysfunction A systematic study of 20 randomized clinical trials was done on the adverse effects associated with the use of botulinum toxin type A for spasticity associated with cerebral palsy. No adverse effects were reported among six studies. Botox use was mostly associated with mild respiratory effects, falls, seizures and unspecified pain. Serious side effects of botox are very rare and only one case of anaphylaxis to botox was found in the literature. However, in that publication, the Botox was reconstituted in 1 % lidocaine, which raises the question that the anaphylaxis may have been due to lidocaine instead of the Botox. Despite the reported safety of any drug, all drugs deserve preparation for an emergency reaction. This is very important with a drug like Botox as it is being used more and more in a wide variety of GI conditions including achalasia.

A PLUMBER'S DREAM Jordan Turk; Aman Shah; Lauren Shapiro. Montefiore Medical Center, Bronx, NY. (Tracking ID #1642381)

LEARNING OBJECTIVE 1: Recognize that mechanical heart valves can cause symptomatic anemia
LEARNING OBJECTIVE 2: Diagnose and treat anemia associated with mechanical heart valves.
CASE: A 39-year-old woman presented with shortness of breath, new dyspnea on exertion, general malaise, and subjective fevers for 2 weeks. She has a history of mechanical aortic and mechanical mitral valve replacement within the past year for a unicuspid aortic valve and mitral valve incompetence of unknown origin. Presenting vitals were a temperature of 98.9 F, blood pressure of 95/65 mmHg and a heart rate of 110 bpm. She appeared jaundiced, tachycardic, with a new 4/6 holosystolic murmur at the cardiac apex, radiating to the axilla, clear lungs, jugular venous distension to 14 cm and 2+ pitting edema extending to the knees bilaterally. Labs: WBC of 11.2 K/ul, hemoglobin of 5.8 g/dL (baseline is 10 g/dL), MCV of 103.6 Fl, LDH of 2499 U/L (normal: 100–190 U/L), total bilirubin of 2.8 mg/dL, direct bilirubin of 0.5 mg/dL, an undetectable haptoglobin level, reticulocyte count of 5 %, and 1+ schistocytes on peripheral blood smear. These labs were normal prior to her valvular replacements. Echocardiogram showed new severe mitral paravalvular regurgitation. The patient was transfused and CT surgery was consulted. The patient had her mitral valve replaced without complication. One month following surgery, the patient's hemoglobin returned to her baseline.
DISCUSSION: An internist will commonly manage patients with mechanical heart valves. An understanding of the complications associated with these valves is essential to decreasing potential morbidity and mortality. A common complication that should be recognized is microangiopathic hemolytic anemia caused by mechanical heart valves. The valves create turbulent flow as blood passes through, exposing cells to greater sheer stress than native valves. Red blood cells lyse under this increased pressure resulting in mechanical hemolysis. The cells may face even greater sheer stress if the mechanical valve develops a paravalvular leak, which is characterized by an abnormal backward flow between the ring of the mechanical valve and the annulus of the native valve. Further hemolysis can occur due to concurrent iron deficiency as it causes increased red blood cell fragility. Patients will present with common complaints of anemia such as fatigue, dyspnea on exertion and palpitations. They also present with signs of intravascular hemolysis such as darkening of their urine, or yellowing of their skin. Physical exam may reveal jaundice, tachycardia, a flow murmur, change in the characteristic of a previous existing murmur, and signs of heart failure. Laboratory assessment favoring diagnosis include anemia, elevated LDH, elevated indirect bilirubin, elevated reticulocyte count, decreased haptoglobin, and schistocytes on peripheral blood smear. This mechanical hemolysis, is generally mild, however it may be severe in up to 15 % of patients. Mild cases of anemia are managed conservatively with iron supplements and/or blood transfusions, while more severe cases may require surgical intervention including valve replacement.

A PUZZLING CASE OF NAUSEA AD NAUSEAM Kavel Visrodia; Raina Shivashankar; Amy T. Wang. Mayo Clinic Rochester, Rochester, MN. (Tracking ID #1642615)

LEARNING OBJECTIVE 1: Recognize causes of thyroid dysfunction in the context of primary adrenal insufficiency.
LEARNING OBJECTIVE 2: Consider adrenal insufficiency in a symptomatic hypothyroid patient who worsens with thyroxine replacement.
CASE: A 58-year-old woman presented with 10 days of worsening nausea, vomiting, fatigue, generalized weakness and dry cough. Her medical history was significant for hypothyroidism diagnosed 18 months ago when she presented to her primary care provider for unremitting nausea. Work up at that time revealed a TSH 7.4 mIU/L, normal T3, T4, TPO antibodies and she was started on thyroxine replacement, though her symptoms worsened. On presentation to our institution, her blood pressure was 61/50 and pulse was 60. Physical examination revealed decreased skin turgor, dry mucous membranes and hyperpigmentation of her face, neck, arms and palmar creases. Over the last year, she noted compliments on her "tan" and questions regarding "dye" on her palms. Labs showed a normocytic anemia (hemoglobin, 9.9 g/dL), hyponatremia (124 mmol/L), hyperkalemia (6.0 mmol/L) and raised creatinine (1.2 mg/dL). Chest x-ray suggested an atypical pneumonia and a random cortisol returned low at 4.2 mcg/dL. She received 9 l of IV fluids, antibiotics, and stress doses of dexamethasone were initiated due to concern for adrenal crisis. She had rapid clinical improvement with resolution of her nausea. Adrenal function tests confirmed primary adrenal insufficiency with baseline AM cortisol <1.0 mcg/dL, which minimally increased to 1.3 mcg/dL 30 min after cosyntropin challenge (0.25 mg IV), and aldosterone <4.0 ng/dL. Repeat TSH was 2.4 mIU/L while on thyroxine. Abdominal CT and extensive infectious workup was unremarkable, while a 21-hydroxylase antibody level was elevated (60 U/mL), confirming the diagnosis of autoimmune adrenalitis.

DISCUSSION: We describe a case of unrecognized primary adrenal insufficiency in which elevated TSH along with symptoms suggestive of adrenal insufficiency may have been a first clue to early diagnosis. Thyroid function abnormalities are often seen with adrenal insufficiency given that cortisol deficiency impairs thyroid function resulting in an elevated TSH. During crises, thyroxine replacement can accelerate cortisol degradation exacerbating symptoms of hypocortisolism, and should be avoided. In the absence of autoimmune thyroid disease, thyroid function abnormalities often resolve with glucocorticoid replacement. Alternative thyroid dysfunction may be secondary to coexisting autoimmune hypothyroidism, supported by elevated antibodies to thyroglobulin or anti-thyroid peroxidase, suggesting autoimmune polyglandular syndrome (APS1 or APS2). APS2 is inheritable, more prevalent and characterized by autoimmune thyroiditis, autoimmune adrenal insufficiency and type 1 diabetes mellitus. 18 months prior, our patient had negative TPO antibodies, thus coexisting autoimmune hypothyroidism (and APS) was thought to be less likely. Because her symptoms worsened with thyroxine replacement, it is likely that her elevated TSH was due to adrenal insufficiency. The patient was discharged with endocrinology follow up for optimizing steroid doses and discontinuation of thyroxine. This case highlights the importance of maintaining a wide differential when working up chronic nausea and fatigue, especially in the setting of thyroid abnormalities. Adrenal crisis is potentially life threatening, and early diagnosis of adrenal insufficiency may help prevent an acute decompensation.

A QUESTION OF AMYLOID? Claiborne Childs. NYH-WCMC, New York, NY. (Tracking ID #1643534)

LEARNING OBJECTIVE 1: Review the diagnostic criteria for primary amyloidosis
LEARNING OBJECTIVE 2: Review useful studies for detecting amyloidosis
CASE: A 38-year-old man presents to his primary care physician with a chief complaint oftwo to three months of fatigue and decreased exercise tolerance. Initial labs revealed anemia, an elevated creatinine, and high urine protein. The patient was subsequently referred to a nephrologist for further work-up of renal disease. One month later, the patient began to develop worsened fatigue, increased swelling in lower extremities, and dyspnea on exertion. Repeat labs showed worsened kidney disease and he was referred to the ED for admission and further work-up. During the hospitalization, the patient was started on dialysis in the setting of acute renal failure. A renal ultrasound showed echogenic kidneys without cysts, malignancies, or other structural abnormalities. Urinalysis was notable for pyuria, microscopic hematuria, and elevated protein. Urine cultures were negative. On physical exam, an abnormal third heart was noted and a subsequent cardiac echocardiogram revealed diffuse hypokinesis, left ventricular hypertrophy, moderate pulmonary hypertension, and aejection fraction of 20 %, findings suggestive of systolic heart failure. In determining how to correlate this patient's renal and cardiac disease multiple studies where ordered. Of note, the kappa and lambda light chains as well as kappa/lambda ratio were found to be elevated, suggestive of a protein deposition disease. Subsequently, an abdominal fat pad biopsy stained positive for apple-green birefringent material on Congo red stain under polarized light, consistent with amyloid. The patient underwent cardiac catheterization, which showed normal coronary arteries and mild pulmonary hypertension. A biopsy of the right ventricular myocardium was obtained and was ultimately negative for amyloid. Cardiac MRI was deferred because of the patient's renal failure. The patient improved following the initiation of dialysis and was later discharged from the hospital.
DISCUSSION: The criteria for diagnosis of primary amyloidosis include all of the following: 1) Presence of an amyloid-related systemic syndrome (ex. renal, liver, heart, or gastrointestinal tract involvement). 2) Positive amyloid staining by Congo red in any tissue (ex. fat aspirate, bone marrow or organ biopsy) or the presence of amyloid fibrils on electron microscopy. 3) Evidence that the amyloid is light chain-related established by direct examination of the amyloid, and 4) Evidence of a monoclonal plasma cell proliferative disorder (ex., presence of a serum or urine M protein, abnormal serum free light chain ratio, or clonal plasma cells in the bone marrow). Approximately 2–3 % of patients with primary amyloidosis will not meet criteria. With regard to evaluation, the initial work-up should include: serum free light chain ration, serum and urine immunofixation, and a fat pad biopsy. Abdominal fat pad biopsies are positive in 60–80 % of cases. When cardiac amyloid is suspected, endomyocardial biopsy hasbeen shown in prior studies to be greater than 90 % sensitive for detecting diffuse cardiac involvement. The sensitivity of cardiac MRI in diagnosis of cardiac amyloid is still unknown. This case illustrates the complexity of amyloidosis and the variability of results. In cases where patients present with multi-organ dysfunction, it should be considered.

A RARE BIRD Brian J. Secemsky; Marcia Glass. University of California—San Francisco, San Francisco, CA. (Tracking ID #1626496)

LEARNING OBJECTIVE 1: Recognize atypical clinical patterns of varicella zoster virus
LEARNING OBJECTIVE 2: Identify characteristic CSF patterns of varicella meningitis
CASE: A 38 year-old man presented to an outside hospital for 3 weeks of worsening headaches, fevers, nocturnal diaphoresis and altered mental status. After 4 days of treatment, the patient came to our medical center for further care. He was fully oriented with photosensitivity, oropharyngeal exudates and tender bilateral cervical lymphadenopathy. His neck was stiff and painful to palpation. He had no rashes. Lumbar puncture revealed cloudy cerebral spinal fluid with an opening pressure of 13, white blood cell count of 428 with 54 % lymphocytic predominance, protein of 88 and glucose of 37 (serum glucose 102). Cellular specimen predominantly consisted of small, mature-looking lymphoid cells with admixed larger lymphocytes. Cerebral spinal fluid workup was positive for varicella zoster virus using polymerase chain reaction. The patient was unsure if he had chicken pox as a child but said he was exposed to varicella from an infant with chickenpox 1 week prior to the onset of his symptoms. He was treated for 2 days as an inpatient with marked clinical improvement. The patient preferred not to take intravenous antibiotics and went home with a regimen of oral acyclovir.
DISCUSSION: Varicella zoster virus (VZV) is a herpesvirus that causes two distinct diseases: varicella (chickenpox) and herpes zoster (shingles). In unvaccinated populations, these clinical forms of VZV have incidences of up to 95 % and 35 %, respectively. While these discrete illnesses classically involve a rash, uncommon manifestations of VZV can make an early diagnosis challenging to internists. As seen in our patient, this is especially true in lieu of skin findings. For this reason, it is imperative for practitioners to be aware of the extra-integumentary signs of VZV infection. Aseptic meningitis is a rare complication of VZV infection that can occur in either stage of infection. Consistent with our patient's CSF analysis, lumbar puncture often reveals a lymphocytic pleocytosis with an elevated protein concentration. A concomitant positive varicella PCR is a useful laboratory finding in diagnosing VZV meningitis. Because oral antivirals have minimal CSF penetration, intravenous acyclovir is the treatment of choice. Since our patient preferred not to take intravenous therapy at home, he was discharged on oral acyclovir. Our patient was admitted for subacute meningitis without a rash, making the diagnosis of VZV infection challenging. After the varicella PCR returned positive, we obtained a key history of VZV exposure. Internists should be wary of atypical VZV manifestations, and should always get an exposure and vaccination history of varicella zoster virus when diagnosing subacute meningitis.

A RARE CASE OF PUSTULAR PSORIASIS AND VANCOMYCIN-INDUCED LINEAR IGA DISEASE MIMICKING TEN Shira Eytan; Celine Mestel; Bradley Flansbaum. Lenox Hill Hospital, new york, NY. (Tracking ID #1635545)

LEARNING OBJECTIVE 1: To recognize a rare but known side effect of Vancomycin.

LEARNING OBJECTIVE 2: To recognize anchoring bias in difficult diagnoses.
CASE: A 77 year old female with a remote history of mild psoriasis, previously controlled with topical medication, presented with erythema of her left forearm and a scaly rash, worse on her thighs. She had multiple erythematous patches with small 2–3 mm pustular clusters across her skin, sparing the face, palms, and soles. Her appearance was consistent with psoriasis; however, her left arm was atypically more erythematous than elsewhere on her body. Her outpatient dermatologist was treating the patient for cellulitis. On admission, she received vancomycin. After several days of antibiotic therapy, her left arm was unchanged and the body wide patches worsened and became more confluent. As the patient was afebrile with a normal WBC count, infection seemed unlikely, and we stopped antibiotics. Her rash began to improve and she went home on topical steroids with dermatology follow-up. Forty-eight hours later, she returned to the ED complaining of leg edema, and again received vancomycin. Her rash worsened. She then developed lesions on her oral and vaginal mucosa, with significant desquamation and >10 % skin sloughing (erythrodermic flare). Given the patient's deterioration, we transferred her to an outside burn unit for management of possible TEN. Punch biopsy revealed Linear IgA Disease. After cessation of vancomycin, her skin improved. However, she developed MSSA bacteremia and required a prolonged hospital stay.
DISCUSSION: Linear IgA Disease (LAD) is a rare autoimmune disorder with an estimated incidence of 1/250,000 cases per year. The etiology may be idiopathic or drug-induced. Drug-induced LAD develops within 1–15 days of medication exposure, and usually improves after cessation of the offending drug. We report a case of a 77-year-old immunocompetent patient with pustular psoriasis who was "misdiagnosed" with cellulitis. She in fact developed linear IgA Disease, mimicking toxic epidermal necrolysis (TEN). Her IgA condition was likely secondary to vancomycin. Our patient had known psoriasis, and her severe skin pathology, "consistent with her prior history," misled the caring physicians. The delayed diagnosis was due to anchoring bias. Although our patient's disease was rare, cognitive bias may have played a role in impeding transfer and altering her care. The diagnosis may have been made earlier by recognizing the uncharacteristically evolving skin lesions. They corresponded to antibiotic administration; the pattern of her clinical progression was also not typical of her baseline diagnosis.

A RARE CASE OF DISSEMINATED MUCORMYCOSIS IN A PATIENT WITHOUT SEVERE IMMUNOCOMPROMISE Arta Lahiji[1]; Yasmeen Kabir[1]; Wilson Quezada[2]. [1]UCLA Olive View Medical Center, Sylmar, CA; [2]Columbia University Medical Center, New York, NY. (Tracking ID #1642929)

LEARNING OBJECTIVE 1: Disseminated mucormycosis should be considered and aggressively managed even in patients without severe immunocompromise.
CASE: This is a 68 year-old female with a past medical history of uncontrolled DMII, end stage renal disease on dialysis, and congestive heart failure (CHF) admitted with acute on chronic CHF. She developed worsening shortness of breath and a chest CT on hospital day (HD) #10 showed a large RLL cavitating pneumonia and she was started on empiric broad spectrum antibiotics. A pigtail catheter and subsequently a larger chest tube was placed on HD #11. Pleural fluid cultures grew H. influenzae, C. albicans and Rhizomucor sp, and amphotericin B and posaconazole were started on HD #16. The patient was not a good surgical candidate and despite aggressive antifungal therapy, suffered two PEA arrests after an episode of severe hemoptysis. Resuscitation was unsuccessful and the patient died HD #20. Post mortem examination revealed disseminated mucormycosis involving the lung, pancreas, thyroid, and spleen.
DISCUSSION: Mucormycosis is a rare fungal infection that typically occurs with an underlying condition including diabetes mellitus (DM), malignancy, organ transplantation, injection drug use, bone marrow transplantation, and renal failure. Common primary infection sites include sinus, pulmonary, cutaneous, cerebral, gastrointestinal, and renal. Patients with DM typically present with rhinocerebral, pulmonary, and sino-orbital disease. Disseminated disease (infection at > 2 non-contiguous sites) has been reported in 23 % of cases, typically occurs in patients with severe immunocompromise, and is associated with a mortality of 96 %. Treatment involves a combination of antifungal therapy, surgical debridement, and/or lobectomy. While mucormycosis may occur in patients with no immune impairment, or greater immunocompetency, such as in DM alone, disseminated mucormycosis typically occurs in patients with severe immunocompromise. In a series of 929 patients, the risk factors that were shown to be associated with disseminated mucormycosis include burns, prematurity, and deferoxamine use, while DM was not shown to be a risk factor, and was actually associated with a decreased odds of disseminated disease (OR=0.29, 95 % CI 0.17–0.51). Disseminated mucormycosis as seen in our patient with underlying DM and renal failure without severe immunocompromise is uncommon but nevertheless was fatal despite aggressive antifungal therapy. While treatment typically significantly improves survival, mortality remains high particularly in disseminated disease, as evident even in our patient without severe immunocompromise.

A RARE CAUSE OF ANGINAL CHEST PAIN Pooja Sethi; Ankit Madan; Philip Putnam; Tamjeed Arshad. University Of Alabama Birmingham Montgomery, Montgomery, AL. (Tracking ID #1642860)

LEARNING OBJECTIVE 1: To learn about a rare cause of anginal chest pain.
LEARNING OBJECTIVE 2: To discuss management of an unusual cause of angina.
CASE: A 52 year old African American male with diabetes mellitus, hypertension, and family history of coronary artery disease presented to clinic with episodes of intermittent, sharp, shooting, non-radiating, mid sternal chest pain which is 10/10 in intensity. The pain was relieved with sublingual nitroglycerin. He denied any palpitations, paroxysmal nocturnal dyspnea or orthopnea. Physical exam showed normal vital signs, no JVD, normal heart sounds without murmurs on auscultation. There was no pedal edema. A 12-lead EKG shows normal sinus rhythm, no ST segment changes, normal QT interval and borderline left ventricular hypertrophy (LVH). His echocardiography showed normal LV ejection fraction with mild LVH. The patient underwent cardiac stress testing that showed inducible angina with apical and septal ischemia. He was treated with aspirin and clopidogrel and taken for elective cardiac catheterization. The cardiac catheterization showed 70 % stenosis in the Left anterior descending (LAD) territory. Incidentally noted was a Right coronary artery (RCA) to left ventricle (LV) fistula. The fistula was considered asymptomatic. The LAD was stented and the patient was discharged. The patient remained asymptomatic for 6 months but again developed recurrent chest pain similar to previous episodes. The possibility of stent thrombosis was considered and a repeat catheterization was done which showed a widely patent stent. Again noted was the RCA to LV fistula but now the RCA was very ectatic and three times the normal size. The patient was scheduled for coronary bypass surgery and the fistula was ligated and repaired. Patient tolerated the procedure well. He remains chest pain free at 12 month follow up visit.
DISCUSSION: A communication between a coronary artery and a heart chamber is called coronary cameral fistula and involvement of any segment of the systemic or pulmonary circulation is called coronary arteriovenous fistula. The incidence of Coronary Artery Fistula (CAF) is 0.1 % in patients undergoing cardiac catheterization and 0.002 % in the general population. Most CAF drain in the right side of the heart. Fistula draining into the left ventricle is extremely rare and account for 3 % of all CAF. Despite the occurrence of systolic murmur in majority of cases, our patient did not have any appreciable murmur throughout patient care. Most coronary artery fistulas are small, do not cause any symptoms, and are clinically undetectable. Larger, detectable fistulae are usually three times the size of a normal caliber of a coronary artery and can cause symptoms or complications such as myocardial ischemia because of a coronary steal mechanism, congestive heart failure, infective endocarditis, and rupture or thrombosis of the fistula. Treatment of CAF depends on presence of

symptoms. Treatment of asymptomatic fistulas remains controversial but expert opinion favors early treatment in most cases. For symptomatic fistulas, coronary artery bypass surgery with fistula repair is the treatment of choice. Newer modalities like percutaneous embolization for fistula repair are being explored.

A RARE CAUSE OF JAUNDICE AND AUTOIMMUNE HEMOLYTIC ANEMIA: DON'T FORGET EBV Shira Eytan; Bartosz Walczyszyn; Robert E. Graham. Lenox Hill Hospital, new york, NY. (Tracking ID #1622219)

LEARNING OBJECTIVE 1: To recognize the less common complications of infectious mononucleosis.
CASE: An 18 year old man with no significant past medical history presented to our emergency room with jaundice. He reported a transient urticarial rash, paroxysmal fevers, sore throat, myalgia, neck fullness, fatigue, abdominal discomfort and yellowing of the eyes and skin 1 week prior to presentation. He denied any medications. Social and family history were noncontributory. On physical exam vital signs were notable for a T-max of 102 °F. Pertinent findings revealed jaundice, scleral icterus, erythematous oropharynx with enlarged tonsils, and 1–2 cm tender posterior auricular, submandibular and cervical lymphadenopathy bilaterally. On abdominal exam, mild tenderness to palpation of left upper quadrant was noted and hepatosplenomegaly was appreciated. Pertinent labs revealed a total bilirubin of 8.2 mg/dL, direct bili 1.8 mg/dL, alk phos 215 U/L, ALT 370 U/L, AST 269 U/L. CBC showed lymphocytosis of 22×103/μL with 52 % lymphocytes, Hgb 12.3 g/dL, Hct 32.9 %, MCV 100.8 fL. Hepatitis screen for transaminitis showed reactive HBsAb, but was otherwise negative, as was the HIV screen. Given his jaundice with elevated indirect bilirubin, further workup was done which showed LDH 1061 U/L, haptoglobin 8.0 mg/dL, and reticulocyte count 4.8 %, consistent with hemolysis. CT Abdomen/Pelvis performed for abdominal pain showed hepatomegaly of 19 cm and splenomegaly of 17.4 cm in cephalocaudal length. Inpatient workup the next day revealed Infectious Mono test for heterophile antibodies to be positive. Furthermore, EBV IgM and IgG both returned positive, consistent with recent infection. Direct Antiglobulin Test was sent for workup of anemia and returned positive, confirming autoimmune hemolytic anemia. The patient was monitored another day to follow his CBC; his Hgb stabilized at 10 gm/dL, LFTS and WBC began to decrease and patient was discharged home with close follow up and diagnosis of infectious mononucleosis complicated by autoimmune hemolytic anemia and transaminitis.
DISCUSSION: Epstein-Barr Virus (EBV) is one of the human herpesvirus and a common cause of infectious mononucleosis and children and young adults, and often presents with symptoms of fever, pharyngitis, lymphadenopathy, and splenomegaly. Autoimmune hemolytic anemia is an established but rare (~1:1000 patients) complication of EBV which may be life-threatening. Our case describes infectious mononucleosis that exemplifies the more uncommon complications that may occur. Our patient's first presentation was jaundice and an urticarial rash, and he was found to have autoimmune hemolytic anemia. Practitioners need to have high clinical suspicion for EBV, even with a presentation of hemolytic anemia and hepatitis, in order to avoid further extensive work up. This complication may be lethal, and needs to be closely monitored.

A RARE CAUSE OF RIGHT UPPER QUADRANT ABDOMINAL PAIN Soujanya Sodavarapu; Amanada Scott; Stephen Hosea. santa barbara cottage hospital, santa barbara, CA. (Tracking ID #1626133)

LEARNING OBJECTIVE 1: Right upper quadrant (RUQ) abdominal pain is often associated with biliary, hepatic or gastrointestinal ailments. This case demonstrates a patient who presented with severe RUQ pain and an initially negative workup. Only after closely reviewing her history of transient upper back pain, was it discovered that vertebral osteomyelitis with radiculopathy was the cause of this patient's abdominal pain.
CASE: This patient is a 50-year-old female with a history of right lower extremity osteomyelitis who presented to the emergency department (ED) with acute onset of upper back pain and shortness of breath. In the ED, her vital signs were normal and her white count was noted to be 14.2 with 30 % bands. In addition, her CRP was elevated at 162. The patient had a chest x-ray and CT of the chest with contrast; both studies were unremarkable. The patient was started on broad spectrum antibiotics and admitted. The next morning, her back pain had resolved, but in its place, a sharp, RUQ abdominal pain began. This pain did not radiate, was constant, and was not associated with nausea, vomiting, diarrhea or constipation, but she did complain of a decreased appetite. On exam, she was extremely tender in the RUQ and was guarding on palpation. The pain was exacerbated by deep breaths, but murphy's sign was negative. Her liver enzymes, liver function tests and ultrasound of the abdomen were normal. She had a HIDA scan that showed patent ducts. Upper Endoscopy also showed no abnormalities. The patient was requiring high doses of I.V. morphine and a proton pump inhibitor did not offer any relief. At this point, a closer review of her initial presentation with transient back pain lead to obtaining an MRI of spine focusing on T6-T8 levels. The MRI revealed early discitis/osteomyelitis at T5-T7. Given her chronic osteomyletitis and many debridements, likely a bacteremia had seeded the vertebral bodies and the disc. The patient was started on I.V. toradol, and her RUQ pain significantly improved. Both her blood cultures and her wound culture grew group B streptococcus which was consistent with the likely etiology. The patient was then discharged with 6 weeks of I.V. antibiotics and outpatient follow up.
DISCUSSION: Right upper quadrant pain is a common complaint and is immediately associated with diseases such as cholecystitis, hepatitis and biliary colic. Other causes such as pneumonia or subdiaphragmatic abscess are also considered by most physicians. But sometimes when the etiology remains elusive, one needs to closely review the case and consider other, more unique causes of abdominal pain such as vertebral osteomyelitis.

A RARE OPPORTUNISTIC INFECTION Himabindu Kadiyala; Zichun Feng. Michael Debakey VA Medical Center, Houston, TX. (Tracking ID #1638752)

LEARNING OBJECTIVE 1: To learn about a rare opportunistic infection causing multi-system disease.
CASE: Our patient is a 54 year old Caucasian male with a past medical history of HIV-AIDS, CD4 count of 4, not on HAART or prophylactic antibiotics, history of multiple pneumocystis pneumonia, who presented with complaints of worsening abdominal pain and diarrhea. One week prior to admission, patient started to experience crampy abdominal pain along with diarrhea, fever, and chills. The diarrhea was non-bloody, small volume, watery, and mucoid. Review of systems is otherwise negative except for 10 lb unintentional weight loss in the last 5 months, and chronic cough productive of greenish sputum. On exam, patient was febrile to 102 F, hemodynamically stable, and O2 saturation 95 % on room air. Lung exam revealed occasional rhonchi but no crackles. There was tenderness to palpation in upper abdomen. CT abdomen showed non-obstructive pattern and likely colitis. Chest X-ray was clear. Quanteferron Gold was negative from 1 month ago. Pt was started on IV fluids, Ciprofloxacin and Flagyl for colitis. Stool studies were ordered. The day after admission, patient suddenly became short of breath and desaturated to 70–80's on 2 L oxygen. Breathing was labored with use of accessory muscles. After giving 100 % non-rebreather mask, patient's oxygen saturation increased to 94 %. A repeat chest x-ray showed widespread interstitial nodular opacities, most concerning for PCP. Bactrim and steroids were started. Patient was transferred to MICU. Overnight, patient had further respiratory distress on 100 % oxygen and was intubated and mechanically ventilated. Bronchoscopy with BAL revealed parasites consistent with Strongyloides larvae. Ivermectin and Albendazole were started immediately. Later, stool cultures were also positive for larvae of Strongyloides. Studies for pneumocystis were negative.
DISCUSSION: Strongyloides is a common parasite in developing countries. However, in developed countries, strongyloides is a rare parasite infection that affects mostly elderly and/or immunocompromised patients. Infection occurs when filariform larvae in soil penetrate the skin, enter the

bloodstream, and are carried to the lungs, where they escape from capillaries into alveoli and ascend the bronchial tree to the glottis. The larvae are then swallowed and carried to the duodenum and upper jejunum, where maturation to the adult stage takes place. The female parasite matures and lives embedded in the mucosa, where its eggs are laid and hatch. Rhabditiform larvae, which are non-infective emerge, and migrate into the intestinal lumen and leave the host via the feces. In the soil, the rhabditiform larvae metamorphose into the filariform or infective larvae. The time from larval penetration of the skin by filariform larvae until their appearance in the feces is 3–4 weeks. Patients usually present with pruritic dermatitis at the site of larval penetration, diarrhea, epigastric pain, nausea, malaise, weight loss, cough, rales, transient pulmonary infiltrates, and eosinophilia. Diagnosis requires finding the larval stages in feces or duodenal fluid. Ivermectin is the drug of choice. In disseminated disease, combination of Ivermectim and Albendazole are used.

A RECURRENT INTESTINAL HEMATOMA IN NEUROFIBROMATOSIS TYPE 1 Yaser Alkhatib[1]; Philip Kuriakose[2]. [1]Henry Ford Hospital, Detroit, MI; [2]Henry Ford Hospital, Detroit, MI. (Tracking ID #1624088)

LEARNING OBJECTIVE 1: Intestinal hematoma can develop in neurofibromatosis type 1, and it has never been described in the literature
CASE: A 32-year-old African American male presented to our hospital with abdominal pain, nausea, and vomiting which started 1 day prior to presentation. He denied any trauma, recent accidents, or history suggestive of coagulopathy. His past medical history was significant for neurofibromatosis type-1 and a laproscopic evacuation of spontaneous intestinal hematoma 1 year ago. He was not on any medications. He admitted drinking 2–3 beers on the weekends, but denies smoking or using illicit drugs. Physical examination showed a patient who was in pain, with diffuse abdominal tenderness mostly in the right upper quadrant. A suspicion of acute pancreatitis was raised; however patient had normal amylase and lipase levels. Ultrasound of the abdomen ruled out presence of gallbladder stones. His hemoglobin was stable initially, but started to drop few hours later. Acute abdominal series was suggestive of small bowel obstruction and CT scan raised a suspicion of intestinal hematoma, which was similar in site to the previous one. Patient was sent to interventional radiology for embolization of the bleeding artery, however, it failed to identify a source of bleeding. Patient was then kept NPO, with naso-gastric (NG) tube for gastric decompression. Two days later, the patient started to improve, and his NG tube was removed. He tolerated oral feeds and didn't require any surgery. His hemoglobin stabilized after transfusing 2 units of PRBCs. A repeat of CT scan 4 weeks later showed resolution of the previously seen hematoma. He was diagnosed with recurrent spontaneous intestinal hematomas secondary to neurofibromatosis type-1.
DISCUSSION: Neurofibromatosis type-1 (von Recklinghausen's disease) is one of the most common autosomal dominant hereditary tumor syndromes. The hallmark of the disease is the presence of café-au-lait spots and cutaneous neurofibromas. Gastrointestinal involvement has been described in different forms, including true neurogenic tumors (neurofibromas, Schwannomas), interstitial cell of Cajal lesions (GIST tumors), neuroendocrine tumors (carcinoids, gastrinoma, insulinoma), and rarely vasculopathies. Spontaneous intestinal hematoma has never been described in the literature. Herein we present the first reported case of recurrent spontaneous intestinal hematoma as a gastrointestinal manifestation of neurofibromatosis type-1 which might be secondary to a vasculopathy, or other unidentified reason.

A SNEAKY SICKLE Kenneth Levin; Caley McIntyre; Deepa Bhatnagar. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640518)

LEARNING OBJECTIVE 1: Recognize the causes of microcytic anemia
LEARNING OBJECTIVE 2: Understand the role of hemoglobin electrophoresis in microcytic anemia Understand the complications of a sickle-cell variant

CASE: A 56 year-old man initially presented with chest pain. This left-sided chest pressure was associated with shortness of breath and fatigue. His past medical history included hypertension, hyperlipidiemia, peripheral vascular disease and coronary artery disease requiring coronary artery bypass grafting. He was initially evaluated for an acute coronary syndrome with three negative troponins and an echocardiogram which showed no change from prior imaging. The patient's laboratory evaluation revealed a hemoglobin of 7.6 g/dL. Mean corpuscular volume was 68.2 fL and red cell distribution width was 17.2 um. Platelets were mildly decreased at 135×103/uL. Serum iron studies were normal. Ferritin was normal. Reticulocyte count was 1.5, corrected to 0.8 with 23 % immature reticulocytes. Colonoscopy and EGD showed no signs of active or recent bleeding. A peripheral blood smear showed occasional schistocytes with no sideroblasts or basophilic stippling. A hemoglobin electrophoresis was performed given the unexplained microcytosis. It showed Hemoglobin A1 of 14.8 %, Hemoglobin S of 73.8 %, Hemoglobin A2 of 6.5 %, Hemoglobin F of 4.9 % and Hgb C of 0 %, consistent with Sickle Beta + Thalassemia. The patient was transfused with 2 units of packed red blood cells in the hospital and started on folate supplementation. He was cautioned against use of iron-containing multivitamins or supplements. He was also instructed to have an annual dilated fundus exam and cautioned to take his blood pressure medication daily.
DISCUSSION: A general internist often encounters anemia in their practice. An approach to the work-up for anemia is key to ensuring no diagnosis is missed. The differential diagnosis for microcytic anemia commonly includes iron deficiency anemia, anemia of chronic disease, lead poisoning, sideroblastic anemia, and hemoglobinopathies. When a hemoglobinopathy is suspected, a hemoglobin electrophoresis should be ordered as the results will usually be definitive for diagnosis. Sickle-beta + thalassemia is an example of a hemoglobinopathy and is a rare variant of sickle cell disease. Patients are compound heterozygotes, inheriting one gene for hemoglobin S and one gene for beta thalassemia. This abnormality results in variably decreased production of Hb A and increased production of Hb S. It is milder than its counterpart, sickle-beta-0-thalassemia, in which the body has no beta-hemoglobin chains and is thus unable to produce Hb A. Most cases are discovered incidentally, with patients on average identified by age 8. Only 14 % of patients will experience acute chest syndrome and about 1/3 will have splenomegaly. Priapism and aplastic crises are uncommon. Sickle-beta + thalassemia does have an association with proliferative retinopathy and can occur in approximately 20 % of patients. Patients also have a higher risk of ischemic cardiac disease than the general population due to small-vessel disease. Recognition of the cause of microcytic anemia is crucial as it can lead to appropriate counseling and treatment for patients.

A SEARCH FOR SCROFULA Matthew T. Corey. Boston Medical Center, Cambridge, MA. (Tracking ID #1637799)

LEARNING OBJECTIVE 1: Diagnose tuberculous adenitis in a patient with unexplained cervical lymphadenopathy
CASE: A 34-year-old woman came to clinic complaining of a painful lump on the right, anterior neck. She first noticed the mass 6 months prior. On swallowing, the patient felt the mass was rising up and impinging on her throat. She had emigrated from Ethiopia 3 years earlier, worked as a nurse's assistant, and was never sexually active. Review of systems elicited a 5 kg, one-year weight loss, with no fevers, night sweats, or dysphagia. On exam, a smooth, mobile mass was palpated, 3×4 cm in size, and tender. Rapid HIV testing was negative. Computed tomography of the neck with contrast showed a conglomerate of necrotic lymph nodes in the right neck, with additional lymphadenopathy found in the right mediastinum and perihilar region. Fine needle aspiration biopsy of the neck mass found necrosis and inflammatory cells, but no malignancy. Tissue staining was negative for acid-fast bacilli, but a DNA:RNA probe revealed drug-sensitive Mycobacterium tuberculosis. The patient was hospitalized with airborne precautions, and induced sputum testing showed no acid-fast bacilli in sputum for 3 days. She was discharged on oral anti-

tuberculosis therapy. At clinic 3 months later, the mass had greatly decreased in size and was no longer painful.
DISCUSSION: When first seeing a young, healthy patient complaining of tender, enlarged lymph nodes, the clinician should consider a wide differential. History and physical, including examination of the axillary, inguinal, and supraclavicular areas, could lead to diagnoses of pharyngitis, mononucleosis, cat-scratch disease, or inflammatory disorders like sarcoid. An HIV test is imperative, as early seroconversion often presents with lymphadenopathy. Fever, weight loss, fatigue, and night sweats in a patient with lymphadenopathy immediately suggest hematologic malignancy, and often prompt excisional node biopsy. However, as patients born in endemic areas become ever more common in the United States, this same constellation of symptoms may suggest TB. Tuberculous lymphadenitis, historically called "scrofula," is the most common extrapulmonary manifestation of tuberculosis. Lymphatic drainage from an infected lung to the right supraclavicular chain is seen as the likeliest etiology of TB adenitis, but dental caries or tonsillar disease have also been proposed. Geldmacher et al. estimate that 7.5 % of TB patients present to clinics in northern Germany with adenitis, and of these cases, 63.3 % involve cervical lymph nodes. Epidemiologic studies worldwide show that TB adenitis is more likely to appear in young women than in older or male patients. To conclude, tuberculous adenitis should appear on the differential of any at-risk patient who appears with lymph node enlargement on history or exam.

A TRICKY TROPONIN Morgan J. Katz; Matthew N. Peters. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640395)

LEARNING OBJECTIVE 1: Identify pseudoaneursym of the mitral-aortic intervalvular fibrosa as a potential primary cause of common cardiac conditions.
LEARNING OBJECTIVE 2: Recognize trans-esophageal echocardiogram as the diagnostic test of choice to identify pseudoaneurysm of the mitral-aortic intervalvular fibrosa.
CASE: A 22 year-old man presented after 6 h of crushing and substernal chest pain and associated shortness of breath. He had recent methicillin resistant staphylococcus aureus endocarditis secondary to intravenous drug abuse for which he underwent treatment with 6 weeks of intravenous vancomycin. This was followed by aortic valve replacement with a bioprosthetic valve. On the current presentation, he was afebrile, had a blood pressure of 103/70 mmHg, a heart rate of 101 beats/min and his oxygen saturation was 98 % on room air. He had a 3/6 systolic ejection murmur loudest at the right 2nd intercostal space with radiation to the right carotid. The initial electrocardiogram revealed sinus tachycardia with T-wave inversions in the lateral precordial leads and his serum troponin I was 0.11 g/dL. A bedside transthoracic echocardiogram (TTE) revealed a left ventricular ejection fraction of 35 % with an eccentric aortic regurgitation jet. The bioprosthetic aortic valve showed no signs of vegetations. A possible abscess was noted at the aortic root. A subsequent transesophageal echocardiogram (TEE) revealed a pseudoaneurysm of the mitral-aortic intervalvular fibrosa (P-MAIVF) with associated partial dehiscence of the aortic valve, causing a paravalvular leak. The patient's chest pain was thought to be secondary to compression of the left circumflex coronary artery by the pseudoaneurysm. After he was stabilized and eradication of endocarditis was confirmed, he was scheduled for repair of the P-MAIVF as well as replacement of the faulty bioprosthetic aortic valve.
DISCUSSION: The mitral-aortic intervalvular fibrosa (MAIVF) is an area of fibrous tissue between the mitral and aortic valves. First described in 1966, P-MAIVF is a rare and potentially fatal condition due to infection of the MAIVF that can cause aneurysmal compression of the surrounding areas leading to myocardial infarction by compression of coronary arteries, pulmonary hypertension from compression of the pulmonary arteries, and mitral regurgitation from compression of the anterior leaflet of the mitral valve. Patients with a history of infective endocarditis or prior aortic valve repair presenting with new anginal symptoms or signs of cardiac decompensation should be evaluated with TEE as TTE is not sufficient to diagnose P-MAIVF. Once identified, surgical intervention should be performed to remove the aneurysm. P-MAIVF formation in endocarditis is a result of the poor vascular supply to the MAIVF. Whereas valvular infections in endocarditis may be cured with intravenous antibiotics, eradication of infection within the MAIVF is more difficult due to poor antibiotic tissue penetration. Infection and aneurysmal formation of the MAIVF is an unusual complication of endocarditis; the risk of infection is enhanced by the presence of aortic regurgitation due to endothelial damage and increased pathogen exposure via the regurgitant jet. Internists must be aware of this serious and potentially fatal complication so that TEE and prompt surgery consultation can be obtained as the symptoms and findings can easily be misdiagnosed as acute coronary syndrome.

A TAP TB RECKONED WITH Jean M. Mensz; Kevin D. Hauck; Lauren Shapiro. Montefiore Medical Center, Bronx, NY. (Tracking ID #1642586)

LEARNING OBJECTIVE 1: Recognize ascites as a clinical presentation of peritoneal tuberculosis.
LEARNING OBJECTIVE 2: Diagnose peritoneal tuberculosis when acid-fast staining and culture are initially negative.
CASE: A 34 year-old man from Mexico with a history of alcohol abuse complained of several weeks of generalized abdominal pain, nausea, vomiting, and increasing abdominal girth. He was febrile with scleral icterus and abdominal distension on exam. Serum amylase was 53 U/L; lipase was 67 U/L; aspartate aminotransferase was 107 U/L; alanine aminotransferase was 57 U/L; total bilirubin was 3.7 mg/dL; direct bilirubin was 1.8 mg/dL; alkaline phosphatase was 147 U/L. The peripheral white blood cell count was 14.4 k/uL. Blood, urine, respiratory and stool cultures did not grow any bacteria. Serologies for hepatitis B, C and HIV were negative. An ultrasound revealed ascites, with fluid analysis showing 960 white blood cells (336 neutrophils and 499 lymphocytes); ascites albumin was 1.6 g/dL and serum albumin-ascites gradient (SAAG) was 0.9 g/dL. The patient continued to have fevers, despite empiric treatment for spontaneous bacterial peritonitis with ceftriaxone, prompting the search for other diagnoses. No malignant cells were found on ascites cytology. Acid-fast bacilli (AFB) staining and culture of the ascites fluid were negative. Tuberculin skin testing was negative, but interferon-gamma release assay (IGRA) was positive. A CT scan of the abdomen revealed hepatic steatosis and peritoneal thickening. The patient was treated with rifampin, isoniazid, pyrazinamide, and ethambutol for suspected peritoneal tuberculosis (TB), with rapid resolution of fever and improvement in ascites. Eight weeks later, Mycobacterium tuberculosis was identified by DNA probe on ascites AFB culture.
DISCUSSION: Global incidence of TB is declining, but nearly 9 million new cases were diagnosed in 2011. Peritoneal TB accounts for less than 5 % of TB cases worldwide, but untreated, has mortality greater than 50 %. Index of suspicion must be high as the symptoms are nonspecific and the diagnostic yield of most tests is low. Infection occurs via hematogenous spread, or by ingestion of infected sputum, unpasteurized milk, or other infected food. The most common signs and symptoms are fever, abdominal pain, and ascites. Risk factors include cirrhosis, peritoneal dialysis, chronic steroid use, and HIV infection. The first step in diagnosis is analysis of ascites, which usually reveals a SAAG less than 1.1 g/dL and a predominance of lymphocytes. The presence of fever and normal ascites cytology distinguish TB from peritoneal carcinomatosis, which can have similar findings on ascites analysis. Tuberculin skin testing is often negative during active disease; IGRAs, which measure release of interferon-gamma by T cells in response to TB-specific antigens, likewise cannot distinguish between active and latent disease. Ascites AFB staining and culture have very low sensitivity, and detection of Mycobacteria may require 4 to 8 weeks. More rapid diagnostic methods are

polymerase chain reaction testing of ascites fluid for TB, and the measurement of ascites adenosine deaminase (ADA), an enzyme involved in lymphocyte maturation. Levels of ADA above 40 IU/L are sensitive and specific for peritoneal TB, but sensitivity declines in cirrhosis. Laparoscopy and peritoneal biopsy are invasive options for diagnosis when other testing is unrevealing. Treatment is as for pulmonary TB, and upon initiation of therapy, symptoms frequently improve rapidly.

A WHOLE CLOT OF PROBLEMS WITH CROHN'S DISEASE
Brandon J. Mauldin; Matthew N. Peters; Morgan J. Katz; Chad S. Miller. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640537)

LEARNING OBJECTIVE 1: Recognize the association between inflammatory bowel disease and venous and arterial thromboembolism.
LEARNING OBJECTIVE 2: Understand the importance of minimizing risk factors associated with thromboembolism in patients with inflammatory bowel disease.
CASE: A 34 year-old man with Crohn's disease presented with 3 week history of increased lower extremity swelling. He noted bilateral ankle swelling which gradually progressed to his upper thighs. He'd been diagnosed with Crohn's disease 7 years prior and experienced frequent flares. His home medications included 250 mg of daily oral azathioprine and biweekly injections of 40 mg adalimumab. Vital signs were a temperature of 99.6° Fahrenheit, blood pressure of 109/72 mmHg, heart rate of 121 beats/min and oxygen saturation of 95 %. Physical exam was significant for a cachectic man with pitting edema extending from his bilateral feet to upper thighs. Laboratory studies were notable for an albumin of 0.5 U/L. The patient's edema was presumed to be secondary to malnourishment and he was started on total parenteral nutrition. Over the next few days the patient was persistently tachycardic (heart rate 110–130 bpm). A CT scan of the abdomen and pelvis with contrast was done to evaluate the extent of his intestinal inflammation due to Crohn's. His associated disease burden appeared unchanged from 6 months prior; however the scan showed the development of a large right renal artery thrombus and the appearance of nearly 20 bilateral pulmonary emboli in the lower lung fields. He was initiated on a therapeutic heparin drip and underwent right renal artery thrombectomy. After the procedure, he was started on 5 mg oral warfarin with concurrent administration of 1 mg/kg of subcutaneous enoxaparin until his warfarin was therapeutic. Within several days the patient's tachycardia began to resolve.
DISCUSSION: Inflammatory bowel disease (IBD) predisposes patients to numerous extra-intestinal manifestations with venous and arterial thromboembolism causing high rates of morbidity and mortality. IBD patients have a 3-fold increase in occurrence of venous thromboembolism and a greater than 2-fold increase in associated mortality. Arterial thromboembolism also occurs at significantly higher rates with a pronounced increase in occurrence of coronary and cerebral artery thrombosis. The overall occurrence of thromboembolism among IBD patients is as high as 10 %; however post-mortem studies within the same population have shown an incidence approaching 40 %. The diagnosis of thromboembolism among IBD patients may be drastically under-recognized. Pathogenesis is attributed mainly to an increased incidence of acquired risk factors, such as increased inflammation and an increase in homocysteine, which is secondary to vitamin deficiency (B9, B6, B12). Support for these mechanisms is that the majority of thromboembolic events have been demonstrated to occur during active IBD flares and in patients with high disease burdens where the levels of inflammation are high and overall nutritional intake is low. It's critical for physicians to recognize the association between IBD and thromboembolism; the threshold for appropriate diagnostic testing should be extremely low. The risk of thromboembolism should be minimized by limiting severity of inflammation with adequate pharmacological therapy, eliminating predisposing risk factors (immobility, use of central intravenous catheters, smoking, use of oral contraceptives), and providing adequate vitamin supplementation.

A CASE OF BILATERAL BELL'S PALSY- AN UNSOLVED CLINICAL PUZZLE
Karuppiah Arunachalam[1,2]; Karthikeyan Venkatachalam[3]; Robert Colgrove[1,2]. [1]Mount Auburn Hospital, Cambridge, MA; [2]Harvard Medical School, Cambridge, MA; [3]Crittenton Hospital, Rochester Hills, MI. (Tracking ID #1640797)

LEARNING OBJECTIVE 1: Recognition of bilateral Bell's palsy, an unusual case and discussion of differential diagnosis.
LEARNING OBJECTIVE 2: Management of a patient with bilateral Bell's palsy
CASE: A 34 year old previously healthy male presented with bilateral facial weakness and difficulty drinking. He had lower extremity tingling sensation and was evaluated at the emergency department 1 week before the above presentation. He had no complaints of extremity weakness, no changes in vision and hearing, no history of fever, headache, recent travel or exposure to insects. He received flu shot 10 days before the presentation. His sibling has a history of HIV with Hodgkin's lymphoma. On exam, he was found to have bilateral lower motor neuron facial palsy with bell's phenomenon. No other focal neurological deficits. White blood count was elevated to 13.18. MRI brain showed 4 mm lesion in left centrum semiovale demonstrating enhancement, two other non enhancing lesion in body and splenium of corpus callosum. Lumbar puncture done showed high white count containing all lymphocytes and monocytes with elevated protein. Presumptive diagnosis of neurological Lyme disease was made and patient was started on intravenous ceftriaxone. However, Lyme antibody, blood and CSF Lyme PCR were negative. Serology for syphilis, west nile virus, HIV, VZV were also negative. Cryptococcal CSF antigen was also negative. Serum ACE level was within normal limits. The patient had gradual improvement of his facial weakness. He was treated with rapid tapering course of prednisone for 6 days. He received ceftriaxone for 14 days intravenously. His facial palsy has nearly completely resolved.
DISCUSSION: The upper part of face is involved in Bell's palsy unlike upper motor neuron lesion of the facial nerve. Bilateral Bell's palsy, an uncommon presentation mostly associated with a complex disease or part of a syndrome. Literature reviews showed most of the bilateral Bell's palsy are caused by Lyme, sarcoidosis, HIV and EBV. Also there was a single case reported after intra nasal influenza vaccine but no case reported after inactivated flu vaccine injection. This patient didn't have any confirmed diagnosis but we empirically treated as Lyme as it was the commonest cause. Prednisone was given for the possibility of idiopathic nature and it reduces the inflammatory process as well. Considering the MRI findings of the patient demyelinating disease like GBS and multiple sclerosis was also ruled out. The lesions found in the MRI brain didn't correlate with the clinical findings. An attempt should be made to rule out all the possibilities that cause bilateral Bell's palsy. Overall, as in unilateral Bell's palsy bilateral involvement also has favourable prognosis.

A CASE OF ADVANCED TESTICULAR CANCER IN A SOCIETY OF RACIAL AND SOCIOECONOMIC HEALTH DISPARITY
Michael Kaufman; Diane L. Levine. Wayne State University, Detroit, MI. (Tracking ID #1642083)

LEARNING OBJECTIVE 1: Recognize the impact of delayed diagnosis of testicular cancer.
LEARNING OBJECTIVE 2: Recognize inequalities related to cancer disproportionately experienced by African-Americans.
CASE: A previously healthy 32-year-old African-American male presented to the hospital with a unilateral 15-cm painless testicular mass and significant abdominal pain. He noticed growth of the mass over a 6–8 months period while concurrently experiencing weight loss of over 40 lb. Physical exam revealed a unilateral enlarged testicular mass as well as a large mass extending into his abdomen. A CT scan revealed extensive metastasis in the retroperitoneum and lungs, with asymptomatic bilateral femoral deep vein thrombosis and a pulmonary embolism. Chemical studies revealed markedly elevated levels of hCG and LDH indicative of malignancy. Diffuse lymphadenopathy compressing multiple vital struc-

tures such as the renal vessels causing hydronephrosis and encasement of the inferior vena cava presented significant challenges for management of his comorbidities. Microscopic analysis revealed pure seminoma, a surprising diagnosis given the extensive metastasis seen on presentation, with staging at pT3N3M1aS3.
DISCUSSION: Testicular cancer is the most common malignancy in males 15–35 years old. The presentation usually includes testicular swelling and, depending on the extent of disease, extra-testicular manifestations of metastatic disease. Additional characteristic biochemical markers can specify the status and progression risk of the cancer. Most cases of seminomatous testicular cancer present at an early stage and are readily treatable. This case presents an opportunity to review a common malignancy in a patient with very few epidemiologic risk factors for developing a seminoma. His advanced disease presentation, complex management of multiple comorbidities combined with his African American race and lower socioeconomic status (SES) highlights an unusual paradigm shift in testicular cancer epidemiology from the more typical high SES Caucasian to the lower SES, less educated male patient. Beyond the unexpected clinical presentation, this case then presents multiple avenues of discussion regarding the unfortunate effects of racial disparities on disease presentation and progression that are plaguing our healthcare system today.

A CASE OF BONE MARROW GRANULOMA Eugenia Tsai; Yelena Averbukh. Montefiore Medical Center, Bronx, NY. (Tracking ID #1638221)

LEARNING OBJECTIVE 1: Identify the differential diagnosis of bone marrow granuloma.
LEARNING OBJECTIVE 2: Recognize the presentation of T-cell lymphoma.
CASE: A 73 year-old man presented with 3 weeks of generalized weakness, confusion, nightly fevers, constipation and anorexia with a 15 lb weight loss. He had a low-grade temperature (37.8C), elevated heart rate (104 bpm), conjunctival pallor and petechial rash on his trunk, upper and lower extremities. His respiratory exam was clear to auscultation. He did not have any palpable lymph nodes or hepatosplenomegaly. Serum chemistries were remarkable for corrected calcium of 13.6 mg/dL, AST of 98 U/L and ALT of 90 U/L. CBC was remarkable for WBC of 2.0×10×6/L (ANC=0.2), hemoglobin of 7.3 g/dL and platelet count of 13×10×9/L. Sputum culture for AFB was negative. Serology tests for HIV, hepatitis B, hepatitis C, cytomegalovirus, Epstein-Barr virus, parvovirus B19, human T-lymphotropic virus Type I (HTLV-1) were negative. Chest x-ray did not reveal any pulmonary consolidation or hilar lymphadenopathy. High-resolution chest CT revealed no lymphadenopathy or pulmonary lesions. Bone marrow biopsy revealed hypercellularity (100 %) of atypical lymphocytes and numerous non-necrotizing epithelioid granulomas. AFB and GMS stains did not reveal microorganisms. Additional studies revealed an abnormal predominance of CD3- and T-cell receptor alpha/beta positive T-cells confirming a T-cell lymphoproliferative disease.
DISCUSSION: Granuloma is a type of inflammation that can occur in a wide variety of diseases. Broadly the diseases associated with granulomas may be classified in three groups: autoimmune/inflammatory, infection and neoplasm. Sarcoidosis is the best known autoimmune/inflammatory disease that may affect the bone marrow. Isolated bone marrow involvement without pulmonary manifestation is uncommon, occurring in <5 % of the cases. Infectious organisms such as mycobacteria, pneumocystis and Cryptococcus should be ruled out as they are culprits amenable to treatment. Tuberculosis is typically, albeit not always, associated with caseation. Viral infections including, but not limited to, HIV, CMV and EBV are also occasionally associated with granuloma formation. Certain drugs, such as procainamide, have been implicated in bone marrow granuloma. Neoplastic diseases, particularly Hodgkin's lymphoma, have been reported to produce granulomas in the bone marrow. The granulomas represent inflammatory responses to the neoplasm that is perceived as foreign. Alternatively, abnormal cytokine release by neoplastic cells may induce local granulomatous inflammation. It is rare for non-Hodgkin lymphoma or multiple myeloma to present initially with bone marrow granuloma. Adult T-cell lymphoma/leukemia (ATL) is a highly aggressive disease that accounts for 15 % of non-Hodgkin's disease. T-cell neoplasms comprise four groups: cutaneous, extranodal, nodal and leukemia, with each group further consisting of several subtypes. Common, albeit non-specific, constitutional symptoms include malaise, fever, weight loss and anorexia. Laboratory findings include pancytopenia and hypercalcemia. Presentation with numerous granulomas in the bone marrow in the absence of hepatosplenomegaly or lymphadenopathy is unusual. Immunophenotyping and T-cell receptor gene rearrangement analysis can confirm the diagnosis by demonstrating malignant clones. ATL should be included in the differential diagnosis of granulomatous inflammation in the bone marrow in patients presenting with pancytopenia.

A CASE OF ERYTHEMA NODOSUM LEPROSUM IN A 23-YEAR-OLD MARSHALLESE MAN PRESENTING WITH RASH. Erin Liu[1]; Chunrong Lin[1]; Kuo-Chiang Lian[2,1]. [1]John A. Burns School of Medicine at the University of Hawai'i, Honolulu, HI; [2]The Queen's Medical Center, Honolulu, HI. (Tracking ID #1626978)

LEARNING OBJECTIVE 1: Lepromatous leprosy is a rare disease affecting the skin and peripheral nerves that should be considered in patients from endemic areas who present with a rash. Rarely, leprosy may present with erythema nodosum. Early recognition of this disease is important as early leprosy treatment is essential to avoid complications.
CASE: A 23-year-old man presented to the emergency departmentwith evolving rash over 2 weeks. The rash was non-pruritic and started on his lower limbs and gradually spread upwards to the rest of his body, including his face and ears. One week after the rash appeared, he developed fever and generalized pain in his hand and foot joints. The patient had no allergies and no family history of skin disease. He was born in the Marshall Islands but had been living in the United States for the past 5 years. He had no known history of STDs. He had no recent history of international travel and none of his close contacts hada similar rash. Physical examinationrevealed multiple erythematous nodules and papules on the head and neck, disseminated brown and erythematous macules and papules on trunk and limbs, including hands. Palpable purpura and hyperpigmented patches were present on his lower anterior legs. Mild synovitis of his finger joints and bilateral inguinal lymphadenopathy were present. There was no mucosal involvement. Diagnostic testing revealed a white blood cell count of 3.0×109/L and erythrocyte sedimentation rate of 80 mm/hr. A skin biopsy was performed and was histologically diagnostic of lepromatous leprosy. Cytology also demonstrated neutrophilic infiltrate and karyorrhectic debris consistent with erythema nodosum leprosum. Fite stain demonstrated numerous intracellular acid-fast bacilli. A modified treatment protocol consisting of dapsone, rifampin and moxifloxacin was initiated. In addition, patient was also treated with prednisone for inflammatory symptoms.
DISCUSSION: This case describes erythema nodosum with systemic symptoms as an atypical presentation of lepromatous leprosy. It illustrates the importance of maintaining a high clinical suspicion for leprosy in a patient who presents with a disseminated erythematous nodular and maculopapular rash. Although it is rare, it should be included in the differential for an unexplained rash in a patient from an endemic area.

A CASE OF MULTIDRUG RESISTANT NOCARDIA PSEUDOBRASILIENSIS. Vimalkumar Veerappan Kandasamy; Ajaykumar Kaja; Khaled M. Abouelezz; Mary Tadros. Creighton University Medical Center, Omaha, NE. (Tracking ID #1642343)

LEARNING OBJECTIVE 1: Emphasize Nocardia pseudobrasiliensis as an emerging pathogen causing disseminated infections in immunocompromised host.
LEARNING OBJECTIVE 2: Recognize the importance of differentiating N. pseudobrasiliensis from N. brasiliensis and choosing appropriate antimicrobials.

CASE: A 79 year old Caucasian male was admitted with multiple abscesses in the lower extremities. Patient had a history of left hand abscess for the past 1 year. Lower extremity abscesses started 6 months ago and were progressively getting worse with increasing pain. He received several courses of antibiotics with moderate relief. His past medical history was significant for Myasthenia Gravis, on prednisone therapy for the last 2 years. Vital signs were stable. On examination, patient had multiple tender swellings in the both lower extremities. Laboratory data was significant only for leucocytosis. Patient was started empirically on vancomycin and piperacillin-tazobactam. Magnetic resonance imaging (MRI) of the lower extremities showed multifocal complex lesions and fluid within the muscle bed without any evidence of osteomyelitis. Largest lesion measured approximately 10×8 cm in the left biceps femoris muscle complex. Ultrasound guided drainage of large abscesses was done. The organism was identified presumptively as Actinomyces based on gram stain and colonial morphology. Vancomycin and piperacillin-tazobactam were discontinued and he was then started on ampicillin. Cultures later revealed the organism to be Nocardia. Genetic analyzer confirmed the species as Nocardia pseudobrasiliensis which was resistant to penicillin, cephalosporins, trimethoprime-sulfomethoxazole and sensitive to moxifloxacin and linezolid. CT chest and MRI brain did not show any disseminated abscesses. Patient was started on moxifloxacin and remarkable improvement was noted.

DISCUSSION: Nocardia pseudobrasiliensis is an emerging species of Nocardia, first identified in 1996. Only few cases have been reported so far. This case emphasizes the difficulties in diagnosing Nocardia infection which may lead to inappropriate antimicrobial therapy. The distinction between Actinomyces and Nocardia species is of extreme clinical importance. On gram stain, Nocardia and Actinomyces species are morphologically indistinguishable. Nocardia species can be identified by modified acid-fast staining and their ability to grow under aerobic conditions, neither of which is a characteristic of Actinomyces. Nocardia infections range from localized cutaneous infections to invasive and disseminated disease. Nocardia brasiliensis is one of the most common species isolated in Nocardiosis. A recent study demonstrated that 60 % of apparent N. brasiliensis associated with pulmonary or disseminated disease, belonged to a new taxonomy named N. pseudobrasiliensis. Because of these associations and a different susceptibility pattern, it is prudent to recommend screening of all N. brasiliensis isolates to rule out possible N. pseudobrasiliensis. Disk-diffusion method for ciprofloxacin susceptibility provides a rapid screening test, as 95 % of N. pseudobrasiliensis strains are susceptible compared with none of N. brasiliensis strains. In a study of 43 cases of N. pseudobrasiliensis, 70 % involved the lung, 23 % involved the CNS, and 37 % had disseminated disease. The majority of patients were receiving corticosteroids (74 %) or had AIDS (14 %). Isolates of N. pseudobrasiliensis, unlike isolates of N. brasiliensis, are strongly associated with invasive disease.

A CASE OF NON-REMITTING MENINGITIS Ravi Thimmisetty; Ritu Madan; Kyle Register; Mansumeet Singh; Mary Tadros. Creighton University Medical Center, Omaha, NE. (Tracking ID #1641996)

LEARNING OBJECTIVE 1: 1. To learn about non-infectious causes of meningitis.

LEARNING OBJECTIVE 2: 2. To learn about diagnosis and management of neurosarcoidosis.

CASE: A 47-year-old African American male presented to ER with complaints of gradually progressive severe headache of 3 weeks duration.He also reported nausea, vomiting, blurring of vision and imbalance for last 1 week. His past medical history was significant for pulmonary sarcoidosis, TIAs, diabetes, COPD, hypertension and hyperlipidemia. He denied any drug abuse.On exam, he was drowsy, had neck rigidity and bilateral papilledema. CT scan of head was normal. Routine labs were normal. ESR was slightly elevated. CSF was obtained for analysis .It was clear, Gram stain did not show any organisms, WBC 93 (97%Lymphocytes), RBC 27, protein 109 and glucose 55. MRI showed leptomeningeal and ependymal enhancement as well as punctate infarcts and hemorrhages. A CT angiography did not show any vascular disease. He was started empirically on treatment for bacterial and viral meningitis as well on high dose steroids with the diagnosis of neurosarcoidosis in mind. He responded well to the treatment in a span of 24 h and was taken off antibiotics and continued to do well over next 72 h. He was discharged home on prednisone 1 mg/kg for 2 weeks and close follow up with neurology.

DISCUSSION: Neurosarcoidosis can be the only manifestation of sarcoidosis in about 1 % of patients.It is a relapsing-remitting or progressive course punctuated by episodic deteriorations. It can affect the central or peripheral nervous system and manifest as meningitis, vasculitis, isolated seventh or eighth cranial nerve involvement, myelopathy, pituitary dysfunction or peripheral neuropathy. The dearth of pathognomonic symptoms,varied presentations, absence of specific diagnostic criteria, and lack of standardized treatment regimens make the diagnosis and management of sarcoidosis challenging even for experienced clinicians. Therefore it is imperative for healthcare providers to consider the Neurosarcoidosis in patients with sarcoidosis who develop neurological symptoms. Treatment is steroids and using alternative agents like mycophenolate, azathioprine, methotrexate if they do not respond to steroid or if steroids are contraindicated and the duration is approximately 1 year. It is important to recognise the disease early as prognosis of acute neurosarcoidosis is often superior to that of chronic disease. By being aggressive, we started treatment at an early stage of disease in our patient.

A CASE OF RECURRENT PULMONARY EDEMA ATTRIBUTED TO CHRONIC OCCLUSION OF OBTUSE MARGINAL BRANCH Karuppiah Arunachalam; Ambalavanan Arunachalam; Indumathy Varadarajan; Eunice Y. Chuang; Jeffrey Leavitt. Mount Auburn Hospital, cambridge, MA. (Tracking ID #1642630)

LEARNING OBJECTIVE 1: To recognise that recurrent pulmonary edema can be caused from the atherosclerosis of obtuse marginal branch as it supplies the posterior papillary muscle, malfunction of which can lead to increasing mitral regurgitation.

CASE: An 80 year old male with 6 recurrent admissions for pulmonary edema over a period of 3 months, presented with sudden onset of dyspnoea associated with palpitations and sweating around 4 AM in the morning awakening from sleep. This was the exact presentation in last few admissions and he was discharged 2 days back after treatment for the same symptoms. Past medical history was significant for paroxysmal atrial fibrillation, COPD, AV malformation of cecum and chronic anaemia. On exam, heart rate found to be irregular, bilateral basilar crackles and pan systolic murmur was present. Lab investigation showed stable hematocrit, mild troponin leak of 0.06 and BNP was 659. He was started on aggressive diuresis, metoprolol tartrate and lisinopril. Echocardiogram showed ejection fraction of 45 %, moderate pulmonary artery hypertension and mitral regurgitation. This patient also had cardiac catheterisation during the sixth admission which showed mild to moderate coronary artery disease with sub-total occlusion of obtuse marginal branch of left circumflex coronary artery. No intervention was done. The reason for recurrence was analysed and cardiac catheterisation was done again to specifically place bare metal stent on obtuse marginal branch and the patient was subsequently discharged next day with dual anti-platelet therapy for 1 month.

DISCUSSION: Our patient's heart failure initially attributed to paroxysmal atrial fibrillation and aortic stenosis was managed adequately during every admission using lasix, metoprolol, lisinopril and digoxin. Failure of medical management to control the recurrence of episodes and findings of coronary angiogram made us to think that transient papillary muscle dysfunction could be a possibility. Papillary muscle ischemia causes transient mitral valve regurgitation. Anatomically obtuse marginal branch supplies the posterior papillary muscle as a single blood supply whereas anterior papillary muscle has a dual blood supply from left anterior descending branch and obtuse marginal branch. Our patient was followed up for over 6 months; he didn't have any further ER visits or admission for pulmonary edema. The decision to take the patient to the cardiac

catheterization lab analysing the recent catheterisation the patient had 1 month ago, and specifically noting the obstruction of the obtuse marginal proved invaluable. Follow up of patient acts as an evidence that recurrent pulmonary edema was caused by obtuse marginal branch occlusion. This case illustrates the need to consider papillary muscle dysfunction in case of recurrent pulmonary edema.

A CASE WITH UNCOMMON CAUSE OF CHEST PAIN PRESENTED TO ED Mirai Ido; Yushi Kawazoe; Junya Okumura; Yasuteru Sugino; Shinichi Mizuno; Mitsunori Iwase. Toyota Memorial Hospital, Toyota Aichi, Japan. (Tracking ID #1642881)

LEARNING OBJECTIVE 1: Learn that Mediastinum tumor can be included in differential diagnosis of chest pain.
LEARNING OBJECTIVE 2: Recognize the diagnostic approach to thymic carcinoma.
CASE: A 59-year-old woman presented to emergency department complaining of cough and chest pain. She had been suffering from a cough for several years. Acute chest pain started a few days ago, which radiated to both of the shoulders. The pain aggravated when she bent forward. Her past medical history was significant for uncontrolled hypertension, uterine myoma, and urolithiasis. Her mother died of AMI and her brother died from unknown cause at the age of 57. She does not take any medications. She was a never smoker and did not drink alcohol. She was alert and oriented with a temperature of 38.5 °C, blood pressure of 202/108 mmHg, heart rate of 110 beats per minute, respiration rate of 18 and oxygen saturation of 98 % on room air. Physical examination was unremarkable except for the tenderness on her chest. CXR showed widening mediastinum. Contrast enhanced CT scan was performed in order to rule out aortic dissection, which showed a tumor in anterior mediasinum, and was enhanced heterogeneously. Lab data including tumor markers was unremarkable. PET-CT scan showed abnormal accumulation of FDG in the tumor region without distant metastatic which indicate stage three in Masaoka staging. The result of biopsy was a thymic carcinoma. Since surgical resection was not feasible, chemotherapy was chosen as the treatment. Following NCCN Guidelines, we selected carboplatin and paclitaxel regimen. After two courses of therapy, tumor regression rate was 35 % and her symptoms had almost dissapeared. As the next step, we planned surgical resection.
DISCUSSION: Thymic tumor is a rare disease, and thymic carcinoma consists of less than 5 % of the tumor. The peak incidence is in the 60s, and most of them are squamous cell carcinoma. Up to one-half of the tymic tumors are diagnosed incidentally, based upon a radiographic abnormality in an asymptomatic patient. Thymic carcinoma tend to be more aggressive than thymomas, and most patient present with cough, chest pain, phrenic nerve palsy, or super vena cava, that are related to the size of the tumor and its effects on adjacent organs. In our case, her chest pain was probably from the invasion to the chest wall or the nerve, and the cough she had for several years might be a cause of compressing airway by the tumor. CXR, CT scan, MRI, PET-CT scan are useful diagnostic tool for making a diagnosis of mediastinum tumor. Differential diagnosis such as lung cancer and aortic aneurysm are easy to rule out using these images. There are no standard treatments but combined modality treatments are commonly selected. When surgical resection is not feasible, chemotherapy and radiotherapy are performed. In our case, carboplatin and paclitaxel therapy regressed the tumor size and improved her symptoms. The prognosis is poor since distant metastasis and lymphotic metastasis are common. We planned surgical resection for improvement of her prognosis. We experienced a case of thymic carcinoma that presented with chest pain at ED.

A CHALLENGING CASE OF NODULAR LYMPHANGITIS Mona Hassan; Eiad Sabia; Sean Drake. Henry Ford Hospital, Dearborn, MI. (Tracking ID #1635043)

LEARNING OBJECTIVE 1: The diagnostic approach to nodular lymphangitis
LEARNING OBJECTIVE 2: Mycobacterium marinum diagnosis and treatment How to treat nodular lymphangitis due to mycobacterium marinum
CASE: A 57-year-old female with a past medical history of hepatis C presented with a single erythematous papule on her right thumb. Her entire thumb later became erythematous and she developed multiple papules in a linear ascending pattern along her forearm in a lymphatic distribution. She was initially treated as an outpatient with clindamycin and Keflex for suspected cellulitis with no improvement. Later, antibiotic therapy was extended to Vancomycin with no response. ID service were subsequently consulted and treated her with Itraconazole for sporotrichosis based on the appearance of the papules. At that time a punch biopsy was performed, which was remarkable only for a dermal abscess with focal necrosis. The patient failed to respond to Itraconazole and the culture remained negative so a repeat punch biopsy was performed a week later. Four weeks later the culture grew Mycobacterium Marinum and Itraconazole was discontinued and Clarithromycin and Ethambutol were started to cover Mycobacterium marinum infection. The patient's nodules began to clear and will continue this regimen for 6 months with close follow up for complete clearing of nodules.
DISCUSSION: Mycobacterium marinum is the most common non-tuberculous mycobacterium that can lead to opportunistc infections in Humans. It usually presents in the form of inflammatory nodules with a sporotrichotic distribution. The extent of cutaneous involvement, number of nodules and systemic features depends on the immunological status of the patient. Mycobacterium marinum is an important condition to consider in a patient presenting with nodular lymphangitis. It can lead to superficial or deep cutaneous infections. Superficial infections can usually be treated with Minocycline, clarithromycin, doxycycline or trimethoprim-sulfamethoxazole as monotherapy. However, M. marinum is a multi-drug resistant species and therefore, combination therapy may be required. In cases of severe infections, including those with a sporotrichoid distribution pattern, a combination of rifampicin and ethambutol seems to be the recommended regimen. Cryotherapy, electrodesiccation, photodynamic therapy and local hyperthermic therapy have been reported as effective therapeutic alternatives. This case demonstrates that M. marinum infection should always be suspected in cases with poor-healing wounds in upper extremities.

A COMMON COMPLAINT UNVEILS A DEADLY DISEASE: A UNIQUE PRESENTATION OF INFECTIVE ENDOCARDITIS Julie M. LeCleir. Medical College of Wisconsin Affiliated Hospitals, Inc., Milwaukee, WI. (Tracking ID #1623938)

LEARNING OBJECTIVE 1: Diagnose infective endocarditis when it presents with lesser known manifestations of the disease.
CASE: A 33-year-old man presented with low back and hip pain described as sharp, constant pain that prevented him from ambulating to the point where he had to be carried by his significant other. His past medical history included anxiety and multiple ankle surgeries for a traumatic injury 5 years prior. He denied bowel or bladder incontinence, fevers, or intravenous drug use. Physical examination was notable for severe back pain with any movement and a previously undocumented holosystolic heart murmur radiating to the axilla. Magnetic resonance imaging of the lumbar spine demonstrated multiple small fluid enhancements in the ileopsoas muscle and bilateral kidneys concerning for abscesses. Empiric antibiotics were begun. A transthoracic echocardiogram was performed and demonstrated a vegetation on the mitral valve. Peripheral blood cultures were positive for Enterococcus faecalis 12 h after they were drawn. Diagnostic work-up was consistent with the diagnosis of mitral valve endocarditis with microembolic spread found in the temporal lobe, ileopsoas muscle, kidneys, and paraspinous muscles. After intravenous antibiotics, his back pain largely resolved.
DISCUSSION: Infective endocarditis is often diagnosed through clinical findings prior to performing definitive tests. Due to its highly variable presentations, many diagnostic criteria have been created and modified over time. The most widely used criteria in current medical literature are Duke's criteria, originally developed in 1994, and later expanded to include

echocardiographic features rather than clinical findings alone. Duke's major criteria include positive blood cultures for organisms typical of endocarditis and echocardiographic evidence of vegetations on valves or new valvular regurgitation, and Duke's minor criteria include intravenous drug use, fever, vascular phenomena, and immunologic phenomena. Musculoskeletal complaints are common in patients with infective endocarditis, but they are not included in these criteria. These musculoskeletal manifestations of endocarditis often mimic rheumatologic conditions, a dilemma which can delay appropriate diagnosis and treatment. Many reports even indicate that musculoskeletal symptoms, including arthralgias, myalgias, arthritis, and back pain, antedate the diagnosis of infective endocarditis by several weeks. Once antibiotic therapy is started for infective endocarditis, these symptoms resolve. The variety of presentations of this disease, specifically in regard to musculoskeletal findings, should encourage clinicians to continue to think beyond the accepted criteria to expedite diagnosis and therapy for infective endocarditis.

A COMPLICATED CASE OF PAGET SCHROETTER SYNDROME (PSS) Haitham Al Ashry; Hamza Tantoush; Ahmed Abuzaid; George Mansour; Nithan C. Birch. Creighton University, Omaha, NE. (Tracking ID #1642223)

LEARNING OBJECTIVE 1: PSS is a relatively rare condition that can be easily missed in the primary care setting. Early recognition is crucial to ensure timely treatment and avoidance of residual disabilities.
LEARNING OBJECTIVE 2: Symptoms can be non specific and often mimic a muscular strain.
CASE: An active 27 y/o ♀ presented to the IM clinic with right upper extremity pain and swelling. After failing an empiric trial of NSAIDS, for presumed muscle strain, a right upper extremity U/S demonstrated a right subclavian vein thrombosis. Warfarin was initiated. Hypercoagulable workup was positive only for a lupus anticoagulant antibody, which was not demonstrated on repeat testing 12 weeks later. After several months of Warfarin therapy, the patient presented with reoccurring symptoms and venography showed a new DVT in the right subclavian vein. Catheter directed intravenous thrombolysis and resection of the first right infraclavicular rib were performed at that time. Symptoms reoccurred for a third time 3 months later and venography showed near total collapse of the distal subclavian vein. Balloon angioplasty was done and stent was placed. Warfarin was discontinued at that time in favor of clopidogrel and aspirin. The patient remained clot free for 6 months after stent placement; however, residual right upper extremity edema persisted despite a compression sleeve and physical therapy.
DISCUSSION: PSS refers to axillary-subclavian vein thrombosis associated with strenuous activity of the upper extremities. It accounts for 10 % for all upper extremity deep venous thrombosis and most commonly presents in young and active men. Anatomical abnormalities and repetitive endothelial trauma from muscular strain are the key pathogenic factors. The role of underlying hereditary thrombophilias is debatable. Compression U/S is the preferred initial test and contrast venography is the gold standard for diagnosis. Therapeutic options include : anticoagulation, fibrinolysis, thoracic outlet decompression (TOD) or combination of any or all of these options. Stent placement without surgical decompression is an independent risk factor for re-thrombosis. The success of fibronylisis diminishes as the time from symptoms' onset to treatment increases.

A FORTY-NINE YEAR OLD IMMUNOCOMPROMISED MALE WITH PNEUMOCOCCAL BACTEREMIA Rebecca Glassman; Howard Libman. Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #1631488)

LEARNING OBJECTIVE 1: Understand the risk factors for developing invasive pneumococcal infection
LEARNING OBJECTIVE 2: Be aware of newly revised Advisory Committee on Immunization Practices (ACIP) recommendations for pneumococcal vaccination in immunocompromised hosts
CASE: A 49 year-old male with a history of HIV infection, Hodgkin's lymphoma (372 days status-post autologous stem cell transplantation), and asplenia presented to the emergency room with rigors, weakness, and hypotension. He was admitted to the intensive care unit with presumptive septic shock. Shortly after admission, blood cultures (4/4 bottles) grew gram-positive cocci, which were identified as Streptococcus pneumoniae. Antibiotic therapy was changed from vancomycin to ceftriaxone, and the patient's hemodynamics quickly improved. He was discharged home on levofloxacin to complete a 14-day course. Notably, the patient had not received pneumococcal vaccination following stem cell transplantation.
DISCUSSION: Invasive Streptococcus pneumoniae infection, including bacteremia and meningitis, is a highly morbid event. The overall incidence of pneumococcal infection has been estimated at 23.2 cases per 100,000 population, with the majority of cases occurring in persons aged <2 and >65 years old. Immunocompromised patients (e.g. HIV-infected persons, transplant recipients, asplenic individuals) carry a 20-fold increased risk of invasive disease. For adults with hematologic cancer, the rate of invasive pneumococcal infection in 2010 was 186 per 100,000, and for those with HIV the rate was 173 per 100,000. Higher risk in these populations is related to impaired cell-mediated and humoral immunity. Vaccines used for prevention of invasive pneumococcal disease include PPSV23 and PCV13. PPSV23 is composed of capsular polysaccharides, which induce the formation of antibodies. In patients with impaired B-cell immunity, this vaccine is not strongly immunogenic. PCV13 couples carrier proteins to the capsular polysaccharides, utilizing a T-cell response, to augment immunologic response. The GRADE trial investigated the efficacy of PCV13 and PPSV23 vaccines in immunocompromised persons and concluded that the use of both preparations conferred the greatest protection. The new ACIP vaccination schedule reflects these findings. Pneumococcal vaccine-naïve adults >19 years with immunocompromising conditions should first receive PCV13 vaccine followed by PPSV23 vaccine no sooner than 8 weeks later. PPSV23 vaccine should be re-dosed in 5 years. In adults previously vaccinated with PPSV23, the recommendation is for PCV13 vaccine to be given at least 1 year after the last PPSV23 dose and for PPSV23 to be repeated no sooner than 8 weeks after PCV13. In patients who have undergone hematopoietic cell transplant, a three-dose series of the PCV13 vaccination is initiated 3 to 6 months post-transplant, with a single dose of PPSV23 given 8 weeks after the final dose of PCV13. Streptococcus pneumoniae can cause life-threatening infection in immunocompromised persons. Primary care practitioners should be aware that the ACIP now recommends the use of both PCV13 and PPSV23 vaccinations in this population to broaden serotype coverage and enhance immunologic response.

A MAN AND HIS ITCHY DRESS Brian Ciampa. Montefiore Medical Center, Bronx, NY. (Tracking ID #1634613)

LEARNING OBJECTIVE 1: Recognize the presentation, severity and diagnostic criteria for DRESS syndrome.
LEARNING OBJECTIVE 2: Understand that telaprevir is associated with severe skin reactions including TEN, DRESS syndrome, and SJS.
CASE: A 66 year-old man presented with 3 weeks of a progressively worsening rash. He also had fever, chills, pruritis and facial edema. He was noted to be rigorous, had a temperature of 101.3, heart rate of 108, and blood pressure of 84/47. He had an erythematous, maculopapular rash with areas of confluence and desquamation on his face, anterior chest, and arms. He was unable to open his eyes because of facial edema. The remainder of the exam was unremarkable. Two months prior to admission he had begun treatment for Hepatitis C with pegylated interferon, ribavirin and telaprevir, a new protease inhibitor. On admission, his aspartate transaminase (SGOT) and alanine transaminase (SGPT) were 41 and 42 respectively, but rose to 120 and 113 on day four, and were 73 and 110 the day of discharge. Eosinophilia was noted with an eosinophil count of 800 per microliter (25 %) on admission, peaking at 1000 per microliter (31 %) on day two, and falling to 500 per microliter (8 %) the day of discharge. Immunoglob-

ulin E was 1394. HHV-6 IGG was positive with a titer of 1:40, and HSV type 1 and 2 antibodies were positive with a high index. Skin biopsy revealed "spongiotic and purpuric perivascular dermatitis with eosinophils." He was given the diagnosis of drug-related eosinophilia with systemic symptoms (DRESS syndrome) secondary to telaprevir. He was treated with antihistamines, topical steroids and a PO steroid taper. He was discharged with close outpatient follow up with an allergist when his symptoms improved.

DISCUSSION: In December 2012 the FDA added a black-box warning for telaprevir in combination with ribavirin and pegylated interferon concerning severe skin reactions including DRESS syndrome, toxic epidermal necrolysis, and Stevens-Johnson syndrome. DRESS syndrome is a life-threatening drug reaction that is characterized by a severe skin eruption, fever, eosinophilia and systemic organ involvement. It normally occurs within 2 to 6 weeks after exposure to a medication, and can worsen despite stopping the offending agent. Classically, carbamazepine and allopurinol have been implicated in DRESS syndrome, but more and more drugs are being added to the list. DRESS syndrome is associated with herpes virus reactivation, specifically HHV-6, but also Epstein-Barr virus (HHV-4) and HHV-7. Diagnosis can be difficult, and a scoring system has been developed that consists of seven points: fever greater than or equal to 38.5 °C, enlarged lymph nodes, eosinophilia, atypical lymphocytes, skin involvement, organ involvement, resolution taking greater than or equal to 15 days, and ruling out other causes. Each of these is worth one point, while two points are given to higher levels of eosinophilia. If the score is >5 it is considered a definite case, 4–5 is a probable case, 2–3 is possible and <2 is considered "no case". The most frequently involved organ is the liver (51 %), but kidney, muscle (including the heart), lung and CNS involvement have also been described. DRESS syndrome is fatal in roughly 5–10 % of cases. Treatment of DRESS syndrome involves corticosteroids and withdrawal of the offending agent. IVIG has also been used with some success. Recovery tends to occur after 6 to 9 weeks.

A NON-MALIGNANT ENDOBRONCHIAL TUMOR IN A SMOKER. Anene Ukaigwe; Oluwakemi Fagbami. The Reading Health System, West Reading, PA. (Tracking ID #1643209)

LEARNING OBJECTIVE 1: Recognise non malignant causes of lung masses.

CASE: A 67 year old man presented with hemoptysis for 3 weeks. There was no fever, weight loss or chest pain. He had a 9 pack year tobacco abuse history, but quit 37 years ago. Physical examination was unremarkable. Chest xray showed old granulomatous changes. CT thorax showed soft tissue mass measuring 7.0×5.6×7.5 cm in right lower lobe of lung extending into the mediastinum, narrowing the right lower lobe bronchi and pulmonary vein. There was associated pretracheal and right hilar lymphadenopathy concerning for granulomatous disease or malignancy. At bronchoscopy a polypoid lesion in the right bronchus occluding the superior segment and cobblestoning down to the basilar segments with right middle lobe extension. Histopathology showed ulcerated polypoid lesions, chronic inflammation with herpes virus inclusions. HSV1 antibody titres were positive, HIV antibody screens; negative and Immunoglobulin levels were normal. A 3 week course of acyclovir led to some resolution of the mass radiologically.

DISCUSSION: Pulmonary Inflammatory pseudotumors are rare, reported to be 0.04–1.4 % of lung tumors. It is speculated to result from exaggerated inflammatory response to injurious lung stimuli including trauma and chronic infections with mycobacteria, actinomyces, nocardia, mycoplasma and herpes viruses. Immunoglobulin G4-related sclerosing disease has also recently been described as an autoimmune process that is histologically similar to inflammatory tumor, which may be explain to the occurrence in adults. More than 50 % of the patients are less than 40 years of age, with no gender or sex differences (10). Symptoms range from none to include cough, fever, hemoptysis, weight loss, chest pain, post obstructive pneumonia or mediastinal invasion. There are no distinguishing radiologic features; it frequently shows a solitary lesion. Pathologic patterns include organizing pneumonia type, fibrous histiocytoma type and lymphoplasmacytic type, suggesting an inflammatory etiology but no prognostic significance of this classification is unknown. Antiviral therapy has also reportedly shrunken HSV associated tumors as was seen in this case. Steroid therapy has shown some benefit, with success speculated to be previously undiagnosed IgG4 sclerosing disease. Surgery in the definitive therapy for all inflammatory tumors but for selected patients trial of appropriate medical therapy, may be worthwhile to shrink this tumor with no malignant potential.

A PICTURE IS NOT ALWAYS WORTH A THOUSAND WORDS: MAKING THE DIAGNOSIS OF ENDOCARDITIS PRIOR TO IMAGING Brent W. Thiel; Harish Jasti. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1642196)

LEARNING OBJECTIVE 1: Identify the signs and symptoms associated with endocarditis.

LEARNING OBJECTIVE 2: Discuss the sensitivity and specificity of imaging studies and the Duke criteria.

CASE: A 49 year-old female, with a history of hepatitis C and IV heroin use, presented with 3–4 weeks of acute worsening of her chronic low back pain and lower extremity weakness, along with a 2-day history of new left foot pain. She reported being clean for 1 year until injecting heroin 2 days ago. Review of systems was notable for subjective fevers, diffuse abdominal pain, oliguria, and increasing shortness of breath. On physical exam, she was afebrile and tachycardic, with a 2-liter oxygen requirement. Pertinent findings included left eye-lid conjunctival and palatal hemorrhages, pretibial petechial rash, nail bed splinter hemorrhages, a dusky/cool left foot, and absence of a cardiac murmur. Notable labs included WBC 15.6 (14 % bands), platelets 9, BUN 114, Cr 4.2, RF 57, total bilirubin 4.8, AST 119, and ALT 50. Urinalysis revealed 6 RBC, 9 WBC, and 30 protein. Blood cultures were positive for gram positive cocci in clusters. CT scan demonstrated multiple peripherally located cavitary and non-cavitary pulmonary nodules. Transthoracic echocardiogram (TTE) was negative for vegetations. She was diagnosed with probable native valve endocarditis by Duke criteria (5 minor criteria) and started on empiric vancomycin and cefepime. The regimen was later changed to high dose continuous infusion nafcillin after blood cultures revealed MSSA. A subsequent transesophogeal echocardiogram (TEE) demonstrated vegetations on the tricuspid, pulmonic, and aortic valves, as well as a patent foramen ovale.

DISCUSSION: Patients with IV drug use are at significant risk for development of infective endocarditis. Estimates range from 150 to 2000 per 100,000 person-years. However, these patients often present with other complaints and without obvious signs of endocarditis. It is critical to make the diagnosis so that empiric therapy can be started expeditiously, especially due to the poor sensitivity of less invasive imaging techniques. TTE has a high specificity (98 %) and moderate sensitivity (60–70 %), but can be non-diagnostic in up to 20 % of patients due to body habitus and anatomy. TEE has a higher sensitivity (75–95 %) and preserved specificity (85–98 %); however, it is not widely available, more invasive, and less rapidly performed. The Duke criteria, developed in 1994, integrate clinical, historical, and imaging data to help make the diagnosis. The criteria have a sensitivity of 90 %, specificity of >95 %, and a negative predictive value of >92 %. A definitive diagnosis of endocarditis by Duke criteria consists of 2 major criteria, or 1 major and 3 minor criteria, or 5 minor criteria. Major criteria include: (1) sustained bacteremia by an organism known to cause endocarditis; (2) endocardial involvement demonstrated by echocardiogram or a new valvular vegetation. Minor criteria include: (1) a predisposing condition (IV drug use, catheters, poor dentition, hemodialysis, diabetes, intracardiac devices); (2) fever; (3) vascular phenomena (pulmonary emboli, splinter hemorrhages, Janeway lesions); (4) immune phenomena (rheumatoid factor, glomerulonephritis, Osler's nodes, Roth spots); (5) blood cultures not meeting major criteria. Our case demonstrates that application of the Duke criteria with careful history taking and examination can more rapidly yield a diagnosis of endocarditis with equivalent sensitivity and specificity to that of a TEE.

A PUZZLING CASE OF MYCOBACTERIUM ABSCESSUS Amrita John; Steven Opal. Memorial Hospital of Rhode Island, Pawtucket, RI. (Tracking ID #1642808)

LEARNING OBJECTIVE 1: The incidence of rapidly growing Non-Tuberculosis Mycobacterium (NTM) infection has been increasing worldwide. There is need for high degree of clinical suspicion in order to accurately diagnose rapidly growing Non-Tuberculosis Mycobacterium (NTM) as the cause for recurrent soft tissue swelling.
LEARNING OBJECTIVE 2: It is equally important to distinguish M.abscessus from other NTM since the management and prognosis are different.
CASE: A 50-year-old female presented with a progressive swelling between the first and second digits of her right hand of 4 months duration. 3 months after onset, she visited the Emergency Department, underwent an incision and drainage and took 7 days of Doxycycline. Within a month the swelling had recurred. Of note, she could recall a small cut on her right thumb while gardening, a week prior to symptom onset. Exam showed a firm 1.5×1 cm swelling between the interdigital space of her right first and second digits. There was no localized lymphadenopathy or limitation in range of movements. MRI of the hand reported a hyper vascular enhancing lesion adjacent to the first metacarpophalangeal joint, without any bony erosions or marrow enhancement. Preliminary report from samples sent from the Emergency Department showed gram-positive, auramine/rhodamine fluorescent and acid-fast positive rods. These organisms were difficult to culture. The sample was processed at three different laboratories before it was identified by nucleic acid analysis as Mycobacterium abscessus, later confirmed by standard culture and methodology. Surgical excision of the mass revealed necrotizing granulomatoid nodules with chronic inflammation, granulation tissue and dense fibrosis suggestive of granuloma annulare on histopathology. Patient was empirically initiated on Clarithromycin and Doxycycline. Inability to tolerate Doxycycline along with sensitivity patterns showing resistance to this antibiotic resulted in switching to a combination therapy of Clarithromycin and Ciprofloxacin which has been successful to date, with no further recurrences.
DISCUSSION: Mycobacterium abscessus (formerly part of "M.chelonae-complex") are the most pathogenic and chemotherapy-resistant of all rapidly growing Non-Tuberculosis Mycobacterium (NTM). Skin and soft tissue infections are often secondary to trauma or as a post surgical complication due to contaminated surgical instruments and supplies. They can occur in both immune competent and compromised hosts. Molecular tools such as the sequence analyses are preferred in the detection since methods based solely on microscopy, solid and liquid cultures, Bactec systems, and species-specific polymerase chain reaction may produce misleading results. M.abscessus is resistant to all first-line tuberculosis drugs. Early combination therapy is preferred to monotherapy with duration guided by clinical response. Surgery is indicated for abscesses, extensive disease, when drug therapy is limited by resistance or adverse effects, and in localized pulmonary disease poorly responsive to medical therapy. This particular case highlights the need for high degree of clinical suspicion even with absence of a pathognomonic clinical picture and variable histopathology findings in order to accurately diagnose rapidly growing Non-Tuberculosis Mycobacterium (NTM) as the cause for recurrent soft tissue swelling. It is equally important to distinguish M.abscessus since the management and prognosis is different from other NTM.

A RARE PRESENTATION OF COCAINE TOXICITY Emerald Banas; Meghan Rane; Aakash Aggarwal; Arman Khorasani-zadeh; Badal Kalamkar. SUNY Upstate, Syracuse, NY. (Tracking ID #1643215)

LEARNING OBJECTIVE 1: To recognize and promptly manage posterior reversible encephalopathy syndrome
LEARNING OBJECTIVE 2: To recognize the more unusual etiologies of PRES
CASE: A 33 y.o. previously healthy man was brought to the hospital after being found unconscious. He regained consciousness and became agitated. As his condition worsened, he had to be intubated for airway protection. On exam, he was hyperthermic at 42.7 C and tachypneic at 32 cycles/min. Cardiac exam revealed distinct S1 and S2, tachycardic rate at 114 without any murmurs. Urine toxicology screen was positive for cocaine and neglible for acetaminophen, salicylate, ethanol and ethylene glycol were within normal limits. His ICU course was complicated with rhabdomyolysis, which led to acute renal failure requiring hemodialysis. He was finally extubated and was stable to be transferred to the floor. At this time, he was noted to be hypertensive with SBP ranging from 150 to 170 mmHg and DBP ranging from 70 to 100 mmHg. However, he started exhibiting confusion, tremors and delirium. He developed blurry vision and he was able to count fingers at 1 ft, OU. On exam, he was not oriented to person, time and place. He could not understand complex sentences and was not able to perform serial 7 subtractions. However, memory was intact. Extraocular movements were limited in terms of rightward gaze. Funduscopic exam was essentially normal. An MRI of the brain without contrast showed confluent subcortical white matter T2/FLAIR hyperintensity involving bilateral occipital and posterior temporal lobes consistent with posterior reversible encephalopathy syndrome. He was then started on nifedipine ER 30 mg daily and labetalol 300 mg BID. Blood pressure was well controlled with these medications and symptoms gradually resolved. On follow up 1 month after discharge, he was already taken off hemodialysis and has adequate urine output. He has been off nifedipine and only required labetalol 100 mg BID for adequate blood pressure control.
DISCUSSION: PRES is a clinical radiographic syndrome with varied etiologies. As in this case, it may atypically present after cocaine overdose. Easily recognized risk factors include a rapid rate of blood pressure elevation in the setting of renal failure, where fluid overload, electrolyte abnormalities and uremia may play a role. It is exemplified here how a high clinical suspicion in the appropriate settings can lead to prompt recognition and management. This played an important role in preventing permanent damage and potential fatal consequences in an otherwise reversible condition.

A RARE CASE OF CAP PRESENTING WITH PNEUMOCOCCAL MENINGITIS WITH PNEUMOCEPHALUS. Kameron Ashker; Sourabh Prabhakar; Nitin Bhanot; Supriya Narasimhan. AGH, Pittsburgh, PA. (Tracking ID #1645011)

LEARNING OBJECTIVE 1: To recognize a cause of pneumocephalus from an infectious process, that is not a gas producing organism.
LEARNING OBJECTIVE 2: The importance of early recognition of sinus disease and treatment in order to prevent complications such as pneumocephalus and menigitis.
CASE: A 68-year-old female with history of hypertension and atrial fibrillation (on anticoagulation) was found unresponsive at home by her daughter. A week prior to this, the patient was prescribed azithromycin for 5 days for an upper respiratory tract infection. On presentation, she had a temperature of 38.5 C and was in respiratory distress. Lab work revealed white cell count of 24,000 per mm3 with 31 % bands. Chest x-ray revealed right lower lobe infiltrate, consistent with pneumonia. CT scan of head showed pneumocephalus anteriorly in the frontal region without any evidence of trauma. Lumbar puncture (LP) was deferred since her INR was elevated secondary to warfarin use. The patient was admitted to the ICU and started on broad spectrum antimicrobials (cefepime, vancomycin, acyclovir, ampicillin), and dexamethasone. MRI brain done 24 h later showed abnormal signal within the sulci consistent with meningitis and extensive sinus disease with fluid in the mastoids bilaterally. Three days into admission, an LP was performed that revealed WBCs 143/mm3 (89 % neutrophils), glucose 99 mg/dl, and protein 221 mg/dl. CSF S. pneumoniae antigen was positive. Blood and sputum cultures drawn at the time of admission grew Streptococcus pneumoniae. Based on the antimicrobial susceptibility pattern, antibiotics were deescalated to vancomycin. The patient's mental status improved and she was discharged to complete a 3 week course of antibiotics. Pneumocephalus is a rare complication of pneumococcal meningitis.
DISCUSSION: An extensive literature review has only revealed 3 case reports that have demonstarted pneumocephalus in the presence of

concomitant mastoiditis or sinusitis. We present an uncommon manifestation of pneumococcal infection in a relatively immunocompetent individual.

A RARE CASE OF VALPROATE INDUCED HYPERAMMONEMIC ENCEPHALOPATHY(VHE). Amareshwar Podugu; Mohamad Adam; Asha Chakka. Canton Medical Education Foundation, Canton, OH. (Tracking ID #1638709)

LEARNING OBJECTIVE 1: To increase clinicians awareness of VHE, a rare but potentially fatal adverse effect of Valproate (VPA) therapy.
CASE: 78 year old male with diabetes mellitus type 2 and anxiety was admitted with hypoglycemia, later had a witnessed generalized tonic clonic seizures and endotracheal intubation for airway protection. No other significant history. Admission vitals, labs and exam were unremarkable other than what mentioned. Home meds include Zoloft 100 mg PO daily, Lantus & Novolog insulin. Levetericetam 1000 mg I.V Q12h and Valproic acid 2000 mg I.V Q12h were initiated. He was extubated on day 3, but subsequently required re-intubation in less than 48 h for worsening mentation. Day 8, with continued treatment for seizures, ammonia levels were noted to be marginally elevated at 82 with 'normal' liver functions (LFT's). VPA level was with in normal limit (79). EEG showed generalized slowing in the theta and delta ranges with predominance of beta noted frontally and bilaterally, indicating encephalopathy. Day 9, a decision was made to withdraw VPA as his clinical picture along with EEG showed encephalopathy associated with marginal hyperammonemia. Day 11, his mentation started improving. Consequently, his mentation was back to his baseline.
DISCUSSION: The above patient encounter describes the rare but extremely dangerous complication of VPA induced hyperammonemic encephalopathy (VHE). Our case features the discordance between encephalopathy and marginally elevated ammonia levels & therapeutic VPA levels with concomitant use of Levetericetam, after a brief exposure to VPA. VPA is one of the most commonly used antiepileptic drugs or mood stabilizers. Common adverse effects include gastrointestinal disorders, bone marrow toxicity, and hepatic injury. VPA-induced encephalopathy is a rare and severe adverse effect. The incidence of VHE is not known, but asymptomatic increases in serum ammonia are seen in 16–52 % of patients receiving VPA therapy. One of the mechanisms by which this occurs is thought to involve valproate induced carnitine deficiency, thus impairing the conversion of ammonia to urea. Clinical signs include mental-status changes, increased seizure frequency and delirium. The symptoms of VHE are often times misdiagnosed as worsening of underlying neurological or psychiatric condition. Barring other underlying conditions, patients with VHE may have no other laboratory derangement's than elevated serum ammonia. VPA levels may be normal and do not necessarily correlate with the degree of hyperammonemia or the severity of symptoms. EEG's show generalized slowing and increased epileptiform discharges. Other anticonvulsants may potentiate the effects of VPA. The primary therapy is withdrawal of VPA; L-carnitine supplementation may decrease ammonia levels and improve symptoms. The diagnosis of VHE needs high index of suspicion. Caution should be exercised while treating patients with abnormal mentation on VPA and emphasis should be made to not to overlook the diagnosis of VHE in the presence of normal valproate levels and marginally elevated ammonia levels as seen in our patient. Untreated VHE can lead to a life-threatening coma. So, it is critical to increase the clinicians' awareness of VHE.

A RARE CAUSE OF HEPATIC VEIN THROMBOSIS IN A YOUNG MAN Dima Dandachi; Habtamu Asrat; Sathish kumar Krishnan; Ahmet A. Oktay. Saint Francis Hospital, Evanston, IL. (Tracking ID #1643150)

LEARNING OBJECTIVE 1: Recognize that hepatic vein thrombosis can occur as a complication of fusobacterium infection
LEARNING OBJECTIVE 2: Recognize that fusobacterium infection might occur even without preceding upper respiratory tract, periodontal or gastrointestinal infection
CASE: A 27-year-old previously healthy man presented to the ED with 3 weeks history of persistent fever with temperature around 102 °F and right sided pleuritic chest pain. Later, he started having night sweats and chills. The chest pain had gradually subsided to a right upper quadrant (RUQ) constant dull ache associated with malaise, poor appetite and 5 lb of weight loss over 3 weeks period. Review of systems was negative otherwise. He was a former cigarette smoker, consumed alcohol socially with no illegal drug abuse. He denied any history of recent travel or sick contacts or risky sexual behavior. His family history was irrelevant. Physical exam was unremarkable except for tachycardia (HR: 119 /min) and fever (Temp: 101 °F, oral). Initial laboratory analysis revealed leukocytosis (WBC 21 k/mm cu, neutrophils; 86 %), elevated ESR; 75 mm/hr, mildly elevated AST, ALT and Alk Phos; 281. Serologies for HIV, CMV, EBV, hepatitis viruses; Quantiferon-gold and blood cultures came back negative. ECG and cardiac enzymes were normal. Transthorasic echocardiograghy did not show any vegetations. He was started on IV ceftriaxone and doxycycline for possible pneumonia because of right basilar infiltrates on CXR. However, fever and RUQ pain did not resolve. So an abdominal MRI was done which showed right hepatic vein thrombus and four lesions with enhancement of thickened rim consistent with multiple hepatic abscesses in the right hepatic lobe. The abscesses were drained. The antibiotic regimen was changed to IV Meropenem and Vancomycin and he was anticoagulated with, initially enoxaparin, and then warfarin. Hypercoagulable workup was negative as well as serologies for E.histolytica, Brucella, Bartonella, Toxoplasmosis. Cultures from the three out of four abscesses grew Fusobacterium Nucleatum (FN) and this was thought to be related to the hepatic vein thrombosis. The patient denied any recent history of dental work, gingival disease or sinusitis. His oral exam and CT-sinus were negative. Immunoglobulin levels were within normal limits. He clinically improved, fever resolved and WBC count normalized. He was discharged home on oral metronidazole and Levofloxacin.
DISCUSSION: Hepatic vein thrombosis is a rare condition, which is usually caused by one or several thrombogenic conditions, of which myeloproliferative disorders are the most frequent. We report a case of hepatic vein thrombosis in association with fusobacterium infection. Fusobacterium species are anaerobic gram negative bacilli that are associated with periodontal infections and jugular vein thrombophlebitis(Lemierre's syndrome). Our literature search revealed only a few cases of portal vein thrombosis associated with fusobacterium. These cases were usually preceded by upper respiratory or gastrointestinal infection. Our patient is unique that he developed hepatic vein thrombosis associated with fusobacterium without evidence of upper respiratory or gastrointestinal infection. Clinicians need to be aware of the life-threatening complications associated with fusobacterium infection

A RARE INSERTION: HTLV-1 INDUCED ADULT T-CELL LEUKEMIA-LYMPHOMA (ATLL) Doyun Park; Geeta Laud. Montefiore Medical Center, Bronx, NY. (Tracking ID #1642824)

LEARNING OBJECTIVE 1: 1. Review epidemiology, clinical presentations, diagnostic criteria, and different subtypes of ATLL
LEARNING OBJECTIVE 2: 2. Recognize indication for chemotherapy and absence of therapeutic guidelines
CASE: A 43 year-old male patient (pt) with no past medical history presented with intermittent left-sided abdominal pain and chronic fatigue. Exam revealed a palpable spleen tip. Labs showed WBC of 136.5 with 94 % lymphocytes, calcium of 11.6, and LDH 524. CT scan revealed splenomegaly and diffuse lymphadenopathy. Peripheral blood cytometry showed 81 % abnormal cells expressing CD4 and CD25 concerning for ATLL. Bone marrow biopsy showed 90 % hypercellularity with patchy infiltration by atypical lymphocytes. Pt's human T-cell lymphotropic virus 1 (HTLV-1) antibody test returned positive and he was diagnosed with stage 4A ATLL. Pt underwent one cycle of the EPOCH before enrollment in a trial therapy of EPOCH plus Bortezomib and Raltegravir. Normalization of cell lines was achieved within 1 month of starting chemotherapy. However, a lumbar puncture performed during prophylactic intrathecal methotrexate revealed atypical cells

with irregular contoured nuclei concerning for CSF involvement of ATLL. Pt has since been receiving intrathecal Cytarabine via an Ommaya. 5 months post diagnosis, Pt's peripheral cytometry showed 6.6 % abnormal T-cells and a repeat CT scan of thorax showed complete resolution of his lymphadenopathy, confirming pt's partial response (PR) to therapy. Throughout treatment, pt has maintained an ECOG score of 0 and a Karnofsky score of 100.
DISCUSSION: Adult T-cell leukemia-lymphoma (ATLL) is a peripheral T-cell neoplasm associated with infection by the oncoretrovirus HTLV-1. Transmission occurs via breastfeeding, sexual intercourse, and blood products. The risk of HTLV-1 infected individuals developing ATLL is only 4–5 % with development usually occurring after a decades-long dormancy period. Diagnostic criteria for ATLL include: immunochemical expression of T-cell surface antigens and cytokine receptors (CD4 or CD25 positivity), presence of atypical mature lymphocytes (with hyperlobulated "flower-like" appearance of their nuclei), and positive HTLV-1 serology. Clinical features of ATLL include hepatosplenomegaly, lymphadenopathy, lytic lesions, and hypercalcemia. ATLL also impairs T-cell mediated immunity, leading to frequent opportunistic infections (OI). ATLL is divided into two major groups: aggressive and indolent, which are then subdivided into acute leukemic/lymphomatous and smoldering/chronic variants, respectively. Therapy is offered to those with aggressive ATLL and "unfavorable" chronic types (characterized by high blood urea nitrogen, high LDH and low albumin), whereas those with favorable indolent types are monitored initially. There is currently no guideline for treatment of ATLL, but once an aggressive disease is diagnosed pts should be enrolled in a clinical trial that consists of multiregimen combination chemotherapy plus intrathecal chemotherapy due to moderate risk for central nervous system involvement at diagnosis. Pts should also receive OI prophylaxes if possible. Prognosis for ATLL is poor, with a median survival of 7.7 months for the acute variant, but a randomized trial with a Japanese multiregimen LSG 15 (VCAP-AMP-VECP) demonstrated a promising 3 year survival of 24 %. As demonstrated by our pt, prompt diagnosis and aggressive chemotherapy can lead to partial response of a meaningful duration and excellent functional status during treatment.

A SIMPLE RASH OR A DEADLY KILLER? Jessica Hurst. Boston University, Boston, MA. (Tracking ID #1642832)

LEARNING OBJECTIVE 1: Distinguish mild drug eruptions from severe cutaneous adverse reactions
LEARNING OBJECTIVE 2: Recognize patients at risk for disseminated strongyloides
CASE: A 79 year old male with Stage IVB mantle cell lymphoma presented with fever several hours after receiving cycle 2 of bendamustine and rituximab. His only other symptom was a pruritic rash for 2 weeks. One week prior to presentation, hydrochlorothiazide and allopurinol (initiated 6 and 4 weeks prior, respectively) were stopped due to concern for drug rash; a prednisone taper was prescribed with no improvement. There was some concern that the patient had not discontinued these medications due to low health literacy and language barrier. The patient emigrated from Haiti to the US 4 years prior. On exam, temperature 102.6, heart rate 120. He was ill-appearing with a mildly erythematous, maculopapular eruption on chest, back, upper extremities with mild excoriations. No desquamation, ulceration, facial edema, oral ulcers, lymphadenopathy. WBC 14.7, eosinophils 7.6 (1.2 8 weeks prior), complete metabolic panel normal. The patient received acetaminophen, cefepime which were stopped after 48 h as he quickly defervesced and CXR, blood, urine cultures were negative. For his rash with eosinophilia, there was high concern for drug eruption including DRESS (drug reaction with eosinophilia and systemic symptoms), early Stevens-Johnson syndrome (SJS), or disseminated strongyloides (DS). Hydrochlorothiazide and allopurinol were held. Skin biopsy showed interface dermatitis consistent with a drug eruption. Strongyloides ELISA and stool O&P exams were normal. Ultimately he was thought to have a drug eruption due to allopurinol, based on the time course of the rash, its morbilliform appearance, and allopurinol's propensity to cause drug eruptions. After several days, the rash began to improve and eosinophils decreased to 1.2
DISCUSSION: Early in the course of a suspected drug rash, it may be difficult to differentiate between benign drug eruptions and more serious cutaneous reactions. Early SJS can present as a morbilliform rash with later development of mucocutaneous involvement; serial exams are thus important. When eosinophilia is present, DRESS must be considered. This patient did not have lymphadenopathy or evidence of organ involvement and had rapid resolution of symptoms after stopping suspected medications, making DRESS unlikely. In certain populations, DRESS may be mimicked by disseminated strongyloides, also presenting with rash, hypereosinophilia, and fever. This patient had many risk factors for DS: prior residence in an endemic area, pre-existing absolute eosinophilia (potentially indicative of chronic strongyloides), use of rituximab. Mortality of DS is nearly 90 % if untreated, largely due to associated gram negative rod sepsis. Patients from endemic areas who present with eosinophilia should undergo testing for strongyloides prior to initiation of immunosuppressants. Early on, it can be challenging to distinguish between a benign drug eruption and potential dangerous rash. Clinicians must have a high level of suspicion for DRESS, SJS, and DS in the appropriate clinical setting.

A SNAKE'S KISS CAN BE AS DEADLY AS HIS BITE Manisha Bhide; Bryan Brimhall. University of Colorado Denver, Aurora, CO. (Tracking ID #1638197)

LEARNING OBJECTIVE 1: To present a case of febrile illness with hematochezia due to non typhoid salmonellosis from handling pet snakes.
LEARNING OBJECTIVE 2: To increase public awareness regarding precautions for pet handling
CASE: A 34 years old male presents with 1 week of fevers upto 103 F, chills, nausea, vomiting, and bloody diarrhea. Past medical history is negative. He works as a veterinarian technician and owns a pet boa constrictor, two dogs, and one cat. On physical exam, his temperature is 101.4 Fahrenheit, pulse is 92 BPM, blood pressure is 102/66 mmHg, respiratory rate is 16, and oxygen saturation is 95 % on room air. He is in moderate distress, lying in bed in the fetal position. His mouth is dry. Abdomen is soft, diffusely tender, and non-distended. Otherwise his physical exam is normal. Laboratory data demonstrate a lactate, cbc, bmp, and urinary analysis within normal limits except a creatinine of 1.36 mg/dl. The most likely etiology of this patient's symptoms are from an infectious source in the gastrointestinal tract. Infectious colitis with bloody diarrhea raises the possibility of invasive bacteria such as E. coli, Salmonella, Shigella, Campylobacter, Yersina, Vibrio parahaemolyticus or Clostridium dificile. Parasites such as E. histolytica could also cause a bloody diarrhea. He was treated for sepsis with marked improvement. On the second day of admission his blood cultures became positive for gram negative bacteria, later found to be salmonella, not typhi, serogroup C1. Our patient likely contracted Salmonella from handling his pet snake and then preparing food without hand washing. The salmonella isolated from the blood cultures was sensitive to ciprofloxacin and he was discharged on a 14 day course. He was instructed on the importance of hand washing and not handling his snake on kitchen counter surfaces.
DISCUSSION: Sources for salmonella infection in the United States vary widely. There are an estimated two to four million cases of salmonellosis per year in the United States with gastroenteritis being the most common presentation. Salmonella accounts for 9 % of all bacterial food borne illnesses. The most common etiology is improperly handled food. In 2006, there were large multi-state outbreaks of salmonella linked to consumption of tomatoes, fruit salad, and peanut butter. Another known food source is egg yolks, with one in every ten thousand egg yolks being infected with Salmonella enteritis. Animals known to cause Salmonella enteritis include ninety percent of reptiles, such as iguanas, bearded dragons, and snakes. Three to five percent of all cases of salmonellosis in humans are due to exposure to turtles, birds, rodents, dogs, and cats. It is not efficacious to treat reptiles with antibiotics for salmonella and only increases antibiotic resistance. All pet stores are encouraged to provide information to customers regarding salmonella when purchasing a reptile. Very few states actually require by law that information be given. The infectious dose of

Salmonella required for clinical illness varies. As little as five bacteria are required to produce illness in disease susceptible hosts. Antibiotic, previous gastric surgery, antacids or H2 blockers can also reduce the infectious dose. Information regarding salmonella transmission from pets and regulations can be found by calling the pet industry joint ad council at 1-800-553-7387.

A SUCCESS AMONG FAILURES: CEFTAROLINE SALVAGE THERAPY IN COMPLICATED METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS (MRSA) BACTEREMIA Bindu B. Yalamanchili; Faisal Khasawneh. Texas Tech University Health Sciences Center, Amarillo, TX. (Tracking ID #1629992)

LEARNING OBJECTIVE 1: Recognize the causes and potential solutions for first-line antibiotic failure in patients with MRSA bacteremia.
CASE: A 29-year-old previously healthy Hispanic male was admitted with a 6-day history of fevers, chills, shortness of breath and left arm cellulitis. He was involved in a scuffle with the police about a week prior. On presentation, he had severe sepsis with acute kidney injury and pulmonary septic emboli. He was started empirically on vancomycin and piperacillin/tazobactam. His blood cultures grew MRSA with a vancomycin minimal inhibitory concentration (MIC) of 1. His condition worsened with higher fevers and WBC counts. He also developed cutaneous pustules that grew MRSA with vancomycin MIC of 2. His antibiotics were changed to daptomycin and clindamycin with no improvement. Fevers peaked at 101.5 ° F with a WBC count of 32,000/μL. CT scan of the chest without contrast showed cavitary changes in some of the septic emboli and new areas of consolidation. CT of left arm and abdomen showed no abscesses. Follow up blood cultures and transesophageal echocardiogram were negative. His antibiotics were changed to ceftaroline with gradual improvement, and he finished a six-week course without side effects.
DISCUSSION: MRSA continues to cause a significant morbidity and mortality. Despite better understanding of its resistance patterns and newly developed antibiotics, it continues to pose a formidable therapeutic challenge. Vancomycin and daptomycin are first line antibiotics for treating MRSA bacteremia. Vancomycin is reasonably well tolerated and is inexpensive. MRSA with MIC≤2 is considered susceptible to vancomycin but clinical failure has been reported in MRSA infections with MIC between 1 and 2. This results from the low probability of current dosage regimens achieving the appropriate vancomycin concentration exposure (AUC/MIC≥400). Daptomycin, on the other hand, is expensive, not suitable to treat pneumonias, and resistance to it has already been reported. Ceftaroline is a novel cephalosporin that has high affinity to penicillin binding protein 2a, a MRSA specific penicillin binding protein, which correlates with its efficacy against this pathogen. It is bactericidal and demonstrates time-dependent killing. It is currently approved for treating community-acquired pneumonia and skin and soft tissue infections. Clinical data to support its use in MRSA bacteremia is limited but in a rabbit endocarditis model it compared favorably to other antibiotics. Further studies to investigate its use in MRSA bacteremia are warranted.

A THYROID NODULE THAT WASN'T: RENAL CELL CARCINOMA METASTATIC TO THE THYROID Archana Satyal Chaudhary; Julian Diaz Fraga; Richard Alweis. The Reading Hospital and Medical Center, West Reading, PA. (Tracking ID #1642382)

LEARNING OBJECTIVE 1: The rare entity of metastatic disease to the thyroid is usually clinically silent and found incidentally or during autopsy. Renal, lung, breast and lymphoid tissue are common sources with renal cell carcinoma (RCC) accounting for most of the cases. Thyroid metastasis from RCC is a late complication, averaging 7.5 years after curative nephrectomy, but it can occur after more than 20 years. Local tumor recurrence and other distant metastases are generally absent in these cases, making surgical resection of the solitary thyroid metastatic site potentially curative.
CASE: 71-year-old female was found to have an incidental, asymptomatic thyroid mass when presenting for an unrelated fall. Clinical examination revealed a 3 cm hard, non-tender, fixed mass on the left thyroid lobe without lymphadenopathy. Blood count, basic chemistries, and thyroid function tests were within normal limits. Ultrasound revealed a solid hypoechoic 5.2×3×2.5 cm left thyroid mass without invasion of surrounding structures. Past medical history was significant for clear cell type RCC with curative right nephrectomy performed 20 years prior. Cytopathology from fine needle aspiration was consistent with metastatic clear cell type RCC. There was no further evidence of local tumor recurrence or other distant metastases by imaging studies. A subtotal thyroidectomy was performed and she has been disease free during one-year of follow up.
DISCUSSION: Only 150 cases of clinically recognized metastatic renal cell carcinoma to thyroid have been reported. The clinical findings are nonspecific, including a neck mass, weight loss caused by hypercalcemia, dysphagia, and hoarseness, but absence of symptoms is common. Although prognosis associated with such metastasis is poor, prompt recognition with appropriate surgical intervention can be curative. Thus, metastatic RCC to the thyroid should be considered in any patient presenting with a thyroid mass and a medical history of even a remote renal cell carcinoma.

A WORD IS WORTH A THOUSAND PICTURES: TIMELY COMMUNICATION TO AVOID DELAYS IN URGENT DIAGNOSTIC IMAGING Christopher J. Smith. University of Nebraska Medical Center, Omaha, NE. (Tracking ID #1636880)

LEARNING OBJECTIVE 1: Recognize risk factors for nephrogenic systemic fibrosis (NSF) and strategies to minimize these risks.
LEARNING OBJECTIVE 2: Understand the importance of proactive communication with other providers to avoid delays in urgent MRI for patients with advanced renal failure.
CASE: Day 1: A 41 year-old woman presented with 1 week of progressive neck pain and 2 days of fevers and chills. Her past medical history included AIDS (CD4 count of 49) and ESRD requiring hemodialysis (HD). On exam, she was febrile and tachycardic with slurred speech. Her tunneled HD catheter had no signs of infection. Pain severely limited the range of motion of her neck. CSF fluid analysis revealed a pleocystosis (WBC 62, neutrophils 47 %, lymphocytes 15 %). Protein was elevated and glucose was low. Gram stain was negative for bacteria. Blood cultures and additional CSF studies were ordered, the HD catheter exchanged, and empiric antimicrobials started for meningitis. An echocardiogram and MRI of the brain and C-spine were also ordered. Day 2: The patient was more confused and somnolent. She was febrile, tachycardic, and hypotensive. She had a new holosystolic murmur heard best at the left upper sternal border, nuchal rigidity, decreased lower extremity strength, and diminished lower extremity DTRs. She was transferred to the ICU and vasopressor support initiated. The CSF culture remained negative. Blood cultures grew S. aureus. The MRI ordered the day prior had not been performed due to a policy prohibiting gadolinium use in patients with renal failure. The ordering physician was not informed of the delay. Following discussion with the on-call Radiologist, MRI was performed and revealed cervical discitis, osteomyelitis, and epidural abscess causing central canal stenosis. A vegetation from the SVC to the right atrium was revealed by transesophageal echocardiogram. After a prolonged stay, including cervical corpectomy and fusion, the patient improved clinically, but ultimately left the hospital against medical advice.
DISCUSSION: Balancing the risks and benefits of contrast agent use in patients with renal failure is a problem frequently encountered by internists. Nephrogenic systemic fibrosis (NSF) is a potentially fatal fibrosing disease caused by gadolinium-based contrast agents (GBCA) seen exclusively in patients with advanced kidney failure. Although it primarily affects the skin, deeper organs can be involved. Patients on HD exposed to GBCA have a 5 % risk of developing NSF. In patients with urgent need for MRI, this risk must be weighed against the benefits of definitive diagnosis and treatment. It is important that internists know their institution's policy for GBCA use in patients with renal failure and that they initiate timely communication with other providers, including Radiologist and Nephrol-

ogists, to avoid delays in patient care. Strategies to minimize the risk of NSF include using safer gadolinium formulations at the lowest possible dose and performing immediate HD after MRI.

A "QUESO FRESCO" CONUNDRUM—ACUTE HEPATITIS DUE TO BRUCELLOSIS Arta Lahiji; Sahar Soleymani; Phuong-Chi Pham; Glenn Mathisen. UCLA, Sylmar, CA. (Tracking ID #1643229)

LEARNING OBJECTIVE 1: Although uncommon, consider the diagnosis of brucellosis in patients with unexplained fever and hepatitis, especially if there is a history of animal exposure or ingestion of raw dairy products

CASE: This is the case of 32 year-old male with no significant past medical history who presented with abdominal pain accompanied by a 20 lb. weight loss, a 2 month history of intermittent high fever (up to 40 ° C) and night sweats. He works in southern California as a cook and denied a history of travel, contact with farm animals or recent ingestion of raw milk or cheese. Vital signs demonstrated fever to 40 ° C, BP: 117/73 mm Hg., heart rate of 76 bpm and RR:17. His physical examination was normal except for a few small petechiae on the soft palate and a palpable spleen tip. Laboratory studies revealed panyctopenia with white count 2.7 cells/mm3, hemoglobin 12.3 gm/dL and a platelet count of 100 K. Liver tests were markedly elevated (AST 1038: ALT 1377: AP 310: TBil:1.4) and abdominal CT revealed a mildly enlarged liver (20 cm) and splenomegaly (15 cm). Serological studies for viral hepatitis were negative for acute or chronic infection. The patient was started on empiric broad spectrum antibiotic therapy (vancomycin and cefepime) but he continued to remain febrile. On day 3, blood cultures taken on admission were positive for small gram negative "coccobacillary" organisms (identified as Brucella melitensis) and the patient was diagnosed with brucellosis. Following the return of the blood cultures, the patient's antibiotic therapy was changed to intravenous gentamicin (5 mg/kg/day) and doxycycline (100 mg PO BID). Over the next 4 days he had resolution of fever/symptoms and he was discharged on a planned 8 week course of rifampin and doxycycline. On closer questioning, the patient stated that he loved dairy products and frequently ingested "queso fresco" (raw cheese) from Mexico. At the 5 week follow-up, the patient felt well and the abnormal laboratory results had completely resolved.

DISCUSSION: Brucellosis is a zoonotic infection that is transmitted to humans after contact from infected animals such as sheep, cattle, or goat, or from their food products such as unpasteurized milk and cheese. It is sometimes called "undulant fever", because of the intermittent, "undulating" quality of the fever as seen in this case. In addition to constitutional signs (fever, weight loss, night sweats), brucellosis can have multi-organ involvement including osteoarticular (SI joints, spondylitis), genitourinary (epididymoorchitis), hematologic (leukopenia, anemia, thrombocytopenia), cardiac (endocarditis, pericarditis), neurologic (meningitis, myelitis, radiculitis), ocular (uveitis), and dermatologic (petechiae, ulcerations) manifestations. Mild liver enzyme elevation is common in brucellosis (50 % of cases); however, overt hepatitis, as in this case is much less common (3–6 % of cases). Although uncommon, consider the diagnosis of brucellosis in patients with unexplained fever and hepatitis, especially if there is a history of animal exposure or ingestion of raw dairy products (milk/cheese).

A.N.C. -THE KEY THAT UNLOCKED THE CAUSE OF MY STOMACH PAIN! Kelli Pitt. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1641524)

LEARNING OBJECTIVE 1: Identify the differential diagnosis of abdominal pain in immunocompromised patients.

LEARNING OBJECTIVE 2: Recognize the clinical presentation of typhlitis (neutropenic enterocolitis) and dangers of invasive evaluation. Understand the pathophysiology of typhlitis, which will aid in management.

CASE: A 31 year-old man presented with 1 month of progressively worsening abdominal pain and fever. He also noted nausea and vomiting but no changes in his bowel habits. He was febrile and tachycardic. There was mild tenderness in the right lower quadrant. There was no guarding or rebound tenderness, although pain was elicited with flexion of the right hip. His medical history was significant for AIDS with a CD4 count of 1. An extensive infectious work-up was performed and included the following: CMV PCR, histoplasma antigen, cryptococcal antigen, cryptosporidium, stool ova and parasite, stool gram stain and culture, C. difficile PCR, serum H. pylori IgM, and serum AFB and blood cultures. All tests returned negative. Abdominal CT revealed diffuse wall thickening of the cecum and proximal ascending colon with associated stranding and edema, no free air or fluid, and a normal appearing appendix. These findings were consistent with typhlitis. Of note, CBC revealed an absolute neutrophil count (ANC) of 370.

DISCUSSION: Abdominal pain with fever is a presenting complaint commonly encountered by the Internist with a vast differential spanning from mild disease, such as gastritis, to more severe and life threatening causes such as pseudomembranous colitis. This differential broadens more so in patients with HIV due to impaired host defense to opportunistic infections including CMV, MAC, and cryptosporidium as well as bacterial, parasitic, and fungal infections. Other entities that should be considered include HIV/AIDs cholangiopathy, mesenteric infiltration, pancreatitis and lymphoma. Typhlitis should be considered in any neutropenic patient who presents with fever and abdominal pain, particularly in the right lower quadrant. Other symptoms can include abdominal distention, nausea, vomiting, diarrhea, and peritoneal signs. Imaging with CT is most useful in supporting the diagnosis of typhlitis and can aid in ruling out other causes in an otherwise negative work-up. HIV patients, such as this one, have loss of cellular immunity and are susceptible to infection in addition to pronounced inflammation that leads to intestinal mucosal injury. Bacterial invasion of the bowel wall occurs, leading to cecal inflammation and edema that may progress to necrosis, ulceration and perforation. These patients are at increased risk of perforation with invasive procedures such that colonoscopy should be avoided and surgery reserved for those with significant complications. Patients should be managed conservatively with bowel rest, broad-spectrum antibiotics, and often granulocyte-colony stimulating factor to aid in increasing the neutrophil count. Typhlitis usually resolves once the ANC rises above 500–1000, at which time the patient can be safely evaluated with colonoscopy to confirm diagnosis. Typhlitis is a well known cause of morbidity and mortality affecting patients with neutropenia. Although most commonly seen in patients post chemotherapy, this diagnosis should be considered in all neutropenic patients who present with fever and abdominal pain, as demonstrated in our patient with AIDS.

AKI AND ITP AND THE INFECTIONS THAT BIND THEM TOGETHER Pooja Sethi; Ankit Madan; Khalid Rasheed; Philip Putnam. University Of Alabama Birmingham Montgomery, Montgomery, AL. (Tracking ID #1642822)

LEARNING OBJECTIVE 1: To recognize Disseminated Histoplasmosis (DH) as an opportunistic infection and understand its clinical manifestations.

LEARNING OBJECTIVE 2: To learn about the rare complications associated with DH and their appropriate management.

CASE: The patient is a 35 year old African American lady recently diagnosed with HIV, not on HAART, presented to the ER with 2 day history of fever, vomiting, diarrhea, and fatigue. On physical exam she had temperature of 103, oral thrush, and lower abdominal tenderness. Urine analysis showed 53 WBC, leukocyte esterase positive. Hemoglobin was 8, WBC 7000 with a normal differential, and platelets of 220,000. Creatinine was 9, elevated from 1.2 2 weeks prior. CD4 was 19 and viral load was 1,000,000. She was treated for pyelonephritis with Ceftriaxone but continued to spike fever. Her antibiotics were broadened to vancomycin and zosyn. On hospital day three, patient developed severe epistaxis and her platelet count dropped to 26,000. Peripheral smear showed schistocytes and intracellular yeast, and

blood cultures confirmed yeast forms. The patient was started on Amphotericin. Fungal culture and urine histoplama antigen confirmed the diagnosis of Disseminated Histoplasmosis. Diagnosis of Thrombotic thrombocytopenic purpura (TTP) was also a concern since she had fever, anemia, thrombocytopenia, and renal failure. The patient was transferred for plasmapheresis, but a repeat peripheral smear showed no schistocytes. ADAMST13 was elevated, favoring alternative diagnosis. The patient was treated as Idiopathic thrombocytopenic purpura (ITP) and started on corticosteroids. Amphotericin B was continued. Her symptoms improved. Initial lab abnormalities returned to normal within a week, and she was discharged with a creatinine of 1.2 and platelets of 165,000.

DISCUSSION: DH should be considered in advanced HIV patient, who present with nonspecific symptoms. It has a multitude of presentations with mucocutaneous, respiratory, GI or hematological derangements. There are very few case reports with complications of AKI and ITP in DH, and to our knowledge none so far with both complications in a single patient. Histoplasma may cause direct platelet membrane damage or antibody-mediated platelet damage, releasing ADP and serotonin, which leads to platelet aggregation and increased clearance from circulation. HIV-associated nephropathy causes FSGS. Clinicians should be careful to exclude other causes, particularly those of acute onset. Histoplasmosis causes renal insufficiency, and shows granulomatous interstitial nephritis on kidney biopsy. Therapy with amphotericin B results in dramatic improvement in symptoms and lab values, whereas HIV-associated nephropathy tends to be more indolent and progressive. A delay in diagnosis can be fatal.

AL AMYLOIDOSIS: WHEN YELLOW MEETS CONGO RED Kendrick B. Gwynn; Tiffany Walker; Kimberly D. Manning; Kristina L. Lundberg; Robin Klein. Emory University School of Medicine, Atlanta, GA. (Tracking ID #1634557)

LEARNING OBJECTIVE 1: AL amyloidosis can involve multiple systems including bone, liver, heart and muscles

LEARNING OBJECTIVE 2: AL amyloidosis must be considered even in the presence of other pre-existing systemic conditions

CASE: 55 year old female history of sarcoidosis presenting with several weeks of bilateral upper extremity weakness and jaundice. She reported having diffuse abdominal pain, decreased oral intake, dark urine but denied nausea, diarrhea, or acholic stools. The patient had a previous history of multiple compression fractures of L1, L4, L5 and bilateral hip replacements. Exam was significant for a thin appearing female with icteric sclerae, jaundiced skin and tender hepatomegaly about 4 cm below the costal margin. Neurologic exam was significant for 4/5 proximal muscle upper extremity strength but no other focal deficits. Labs on admission were significant for AST 82 U/L, ALT 45 U/L, alkaline phosphatase 1828 U/L, total bilirubin 5.7 mg/dL, total protein 6.1 gm/dL and albumin 2.9 gm/dL, CPK 16 U/L, ESR 82 mm/hr. Throughout the hospital course total bilirubin peaked at 17.4 mg/dL. Muscle biopsy showed Type II fiber atrophy and EMG showed primary myopathy. Liver biopsy showed proteinaceous infiltrate staining positive for amyloid. SPEP and UPEP were within normal limits. Transthoracic echocardiogram showed preserved systolic and diastolic function. Serum free light chains were elevated with kappa/lambda ratio of 0.10. Bone marrow biopsy was significant for primary immunoglobulin light chain amyloidosis (AL) without clonal cell population. She was discharged with follow up with oncology with plans to begin dose adjusted bortezomib and dexamethasone.

DISCUSSION: Immunoglobulin light chain amyloidosis, previously known as primary amyloidosis is a disease caused by light chain deposition in various organs. Presenting features of systemic AL amyloidosis include non-diabetic nephrotic range proteinuria, restrictive cardiomyopathy, increased BNP in the absence of primary heart disease, hepatosplenomegaly, carpal tunnel syndrome, unexplained facial or neck purpura, or macroglossia. Diagnosis is made by tissue biopsy with immunohistochemical staining. Liver involvement in AL amyloidosis is seen in up to 70 % of patients. Most frequent presenting lab abnormality is an alkaline phosphatase greater than 500. Poor prognostic indicators include the presence of heart failure, total bilirubin greater than 2 or platelets greater than 500,000. Median survival is 9 months with five-year survival of 17 %. Myopathy is uncommon in systemic amyloidosis but can present with nerve conduction abnormalities seen in up to 82 % of patients and patients typically presenting with muscle pseudohypertrophy. Osteolytic lesions of the bone can lead to pathologic fractures and bone pain. Treatment involves chemotherapy plus hematopoietic stem cell transplant or chemotherapy alone in transplant ineligible patients. The aforementioned case highlights the hepatic manifestations of AL amyloidosis. Furthermore, it underscores the importance of considering all possible diagnoses as the patient's history of sarcoidosis was proved to be inactive and unrelated in this case and obscured the initial workup.

ABDOMINAL PAIN AND QUADRIPARESIS: ACUTE INTERMITTENT PORPHYRIA AT ITS WORST Venkata N. Kollipara; Jingdong Su; Roger D. Smalligan; Bindu B. Yalamanchili; Steven Urban. Texas Tech University Health Sciences Center, Amarillo, TX. (Tracking ID #1634959)

LEARNING OBJECTIVE 1: Diagnose porphyria in patients with intermittent abdominal pain, especially if there is any associated neuropathy.

LEARNING OBJECTIVE 2: Recovery from porphyria associated neuropathy can take months to years for complete recovery, Early diagnosis and promt management can prevent disabillity and suffering of affected patients.

CASE: A 21-year-old female presented with severe abdominal pain, nausea and intractable vomiting for 4 days. She had been having similar symptoms intermittently for the past 4 years requiring multiple admissions. She had a cholecystectomy on the previous admission with no relief of pain. The pain was severe, diffuse, and constant with no aggravating or relieving factors. Her appetite was decreased and she was constipated. On examination, she was hypertensive and tachycardic. Lungs were clear and heart sounds normal. The abdomen was diffusely tender without guarding or rebound tenderness and bowel sounds were present. She developed profound bilateral wrist drop and foot weakness over several days after admission leading to quadriparesis. Lab work revealed hyponatremia, hypokalemia, and hypomagnesaemia. Her urine was dark-colored hence blood, urine and fecal samples were sent on suspicion of porphyria early on. Porphyrin was markedly elevated in the blood and porphobilinogen and ALA were high in the urine. The diagnosis of Acute Intermittent Porphyria (AIP) was made and the patient was treated with intravenous Hematin for 7 days, dextrose solution IV and nutritional support. Her abdominal pain resolved promptly, however, her peripheral neuropathy with profound weakness, (distal motor dysfunction > proximal) was treated for weeks with physical and occupational therapy.

DISCUSSION: Acute intermittent porphyria (AIP) is a rare autosomal dominant metabolic disorder caused by a defect in the hepatic pathway of heme biosynthesis. It was first described by Stokvis in 1889. Inherited deficiency of porphobilinogen deaminase (PBGD) is the underlying cause of acute intermittent porphyria. Acute attacks are usually precipitated by stressors such as fasting, low carb diets, alcohol intake, infections and certain medications. Typical symptoms of AIP include intermittent abdominal pain and bloating, nausea, vomiting, constipation or diarrhea, urinary retention or incontinence, tachycardia, fever, sweating, tremor, and peripheral neuropathy. Our patient's abdominal pain had caused repeated admissions where cholecystitis, idiopathic gastroperesis, and IBS had been considered. We also thought of marijuana-induced hyperemesis syndrome and drug-seeking behavior. Once the patient developed quadriparesis and her screening tests returned positive for porphobilinogen the diagnosis of AIP was confirmed. The neuropathy of AIP is due to the metabolic effects on the peripheral as well as central sensory and motor nervous systems. Recovery from the neuropathy can take months to years. As mentioned, our patient's neuropathy showed very slow improvement during her 60 days of hospitalization though she could walk with help at the time of discharge. This case reminds internists to include porphyria in the differential of young patients with intermittent abdominal pain, especially if there is any associated neuropathy. Early diagnosis with avoidance of inciting factors,

as well as prompt management if complications occur, can prevent severe disability and suffering for affected patients.

ABDOMINAL PAIN AND NEUROPATHY Manisha Bhide. University of Colorado Denver, Aurora, CO. (Tracking ID #1633757)

LEARNING OBJECTIVE 1: Recognize and review Acute Intermittent Porphyria. This case illustrates a typical presentation of an uncommon illness.
CASE: 34 year female presented with severe epigastric pain since 2 days. This was associated with nausea, uncontrolled hypertension, headache, fatigue, anxiety, muscle weakness and paresthesia in hands and legs. Past Medical history was significant for Hypertension controlled with Labetalol 600 mg BID and Diltiazem 240 mg/day. She had a similar episode of abdominal pain 20 year ago, that was associated with confusion. Details of this attack were not available. Family History was negative. Exam revealed BP 170/99, pulse 90/min, age appropriate well oriented afebrile pt, in obvious distress due to abdominal pain. Epigastric tenderness was noted. Neurological evaluation noted 4/5 strength in biceps and hand muscles bilaterally and 5/5 in all other muscles. Reflexes were normal. Red urine with large blood on dipstick was noted, but no RBC on urine microscopy. Leukocyte esterase and nitrite was negative. Pt was given opiates to control pain. Higher dose anti-hypertensives were given along with hydration. A diagnostic test was done. This helped guide the further management. Differential diagnosis of her abdominal pain is broad and includes gastritis, cholecystitis, appendicitis, pancreatitis, pyelonephritis, diabetic Ketoacidosis, vasculitis, Sarcoidosis, Botulism, lead toxicity and Guillain-Barre syndrome can cause epigastric pain with neuropathy. Acute intermittent porphyria (AIP) should always be in differential diagnosis of acute abdominal pain and neuropathy. A high index of suspicion is needed to diagnose this life threatening illness and avoid inappropriate therapies that can exacerbate the attack. Pt had red urine and urine porphyrins (porphobilinogen and coproporphyrin) were high consistent with diagnosis of AIP. Pt was given IV dextrose 300–500 g as a 10 % solution, with monitoring of serum sodium, since that can cause hyponatremia. Pt also received Panhematin infusion 3–4 mg/kg. Her attack slowly resolved and pt was sent home with regular Panhematin infusions.
DISCUSSION: Porphyria is caused by deficiency of enzymes in heme synthesis. AIP is due to Porphobilinogen (PBG) deaminase deficiency. It is autosomal dominant condition with variable penetrance. Incidence is about 1 in 20,000. Alcohol, Barbiturates, starvation, infections and many medications acutely worsen the accumulation of porphyrins, precipitating an attack. The pain of acute abdomen is due to toxic neurological effect of the porphyrins. Acute abdomen is the most common presentation of AIP. Typical Neuropathy of AIP is proximal motor neuropathy. This happens in 10–40 % of AIP attacks. Neuropsychiatric symptoms are manifested by anxiety, hysteria and altered mental status. Paresis involving respiratory muscles and hands can occur. Autonomic neuropathy is manifested by ileus, tachycardia and hypertension. Hypothalamic involvement can cause SIADH and hyponatremia. Photosensitive dermatitis can occur, but is rare during acute attacks. Panhematin and dextrose both act by decreasing porphyrins- ALA and PBG. Frequent Hemin therapy will cause increase in ferritin and pt may need phlebotomy. Liver transplant can be considered in extreme cases and is curative. AIP increases risk for renal insufficiency and hepatocellular carcinoma and this needs long term monitoring.

ABSTRACT TITLE: "AN INTERESTING SUMMER EXPERIENCE" Mahmoud A. Abu Hazeem. Creighton University Medical Center, Omaha, NE. (Tracking ID #1642684)

LEARNING OBJECTIVE 1: To recognize hyperthermia as a cause for shock, NSTEMI and multiorgan failure.
CASE: 39 y/o Caucasian male was brought to the emergency room unconscious, found lying near a lake in bright sunlight on a hot summer day. On examination he was completely unresponsive, Vitals—Temperature-109.1. BP: 82/28, HR: 170, RR- 26. Heart, lung and abdomen examination was normal. Neurologic examination revealed hyporeflexia, meningeal signs were negative. He was intubated in the ER for airway protection. Relevant labs include- Anion gap- 18, Osmolar gap-normal, Lactate- 4.6, Bicarbonate- 19, Creatinine-2.0, AST- 130, ALT- 251, CPK- 3838, Urine drug screen was positive for THC, amphetamines and opiates, blood alcohol level- negative. CT head was negative. Aggressive passive and active cooling interventions via a femoral vein catheter, cold IV fluids, cooling blankets were initiated. He remained intubated in the ICU for 5 days during which his clinical course was complicated by mixed shock, disseminated intravascular coagulation, non ST elevation myocardial infarction, GI bleed, rhabdomyolysis and seizures. He was treated with pressors, antibiotics, anti epileptics, also received blood and cryoprecipitate. On day 6 following extubation he was back to his baseline and was discharged home after an outpatient referral to a drug rehabilitation program.
DISCUSSION: Heat related illnesses occur when there is an imbalance between heat production and heat loss, resulting in elevated body temperature. These syndromes can vary from minor heat illnesses namely heat cramps, heat rash to more significant heat exhaustion, heat syncope and the most severe and life threatening heat stroke. Heat stroke in addition to elevation in body temperature is characterized by mental status changes which usually occur when body temperatures are over 105.8 °F when the body often looses the ability to sweat. Symptoms range from nausea, weakness, lightheadedness, headache and muscle cramps to hallucinations, vertigo, syncope or coma. Classical heat stroke occurs more common in elderly or young children where there is elevation in ambient temperatures.. In addition to mental status changes patients with heat stroke present with severe dehydration, hypernatremia, elevated liver, renal function tests, coagulopathy and rhabdomyolysis which were all present in our patient. Imaging of the brain is important to rule out an intracerebral bleed. Management includes rapid cooling to achieve a core temperature goal of at least 102.2. In addition to the passive cooling techniques intravascular heat exchange catheter systems and hemodialysis with a cold dialysate were proven successful. Aspirin and acetaminophen have no effect on hyperthermia and are not recommended. Sedation with benzodiazepines and often paralytics may be necessary to eliminate any further heat production. Cooling alone improves cardiac function, hypotension and eliminates dysrhythmias. In conclusion heat stroke is highly fatal and early diagnosis and prompt resuscitation is the key in management.

ACQUIRED FACTOR VIII DEFICIENCY: A RARE BUT OVERLOOKED BLEEDING DIATHESIS Christopher Sankey; Radhika Shah. Yale New Haven Hospital, New Haven, CT. (Tracking ID #1633120)

LEARNING OBJECTIVE 1: Recognize Acquired Factor VIII Deficiency as a cause for bleeding diathesis.
CASE: An 81 year old woman presented with a 5 day history of worsening left upper extremity edema in the absence of trauma. Upon admission, vitals signs were stable and physical exam was remarkable for ecchymosis and non-pitting edema of the left mid-forearm extending proximally past the elbow. Upper extremity venous doppler was notable for a hematoma with no evidence of thrombosis. A bleeding diathesis was suggested by an elevated aPTT of 58 s. Subsequent hematologic testing demonstrated no correction of aPTT with mixing and a factor VIII inhibitor level of 105 Bethesda Units, the highest level ever recorded in our hospital. Collectively, these results suggested a diagnosis of acquired factor VIII deficiency. Over the next several days, the left arm edema progressed, with subsequent involvement of the right upper extremity, neck, and back. The patient was aggressively treated with activated factor VII, prednisone, and rituximab. No compartment syndrome developed in the upper extremity and she remained hemodynamically stable. After treatment, there was a reduction of her inhibitor titer to 38 Bethesda Units. Further investigation did not reveal a malignancy or autoimmune precipitant. She was ultimately discharged home with arrangements for outpatient hematology follow up.
DISCUSSION: This case describes a bleeding diathesis attributed to an acquired factor VIII inhibitor in an elderly patient. Acquired factor VIII

deficiency is a rare bleeding disorder (1 to 4 cases per million per year) caused by antibodies against factor VIII clotting factor. While uncommon, it is associated with significant morbidity and mortality in the setting of severe bleeding. The typical age distribution of the disorder is biphasic, with a minor peak at age 20–30 and a major peak at age 68–80, as in the case of our patient. Bleeding usually occurs in the skin, muscles, soft tissues and mucus membranes; this is in contrast to hereditary factor VIII deficiency, which usually presents with hemarthrosis. Diagnosis of factor VIII inhibitor in a patient with a suspected bleeding diathesis is suggested by a prolonged aPTT and a negative mixing study. Subsequently, factor VIII and factor VIII inhibitor levels can be established and used to guide therapy. Acquired factor VIII inhibitor is usually associated with other medical conditions, including malignancies and autoimmune disorders and should be investigated at the time of diagnosis. In 50 % of cases, no associated medical condition is found. In conclusion, acquired factor VIII inhibitor should be considered in the differential diagnosis of a bleeding diathesis, especially in the elderly population. This disorder can cause significant morbidity and mortality, requires immediate hematology evaluation, and can easily be screened with an initial aPTT.

ACUTE ASEPTIC MENINGITIS ASSOCIATED WITH HERPES ZOSTER REACTIVATION IN AN IMMUNOCOMPETENT ADULT Iani Patsias; David Paje. Henry Ford Hospital, Detroit, MI. (Tracking ID #1640203)

LEARNING OBJECTIVE 1: Recognize aseptic meningitis as a rare but potential complication of shingles in patients who develop acute neurologic symptoms.
LEARNING OBJECTIVE 2: Describe the appropriate management of aseptic meningitis due to varicella zoster.
CASE: A 61-year-old female with a history of hypertension and neurofibromatosis type 2 with chronic occipital headaches, presented to the emergency department with a 3-day course of frontal headache and a painful rash on her left flank. She described the headache as dull, different from her usual, 10/10 in intensity, worsened by sitting upright, unrelieved with NSAIDs, and associated with nausea, vomiting, photophobia and phonophobia. On admission, she was afebrile and had a blood pressure of 176/86 mmHg. Examination revealed a vesicular rash with erythematous base from the left paravertebral area extending anteriorly following the left T6-T7 dermatome. She was lethargic with poor attention span, but otherwise she had no other significant neurologic findings. Her blood tests were all within normal limits. MRI showed chronic findings related to neurofibromatosis type 2, including stable bilateral acoustic neuromas, mildly enlarging meningiomas involving the posterior falx and left anterior middle cranial fossa, and probable schwannoma or neurofibroma in the left Meckel's cave. CSF obtained through lumbar puncture revealed normal glucose, elevated protein and lactic acid, and leukocytosis (635/cu mm) with lymphocytosis (91 %). CSF cultures were negative, but PCR was positive for Varicella Zoster and Epstein-Barr virus. The patient was given Gancyclovir 2.5 mg/kg IV bid for 14 days, resulting in prompt resolution of symptoms.
DISCUSSION: Aseptic meningitis is a rare complication of herpes zoster reactivation. While subclinical meningeal irritation can occur in as much as 30–40 % of patients with shingles as manifested by CSF pleocytosis, only a rare few (0.5–2.5 %) develop full blown clinical aseptic meningitis. The underlying pathophysiology is unclear, particularly in immunocompetent patients. Symptoms may include high fever, severe headache, cervical rigidity, seizure, ataxia, hemiplegia, or even coma. These symptoms may occur within days after the appearance of the skin lesions. A high index of suspicion is important since some patients, such as in this case, may only complain of new onset headaches. CSF analysis is necessary for definitive diagnosis; PCR is widely used because of its speed and accuracy. Effective treatment requires intravenous administration of nucleoside analogues, such as acyclovir or ganciclovir, since oral regimens do not achieve sufficient drug levels. Patients usually recover fully without significant complications. While there are rare reports of Varicella Zoster meningitis in vaccinated patients, vaccination remains the most important strategy in the management of herpes zoster infections. Aseptic meningitis should be considered in patients with shingles who develop acute neurologic symptoms. Prompt recognition leads to appropriate management with intravenous antiviral agents.

ACUTE DIVERTICULITIS: NOT JUST FOR THE YOUNG AT HEART Komal D'Souza; Stacie Schmidt. Emory University School of Medicine, Atlanta, GA. (Tracking ID #1634945)

LEARNING OBJECTIVE 1: Recognize that diverticulitis can occur in individuals less than 40 years of age.
LEARNING OBJECTIVE 2: Identify the factors predicting a worse prognosis in young persons with diverticulitis.
CASE: A 26 year old male with no significant past medical history presented to the walk-in clinic of a large urban academic hospital reporting sub-acute left lower quadrant abdominal pain for 1 month. The pain was worsened with straining during defecation. There was associated hematuria at the end of his urinary stream, but he denied frank blood loss, fevers/chills, emesis, scrotal/perineal pain or penile discharge. The patient had presented to multiple ERs and was diagnosed with UTI/prostatitis for which he was discharged with antibiotics on several different occasions. He noted no change in symptoms despite completing the medications prescribed. On exam, he was obese, afebrile and tachycardic (HR 114). There was tenderness to palpation in the left lower quadrant, along with significant subcutaneous firmness extending from the superior iliac spine to the midline abdomen. No overlying cellulitis or abscesses were noted, andthere was no rebound or guarding. Labs from a recent ER visit were notable for a leukocytosis of 9.7 K/mol with a left shift, and a hemoglobin of 9.8 (microcytic). A urinalysis was notable for proteinuria, hematuria, pyuria, leukocyte esterase and nitrites. A urine culture was negative for micro-organisms. Given his prolonged symptoms and abdominal findings on exam, a CT of the abdomen/pelvis was ordered. It revealed perforated sigmoid diverticulitis with multi-loculated, multifocal pelvic abscesses and a colo-vesicular fistula. The patient was urgently admitted to the general surgery service, where he underwent exploratory laparotomy with sigmoid colectomy and end colostomy, small bowel resection, and ureteral stent placement. The pathology specimen from the original surgery revealed diverticuli with fibrosis.
DISCUSSION: Acute diverticulitis is a common disease in North America, with greater than 300,000 related hospital admissions in the U.S. in 2004. Diverticular disease is caused by herniation of the mucosa and sub-mucosa of the colonic walls. Diverticulitis arises from diverticulosis when inflammation in the diverticulum leads to perforation or abscess formation. The burden of disease mostly occurs in the elderly, with diverticulosis present in less than 10 % of individuals under 40, but between 50 % and 60 % in adults over the age of 80. There are some studies that indicate that diverticulitis may present more aggressively in younger patients, perhaps secondary to a delay in diagnosis in younger individuals simply because of their age. A retrospective chart review of patients age 40 and younger showed that obesity and fever upon presentation may be associated with a complicated course in younger patients with diverticulitis. This case highlights the importance of a broad differential for abdominal pain in all patients, regardless of their age. Just as older adults can present with acute appendicitis, younger individuals can present with acute diverticulitis. This patient had numerous encounters with physicians before the diagnosis was made. Despite having symptoms classic for diverticulitis—left lower quadrant abdominal pain and signs of systemic illness, the diagnosis was missed on several occasions. Although this diagnosis may not be common among younger adults, it must always be considered in patients who present with similar symptoms.

ACUTE EPIGLOTITIS AS THE PRESENTING FEATURE OF MULTIPLE MYELOMA Andreea Bujor; Eunice Y. Chuang; Indumathy Varadarajan. MAH, Cambridge, MA. (Tracking ID #1642553)

LEARNING OBJECTIVE 1: Recognize that bacterial infections, especially from encapsulated organisms such as Streptrococcal pneumonia, can be the initial presentation of Multiple Myeloma.

CASE: 72 year old gentleman with diabetes presented with 2 days of fever, progresive shortness of breath and sore throat. On admission, vitals where as follows: T 104.2 F, RR 40, oxygen saturation 92 % on 2 L NC. A laryngoscopy revealed redness and swelling of epiglottis with abundant secretions. Laboratory data showed WBC 7250/cmm, hemoglobin 9.8 g/dL, hematocrit 28 %, platelets 81000/cmm, creatine 0.9, albumin 3.7 g/dL, total protein 10.9 g/dL, calcium 10.2 mg/dL. A CT scan of the neck and chest showed diffuse thickening of the epiglottis with regional narrowing. Patient developed respiratory distress, requiring endotracheal intubation and he was admitted to the ICU. Blood cultures grew Streptococcus pneumoniae, treated with Ceftriaxone. Serum protein electrophoresis revealed an abnormal band measuring 3.6 g/dL in the gamma region. Serum immunofixation electrophoresis identified monoclonal IgG kappa. IgA and IgM levels were diminished. Bone marrow showed abnormal plasma cells consistent with plasma cells myeloma. Free kappa lambda was 120.35 and beta 2 microglobulin 4.91 mg/L. Therefore, new diagnosis of multiple myeloma was established. Patient made an uneventfull recovery from epiglottittis and was extubated 6 days later. He was discharged and started on Bortezomib, Lenalidomide and Dexamethasone as outpatient.
DISCUSSION: The most common presenting features of multiple myeloma (MM) are anemia, lytic lesions, hypercalcemia, and renal failure. MM is associated with a susceptibility to bacterial infections, specifically for encapsulated organisms. However, there are only scattered case reports of pneumococcemia at the time of diagnosis of multiple myeloma, and to the best of our knowledge this is the first report showing pneumococcal epiglottitis as the initial presentation of MM. Thus, this clinical scenario might be a red flag for underlying MM in patients without other risk factors for pneumococcal infection. Furthermore, adult cases of epiglotittis are rare, with an overall incidence of 0.98/100,000/year. In the majority of cases in adults, blood cultures are negative, but when positive the etiology is predominantly H. influenzae. Our case highlights the importance of a thorough evaluation in cases of adult pneumococcemia. Therefore, MM should be considered in a patient presenting with pneumococcal infection. Suspicion should be especially high when there is evidence of leukopenia, anemia, prior bacterial infections, renal failure, and indirect evidence of a paraproteinemia.

ACUTE GENERALIZED EXANTHEMATOUS PUSTULOSIS IN A LUPUS PATIENT RECENTLY INITIATING HYDROXYCHLOROQUINE. Mary E. Wiles; Robin Klein; Daniel D. Dressler; Francois Rollin. Emory, Atlanta, GA. (Tracking ID #1635453)

LEARNING OBJECTIVE 1: Promote awareness of dermatologic side effects, including Acute Generalized Exanthematous Pustulosis, that may be caused by hydroxychloroquine
LEARNING OBJECTIVE 2: Recognize the rash of Acute Generalized Exanthematous Pustulosis
CASE: A 36 year old female with systemic lupus erythematosus presented to the Emergency Room with rash and lip swelling. Two weeks prior, the patient started taking Hydroxychloroquine 400 mg daily and prednisone 20 mg daily. She developed swelling, redness, and pain on her lips, but attributed this to something she had eaten. She took Benadryl but the rash continued to spread over her face and neck over the next few days. The rash worsened prompting her to visit the ER twice, where she was treated with IV Benadryl and Bactrim. Her rash continued to worsen and she was admitted for further evaluation. Exam revealed diffuse, pruritic, pustular rash involving her oral mucosa, palms, and soles, with convalescence and superimposed impetigo in the malar region. She was afebrile. Posterior cervical lymphadenopathy and difficulty opening her mouth were noted. She had joint pain with active and passive movement of the knees, wrists, and ankles but no effusions. Laboratories revealed a leukocytosis with a WBC of 25.1×109/L with 8 % bands, 1 % eosinophils. Transaminases were normal. Treponemal IgG, HIV, and hepatitis serologies were negative. Blood cultures grew coagulase negative staph and wound cultures showed normal skin flora. Skin biopsy showed focal spongiosis along with edema in the papillary dermis and dermal scattered perivascular lymphohistiocytic infiltration with rate neutrophils and eosinophil's, which was consistent with Acute Generalized Exanthematous Pustulosis. The patient was seen by Dermatology and Rheumatology who felt like the rash was likely a reaction to Hydroxychloroquine. The patient was started on hydroxyzine, topical steroids, antibiotics for possible superimposed cellulitis, and prednisone. She had complete desquamation of her skin over the next few weeks and approximately 3 months after discharge experienced telogen effluvium.
DISCUSSION: Our patient presented with Acute Generalized Exanthematous Pustulosis, an acute progressive rash attributed to hydroxychloroquine therapy. The differential diagnosis of acute skin reactions is broad and includes viral infection, drug reactions, and autoimmune diseases. Drug reactions are a common cause of skin eruptions or rashes and common offenders include sulfa drugs, antibiotics, and anti-inflammatory medications. Drug reactions may range from mild skin eruptions to severe cases including Stevens-Johnson syndrome, toxic epidermal necrolysis, hypersensitivity vasculitis, DRESS syndrome, and exanthematous pustulosis. Acute Generalized Exanthematous Pustulosis is an acute rapidly progressive rash—a reaction characterized by sudden eruption of numerous small pustules arising within large areas of edematous erythema, which usually begins on the face—attributed to HCQ therapy in this patient. 90 % of cases are related to medication administration and it appears, on average, 5 days following medication administration. Presentation may be profound, accompanied by fever, hepatitis and eosinophilia in some cases. AGEP is usually self-limited and resolves with removal of the offending agent. Incidence of AGEP is 1–5 cases/million per year and there are less than 25 reported cased in the literature of AGEP induced by HCQ. Mortality approaches 5 % so caution is warranted.

ACUTE HYPOXIA AND FEVER: INFECTION UNTIL PROVEN OTHERWISE? Elizabeth Snapinn; Alda Maria Gonzaga. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1638815)

LEARNING OBJECTIVE 1: To recognize the importance of avoiding premature closure of the differential diagnosis
LEARNING OBJECTIVE 2: To recognize Antisynthetase syndrome as a cause of interstitial lung disease (ILD)
CASE: A 45 year old healthy woman presented with fevers and 22 lb. weight loss. She was in her usual state of health until 2 months prior to presentation when she was treated for an eyelid rash concerning for contact dermatitis, and soon began experiencing weight loss. A week prior to presentation, she began to have daily fevers, cough and dyspnea. She presented to her PCP, was found to have an opacity on chest x-ray, and was treated for community acquired pneumonia as an outpatient. When she did not improve and continued to have daily fevers she was admitted for further evaluation. In the hospital, a chest CT showed atelectasis and infectious workup including blood and urine cultures, EBV, CMV and HIV serologies was negative. She was found to have an elevated ESR and CRP, and so an ANA, anti-phospholipid antibodies, anti-dsDNA and ANCA were drawn and all were found to be negative. She improved over several days and was discharged, however over the next 3 weeks she had a significant progression of her dyspnea with ongoing daily fevers. She presented to the ED and was found to be hypoxic to a pOx of 88 % with activity, to have anterior dry crackles on exam, and to have new basilar opacities on chest x-ray. Further history was significant for contact with chickens and rabbits as well as recent travel to the Caribbean. Repeat chest CT showed bibasilar ground glass opacities. An expanded infectious differential was considered, but blood cultures and BAL for viruses, fungus, AFB and Nocardia were negative. VATS was performed, and the biopsy showed acute organizing pneumonia without specific cause. Pulmonary function tests (PFTs) showed a restrictive pattern with loss of diffusing capacity. Further rheumatologic workup was then pursued and was significant for PL-12 antibodies consistent with antisynthestase syndrome. She was treated with a course of oral steroids with resolution of her dyspnea and improvement in her PFTs over the next several months.
DISCUSSION: Antisynthetase syndrome is a sub-group of inflammatory muscle disease characterized by the presence of one of several antisynthetase antibodies and comprises 20–40 % of cases of dermatomyositis and polymyositis. Interstitial lung disease is a common feature of this

syndrome and can present without symptoms of myositis, especially when the antibodies are to PL-12. Though this syndrome is quite rare, several studies have found that in populations of patients with idiopathic interstitial lung disease and no other signs of connective tissue disease, 6–8 % have antisynthetase syndrome. Thus, when considering a patient who presents with interstitial lung disease and no obvious cause, antisynthetase syndrome should be a consideration. The case also highlights the importance of preventing premature closure. In this case, the patient's unusual exposures led to prolonged exploration of the infectious pathway, and her previously negative rheumatologic workup led away from rheumatologic causes. The history of an eyelid rash could have been helpful in making the diagnosis, but only retrospectively was this felt to be a heliotrope rash. The focus on the patient's infectious exposures without consideration of all of her presenting symptoms led to a delay in diagnosis and more testing than required.

ACUTE INTERMITTENT PORPHYRIA ATTACK BY A 'SAFE' MEDICATION Andrew Goins[1]; Jacob Lepard[2]; Gregory Nieckula[1]; Maria Tudor[1]. [1]University of Tennessee College of Medicine Chattanooga, Chattanooga, TN; [2]University of Tennessee Health Sciences Center, Memphis, TN. (Tracking ID #1623969)

LEARNING OBJECTIVE 1: Maintain a high index of suspicion of possible drug interactions
LEARNING OBJECTIVE 2: Recognize repeated presentations may represent undiagnosed disease
CASE: A 29 year-old female with past medical history significant for multiple medical visits for abdominal pain, bipolar disorder and endometriosis presented to the emergency department complaining of difficulty ambulating and paresthesias in her hands and arms. Four weeks earlier, the patient had been placed on an increased dose of duloxetine. Her family history was positive for porphyria. Neurologic exam revealed generalized weakness with 1/5 strength in the upper extremities and 2/5 in the lower extremities, intact cranial nerves, no sensory deficits, and absent bilateral patellar, biceps, and brachioradialis reflexes. The patient recalled having had recent outpatient studies at an outlying facility for evaluation of weakness. They included an electromyelogram and magnetic resonance imaging of the cervical spine, as well as Hepatitis A, B and C antibodies, free thyroxine, thyroid stimulating hormone, glycosylated hemoglobin, human immunodeficiency virus, C-reactive protein, Lyme titers, serum protein electrophoresis, anti-neural antibodies, and a myasthenia gravis panel. The day after admission, the results became available: they were within normal limits—with exception of the electromyelogram, which showed a pure motor neuropathy. It was considered that she may have an attack of acute intermittent porphyria (AIP)—which could explain her symptoms and neurological findings. Urine porphobilinogen and erythrocyte porphobilinogen deaminase (ePBG) were ordered. Intravenous panhematin was started; Neurology and Hematology consults were requested. The patient experienced a rapid deterioration in her condition, including delirium and respiratory muscle weakness, requiring intubation and transfer to intensive care. Shortly thereafter, AIP was confirmed with a urinary porphobilinogen level of 72 mg/L (0–2 mg/L). She recovered slowly with supportive care and was discharged.
DISCUSSION: The porphyrias are caused by partial deficiencies of enzymes used in the synthesis of heme. Heme is required for many cell processes, one of which is the production of cytochrome P450 (CYP) enzymes. Many medications up-regulate the CYP system, which requires de novo synthesis of heme. The enzyme deficiency, coupled with increased pathway demand, leads to a high concentration of intermediate components (porphyrins) of the heme production pathway. It is the buildup of this intermediate that causes the toxicity seen in acute intermittent porphyria, manifested by abdominal pain, vomiting, constipation, and psychiatric symptoms. Drug reactions are sometimes occult and often unanticipated. In this particular case, the chronology of events reveals a dramatic adverse drug reaction. A literature review reveals that duloxetine is listed as probably not porphyrinogenic. A single case report showing a causal association was found, but was brought into question because the symptoms could have been explained as side effects of duloxetine and ePBG levels were not measured. Based on the Naranjo probability score of "probable likelihood", timing of events, and unclear safety of duloxetine in porphyria, this patient likely experienced a porphyric crisis induced by duloxetine. To our knowledge, this is the first report with supporting lab data to suggest a possible association between duloxetine and AIP.

ACUTE KIDNEY INJURY IN AN HIV-INFECTED PATIENT: A COMPLEX CLINICAL SCENARIO Monique Duwell; Sara Wikstrom. The George Washington University, Washington, DC. (Tracking ID #1642471)

LEARNING OBJECTIVE 1: Recognize the multiple potential etiologies of renal failure unique to the HIV-infected population
CASE: The patient is a 61 year-old African-American male who presented with 4 weeks of progressively worsening shortness of breath, leg swelling and fatigue. Medical history was significant for HIV (CD4 97) diagnosed 6 months previously. Medications were emtricitabine, tenofovir, lopinavir, ritonavir, and trimethoprim/sulfamethoxazole (TMP-SMX). Physical exam was notable for crackles of the lung bases, and pitting edema of the lower extremities. Initial labs revealed acute kidney injury (creatinine 11.2 mg/d), as well as metabolic acidosis (CO2 10.8 mmol/L). Urinalysis showed glucosuria (200 mg/dl) and proteinuria (100 mg/dl) and granular casts were visualized. Ultrasound showed echogenic kidneys and left hydronephrosis. CT revealed a soft tissue mass of the left renal hilum and ureter, shown to be 8×5 cm by MRI. A left ureteral stent was placed, but the patient's renal function failed to improve, and he initiated hemodialysis. Percutaneous biopsy of the renal/ureteral lesion showed atypical lymphoid proliferation suggestive of plasma cell neoplasm, but was insufficient for diagnosis. Bone marrow biopsy then confirmed plasmablastic lymphoma. The patient's serum kappa/lambda ratio (233), was consistent with kappa light chain gammopathy. Additionally, his uric acid level rose to 20.1 mg/dL, necessitating rasburicase and allopurinol. The patient tolerated one round of chemotherapy for the plasmablastic lymphoma and was discharged to a rehabilitation facility with plan for continuation of hemodialysis and chemotherapy.
DISCUSSION: HIV-infected patients are at risk for a variety of unique causes of acute kidney injury (AKI), in addition to those that impact the general population. As this case demonstrates, these causes may co-occur in the HIV-infected patient with AKI, creating a complicated clinical picture. First, HIV antiretroviral therapy can causes nephrotoxicity. The patient's initial metabolic acidosis and glucosuria was suggestive of Fanconi Syndrome, which can be caused by tenofovir. The evidence of acute tubular necrosis seen on urine microscopy was also consistent with tenofovir nephrotoxicity. In addition, medications given to prevent opportunistic infections in patients with HIV, such as the SMX-TMP, are also potentially nephrotoxic. Second, HIV-associated nephropathy (HIVAN) may also have been contributing to this patient's renal failure. The patient's African descent and advanced HIV disease placed him at higher risk for development of HIVAN. However, renal biopsy, required for definitive diagnosis, was not completed. Third, the patient's lymphoma also likely contributed to his renal failure. Plasmablastic lymphoma is a rare variant of diffuse large B-cell lymphoma, which is more common in HIV-infected patients. Lymphoma infiltration into the kidney may have contributed to renal failure. Additionally, light chain gammopathy and the elevated uric acid, both associated with the patient's lymphoma, may have caused light chain or urate nephropathy. In summary, the internist must recognize the range of unique etiologies of AKI in patients with HIV. As this case shows, these causes may include nephrotoxicity associated with medications, such as tenofovir; HIV-associated nephropathy; and complications from rare malignancies that disproportionately affect patients with HIV, such as plasmablastic lymphoma.

ACUTE CHEST SYNDROME IN PREGNANCY-DOUBLE TROUBLE Ankit Madan; Pooja Sethi; Kavita Tripathi. University of Alabama at Birmingham,Montgomery, Montgomery, AL. (Tracking ID #1642869)

LEARNING OBJECTIVE 1: Recognize acute chest syndrome as an important cause of morbidity and mortality in pregnant sickle cell patients.

LEARNING OBJECTIVE 2: Identify that early recognition and aggressive management is very important to prevent adverse maternal and fetal outcomes.
CASE: A 23 year old African-American female with past medical history of sickle cell disease presented with chief complaints of bilateral upper extremity and back pain. She was 28 weeks pregnant. These symptoms were recurrent and she had numerous admissions for sickle cell crises in the last 4 months. She denied any other symptoms. She was on folic acid but had stopped taking hydroxyurea 9 months back. Her heart rate was 127 beats per minute. Other vitals were stable. Physical examination was within normal limits. Pertinent labs include white cell count 18000, hemoglobin 8.4, and hematocrit 23. Hemoglobin electrophoresis revealed hemoglobin S 84 % and hemoglobin A 2.8 %. Chest x-ray was clear On day 3, patient developed shortness of breath, cough productive of greenish phlegm and mid-sternal chest pain. Oxygen saturation was 92 % on 4 l by nasal mask. Patient was using accessary muscles of respiration and had bibasilar crackles. Chest x-ray and CT scan of chest revealed right middle and lower lobe infiltrates consistent with consolidation. Patient had elective cesarean section the same day and received full red-cell exchange transfusion and was placed on piperacillin-tazobactam. She improved symptomatically. Post-transfusion hemoglobin S was 22 %. Male infant was born 28 weeks preterm and was admitted to neonatal intensive care unit. His respiratory and hemodynamic status was stable.
DISCUSSION: Acute chest syndrome is defined as new pulmonary infiltrate on chest x-ray consistent with consolidation involving at least one complete lung segment accompanied by chest pain, fever, tachypnea, wheezing, cough or hypoxemia. Three primary mechanisms include pneumonia or systemic infection, fat embolism and direct pulmonary infarction from Hemoglobin-S containing erythrocytes. Higher incidence of acute chest syndrome is reported in pregnant women with painful episodes. Higher incidence of sickle cell crises can be expected as use of hydroxyurea is contraindicated in pregnancy. Maternal adverse outcome includes preterm labor, increased likelihood of cesarean delivery, pre-eclampsia, eclampsia and placental abruption. Adverse fetal outcomes arise from complications of prematurity like respiratory distress syndrome, necrotizing enterocolitis, patent ductus arteriosus, intraventricular hemorrhage, apnea and retinopathy of prematurity. Moderate to severe episode which our patient had is defined as involvement of at least two or more lobes along with decreased oxygen saturation require full red-cell exchange transfusion. Goal is to reduce hemoglobin S to less than 30 % while keeping hemoglobin to less than 10 gm/dl. Full exchange transfusion appears to be more iron-neutral than partial exchange transfusion. Exchange transfusion can be performed manually or by apheresis machine. Third generation cephalosporin and a macrolide can be safely used in pregnancy to cover for atypical bacteria as well as streptococcus pneumonia and hemophilus influenzae. Prognosis depends on timing of institution of therapy.

ACUTE HEPATIC FAILURE IN ADULT-ONSET STILL'S DISEASE - A RARE MANIFESTATION: DRAMATIC RESPONSE TO PULSE METHYLPREDNISOLONE THERAPY Nalini Valluru; Michael Windham; Venkata S. Tammana; Eyasu Mekonen. Howard University Hospital, Washington, DC. (Tracking ID #1645499)

LEARNING OBJECTIVE 1: Manage potentially fatal hepatic failure in the setting of Adult Onset Still's Disease
CASE: We present a case of 22-year-old woman with no significant medical history who initially came with fever, arthralgias, myalgias and sore throat. On examination she was noted to have maculopapular skin rash, cervical and axillary lymphadenopathy. Laboratory data showed elevated transaminases, markedly elevated ferritin levels and negative HIV ELISA test. Serologic markers for rheumatic diseases were negative. Bone marrow and excisional lymph node biopsies ruled out lymphoproliferative disorders. She was then diagnosed with Adult Onset Still's Disease based on Yamaguchi diagnostic criteria and was started on prednisone. Three months later, while being on tapering dose of steroid, she presented with fever, arthritis and abdominal pain. She denied history of tobacco, alcohol or recreational drug abuse. Physical examination was significant for fever of 101.6 F, conjunctival pallor, icteric sclera, cervical lymphadenopathy, right upper quadrant tenderness with negative murphy's sign. Laboratory data revealed elevated bilirubin, markedly elevated transaminases, normocytic anemia and abnormal coagulation panel. Serum ferritin levels were markedly elevated. Ultrasound abdomen was unremarkable. Extensive workup excluded possible causes of liver failure including drug-induced liver injury, viral hepatitis, autoimmune hepatitis, hereditary disorders and other collagen diseases. She was promptly started on intravenous methylprednisolone pulse therapy with remarkable improvement in her symptoms and normalization of liver enzymes.
DISCUSSION: Adult-Onset Still's Disease (AOSD) is a rare systemic inflammatory disorder of unknown etiology, first described by Eric Bywaters in 1971. It is characterized by daily fevers of at least 39 F arthralgias or arthritis, evanescent, salmon-colored, nonpruritic, macular or maculopapular rash, and leukocytosis >10,000 cells/mm3. Other common symptoms include sore throat, myalgia, lymphadenopathy, splenomegaly, and abdominal pain. Markedly elevated serum ferritin levels have been frequently seen. AOSD is a clinical diagnosis and several diagnostic criteria have been proposed of which Yamaguchi criteria is widely accepted. Hepatic involvement is frequently observed in the course of AOSD. Abnormal liver function tests is seen in 76 % and about 44 % of patients have hepatomegaly. Severe hepatitis and hepatic failure are rare complications of AOSD. Liver dysfunction and fulminant hepatic failure may occur at the time of AOSD diagnosis, during the corticosteroid taper, or many years after symptom control. It has been shown that circulating Interleukin-18 is markedly increased in patients with fulminant hepatic failure or acute hepatitis. Principal treatment options for AOSD include NSAIDs, glucocorticoids, disease modifying anti rheumatic drugs (DMARDs), biologic agents. Review of the literature showed that pulse steroid therapy is efficacious in treating acute systemic flares of the disease such as severe hepatic involvement, pleuritis, cardiac tamponade, disseminated intravascular coagulation and other complications. Acute liver failure is a rare complication of AOSD. Exclusion of all potential causes of liver failure is essential prior to making the diagnosis of AOSD-associated liver injury. Prompt diagnosis and initiation of right therapy helps in recovery from serious liver injury, preventing the need for urgent liver transplantation.

ACUTE ISCHEMIC MYOCARDIAL INJURY FOLLOWING ADMINISTRATION OF DEFINITY CONTRAST IN A PATIENT WITHOUT CORONARY ARTERY DISEASE Katherine Fyall; Shadi Ayyoub; Lisa Staton. University of Tennessee College of Medicine Chattanooga, Chattanooga, TN. (Tracking ID #1623771)

LEARNING OBJECTIVE 1: Report an undocumented adverse event following administration of the Definity echocardiography contrast agent
CASE: A 57 year-old white female with a history of postpartum cardiomyopathy diagnosed 11 years prior presented to the emergency department with progressive exertional dyspnea, orthopnea, and peripheral edema for the previous few days. She had neither seen a cardiologist nor had symptoms for many years. The patient was admitted with a diagnosis of acute congestive heart failure and her symptoms resolved quickly with diuretic therapy. Physical examination was only remarkable for trace peripheral edema. Other than a very mildly elevated brain natriuretic peptide (BNP) at 158 pg/ml, her initial laboratory tests including 3 sets of cardiac enzymes were within normal limits. Electrocardiogram (EKG) showed normal sinus rhythm with a previously documented left bundle branch block. Chest x-ray revealed cardiomegaly with pulmonary congestion. An echocardiogram was ordered to evaluate her heart failure, and Definity was used during the study to improve the diagnostic yield due to her large body habitus Immediately after Definity injection, the patient started having a burning sensation at the site of the injection followed by burning in the chest and shortness of breath. She was able to complete the test, but the pain intensified and was severe before subsiding after approximately 30 min. ECG at the time of the event did not reveal any ischemic changes, but troponin I rose to peak at 10.68 ng/ml 6 h later. The

echocardiogram showed a left ventricular ejection fraction of 35 %, grade II diastolic dysfunction, and moderate mitral regurgitation. Cardiac catheterization done the following morning was negative for coronary artery disease (CAD). She was observed throughout the day without further incident and was discharged to follow up with her cardiologist.
DISCUSSION: Definity is a contrast agent used to improve the diagnostic yield of echocardiography. The agent has survived a battery of clinical investigations after the Food and Drug Administration (FDA) placed a black box warning on the label, declaring it contraindicated for patients with cardiopulmonary disease such as myocardial infarction and pulmonary hypertension. The FDA subsequently recalled the contraindications after further exploration yielded a favorable risk-safety profile. Studies continue to be published that demonstrate the safety and utility of the agent. In the articles reviewed, we did not identify any cases of Definity-related acute coronary syndrome or myocardial injury in a patient without CAD. The immediacy of the reaction and lack of catheterization findings support our theory that the Definity-induced vasospasm was significant enough to cause myocardial injury. Although Definity is a crucial tool for the evaluation of patients with functional heart disease, it is important to recognize and anticipate occasional adverse reactions. Other serious reactions include anaphylactoid reactions, respiratory distress, and cardiac arrhythmias. We are reporting this case of probable Definity-induced vasospasm as an adverse event so that other clinicians are aware and prepared for such events. We support the continued observation of the FDA's recommendation for a 30-minute monitoring period after administration of the agent.

ACUTE KIDNEY INJURY DUE TO OXALATE NEPHROPATHY Sarah Apgar. Yale-New Haven Hospital, New Haven, CT. (Tracking ID #1641916)

LEARNING OBJECTIVE 1: Recognize the association of Roux-en-Y gastric bypass with oxalate nephropathy, a rare cause of acute kidney injury.
CASE: A 52-year-old man with a history of obesity with Roux-en-Y gastric bypass (RYGB) in 2002, chronic back pain, diabetes, hypertension and benign prostatic hypertrophy presented with 1 day of alteration in mental status and tremors. In the preceding 4 months, he had two similar admissions for altered mental status secondary to acute kidney injury (AKI) and poor clearance of narcotics. He was on multiple medications including gabapentin, topiramate, OxyContin and benazpril. Physical examination demonstrated a lethargic male with intermittent myoclonic jerks. After foley catheter placement, 350 cc of urine output was recorded. Blood work revealed a creatinine of 7.0 mg/dL (2.2 mg/dL 1 week prior), potassium 5.7 mmol/L, and bicarbonate 11.3 mmol/L. Urinalysis showed 1+ protein with many white blood cells and occasional granular casts on microscopic analysis. No evidence of hydronephrosis was found on renal ultrasound. The patient was admitted and a naloxone drip and intravenous fluids were administered. Despite treatment, his creatinine continued to rise and myoclonic jerks persisted. Hemodialysis was initiated for treatment of possible gabapentin toxicity. Renal biopsy was consistent with oxalate nephropathy. Subsequent interview revealed that the patient was eating one pound of almonds per week. Creatinine stabilized and he was discharged off dialysis and on a low oxalate diet. Subsequent outpatient evaluation showed hyperoxaluria. Serum creatinine 7 months later is stable at 1.8 mg/dL.
DISCUSSION: Oxalate nephropathy is characterized by tubular crystalline deposits of calcium oxalate that result in tubular injury, interstitial fibrosis and progressive renal insufficiency. Etiologies include primary (hereditary) hyperoxaluria, ingestion of substances which are metabolized to oxalate, such as ethelyene glycol or high doses of vitamin C, and enteric hyperoxaluria. Enteric hyperoxaluria occurs with inflammatory bowel disease, pancreatic insufficiency or gastric bypass. First described in patients who underwent jejunoileal bypass in the 1970s, oxalate nephropathy has also been documented as a complication of RYGB. The mechanism of hyperoxaluira after RYGB is uncertain but presumed to be related to fat malabsorption. Normally, calcium binds oxalate in the colonic lumen and is excreted in the feces. In the setting of fat malabsorption, free fatty acids bind calcium, resulting in increased free oxalate levels. Free fatty acids also increase the permeability of the colon to oxalate. Oxalate nephropathy can occur anywhere from 4 to 96 months after RYGB. Most cases lead to progressive renal failure requiring chronic dialysis. Treatment includes a low oxalate diet and calcium supplementation to help bind intestinal oxalate.

ACUTE LEUKEMIC PERICARDITIS IN A CHALLENGING CLINICAL SITUATION: A CASE REPORT Arshad A. Javed[2,1]; Muhammad A. Shahzad[2,1]; Sagar Mallikethi Lepakshi Reddy[3,1]. [1]Detroit Medical Center, Detroit, MI; [2]WSU/DMC, Detroit, MI; [3]WSU/DMC, Detroit, MI. (Tracking ID #1625991)

LEARNING OBJECTIVE 1: Assess your patient daily anticipating new physical findings leading to specific diagnosis.
LEARNING OBJECTIVE 2: Recognize patient with acute leukemic pericarditis when other possible causes of pericarditis are also present.
CASE: A 71-year-old African American male with history of AML (FLT3−, NPM1+) in remission for 2 years, and chronic obstructive pulmonary disease presented to our hospital with gradually worsening dyspnea, fatigue and weakness for 2 days. Few hours after presentation, patient had an episode of massive hematemesis followed by abdominal pain and severe respiratory distress that necessitated endotracheal intubation. Laboratory examination was remarkable for white blood cell count of 221,000/μL, hemoglobin of 2.3 g/dL and platelet count of 19,000/μL. There was neutropenia and peripheral blood smear was full of blast cells. His creatinine increased gradually from baseline of 1.5 to 3.9 mg/dL and BUN was elevated at 60 mg/dL. On the third day of admission, physical examination demonstrated characteristic pericardial friction rub with three components. Electrocardiogram showed low voltage complexes. Echocardiography showed moderate pericardial effusion without signs of constrictive pericarditis or pericardial tamponade. Family members were explained poor prognosis and they opted for no aggressive treatment. Patient eventually died after 6 days of hospitalization. His family declined autopsy.
DISCUSSION: Leukemic infiltration of the pericardium is extremely rare but still exists. This case describes the clinical characteristics of rapidly progressive leukemic pericarditis in a patient with AML in relapse. Cytarabine induced pericarditis mostly occurs within hours to days of initiation of chemotherapy and hence was unlikely cause in our patient. This patient developed mild uremia secondary to tumor lysis syndrome, which rarely causes pericarditis within 2 days. Hence, pericarditis and pericardial effusion was attributed to relapse of AML. Pericardial effusion has little impact on outcome of patients with leukemia. Pericarditis in leukemia can be from hemorrhage, infection or rarely direct infiltration by leukemic cells. Mostly these effusions are trivial or minimal and only 5–7 % are moderate to large. Left and right heart catheterization shows equalization of diastolic pressures in right and left ventricles with dynamic respiratory variations. But, definitive diagnosis of leukemic pericarditis is only possible after pericardial biopsy. Clinicians need to be aware of such rare diagnosis, which helps in avoiding unnecessary therapeutic modalities such as hemodialysis.

ACUTE URINARY TRACT INFECTION INDUCED PULMONARY EMBOLISM Masato Yoshihara[1]; Naomi Otowa[2]; Hiroshi Miyake[3]; Mitsunori Iwase[1]. [1]Toyota Memorial Hospital, Toyota, Japan; [2]Toyota Memorial Hospital, Toyota, Japan; [3]Toyota Memorial Hospital, Toyota, Japan. (Tracking ID #1630379)

LEARNING OBJECTIVE 1: Note that pulmonary embolism (PE) presents with non-specific symptoms.
LEARNING OBJECTIVE 2: Recognize acute infection as a risk factor for PE.
CASE: A 75-year-old woman with no significant past medical history presented to the emergency department with an episode of syncope after voiding. Five days prior to admission, right-sided flank pain had

developed. The following day, she began to feel short of breath which was exacerbated when lying supine at night. Two days prior to admission, the patient visited her primary care physician and was diagnosed as having urinary tract infection with hydronephrosis in the right kidney. Treatment with cefcapen was initiated. On the day of admission, the patient transiently lost her consciousness and fell down after urination. On arrival, the patient reported dyspnea but denied having chest pain, nausea, diarrhea, or tarry stool. Throughout the course of illness, the patient was afebrile. She took no regular medications and had no known allergies. She did not smoke and denied regular use of alcohol. Her family history was negative for cardiovascular disease. On examination, the temperature was 35.5 °C, the systolic blood pressure was 90 mmHg, the heart rate was 110 beats per minute, the respiratory rate was 30 breaths per minute, and the oxygen saturation was 80 % while breathing ambient air. The heart and lung examinations were normal. Aside from the right-sided hydronephrosis, plain chest-and-abdominal computed tomography (CT) was normal. An echocardiogram revealed normal contractility of left ventricle, but tricuspid valve regurgitation was noted with mild right ventricle dilatation. The estimated atrio-ventricular pressure gradient was 60 mmHg. Contrast-enhanced CT revealed bilateral pulmonary emboli. No evidence of emboli or thrombi was revealed elsewhere in the body. The patient was diagnosed with submassive PE and anticoagulant therapy was administered along with supplemental oxygen. On the 6th day of admission, involution of the emboli was confirmed by contrast-enhanced CT. On the 8th day, the patient became independent of supplemental oxygen. On the 14th day of admission, the patient was discharged. Screening tests for coagulopathies, including protein-C deficiency, were negative.

DISCUSSION: Prompt recognition and initiation of therapy is essential to improve the outcome in patients with pulmonary embolism (PE). Its presenting symptoms and signs, however, are variable and often non-specific. Classical risk factors for PE include immobilization, recent surgery, and malignancy. On the other hand, acute infectious disease is a less well-known risk factor for PE. Liam Smeeth et al. found that acute infection transiently increase the risk for PE. Especially in patients with urinary tract infection (UTI), the incidence ratio for PE is 2.11 in the first 2 weeks after the onset of symptoms. Venous thrombosis has three major precipitants; venous stasis, increased coagulability, and vascular damage. Infection could affect all of these via physical damage to the vessel walls and subsequent endothelial activation. In our case, the patient did not have the typical risk factors for PE, thus UTI could have contributed to the development of PE. Clinicians must always keep in mind that PE may coexist in patients with an acute infectious disease.

AGRANULOCYTOSIS DUE TO UNNECESSARY TRIMETHOPRIM-SULFAMETHOXAZOLE THERAPY Pierre E. Blais[1]; Priti Dangayach[1]; Curtiss Moore[1]; Himabindu Kadiyala[2,1]. [1]Baylor College of Medicine, Houston, TX; [2]Michael E DeBakey VA Medical Center, Houston, TX. (Tracking ID #1642466)

LEARNING OBJECTIVE 1: 1. Recognize agranulocytosis as an adverse effect of trimethoprim-sulfamethoxazole, and remember to weigh the benefits versus risks in the administration of all medications.

LEARNING OBJECTIVE 2: 2. Develop an approach to the work-up of new onset agranulocytosis.

CASE: A 68-year-old Hispanic male smoker with no significant medical history presented to his primary care doctor with pharyngitis, dysphagia, odynophagia, and hoarseness. One week prior to the development of his symptoms, he had completed a 5 day course of trimethoprim-sulfamethoxazole following an incision and drainage of a 2×2 cm furuncle on his back. He denied any weight loss, night sweats, fevers, or chills. On presentation he was afebrile with a heart rate of 84 and blood pressure 138/80. Profuse thrush was noted on his tongue, soft palate, and posterior pharynx. ENT was consulted and performed a direct laryngoscopy which revealed extention of thrush to the vallecula, epiglottis, arytenoids, and false vocal cords. His initial white blood count was 1,600 cells/cmm with an absolute neutrophil count of zero. One year ago his blood counts were in normal range. Peripheral blood smear demonstrated no atypical leukocytes or leukoblasts. Serologies for HSV and CMV were negative. HIV, hepatitis panel, blood cultures, ANA were negative. B12 and folate levels were within normal limtis. His acquired agranulocytosis was determined to be secondary to trimethoprim-sulfamethoxazole use. His hospital course proceeded favorably. Cell counts rose briskly and normalized by day four of admission. Thrush and hoarseness resolved, and his counts continued to be normal on follow-up studies 2 weeks after discharge. He was advised to avoid trimethoprim-sulfamethoxazole in the future.

DISCUSSION: Trimethoprim-sulfamethoxazole has been found to have potential to cause a decrease in any of the hematologic cell lines, but isolated agranulocytosis is very uncommon. The literature proffer a rate of 1.2 cases of agranulocytosis per million in patients treated with this medication. Recovery of neutrophil counts usually begins within 1–3 weeks after stopping the offending agent. Outside the setting of hematologic malignancy or recent chemotherapy, the differential diagnosis for acquired, symptomatic agranulocytosis includes drug-induced, infectious, and primary immune etiologies. Initial work-up of agranulocytosis should include a peripheral blood smear to rule out atypical leukocytes and evidence of autoimmune sequelae. Conditions that cause immunosuppression such as HIV should also be investigated. Bone marrow biopsy should be reserved for cases of neutropenia prolonged beyond 1–3 weeks. In this case, trimethoprim-sulfamethoxazole was administered following incision and drainage of a superficial abscess. Antibiotic use for this purpose has been unequivocally proven to be unnecessary in the literature. While empiric antibiotic therapy often has a role in evidence-based clinical practice, this case provides another example in which the risks have proven to far exceed the benefits.

ALCOHOL WITHDRAWAL AFTER WEEKS OF ABSTINENCE: AN UNEXPECTED COMPLICATION Juliana Yang[1]; Amber Galarowicz[1]; Sarah Nickoloff[1,2]. [1]Medical College of Wisconsin, Milwaukee, WI; [2]Zablocki VA Medical Center, Milwaukee, WI. (Tracking ID #1596686)

LEARNING OBJECTIVE 1: Recognize alcohol withdrawal and delirium tremens in patients weeks after last ingestion.

CASE: A 58 year old male with a past medical history significant for alcohol dependence and type 2 diabetes was admitted to the VA for right third toe osteomyelitis. He reported drinking six to eight beers per day and his last drink was the night before admission. Urine drug screen was negative for illicit drugs, and he had no symptoms of alcohol withdrawal during initial admission. He was started on culture directed therapy, underwent toe amputation, and was subsequently transferred to a subacute unit. On hospital day 17, 16 days after his last alcohol ingestion, the patient became acutely confused and started to experience vivid hallucinations. He was transferred to the acute hospital unit. Minutes after transfer, the patient had a witnessed tonic-clonic seizure. He was given lorazepam and transferred to the intensive care unit (ICU). His condition deteriorated, and he developed metabolic acidosis and respiratory distress. Due to high lorazepam requirement in the setting of respiratory compromise he was placed on noninvasive positive pressure ventilation and started on lorazepam infusion. His clinical status then stabilized. Series of studies were done to investigate alternate causes of seizure, including images studies, transthoracic echocardiogram, infectious, metabolic and nutritional deficiency workups. Antibiotics were reviewed with pharmacy and infectious disease consultants. The workup was unremarkable, and it was determined that delayed delirium tremens was the cause of his seizure.

DISCUSSION: Mortality caused by excessive alcohol consumption shows no signs of abatement. The World Health Organization attributes an estimated 2.5 millions deaths worldwide per year to the consumption of alcohol. It is essential that physicians recognize symptoms of alcohol withdrawal in a timely manner so that treatment can be initiated. Alcohol causes both enhanced inhibitory tone and depressed excitatory tone in the central nervous system (CNS). Chronic and constant alcohol intoxication

causes adaptive changes in the CNS. During withdrawal, the suppressive effects of alcohol are abruptly stopped, and the CNS demonstrates compensatory overactivity. Patients experience symptoms of increased sympathetic tone ranging from anxiety and agitation to hallucinations and seizures. Alcohol withdrawal symptoms usually start 6 to 12 h after the last ingestion. Early symptoms typically include tremors, anxiety, headaches and palpitations. The peak of these symptoms, in addition to hallucinations and withdrawal seizures, usually occur after 24 to 48 h. Approximately 5–20 % of patients who experience alcohol withdrawal will progress to delirium tremens (DT) within 2 to 4 days if not treated. The associated mortality rate for DT is 1–5 %. It is nearly impossible to predict which patients will progress from early to late stages of alcohol withdrawal. There is a paucity of cases in the current literature describing delayed DT, and the exact pathophysiology remains unclear. Due to the high mortality rate associated with DT, it is important for clinicians to be aware that DT may occur 2 weeks or later after the last alcohol ingestion, as seen in this patient.

ALL HANDS ON DECK: NEUROCOGNITIVE EFFECTS OF HIV Ryan Brown; Deepa Bhatnagar. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640080)

LEARNING OBJECTIVE 1: Identify a cause of lower extremity weakness in HIV
LEARNING OBJECTIVE 2: Recognize HIV-Associated Neurocognitive Disorders (HAND). Understand HAND's subtypes and categorization.
CASE: A 35 year old man presented with lower extremity weakness for approximately 6 months. The weakness originally manifested with a limp, which progressed to a need for a walker and finally wheelchair use for the 2 weeks prior to presentation. He also complained of worsening vision and a rash for "several months." His family reported the patient had decreased cognitive abilities, including memory and emotional lability. He had recently begun to have bladder incontinence. He was alert, oriented, and able to follow commands. He had 1/5 strength in his lower extremities and 5/5 in his upper extremities. Sensation was intact diffusely. He had hyporeflexia in his Achilles' tendon. Sphincter tone was intact. Vision in his left eye was absent. He had a diffuse maculopapular rash. Laboratory data revealed a positive HIV test with a CD4 count of 17. CSF studies had a glucose of 53, protein of 100 and a white blood cell count of 3. It grew no organisms or fungi. RPR and CSF VDRL were negative. His ANA level was normal. Brain MRI revealed diffuse subcortical white matter hyperintensity. Images of the cervical and lumbar spines were negative. T-Spine MRI suggested meningitis. The diagnoses were HIV-Associated Neurocognitive Disorders (HAND) and CMV Retinitis. He was discharged to an HIV clinic for initiation of highly active anti-retroviral treatment (HAART) and started on ganciclovir.
DISCUSSION: HIV-Associated Neurocognitive Disorders (HAND) is a term encompassing a continuum of neurological disease within the HIV/AIDS population. It represents a wide range of symptoms, including memory, attention, language and motor function. The term was first introduced in 1987, revised in 1991 by the American Academy of Neurology and updated again in 2007 by a National Institutes of Health working group. The current HAND continuum has three stages: it begins with Asymptomatic Neurocognitive Impairment (ANI), worsens to Mild Neurocognitive Disorder (MND) and progresses to HIV-Associated Dementia (HAD). Literature sometimes, albeit confusingly, also uses the terms HIV Encephalopathy or HIV Dementia Complex in replacement of HAD. The diagnosis of HAND is determined by assessing five areas of neurocognitive functioning. The number of neurocognitive domains affected and the extent of impairment on daily living are the main factors used to determine the classification. There is variability within the course of HAND and much improvement can be seen with the mainstay therapy, HAART. The patient's lower extremity weakness affecting ambulation has also been reported in four cases in South Africa. In all cases, lower extremity reflexes were affected, while sensory and sphincter symptoms were spared. Similar to our patient, the other reported cases were new diagnoses of HIV who had been previously healthy. The most likely etiologies are HIV-related motor neuropathy or an unusual variant of Guillain-Barre Syndrome, both of which are not well understood. Given our patient's clinical presentation and negative infectious work-up, our patient was diagnosed with HAND's most severe form, HAD.

ALL THAT IS TRANSIENT IS NOT TIA Sarah H. Van Tassel; Michael J. Plakke; Khan K. Chaichana; Anthony A. Donato. Reading Health System, West Reading, PA. (Tracking ID #1635133)

LEARNING OBJECTIVE 1: Develop a differential diagnosis for transient focal neurological events
LEARNING OBJECTIVE 2: Recognize disease processes that mimic transient ischemic attacks (TIA)
CASE: A 77-year-old right-handed male with hypertension presented to the emergency department reporting an episode of anomic aphasia and alexia. The patient was in his usual state of health until he returned from the mailbox the previous afternoon and was unable to read the mail. He further discovered he was unable to name familiar people and objects such as his children, grandchildren, and golf clubs. These symptoms lasted for several hours but resolved completely by the morning. He denied prior similar episodes, headache, head injury, loss of consciousness, seizure-like activity, fever, and sick contacts. He had no history of stroke, transient ischemic attack (TIA), or psychiatric diagnoses. He had a remote history of Bell's Palsy with incomplete recovery. On admission, his vital signs were stable, and complete neurological examination was non-focal except for an old right facial droop. A computed tomography (CT) scan of his brain showed no abnormalities. Subsequent magnetic resonance imaging (MRI) with contrast demonstrated vague areas of signal hyperintensity in the FLAIR and T2 weighted images involving the parenchyma of the entire left temporal lobe and into the left occipital lobe. Lumbar puncture was negative for Lyme and herpes simplex virus by PCR and cryptococcal antigens. He was discharged from the hospital in stable condition and readmitted several weeks later for stereotactic guided needle biopsy of the left temporal lobe tumor. Microscopic examination diagnosed diffuse astrocytoma. Follow up for radiation therapy was scheduled.
DISCUSSION: While transient ischemic attack is the most common diagnosis in patients with cardiovascular risks and transient neurological symptoms, the differential also includes brain tumors, metabolic disturbances, multiple sclerosis, subdural hematomas, cerebral amyloid angiopathy, encephalopathies, compressive myelopathy, arteriovenous fistulas, and psychiatric disorders. The mechanism by which brain tumors result in transient focal neurological symptoms is thought to involve mechanical changes that result in pressure on structures adjacent to the tumor. Given the history and physical examination, TIA was the working diagnosis in our patient prior to the MRI findings. Recent scientific studies have advanced our understanding of the definition and evaluation of TIA. In particular, the new tissue-based definition of TIA highlights the importance of early MRI. Until recently, patients who presented with transient neurological symptoms that resolved completely and normal CT scans were often discharged with the frustrating diagnosis of "possible TIA." Early MRI distinguishes patients with and without evidence of cerebral infarction, thus enhancing risk stratification. Moreover, early MRI may more accurately identify disease processes that mimic TIA, such as with our patient. Physicians caring for patients with transient focal neurologic symptoms should consider neuroimaging with MRI when presented with similar diagnostic dilemmas. Following MRI, our more focused differential diagnosis included viral encephalitis versus infiltrating neoplasm, and the diagnosis of diffuse astrocytoma was confirmed with biopsy.

AMIODARONE-INDUCED MYXEDEMA COMA: DON'T FORGET THE THYROID GLAND Balakumar Krishnarasa; Donna Seminara; Abhirami Vivekanandarajah. STATEN ISLAND UNIVERSITY HOSPITAL, Staten Island, NY. (Tracking ID #1641774)

LEARNING OBJECTIVE 1: Recognize the potential life threatening thyroid conditions associated with amiodarone use especially in the geriatric population.

LEARNING OBJECTIVE 2: Assess thyroid function periodically during and after amiodarone therapy.

CASE: A 78-year-old man with hypertension, atrial fibrillation, hypercholesterolemia and gastroesophageal reflux disease presented to the hospital with confusion, new-onset ascites, hypotension (BP 90/50) and hypothermia (temperature 93.9 F). He underwent a paracentesis that did not reveal infection. Laboratory parameters including a complete metabolic profile and complete blood count were normal. CT of the head was negative. Chest x-ray was negative. Microbial cultures were ordered; he was placed on empiric antibiotics and admitted to the general medical floor. Shortly after, he suffered a cardiac arrest. CPR was successful and he was transferred to the ICU. Medications on admission included metoprolol, amiodarone, simvastatin, omeprazole and tamsulosin. The patient had been taking amiodarone for 6 months prior to admission to the hospital for atrial fibrillation. The thyroid function studies prior to initiation of amiodarone were normal. Physical examination was significant for ascites, bilateral lower extremity non-pitting edema and delayed deep tendon reflexes diffusely. Further laboratory testing reveled TSH of 314 mIU/L. The patient was presumed to have myxedema coma likely induced by amiodarone. He was given a loading dose of intravenous levothyroxine 200 mcg followed by 100 mcg daily. He was also given intravenous glucocorticoids. Amiodarone was discontinued. His clinical condition improved. Eventually, intravenous levothyroxine was switched to oral levothyroxine.

DISCUSSION: Amiodarone is a potent anti-arrhythmic agent used in the treatment of ventricular and supraventricular tachyarrhythmias. It is an iodine-rich compound which contains approximately 37 % of iodine by weight. Pathophysiology of amiodarone-induced hypothyroidism (AIH) is enhanced susceptibility to inhibitory effect of iodine on synthesis of thyroid hormone which can be explained by Wolff-Chaikoff effect. This effect can be accelerated in pre-existing thyroid conditions. It can also happen in patients without underlying thyroid disease. Although AIH is a mild entity, it can be rarely severe and a life-threatening disease resulting in myxedema coma. The risk of AIH is increased in elderly patients due to pre-existing thyroid disease. The risk is independent of daily or cumulative dose of amiodarone. Myxedema coma can be defined by decreased mental status, hypothermia, hypotension, hypoventilation, hyponatremia, bradycardia, and generalized non-pitting edema. Laboratory findings include a very high TSH, and very low free T4 values. Treatment includes discontinuing amiodarone and intravenous supplementation of levothyroxine and glucocorticoids. In conclusion baseline thyroid function should be evaluated when initiating amiodarone therapy. Serum TSH and free T4 levels should be reassessed periodically during the amiodarone treatment period and at least for 1 year after amiodarone is discontinued.

AMYLOIDOSIS: THE FORGOTTEN FACTOR X DEFICIENCY
Anita Pudusseri; Ellen Wexler; Robert E. Graham. Lenox Hill Hospital, New York, NY. (Tracking ID #1596722)

LEARNING OBJECTIVE 1: Recognize that amyloidosis may present with acquired coaguloapathies

CASE: A 51 year old male presented to the hospital with chief complaint of persistent nausea and cough for over 1 year. Past medical history was significant for hypertension and gastroesophageal reflux disease. His cough was productive of "white- sticky, non bloody" sputum, associated with 10 episodes of a "dark- green, non bloody" vomitus within the last 24 h. Upon review of systems, he endorsed a 55 lb weight loss in 6 months, fatigue, weakness, subjective low grade fevers and depression from this on-going problem. Admission vital signs and physical examination was normal besides a 2×2 cm, immobile, non-tender left submandibular palpable lymph node. Initial laboratory analysis were as follows: white cell count, 11,100 μl with a normal differential; hemoglobin, 12.7 g/dL; hematocrit, 36.9 g/dL. Coagulation studies revealed a prothrombin time, 16.2 s and partial thromboplastin time, 31.3 s. There was complete correction of the PT upon mixing studies. Complete metabolic panel revealed normal values with exception of total protein of 10.7 g/dL and alkaline phosphatase of 278 U/L. Urinalysis was significant for 100+ mg/dL of glucose; small bilirubin; 15 mg/dL of ketones; 300+ mg/dL of protein. CXR and a right upper quadrant sonogram were normal. His primary care doctor had conducted an esophagealgastroduodenoscopy (EGD) positive for severe gastritis and negative colonoscopy. He had also seen a hematologist with work up significant for an "M-spike" but no evidence of cancer (negative skeletal survey, CXR, MRI Brain and CT Chest). Factor X level was 30 % (normal 50–150 %). Excisional lymph node biopsy revealed amyloidosis.

DISCUSSION: This case highlights the difficulty in establishing a diagnosis of amyloidosis. However, the association between acquired coagulopathies and amyloidosis should not be forgotten. What prompts internists to pursue factor deficiencies is the complete correction of the prothrombin time (PT) and partial thromboplastin time (PTT) upon mixing studies. Factor X is a coagulation factor involved in both the intrinsic and extrinsic pathways. Thus, it would be reasonable to suspect prolongation in both the PT and PTT; yet in our case only the PT was prolonged. Factor X deficiency, specifically, is the most common coagulation factor deficiency in AL amyloidosis patients. There is a reported incidence of 8.7–14 %. The insufficiency arises as the half-life of factor X is reduced due to its fusion to amyloid fibrils. In a study of 368 patients with AL amyloidosis, factor X activity below 50 % of normal were found in 32 of the 368 patients. 18 of these patients had bleeding complications. The most severe complications were seen in the 12 patients with factor X activity below 25 % of normal. Fortunately, our patient did not experience any bleeding complications with a factor X activity at 30 %. Most of the evidence of treatment plans in patients with factor X deficiency associated with AL amyloidosis arise from of case reports. Complete remission and normalization of the factor X levels have been reported with high-dose chemotherapy, autologous stem cell transplantation, recombinant factor VIIa and plasma exchange. Splenectomy has been shown to improve coagulopathies as it removes a considerable amount of amyloid deposition.

AN INFARCTION COMPLICATION: A REVISIT FROM THE PAST
Armaan Shaikh; Benjamin Jenny. Medical College of Wisconsin Affiliated Hospitals, Milwaukee, WI. (Tracking ID #1624131)

LEARNING OBJECTIVE 1: Recognize a ventricular septal infarct as a complication of a myocardial infarction

LEARNING OBJECTIVE 2: Treat an infarct related ventricular septal defect medically

CASE: A 92 year-old woman with a history of hypertension, dyslipidemia and coronary artery disease (CAD) with remote four-vessel coronary artery bypass grafting presented to the emergency department with a 4 days history of nausea, vomiting, and generalized weakness and a 24-hour history of presyncope. On initial evaluation, the troponin T was significantly elevated (30 times the upper limit of normal) with a small increase in creatine kinase muscle isoenzyme (CKMB). In addition, the patient was found to be in complete heart block with a left bundle branch block and sporadic sinus pauses lasting roughly 10 s. On exam, a 3/6 holosystolic murmur was heard throughout the entire heart field and noted to be loudest along the left parasternal border. Transthoracic echocardiogram (TTE) revealed a thinned, dyskinetic anteroseptum and anterior wall with color Doppler evidence of a serpiginous, moderately sized ventricular septal defect (VSD) with active left to right flow. Transvenous pacing and afterload reduction were initiated and options of VSD repair (open verses percutaneous) were discussed with the patient. On hospital day 4, the patient's predominant rhythm was noted to be sinus rhythm with first-degree AV block with an underlying left bundle branch block and premature ventricular contractions. Follow-up TTE revealed a preserved ejection fraction with a decrease in pulmonary systolic

pressures when compared to the initial TTE. The patient continued to have intermittent complete heart block, leading to permanent pacemaker placement on hospital day 6. Given the patient's continued hemodynamic stability and disinterest in VSD repair, medical management was continued for this condition, and the patient was discharged home in improved condition.

DISCUSSION: In an era when early coronary reperfusion is commonly achieved through either percutaneous intervention or thrombolytic therapy, late mechanical complications, such as VSDs, are less frequently seen. These mechanical complications are the result of completed transmural infarcts that did not have the benefit of early reperfusion therapy. Our patient presented several days following an anterolateral myocardial infarction with classic enzyme patterning: mild CK and CKMB elevation along with a significantly elevated troponin T. This pattern is typical of a late presenting MI given the short duration of CKMB and long duration of troponin elevation. Infarction VSDs can be repaired with an open approach or percutaneously. However, the repair is limited by the health of the surrounding myocardium and typically requires several weeks before the surrounding tissue is able to support sutures. If medical management is pursued, care is centered on minimizing afterload and controlling heart rate.

AN ODYSSEY OF THE MIND: CONFIRMING THE DIAGNOSIS OF CONVERSION DISORDER Gary Mitrevolis[1]; Changwan Ryu[1,2]. [1]SUNY Upstate Medical University, Syracuse, NY; [2]Syracuse VA Medical Center, Syracuse, NY. (Tracking ID #1618570)

LEARNING OBJECTIVE 1: Promote awareness of underlying mental health disorders among our veterans.

LEARNING OBJECTIVE 2: Encourage innovation to facilitate the diagnosis of complex disorders.

CASE: The patient is a 59 year old veteran with no past medical history who presented to our facility for a 2 month history of increasingly frequent, involuntary jerking movements in both of his legs. He also complained of diffuse leg cramps and weakness with ambulation. He denied any recent history of trauma, fevers, chills, rashes, exposure to toxins or drugs, travel, or dietary changes. His neurologic examination was significant for synchronous, myoclonic spasms in both legs. Within 2 weeks of admission, he developed dysarthria, diplopia, and weakness in the right side of his face and body. His work-up proved to be negative, which included MRI of his brain and spine, electroencephalograms, lumbar punctures, duodenal biopsy for Whipple's disease, Creutzfeldt-Jakob antibodies, paraneoplastic antibodies, and tests for heavy metals, TSH, folate, B12, RPR, ANA, ESR, CRP, HIV, and Lyme. Along with these symptoms, he began having generalized seizures. However, during these episodes, the patient was trembling, not tonic-clonic jerking, and we started to suspect that his symptoms were psychogenic. With our neurology service, we tested this theory by telling him that he would receive an "anti-seizure medication," which was actually normal saline. When he had another seizure-like episode and gave him the "anti-seizure medication," the episode ended. We then told the patient that we would give him a "seizure-inducing medication," which was also normal saline. When we gave him the "seizure-inducing medication," the seizure-like activity resumed, and when we immediately infused his "anti-seizure medication," the activity stopped. This helped to confirm our diagnosis of a conversion disorder. After consulting our psychiatry service, we found that his conversion disorder stemmed from his long-standing post-traumatic stress disorder from his combat duty in Vietnam, and recent life stressors triggered these neurologic symptoms. With further psychological support, he clinically improved and was discharged home.

DISCUSSION: Conversion disorders typically present with neurologic symptoms that cannot be explained by another condition. Its diagnosis requires a complete investigation for other diseases, exclusion of deliberate feigning, and identification of a psychological mechanism. The determination of conversion disorder is wrought with unnecessary laboratory tests, excessive imaging studies, and fruitless invasive procedures. However, there are no accepted strategies for making this diagnosis, and we present this case to demonstrate one unique method. When encountering a medical challenge like a conversion disorder, innovation and creativity play an instrumental role for timely diagnosis and optimal management. Another objective for this case was to illustrate the significance of addressing the mental health of our veteran population. Our case demonstrated one of the consequential pitfalls of neglecting a vital area of need among our veterans. Our VA medical centers will need to be more cognizant of the mental health issues that prevail among our growing veteran population, and as physicians, our charge will be to lead initiatives that promote these issues.

AN OLD ROOKIE OF TAKAYASU ARTERITIS Tatsuya Sato; Junwa Kunimatsu; Riri Watanabe; Atsuto Yoshizawa. National Center for Global Health and Medicine Hospital, Tokyo, Japan. (Tracking ID #1636040)

LEARNING OBJECTIVE 1: Recognize Takayasu arteritis as a potential candidate of fever of unknown origin even in elderly patients.

LEARNING OBJECTIVE 2: Recognize that 18 F-FDG PET/CT is a reasonable modality as a diagnostic tool when clinicians work-up an elderly patient with fever of unknown origin plus impaired renal function.

CASE: An 80 year-old Japanese man with past medical history of lung tuberculosis presented with a month of neck pain, low-grade fever and fatigue. He first saw his primary care physician and subacute thyroiditis was suspected based on cervical pain, low-grade fever up to 37.5 °C and marked elevation of C-reactive protein levels: 33 mg/dL (reference range: 0–0.3). Thyroid function tests were, however, within normal limits and his cervical pain continued after a month follow-up. He visited our department for further investigation. On examination the patient reported fatigue, mild pain in the left posterior neck. No goiter, lymphadenopathy, headache, or muscle pain was observed. There was no difference in blood pressure between both arms. No cutaneous lesion or rash was noted. Muscle tenderness and weakness were absent. The temporal arteries were pulsatile, with no tenderness on palpation, and the visual acuity was normal. His chest was clear on auscultation and his heart sounds were regular with no murmur. The examination was otherwise normal. Enhanced body CT revealed diffuse thickening of arterial wall including left common carotid artery, aorta, brachiocephalic artery, and mesenteric arteries. 18 F-FDG PET/CT was conducted to detect the focus of inflammation and strong linear 18 F-FDG uptake was observed in these arteries. No uptake was found in either of temporal arteries. He was diagnosed as Takayasu Arteritis (TA) before symptoms due to ischemia develops and corticosteroid treatment was started.

DISCUSSION: In this case, giant cell arteritis (GCA) is naturally another differential diagnosis considering his age, but for three reasons we believe TA is the more likely diagnosis. First, there were no clinical symptoms and signs of polymyalgia rheumatic (PMR) and/or GCA such as visual disturbance, jaw claudication, temporal artery tenderness, shoulder and pelvic girdle muscle pain or upper arm tenderness. GCA presents with some localized symptoms more often than TA. Second, TA is more common than GCA in Japan. Third, a nationwide cohort study in Japan has shown that TA occurs in elderly population. This result supports the fact that age is not used to distinguish TA and GCA in Asian countries. The possibility of GCA still remains since neither ultrasonography nor a biopsy of temporal arteries was performed on this patient. However, the reasons listed above indicate that TA is more likely diagnosis for this patient. "An old rookie" is celebrated in Japan, although we know TA most commonly affects women of childbearing age. 18 F-FDG PET/CT is an emerging modality that can be applied to variety of inflammatory diseases, since it can visualize inflammation and increased metabolism in earlier stages of the disorders. It has been featured in Japan as a

tool to diagnose fever of unknown origin (FUO). The application of 18 F-FDG PET/CT can safely assist the diagnosis of aortitis in its early phase. This case illustrated that TA is a potential candidate of FUO even in elderly patients. 18 F-FDG PET/CT can be a reasonable modality when clinicians work-up an elderly patient with FUO plus impaired renal function.

AN OPIATE RUSH DUE TO ORAL THRUSH Matthew George; Sean Drake. Henry Ford Hospital, Detroit, MI. (Tracking ID #1638548)

LEARNING OBJECTIVE 1: Recognize the possibility of Fluconazole inhibiting metabolism of opiate medications
LEARNING OBJECTIVE 2: Recognize when it is appropriate to use systemic anti-fungal medications.
CASE: 45 year old female with a significant past medical history of chronic back pain for which she takes Oxycodone and Oxycontin. She was recently diagnosed with Tinnitus by ENT and started on oral steroids and later transitioned to steroid injections into tympanic membrane. She presented to General Medicine clinic complaining of oral thrush and was started on fluconazole 200 mg Q day for a week. Over the next 7 days she developed intense lethargy, dizziness, episodes of passing out in her food while eating, and had extreme weakness. She came back to the General Medicine clinic 1 week later with these new symptoms. She was found to be tachycardic, hypotensive, and hypoxic. There was concern that she may be showing signs of sepsis and was admitted to the hospital for further infectious workup. In the hospital, she had a work-up including: CBC, chest xray, CT PE protocol, U/A and culture, blood culture, abdominal ultrasound, head CT, and influenza test—all of which were negative.. The fluconazole was stopped and she was treated with nystatin mouth wash instead. Her vitals, symptoms, and mental status all improved during the admission and she was discharged on hospital day number 3. The working discharge diagnosis was that her fluconazole had inhibited the metabolism of her chronic opioid pain medication, therefore causing signs and symptoms of overdose. Patient was seen 2 weeks after discharge from hospital and had re-started opioid medications at home without any further symptoms.
DISCUSSION: There have been various case reports and studies implicating ketoconazole causing opiate and other drug toxicities. Fluconazole, however has historically been thought of as only a moderate inhibitor of cytochrome p450 3a4 and has been less well studied. There have been case reports implicating it with fentanyl and carbamazepine, and also a study with midazolam. This case highlights two important considerations. The physician should either decrease a patient's opiate dosage if giving fluconazole, or if possible, avoid systemic anti-fungal for oral thrush and use local antifungal mouth wash instead.

AN UNCOMMON CAUSE OF DYSASTHESIA AND PRURITUS Julie B. Silverman[1,2]; Nicholas Compton[1,2]. [1]VA Puget Sound, Seattle, WA; [2]University of Washington, Seattle, WA. (Tracking ID #1638993)

LEARNING OBJECTIVE 1: Recognize the signs and symptoms of Sezary syndrome
LEARNING OBJECTIVE 2: Review the epidemiology and clinical course of Sezary syndrome
CASE: A 62-year-old man presented to establish care. He complained of numbness and tingling on his chest and arms for 2 years. His past medical history was notable for a long history of untreated pernicious anemia, now treated with vitamin B-12 injections. He was previously diagnosed by a neurologist with peripheral neuropathy and prescribed gabapentin. The patient denied fevers, weight loss, rash, and pruritus. Neurologic and skin exams were unremarkable. Labs -including CBC, electrolytes, LFTs, vitamin B-12, hemoglobin A1c, iron studies and TSH- were within normal limits. Months later, the patient returned complaining the dysasthesia, which he likened to "hundreds of fire ants crawling on your skin and biting you," had spread to his groin and back. He again denied constitutional symptoms or skin changes. He was referred to neurology, where workup revealed normal thiamine, copper and zinc levels and an unremarkable EMG. The patient returned to primary care complaining the burning was now intolerable. He also reported daily episodes of skin flushing. Exam was negative for lymphadenopathy or rash. However, his skin was notable for doughiness and deep furrows on his forehead, which had previously not been observed. Repeat CBC showed lymphocytosis with highly suspicious atypical lymphoid cells. Flow cytometry revealed an abnormal T-cell population comprising 49 % of WBCs. PCR analysis confirmed T-cell clonality. The patient was diagnosed with T-cell lymphoma. Due to the level of blood involvement and immunohistochemical analysis, the lymphoma was further characterized as Sezary syndrome (SS). Skin biopsy revealed an atypical lymphoid infiltrate in the superficial dermis along with large cell transformation, which occurs in about 25 % of Sezary patients. The patient completed two rounds of romidepsin with inadequate response. He is undergoing treatment with pralatrexate.
DISCUSSION: This case illustrates the potential difficulty in diagnosing SS. SS is a leukemic type of cutaneous T-cell lymphoma (CTCL) characterized by adenopathy, erythroderma and circulating atypical lymphoid cells. Incidence is estimated to be 0.3 per million persons. The average age of diagnosis is 55 years, and there is a 2:1 male predominance. Because of the non-specific symptoms, diagnosis can be delayed, with a 4.2-year median time to diagnosis. In this case, more than 3 years elapsed between onset of dysasthesia and diagnosis. The most common symptom of SS is pruritus, which is often resistant to antihistamine treatment. Erythroderma is another frequent sign. Like pruritus, the differential for erythroderma is broad -including dermatitis, psoriasis and drug reaction. Dysasthesia is a less common, but not unusual, symptom. Other signs include alopecia, keratoderma, nail dystrophy and skin edema. Occasionally patients develop leonine facies, as in this patient, due to dermal infiltration of the face. CTCL prognosis varies by age and stage at time of presentation. Most patients with early-stage disease have indolent courses and may never require systemic therapy. For those with advanced disease, prognosis is generally poor. Median survival for patients with SS is less than 4 years. Despite its low prevalence, SS should be considered in patients presenting with unrelenting pruritus, unexplained erythroderma or other unusual dermatologic complaints.

AN UNFORGETTABLE CAUSE OF GI BLEEDING! Hani Snounou; Samian sulaiman; Luis F. Guzman; Salih Samo. Saint Francis Hospital, Evanston, IL. (Tracking ID #1624285)

LEARNING OBJECTIVE 1: -To recognize a rare congenital cause of massive gastrointestinal (GI) bleeding.
CASE: A 32 year old male presented with sudden onset, massive rectal bleeding which was not associated with defecation or trauma. He had a history of Klippel Trenaunay Syndrome (KTS) with multiple admissions for bleeding, mainly as hematuria and one episode of self limited rectal bleeding 4 years ago. Physical examination at time of admission was remarkable for BP 55/29, HR 135, RR 22. His abdomen was soft and non tender, with active red blood oozing from his rectum. He was noted to have extensive varicose veins on the right leg and scrotum. His labs showed Hg 7.1 g/dL, Platelets 148 K/mL, AST 522 IU/L, ALT 257 IU/L, Bilirubin 1.7 mg/dL, and INR 1.7. The patient underwent EGD and no active bleeding was found; colonoscopy showed long, large, and dilated tortuous veins in the rectosigmoid colon, with large amount of red and clotted blood all the way to the ascending colon. He underwent angiography which showed hypervascularity of one of the superior mesenteric artery branches supplying the right colon. This area was embolized, but the patient continued to bleed. Subsequently, he underwent rectosigmoid resection. Grossly, the resected left colon and rectum showed extensive varicosis. During his hospitalization he required transfusion of total of 50 units PRBCs, 18 units FFP, 26 units

platelets, and 10 units cryoprecipitate. Post OP course was complicated by hemoperitoneum, worsening Coagulopathy, fecal peritoinitis, sepsis, and right leg DVT. He was sent to OR 3 times for hemoperitoneum evacuation and wound dehiscence closure. Eventually, he was intubated because of worsening of the sepsis and respiratory failure. Later on he was transferred to a tertiary care center for more advanced care.
DISCUSSION: Klippel Trenaunay Syndrome (KTS) is a rare congenital vascular anomaly. The syndrome is characterized by a triad of varicose veins and venous malformation, cutaneous capillary malformation and hypertrophy of the bone and soft tissue. Visceral vascular malformation in KTS can involve GI tract, spleen, liver, bladder, lung and heart. The most common bleeding sites in the GI system are the distal colon and the rectum. The spectrum of the GI bleeding varies from asymptomatic occult to life threatening bleeding. Transfusion dependent and life threatening bleeding episodes necessitate definitive surgical therapy with resection of the involved bowel segment.

AN UNLIKELY CULPRIT CREATING AN UNCONTROLLED INR Joshua Kra; Alfred Burger. Beth Israel Medical Center, New York, NY. (Tracking ID #1628745)

LEARNING OBJECTIVE 1: Recognize that in patients on warfarin, moderate doses of acetaminophen can significantly raise the INR
LEARNING OBJECTIVE 2: Discuss the mechanism of this drug-drug interaction, via direct effect of acetaminophen on the vitamin K cycle, not hepatotoxicity or alterations in warfarin metabolism
CASE: A 63 yo man with multiple prior DVTs on long-term warfarin therapy presented with rectal bleeding. He was compliant with medications, had no changes to his warfarin dosing, no recent antibiotic or herbal supplement use, and no changes in dietary habits. He fell 2 weeks prior to admission and was using acetaminophen 650 mg q6 h for severe wrist pain. On the day of admission, the patient was seen by his primary doctor and had an INR of 7.5 - it was 2.3 3 weeks prior; he was advised to hold warfarin and go to the ED if he began to bleed. Later in the day after having a bowel movement he saw blood on the toilet paper and in his underwear but had no abdominal pain, blood in the actual stool, or change in stool color. The bleeding resolved with EMS applying pressure to the area on the way to the ED. PE revealed external hemorrhoids with evidence of recent bleeding. Labs were INR of 9.8, hemoglobin 10.4, LFTs normal. He was given vitamin K 2 mg sq in the ED and 2.5 mg PO. After admission he had no more bleeding episodes, with vital signs and CBC remaining stable. An x-ray revealed a distal radial fracture which was treated by splint immobilization and oxycodone. The INR decreased to 2.6 within 48 h, and the patient resumed his home dose of warfarin. He was advised to stop acetaminophen, as this was a possible etiology for the elevated INR.
DISCUSSION: Acetaminophen is generally the analgesic of choice for people on warfarin. It is considered to have a better safety profile than aspirin or NSAIDs, which predispose people to increased bleeding through platelet inhibition or injury to gastric mucosa. However there is a recognized but underappreciated drug-drug interaction which causes an elevation in INR if acetaminophen is taken at moderate doses of 1.5–4 g per day for over 3 days. These doses are generally considered safe from a hepatotoxicity standpoint. This interaction was first reported in 1968, and several early cases described this potentiating effect of acetaminophen on warfarin. Prospective randomized trials studying this relationship have found a statistically significant rise in the INR and bleeding episodes at the previously mentioned doses. The explanation as to how acetaminophen effects the INR of patients on warfarin is quite novel. As opposed to other agents that alter the metabolism of warfarin thus increasing or decreasing its effect, acetaminophen acts through its metabolite NAPQI causing a direct inhibition of the vitamin K cycle. Vitamin K is reduced to its active form by vitamin K reductase (VKOR), the enzyme inhibited by warfarin. NAPQI disrupts the vitamin K cycle directly, including direct inhibition of VKOR and raising the INR of patients on warfarin. Currently there are no specific recommendations on reversing over-anticoagulation from the combination of warfarin and acetaminophen, outside the general recommendations of treating an elevated INR. Thus, patients on warfarin who are on significant doses of acetaminophen for several days should have the INR closely monitored for any possible interaction.

AN UNUSUAL CASE OF CHEST PAIN: PERICARDITIS SECONDARY TO HYDRALAZINE-INDUCED LUPUS Katherine Wrenn. Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #1642457)

LEARNING OBJECTIVE 1: Recognize clinical manifestations of drug-induced lupus
LEARNING OBJECTIVE 2: Diagnose drug-induced lupus
CASE: A 60-year-old male with hypertension, hyperlipidemia, diabetes, and coronary disease presented to the emergency department reporting a two-day history of intermittent chest pain with exertion, followed by an episode of chest pain at rest. He denied associated symptoms. His electrocardiogram was unchanged, and cardiac enzymes were negative. He was admitted for a stress test, which was negative for ischemia. During the admission, he developed fevers, leukopenia, transaminitis, arthritis, and new onset atrial fibrillation. His exam was notable for a pericardial friction rub and pulsus paradoxus of 12. Echocardiogram revealed a moderate pericardial effusion with evidence of elevated intra-pericardial pressure, and he underwent pericardiocentesis. Diagnostic work-up revealed a positive antinuclear antibody (ANA) with a 1:160 titer. Anti-dsDNA antibody was negative, but anti-histone antibody was positive. He had been on hydralazine for 1.5 years, and was diagnosed with hydralazine-induced lupus. Hydralazine was discontinued, he was started on prednisone and hydroxychloroquine, and he has since fully recovered.
DISCUSSION: More than 80 medications have been identified as causes of drug-induced lupus (DIL). Procainamide, hydralazine, and quinidine are most commonly implicated; other medications include minocycline and anti-TNF alpha therapy. Unlike idiopathic systemic lupus erythematosus (SLE), which usually affects females ages 20–40, DIL affects men and women equally, with the average age of onset around 50. Clinical manifestations vary based on the inciting agent, and range from limited cutaneous involvement to systemic symptoms including fever, myalgias, arthralgias, arthritis, hepatosplenomegaly, and serositis. Hematologic abnormalities, renal disease, and neurologic disease are less common. Symptoms are generally milder than with SLE, but some cases are life threatening. Typical symptoms of hydralazine-induced lupus include fever, rash, arthralgias, myalgias, pleuritis, and leukopenia (1). Pericarditis is less common, occurring in <5 % of cases (2). Approximately 95 % of patients with DIL have a positive ANA, and >90 % have anti-histone antibodies. Anti-dsDNA antibodies are rare. When a patient taking one of the implicated medications presents with the above symptoms, DIL should be suspected. However, confirming the diagnosis can be difficult, as there are no formal diagnostic criteria for DIL. A proposed set of criteria includes sufficient and continuing exposure to a specific medication, at least one symptom compatible with SLE, no previous history of SLE, and resolution of symptoms within weeks to months after discontinuation of the medication (2). The presence of anti-histone antibodies in the absence of anti-dsDNA antibodies strongly suggests DIL, but is not an official criterion for diagnosis (2). ANA positivity is also not a requirement for diagnosis. In general, DIL is a reversible condition with a favorable prognosis, but it is critical to diagnose early. Treatment involves cessation of the medication and supportive care. NSAIDs and anti-malarial agents may be used for musculoskeletal symptoms, and severe cases may benefit from treatment with corticosteroids. If symptoms do not resolve after stopping the medication, other diagnoses should be considered. 1. Chang C, et al. Drug Saf 2011; 34(5):357–374. 2. Borchers AT, et al. Ann NY Acad Sci 2007; 1108:166.

AN UNUSUAL CASE OF FATIGUE Kevin A. Johnson; Maryam Sattari. University of Florida, Gainesville, FL. (Tracking ID #1638182)

LEARNING OBJECTIVE 1: 1. Recognize potential role of vitamin D deficiency in fatigue and daytime sleepiness.

LEARNING OBJECTIVE 2: 2. Diagnose and treat vitamin D deficiency.
CASE: A 61 year old male presented with complaint of daytime sleepiness, specifically in the afternoons. His past medical history was only significant for colon cancer that has been in remission since surgical resection and completion of systemic adjuvant chemotherapy in 2005. Previously, he worked fulltime and exercised on an almost daily basis. However, the fatigue had gradually worsened over last 2–3 months and now despite continuing to get 7–8 h of sleep, he had started to experience difficulty with his normal tasks at work, napped almost daily after work, and had even started to skip some of his exercise sessions due to fatigue. He reported good sleep hygiene and denied new familial or occupational stressors, snoring, apnea, difficulty sleeping, sleep disruptions, depression, or anxiety. In fact, his review of symptoms was only positive for chest pain that was worse in the afternoon when he felt tired. He did not take any prescription medications and denied use of tobacco, alcohol, or recreational drugs. Physical exam did not reveal any significant abnormalities. All investigative studies including serum testosterone, thyroid function tests, vitamin B12 level, CBC, EKG, and exercise stress echocardiogram were normal. In absence of a common etiology explaining patient's symptoms, serum Vitamin D level was checked and found to be low (18.4 ng/mL; reference range >30 ng/mL). Vitamin D replacement with ergocholecalciferol 50,000 IU weekly was initiated and follow up in 2 months revealed appropriate increase in vitamin D level (28.2 ng/mL) and complete resolution of daytime sleepiness. Patient reported improvement of his previous symptoms within 2 weeks of initiation of vitamin D supplementation and was now able to perform his previous daily routine without difficulty.
DISCUSSION: A growing body of evidence points to effects of vitamin D beyond its classically described impact on metabolism of calcium and phosphorus. Vitamin D deficiency has recently been linked with a wide range of disease states including metabolic syndrome, type 2 diabetes mellitus, incident hypertension, malignancies of breast, prostate, and colon, poor stress resilience, depression, cognitive decline, increased risk for fall and disability among elderly, multiple pulmonary disorders, chronic pain, low back pain, overt painful myopathy, and all-cause mortality. However, to our knowledge, there has only been one previous published report of hypersomnia that was attributed to vitamin D deficiency. Fatigue and daytime somnolence are symptoms which may result from a vast number of etiologies and a comprehensive approach to each patient is needed. If well-known causes of fatigue and daytime sleepiness are ruled out, vitamin D deficiency should then be considered, based on our case coupled with the previous report. We suggest that clinicians entertain vitamin D deficiency as a rare cause of otherwise unexplained fatigue and daytime somnolence. This easily detectible deficiency can be managed effectively, potentially preventing more invasive and expensive work-up.

AN UNUSUAL CASE OF HYPERCALCEMIA Yan Yan S. Xie; Danit Arad. Montefiore Medical Center, Bronx, NY. (Tracking ID #1633815)

LEARNING OBJECTIVE 1: Review the clinical features and pathogenesis of sarcoidosis.
LEARNING OBJECTIVE 2: Recognize a rare side effect of pegylated interferon and ribavirin in the treatment of Hepatitis C virus infection.
CASE: 54 year-old man presented with 2 months of worsening shortness of breath and generalized weakness. He had a history of Human immunodeficiency virus infection (HIV) on antiretroviral therapy and hepatitis C virus (HCV) infection. Patient reported his symptoms started shortly after he was initiated on triple therapy for HCV with Telaprevir, ribavirin and peginterferon alfa-2a. He completed 14 out of 48 weeks of therapy. Treatment was terminated 5 weeks prior to admission for waxing and waning course of anorexia, lethargy and constipation. Despite termination of treatment, patient continued to have worsening symptoms. Physical exam showed hyperpigmented scaling plagues on scalp and dermal flesh-colored plaque on the face. Laboratory results were significant for serum calcium corrected for albumin of 14.5 mg/dl and an elevated serum Angiotensin-converting enzyme at 256 U/L. Computed tomography scan of the chest showed bilateral mediastinal lymphadenopathy. Skin biopsy of the scalp revealed granulomatous dermatitis, sarcoidal type. A diagnosis of sarcoidosis with severe hypercalcemia likely induced by HCV antiviral therapy was made.
DISCUSSION: Sarcoidosis is a multisystem granulomatous disorder of unknown etiology. It is characterized by the presence of non-caseating granulomas in involved organs such as the skin, lung, lymph nodes, brain, kidneys and heart. The prevalence of sarcoidosis in the general population varies from 0.001 % to 0.04 %. Sarcoidosis has been associated with several environmental and infectious agents whose pathogenesis involves immunological mechanisms that are only partially understood. However, the immunological abnormalities of the early sarcoid reaction are well-known. Immunological hallmarks of the disease include highly polarized expression of type 1 T helper (Th1) cells response, leading to increased productions of cytokines such as interleukin (IL)-2, tumor necrosis factor (TNF)-α, and interferon (INF)-γ. The release of INF-γ and TNF-α promotes macrophages activation and aggregation, resulting in development of granulomatous inflammation. The prevalence of sarcoidosis in HCV infected patients is reported to vary from 0.1 % to 0.2 %, which is higher than the general population. A recent analysis revealed that among cases of coexisting sarcoidosis and chronic HCV infection, nearly 75 % of sarcoidosis was triggered by antiviral therapy. The precise mechanism behind antiviral therapy induced sarcoidosis is not completely understood. However, it is well recognized that pegylated interferon is a potent simulator of the differentiation of CD4+ T-cells towards a Th1 type immune response which is strongly involved in the pathogenesis of sarcoidosis. Ribavirin may also play a role in enhancing the Th1 response by increasing production of IL-12, INF-γ, TNF-α, and by lowering the Th2 response. More than 180 million people are infected with HCV worldwide. The recommended therapy for HCV infection is the combination of a pegylated interferon and ribavirin. This is an uncommon case of sarcoidosis manifested by severe hypercalcemia, bilateral hilar lymphadenopathy and cutaneous lesions in a man who received antiviral therapy. Internists should be aware of this unusual but clinically important complication of combined pegylated interferon and ribavirin therapy.

AN UNUSUAL CAUSE OF HYPERTHYROIDISM Mary Anne Mani; Kenneth C. Raney. Methodist Dallas Medical Center, Dallas, TX. (Tracking ID #1641176)

LEARNING OBJECTIVE 1: Recognize cystic teratoma as a cause of hyperthyroid symptoms
CASE: A 31-year-old Caucasian female with a past medical history significant for hypertension and hyperlipidemia presented with a one-week history of weakness, tachycardia, palpitations and periodic sweats. She denied headache, shortness of breath, fever, chills, nausea, vomiting, diarrhea or weight change. She denied any pain or lumps in her neck. She had similar symptoms several months earlier and was treated with Avapro for hypertension. Her family history was significant for hypertension, diabetes and coronary artery disease. There was no family history of thyroid disease. Social history was non-contributory. Review of systems was positive for palpitations, tremors and anxiety. Vital signs were within normal limits except for tachycardia. Physical exam did not show thyromegaly or neck tenderness. Supraclavicular and axillary lymphadenopathy were absent. Lungs were clear to auscultation bilaterally. Heart exam showed tachycardia with regular sinus rhythm and a 2/6 systolic murmur along the left sternal border. Neurological exam was significant for the absence of tremors. Laboratory results indicated normal CBC and BMP but decreased TSH (<0.01 uIU/mL) and increased free T4 levels (3.23 ng/dL). Thyroid hormone levels had previously been normal. The tumor markers alpha fetoprotein, beta hCG, metanephrine and normetanephrine were within normal limits. EKG showed sinus tachycardia. Chest x-ray indicated a soft tissue density on the superior left heart border. CT angiogram showed a complex, left mediastinal mass measuring 7.1×6.1×6.3 cm containing fatty and soft tissues as well as calcification. There was some mass effect on the pulmonary outflow tract but no vascular

encasement. There was no adenopathy, pleural effusions or metastases. A thyroid uptake scan was not performed. Echocardiogram showed mild mitral and tricuspid regurgitation. A biopsy of the anterior mediastinal mass confirmed a benign mature cystic teratoma with abundant epithelium, keratin, sebaceous glands and patchy chronic inflammation and fibrosis. Immature and neuroepithelial elements were absent. The patient was treated with a high dose of methimazole (30 mg BID) to control hyperthyroid symptoms. Surgery, which was delayed till thyroid hormone levels were controlled, involved left thoracotomy with resection of the mediastinal mass. The patient did not require methimazole after surgery.

DISCUSSION: The altered level of thyroid hormones could have been caused by acute thyroiditis, a thyroid nodule or a thyroid adenoma. However, the patient had no goiter or neck tenderness. The patient was not taking any medications that could have caused thyroiditis, or have a recent history of radiation or parathyroid surgery. There was no evidence for struma ovarii or metastatic thyroid cancer. Symptoms could have been caused by a germ cell tumor via direct stimulation of the TSH receptor. Germ cell tumors account for 15 % of anterior mediastinal masses and can be mature teratomas, seminomas or nonseminomatous germ cell tumors. The normal levels of beta hCG and alpha-fetoprotein ruled out the presence of seminomas or nonseminomatous germ cell tumors. Biopsy showed that the mass was a mature teratoma and surgical removal resulted in alleviation of symptoms. To our knowledge, this is the first report of hyperthyroid symptoms being caused by a teratoma. Histological studies are ongoing to examine the mass for the presence of thyroid tissue.

AN UNUSUAL CAUSE OF HYDROCEPHALUS Zhe Chen; Yelena Averbukh. Montefiore Medical Center, Bronx, NY. (Tracking ID #1636545)

LEARNING OBJECTIVE 1: To consider multiple etiologies in patients presenting with dural enhancement.

LEARNING OBJECTIVE 2: To recognize a clinical syndrome consistent with Idiopathic Hypertrophic Pachymeningitis.

CASE: A 48 year old African-American woman presented with headache and nausea for 3 weeks. On examination, she also had pain with flexion and extension of her neck. Neurological exam was otherwise normal. Her initial laboratory tests were normal. Head CT showed hydrocephalus of unclear etiology, and brain MRI showed significant right-sided dural enhancement. Subsequent CSF studies showed no signs of meningitis with negative bacterial and mycobacterial cultures. Tests for infectious etiologies such as syphilis, HIV, and Lyme disease were negative. Rheumatologic studies were also negative. Chest CT was negative for evidence of sarcoidosis or malignancy, as well as other infectious or inflammatory processes. She underwent placement of a ventricular-peritoneal shunt and dural biopsy. Biopsy showed dura with reactive and inflammatory changes, but no organisms and granuloma. Given the finding of dural enhancement without evidence of other clear infectious, inflammatory, and malignant etiologies, and the exclusion of other causes of hydrocephalus, the patient was subsequently diagnosed with Idiopathic Hypertrophic Pachymeningitis (IHP) and discharged with improvement of her symptoms.

DISCUSSION: General internist commonly encounter complaints of headache and nausea. Careful evaluation for commonly encountered conditions that tailor to specific risk factors in a systematic manner would usually lead to the diagnosis. But at times, even a extensive work up would only lead to a diagnosis of exclusion. There is a wide array of causes of dural enhancement, including infectious, inflammatory and neoplastic disorders. Infectious etiologies include tuberculosis commonly seen in immunocompromised patients from endemic areas and neurosyphilis seen in patients with limited access to healthcare resources. Neurosarcoidosis should also be considered in the differential, as well as other vasculitides. Finally, malignancy can also cause dural enhancement and thus must be considered. The initial clinical approach to this radiologic finding is to assess for these possible causes. However, in rare instances, an etiology of dural enhancement cannot be elucidated, and a subsequent diagnosis of exclusion of Idiopathic Hypertrophic Pachymeningitis (IHP) would be made that literally translates from Latin as 'thickened fat meninges'. Patients with IHP usually present with headache, cranial nerve palsies, and ataxia, but the clinical presentation can be highly variable. Patients may present with clinical entities secondary to compression by a thickened inflamed meninges such as venous sinus occlusions, cerebral ischemia, intracranial hemorrhage, and obstructive hydrocephalus, which we saw in our patient. Meningeal biopsy may be required to exclude other causes of dural enhancement. Pathological findings usually consist of fibrous thickening and inflammatory changes. The treatment of IHP is also variable and based on the clinical progression of disease. Often times, spontaneous resolution of both clinical symptoms and signs occur. Corticosteroid therapy is also effective in controlling disease progression. Rarely, steroids are ineffective, and treatment with chemotherapy such a cyclophosphamide and azathioprine have also been tried. In some rare instances, surgical incision may be warranted.

AN UNUSUAL COMPLICATION OF INFECTIVE ENDOCARDITIS Megha Prasad. Mayo Clinic, Rochester, CA. (Tracking ID #1642862)

LEARNING OBJECTIVE 1: Recognize small vessel vasculitis as a potential complication of infective endocarditis

LEARNING OBJECTIVE 2: Understand the management of c-ANCA vasculitis

CASE: A 69 year old veterinarian with a history of myelodysplastic syndrome and aortic valve replacement 3 years prior, presented with a 3 month history of fever, 20 lb weight loss, purpuric lower extremity rash and progressive kidney failure. Our patient had blood cultures positive for streptococcus acidominimus 2 months prior to presentation, with a transesophageal echocardiogram confirming vegetations on his prosthetic aortic valve placed in 2009, and a mitral paravalvular abscess with native vegetations. He was treated for endocarditis with intravenous penicillin, ceftriaxone and gentamicin. On repeat transesophageal echocardiogram, vegetations and abscess had resolved. On admission, the patient underwent extensive laboratory testing. Creatinine was 6.5 mg/dL, increased from 1.0 mg/dL 4 months prior. Urinalysis was significant for >100 RBCs, RBC casts, and dysmorphic RBCs. Initial antineutrophilic cytoplasmic antibody (c-ANCA) was negative and anti-proteinase antibody-3 (PR-3) was 6.3 U (reference: <1 U). c-ANCA was later found to be positive on subsequent titers. The patient underwent renal biopsy to further evaluate the abnormal urinalysis in the setting of positive PR-3 and c-ANCA. Renal biopsy was consistent with c-ANCA positive focal segmental necrotizing and crescentic glomerulonephritis in addition to mesangial proliferative glomerulonephritis compatible with IgA nephropathy. Further renal decline prompted dialysis. Skin biopsy of the lower extremity lesion revealed leucocytoclastic vasculitis. Our patient's hospital course was further complicated by the development of seizures revealing a subarachnoid hemorrhage on computed tomography (CT) of the head. Our patient was diagnosed with ANCA-associated systemic vasculitis. His renal dysfunction and subarachnoid hemorrhage were explained by this vasculitis. We initiated prednisone 60 mg daily and gradually noted improvement in his functional capacity, resolution of his seizures, and improvement of his renal function. PR-3 decreased to 1.9 U at dismissal.

DISCUSSION: We describe the need to consider a rheumatological etiology when managing a patient with persistent symptoms after treatment for endocarditis. In these patients, it is important to consider vasculitis as a potentially fatal complication. Our patient's initial fever of unknown origin was attributed to endocarditis. Further evaluation upon transfer, in the setting of his constellation of symptoms including renal failure, rash, and systemic symptoms led us to the diagnosis of c-ANCA vasculitis, which has been described in the literature as a rare complication of infective endocarditis. Immunosuppression was successful in managing this patient's symptoms and decreasing his antibody titers.

AN UNUSUAL PRESENTATION OF WEST NILE VIRUS Katrin Usifo; Jennifer Dooley; Shadi Ayyoub; William C. Crowe. University of Tennessee College of Medicine Chattanooga, Chattanooga, TN. (Tracking ID #1623688)

LEARNING OBJECTIVE 1: Recognize the clinical features of West Nile Virus.
LEARNING OBJECTIVE 2: Suspect West Nile Virus encephalitis even when diagnostic testing is negative.
CASE: A 56 year-old female with no significant past medical history presented to the hospital in July after being found unresponsive at home. She had nausea, vomiting, and diarrhea 1 week prior. In the emergency department she was obtunded, tachycardic, tachypneic, and had a temperature of 103 °F. She was intubated for airway protection. Head CT was negative. LP revealed clear fluid with 36/mm3 RBCs, 92 mg/dL protein, 84 mg/dL glucose, 81/mm3 WBCs, 80 % lymphocytes. CSF gram stain showed no organisms and rare WBCs. CSF was negative for Neisseria meningitidis, Steptococcus pneumoniae, Haemophilus influenzae, Mycobacterium tuberculosis, and Cryptococcal antigen. VDRL, HIV, and HSV were negative. CSF ELISA for West Nile Virus (WNV) IgG and IgM were negative. She was initially treated with Rocephin, Zosyn, Vancomycin, Acyclovir, and Flagyl. The patient remained unresponsive to deep painful stimuli. MRI was suggestive of encephalitis. Testing for Ehrlichia chaffeensis and Human granulocytic ehrlichiosis IgG and IgM was negative. LP repeated 9 days after initial presentation showed clear fluid with 45/mm3 RBCs, 68 mg/dL protein, 59 mg/dL glucose, 5/mm3 WBCs, 95 % lymphocytes. This CSF culture had no growth and no isolated viruses. CSF cytology showed lymphocytes and monocytes with rare granulocytes and no evidence of malignancy. Serum WNV IgG and IgM checked 17 days after initial presentation were negative. Seizure activity developed 11 days into the hospital course and was confirmed by EEG. Unfortunately, her neurological status never improved despite treatment with antibiotics, steroids, and anti-epileptics. The family elected to withdraw care, and the patient passed away with an unclear cause of encephalitis. An autopsy determined the cause of death to be from encephalitis, but the cause of encephalitis was not determined until tissue samples were sent to the Center for Disease Control (CDC) for further analysis. The CDC identified the cause of her encephalitis as West Nile Virus.
DISCUSSION: WNV should be strongly considered in patients greater than 50 years old who have onset of unexplained fever, encephalitis, meningitis, or flaccid paralysis during mosquito season (June to October). Evidence of cases of WNV infection in 2012 in the United States have exceeded that of any other—with 1590 cases and 65 deaths as of August 2012. Eighty percent of persons infected with the WNV are asymptomatic. Twenty percent present with fever, lymphadenopathy, myalgia, headache, or rash. Less than 1 % of infected patients present with neuroinvasive disease, and in these patients LP and testing of the CSF for detection of WNV IgM antibody as well as serologic testing are recommended. WNV ELISA tests have a sensitivity of 96.2 %and specificity of 98.4 %. A single negative test does not rule out infection. WNV IgM antibodies in the blood or CSF are positive in most infected patients within 8 days of symptom onset. Viral culture is the gold standard, but it is rarely positive except in autopsy material from the brain and other solid organs.

AN ATYPICAL PRESENTATION OF IGA NEPHROPATHY Christopher Rombaoa; Kah Poh Loh; David Burgess; Owolabi Ogunneye; Ashish Verma. Baystate Medical Center/Tufts University, Springfield, MA. (Tracking ID #1642954)

LEARNING OBJECTIVE 1: Recognize the atypical clinical presentations IgA nephropathy
LEARNING OBJECTIVE 2: Recognize the variability of light microscopic findings in IgA nephropathy
CASE: Our patient is a 55-year-old Caucasian male who presented with a three-week history of progressively worsening lower extremity and trunk edema associated with a 70 lbs weight gain; preceded by a flu-like illness. He denied any significant flank pain, fever, shortness of breath, orthopnea, gross hematuria, or change in urine output. His past medical, family and social history were non-contributory. On admission he was hypertensive with a blood pressure of 144/79, with otherwise stable vital signs. Physical examination demonstrated anasarca of the trunk and bilateral lower extremities. His initial creatinine on presentation was 1.4 mg/dL and peaked at 3.4 during the hospitalization. Total and LDL cholesterol were elevated at 420 and 314 respectively. Liver function test was normal. A 24-hours urine collection revealed 28 g of daily proteinuria. Urinalysis revealed several red cell casts, Maltese crosses, and fat droplets. Immunological studies were positive for ANA, with normal complement and immunoglobulin levels. Serum and urine immunofixation studies, viral serology, lupus screen, anti-GBM and ANCA were all within normal limits. Given the highly suggestive findings of intrinsic renal disease, a kidney biopsy was performed. Light microscopy revealed hypercellular glomeruli with varying degrees of endocapillary proliferation. In addition, there was some evidence of focal double contours and lobulation, suggestive of membranoproliferative glomerulonephritis. Electron microscopy demonstrated significant effacement of foot processes as well as electron dense deposits in subepithelial and subendothelial locations. Finally, Immunofluorescence studies showed diffuse mesangial deposits of IgA and C3, clinching the diagnosis of IgA nephropathy. The patient was treated with aggressive diuresis, high dose corticosteroids, and cyclophosphamide with gradual resolution of his symptoms.
DISCUSSION: IgA nephropathy is the most common primary glomerulonephritis in the majority of developed countries. This case is interesting in that it outlines that atypical clinical and histological presentations of IgA nephropathy. Less than 10 % of IgA nephropathy presents with nephrotic syndrome or rapidly progressive glomerulonephris; our patient on presentation was found to have both. On light microscopy, the typical morphological lesion observed is mesangial proliferation nonetheless in 20 % of the cases, double contours resembling idiopathic membranoproliferative glomerulonephritis may also be observed. Despite the uniform aspect of immunofluorescence findings in IgA nephropathy, the variability of light microscopic findings still poses significant challenges in histological classification.

AN INTERESTING AND RARE CAUSE OF ABDOMINAL PAIN Alpa Vora. Saint Francis hospital, Evanston, IL. (Tracking ID #1624370)

LEARNING OBJECTIVE 1: To know that Splenic infarct is an uncommon cause of abdominal pain.
LEARNING OBJECTIVE 2: To accurately and diagnose and to know work up and management of Splenic infarct. To timely detect life threatening complications of Splenic infarct.
CASE: 55 year old patient with PMH of pancreatitis in 2000, GERD, HTN, Gout, Kidney stones and Migraine, presented to ER with complaint of Lt UQ abdominal pain associated with nausea without vomiting, girdle like burning pain 10/10, constant, better with Advil, worse with food, lying on left side. No h/o Fever/ chills /melena or hematochezia/ urinary symptoms. He had h/o EGD and colonoscopy about 3–4 year back, with normal results. Social history- Chronic Alcoholic, regularly takes neat Scotch 6 to 8 Oz, Smoker–3PPD×40 year. Physical Examination: Vitals normal, Pt Alert and oriented, no distress, Chest: CTAB, Cardiac: S1S2+, No murmur/ rub/gallop, Abdomen: Soft, NT, ND, BS+, Digital Rectal Exam: Normal, non significant prostate, heme-occult negative. Labs: Hb- 16.9, WBC- 15, 300, Platelets-210,000, BMP- normal,Amylase- 84, Lipase- 6, UA, LFT, Cardiac markers- normal. EKG- NSR, No ST- Tchanges Imaging: CT Abdomen- Splenic infarct. Hypercoagulable workup- positive for Lupus anticoagulant, aPTT- raised TEE - mobile arch atheroma as well as multiple non mobile atheromas in the descending aorta, no intracardiac clots, vegetations/ no shunts. Clinical course: Pt was

initially started on anticoagulation with Lovenox, hydration, analgesics. Surgical service was put on consult. Patient was treated conservatively. He was started on Aspirin, plan was to start Coumadin only if there is any evidence of future embolism, per Cardiology. Hematology service was on consulted, lupus anticoagulant was positive. He was started on Coumadin due to high risk of thrombosis, to be continued life long. He was watched for any complications and was discharged home in 10 days.
DISCUSSION: Splenic infarction is a rare cause of acute abdomen. It must be suspected in patient with hematologic diseases or thromboembolic conditions. The most common onset symptom is left-upper quadrant abdominal pain. Additional symptoms include fever and anemia. Laboratory may show elevated white blood cell and platelet counts. The diagnosis of splenic infarction is based both on clinical presentation and imaging studies. Angio-computed tomography is the diagnostic procedure of choice. Ultrasonography and conventional radiology are useful in the differential diagnosis with other abdominal and thoracic diseases mimicking splenic infarction. Splenectomy is performed for persistent symptoms or a complication of the infarct (splenic pseudocyst, abscess, or hemorrhage). An uncomplicated splenic infarction can be managed safely with medical treatment, but early surgical intervention (splenectomy) is necessary to lower the mortality rate of a complication of the infarct.

AN UNUSUAL AND TERMINAL CAUSE OF SYNCOPE Yogita Segon; Ankur Segon. Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #1619494)

LEARNING OBJECTIVE 1: To recognize that aggressive orophyrangeal squamous cell cancer can lead to syncope
LEARNING OBJECTIVE 2: To appreciate a clinical scenario in which evaluation of carotid arteries is an appropriate part of syncope work up
CASE: 63 year old male with history of locally advanced ((T4 - deep muscle invasion, N2b - multiple ipsilateral neck lymph nodes, M0), left sided base of tongue squamous cell cancer presented to the emergency room with multiple episodes syncope over 2–3 weeks. He was treated with chemoradiation 6 months prior to current admission. Follow up imaging after chemoradiation showed progressive disease. He was then started on palliative cetuximab 1 month prior to current admission. During current admission, work up for syncope was commenced. EKG and cardiac enzymes were negative. There were no events on telemetry. Review of his last CT scan from 4 months prior to admission showed encasement of left carotid artery. A repeat CT scan of his neck was performed. It showed remarkable tumor progression with extensive lymphadenopathy and compression of both of his carotid arteries by a combination of tumor burden, lymph nodes and post-radiation edema. Surgical resection of the mass and local radiation therapy were both deemed inappropriate due to location of tumor and its relative radioresistance in the past. In addition, there was concern that radiation could cause worsening edema and precipitous worsening of patient's condition by causing complete occlusion of the carotid arteries. This information was discussed with patient and his wife and he is currently in home hospice. In the 2 weeks since discharge, he feels he has been able to minimize further episodes of syncope by limiting and modifying his activities.
DISCUSSION: Recurrent syncope due to malignancy is uncommon. Head and neck cancer can lead to recurrent syncope by two mechanisms. Neurally mediated syncope can occur due to carotid body invasion or involvement of the vagus nerve. Syncope due to reduced blood flow in carotid arteries is uncommon and requires involvement of both carotids. While it is possible that our patient was passing out due to tumor pressure mediated firing of baroreceptors in his carotid bodies, we think reduced carotid blood flow was the more likely culprit. This is based upon the fact that he only started having syncopal events after involvement of his contralateral carotid artery. Finally, our case highlights the importance of imaging the carotid arteries in patients with history of head and neck cancer who present with syncope. Imaging of carotid arteries is not merited during routine diagnostic work up of syncope unless a neurological event is suggested by history or if focal signs and symptoms are present. However, such an evaluation should be considered in patients who have a history of head and neck cancer, especially if the cancer has been relatively resistant to treatment or locally advanced in the past.

AN UNUSUAL CAUSE OF COUGH Aparna Sharma; Kokila Bindiganavile Nagendran; Harvey Friedman. Saint Francis Hospital, Evanston, IL. (Tracking ID #1631543)

LEARNING OBJECTIVE 1: Recognize an unusual presentation of Allergic Bronchopulmonary Aspergillosis (ABPA)
CASE: An 89 year old Caucasian male with a history of coronary artery disease, stroke and aortic valve replacement was evaluated due to an abnormal chest x-ray showing right upper lobe collapse. The patient reported productive cough with whitish sputum for the preceding 5–6 months but denied fever, chills, hemoptysis, wheezing, chest pain, dyspnea, sick contacts, weight loss, night sweats, tobacco use or seasonal allergies. His travel history included a trip to California 8 months back. His vital signs were normal and physical exam was significant for mildly decreased breath sounds in the right upper lung field. Laboratory values were significant for a white cell count of 7.2 k/mm3 with eosinophilia (15.9 % eosinophils) 4 months back, the patient was hospitalized for "pneumonia" at which time the chest x-ray showed a similar appearance. CT scan of the chest demonstrated right main stem bronchus narrowing with resultant collapse and post-obstructive pneumonia in the right upper lobe. Bronchoscopy was notable for thick inspissated mucous obstructing the right upper lobe bronchus but no endobronchial lesions were noted. Biopsy showed benign bronchial mucosa with chronic inflammation and numerous Charcot Leyden crystals. Cytology was negative for malignant cells. Fungal, acid fast bacilli (AFB) cultures and fungal serologies (Blastomyces, Coccidioides and Histoplasma) were negative as well. Upon current presentation, bronchoscopy showed an obstructed right upper lobe bronchus with thick and tenacious mucus. Bronchial cultures were negative for fungus and AFB. Cytology was negative for malignant cells. Serum total IgE levels were 1134 kU/L (normal range 2–114) and IgE specific to A. terreus was positive. A diagnosis of ABPA was made and treatment with Prednisone and Itraconazole was initiated. Serum total IgE levels were 708 kU/L at 2 weeks, 129 kU/L at 2 months and 100 kU/L (within normal range) at 5 months.
DISCUSSION: Allergic bronchopulmonary aspergillosis (ABPA) is an IgE mediated hypersensitivity reaction directed against Aspergillus antigens that are inhaled into the upper and lower respiratory tract. It is known to occur mostly in patients with underlying asthma and less commonly in patients with cystic fibrosis. This vignette highlights an unusual presentation of the disease due to the lack of a prior history of asthma in the patient described above. Moreover, the mean age of onset of ABPA is usually in the third or fourth decade of life whereas this patient first developed symptoms at the age of 89 years. ABPA caused by A. terreus is rare and most cases reported in the literature describe a different species, A. fumigatus as the etiologic agent. Treatment involves a combination of steroids and antifungals (Itraconazole or Voriconazole) for a period of 3–6 months. Treatment efficacy is monitored via serial serum IgE levels. It is important to recognize unusual presentations of ABPA as early detection and treatment reduces the risk of progression to fibrotic disease and subsequent morbidity.

AN UNUSUAL PRESENTATION OF AN ACOUSTIC NEUROMA—BILATERAL PAPILLEDEMA WITHOUT HYDROCEPHALUS Maryam Mahmood; Anthony A. Donato. Reading Health System, Reading, PA. (Tracking ID #1628842)

LEARNING OBJECTIVE 1: Recognize an unusual presentation of acoustic neuromas

CASE: Bilateral papilledema is a relatively rare condition that is typically accompanied by increased intracranial pressure. We present an unusual case of a unilateral acoustic neuroma associated with bilateral papilledema in the absence of increased intracranial pressure. A 57-year-old woman presented with a two-week history of worsening morning headaches, bilateral blurred vision and loss of color vision. Review of symptoms also found intermittent right-sided hearing loss and tinnitus. Examination revealed an alert, normotensive patient. On fundoscopy bilateral optic disc edema and retinal edema were noted. Visual acuity of 20/150 OD and 20/400 OS were significantly worsened from her previous refractive error. Extraocular muscle, visual field and slit lamp examinations were normal. Sensorineural hearing loss in the right ear was confirmed by pure tone audiometry, hearing in the left ear was normal, as was the rest of the neurologic exam. MRI of the brain demonstrated a smooth 20 mm by 24 mm acoustic neuroma at the right cerebellopontine angle cistern with localized mass effect. No evidence of increased intracranial pressure was apparent on neuroimaging. A lumbar puncture revealed opening pressure of 24 cmH2O and mildly elevated cerebrospinal fluid protein of 95 mg/dL, with an otherwise unremarkable cerebrospinal fluid analysis. The patient was referred for radiation therapy for the symptomatic acoustic neuroma.
DISCUSSION: Acoustic neuromas account for about 8 % of all intracranial tumors, usually presenting with hearing loss, tinnitus, disequilibrium, facial numbness and headache. Visual symptoms are much less common, but when they occur they are associated with larger tumors that compress the adjacent fourth ventricle. Papilledema in the absence of increased intracranial pressure is believed to be the result of an unusual constituent of CSF that impairs CSF reabsorption through blockage of the arachnoid granulations with a resulting communicating hydrocephalus.

ANAPHYLAXIS TO LEVOFLOXACIN: RARE REACTION TO A COMMON DRUG Qura Tul Ain Rashid; Joseph T. Knapper; Robin Klein. Emory University School of Medicine, Atlanta, GA. (Tracking ID #1638348)

LEARNING OBJECTIVE 1: Review the serious side effects of levofloxacin.
LEARNING OBJECTIVE 2: i) Recongize anaphylaxis associated with flouroquinolones as rare but severe reaction to flouroquinolones. ii) Appreciate the potential for these anaphylactic reactions when prescribing floroquinolones to patients.
CASE: A 63 year old woman presented to the emergency department with 2 weeks of shortness of breath, productive cough and chest tightness. She denied any chest pain, fevers, chills, or hemoptysis. Past history was significant for hypertension and chronic obstructive pulmonary disease (COPD) requiring home oxygen. Patient reported compliance with Symbicort and Ipratropium inhaler. She reported medication allergies to Darvocet and Benadryl. Severity of the reaction to these medication was unclear. On admission, her heart rate was 97 bpm and blood pressure was 125/68 mmHg. Exam revealed expiratory wheezes diffusely in all lung fields. Chest X-ray revealed no acute infiltrate. She was admitted for a COPD exacerbation and treated initially with oral prednisone and doxycycline. The patient became more dyspneic and medication was switched to oral Levofloxacin and intravenous steroids. The patient reported the sensation of throat swelling and difficulty breathing within minutes of taking first dose of levofloxacin. She became acutely tachypneic and diaphoretic. She had swelling of the tongue and face and developed an urticarial rash on trunk, face and all four extremeties. She became hypotensive and developed PEA arrest. Chest compressions were initiated and return of spontaneous circulation was obtained. She was intubated, transferred to the intensive care unit, and was treated with epinephrine, steroids and H2 blockers. Her clinical status improved, facial swelling decreased, and rash resolved. She was extubated and ultimately discharged home a few days later.
DISCUSSION: Fluoroquinolones are broad-spectrum antibiotics used for the treatment of many types of infections including those of the respiratory tract. Levaquin in particular is one of the most prescribed drugs in the world, with sales exceeded $1.5 billion in 2010. It is generally well-tolerated. The most frequently cited side effects in adults are gastrointestinal problems such as nausea, vomiting, and diarrhea and CNS problems including headaches, dizziness, and insomnia. Serious side effects include prolonged QT, torsades de pointes, hypersensitivity reactions, and Stevens Johnsons syndrome. Anaphylaxis is a severe reaction that arises in response to the release of inflammatory mediators and cytokines. Anaphylaxis associated with flouroquinolones is rare with an estimated frequency of 1.8 per 10 million days of treatment based on reports. Studies show that the rates of anaphylaxis are comparable with different fluoroquinolones. Anaphylaxis after the first dose or within the first 3 days of starting the medication occurred in 43 % of cases in one study. The occurance after first-ever intake suggests a mechanism where sensitization is not necessary. This case illustrates the rare but grave potential for anaphylactic reactions with fluoroquinolone use. Despite their frequent use and good overall safety profile, fluoroquinolones can prompt serious reactions that are difficult to predict. Class-based cross-reactivity is high and anaphylaxis cannot be reliably predicted with either skin-testing or basophil activation testing. Physicians need to be aware of these consequences when prescribing floroquinolones to their patients.

ANOMALOUS AORTIC ORIGIN OF CORONARY ARTERY AND SUDDEN CARDIAC DEATH: CONSIDERATION OF DIAGNOSTIC AND TREATMENT APPROACHES. Beata A. Kaczkowska; Terrence J. Sacchi. New York Methodist Hospital, Brooklyn, NY. (Tracking ID #1643518)

LEARNING OBJECTIVE 1: Coronary artery anomalies are the fifth most common cause of sudden cardiac death (SCD). Despite having a low prevalence, they account for approximately 15 % of all sudden cardiac deaths. We assess and recognize diagnostic, preventive and therapeutic approaches of this rare coronary anomaly.
CASE: A 43 year-old previously asymptomatic female with a long history of aerobic exercise and no personal or family history of heart disease or cardiac arrest presented as SCD after a witnessed collapse while running on a treadmill. The subjective data were unobtainable due to her unconscious state. The physical examination was unremarkable. The objective data showed normal hemogram, chemistry, cardiac biomarkers, electrocardiogram (EKG) and echocardiogram (ECHO). Coronary angiography revealed an anomalous origin of the left anterior descending (LAD) and left circumflex (LCX) coronary arteries from the right sinus of Valsalva. The LAD, LCX and right coronary artery (RCA) had separate ostia. These findings were subsequently confirmed by computer tomography coronary angiography (CTCA). Intraoperatively, in addition to an anomalous aortic origin of coronary arteries, the LCX demonstrated an unusual course, turning sharply off the sinus and coursing rightward behind the aorta. The vessel was also tightly encased in a fibrous sheath in an almost intramural fashion. No vessel coursing between the great arteries was found. She underwent an unroofing surgical repair. Postoperatively, a cardioverter-defibrillator (ICD) was implanted. She remains symptom-free.
DISCUSSION: The clinical presentation of individuals with coronary artery anomalies may be chest pain, palpitations or syncope, especially with exercise, although it can be sudden death. Anomalous coronaries are rarely diagnosed in asymptomatic individuals. Diagnostic modalities such as EKG, stress testing and ECHO can miss 80–100 % of coronary anomalies. Preceding symptoms may be the only predictors of SCD therefore unexplained symptoms of cardiac ischemia or syncope especially in young individuals should receive further scrutiny. The prevalence of an anomalous aortic origin of a coronary artery from the opposite sinus is 0.1–0.3 %. The incidence and associated SCD risk remain unclear due to lack of diagnostic criteria and reliance on postmortem data. Mortality is 0–

50 % and 30–100 % with anomalous RCA and LAD respectively. Five documented cases of several affected family members support its possible hereditary transmission yet no guidelines exist for screening families. Transthoracic ECHO with attention to the coronary arteries, transesophageal ECHO, CTCA, cardiac magnetic resonance imaging and coronary angiography are diagnostic. The ultimate treatment is surgical repair, making timely identification crucial in this repairable condition. Postsurgical mortality is rare (1.5 % incidence). Although no recommendations exist, given the highly atypical coronary course an ICD was recommended in our patient solely on clinical impression, not per published guidelines. The question arises whether an ICD can be protective and further reduce mortality.

ANOTHER LUPUS FLARE? Eric M. Nelsen; Tony Chon. Mayo Clinic, Rochester, MN. (Tracking ID #1636459)

LEARNING OBJECTIVE 1: Recognize the infectious causes of elevated liver enzymes and abdominal pain in patients with SLE.
LEARNING OBJECTIVE 2: Diagnosis and treat systemic CMV infection.
CASE: A 51 year old female with a history of SLE on mycophenolate mofetil therapy presented to an outside facility with 2 weeks of multiple systemic complaints including subjective abdominal pain, nausea, fevers, fatigue and headache. Her fevers were as high as 38.9 celsius. Her headaches were described as a dull ache wrapping around her head. On admission she was found to have elevated liver enzymes, AST 349 U/L, ALT 503 U/L and an alkaline phosphatase of 459 U/L with a normal bilirubin. CT and ultrasound imaging were negative for acute cholecystitis with no evidence of cholelithiasis; but did show some liver parenchymal inflammation with gallbladder wall thickening. Due to strong concern for SLE flare, she was subsequently transferred to our facility. Her anti-DNA and complement levels were within normal limits thus our Rheumatology colleagues believed the patient was not having a flare of her SLE and recommended holding the mycophenolate until infection was ruled out. Due to the severity of her headache and her overall clinical picture, she underwent lumbar puncture on admission. CSF showed a protein of 38 mg/dL, glucose of 40 mg/dL with 2 total nucleated cells. Additional history found that the patient had been camping the last two weekends with multiple mosquito bites, however no known tick exposure. Infectious disease work-up was negative for West Nile, anaplasma, Ehrlichia, Q fever, and Lyme disease. Due to her elevated liver enzymes and systemic symptoms, hepatitis serologies for B and C were checked and found to be negative. Additionally her HSV IgM antibodies and EBV PCR were negative. Due to her immunosuppressive history a CMV IgM serology was checked and found to be positive. The elevation in liver enzymes and the thickening of the gallbladder were thought to be due to her CMV infection. For treatment of her systemic CMV infection with IV ganciclovir which was transitioned to PO valganciclovir after 24 h. Given her low serum CMV PCR, it was felt that she did not need an ophthalmology evaluation for retinitis. Her symptoms improved and she was discharged home on valganciclovir in stable condition.
DISCUSSION: Abdominal pain with nausea and vomiting can occur in up to 30 % of patients with SLE. Additionally, liver enzyme abnormalities in SLE are relatively a common presentation. Most patients have low level elevation in AST, ALT. Autoimmune liver disease is uncommon in patients with SLE. It is important to recognize the pattern of liver enzyme elevation related to SLE and rule out other causes. In this patient her SLE markers of disease (complement and anti-DNA levels) were stable pointing away from a SLE flare thus leading to an infectious disease work-up. Systemic CMV infection can have a wide range of clinical presentation. It is important to recognize which patients are at risk for systemic CMV infection. This patient had been on long standing immunosuppressive medications thus putting her at risk. Her presenting symptoms and elevated liver enzymes could all be explained by systemic CMV infection. Once her CMV infection was treated, her symptoms and clinical status improved. Systemic CMV infection should remain on the differential in immunosuppressed patients presenting with constellation of symptoms including fever, malaise, fatigue, headaches, and abdominal pain.

ANTISYNTHETASE SYNDROME: THE TIP OF THE ICEBERG. Anna Corey. University of Wisconsin Hospital and Clinics, Madison, WI. (Tracking ID #1642768)

LEARNING OBJECTIVE 1: Identify the constellation of symptoms that comprise the antisynthetase syndrome.
LEARNING OBJECTIVE 2: Recognize the importance of evaluating for underlying malignancy in all patients presenting with inflammatory myopathy.
CASE: A 65-year-old woman with a history of GERD presented with 3 months of exertional dyspnea, dry cough, and worsening reflux symptoms. She had completed several courses of antibiotics for presumed community-acquired-pneumonia without improvement in her symptoms. Vital signs were normal and physical exam unremarkable. Chest radiograph showed multifocal bibasilar opacities. She was diagnosed with aspiration pneumonitis and treated with high dose proton-pump inhibitor and anti-reflux measures. After some initial improvement in her symptoms, she returned several weeks later with worsening dyspnea, fatigue, myalgias and arthralgias of her hands, wrists and knees. She also complained of dry eyes and thickening of the skin on her hands. Vital signs were normal. Physical exam revealed tenderness and swelling of both wrists and right 2nd and 5th MCP joints and tenderness upon palpation of the upper arms. There was also dry, thickened skin on the palmar surfaces of her fingers. Lung exam revealed bibasilar crackles. No lymphadenopathy or rashes were noted. Initial laboratory evaluation revealed mildly elevated CK and transaminitis. Chest CT showed basilar peribronchovascular groundglass, nodular and reticular pattern opacities associated with bronchiectasis, consistent with nonspecific interstitial pneumonia (NSIP). Transbronchial lung biopsy revealed interstitial mononuclear inflammation and mild fibrosis, also consistent with NSIP. By this time, anti-Jo-1 antibody returned positive. The unifying diagnosis was thought to be antisynthetase syndrome and she was started on prednisone 1 mg/kg daily with improvement in her symptoms. Unfortunately, the CT chest had also revealed left axillary lymphadenopathy. A workup for breast cancer was pursued and although clinical breast exam and diagnostic mammogram were negative, lymph node biopsy revealed carcinoma consistent with a breast primary. She underwent mastectomy and axillary lymph node dissection and is currently undergoing chemotherapy. In terms of her antisynthetase syndrome, the myalgias and arthralgias have resolved, dyspnea has significantly improved, and CK has normalized. She is still followed closely by Rheumatology, as it is unclear if her symptoms will return after completion of chemotherapy.
DISCUSSION: Antisynthetase syndrome is an idiopathic inflammatory myopathy characterized by interstitial lung disease, myositis, arthritis, Raynaud's phenomenon and "mechanic's hands". It is associated with antibodies against aminoacyl-tRNA-synthetases, the most common of which is anti-Jo1 antibody (anti-histidyl-tRNA synthetase). Although dermatomyositis is known to be associated with underlying malignancy in up to a third of patients, there is thought to be a negative association between interstitial lung disease, particularly in the antisynthetase syndrome, and malignancy in patients with inflammatory myopathy. Newer studies and case reports, however, are showing that there is greater association between the antisynthetase syndrome and underlying malignancy than was previously thought. Thus, as this case demonstrates, it is important to evaluate for maligiancy in all patients diagnosed with inflammatory myopathy.

AORTOESOPHAGEAL FISTULA AS A RARE CAUSE OF CHEST PAIN Christopher Sankey. [1]Yale School of Medicine, New Haven, CT; [2]Yale-New Haven Hospital, New Haven, CT. (Tracking ID #1637197)

LEARNING OBJECTIVE 1: Understand aortoesophageal fistula (AEF) as a rare cause of chest pain and upper gastrointestinal hemorrhage.
LEARNING OBJECTIVE 2: Review clinical characteristics and etiologic factors in AEF.
CASE: A 47-year-old Hispanic male with active intravenous heroin abuse presented with 2–3 weeks of severe ("11"/10) chest discomfort. The pain was described as constant, though the severity waxed and waned, and located sub-sternally with intermittent radiation to the left arm. The patient's symptoms were exacerbated by movement, and there was no relationship to oral intake. His intravenous heroin use was intermittent, with last use reported 3 days prior to presentation. On admission, the patient was febrile to 101.7 °F, and physical examination was remarkable for point tenderness of the xiphoid process but otherwise without cardiac murmur or peripheral stigmata of infective endocarditis. Laboratory testing revealed normal chemistries, a mild leukocytosis of 16,000/μL, and negative troponin T. Electrocardiogram, chest radiograph, and echocardiogram were unremarkable. CT of the chest demonstrated diffuse esophageal thickening and extensive mediastinal soft tissue enhancement. The patient underwent an upper endoscopy, which revealed no luminal irregularities of the esophagus or stomach. Esophagram suggested a mild degree of inflammatory narrowing, but no extravasation of contrast. A diagnosis of mediastinitis was made, though etiology remained elusive. The remainder of the patient's medical course was complicated by two separate against medical advice discharges. Ultimately, the patient returned to the Emergency Department with abrupt-onset hematemesis, occurring the day prior and on the morning of re-admission. Hemoglobin dropped from 14 to 7 g/dl, and he was admitted to the intensive care unit. In the MICU, he manifest an acute upper gastrointestinal hemorrhage, hemodynamic instability, and died that afternoon. Autopsy revealed the presence of an aortoesophageal fistula.
DISCUSSION: Aortoesophageal fistula (AEF) is a rare entity, accounting for a small percentage of all upper gastrointestinal hemorrhages at autopsy. Aorto-enteric fistula is most often located in the third portion of the duodenum, but has been described in all segments of the gastrointestinal tract from esophagus to rectum. The AEF may permit high-pressure aortic blood to enter the esophagus (and yield an often fatal gastrointestinal hemorrhage) or less frequently for bacteria to enter the aorta and mediastinum (and yield aortitis or mediastinitis), both of which occurred in our patient. The massive hematemesis encountered with AEF can possibly be differentiated from esophageal variceal bleeding due to the "bright" arterial hue of an AEF-related hemorrhage in contrast with a darker venous variceal source. An additional clinical characteristic to distinguish AEF is Chiari's triad, present in approximately 65 % of cases. This classically includes an esophageal injury, a self-resolving or "sentinel" hemorrhage, and re-bleed with exsanguination hours to days later. Chest pain is present in approximately 60 % of cases. The majority (90 %) of AEFs can be attributed to thoracic aortic aneurysms, foreign body ingestions, or esophageal malignancies. The etiology of our patient's AEF remains a mystery, as there was no evidence for any causative etiology at autopsy.

APICAL HYPERTROPHIC CARDIOMYOPATHY, A BENIGN FORM OF HEART DISEASE? Hannah HallMaria G. Frank[2]. [1]University of Colorado Internal Medicine Residency, Denver, CO; [2]Denver Health and Hospital Authority, Denver, CO. (Tracking ID #1624629)

LEARNING OBJECTIVE 1: Recognize classic EKG findings of apical hypertrophic cardiomyopathy.
LEARNING OBJECTIVE 2: Recognize apical hypertrophic cardiomyopathy is not a benign form of heart disease.
CASE: Apical hypertrophic cardiomyopathy (AHCM) is a subtype of hypertrophic cardiomyopathy first described as a benign disease in Japan. The risk of sudden cardiac death in AHCM is thought to be lower than classic hypertrophic cardiomyopathy. However, recent cases in the literature report adverse outcomes in AHCM, especially in the non-Asian population. We present a patient with ventricular fibrillation (VF) arrest secondary to AHCM which raises the question of whether further intervention and monitoring is necessary. A 52 year old Hispanic male with history of epilepsy and untreated diabetes presented with VF arrest followed by return of spontaneous circulation. His exam was significant for a systolic murmur and amnesia post-event. There was no family history of sudden cardiac death. Initial EKG showed ST elevations without evidence of significant coronary artery disease on cardiac catheterization. Troponins peaked at 594. Subsequent EKGs revealed prominent T wave inversions in the anterolateral leads. Transthoracic echo (TTE) showed apical hypertrophy, akinesis, and thrombus. MRI revealed left ventricular AHCM with the "ace-of-spades" sign at end diastole, apical thrombus with edema and scar consistent with myocardial infarction due to subendocardial hypoperfusion. An automatic implantable cardioverter defibrillator was placed before discharge.
DISCUSSION: AHCM was first described in Japanese patients with left ventricular apical hypertrophy with wall thickness of 15 mm and above, giant negative T waves in the precordial leads and a spade-like configuration of the LV at end-diastole. The prevalence of AHCM is 15 % in Japan vs. 3 % in the US. One Canadian retrospective study of 105 patients with AHCM found 0.1 % annual mortality, with 30 % experiencing morbid events (12 % atrial fibrillation, 10 % myocardial infarction). They concluded AHCM has a benign prognosis and not a risk for cardiac death. However, there have been multiple reports of supraventricular tachycardia, sustained monomorphic ventricular tachycardia, VF and myocardial ischemia. A 3-year prospective South Korean observational study with 454 AHCM patients showed an all-cause mortality of 9 % with 5 % cardiovascular mortality. Our case illustrates the need for further research to address clinical predictors and guidelines for the management of AHCM, where adverse clinical events seem to be more prevalent than previously considered.

ARIPIPRAZOLE INDUCED RHABDOMYOLYSIS Eunice Y. Chuang; Indumathy Varadarajan; Arooj Hyat. Mount Auburn Hospital, Cambridge, MA. (Tracking ID #1642299)

LEARNING OBJECTIVE 1: - Recognize the clinical features of rhabdomylosis
LEARNING OBJECTIVE 2: - Identify aripiprazole as a potential cause for rhabdomyolsis
CASE: 30 year old former gymnast women presented with excruciating pain in her quadriceps for few hours. One day prior, she returned to the gym after more than 1 year of being physically inactive. She spent an hour doing lower extremity thrusts and felt sore afterwards. However, the pain progressed throughout the night and she noticed her urine was darker. Past medical history is significant for compartment syndrome 6 months prior related to history of surgeries in tibia, factitious disorder, self-mutilation and borderline personality disorder. Medications included fluoxetine, aripiprazole and guanfacine. She denied family history of rheumatological or muscle disease. Physical exam was unremarkable with stable vital signs. Laboratory data showed normal electrolytes, BUN and creatine. CPK was 34787 U/L. Urinalysis showed 3+ blood, 1+ albumin and some amorphous crystals. Toxicology screen was negative. Patient was admitted and given high-volume intravenous solution replacement daily. CPK trended up to 93815 U/L 2 days later but it was down to 8146 U/L 4 days later. Renal function was always stable. She was discharged home to see rheumatology as outpatient. Rheumatology recommended discontinuing the aripiprazole 20 mg daily as a possible cause of the rhabdomyolysis. Patient had been on aripiprazole for 4 years, however the day she returned to the gym before admission, was the first time she had worked out on aripiprazole. CPK checked 2 months later was 57 U/L.
DISCUSSION: Aripiprazole is a drug used commonly. It is a partial agonist at dopamine-2 (D2), dopamine-3 (D3), and serotonin-1A (5-HT1A) receptors, with antagonist activity at serotonin 2A (5-HT2A) receptors used for schizophrenia, bipolar disorder and depression. Common side effects include headache, anxiety, nausea, dizziness, insomnia and weight gain. All

atypical antipsychotics can cause rhabdomyolysis in the neuroleptic malignant syndrome. However, there are a few reports of isolated increases in CPK levels with atypical antipsychotics. RM is a rare side effect of Aripiprazole. Its proposed mechanism is the antagonist activity at 5-HT2A receptors in the skeletal muscle, which would compromise the uptake of glucose and lead to changes in the sarcolemma; ultimately increasing its permeability to creatine kinase. We report a case of rhabdomyolysis in a patient on aripiprazole associated with a modest amount of physical activity. The patient's rhabdomyolysis was finally resolved after discontinuation of aripiprazole. It is important to recognize the possibility of the individual susceptibility for rhabdomyolysis in every patient on this medication. RM is a potentially life-threatening complication that can lead to electrolyte imbalances and acute kidney injury. This adverse event should be evoked when a patient on aripiprazole presents with muscle pain, unexplained fatigue or weakness.

ASYMPTOMATIC PROSTATITIS, AN UNCOMMON MANIFESTATION OF BRUCELLOSIS Elizabeth Selden[1]; Lindsay Innes[1]; Seagram M. Villagomez[2,3]. [1]NYU Medical Center, New York, NY; [2]VA Harbor New York Healthcare System, New York, NY; [3]NYU, New York, NY. (Tracking ID #1642410)

LEARNING OBJECTIVE 1: Recognize an unusual clinical manifestation of Brucellosis

CASE: A 66 year old Hispanic man with no known medical history presented to the emergency room with 1 month of fever. He was well prior to this illness and denied cough, nausea, vomiting, diarrhea, abdominal pain, dysuria, or rash. Over the past month, he had daily drenching night sweats and developed new right hip and back pain. He moved to the United States from Ecuador in 1972 and last visited Ecuador 5 years ago. Most recent travel was to Florida 6 months ago. He worked in a seafood restaurant cooking and gardening and 3 months ago noticed several "mosquito bites" after pruning bushes. He had unprotected sex with 3 female partners in the past year and no prior HIV tests. He served in the US military in the Vietnam War where he was treated for gonorrhea twice. Friends in Ecuador had sent him soft cheese, which he ate 1 month ago. He was up to date with cancer screening: colonoscopy was unremarkable in 2008 and PSA was normal in 2011. Laboratory studies on admission showed mild elevation in transaminases and hyponatremia, which normalized with intravenous fluids. Complete blood count and differential were normal. CT scan of the chest, abdomen and pelvis were significant only for enlarged prostate. Prostate-specific antigen was elevated to 10. Urinalysis was unremarkable. Exam demonstrated an enlarged, boggy and non-tender prostate. The patient remained febrile. Admission blood cultures were initially interpreted as gram-positive bacilli and the patient was empirically treated with vancomycin. On day 3, blood culture results were changed to gram-negative coccobacilli. Further speciation revealed Brucella species, confirmed by the New York State Department of Health to be Brucella abortus. The patient had an unremarkable transesophageal echocardiogram. He was started on a six-week course of rifampin and doxycycline, defervesced and was discharged on hospital day 11.

DISCUSSION: Brucellosis is a serious public health problem in the Mediterranean, Western Asia, Latin America and Africa; however in the US, the CDC estimates that there fewer than 200 cases reported yearly (1). Since implementation of domestic livestock eradication programs, risk factors for Brucella infection include hunting and butchering, consumption of unpasteurized dairy products from endemic areas, and laboratory work (1). Given that only 25–35 % of cases present with focal organ system involvement and presenting symptoms are often non-specific, it is thought to be greatly underreported (2). Concerns about future use as a biological weapon due to the ease of transmission via aerosolization make familiarity with Brucellosis paramount (1; 3). Almost any organ system can be involved although most common is musculoskeletal. The genitourinary system is second most-affected, more often in the form of epididymoorchitis—Brucella prostatitis is rare (3). In this case the key historical element, consumption of unpasteurized cheese, was elicited on admission. However diagnosis lagged by several days, hinging on blood culture results, highlighting the difficulty in making an uncommon diagnosis when the presentation is atypical. References: 1. Summary of notifiable diseases: United States, 2009. MMWR weekly report 2011 May;58(53):1–100. 2. Wise RI. Brucellosis in the United States. Past, present, and future. ATHLETE'S HEART Mohammed Bahaa Aldeen; Rahul Chandra. Texas Tech Univ Health Sciences Center, Amarillo, TX. (Tracking ID #1631234)

LEARNING OBJECTIVE 1: Recognize athletic training as an important physiologic cause of cardiac repolarization abnormalities manifest as ST and T wave changes seen on a 12 lead EKG.

LEARNING OBJECTIVE 2: Distinguish above physiologic changes from other serious pathology like hypertrophic obstructive cardiomyopathy in the differential diagnosis.

CASE: A 27-year-old healthy young man was sent for evaluation of his unusual EKG. Patient had complaint of mid-sternal, sharp, burning chest pain. There was also associated sour taste in the mouth. Episode had lasted only 20 min, promptly responded to antacids, and did not reoccur. Past medical history was esophageal reflux only. Patient did not smoke or take any medications. No history of street drug abuse. No family history of cardiomyopathy or sudden cardiac death. He exercised regularly. Activities included lifting 300 lb of weights and also running. There was no chest discomfort with exercise. No history of exertional syncope. No history of thromboembolic events or leg swelling. No fever or flu like illness. On examination BP was 130/80, pulse 60/min, afebrile, normal oxygen saturation. He was very well built and muscular. BP was equal in both arms. No jugular venous distention. His cardiac exam was normal, no murmurs or rubs. Respiratory exam was normal. No leg swelling. Remaining exam was normal. Patient's EKG had significant deep asymmetric T wave inversions in the V4-V 6, I, aVL, II, III and aVF leads. T waves in lead V3 were biphasic. He also had 1 mm ST depression in V 5- V6, II, III and aV. There were no PR depressions and changes were not consistent with pericarditis. QT interval was normal. Repeat EKG showed these changes persisted, though he remained pain free. Cardiac troponins were negative. Other labs hemoglobin, toxicology, electrolytes, renal function were normal. White count and ESR were normal. Chest X ray was normal. Though chest pain description was non-cardiac (reflux related); he underwent investigations to explain his bizarre and unexplained EKG. Echocardiography showed normal LV systolic and diastolic function, LVEF 65 %, normal chamber size, normal valves, and normal wall motion. No features of hypertrophic obstructive cardiomyopathy seen. However, left ventricular posterior wall was thick (15 mm). Nuclear stress test showed no reversible ischemia. Telemetry negative for arrhythmia. Patients EKG changes were diagnosed to be a physiologic finding due to his intense athletic training.

DISCUSSION: The Athlete's heart develops physiologic adaptation to meet increased cardiac output demand by increases in LV End diastolic diameter and increase in left ventricular wall thickness (up to 16 mm). EKG in athletes can manifest sinus bradycardia, isolated voltage criteria for LVH, early repolarization, ST elevation, ST depression and T wave changes. Diagnostic dilemma occurs in distinguishing these physiologic EKG findings from those in true cardiac pathology like hypertrophic obstructive cardiomyopathy (HOCM). Echocardiogram and occasionally cardiac MRI may be needed to help distinguish these. It's important to consider the type and intensity of physical training, race, body habitus, and the time the EKG was obtained in relation to training; in order to better understand the 'normal' spectrum of EKG changes in athletes. Career implications arise here. Not recognizing physiology would unnecessarily end a promising athletic career. Not recognizing HOCM would put the person at risk of sudden death.

ATYPICAL PRESENTATION OF ATYPICAL CHEST PAIN Rupel Dedhia; Elizabeth L. Bolen. Rush University Medical Center, Chicago, IL. (Tracking ID #1619827)

LEARNING OBJECTIVE 1: Recognize sternoclavicular joint septic arthritis as an unusual cause of atypical chest pain.
LEARNING OBJECTIVE 2: Diagnose and manage sternoclavicular joint septic arthritis.
CASE: A 54-year-old man with a history of Hepatitis C, heroin abuse, and hypertension presented with a 1 day history of sharp, non-exertional, non-radiating right sided chest pain with associated dyspnea. Symptoms lasted 15–20 min at rest. Patient also reported neck and right shoulder pain. The initial evaluating physician documented a normal physical examination. The patient was ruled out for acute coronary syndrome by ekg and laboratory markers and radiographic evaluation including a doubutamine stress echo and CT chest PE protocol was normal. The patient was discharged home with a diagnosis of atypical chest pain. He returned 6 days later with worsening chest and shoulder pain. Upon examination, he was febrile at 100.9 and was noted to have erythema and warmth of the right sternoclavicular joint with decreased range of motion in the right shoulder. Labs revealed a WBC count of 18.9 and urine toxicology was positive for opiates. Plain radiographs of the right shoulder were normal. Initial peripheral blood cultures grew gram-positive cocci in clusters so broad spectrum antibiotics including Vancomycin and Zosyn were administered. The patient remained febrile with a Tmax of 101.7. A CT chest was repeated and revealed a mixed solid and cystic soft tissue process extending from the level of the thyroid cartilage down to the anterior portion of the superior mediastinum. The patient went to the operation room where debridement of the sternoclavicular joint revealed a yellow, purulent discharge (culture grew MSSA). Final speciation and sensitivities of the peripheral blood cultures also revealed MSSA. The head of the clavicle was debrided and partially excised. Pathology revealed inflammation and necrotic tissue. Patient's antibiotics were switched to IV cefazolin to complete 6 weeks of therapy. The patient continues to do well and has closely followed up in our clinic.
DISCUSSION: Sternoclavicular (SC) joint septic arthritis is a rare (comprising <1 % of all joint infections) cause of atypical chest pain that is often life threatening if not diagnosed correctly. Plain radiographs are frequently normal; therefore identification of risk factors along with a thorough physical examination can assist providers in early diagnosis to prevent serious complications such as abscess formation, osteomyelitis, mediastinitis, and empyema. Risk factors include IVDU, peripheral infections, diabetes mellitus, trauma and infected central venous access. Recognizing common presenting symptoms of SC joint septic arthritis can be challenging. Symptoms can be vague from chest pain (reported in 78 % of cases) to shoulder and neck pain. Treatment involves early surgical debridement and long-term IV antibiotics. Treatment duration depends on the identified organism and the extent of the infection. The most commonly isolated pathogen in intravenous drug users is Staphylococcus aureus, followed by Pseudomonas aeruginosa. Identifying unusual causes of atypical chest pain such as SC joint septic arthritis necessitates a high level of clinical suspicion by identifying risk factors (intravenous drug use in our patient) and performing a thorough physical examination.

AUSTRIAN SYNDROME: A RARE TRIAD Justin L. Guthier; Rita Pechulis. Lehigh Valley Health Network, Allentown, PA. (Tracking ID #1628699)

LEARNING OBJECTIVE 1: Increase awareness of a deadly clinical syndrome, rare now in a culture of pervasive antibiotic therapy
LEARNING OBJECTIVE 2: Recognize the association of pneumonia, endocarditis and meningitis seen with invasive pneumocccal bacteremia
CASE: A 64 year old male, with no medical history, presented in respiratory distress to the emergency department. The patient had not seen a doctor in 20 years and had been ill for 3 weeks with cough, fever and lethargy. The patient's wife admitted the patient had a significant history of alcohol and tobacco use. On the day of admission, the patient was found lying on the floor nonverbal and disoriented. A chest x-ray found a right upper lobe infiltrate and an EKG revealed Afib with RVR. Early differential diagnosis included meningitis/encephalitis vs. CVA vs. sepsis. A lumbar puncture revealed hazy CSF, glucose <1, WBC 174 and neutrophils 86. The patient was admitted to the intensive care unit for management of VDRF, meningitis, pneumonia and rate control of Afib. The patient was initiated on broad spectrum antibiotics and dexamethasone. Microbiology results returned positive for pneumococcal urinary antigen, as well as blood cultures positive for s. pneumonia. Given the presence of disseminated bacteremia, the patient underwent TEE which revealed a mitral valve vegetation of 0.4 cm and a 0.3 cm aortic valve vegetative strand. Since there was no evidence of aortic insufficiency and only mild mitral regurgitation, valve replacement was deferred and the patient was managed medically. Numerous MRI's were performed which revealed development of and subsequent worsening subdural empyemas. The patient deteriorated over the course of his ICU stay. Eleven days after admission, the patient suffered a cardiac arrest but was successfully resuscitated. With no clinical improvement and continued deterioration, discussions with family ultimately yielded a decision for comfort care.
DISCUSSION: Invasive pneumococcal illness is a rare clinical occurrence, with only 54 cases having been reported. In 1881, Osler wrote, "Meningitis is a very rare complication of pneumonia and may occur apart from endocarditis…". Today, with common use of antibiotics, invasive pneumococcal disease is rare, yet still carries a high mortality. The triad, now termed Austrian syndrome, was described in a 1956 paper by Robert Austrian. Patients typically are chronically ill males in their 5th–6th decade and have a history of alcoholism. Other risk factors include splenectomy, dural fistulas and immunosuppression. Endocarditis is typically left sided and predominantly involves the aortic valve. However, there are subtle presentations which involve the mitral valve. Our case is unique in that both the aortic and mitral valves exhibited vegetations. Given increasing rates of penicillin resistance, effective treatment necessitates analyzing antibiotic sensitivities. In patients with indications for valve replacement, urgent surgery has been associated with more favorable outcomes rather than conservative management. Dexamethasone has been shown to improve outcomes in patients with pneumococcal meningitis and in patients with Austrian syndrome. Despite medical and surgical advancements since Osler first described the triad in 1881, invasive pneumococcal infection still carries a high mortality. Prompt diagnosis and aggressive treatment are tantamount to surviving this severe infection.

BACK PAIN AND BLINDNESS: UNUSUAL COMPLICATION OF ULCERATIVE COLITIS Artur Viana; Jacob Feldman. Boston Medical Center, Boston, MA. (Tracking ID #1642357)

LEARNING OBJECTIVE 1: Recognize arterial thromboembolism as a complication of active inflammatory bowel disease
CASE: A 31 year old black male recently discharged for ulcerative colitis (UC) exacerbation returns to the hospital with worsening bloody diarrhea, back pain, and fevers up to 102 F. Examination revealed a febrile, tachycardic, well developed man in mild distress, mild left lower quadrant pain and no CVA tenderness. Laboratory findings were significant for WBC 12.7 K/μL (70 % PMNs), Hgb 9.0 g/dL, Platelets 555 K/μL, and Cr 0.7 mg/dL, negative Clostridium difficile toxin assay and a UA showing 1+ protein, trace leukocyte esterase, 11–30 WBCs and 1+ bacteria. After urine and blood cultures were obtained, the patient was started on IV cefepime, vancomycin and metronidazole, given concerns for sepsis of unclear source. Intravenous hydrocortisone was initiated for UC flair and home oral and rectal mesalamine were continued. On hospital day 4, the patient had an episode of transient right monocular vision loss that resolved within 1 min. Ophthalmologic evaluation was unremarkable

and MRI/MRA brain showed no acute intracranial abnormalities. Multiple blood and urine cultures were negative and despite broad-spectrum antibiotics, the patient continued to have daily fevers. CT abdomen showed several new wedge-shaped hypoattenuating regions in both kidneys, which could represent either renal infarcts or pyelonephritis. A TTE, as well as a TEE did not show any evidence of cardiac, aortic root or ascending aorta thrombus. Hypercoagulable work up was significant for increased factor VIII activity, at 178 % (normal 50–150 %), normal AT3, protein C and S, homocysteine, cardiolipin antibody and lupus anticoagulant. Anticoagulation was deferred given the patient's significant hematochezia with anemia and he was started on aspirin alone. Antibiotics were discontinued and the patient remained afebrile for the remainder of his hospital stay. His bowel movements decreased in frequency and returned to normal. He was discharged on oral prednisone, oral and rectal mesalamine as well as a daily aspirin.

DISCUSSION: This is a case of bilateral renal infarcts and transient monocular vision loss related to a severe ulcerative colitis flair. Inflammatory bowel disease (IBD)-associated arterial thromboembolism (TE) is uncommon but may result in significant morbidity and mortality. Arterial TE involving cerebral, retinal, coronary, carotid, splanchnic, iliac, renal, upper and lower limbs arteries and aorta have been described and seem to parallel disease activity, although the mechanism is unknown. The differential diagnosis for this patient's renal lesions included pyelonephritis. However, given negative urine cultures in the absence of urinary symptoms, as well as bilateral nature of radiographic findings, in conjunction with the patient's recent amaurosis fugax strongly support the diagnosis of a renal arterial thromboembolic event. This is corroborated by continued clinical improvement after antibiotics were stopped. Optimal treatment of arterial TE in IBD patients remains ill-defined, but should be directed to the clinical scenario and very frequently involves anticoagulation, which is often limited by bleeding. In this case, due to severe anemia requiring transfusion, anticoagulation was deferred and the patient was treated with aspirin alone.

BACK TO SCHOOL: A CASE OF INFECTIOUS DIARRHEA Kristen Marrone; Dinah Foer. Yale New Haven Hospital, New Haven, CT. (Tracking ID #1642574)

LEARNING OBJECTIVE 1: 1. Discuss clinical signs and symptoms of acute giardial infection

LEARNING OBJECTIVE 2: 2. Review of the diagnostic options for infectious diarrhea

CASE: A 42-year-old female elementary school teacher with past medical history of irritable bowel syndrome and obsessive-compulsive disorder was admitted to a general medical service with 11 days of abdominal cramping and watery, non-bloody diarrhea. She had presented to her primary physician at symptom onset, where initial workup was negative and she was empirically started on a proton pump inhibitor. She subsequently came to the Emergency Department due to continued symptoms 1 week later. On admission, her physical exam revealed normal vital signs including orthostatics, hyperactive bowel sounds, diffuse tenderness to palpation in her abdomen, and a hemoccult negative rectal exam. She denied any nausea, vomiting, bloody or dark stool, changes in diet, recent antibiotic use, recent travel, outdoor activities, or sick contacts. Her admission laboratory data was within normal limits except for a mild transaminitis with aspartate aminotransferase (AST) of 57 U/L and alanine aminotransferase (ALT) of 70 U/L, hypomagnesemia with magnesium 1.6 mg/dL, and hypophosphatemia to 1.9 mg/dL. Stool studies were significant for positive fecal leukocytes and positive giardia antigen. Her stool ova and parasites exam revealed moderate giardia lamblia trophozoites. She was aggressively rehydrated and started on metronidazole with dramatic improvement in her symptoms prior to discharge.

DISCUSSION: This case is of interest to General Internists because diarrhea is a common symptom prompting patients to seek medical care, and giardia is a unique etiology that requires specific diagnostic tests and treatment. Acute giardiasis presents with 1 to 8 weeks of watery diarrhea, steatorrhea, malaise, abdominal discomfort and flatulence; 50 % of symptomatic patients have significant weight loss. Vomiting, fever, blood- or mucus-tinged feces are rare. It should be included in the differential diagnosis of patients with diarrhea with exposure to daycare centers, the wilderness, known recent travel, is immunosuppressed, or lives in an area with known recent outbreak. In the evaluation of suspected severe infectious diarrhea, initial testing includes fecal leukocytes or lactoferrin, fecal occult blood test, and routine stool culture. Stool testing for ova and parasites should also be part of the evaluation in patients with those exposures listed above, and clostridium difficile stool antigen for those with recent antibiotic exposure. Recently developed stool antigen immunoassays for giardia may also be used. Acute giardiasis should be treated with aggressive rehydration therapy with diet alterations to correct fluid and electrolyte abnormalities. All symptomatic patients with giardiasis should be treated with an antibiotic of the nitroimidazole class or nitazoxanide.

BARTONELLA ENDOCARDITIS PRESENTING WITH GASTRO-INTESTINAL SYMPTOMS Prabhat Singh[1]; Hammad Arshad[1]; Ross DiMarco[2]; Mohamed H. Yassin[3]. [1]UPMC mercy, Pittsburgh, PA; [2]UPMC mercy, Pittsburgh, PA; [3]UPMC mercy, Pittsburgh, PA. (Tracking ID #1617867)

LEARNING OBJECTIVE 1: Recognize Bartonella as one of the cause of culture negative endocarditis.

LEARNING OBJECTIVE 2: Bartonella serology should be sent early in cases of culture negative endocarditis. Although serology is usually not diagnostic but it is the main screening test to suspect Bartonella endocarditis.

CASE: We present a case of 28-year-old female who came with fever, abdominal pain and diarrhea. Her symptoms were progressively worsening and included generalized fatigue, fever and exertional dyspnea. The patient was taking ibuprofen multiple times daily for 2 months to control her symptoms. She was previously healthy except for history of mitral valve prolapse and denied history of intravenous drug abuse. She worked as a schoolteacher, and she got a healthy cat just before getting sick. On presentation, she was worked up for possible cholecystitis. Her work up was negative for gastro-intestinal source. Echocardiogram revealed moderate to severe mitral valve regurgitation and 1.5×0.9 cm vegetation in the posterior leaflet of mitral valve. The patient was transferred to our facility for valve surgery. Her Bartonella serology was positive with IgG titer of 1: 1024. Subsequently, she underwent mitral valvuloplasty along with excision of vegetation, reconstruction of posterior leaflet and annulus. The vegetation was sent for molecular testing with polymerase chain reaction (PCR) and DNA sequencing which came back positive for Bartonella henselae. All Blood cultures including bartonella cultures remained negative.

DISCUSSION: Bartonella is a major cause for culture-negative endocarditis. The diagnosis of Bartonella endocarditis is made based on serological or molecular testing as it is difficult to grow on routine laboratory culture. Bartonella is a fastidious, facultative intracellular, Gram-negative bacillus. It causes multiple clinical syndromes including cat-scratch disease, bacteremia, chronic lymphadenopathy, myelitis, endocarditis, osteomyelitis and bacillary angiomatosis. Bartonella henselae and B. quintana are two major species causing most of illnesses in human. B. Quintana is common in homeless and alcoholic whereas B. Henselae is common in patients with underlying valvular disease and transmitted by cat bite, scratch and cat fleas. Kittens are more likely to be infected and to pass the bacterium to people. Culture negative endocarditis remains a diagnostic dilemma accounting for 5 % to 30 % of the cases. Serological detection is a good screening test for the diagnosis of bartonella endocarditis. As per previous studies serum with an IgG antibody titer≥1:800 predicts bartonella endocarditis in 95.5 % of the cases. Molecular diagnosis with PCR is a very useful technique for demonstrating Bartonella DNA in cardiac valvular tissue, especially when fresh valvular tissue is used. As per modified Duke's criteria, this case demonstrated 1 major (endocarditis) and 2–3 minor clinical criteria of infective endocarditis i.e. fever and positive serology/PCR. However it presented with gastro-intestinal symptoms that are uncommonly reported in literature. Thus endocarditis should be considered a part of disease spectrum caused by bartonella and more cases will emerge with the progress in medical diagnostics. Patients with pre-existing valvular disease should be educated about the risk of transmission of these organisms with cat exposure and cat fleas.

BEWARE OF DOXIES: TARGETING THE DRUG REACTION WITH EOSINOPHILIA AND SYSTEMIC SYMPTOMS (DRESS) SYNDROME Jay Liu[1]; Julie Simpson[5]; Mona Rizeq[4,6]; Robert Burke[2,3]. [1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Department of Veterans Affairs Medical Center; Eastern Colorado Healthcare System, Denver, CO; [3]University of Colorado School of Medicine, Aurora, CO; [4]Department of Veterans Affairs Medical Center; Eastern Colorado Healthcare System, Denver, CO; [5]University of Colorado School of Medicine, Aurora, CO; [6]University of Colorado School of Medicine, Denver, CO. (Tracking ID #1638171)

LEARNING OBJECTIVE 1: Recognize and appropriately manage the DRESS syndrome
LEARNING OBJECTIVE 2: Risk-stratify patients with drug reactions
CASE: A 64 year-old man presented 5 days after developing a pruritic rash on his hands, which rapidly spread to involve his entire body despite a 4 day course of topical and oral steroids. He also noted shortness of breath, lower extremity edema, and 2 days of fever. He had returned from sub-Saharan Africa approximately 4 weeks prior and was taking doxycycline for malarial prophylaxis; other medications included hydrochlorothiazide and lisinopril for hypertension, and meloxicam for osteoarthritis. On physical exam, he had a violaceous, non-blanching targetoid rash on his limbs and trunk. A single buccal ulcer was noted; his oropharynx was otherwise normal.. There was non-painful cervical lymphadenopathy but no other lymph node involvement. No obvious ulcers were noted on examination of his ocular membranes but golden-colored crusting of his eyelids was present. His penile exam was negative for ulcers and examination of his joints was unremarkable. No hepatosplenomegaly was noted on physical exam. Eosinophilia (peaking at 5,000 cells/ul) with leukocytosis (without atypical lymphocytes), mild transaminitis, and acute kidney injury were found on laboratory testing. Testing for the presence of tick-born, parasitic, bacterial, treponemal, and viral infection was negative; imaging did not suggest malignancy. A skin biopsy 1 week after presentation demonstrated changes consistent with a drug reaction. His RegiSCAR score was calculated at 6 (definite case of the DRESS syndrome). With discontinuation of his doxycycline and treatment with high-dose corticosteroids, the patient's symptoms resolved and did not return.
DISCUSSION: Drug reactions are a common challenge in the general physician's practice. A systematic approach is needed to assess the severity of the illness; awareness of less common manifestations is critical to appropriate triage. The presence of a targetoid rash and involvement of mucosa triggered concern for potential Stevens Johnson Syndrome (SJS) spectrum disease and led to hospitalization in the ICU. However, in this case, the lack of epidermal sloughing, high fever, and evidence of organ involvement did not suggest this diagnosis, but rather erythema multiforme (EM), an uncommon initial presentation of the DRESS syndrome. Other diagnostically confounding infectious, inflammatory, and malignant conditions were ruled out before a diagnosis of DRESS syndrome was made. The DRESS syndrome is a clinical diagnosis supported by tissue pathology. The use of the RegiSCAR score helps categorize the likelihood of DRESS and allows development of a growing body of literature on this rare condition. Many medications have been associated with DRESS, but doxycycline is a rare cause, with only 4 cases reported. Supportive treatment with recognition of the DRESS syndrome may make the difference between a positive outcome and multi-organ failure. As our medical pharmacopeia grows, the general internist will increasingly be depended upon for early detection and coordination of care in these complex drug reactions.

BEYOND THE DARKNESS … AN ENLIGHTENING OVERVIEW OF OPTIC NEURITIS WITH NORMAL IMAGING. Javeria Haque; Harvey Friedman. Saint Francis Hospital, Evasnton, IL. (Tracking ID #1642403)

LEARNING OBJECTIVE 1: To identify the diagnostic dilemma of optic neuritis.
LEARNING OBJECTIVE 2: To learn about the risk of developing multiple sclerosis in a patient with optic neuritis but normal brain imaging.
CASE: 34 year old female presented with blurring of vision for the past 2 weeks. The patient had trouble seeing from her left eye, as if there was a black hole in the center of her vision. She had mild dull pain behind her left eye as well. She denied headaches, fevers or chills. She experienced no weakness in her body and did not have any sensory deficits. She did not have bowel or bladder dysfunction. The patient has no past medical history and family history was significant for an aunt having multiple sclerosis. On exam, the patient had normal vitals. Her neurological exam was essentially normal except for left eye central and temporal upper quadrant visual impairment. She had afferent pupillary delay in the left eye. Ophthalmoscopy revealed a normal appearing fundus and optic disc. All pertinent labs were normal except for positive ANA and AntiRNP antibodies. An MRI of the brain and orbits with contrast showed no evidence of demyelinating disease or optic nerve signal alteration. Cerebrospinal fluid analysis (CSF) revealed normal cell counts, protein and glucose. She had an elevated IgG index 0.87 (normal<0.66) and more than 5 well defined gamma restriction oligoclonal bands that were absent in the corresponding serum. She received 3 doses of intravenous Solumedrol. The patient endorsed to improvement in her symptoms gradually.
DISCUSSION: Optic neuritis is a demyelinating, inflammatory condition of the optic nerve usually resulting in monocular visual loss. About 92 % patients experienced retro-orbital pain in the optic neuritis treatment trial (ONTT). Optic neuritis is widely associated with multiple sclerosis (MS), with up to 50 % of patients with MS experiencing it at some point in their illness. Optic neuritis was the initial presentation of MS in about 15–20 % patients. The diagnosis of optic neuritis with or without MS is made with magnetic resonance imaging (MRI), CSF analysis (presence of myelin basic protein, IgG index and oligoclonal bands), Visual evoked responses and optical coherence tomography. MRI of the brain and orbits with gadolinium helps prognosticate the risk of developing MS. Optic nerve inflammation can be demonstrated in up to 95 % of patients on contrast MRI in acute demyelinating optic neuritis. The longitudinal extent of nerve involvement as seen on MRI correlates with visual impairment at presentation and with visual prognosis. In the ONTT, the risk of MS after 15 years was 72 % among those with one or more lesions on MRI versus 25 % among those with no lesions. The risk did not significantly differ between single versus multiple lesions. The risk of developing MS is even lower with normal brain MRI along with atypical features of optic neuritis such as no pain, no light perception vision at presentation, severe disc swelling or retinal exudates.

BEYOND "COMPLICATED" UTI: EMPHYSEMATOUS PYELONEPHRITIS SECONDARY TO PERFORATED DIVERTICULITIS WITH COLOCOLONIC FISTULA Melissa Y. Wei; Lesley Miller. Emory University, Atlanta, GA. (Tracking ID #1638868)

LEARNING OBJECTIVE 1: Recognize and manage emphysematous pyelonephritis
LEARNING OBJECTIVE 2: Learn how the "poppy seed test" can be used to identify the source of an intra-abdominal abscess
CASE: A 58 yo obese female smoker with chronic UTIs and urolithiasis s/p recent bilateral ureteral stent removal presents with 1 week of fatigue, nausea and sharp lower abdominal pain, 8/10 severity, worse with urination, and associated with dysuria, malodorous urine and hematuria but no fevers, chills, sweats, emesis or flank pain. She took Bactrim for symptom-triggered UTIs for 3 months. On admission she is afebrile with heart rate 85 and blood pressure 102/65. Her lower abdomen is mildly tender but soft and nondistended. There is no costovertebral angle tenderness. Labs reveal leukocytosis of 18.7×10^9/L (66 % neutrophils), microcytic anemia with hemoglobin 9.1 mg/dL and MCV 78, thrombocytosis of 843×10^9/L, creatinine 1.9 mg/dL (baseline 1.2 mg/dL) and HgbA1c 7.1. Urinalysis has 3+ protein, 3+ hemoglobin, >50 WBC, >50 RBC and bacteria. CT reveals a severe gas-forming infection of the left kidney tracking into the left retroperitoneum and left psoas, bilateral hydronephrosis, bilateral large calculi, extensive bladder wall thickening and a pelvic mass vs. fluid collection. Zosyn and levofloxacin are initiated for Klebsiella pneumonia on urine culture. Progression of the left psoas abscess, pelvic fluid collection and right hydronephrosis necessitates bilateral percutaneous nephrostomy placement. A positive poppy seed test

reveals perforated diverticulitis with colocolonic fistula as the abscess source. Meanwhile, fine needle aspiration of the pelvic mass reveals poorly differentiated carcinoma with unknown primary. She undergoes pelvic mass resection, left hemicolectomy, ileostomy, total abdominal hysterectomy and bilateral salpingo-oophorectomy. Operative findings include a large retroperitoneal abscess communicating with the colon. Gynecologic pathology is negative but cystoscopy reveals high grade urolitheal tumor. Postoperatively she develops right arm pain from a pathologic humerus fracture. PET shows extensive bone metastasis. She is not a candidate for palliative radiation or chemotherapy and discharges to hospice.

DISCUSSION: Emphysematous pyelonephritis (EPN) is a rare, acute, life-threatening necrotizing infection characterized by gas formation in the renal parenchyma, collecting system or perinephric tissue. EPN primarily affects middle-aged female diabetics whose excess glucose kindles a favorable environment for gas-forming microbes. Patients may present with vague symptoms that delay diagnosis, but rapid deterioration frequently follows. Diagnosis and classification are achieved through X-ray or CT. Radiographic staging directs definitive treatment with percutaneous drainage or possibly nephrectomy in the presence of diffuse gas with renal destruction (Pontin 2009). Patients should receive resuscitation and gram-negative rod coverage. The course can be severe and fatal if not treated promptly. One must distinguish EPN from emphysematous pyelitis, or gas in the collecting system only, which has an excellent prognosis and recovery with antibiotics alone. While CT promptly diagnosed EPN it did not reveal whether the psoas abscess was the consequence or etiology of EPN. Rather a highly sensitive and specific poppy seed test (Kwon 2007) involving oral ingestion of poppy seeds followed by visualization of the seeds in the psoas abscess drain revealed perforated diverticulitis as the source of EPN.

BILATERAL BELLS PALSY IN ACUTE LYMPHOBLASTIC LEUKEMIA Rigoberto Ramirez[1]; Daniel Cheeran[1]; Philippe Prouet[2]; Ronni M. Miller[3]; Ivan Carabenciov[4]; Eileen Marley[3]; Harris Naina[5]. [1]University of Texas Southwestern Medical Center, Dallas, TX; [2]LSU Health Shreveport, Shreveport, LA; [3]Parkland Health and Hospital Systems, Dallas, TX; [4]University of Texas Soutwenstern Medical Center, Dallas, TX; [5]University of Texas Southwestern Medical Center, Dallas, TX. (Tracking ID #1644258)

LEARNING OBJECTIVE 1: Recognize that bilateral Bells palsy in acute lymphoblastic leukemia can be sign of central nervous system involvement.
LEARNING OBJECTIVE 2: Management of bilateral Bells palsy in acute lymphoblastic leukemia

CASE: A 41 year old Hispanic man with history of Type 2 diabetes mellitus was admitted to outside hospital after presenting with profound weakness, weight loss, and syncope. A complete blood count showed hemoglobin of 3.6 gm/dL, WBC 224 X 109/L, platelet count 54×109/L. His peripheral blood smear showed 72 % immature blasts. A bone marrow biopsy confirmed the diagnosis of Acute pre-B-cell Lymphoblastic Leukemia (ALL). He was started on combination chemotherapy Hyper CVAD. He was discharged from the hospital following chemotherapy and advised to follow up in local county hospital due insurance issue. Unfortunately, patient was lost to follow-up. Almost 2 months later patient reported experiencing new onset posterior occipital headache, teeth numbness, and right lower facial tingling. He subsequently developed right-sided facial droop and returned to outside hospital for evaluation where he was again noted to have a very high white count and treated with hydroxyurea and fluids. Work up for stroke and meningitis were negative. Ten days later patient presents to our institution now with progression of his numbness, tingling, and bilateral facial weakness. General exam was remarkable for thinly built man with bilateral temporal wasting, and alopecia. A CNS examination revealed bilateral facial droop, inability to raise eyebrows, or perform facial expressions. Sclera remained visible when patient shut eyes. Facial sensation remained intact. Notable hyporeflexia on musculoskeletal exam with 1+ reflexes in upper and lower extremities. On admission his WBC was 5.4 with 65 % blasts. An MRI of brain was unremarkable. A CSF analysis showed lymphoid blasts. Further studies confirmed the relapse of his initial ALL. He received part 1B of hyper CVAD which consist of both cytarabine and methotrexate, with good CNS penetration. In addition he received twice a week intra thecal chemotherapy with methotrexate. Though his CSF blasts cleared after 3 doses, his symptoms did not improve at all. After 4 weeks of this treatment there no symptomatic improvement, hence we proceeded with 24 cGy of whole brain radiation (WBRT). Unfortunately there was neither clinical nor symptomatic improvement after chemo and WBRT.

DISCUSSION: Central nervous system (CNS) involvement is identified at the time of diagnosis in less than 10 % of adult (ALL). Peripheral type facial nerve paralysis (Bell's palsy) is mainly seen clinically as the idiopathic type. Patients who develop CNS leukemia only 20 % develop cranial nerve palsies. Very rarely Bell's palsy could be the initial presentation of ALL. Majority of these patients will have a complete response following either radiation or chemotherapy or combination treatment. Occasionally these damages can be permanent. Unfortunately our patient did not respond to either chemotherapy or radiation. It is possible that a delay in treating his leukemia could have contributed to permanent damage. It is important to keep ALL as a differential diagnosis for either unilateral or bilateral Bell's palsy

BLIND FROM A GI BLEED-A UNIQUE CARE OF BILATERAL OPTIC NEUROPATHY Dmitriy Dvoskin; Pratik K. Dalal; Tanya George. SUNY Upstate Medical Center, Syracuse, NY. (Tracking ID #1642034)

LEARNING OBJECTIVE 1: Recognize serious complication of GI Bleeding.
LEARNING OBJECTIVE 2: Rapid diagnosis and intervention is the key to saving vision.

CASE: Optic neuropathy is defined as visual loss associated with optic disc swelling of pallid nature. In adults over 50 years of age, ischemia is the most common cause of optic neuropathy. Specific causes associated with atherosclerosis, hypertension, surgical complications have been noted in the literature. However loss of vision from bilateral optic neuropathy secondary to a GI bleed is an exceedingly rare but important complication. Fifty-six year old male presented with the chief complaint of bilateral vision loss for 2 days. His vision was limited to light sources, sharp movements, and silhouettes of people. Concomitantly he was experiencing weakness and worsening dyspnea on exertion. The patients past history was significant for chronic back pain for which he takes 10, 325 mg aspirin daily. Patient admits to having a mild occipital headache associated with the sudden vision change. He also had "black and thin" diarrhea for the past 2 days and two episodes of coffee ground emesis 2 days. Physical examination revealed stable vital signs. Ophthalmologic exam showed PERRL, poor visual fields, unable to identify objects at a distance of 6 inches. Rectal examination was positive for occult blood. Complete blood count revealed hematocrit of 14.6, hemoglobin of 4.7, and normal white blood cell and platelet count. CT head was negative. Bidirectional endoscopy was significant for mild striped erythema in antrum. Colonoscopy showed diverticulosis in the sigmoid colon. Ophthalmology was consulted secondary to suspicion for Giant Cell Arteritis and performed an intravenous fluorescein angiography (IVFA) which was normal, and; concluding that the diagnosis is consistent with posterior ischemic optic neuropathy secondary to acute on chronic anemia secondary to a small intestine GI bleed secondary to NSAID usage

DISCUSSION: Posterior ischemic optic neuropathy (PION) is a diagnosis of exclusion thought to result from infarction of the retro-bulbar optic nerve. Our literature review shows that PION is a rare occurrence and mostly associated with surgical complications and dialysis, but rarely reported secondary to gastrointestinal bleeding. Few studies to date have evaluated the etiology of PION. The study by Sadda et al. showed, retrospectively, that 39 % of patients are secondary to surgical procedures, 8 % secondary to Giant Cell Arteritis (GCA), and 44 % secondary to non-arteritic systemic disease. Study further supported that patients with Non-arteritic disease was more amenable to recovery. The primary differential diagnosis is Anterior Ischemic Optic Neuropathy (AION), which is more commonly seen. In order to distinguish between these two diagnoses one must perform a dilated ophthalmologic examination. AION presents with a normal appearing optic nerve head. Treatment in the case of acute gastrointestinal bleed is the replacement of volume and providing optimal oxygenation to tissue. Strong suspicion of GCA is always imperative and steroids should be given

immediately followed by temporal artery biopsy. Patients with non-arteritic PION experience about a one third improvement in their visual deficit with time but arteritic PION has shown to rarely improve. In the case of our patient, immediate fluid resuscitation and blood product resuscitation resulted in mono-ocular vision improvement by approximately 50 %.

BRAIN ABSCESS: WHEN COMMON HEADACHE BECOMES UNCOMMON Sarah W. DeParis; Khan K. Chaichana; Anene Ukaigwe; Michael J. Plakke; Richard Alweis. Reading Health System, West Reading, PA. (Tracking ID #1607500)

LEARNING OBJECTIVE 1: Identify the most common presenting symptoms of brain abscesses and the frequency at which they occur.
LEARNING OBJECTIVE 2: Recognize that the diagnosis of brain abscess requires a high index of suspicion in the setting of head and neck infections.
CASE: A previously healthy 66-year-old woman presented to the emergency department with complaints of headache, confusion, and clumsiness of 2 days' duration. She stated she was "not feeling like herself" and had a bifrontal headache that later localized to the right occipital region. Additionally, she had been dropping things and bumping into things on her left side. She endorsed nausea but denied vomiting, fever, diplopia, and seizures. At presentation, she was afebrile and normotensive with a normal white count. Physical examination revealed a subtle left sided hemiparesis and a left visual field defect to confrontation, but no other focal abnormalities. An initial concern for stroke led to a CT scan of the brain and subsequent MRI, which indicated an 18 by 20 mm ring-enhancing lesion in the posterior right parietal lobe with surrounding edema without midline shift. Stereotactic-guided lesion aspiration yielded purulent material that was culture positive for Streptococcus viridans and Haemophilus influenzae. Further questioning elicited a history of chronic sinusitis with an episode 2 weeks prior to admission. She received ceftriaxone for 1 month and has had no long-term sequelae.
DISCUSSION: Brain abscesses are foci of infection within the brain parenchyma. Although uncommon, they are a serious complication of common head and neck infections and often present nonspecifically, which can result in delayed diagnosis. Headache is the most common symptom of brain abscesses, which may present with few or no other findings. Fever is only present in about 50 % of patients, focal neurological deficits in 50 %, seizures in 25 %, and neck stiffness in 15 %. Patients with a history of sinusitis may have direct spread of infection from the paranasal sinuses, with Streptococcus and Haemophilus species being among the most common causative organisms. Therefore, a high index of suspicion is necessary to prevent delay in diagnosis.

BREAST MALIGNANCY MASQUERADING UNDER THE CLOAK OF ACUTE URTICARIA Erin P. O'Donnell; Cooper Wriston; Rachel Havyer. Mayo Clinic, Rochester, MN. (Tracking ID #1625048)

LEARNING OBJECTIVE 1: Recognize the potential association between urticaria and underlying systemic disease, including malignancy.
CASE: Presenting in more than 20 % of the general population, urticaria is a common disorder characterized by intensely pruritic, erythematous, raised plaques with or without associated angioedema. Common triggers of new onset urticaria include infection, allergic reactions, or medications. Although often idiopathic, the presence of urticaria can be associated with underlying systemic disease. A 58-year-old woman presented with a flat, erythematous, pruritic rash involving her palmar surfaces bilaterally. Within days, the rash progressed to generalized edematous annular plaques located on her forearms, lower extremities, upper abdomen, suprapubic area, and buttocks. She then developed deep dermal swelling of her hands, lip and face prompting initiation of systemic steroid treatment, resolving the eruption. Skin biopsies were consistent with urticaria showing dermal edema with mixed dermal and pannicular inflammation with abundant eosinophils. Due to unknown etiology, a thorough workup was pursued. Laboratory studies including thyroid function, serum protein electrophoresis, complement, anti-nuclear antibody, autoimmune blistering disease studies, flow cytometry, and Lyme disease serology were normal as was a chest x-ray and urinalysis. Routine age-appropriate cancer screening was ordered. Mammography revealed four lesions in her left breast. Ultrasound-guided core needle biopsies revealed that three of the four lesions demonstrated grade 1 invasive ductal carcinoma. Mastectomy was performed with clear margins and negative sentinel node biopsy. Following surgery, steroids were gradually tapered off and no recurrence of rash had occurred at 4 weeks post operation.
DISCUSSION: This case demonstrates the atypical association between breast malignancy and acute urticaria and emphasizes the importance of age-appropriate cancer screening in patients presenting with urticaria of unknown etiopathogenesis. Acute urticaria is a clinical diagnosis based on history and physical exam findings and confirmed by skin biopsy. Careful history focused on typical triggers of urticaria, including ingestion, infection, travel, medication, endocrinopathies, physical triggers, and systemic symptoms should be reviewed. Importantly, many systemic diseases may initially present as urticaria. To date, only two cases have been reported connecting breast cancer with chronic or acute urticaria. Although more commonly associated with paraproteinemias, other investigations have shown the association between urticaria and solid tumors of the lung, brain, ovary, thyroid, colon or rectum. The case we described supports a possible association between breast malignancy and urticaria. Thus, symptoms and signs of urticaria with unknown cause should prompt a thorough history, physical examination, and review of age-appropriate cancer screening.

BUBBLE IN THE BRAIN- NOT TO BE TAKEN LIGHTLY! Kalpana Nagarkar; Nazish Ahmad; Muhammed Bokhari. Capital Health Regional Medical Center, Trenton, NJ. (Tracking ID #1628465)

LEARNING OBJECTIVE 1: There is an abundance of literature describing best practice, complications, and treatment of venous air embolism associated with central line catheter use. Utilization of central venous catheters is increasing. With increased utilization comes the responsibility to improve commonplace knowledge and ensure that practice guidelines and protocols are dependable and consistent.
LEARNING OBJECTIVE 2: Air embolism should be taken into consideration when treating venous catheters, and appropriate treatment administration and radiological examinations must be performed immediately if level of consciousness or vital signs deteriorate.
CASE: Air embolism is a well-published complication arising from central venous catheter use. Literature and case studies provide information regarding clinical sequelae. This case report describes the neurological complications likely caused by a cerebral air embolism related to central venous catheter removal. We report a 48 year old Caucasian man who was admitted due to swelling of his left leg. Venous duplex of the left leg showed presence of a large DVT and the CT of his chest showed multiple sub segmental PE. The patient was started on heparin drip and later bridged with warfarin therapy. His work up for hypercoagulable state was negative. The patient was being discharged. While he was sitting in a reclining position in his chair, during the process of removal of his central venous catheter from the right side of the neck, he rapidly became confused, diaphoretic, and his mental status declined. He also had a seizure activity with incontinence of bladder. He received 2 doses of 1 mg IV lorazepam. After sometime the patient regained consciousness. Patient remained in postictal phase for some time. Later on examination he did not show signs of any cranial nerve involvement nor was there any weakness. EEG was unremarkable. CT angiography of the brain showed presence of air in the cavernous sinus and along the pterygoid plexus. The patient was then transferred to ICU for overnight observation. He gradually improved and at the time of discharge, the patient did not have any neurological deficit.
DISCUSSION: Venous air embolism is an infrequent complication of invasive diagnostic and therapeutic maneuvers. The cardiovascular, pulmonary, and central nervous systems may all be affected, with severity ranging from no symptoms to immediate cardiovascular collapse. Therapeutic interventions include mechanical measures, such as positioning, withdrawal of air from the right atrium, and measures aimed at reducing bubble size and treatment with hyperbaric oxygen.

BUGS, DRUGS, OR IMMUNE SYSTEM FLUBS, WHAT CAUSES LIMBIC ENCEPHALITIS? MOREOVER, WHAT CAUSES ANTI-N-METHYL-D-ASPARTATE RECEPTOR ENCEPHALITIS? Maria G. Frank[1,2]; Camille Ladanyi[2]; Paul Brittain[2]. [1]Denver Health Hospital Authority, Denver, CO; [2]University of Colorado, School of Medicine, denver, CO. (Tracking ID #1641416)

LEARNING OBJECTIVE 1: To promote awareness over a recently described cause of limbic encephalitis (LE).
LEARNING OBJECTIVE 2: To describe a case of encephalitis clinically consistent with N-methyl-D-aspartate Receptor (NMDAR) encephalitis (NMDARE) .
CASE: A previously healthy 27 year-old female, initially admitted to the inpatient psychiatry service for psychosis, progressed to catatonia, autonomic dysfunction, and respiratory failure requiring tracheostomy. Her medical history was significant solely for poly-substance abuse including methamphetamines. Her current illness was preceded by a self-reported "influenza" 2 months prior to developing progressive behavioral changes, movement disorders, and delusions. These symptoms lead to a diagnosis of schizophrenia. Her exam was significant for catatonia, aphasia, dyskinesias, intermittent hypotension, hyperthermia, and hyper-salivation. EEG showed intermixed slowing consistent with a catatonic state. CSF was normal, with negative NMDAR antibodies, bacterial culture, and viral PCRs. Autoimmune and malignancy work-ups were also negative. Despite laboratory evidence, clinical suspicion for NMDARE remained high. Thus the patient received treatment with IVIG, methylprednisolone, plasmapheresis and rituximab leading to a pronounced clinical improvement. She was discharged to the acute rehabilitation service.
DISCUSSION: Anti-NMDARE, a type of LE, was first described in 2007 as a paraneoplastic syndrome presenting in young females (median age: 22) with teratomas (49–59 %). Since then, numerous cases not associated with malignancy, affecting both genders have been reported. The California Encephalitis Project conveyed that NMDARE is more frequent than any viral encephalitis alone. Most cases begin with viral prodromes, either respiratory or gastrointestinal, with subsequent development of psychiatric disorders (72–83 %) or seizures (76–82 %). Within 10–21 days secondary stages develop which are characterized by decreased levels of consciousness, hypoventilation, autonomic instability, and dyskinesias. NMDARE has a predictable course as well as highly effective treatment options. Therefore, a high degree of suspicion for NMDRE must be maintained, as 75 % of adults will show complete recovery after early treatment. Even though most cases are consistent both clinically and in response to treatment, the real etiology remains elusive (infectious vs. paraneoplastic vs. autoimmune). This raises the question of whether different subsets of patients are suffering from the same malady. Our patient displayed the typical clinical course for NMDARE, EEG findings consistent with LE, unrevealing MRI (50 % of cases), as well as an exceptional response to immunosuppressive therapy. However, NMDAR antibodies were negative in both the serum and CSF. Few case reports exist noting patients presenting with classic clinical NMDARE progression, without laboratory evidence of antibodies, but with profound response to treatment. Several studies have questioned etiologies other than malignancy including molecular mimicry and methamphetamine use. In light of 41 % of patients presenting without an identifiable tumor, the possibility of other unknown immunological triggers presents an intriguing topic for further research. Although research and education are vital to furthering our knowledge regarding NMDARE, maintaining a multidisciplinary approach to the diagnosis, treatment, and rehabilitation are cardinal to the recovery of our patients.

CATCHING A BAD BREAK Michael T. Shoffeitt; A Domnica Fotino. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1641599)

LEARNING OBJECTIVE 1: Recognize a pathologic fracture.
LEARNING OBJECTIVE 2: Understand the indications to test for vitamin D deficiency. Be familiar with the importance of maintaining proper vitamin D metabolism.
CASE: A 26 year-old Hispanic man presented complaining of right ankle pain following a twisting injury on a curb. History was notable for working nights as a bartender and regularly drinking alcohol to excess. He had a poorly balanced diet consisting largely of hamburgers. Body mass index was normal. His right ankle was ecchymotic with swelling of the medial and lateral aspects. There was tenderness to palpation of the right medial malleolus, and he was unable to bear weight on his right. Radiographs of the ankle revealed a non-displaced fracture of the lateral malleolus. A 25-hydroxyvitamin D level was obtained and resulted at 6.9 nanograms per milliliter. All other laboratory data was unremarkable. The patient underwent open reduction and internal fixation of his fractured distal tibia. Oral supplementation with ergocalciferol (vitamin D2) was initiated at a dose of 50,000 International Units (IU) twice weekly for 4 weeks, to be followed by 50,000 IU weekly. He was also given nutritional counseling.
DISCUSSION: Vitamin D deficiency is common, with a worldwide prevalence estimated around one billion, and commonly underdiagnosed. It should be considered in anyone with a fragility fracture, defined as a fracture occurring spontaneously or following a minor trauma. Risk factors for deficiency include old age and obesity; reduced skin synthesis (from inadequate outdoor exposure, dark skin pigment, sunscreen use, or living above 35° latitude); low dietary vitamin D intake; chronic glucocorticoid or anti-epileptic drug use; chronic liver and kidney disease; and malabsorptive conditions, such as irritable bowel syndrome, celiac disease, and following bariatric surgery. This patient's deficiency likely resulted from a combination of low sun exposure, dark skin, and poor diet. In addition to the fracture this patient suffered, vitamin D deficiency places him in a cohort at risk for various extraskeletal manifestations. These include an increased risk of colorectal and prostate cancer, cardiovascular disease, autoimmune disease, and infections. All professional societies with a position on the matter agree that 25-hydroxyvitamin D levels below 20 nanograms per milliliter are suboptimal for skeletal health. The target level for replacement is 20–30 nanograms per milliliter. Less certainty exists as to the optimal level of 25-hydroxyvitamin D or the benefits of replacement as regards extraskeletal health. Treatment consists of encouraging food consumption high in vitamin D and supplementation. Cod liver oil, sardines, salmon, and tuna have the highest concentration of vitamin D, as well as certain fortified foods. Deficient individuals should initially receive 50,000 IU of vitamin D2 per week for at least 8 weeks, and when starting levels are below 15 nanograms per milliliter initial therapy can be twice weekly. Following repletion, the Institute of Medicine recommends 200 IU of dietary vitamin D for children and adults to maintain healthy levels, but many experts agree that 800 to 1,000 IU a day is more appropriate for individuals with inadequate sun exposure.

CEREBRAL VENOUS THROMBOSIS IN A PATIENT WITH SICKLE CELL TRAIT Navitha Ramesh; Sarah Suliman; Ziad Alkhoury. Unity Health System, Rochester, NY. (Tracking ID #1642296)

LEARNING OBJECTIVE 1: Sickle cell disease (homozygous) is a well known cause of cerebrovascular thrombosis. Very few cases of cerebrovascular thrombosis associated with sickle cell trait(heterozygous) have been reported in literature.It is a challenging condition because of the variability of clinical symptoms and is often unrecognized at the initial presentation.
LEARNING OBJECTIVE 2: The key point here is that we should always look for a cause of the cerebral venous thrombosis even after the patient is stabilized and treated appropriately with intravenous fluids, heparin and anticoagulants.
CASE: Our patient is a relatively healthy 49 year old African -American female who presented with severe, right sided, 8/10 headache for 5 days duration. Associated symptoms included nausea and vomiting. Patient denied visual symptoms, fever, chills, weakness, numbness, chest pain, palpitation, involuntary movements or loss of consciousness. She does not consume alcohol, smoke or use recreational drugs. She has never been on oral contraceptive medications. Her family history is not significant for any cardiovascular disorders, stroke or malignancy. Upon admission, her vitals were stable, she was not in acute distress. She appeared mildly dehydrated. Funduscopy was done with no papilledema. Physical examination including cardiovascular, pulmonary, abdominal and central nervous

system examination were within normal limits. Blood work including complete blood count, comprehensive metabolic profile, prothrombin time and activated partial prothrombin time were within normal limits. Lumbar puncture showed normal opening pressure, normal cell count, normal protein and normal glucose levels. CT scan of the head revealed abnormal appearing transverse sinus suspicious for possible sinus thrombosis. Hence, an MRV was done which showed transverse and sigmoid sinus thrombosis. Patient was started on IV heparin and coumadin, heparin was discontinued after 2 days of therapeutic INR. Patient was discharged home after 4 days in the hospital. Coagulation panel including Anti thrombin III, protein C, protein S, factor V Leiden were all normal. Hemoglobin electrophoresis was also done which showed that the patient had HgA 56.4 %, HgA2 3.8, HgS 39.8. Hence our patient was diagnosed to have cerebral venous thrombosis due to sickle cell trait.
DISCUSSION: Cerebral venous thrombosis is a rare type of cerebrovascular disease affecting about 5 people per million and accounts for 0.5 % of all strokes. Headache is the most common presenting complaint occurring in about 90 % of cases. Many studies have suggested that the risk of sickling in sickle cell trait with high hemoglobin S approaches that in sickle cell disease. Hemoglobin S values were >36 % in the few cases of cerebral venous thrombosis associated with sickle cell trait that were reported in literature. Hemoglobin electrophoresis should be carried out in young African -American patients, especially women with unexplained thrombotic phenomenon.

CLOTS OF DEFICIENCIES Meredith Barnes; Michelle M. Guidry. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1639836)

LEARNING OBJECTIVE 1: Understand the diagnosis and rapid initial treatment of suspected thrombotic thrombocytopenic purpura (TTP).
LEARNING OBJECTIVE 2: Recognize the role of ADAMTS13 in idiopathic TTP.
CASE: A 19 year-old man with no prior medical history presented with 1 month of lethargy and headache as well as 2 weeks of abdominal pain and vomiting. On the day of presentation, family members found the patient speaking incoherently and dragging his left leg while walking. He was febrile to 101.8 °F and unable to follow commands. He withdrew to painful stimuli with his right arm and leg, but there was no spontaneous movement or pain response of the left arm or leg. His muscle stretch reflexes were 2+ throughout. His pupils were equal, pinpoint and sluggish. The abdomen was tender to palpation with no organomegaly. A non-contrast CT of the head was normal. His urine toxicology revealed tetrahydrocannabinol. His platelet count was 8,000/μL, hemoglobin 7.4 g/dL, hematocrit 21.3 %, creatinine 1.34 mg/dl, LDH 885 U/L, reticulocyte count 7.5 % and total bilirubin 4.5 mg/dL. Numerous schistocytes were seen on peripheral blood smear. Coagulation studies were normal. While a central line was placed, he received IV methylprednisolone, immediately followed by plasmapheresis. Plasma exchange of 1.5 times the plasma volume was administered for five consecutive days. The platelet count was stable around 200,000/μL and the LDH was <200 U/L. His mental status and neurologic function recovered by the third day. Plasma exchange was continued every other day for another week. At the time of discharge, the creatinine and hemoglobin were within normal limits. The ADAMSTS13 activity level, drawn prior to plasmapheresis, returned at <10 % of normal.
DISCUSSION: The internist must quickly recognize suspected thrombotic thrombocytopenic purpura (TTP) so treatment can begin immediately. Mortality exceeds 90 % without treatment. Cases rarely present with all the features of the classic pentad: fever, microangiopathic hemolytic anemia (MAHA), renal abnormalities, neurological changes, and thrombocytopenia. TTP must always be considered in the differential of unexplained thrombocytopenia and anemia. Plasma exchange is the treatment of choice for TTP and is performed daily to replace 1.0 to 1.5 times the patient's plasma volume with fresh frozen plasma. Treatment continues until the platelet counts remain >150,000/μL for several days. Addition of steroids, aspirin or dipyridamole has not demonstrated benefit. If plasma exchange must be delayed, steroids and a fresh frozen plasma infusion can be used in the interim. Approximately 75 % of patients with idiopathic TTP have either an acquired or congenital deficiency of a von Willebrand factor (vWF) cleaving protease, known as ADAMTS13. Without this protease, abnormally large vWF multimers cause excessive platelet accumulation, leading to microvascular thrombosis. ADAMTS13 activity levels are clinically useful at the time of diagnosis as a prognostic indicator: more severe deficiency indicates greater risk for relapse. The utility of measuring the level serially or during remission is unknown.

CLOZAPINE AND BRUGADA - UNLIKELY BUT TRUE Anene Ukaigwe; Adetokunbo Oluwasanjo; Anthony A. Donato. The Reading Health System, West Reading, PA. (Tracking ID #1643064)

LEARNING OBJECTIVE 1: Early recognition and management of potentially fatal cardiotoxic effects of the antipsychotic, clozapine.
CASE: A 47-year-old man presented with a 3 day history of fever, cough, dyspnea, orthopnea and one episode of syncope. His past history was significant for treatment resistant schizophrenia and he had recently been started on clozapine. He had no prior history of cardiac arrest, ventricular fibrillation or syncope. There was no family history of sudden cardiac death. Physical examination revealed fever and tachycardia. Cardiovascular exam was normal. EKG showed a new RSR' pattern in V1 and V2 with a coved ST segment elevation in V1-V3 in keeping with a type 1 Brugada pattern. Echocardiogram was normal. Troponins were negative. The Brugada pattern spontaneously resolved 24 h later, after cessation of the recently started clozapine. Fever and tachycardia resolved 72 h after presentation with treatment of underlying community acquired pneumonia. He was counseled to avoid tricyclic antidepressants, Selective Serotonin Reuptake inhibitors(SSRIs), class I antiarrhythmic agents like flecainide and propafenone.
DISCUSSION: Clozapine is a dibenzodiazepine antipsychotic with strong affinity for D4-dopaminergic receptors. It also has serotonergic, noradrenergic, histaminergic and cholinergic receptor blocking abitities. It has been shown to have the lowest mortality of the antipsychotic drugs. It is indicated in treatment resistant schizophrenia or schizoaffective disorders, and is especially useful in cases of schizophrenia associated with suicide. It has the added advantage of causing less extrapyramidal side effects due to its limited D2 receptor antagonism. In spite of these benefits, its use has been limited by need to monitor for side effects with complete blood counts and echocardiograms for life threatening agranulocytosis and cardiomyopathy. Brugada pattern is due to genetic defects that result in altered action potential in the right ventricle without structural changes. It predisposes to syncope, ventricular arrhythmia and sudden cardiac death. Brugada pattern may be unmasked by fever and tachycardia, but in our index case, the Brugada pattern resolved with persistence of the fever and tachycardia making those unlikely causes. Brugada pattern or any other specific EKG changes have not been previously associated with clozapine. The potential mechanism by which clozapine may cause this is unknown. This case illustrates that clozapine may unmask Brugada pattern and this has implications in establishing guidelines for monitoring therapy. Clinicians should be aware that even when the echocardiogram is normal, EKG may reveal other life threatening abnormalities that are easily treated with cessation of offending agents and avoiding other potential triggers of fatal arrhythmias.

CMV MONONUCLEOSIS AND COLITIS IN A PREVIOUSLY HEALTHY ADULT Maureen C. Dale; Christine D. Jones. University of North Carolina- Chapel Hill, Chapel Hill, NC. (Tracking ID #1640588)

LEARNING OBJECTIVE 1: Recognize the symptoms concerning for mononucleosis in an adult patient.
LEARNING OBJECTIVE 2: Recognize the importance of investigating possible immunocompromised states in patients with organ-specific manifestations of CMV infection.
CASE: A 30-year-old woman with a history of migraines presented to the emergency department with approximately 2 weeks of headaches not consistent with her previous migraines that coincided with fevers, nausea, vomiting, diarrhea, and general malaise. Her diarrhea had resolved 1 week prior

to presentation, and for the past week she had been constipated, intermittently passing stools that were mostly blood. She was febrile to 38.5 °C. A non-contrasted CT of her head was unremarkable, and a lumbar puncture showed less than 1 RBC/mm3, 1 total nucleated cell/mm3, protein <10 mg/dl and glucose 54 mg/dl. CSF bacterial cultures were also negative. She was sent home from the ED but returned 2 days later due to her ongoing fever, malaise, and headache. Her exam was notable for an absence of cervical lymphadenopathy or splenomegaly. Her abdomen was mildly distended and tender to palpation throughout. Rectal exam revealed 2 large collapsed external hemorrhoids but no gross blood. Labs were notable for a drop in her hemoglobin from 7.1 to 6.6 g/dL, an MCV of 67, WBC of 5.6×109/L, ALC of 2.8×109/L, ANC of 1.6×109/L, with atypical lymphocytes noted in the blood smear. Iron levels were found to be <10 mcg/dL, ferritin was 13 ng/ml, and reticulocyte percentage was 2.2 % for a reticulocyte index of 0.6. Her AST and ALT were elevated at 96 and 127 u/L respectively, with normal bilirubin and alkaline phosphatase levels. Monospot testing was negative. Further testing revealed a negative HIV Ab and positive CMV IgM. She was transfused 2 units of packed red blood cells with appropriate elevation of her hemoglobin, and underwent colonoscopy, which showed diverticulosis and erythematous mucosa in the rectum. Biopsy revealed mild chronic active colitis and CMV viral cytopathic effect; CMV PCR from the biopsy was also positive. She was treated with a two-week course of valgancyclovir with resolution of her hematochezia.

DISCUSSION: CMV mononucleosis is frequently associated with systemic symptoms such as malaise, myalgias and headache and is less typically associated with cervical lymphadenopathy and exudative pharyngitis than EBV mononucleosis. Transmission is similar: by close contacts, most likely from contact with bodily secretions, or after transfusion of leukocyte containing blood products. Labs are often notable for relative lymphocytosis with presence of atypical lymphocytes, as well as moderate elevation of AST, ALT and alkaline phosphatase. Infection typically lasts for 2–6 weeks. Gastrointestinal CMV infections rarely occur in immunocompetent hosts although can be seen in primary CMV infection. Indeed, this patient's biopsy revealed possible underlying ulcerative colitis, which may have increased her vulnerability to infection. Immunocompetent patients do not typically undergo treatment with antivirals for CMV mononucleosis as it is a self-limited illness, however drug therapy is often initiated in patients with organ-specific manifestations such as colitis.

COUGH SYRUP TO EASE A TROUBLED HEART Naomi Karlen; Morgan J. Katz; Ardalan Minokadeh. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640331)

LEARNING OBJECTIVE 1: Recognize the importance of having a systematic way of diagnosing the cause of chronic cough.

LEARNING OBJECTIVE 2: Understand the importance of regular healthcare maintenance in preventing life altering disease consequences.

CASE: A 39 year-old man with no past medical history presented with 8 weeks of cough. The cough occurred every 3–4 days, more frequently at night and in the morning, was productive of greenish-yellow phlegm, and was relieved by cough syrup. He reported 30–40 lb of weight loss, subjective fevers, fatigue, lower extremity edema, and posttussive vomiting. He denied smoking and healthcare check-ups for 5 years. Blood pressure was 160/129 mmHg, heart rate 103, mucous membranes were dry, JVD was present, heart was regular rate and rhythm, PMI was non-palpable, breath sounds were clear bilaterally, and 1+ pitting edema from foot to mid-shin was present bilaterally. Sputum culture was negative, WBC 5.4 103/μL, troponin-I 0.13 ng/mL, BNP 1476 pg/mL. Chest radiograph showed mild-moderate cardiac silhouette enlargement and intersitial lung markings. EKG revealed sinus tachycardia, left axis deviation, left atrial enlargement, and left ventricular hypertrophy. Transthoracic echocardiogram revealed four chamber enlargement, severely decreased left ventricular systolic function, ejection fraction less than 20 %, moderately increased systolic pulmonary artery pressure, restrictive filling consisted with severely elevated left atrial pressure, and left ventricular end diastolic pressure.

DISCUSSION: While "common diseases are common," patients do not always present commonly with those diagnoses. In these cases, clinicians may be treating test findings instead of symptoms. Chronic cough is a frequent complaint seen by health care providers. Pulmonary causes often spring to mind, especially in younger patients. However, although less prevalent, cough can be the presenting symptom in heart failure. The mechanism cough plays in heart failure is well documented, and usually is the byproduct of pulmonary congestion. It is useful to have an approach to chronic cough when a patient's symptoms do not match their physical exam or test findings. A thorough way of navigating the differential is anatomically followed by non-anatomical causes—sinuses (post nasal drip), esophagus (gastroesophageal reflux disease), cardiac (congestive heart failure), pulmonary (asthma, bronchitis, infection), malignancy (multiple anatomical locations), smoking, and medications (angiotensin-converting enzyme inhibitors). Using a systematic approach to narrow down causes assists in faster evaluation and treatment. This case highlights the importance of regular health care maintenance with early intervention and treatment of hypertension, which is unfortunately ubiquitous in many patient populations. Early detection and appropriate treatment can easily prevent long-term morbidity and mortality. In this particular case, had the patient sought a general check up earlier, it is likely that the development of heart failure could have been avoided. Thus, when serving patients who have not had appropriate health care maintenance, physicians should keep in mind that common disease processes can lead to disastrous consequences that present in seemingly innocuous ways.

CALMING THE HEART. Elinor Lee[1]; Anna Kolpakchi[1,2]; Lee Lu[1]. [1]Baylor College of Medicine, Houston, TX; [2]MEDVAMC, Houston, TX. (Tracking ID #1621418)

LEARNING OBJECTIVE 1: Recognize that cisplatin can cause sinus bradycardia.

LEARNING OBJECTIVE 2: Realize that cisplatin does not have to be discontinued; however, patients, especially those with resting bradycardia or on AV nodal blocking agents, should be monitored.

CASE: A 29-year-old female with nodular sclerosing stage IIB Hodgkin's lymphoma had a relapse after receiving 6 cycles of ABVD (doxorubicin, bleomycin, vinblastine, and darcarbazine) and 2 cycles of AVD and was admitted for ESHAP (cisplatin, etoposide, methylprednisolone, and cytarabine) salvage therapy. Patient had no history of heart disease. On admission, patient's heart rate (HR) was 76 and regular with BP 120/70. Physical exam was normal except for four enlarged left anterior cervical and left supraclavicular lymph nodes. After day two of chemotherapy, patient's pulse was 52, and on day three, HR was 42 and regular. BP remained 120/70. Patient denied dizziness, lightheadedness, syncope, shortness of breath, palpitations, or chest pain. Serial EKGs showed sinus bradycardia. All electrolytes, including magnesium and potassium, were normal. Thyroid studies and transthoracic echocardiogram were normal. On day four of hospitalization, patient developed abdominal pain, nausea, and vomiting. She was diagnosed with cholecystitis, requiring cholecystectomy. Chemotherapy was stopped, and after 2 days, HR improved to 70 s. On a follow up outpatient visit a week after discharge, HR was 81, and clinical response to chemotherapy was excellent. A month later, patient was admitted for cycle 2 of ESHAP. On admission, HR was 76. After 2 days of cisplatin, HR trended down to 50, and by the third day, HR reached 40. EKG showed sinus bradycardia. Mild hypokalemia and hypomagnesemia were corrected without changes in heart rate. She remained asymptomatic. The patient completed a 5 day course of chemotherapy, and 2 days later, HR was 86. After a thorough literature search, cisplatin was identified as a cause of the bradycardia.

DISCUSSION: Well known arrhythmias attributed to cisplatin include atrial fibrillation, supraventricular tachycardia and bundle-branch blocks. Sinus bradycardia is rare. Our literature search yielded two case reports. The pathophysiology remains unclear, but cisplatin may play a direct toxic effect on the myocardial cells or disrupt the cardiac conduction system by depositing around the sinoatrial node. In our patient, the resolution of bradycardia after discontinuation of cisplatin suggests a temporal relationship. Sinus bradycardia due to cisplatin is asymptomatic and reversible; hence, there is no need to stop cisplatin or adjust the dose. To recognize

this side effect is important because patients like ours have limited options but respond well to salvage chemotherapy. Additionally, patients with resting bradycardia and those taking AV nodal blocking medications need to be monitored while receiving cisplatin.

CAN TREATMENT OF A COMMON MEDICAL ILLNESS EXACERBATE AN UNDERLYING MALIGNANCY? Dean Drizin; Luke Peters; Kelly McCaffrey; Kristin A. Stratton. University of Colorado School of Medicine, Aurora, CO. (Tracking ID #1631752)

LEARNING OBJECTIVE 1: Recognize the potential for adverse effects of digoxin use on patients with active estrogen-sensitive cancers
CASE: A 76-year-old man presented with a six-week history of progressively worsening dyspnea on exertion. He also noted new lower extremity edema and three-pillow orthopnea. His past medical history included moderate aortic stenosis, rate controlled atrial fibrillation, and locally-advanced ductal carcinoma of the breast that was estrogen receptor (ER)/progesterone receptor (PR) positive (+), human epidermal growth factor receptor two negative (−). This was previously treated with mastectomy and six cycles of docetaxel, doxorubicin, and cyclophosphamide therapy. His medications included diltiazem, digoxin, warfarin, and tamoxifen. He had a three out of six mid-peaking systolic murmur at his right upper sternal border that radiated to the carotids, his jugular venous pressure was elevated at 16 cm, and his heart rate was irregularly irregular. There were decreased breath sounds at the right lung base with dullness to percussion and decreased tactile fremitus. He had warm distal extremities with significant bilateral lower extremity pitting edema. There was severe aortic stenosis on trans-thoracic echocardiogram with a left ventricular ejection fraction of 25 %. A computerized tomography scan revealed widely metastatic disease with a right-sided pleural effusion, bony sclerotic lesions, enlarged lymph nodes, and a renal mass. The patient opted for limited evaluation and medical treatment of his newly-diagnosed congestive heart failure given his concurrent metastatic breast cancer. Tamoxifen was discontinued due to the cancer progression and the patient was started on anastrazole. Digoxin was discontinued given the drug's possible association with breast cancer.
DISCUSSION: Heart failure, atrial fibrillation, and breast cancer are common conditions encountered by the internist. Digoxin is a medication used to treat both cardiac conditions. Digoxin has a narrow therapeutic index and well known adverse effects when outside of the therapeutic range including vision and mental status changes, gastrointestinal symptoms, and dysrhythmias. Digoxin is also associated with gynecomastia in males even when used within the therapeutic range, perhaps due to the drug's similarity in structure with estradiol. Recent observational studies in women show digoxin use increases the incidence of ER+ breast and uterine cancers but has no impact on the incidence of relatively ER- ovarian and cervical cancers. While these observational studies are cause for concern, the safety of digoxin use in patients with established ER+ cancers has not yet been examined in prospective randomized controlled studies nor is it known whether tamoxifen, an antagonist of the ER in breast tissue, inhibits digoxin's possible effects on estrogen-sensitive cancers. The prevalence of congestive heart failure, atrial fibrillation, and breast cancer is increasing worldwide. Internists should be aware of the potential for adverse interactions between treatments for these common medical conditions.

CANNABIS ABUSE : A RARE CAUSE OF ACUTE PANCREATITIS Tabish Jalal; Harsha Ramchandani. St Mary Mercy Hospital, Livonia, MI. (Tracking ID #1636378)

LEARNING OBJECTIVE 1: 1. To increase awareness of adverse effects of cannabis
LEARNING OBJECTIVE 2: 2. To learn how to approach a case of acute pancreatitis
CASE: Our patient is a 26 year old Caucasian male who was admitted to the hospital for severe abdominal pain for 1 day. Past medical history was significant for lower back pain. He denied smoking cigarettes, drinks alcohol socially and smokes medical marijuana for back pain. On admission, his vitals were normal, physical exam was positive for epigastric and right lower quadrant tenderness. His significant labs were elevated lipase 860 (reference range: 0–60 U/L), TG 301, LDL 136, HDL 35 and Cholesterol 231. Urine drug screen was positive for cannabis. Serum alcohol level was <3. Ultrasound abdomen, HIDA scan and CT abdomen were normal. With conservative measures, his symptom improved and was discharged on third day of admission with the instructions to avoid marijuana. When performing the Naranjo algorithm for assessing probability of an adverse drug reaction, the patient was considered to have "probable" pancreatitis secondary to THC.
DISCUSSION: According to NIH, 16.7 million Americans over the age of 12 year use marijuana. Side effects of marijuana include nausea, vomiting, pancreatitis, decreased short-term memory, dry mouth, red eyes, impaired perception and motor skills. More serious side effects include panic, paranoia, or acute psychosis. Medication-induced pancreatitis is a rare cause, only accounting for approximately 2 % of all cases of pancreatitis. The most frequently implicated medications are metronidazole, tetracycline, azathioprine, furosemide, thiazide diuretics, angiotensin converting enzyme inhibitors, didanosine, aspirin, valproic acid, and codeine. An even rarer cause that has been implicated recently in the literature is tetrahydrocannabinol (THC). Exact mechanism of cannabis induced pancreatitis is not known. It should be a diagnosis of exclusion. In our patient, other causes of pancreatitis were ruled out. He did not have significant alcohol use, nor was there any family history of pancreatitis. Cholelithiasis was not present and triglyceride levels were slightly elevated not enough to cause pancreatitis. Furthermore, he was not receiving any medications known to cause pancreatitis, except marijuana. Although the exact mechanism remains a mystery, cannabis use should be considered a risk factor for the development of acute pancreatitis and among general population awareness should be created for side effects of Cannabis.

CATASTROPHE! Auras R. Atreya; Eimear Kitt; Behdad Besharatian; Ashish Verma; Michael DeMatteo. Baystate Medical Center/Tufts University School of Medicine, Springfield, MA. (Tracking ID #1639085)

LEARNING OBJECTIVE 1: Recognize early the challenging diagnosis of Catastrophic Antiphospholipid Antibody Syndrome (CAPS), in order to direct management appropriately as the condition is life-threatening.
CASE: KP, a 26 years old African-American male with SLE, non-compliant with his outpatient steroid therapy, presented with 3 days of constitutional symptoms and was found to have acute kidney injury, pancreatitis, profound anemia needing transfusion (Hb 5.7), thrombocytopenia, acute decompensated heart failure with troponin elevation. Echocardiogram showed global hypokinesis with regional areas of akinesis, suggestive of infarction. He was started on high dose steroids for presumed SLE flare. Subsequently, he had massive upper GI bleed; EGD revealed gastritis as well as esophageal varices. US of liver revealed portal vein thrombosis with cavernous transformation and splenic vein thrombosis. His renal function worsened necessitating dialysis. He became more somnolent with development of neurological deficits; CSF analysis showed no signs of infection and an MRI demonstrated disseminated sub-acute ischemic infarcts. At this point, concern for a more serious condition such as concomitant antiphospholipid syndrome was raised. Renal biopsy showed multifocal arterial and arteriolar thrombi, consistent with CAPS. There was no evidence of lupus nephritis. Positive serology (anti-cardiolipin IgM 25 ug/mL) helped confirm diagnosis of CAPS and he was started on anticoagulation, cyclophosphamide and plasmapheresis. Eventually, KP recovered from his cataclysmic disease and was discharged to a rehabilitation center with long-term warfarin and prednisone therapy.
DISCUSSION: Catastrophic antiphospholipid syndrome (CAPS) was first described by Ronald Asherson in 1992 and is diagnosed using the classification criteria proposed by the International Congress on Antiphospholipid in 2011. This includes the presence of all of the following: evidence of involvement of≥3 organs; manifestations occurring simultaneously or in less than 1 week; histopathological confirmation and serological confirmation (anticardiolipin/lupus anticoagulant/anti-beta2 glycoprotein antibodies). Although this condition is fairly uncommon in patients with antiphospholipid syndrome (<1 %), it is a life-threatening

condition with greater than 50 % mortality. The pathogenesis of this disease is still unclear, but it is postulated that certain triggers (eg. infection) facilitate a 'cytokine storm' that promotes inflammation and thrombosis. Treatment options include anticoagulation, steroids, cyclophosphamide, plasmapheresis. Additional therapies such as rituximab, eculizumab and IVIG have been used with some success for refractory CAPS. In our patient, the presence of cerebral infarcts, myocardial infarcts, renal thrombosis, ischemic gastritis, portal vein thrombosis, pancreatic injury within a short duration raised concerns for a serious disorder. Histological and serological tests confirmed the diagnosis. Despite lack of experience with this disorder, prompt review of medical literature and early sub-specialist consultation were vital to ensure a favorable outcome.

CAUTION:LITHIUM INDUCED MULTIORGAN DYSFUNCTION IN THE ELDERLY Amitpal S. Nat; Amritpal S. Nat; Meghan Rane; Josh Harrison. SUNY Upstate, Liverpool, NY. (Tracking ID #1642895)

LEARNING OBJECTIVE 1: Recognize medications/ conditions that can predispose patients to Lithium toxicity.
LEARNING OBJECTIVE 2: Management options in patients with Lithium toxicity.
CASE: We present a 72 y.o. minimally responsive male with Parkinson's disease, HTN, diabetes, and bipolar disorder on lithium carbonate 450 mg ER qHS and 300 mg daily. Patient presented with hypotension at 80/47 mmHG, hypothermia at 35.4 °F, and bradycardia with heart rate of 40 bpm, and apneic respirations. Atropine was given and heart rate responded to 60's. The patient was admitted to the ICU for chronic lithium toxicity. Lithium level was 3.5 mEq/L. Patient underwent urgent intubation, aggressively hydrated with saline, and underwent hemodialysis and made a fully recovery after prolonged stay in the ICU. Lithium levels and creatinine normalized. ROS were unobtainable secondary to patients' clinical status. Other medications included lisinopril, aspirin, duloxetine, olanzapine, paroxetine, metformin, and aripiprazole. Lithium was discontinued from the medication list. CBC was remarkable only for WBC of 11.2 mcL. BMP was remarkable for hyponatremia at 134 mEq/L and creatinine level of 3.5 mg/dL with baseline level 0.7 mg/dL prior. Anion gap was 0. Calcium was 7.1 mg/dL. TSH, free T4, PT/INR, lactate, and all cultures were unremarkable. Chest x-ray revealed a left lower lobe pneumonia. Ct head was unremarkable. Physical exam revealed a minimally responsive patient with GCS of 10 and severely dry oral mucosa. Cardiac and pulmonary auscultation revealed bradycardia and decreased breath sounds on left lower lobe respectively. Neurologic exam was unremarkable except for altered mental status.
DISCUSSION: Lithium carbonate is a well known and effective drug used in the treatment of bipolar disorder. It has a narrow therapeutic index and is cleared by the kidneys. Hypovolemic states, underlying renal insufficiency and increased age can predispose patients to Lithium toxicity. Three classes of drugs to avoid in these patients are angiotensin converting enzyme inhibitors (ACEi), nonsteroidal anti-inflammatory drugs (NSAID's), which cause an acute decline in GFR, and diuretics, which promote renal sodium wasting. This was supported by Juurlink and colleagues who concluded initiating loop diuretics or ACEi significantly increased the risk of lithium toxicity and hospitalization was almost six times and four times more likely for those initiating loop diuretic and ACE inhibitors respectively compared with case controls. This was evident with our elderly patient whose pneumonia, dehydration, and medications such as lisinopril and aspirin predisposed him to severe chronic Lithium toxicity. The mainstay of treatment for Lithium toxicity is fluid therapy. The goal of saline administration is to increase GFR, urine output, and promote the excretion of lithium. Hemodialysis is indicated for severe lithium toxicity with levels >4 mEq/L and >2.5 mEq/L with clinical signs of toxicity. Toxicology and nephrology are important consultations in Lithium toxicity. Our case is of importance because it cautions clinicians to recognize certain medications/conditions that can predispose patients to toxicity. Close monitoring of lithium levels and frequent office visits can allow physicians to have better control over preventing complications of the drug. The importance of hydration, correcting the underlying etiology, and dialysis play a pivotal role in patient outcomes to minimize multiorgan dysfunction and possibly death.

CHALLENGES AND MANAGEMENT OF CENTRAL NERVOUS SYSTEM COCCIDIOIDES Morgen Yao-Cohen; Ami Parekh; Melicent Peck; Sarah Doernberg. UCSF, San Francisco, CA. (Tracking ID #1640777)

LEARNING OBJECTIVE 1: Identify unique presentations of Coccidioides immitis CNS infection.
LEARNING OBJECTIVE 2: Management of chronic coccidioidal meningitis and simultaneous reactive myelitis.
CASE: A 35 year-old man with past medical history significant for coccidioidal meningitis (CM) presented in November 2012 with severe shoulder pain worsening over several weeks and right arm weakness. In 2010, he had no known medical conditions and was vacationing in San Diego, CA. He returned home to Australia, where 6 months later he presented with pleuritic chest pain. He was initially treated for bacterial pneumonia and then bacterial meningitis with worsening symptoms of headache, photophobia and fever. Eventually, a CT chest showed a cavitary lesion and a biopsy grew Coccidioides. He completed a six-week course of intravenous amphotericin before transition to oral fluconazole. He was maintained on fluconazole 800 mg daily. Despite this, he had ongoing fatigue, shoulder spasms and pain radiating down his right arm that worsened several weeks before his November 2012 presentation. He also had several weeks of low-grade fevers, but no photophobia or headache. On presentation, he had a temperature of 100 F, 4/5 strength in right deltoid and biceps with absent right biceps reflex, negative jolt test and severe pain with palpation of the cervical spine and neck flexion (positive Lhermitte's sign). Lumbar puncture had leukocytosis to 103, total protein 1028 and glucose 13. MRI of the cervical spine showed increasing leptomeningeal enhancement of C2–C7 with myelitis at C3–C4 and pre-syrinx formation from CSF block. HIV test was negative. Fluconazole was increased to 1200 mg daily and intravenous amphotericin was added when no improvement was seen after 4 days. After 10 days of treatment, he became unable to abduct his shoulder. Repeat MRI showed interval worsening of cord involvement extending to T1-2 with worsening pre-synrinx and extramedullary cystic components concerning for microabscesses. Within 24 h of starting steroids, he had dramatic improvement of his neurologic examination and pain symptoms. He was treated for 24 days with intravenous amphotericin. Steroids were tapered off with stable neurologic findings. High dose fluconazole will be continued indefinitely.
DISCUSSION: CM is challenging to treat because of associated complications and difficulty clearing the pathogen from CSF. Presentation of CNS exacerbations can be varied and it can be difficult to differentiate whether an acute presentation is from progression of disease or inflammatory response to the pathogen. Management of CM has shifted over time. Prior to development of azoles in the 1980s, treatment centered on intrathecal amphotericin because of poor intravenous CSF penetration. Treatment of CM has evolved to rely on high dose azoles. Intrathecal or intravenous amphotericin is reserved for azole non-responders. Although highly controversial, steroids may be given to patients with focal neurologic deficits even in the setting of active fungal infection given the morbidity and potential irreversibility of neurologic sequelae. Data for this is scarce. Ventriculoperitoneal shunts are placed in patients with hydrocephalus. Some patients may benefit from neurosurgical procedures to remove fungal abscesses. Patients presenting with CNS symptoms and CM benefit from a multispecialty team including infectious disease, neurology, medicine, pain specialists and neurosurgery.

CHEST PAIN IN A YOUNG, HEALTHY FEMALE. IS PHYSICAL EXAM REALLY NECESSARY? Maria G. Frank[1,2]; Susan L. Calcaterra[1,2]; John Cunningham[1,2]. [1]Denver Health Hospital Authority, Denver, CO; [2]University of Colorado School of Medicine, Denver, CO. (Tracking ID #1641305)

LEARNING OBJECTIVE 1: - To promote awareness and to remind providers about the diversity of entities leading to chest pain and to stress the importance of performing a detailed physical examination.

LEARNING OBJECTIVE 2: To describe a case of a spontaneous left radial artery occlusion in a previously healthy 27 year-old female

CASE: A previously healthy 27 year-old female presented to the emergency department complaining of sudden onset of upper left-sided chest pain radiating to left upper extremity associated with clamminess of the hand. The pain started at rest and she had no prior history of similar episodes. She denied trauma to chest, neck or upper extremity. She was not on any medications or herbal preparations and had no significant past medical or surgical history. Her social history revealed tobacco dependence and family history was relevant for mother with thrombophilia and multiple episodes of thromboembolic events. There were no pertinent findings during review of systems. Physical examination was noteworthy for markedly decreased left radial pulse when compared to the right, all other pulses were symmetric, and left hand was warm and appeared well perfused. There was tenderness to palpation over left infra-clavicular area. Exam was otherwise unremarkable. Laboratory tests including Basic Metabolic Panel, Liver Function Tests, Cellular Blood Count, INR, prothrombin, PTT and urine-analysis were normal. Computed tomographic angiogram (CTA) of chest and upper extremities revealed a lack of opacification of the left radial artery. Trans-Thoracic Echocardiogram (TTE) showed no embolic source. General Surgery was consulted with concern for acute limb ischemia; with decision to anti-coagulate patient and to pursue hypercoagulability work up. Results are pending at the time of this report but based on patient's family history, clinical presentation and CTA results, it was presumed that patient's spontaneous arterial occlusion was secondary to thrombophilia. She will be followed at Hematology clinic.

DISCUSSION: Spontaneous radial artery occlusion is rarely found in young patients and certainly hardly included among chest pain differential diagnosis. It has been described in older individuals with known thromboembolic disease, as well as malignancy. Radial artery occlusion has been identified as a complication of trauma and surgical or vascular interventions. There has been limited case reports of patients with Factor V Leiden mutation (FVLM) and associated arterial thromboembolic events, and only one report referred to radial artery occlusion associated with FVLM. Other thrombophilic disorders including protein C deficiency, protein S deficiency and anti-thrombin III deficiency have been infrequently associated with arterial thrombosis. In our case, a comprehensive history and meticulous physical examination prompted the CTA that led to diagnosis and treatment of an unusual malady. In these times of rapidly advancing technology and minimal face-to-face time spent with patients it is imperative to reinforce the use and teaching of examination skills as it can have a substantial effect in medical care, as demonstrated by our case.

CHEST PAIN IN A YOUNG WOMAN WITH SPONTANEOUS CORONARY ARTERY DISSECTION Hirotaka Matsuura; Christine Kwan. Teine Keijinkai Hospital, Sapporo, Japan. (Tracking ID #1639470)

LEARNING OBJECTIVE 1: To recognize that spontaneous coronary artery dissection (SCAD) is one of the causes of acute coronary syndrome (ACS)

LEARNING OBJECTIVE 2: To consider SCAD in young women who present with chest pain without coronary artery disease (CAD) risk factors

CASE: A 40-year-old Japanese woman with no significant past history presents with one-hour history of sudden onset chest pain while showering after swimming for an hour. She describes the pain as squeezing, continuous, located substernally, 8–10/10, non-radiating, and not worsened or improved by anything. She has no diaphoresis, palpitations, respiratory or gastrointestinal symptoms, fever, sick contacts, back or leg pain, recent immobilization, trauma or new activities. She denies family history of premature cardiac disease. She has a 3.75 pack-year smoking history, one beer occasionally and no drug use. She only swims once a year. On exam, her body mass index is 28 kg/m2 with blood pressure 146/100 mmHg, pulse 78 beats/minute, respiratory rate 24 /minute, O2 saturation 97 % room air, and temperature 36.1C. She is alert and oriented ×3 and not in acute distress. Her cardiac exam shows regular S1 and S2 with no murmurs, gallops or rubs and no tenderness to palpation of the chest wall. The rest of the exam is within normal limits. Electrocardiogram (ECG) reveals ST elevation in leads I, aVL, and V1–V6 with no reciprocal changes; troponin and creatine kinase are negative. Total cholesterol is 238 mg/dL, LDL 127 mg/dL, HDL 33 mg/dL, TG 530 mg/dL, and HbA1C 5.2 %. Coronary computed tomography (CT) reveals a lesion in the proximal left anterior descending artery. Coronary angiography then shows a 99 % occlusion in the corresponding area; intravascular ultrasonography (U/S) shows the true lumen's being compressed by a false lumen. Percutaneous coronary intervention (PCI) with a drug eluting stent is performed to reopen the lesion with initiation of aspirin, clopidogrel, carvedilol, candesartan and rosuvastatin. She is discharged after 8 days.

DISCUSSION: This woman has symptoms concerning for ACS but no CAD risk factors except for a mild smoking history and low HDL. ECG certainly shows ST elevation, but it may be interpreted as early repolarization syndrome. Her biomarkers are also negative except for heart-type fatty acid binding protein. Even though she has a relatively low pre-test probability of ACS, it should still be considered because the causes of ACS do not only include atherosclerotic plaque rupture; while SCAD can also cause ACS in 0.2 % of cases. Vanzetto et al. report that 8.7 % of ACS cases in women younger than 50 years old are caused from SCAD. Also, more than 70 % of SCAD cases occur in women. SCAD occurs when an intimal tear followed by intramedial hemorrhage into the false lumen compresses the true lumen resulting in obstruction of blood flow causing myocardial infarction. The causes of intimal tears include atherosclerosis, peripartum episode, connective tissue disorders, vasculitis, exercise, oral contraceptive use, and idiopathy. Symptoms depend on the amount of flow but are similar to ACS from atherosclerotic plaque rupture. Diagnosis is made by coronary CT, angiography, intravascular U/S, and/or optical coherence tomography. Like treatment for ACS from atherosclerosis, SCAD patients are medically managed along with PCI and coronary artery bypass graft. In conclusion, because SCAD can cause ACS, one should consider this life-threatening syndrome even in younger women with chest pain.

CHICKEN-AND-EGG DILEMMA: A CASE OF GLIOSARCOMA AS AN UNUSUAL PRIMARY NEOPLASM Khan K. Chaichana; Michael J. Plakke; Sarah H. Van Tassel; Anthony A. Donato. Reading Health System, Reading, PA. (Tracking ID #1642597)

LEARNING OBJECTIVE 1: Identify the fundamental features of gliosarcoma.

LEARNING OBJECTIVE 2: Recognize the metastatic potential of gliosarcoma.

CASE: A previously healthy left-handed 72-year old male presented to the emergency department with complaints of left facial numbness and spasms of his left upper extremity, as well as an episode of slurred speech and expressive aphasia that had completely resolved before arrival. On physical examination he had stable vital signs and was asymptomatic. Neurological exam was completely non-focal. Computed tomography (CT) scan and magnetic resonance imaging (MRI) of the brain identified a large, 3.2-cm mass in the posterior right frontal lobe with extensive edema, without herniation, hemorrhage, or ischemia. CT scan of the chest, abdomen, and pelvis revealed an irregular, 9.0-mm left upper lobe lung mass concerning for a primary pulmonary neoplasm. Given the high risk of the intracranial mass causing increasing intracranial pressure and possibly cerebral herniation, craniotomy with resection was urgently performed. Examination of the permanent sections of the surgical specimens showed biphasic glial and metaplastic mesenchymal components, diagnostic of gliosarcoma (GSM). Subsequent non-invasive work-up of the pulmonary lesion discovered on pre-operative CT scan was highly indicative of metastatic GSM. After discussing these findings with the patient, he elected to forgo further interventions and was discharged home.

DISCUSSION: Identification of an intracranial neoplasm on diagnostic imaging often creates a diagnostic quandary: is it a metastatic focus or primary brain tumor? Suspicious extracranial lesions found on work-up are considered possible primary sites. Given the low probability of intracranial neoplasms to metastasize, rarely do internists consider the intracranial

neoplasm a primary malignancy and the systemic lesions as possible metastatic foci. However, this is precisely the case with GSM. GSM is a rare type of glioblastoma (GB) consisting of both gliomatous and sarcomatous tissue. It is estimated that GSM accounts for 2.1 % of GB. As with GB, it has a predisposition for older men and a clinical presentation consistent with a rapidly expanding brain tumor, including aphasia, headache, hemiparesis, and seizures. GSM is notable for its strong propensity to spread hematogenously to the lungs and liver, with reports of metastatic foci to numerous other sites. The metastatic potential of GSM is thought to be due to the sarcomatous component, reflecting the tendency of sarcomas to disseminate through the bloodstream. The brain is a common site for metastatic foci, but internests seldom consider that primary intracranial malignancies have the potential for systemic dissemination. GSM is an example that this is possible and should be included in the differential diagnosis when lesions suspicious for malignancy are found inside and outside the brain.

CHOLEDOCHAL CYSTS: A DISEASE OF ALL AGES Vimalkumar Veerappan Kandasamy; Ajaykumar Kaja; Nachiket Patel; Pallavi Bellamkonda. Creighton University Medical Center, Omaha, NE. (Tracking ID #1642305)

LEARNING OBJECTIVE 1: Understand the principles of diagnosis and treatment of choledochal cysts.
LEARNING OBJECTIVE 2: Recognize the atypical presentation of choledochal cyst in adults.
CASE: An 80-year-old Hispanic female with a past medical history of hypertension and hyperlipidemia presented to the emergency room with complaints of a 4-hour history of severe epigastric abdominal pain, nausea and vomiting. She had a history of a cholecystectomy 25-years ago. Patient denied alcohol use. Her vitals were within normal limits. Physical examination was significant for epigastric abdominal tenderness. Pertinent laboratory data included: total bilirubin of 1.7 mg/dL, alkaline phosphatase of 183 IU/L, AST of 536 IU/L, ALT of 266 IU/L, lipase of 3386 units/L, white blood cell count of 10.71 k cells/mcL, and triglycerides of 66 mg/dL. A diagnosis of pancreatitis was made, but there was no clear etiology. Magnetic resonance cholangiopancreatography(MRCP) was done which showed a dilated common hepatic duct with a maximal diameter of 10 mm, and a common bile duct (CBD) diameter of 8 mm. There were no stones in the CBD. Endoscopic ultrasound showed sludge in a type 1 choledochal cyst with no mass lesions. An endoscopic retrograde cholangiopancreatography (ERCP) confirmed the presence of a type 1 choledochal cyst. Multiple balloon sweeps with removal of sludge and a biliary sphincterotomy were performed. There was good drainage of barium contrast at the end of procedure. The patient improved clinically and her lab values normalized.
DISCUSSION: Choledochal cysts are classified into five categories based upon the site, extent and shape of the cystic anomaly. A type 1 choledochal cyst is the most common biliary cyst representing 79 % of all choledochal cysts. Although symptoms can occur at any age, 80 % of patients with biliary cysts will present before the age of 10. Neonatal patients generally present with obstructive jaundice and an abdominal mass, whereas, adult patients present with abdominal pain, fever, nausea, vomiting and jaundice. The symptoms from a choledochal cyst usually result from bile stasis, stone or sludge formation, recurrent super infection and inflammation. About 20 % of cases in adults initially present as pancreatitis due to stone and protein plug formation. Protein plugs form from albumin-rich exudates, chronic inflammation, or mucin hypersecretion from dysplastic epithelium. Diagnostic workup includes abdominal ultrasonography, which may show a cystic mass in the right upper quadrant separate from the gallbladder. Endoscopic ultrasound allows for good visualization of the intrapancreatic portion of the common bile duct. Computed tomography is superior to ultrasonography in imaging the intrahepatic bile ducts, distal bile duct and the pancreatic head. Nevertheless, MRCP is considered the gold standard for diagnosing choledochal cysts. ERCP allows for the performance of therapeutic procedures. Patients with type I cysts are treated with surgical resection of the cysts due to the significant risk of malignancy, provided they are good surgical candidates. In poor surgical candidates, interventions such as laparoscopic cholecystectomy or ERCP can be performed. A high level of suspicion is required for diagnosis, particularly for type I cysts, which may go undiagnosed unless considered in the differential diagnosis of patients found to have ductal dilation, as it can clinically mimic many other conditions like acute or chronic biliary obstruction.

CHRONIC DIARRHEA IN A VIETNAM WAR VETERAN Alisa Thamwiwat; Jeffrey T. Bates. Baylor College of Medicine, Houston, TX. (Tracking ID #1642018)

LEARNING OBJECTIVE 1: Diagnose strongyloides infection accurately when stool samples are negative for parasites.
LEARNING OBJECTIVE 2: Recognize the availability of the newer luciferase immunoprecipitation systems (LIPS) assay in the diagnosis of strongyloides infection.
CASE: A 63-year-old-male Vietnam War veteran noted a six-month history of watery diarrhea; he was admitted for volume depletion. The patient had been in Vietnam for 1 year in 1970; there were no recent travels. Vital signs demonstrated a BP of 85/41 mmHg and a pulse of 101 beats per minute; the physical examination was otherwise unremarkable. His hypotension and tachycardia resolved with volume repletion. Lab work revealed peripheral eosinophilia of 20.9 %. Three stool samples were negative for ova and parasites. Serum enzyme-linked immunosorbant assay (ELISA) demonstrated a positive strongyloides IgG Ab. His serum was sent to the National Institutes of Health (NIH) for a luciferase immunoprecipitation systems (LIPS) assay; it was also positive for strongyloides. The patient was treated with ivermectin 200 ug/kg/day for 2 consecutive days. Two weeks post-discharge, his eosinophilia had decreased to 11.6 %; 2 months post-discharge, it had decreased to 5.3 %, and his diarrhea had resolved.
DISCUSSION: Invasive strongyloidiasis is endemic in the tropical and subtropical areas of Southeast Asia and Africa. It is uncommon in the United States, with a prevalence of approximately 4 % concentrated in the eastern areas of the country; for those patients diagnosed in this country, the infection is most commonly found in immigrants and refugees from endemic areas. Although three stool samples were negative for parasites, the sensitivity of detecting strongyloides in the stool is low, estimated at only 50 % with three samples. Additionally, although the strongyloides IgG ELISA was positive, the positive test can be secondary to cross-reactivity from helminth infections. The newer LIPS assay for strongyloides has been shown to be not only more sensitive, but also more specific, as studies demonstrate no cross-reactivity from helminth infections. Further, for patients who either are immunocompromised at baseline or will be administered corticosteroids, an accurate diagnosis becomes particularly important, because hyperinfection syndrome and disseminated disease can develop; without treatment the mortality rate approaches 100 % in these super-infected patients. Clinicians must consider invasive strongyloidiasis in patients with chronic diarrhea and peripheral eosinophilia, especially in people who inhabit endemic areas. Negative stool studies for parasites should not exclude its diagnosis, and the newer LIPS assay can identify strongyloides infection with greater sensitivity and specificity than the more commonly used ELISA.

CIPROFLOXACIN IMPLICATED IN ACUTE HEPATITIS Youssef Nasr; Edgardo M. Flores Anticona; Alex Essenmacher; Kassem Bourgi; Lucero C. Chueca Villa. Henry Ford Hospital, Detroit, MI. (Tracking ID #1625032)

LEARNING OBJECTIVE 1: Recognize that drug-induced liver injury is a possible but rare side effect of ciprofloxacin.
LEARNING OBJECTIVE 2: Understand that ciprofloxacin-induced liver injury is reversible by stopping this antibiotic early.
CASE: The patient is a 41-year-old woman with a history of recurrent right kidney stones and one episode of urinary tract infection (UTI) many years ago treated with Bactrim. She presented to primary care with 1 week of right-sided flank pain and urinary symptoms. She was diagnosed with a

Streptococcus viridans UTI and treated with ciprofloxacin. The urinary complaints resolved, but she started to have right upper quadrant discomfort and jaundice a few days after starting the antibiotic; this led to hospital admission for further evaluation. Laboratory testing showed elevated liver function tests: aspartate aminotransferase (AST) 1058 IU/L, alanine aminotransferase (ALT) 806 IU/L, total bilirubin of 11.5 mg/L with a direct bilirubin of 6.5 mg/L, and alkaline phosphatase 315 IU/L. Other causes of acute hepatitis such as acetaminophen intoxication, acute viral hepatitis, and autoimmune liver disease were ruled out. Doppler ultrasonography of the liver was negative for vascular obstruction and cholelithiasis. A liver biopsy was performed, and the pathology revealed marked lobular disarray, lobular and portal lymphocytes, occasional eosinophils, and no plasma cells consistent with drug-induced liver injury. Ciprofloxacin was discontinued, and symptoms as well as liver injury markers improved.

DISCUSSION: Ciprofloxacin is a fluoroquinolone antibiotic commonly used to treat a variety of bacterial infections of the urinary tract, gastrointestinal system, skin, and complicated intraabdominal infections. Ciprofloxacin is generally well tolerated and has a favorable side-effect profile. Liver injury can develop following the use of many drugs both prescription and over-the-counter. Fourteen cases of ciprofloxacin-induced liver injury were reported but only two patients, similar to our case, were not on any other medication, confirming this rare side effect. Drug-induced liver injury (DILI) can be classified in several ways: by its clinical presentation and laboratory features, the mechanism of hepatotoxicity, and/or its histological findings. The diagnosis of DILI can be difficult, so obtaining a careful drug history is important but not always reliable. Features suggesting drug toxicity include lack of illness prior to ingesting the drug, clinical illness or biochemical abnormalities developing after beginning the drug, and improvement after the drug is withdrawn. A high index of suspicion is necessary to expeditiously establish the diagnosis and permit withdrawal of the drug before the damage is irreversible.

CLASSIC HEMATOLOGIC FINDINGS HELP DIAGNOSE PERNICIOUS ANEMIA IN A PATIENT WITHOUT NEUROLOGIC DEFICITS Andrew Antony[1]; Yelena Averbukh[2]. [1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, Bronx, NY. (Tracking ID #1625104)

LEARNING OBJECTIVE 1: To construct a wide differential diagnosis in patients presenting with megaloblastic anemia

LEARNING OBJECTIVE 2: To recognize the presentation of B12 deficiency in patients presenting with non-specific complaints

CASE: A 47 year-old Dominican man with no significant past medical or surgical history presents with weakness and weight loss. Review of systems is negative for chest pain, shortness of breath, melena, numbness and tingling in his extremities or abnormal balance and gait. Physical exam reveals conjunctival pallor, but there is no rash, scleral icterus, thrush, lymphadenopathy, ascites, hepatosplenomegaly, or edema. There are no focal deficits on neurologic exam. Laboratory values are significant for: hemoglobin 5.8, hematocrit 16.7 %, MCV 112, reticulocyte index 2.1, platelets 136,000, INR 1.1, PT 11.4, aPTT 24.1, LDH 3522, haptoglobin 6, total bilirubin 1.6. Coombs test is negative, iron is 126, TIBC is 244, transferrin is 195, percent saturation is 52, ferritin is 751. He has a folate of 10.8 and a vitamin B12 of 60. Anti-intrinsic factor antibody is negative, and anti-parietal cell antibody is positive. Blood smear demonstrates hypochromia, macrocytosis, basophilic stippling, anisocytosis, poikilocytosis, normoblasts, hypersegmented neutrophils and teardrop cells. The patient improved rapidly after transfusion of 2 units packed red blood cells. He was treated with cyanocobalamin 1000 mcg IM daily for 7 days, and discharged with a plan for weekly injections for 1 month, and then monthly injections with follow-up.

DISCUSSION: Folate and B12 deficiency must be ruled out in patients with megaloblastic anemia. This patient has very low levels of B12, and demonstrates classic laboratory findings of B12 deficiency such as anemia and thrombocytopenia. Peripheral smear shows hypersegmented neutrophils and teardrop cells, consistent with B12 deficiency. Once decreased nutrient intake and malabsorption are ruled out, autoimmune processes are considered. Pernicious anemia is an autoimmune disease with peak onset at age 60, which results in decreased B12 absorption. It is most commonly associated with anti-intrinsic factor antibodies, but patients may only have anti-parietal cell antibodies. Serum gastrin may be elevated, while pepsinogen is often decreased. Patients may have co-morbid autoimmune diseases such as thyroid abnormalities or vitiligo. Less common causes of megaloblastic anemia including tropical sprue and Diphyllobothrium latum infection should be considered if travel history is appropriate. In older patients, myelodysplastic syndrome is possible and may warrant bone marrow biopsy. This previously healthy 47 year-old man presents with nonspecific symptoms of weakness and weight loss. He does not have focal neurologic deficits associated with B12 deficiency, but has classic hematologic abnormalities. Prevalence of B12 deficiency increases with increasing age. The classic lesion is subacute combined degeneration of the spinal cord, but more subtle findings such as decreased vibration sense are common. Hematologic and neurologic manifestations may both be present, but either may occur in isolation. Neurologic manifestations are thought to be a late-stage phenomenon, most often occurring after 3–6 months of deficiency. If not treated, damage may become irreversible after 6–12 months. It is important to consider B12 deficiency as patients may only present with nonspecific symptoms, and if untreated, B12 deficiency may result in irreversible neurologic damage.

CLOMIPHENE-INDUCED HYPERTRIGLYCERIDEMIA AND ACUTE PANCREATITIS Sean Iwamoto; Anthony Yin; Susanna Tan; Sara L. Swenson. California Pacific Medical Center, San Francisco, CA. (Tracking ID #1642795)

LEARNING OBJECTIVE 1: Recognize clomiphene's role in male reproductive endocrinology and the mechanism of clomiphene-induced hypertriglyceridemia and acute pancreatitis.

LEARNING OBJECTIVE 2: Distinguish secondary causes of hypertriglyceridemia and acute pancreatitis.

CASE: A 43-year-old male presented to the emergency department with acute epigastric pain, nausea, and vomiting. He had a history of severe hypertriglyceridemia with prior elevations to 1000 mg/dL that had been lowered to normal levels with omega-3 fatty acids and simvastatin. He denied prior episodes of pancreatitis, cholelithiasis, peptic ulcer disease, reflux symptoms, alcohol abuse, and increased fat intake. The patient was hemodynamically stable, and his abdominal examination demonstrated tenderness to palpation in the epigastric region without distension, rigidity, rebound, or guarding. Pertinent initial labs included: lipase of 2702 U/L, total cholesterol of 251 mg/dL, triglycerides of 1099 mg/dL, and glucose of 257 mg/dL. A CT with contrast revealed an acute, mild pancreatitis of the body and tail without necrosis or hemorrhage as well as fatty liver and a normal biliary tree and gallbladder. The patient received antiemetics, aggressive intravenous fluids, analgesics, and bowel rest. We discontinued his home clomiphene. By day 2, his triglycerides and lipase had decreased to 341 mg/dL and 413 U/L, respectively. The patient was discharged on gemfibrozil and a higher dose of omega-3 fatty acids and counseled to stop clomiphene and abstain from high fat and cholesterol-rich foods and alcohol.

DISCUSSION: This case illustrates a rare association between clomiphene and both hypertriglyceridemia and acute pancreatitis. Our patient had been taking clomiphene for hypoandrogenism for 4 months prior to presentation. Although he had a history of hypertriglyceridemia, his triglyceride level had been normal for at 1 year. Clomiphene, a selective estrogen receptor modulator, stimulates gonadotropin release from the anterior pituitary by inhibiting testosterone aromatization to estrogen and metabolization to dihydrotestosterone via 5alpha-reductase. It is indicated for ovulation induction in females with ovulatory disorder or polycystic ovary syndrome. It has also been administered to treat male oligospermia and hypoandrogenism secondary to hypogonadism. Our literature review found only four case reports describing hypertriglyceridemia and/or acute pancreatitis following clomiphene treatment, all involving women. This may be the first reported case in a man. Clomiphene is proposed to exacerbate hypertriglyceridemia, especially in patients with familial

hypertriglyceridemias. Proposed mechanisms include: 1) increasing hepatic production of triglyceride-carrying very low density lipoproteins, 2) decreasing triglyceride clearance by reducing the levels of lipoprotein lipase and hepatic lipase, and 3) augmenting insulin resistance. Clomiphene has mixed estrogen agonistic effects but is mainly antagonistic. Its chemical structure resembles that of tamoxifen, another estrogen analog that has been shown to increase triglyceride levels and cause acute pancreatitis. Other medications or disease states that elevate triglyceride levels and can lead to acute pancreatitis include corticosteroids, beta-blockers, diuretics, isotretinoin, protease inhibitors, hyperestrogenemia of pregnancy, poorly controlled diabetes, hypothyroidism, multiple myeloma, systemic lupus erythematosus, lymphoma, and alcohol excess, all of which were absent in our patient.

CLOPIDOGREL HYPERSENSITIVITY REACTION AFTER PLACEMENT OF A DRUG-ELUTING STENT Saifullah Nasir[1,2]; Jeffrey T. Bates[2,1]. [1]Baylor College of Medicine, Houston, TX; [2]Houston VAMC, Houston, TX. (Tracking ID #1640757)

LEARNING OBJECTIVE 1: Recognize thienopyridine-induced drug reactions in patients who have undergone a percutaneous coronary intervention with stent placement.
LEARNING OBJECTIVE 2: Manage thienopyridine-induced drug reactions in patients who have undergone a percutaneous coronary intervention with stent placement.
CASE: A 65-year-old Caucasian male with a history of coronary artery disease was admitted with acute coronary syndrome. He underwent a percutaneous coronary intervention (PCI) with placement of an everolimus drug-eluting stent and was discharged on dual anti-platelet therapy with aspirin and clopidogrel. He returned 6 days later with a skin rash. He had not taken clopidogrel previously; there had been no other changes to his medications. He had neither recent travel or camping history nor recent changes in his diet. His vital signs were normal. His rash was morbilliform, fixed, pruritic, and located throughout his anterior trunk, back, and thighs. There was no involvement of mucous membranes or airway compromise. Laboratory studies, including a CBC, were normal; there was no peripheral eosinophilia. During his three-day admission to the hospital, we did not discontinue his clopidogrel; he was treated with loratadine, ranitidine, diphenhydramine, and prednisone at 1 mg/kg. His rash resolved within 24 h of initiation of treatment; he was discharged on these medications with a 15-day taper of prednisone. At post-discharge follow-up visits at both 1 week and 1 month he continued to be asymptomatic.
DISCUSSION: Clopidogrel hypersensitivity reactions present clinicians with the dilemma of how to continue dual anti-platelet therapy in patients who have recently undergone a stent placement. Although not widely reported, clopidogrel hypersensitivity has been documented to be as high as 1.6 %. In this case we were able to successfully continue clopidogrel in a patient with a clopidogrel allergy by transiently employing both steroids and histamine receptor blockers. This method has been described in the literature as a safe way to manage patients with a cutaneous reaction but without airway angioedema or a desquamating (Stevens-Johnson type) reaction. Another option might be to substitute a non-thienopyridine such as ticagrelor. Different thienopyridines such as prasugrel and ticlopidine may have significant cross-reactivity in patients with a clopidogrel allergy and should not be given. Clinicians need to be prepared to recognize and manage thienopyridine-induced drug reactions, as dual anti-platelet therapy remains necessary in patients who have undergone a recent PCI.

CLOZAPINE INDUCED ACUTE COLONIC PSEUDO-OBSTRUCTION David Weir; Casey R. Benton. Mount Sinai, New York, NY. (Tracking ID #1617891)

LEARNING OBJECTIVE 1: To recognize the signs and symptoms of acute colonic pseudo-obstruction or Ogilvie's syndrome
LEARNING OBJECTIVE 2: To review the physiology and management of acute colonic pseudo-obstruction
CASE: A 26-year-old man with a history of paranoid schizophrenia presented to our emergency department with fever and altered mental status after recent initiation of clozapine therapy. He was unable to give a coherent history because of his mental status. His vital signs were notable for a temperature of 39 C, pulse of 144, and blood pressure of 86/48. A chest radiograph was unremarkable, and laboratory studies revealed a WBC of 9,800 with 40 % bands, CPK of 2977 U/L, lipase of 810 U/L, ALT of 86 U/L and AST of 116 U/L. He required endotracheal intubation for airway protection and his hypotension improved with IV fluids and antibiotic therapy. On hospital day 2 he developed increasing abdominal distension and rigidity. A CT scan with oral contrast revealed a diffusely distended large bowel to 11.8 cm with air-fluid levels and no transition point consistent with Ogilvie's syndrome. Colonoscopic decompression showed inflammation and ischemia throughout the transverse and descending colon with some superficial ulcerations but no overt perforation, however, clinically he failed to improve. Given the concern for ischemia he was taken to the operating room for a laparotomy which revealed multiple transmural ulcerations and two contained perforations.
DISCUSSION: The gastrointestinal (GI) side effects of psychotropic medications are commonplace and vary from mild dyspepsia to life-threatening illnesses. Clozapine, an atypical antipsychotic, has been shown to be effective in patients with treatment-resistant schizophrenia. Well known for the life threatening side effect of agranulocytosis, more common and equally serious are the myriad of GI reactions. Constipation associated with clozapine occurs in 15–60 % of patients while acute obstruction remains relatively uncommon. Acute colonic pseudo-obstruction (Ogilvie's syndrome) is the dilation of the colon and symptoms of obstruction without a mechanical cause of obstruction. This condition is frequently associated with medications, infection, metabolic disturbances, and trauma or surgery. In a series of 22 cases of clozapine induced GI hypomobility the most common clinical findings were abdominal pain and distension in 55–73 % and vomiting or constipation in 45–55 % of patients. The pathophysiology of Ogilvie's syndrome is thought to be a result of unbalanced autonomic innervation of the gut. Clozapine has been implicated via both its anticholinergic and antiserotonergic properties. It's a high-affinity antagonist for 5-HT3 receptors which reduce colon transit time and reduce intestinal sensitivity to distension. Treatment of Ogilvie's syndrome includes both surgical and medical interventions. In the presence of ischemia, perforation, or cecal volvulus surgery is first-line therapy. In their absence conservative management can be considered by keeping the patient NPO, NG and rectal tube suctioning, correction of electrolyte disturbances, and treatment of reversible causes. If unsuccessful, a trial of neostigmine should be considered and if this fails colonoscopic decompression should be attempted. In the absence of a response to conservative medical, pharmacologic, and endoscopic interventions surgical decompression should be pursued. This case illustrates an under recognized and often life-threatening complication of clozapine therapy.

COGNAC ENEMA MIMICKING ACUTE ISCHEMIC COLITIS Giovanna Rodriguez; Prashant Sharma; Francesco Notar. New York Methodist Hospital, Brooklyn, NY. (Tracking ID #1642454)

LEARNING OBJECTIVE 1: Recognize the clinical features of patients using alcohol enemas
LEARNING OBJECTIVE 2: Manage patients with severe colonic mucosal damage from alcohol enemas
CASE: A 57 year-old male with a history of obesity with laparoscopic adjustable gastric band, hypertension, and dyslipidemia presented because of a 1 day history of rectal bleeding associated with nausea, left lower quadrant (LLQ) pain, and tenesmus. He self-administered a cognac enema a day earlier but did not reveal this on admission. He denied fevers, chills, or diarrhea and had no recent travel history or sick contacts. A colonoscopy 2 years earlier for cancer screening showed normal results. He denied recreational drug use and smoking, but admitted to occasional alcohol use. Physical examination was benign except for LLQ tenderness and guaiac-positive stools. Blood test results were pertinent for leukocytosis of 15,000/mm3 on admission. Lactate, stool culture and PCR for Clostridium difficile

were negative, while stool was positive for WBCs. Abdominal x-ray showed dilated small bowel loops in the left abdomen, and CT with contrast showed colonic thickening of the entire colon. The patient revealed the next day that he had used an unspecified amount of a cognac enema intentionally before sexual relations with his wife. Sigmoidoscopy showed moderate colitis with erythema, scattered ulcerations, and a 2 cm laceration in the distal rectum. Histopathology showed edema and hemorrhage in the lamina propia and superficial necrosis, and was interpreted as "consistent with acute ischemic colitis". He was initially treated with intravenous ciprofloxacin and metronidazole, given his leukocytosis, WBCs in stool and colitis seen on imaging. Once the self-administered an alcohol enema was acknowledged, antibiotics were discontinued and he received mesalamine orally and rectally, with resolution of symptoms.
DISCUSSION: Identifying patients who use alcohol enemas requires a high index of suspicion. There are no identifiable features that can be recognized early on admission, so as to avoid going through extensive, expensive and even avoidable work up. The clinical characteristics include an afebrile patient with bright red blood per rectum, tenesmus, negative lactate, negative stool work up, evidence of colitis on imaging, endoscopic evidence of colitis and superficial mucosal damage on histopathology. It is unknown how common the use of alcohol enemas is, but there are some isolated incidents in the news. For example, a college student was found to have a blood alcohol content (BAC) of 0.4 % in 2012 after a fraternity party, while in 2004 a woman gave her husband 2 bottles of sherry per rectum, which raised his BAC to 0.47 % and led to his death. Alcohol is known to cause severe mucosal damage, which can mimic acute ischemic colitis. In laboratory animals, the changes demonstrated by alcohol throughout the gastrointestinal tract include epithelial disruption, vascular congestion, lymphatic damage. Seven cases of colonic damage caused by alcohol enemas have been reported, either accidentally or intentionally, and despite the severity of mucosal damage, all patients recovered within a week of conservative management.

COLONIC SCHISTOSOMIASIS AS INCIDENTAL FINDING IN A PEDUNCULATED POLYP. Ahmad Aldeiri; Abdallah Kobeissy; Osama Alaradi. Henry Ford Hospital, Detroit, MI. (Tracking ID #1638280)

LEARNING OBJECTIVE 1: Diagnose Schistosomiasis in a colonic polyp.
CASE: A 50 year old man was referred to outpatient gastroenterology clinic for evaluation of chronic abdominal discomfort and intermittent rectal bleeding. The patient is originally from Yemen, but he moved to the United States more than 40 years ago. There was no personal or family history of colon cancer or bleeding. His physical examination was normal with no signs of portal hypertension. Further laboratory tests showed a white blood cell count of 10,400/mm3 (4000–11,000/mm3) with 5 % eosinophils (0.5–4 %). There was no evidence of anemia, or abnormal liver and kidney function tests. Upper endoscopy revealed hiatal hernia but no evidence of ulcer or mass. Colonoscopy demonstrated a single pedunculated polyp (5–9 mm in size) in the transverse colon without any stigmata of bleeding. The polyp was completely removed by hot snare. Medium-sized hemorrhoids were also seen in the anus during the procedure. Pathologic examination showed colonic mucosa with edema and non-caseating granulomas surrounding foreign-body type material consistent with schistosomiasis. The patient was treated with a 1 day course of praziquantel 60 mg/kg.
DISCUSSION: Schistosomiasis is an endemic disease in South America, Africa, Asia and the Middle East, affecting over 200 million people worldwide. Intestinal schistosomiasis is rarely reported in the United States, and is exclusively seen among travelers from endemic areas. Two species of schistosomes commonly produce intestinal disease: Schistosoma mansoni and japonicum. Colonic schistosomiasis occurs due to deposition of schistosoma ova in submucosa producing inflammatory reaction and granuloma formation, which can result in ulceration, bleeding, microabscess formation, and can also give rise to polyps and result in neoplastic transformation. On colonoscopy mucosa may appear normal, edematous, with petechial hemorrhage in acute schistosomal disease, and flat or elevated yellow nodules, polyps in chronic schistosomiasis.

COMA: HYPERTHYROID OR HYPOTHYROID. Pakhadi Buddhadev; Mihir S. Shah. St Francis Hospital, Evanston, IL. (Tracking ID #1635012)

LEARNING OBJECTIVE 1: Thyroid storm is a severe form of thyrotoxicosis that usually presents with tachycardia, fever, seizures, vomiting, diarrhea or arrhythmia. It can also present with atypical features like apathy and coma. If not treated aggressively, it can be rapidly fatal. We present such a case which was a diagnostic challenge.
CASE: An 87 year old gentleman presented to the ER with nausea, vomiting and fever. He complained of feeling weak since the past 1 week. Past medical history was significant for Diabetes Mellitus type 2, hypertension, CHF, pacemaker placement and stroke. He had no history of thyroid disease in the past. Within 2 h of being admitted, he became incoherent, and confused. He was transferred to the ICU for evaluation of encephalopathy. In a few minutes he slipped into coma and was intubated to protect his airways. His pulse was 124/min, regular, BP 138/68 mmHg, RR 24/min, temperature 100.4 F, and saturating at 98 %. On physical exam he was sweating diffusely, pupils were reactive to light; neck showed a prominent thyroid gland, heart, lung and abdomen exam was normal. Laboratory tests revealed blood glucose of 145 mg/dl, a normal renal and liver panel, and normal cardiac markers. Hemoglobin was 10.5 gm/dl, WBC 5.8, HgA1C 6.7 %, BNP 2032 pg/ml (normal<100), HbA1c 6.8, TSH<0.005 uIU/ml (normal, 0.4–5.4), Free T4 5.36 ng/dl (normal, 0.70–2.0), T4 19 μg/dL(normal, 4.6 to 12.0 μg/dL), T3 407.5 ng/dl (normal, 80 to 200 ng/dL), free T3 14.1 pg/ml (normal 1.70–4.20), TSI 1298 %(normal<130 %), TPO antibody 14 IU/ml (normal<35). Repeat TFT showed same results. EEG was suggestive of encephalopathy, CT head showed old infarct. Ultrasonography of thyroid showed diffuse thyromegaly and increased vascularity. A diagnosis of thyroid storm was made and patient was started on Propylthiouracil, Lugol's iodine, propranolol and methylprednisone. Our patient gradually improved and was extubated on day 8 of admission. He was coherent and back to baseline. He was discharged to a rehabilitation center. On follow up I123 uptake scan was done which showed 60 % uptake.
DISCUSSION: Apathetic thyrotoxicosis is an exceedingly rare presentation of thyroid storm. The clinical picture is of apathy rather than hyperactivity and cardiovascular manifestations may predominate, tachycardia is almost always present. Although this is a disease of the elderly, it has been reported in all age groups. Our search revealed only a few case reports of elderly hyperthyroid patients presenting with apathy and coma during thyroid storm. Almost all report improvement in mental status after antithyroid therapy. Our patient's mental status was assessed daily by holding sedation every morning; there was good correlation between mental status and thyroid hormone levels. Our case is a little unusual since we did not have elevated TSI or TPO levels. We want to present this case to highlight that in elderly individuals, checking the thyroid hormone levels is important and the presence of atypical features like apathy or coma should not defer one from contemplating the diagnosis.

COMMON VARIABLE IMMUNODEFICIENCY: AN UNCOMMONLY DIAGNOSED DISORDER IN COMMON POPULATION Hirva Mamdani; Diane L. Levine. Wayne State University, Detroit, MI. (Tracking ID #1640760)

LEARNING OBJECTIVE 1: Recognize Common Variable Immunodeficiency as an uncommon yet possible cause of recurrent infections.
CASE: A 25 years old African American man presented with fever, productive cough, and shortness of breath with chest X ray showing consolidation in the left lower lobe. He was treated for community acquired pneumonia with appropriate antibiotics. Two months later, the patient returned to the hospital with similar complaints and chest X-ray showing left upper lobe consolidation. Patient had history of multiple hospitalizations in the preceding years for pneumonia involving different locations (one of which was associated with H. influenza bacteremia which is very rare in this age group in the context of pneumonia). CT thorax during each episode revealed consolidation in different locations along with stable

mediastinal, bilateral hilar and subcarinal lymphadenopathy. A transbronchial lung biopsy during past admissions revealed patchy interstitial thickening with fibrosis and acute neutrophilic inflammatory infiltrates. Recurrent infection with encapsulated organisms (H. influenza and Strep pneumoniae) raised the possibility of humoral immune deficiency which was further reinforced by indeterminate rapid HIV test (an antibody mediated response based test). This fact prompted us to check immunoglobulin levels which revealed very low IgG, A, M and E levels with low CD 19 (mature B cell marker) consistent with the diagnosis of Common Variable Immunodeficiency. CD3 (T cell marker) and CD56 (natural killer cell marker) were normal. Anti pneumococcal antibody titer was also negative indicating deficient immune response to previous infections/immunizations. HIV quantitative RNA was un-detectable. Hilar lymphadenopathy on previous CT scans can be secondary to infectious process or be a part of CVID associated non sarcoid granulomatous disease/lymphoma. Patient was treated with antibiotics and given IV Immunoglobulin infusion.
DISCUSSION: Common Variable Immunodeficiency (CVID) is a primary immunodeficiency disorder characterized by impaired B cell differentiation with defective immunoglobulin production. The condition affects about 1 in every 25,000 individuals, involves multiple organ systems, and typically remains undiagnosed for 5 to 7 years after the onset of symptoms. Although recurrent infections warrant testing for common conditions like HIV and cystic fibrosis, uncommon conditions such as common variable immunodeficiency should also be included as a part of differential diagnosis. Having a high index of suspicion for humoral immune deficiency when confronted with recurrent infections with encapsulated organisms, especially when associated with bacteremia, could have led to earlier diagnosis, avoidance of multiple invasive investigations, and early institution of appropriate treatment in this patient.

CONNECTING THE DOTS: CUSHING'S SYNDROME AND ANTERIOR MEDIASTINAL MASS Lena Scotto; Yukako Honda; Susanna Tan; Melissa E. Weinberg; Sara L. Swenson. California Pacific Medical Center, San Francisco, CA. (Tracking ID #1631570)

LEARNING OBJECTIVE 1: Recognize thymic neuroendocrine carcinoma as a rare cause of an anterior mediastinal mass and Cushing's syndrome.
LEARNING OBJECTIVE 2: Treat thymic neuroendocrine carcinoma and the symptoms and complications of ectopic Cushing's syndrome.
CASE: A 31 year old gentleman with past medical history of testicular cancer status post orchiectomy presented to an outside hospital with shortness of breath caused by hypertensive emergency and pulmonary edema. A CT angiogram of the chest demonstrated a 5.5×6.4×5.1 cm anterior mediastinal mass that encircled and narrowed the left innominate vein, as well as elevation of the right hemidiaphragm. Once stabilized, he was transferred to our hospital for work-up of his mediastinal mass. He described a 40 lb weight gain, multiple rib fractures after minimal trauma, and sensation of substernal "bulge" for 1 year. On physical exam, he exhibited a moon face, gynecomastia, dorsocervical fat pad, truncal obesity, abdominal striae, and muscle wasting. His clinical presentation in the context of the mediastinal mass raised concern for Cushing's syndrome caused by ectopic ACTH production. Morning cortisol was elevated at 61.5 μg/dL, ACTH at 190 pg/mL, and urine free cortisol at 4738.9 μg/24 h (urine creatinine 2.07 g/24 h). An 8-mg overnight high-dose dexamethasone suppression test confirmed ACTH-dependent Cushing's syndrome with a post-test morning cortisol of 60.2 μg/dL and ACTH of 277 pg/mL. His high ACTH level suggested an ectopic source. A CT-guided needle core biopsy of the mass demonstrated features most consistent with thymic neuroendocrine carcinoma, focally varying from well-differentiated (carcinoid) to poorly differentiated (small cell carcinoma). Given possible phrenic nerve and vasculature invasion, the patient was not a surgical candidate. His hospitalization was complicated by diabetes mellitus, hypokalemic alkalosis, depression, and hypertension necessitating eight anti-hypertensive medications. Ketoconazole was initiated for management of ectopic Cushing's syndrome. He was treated with cisplatin, etoposide and fosaprepitant and discharged with plans for continued outpatient chemotherapy and radiation.
DISCUSSION: An ACTH-producing neuroendocrine thymic tumor is a rare cause of both Cushing's syndrome and an anterior mediastinal mass. Approximately 92 cases have been reported in the literature since 1980. The peak incidence is in the second to fourth decade, with a ratio of men to women of 1.5:1. Our case illustrates how the co-existence of two entities—Cushing's syndrome and mediastinal mass—can make an otherwise rare diagnosis very plausible. ACTH-dependent Cushing's syndrome was diagnosed by extremely elevated serum ACTH and 24 h urine free cortisol and by failure to suppress serum ACTH and cortisol with dexamethasone administration. While surgery is the treatment of choice, patients with locally infiltrative tumors or metastasis, such as our patient, are not surgical candidates and less established treatment with chemotherapy and/or radiotherapy is pursued. As evidenced by our patient, management of Cushing's symptoms, especially hypertension, presents a significant challenge. Hypertension caused by elevated cortisol does not respond well to typical anti-hypertensive medications, but may respond to spironolactone, ARBs/ACE inhibitors and ketoconazole. Treatment of patients with thymic neuroendocrine tumors requires close follow-up and careful medication adjustments as the tumor shrinks and symptoms diminish.

CONSERVATIVE ANTICOAGULATION FOR ATRIAL FIBRILLATION IN THE ELDERLY: A CASE, A WARNING AND A LITERATURE REVIEW Kamesh Sivagnanam; Dhara Chaudari; Mohammad Al Madani; Atif Saleem; Kais Al-Balbissi. East Tennessee State University, Johnson City, TN. (Tracking ID #1642136)

LEARNING OBJECTIVE 1: Clinicians should be less conservative with anticoagulation of AF in the elderly given substantial benefit. Risks must be evaluated on a case by case basis without prejudice.
LEARNING OBJECTIVE 2: Multiple studies have shown that age related fall risk is usually not a contraindication for anticoagulation as benefit substantially outweighs risk in most situations.
CASE: A 91 year old lady with chronic atrial fibrillation on digoxin but not anti-coagulated for fall risk, congestive heart failure on furosemide, hypothyroidism on levothyroxine and normal renal function presented with complaints of persistent diarrhea for 3 months that was exacerbated for 1 day. Patient also had diffuse abdominal pain, dyspnea, chest pain radiating to her throat, dry cough, lightheadedness, vomiting and palpitations. Examination revealed rapid irregularly irregular heart rate, mild hypotension, crepitations in lung bases and diffuse abdominal tenderness. There were non specific ST segment changes on the electrocardiogram. Labs revealed elevated troponins (0.15 ng/ml->0.39 ng/ml->0.43 ng/ml) and positive stool hem-occult. Gastrointestinal work up was negative for inflammatory bowel. Chest X-Ray showed small pleural effusions and atelectasis versus pneumonia. CT scan of the abdomen with contrast showed thickened walls of the intestinal loops (~1 cm), a clot in the superior mesenteric artery and bilateral renal subacute infarcts. Echocardiogram was baseline. A diagnosis of atrial fibrillation with rapid ventricular rate, non- ST elevation myocardial infarction (NSTEMI) and mesenteric ischemia was made. Patient was admitted and started on fluids, IV heparin and empiric antibiotics and was kept Nil per oral. A Cardiology consult was placed and no further interventions were recommended for a non-coronary troponin elevation. Gastroenterology recommended conservative management with continued anticoagulation with chronic warfarin and heparin for bridging. With time, patient's symptoms improved. She tolerated a diet and was eventually discharged to an assisted living facility with a therapeutic INR.
DISCUSSION: There exists a great discrepancy between evidence based medicine and clinical practice in the realm of anticoagulation for atrial fibrillation(AF) in the elderly. History of falls, mild bleeding risk and mental status are often used as excuses for not anticoagulating a patient. In the above patient, not anticoagulating atrial fibrillation was the primary culprit causing thromboembolism to the kidneys and bowel. She also had a component of chronic ischemia of the bowel (bowel thickening on CT, prolonged symptoms) secondary to chronic thromboembolism. Multiple studies have observed clinicians taking a conservative approach to anticoagulating AF in the elderly although they constitute the group that derives the most benefit from anticoagulation. Meta-analyses have shown

that a patient needs to have close to 300 falls in a year for the risk of anticoagulation to outweigh benefit. Treatable bleeding risk and age are not justifiable reasons for withholding anticoagulation.

CONSTIPATION AS A PRESENTATION OF PERNICIOUS ANEMIA Rebecca Witt; Sara Wikstrom. George Washington University, Washington, DC. (Tracking ID #1644082)

LEARNING OBJECTIVE 1: Recognizing significant constipation as a unique presentation of pernicious anemia
CASE: An otherwise healthy 48 year-old woman presented to our hospital with 5 weeks of constipation. She reported having only 1–2 bowel movements per week and stated that they required significant straining. A high fiber diet, stool softeners and enemas did not provide any relief. She denied any melena or hematochezia. She denied abdominal pain but endorsed significant rectal pain for 3–4 weeks that initially occurred only with defecation but then became constant. Review of systems was positive for a 30-lb weight loss over 6 weeks, but no fevers or night sweats. Her vital signs were significant for a heart rate of 125 with a blood pressure of 119/80. Physical exam was significant for pale conjunctiva, anicteric sclera and yellow oral mucosa with petichiae. Her abdomen was soft, non-tender and non-distended. Bowel sounds were normal. Rectal exam revealed stool in the rectal vault but was negative for masses or hemorrhoid. Stool guaiac was negative. Extremity, neurologic, and skin exams were normal. Initial labs were significant for Hb 3.8 and Hct 12.1, MCV 100, WBC 2.41, platelet 55. Total bilirubin was 2.3, direct was 0.0. Workup for hemolysis revealed a reticulocyte index of 0.3, LDH of 10,582, undetectable haptoglobin, and negative DAT. The peripheral smear revealed poikilocytosis, tear drop cells, occasional nucleated RBCs and dysplastic WBCs. HIV, hepatitis, and parvovirus studies were negative. Her vitamin B12 level was <159. Blood flow cytometry was normal, and the patient declined a bone marrow biopsy. Gastric parietal cell antibody was elevated at 47.6 units (nl <=20.0) and qualitative study for intrinsic factor blocking antibody was positive. She was diagnosed with pernicious anemia and discharged on vitamin B12 supplementation. Two weeks later she followed up in clinic where her CBC had nearly normalized.
DISCUSSION: Our patient presented with significant pernicious anemia. Interestingly, she also presented with a unique but previously described symptom of vitamin B12 deficiency: constipation. The hematologic abnormalities in B12 deficiency are secondary to a failure in DNA synthesis. Cobalamin is a co-factor in the conversion of homocysteine to methionine, which is necessary for DNA synthesis and normal neural function. In cobalamin deficiency, abnormal fatty acids may accumulate in myelin or methylating reactions may be defective. Damage to the posterior columns of the spinal cord gives rise to paresthesias, sensory loss and ataxia. Damage to the corticospinal tracts presents with weakness, spasticity, and hyperreflexia. It is conceivable that the enteric nervous system can be affected by similar mechanisms leading to autonomic dysfunction of the gut, which would manifest as a motility disorder such as constipation. Other symptoms of autonomic dysfunction associated with vitamin B12 deficiency are impotence, urinary incontinence and orthostatic hypotension. In fact, 35 % of cases of vitamin B12 deficiency are associated with some form of autonomic dysfunction.

CORD COMPRESSION: AN ONCOLOGIC EMERGENCY NECESSITATING PROMPT AND EVIDENCE BASED INTERVENTION Jeffrey V. Brower[1]; Gary Schreiber[2]. [1]St.Francis Hospital, Evanston, IL; [2]St. Francis Hospital, Evanston, IL. (Tracking ID #1622177)

LEARNING OBJECTIVE 1: To recognize the presentation of spinal cord compression.
LEARNING OBJECTIVE 2: To assess and manage cord compression in a timely and evidence based manner.
CASE: 63 yo male presented with complaints of numbness and weakness in bilateral lower extremities from mid-thigh to pedal plantar surface × 2 days. He also endorsed abdominal bloating with absence of bowel movement × 3 days and inability to void urine × 1 day. He reported hemoptysis with mild SOB as well as 10 lb weight loss over the last 1 month. Denied other constitutional symptoms, hemi-weakness or N/V. Endorsed 10 pack/year history of smoking. On physical examination he was awake, alert and appeared cachectic. Vital signs within normal limits. Neck and axillary exam revealed palpable adenopathy with the largest measuring 2 cm in the right axilla. Cardiovascular; normal rate and rhythm. Lung exam revealed decreased breath sounds left upper lobe. Abdomen; normal bowel sounds, soft slightly distended, non-tender. Rectal exam; normal tone, FOBT negative. Neurologically strength was 5/5 with no sensory deficits bilateral upper extremities, 3/5 bilateral lower extremities with parasthesias from mid-thigh to pedal plantar surface. Reflexes 2+ bilateral upper and lower extremities. Gait was unable to be assessed. The remainder of the neurological examination was within normal limits. Chest X-ray revealed focal consolidation/mass in medial aspect of left upper lung. Lumbar spine MRI demonstrated spondylotic changes without evidence of cord compression. Thoracic MRI revealed an 8.5 cm mass originating in the left upper lung extending into the bodies of T2-T5 with compression at T3-T4 by direct extension into the spinal canal. Radiation Oncology and Neurosurgery were consulted with deferred management to Radiation Oncology due to the extent of local disease. Corticosteroids were initiated and he emergently received 300 cGy of radiation therapy prior to admission. While hospitalized he required Foley catheterization re: urinary retention. Further work-up and evaluation included a biopsy of the right axillary node revealing poorly differentiated squamous cell carcinoma. He subsequently received nine more fractions of 300 cGy for a total of 3000 cGy utilizing anterior and posterior fields. At the completion of palliative radiotherapy the Foley catheter was removed with resumption of bladder control. He had some persistent difficulties with bowel movement and regained minimal function of his lower extremities.
DISCUSSION: Cord compression occurs in 5–10 % of all cancer patients and represents and oncologic emergency requiring rapid and appropriate intervention. Thoracic spine is the most common site of compression from malignancy. This case thus highlights an important presentation for internists to recognize. Radiotherapy is the definitive treatment modality for cord compression along with concomitant steroid administration. Studies have demonstrated that radiotherapy alone provides equivalent results to laminectomy plus radiation and is effective in over 85 % of cord compression cases. Radiation therapy is often incompletely understood by many physicians. Here we will present the evidence-based recommendations for the delivery of radiotherapy and initiation of corticosteroids in order for internists to better understand treatment in the setting of cord compression. We also intend to provide internists the ability to more effectively communicate with radiation oncologists to improve overall patient care.

CORONARY ARTERY DISEASE IN A YOUNG WOMAN WITH TURNER SYNDROME Miriam T. Levine. Wayne State University School of Medicine, Detroit, MI. (Tracking ID #1642521)

LEARNING OBJECTIVE 1: Recognize the increased risk of atherosclerosis and coronary artery disease (CAD) in women with Turner's Syndrome (TS).
LEARNING OBJECTIVE 2: Treat women with TS with hormone replacement therapy (HRT) to reduce CAD risk.
CASE: A 40-year-old woman with TS, hypertension, and obesity presented with a 3-hour history of non-radiating retrosternal chest pressure, dyspnea, diaphoresis, nausea and restlessness. Home medications were chlorthalidone and levothyroxine. She had discontinued HRT 10 years prior. She had no family history of CAD and had never smoked. Admission vitals were T 36.6, BP 142/82, HR 59, RR 20, SpO2 98 %, BMI 31.6. She was diaphoretic and in pain. Cardiac and respiratory exams were normal. EKG revealed STEMI. Cardiac catheterization showed 100 % occlusion of the left anterior descending artery and an ejection fraction (EF) of 25 % with severe apical hypokinesis. A drug-eluting stent was placed and she was started on aspirin, clopidogrel, carvedilol, lisinopril, and rosuvastatin. Lipid profile was LDL 174 and HDL 38. Chest pain resolved and she was

discharged on hospital day 4; however, she was readmitted 2 days later with worsening chest pain. EKG showed ST elevation in leads I and II, V1 and V2. Cardiac catheterization revealed in-stent re-thrombosis despite adherence to antiplatelet therapy. Thrombolysis was performed and clopidogrel was switched to prasugrel. Her EF as per ventriculogram was estimated at 30 % but she had no signs or symptoms of heart failure. She was discharged on hospital day 3 in stable condition.

DISCUSSION: TS is associated with increased CAD risk; this increased risk is multifactorial. TS is associated with an atherogenic lipid profile. A Polish study found women with TS had higher BMI and waist-hip ratios, lower HDL, higher LDL levels, and higher fasting glucose levels. A Danish study noted that women with TS may be twice as likely to develop CAD compared with the general population. Women with TS are also at increased risk of insulin resistance. Type 2 diabetes mellitus is 2–4 times more common in women with TS and tends to develop at a younger age. Impaired glucose tolerance affects 10–34 % of women with TS, including girls as young as 5 years old. Fortunately, the cardiovascular risk profile of young women with TS is modifiable. 24 % of patients discontinue HRT after puberty induction. As HRT improves fat-free mass, waist-hip ratio, and insulin sensitivity, women with TS should maintain HRT until the natural age of menopause. TS patients should also have annual fasting blood glucose and lipid profiles and (as applicable) weight-loss counseling. Some questions remain. The effect of aggressive lipid lowering is unknown. The root cause of increased CAD risk is also still in question. A comparison of women with TS and women with 46,XX karyotype and premature ovarian failure found those with TS had higher LDL and triglyceride levels, and smaller LDL and HDL particle size, than their counterparts. This supports the role of as-yet undetermined genes on the X chromosome and not just hypoestrogenism. Recognizing the increased CAD risk of women with TS is crucial to providing appropriate care. Physicians should provide appropriate counseling about lifestyle modifications, screen for modifiable risk factors, and treat accordingly. They should also encourage patients to remain on HRT until the natural age of menopause. This may decrease morbidity and mortality in TS patients

CRYOFIBRINOGENEMIA: NOT JUST SKIN DEEP. Zahrae Sandouk; Zaid Alirhayim; Syed Hassan; Waqas Qureshi. Henry Ford Hospital, Detroit, MI. (Tracking ID #1617882)

LEARNING OBJECTIVE 1: Recognize the clinical features of cryofibrinogenemia and its relationship with connective tissue disorders.

LEARNING OBJECTIVE 2: Identify the reasons for under-diagnosis and misdiagnosis of cryofibrinogenemia.

CASE: A 61-year-old woman with rheumatoid arthritis presented to the hospital with a four-day history of palpable purpura. They first appeared on her arms and progressed to her thighs and legs. The patient had no other skin lesions or ulcers, no joint or muscle pain. She denied any sick contacts, fever, confusion, bleeding or easy bruising. She had not been taking any new medications or anticoagulants. There was no family history of hematologic disorders. Her examination was significant for numerous large, irregularly shaped purpuric lesions over her lower extremities and buttocks. The lesions were non-tender to palpation and distributed randomly. The rest of her examination was non-contributory. Her disseminated intravascular coagulation profile that included D-dimer, fibrinogen levels and fibrin split products, was negative. A vasculitic work up was done. Skin punch biopsy showed dermal edema with fibrin thrombi within superficial dermal vessels without vasculitis. She left against medical advice before a diagnosis was made. The patient had presented few months earlier with similar symptoms. The working diagnosis was drug-induced rash attributed to hydroxycloroquine. The medication was held, she was given steroids with mild improvement. She returns to the emergency department 2 days later with ischemic necrosis of the skin and sepsis. She was admitted to the intensive care unit, treated with intravenous antibiotics and fluids. Her wounds were debrided. Further laboratory work up showed positive cryofibrinogens and negative cryoglobulins with α2-macroglobulin in her protein panel.

DISCUSSION: Patients with cryofibrinogenemia are usually asymptomatic and sometimes present with purpuric lesions that may complicate into necrosis and sepsis. The prevalence of asymptomatic cryofibrinogenemia is approximately 2 to 9 % of normal subjects. One reason for misdiagnosis is that the presenting symptoms offer a wide differential diagnosis. Although there are no specific criteria for diagnosis, case series have identified common clinical features of the disease to include presence of cryofibrinogens, absence of cryoglobulins, elevated serum levels of α1-antitrypsin and/or α2-macroglobulin, and skin biopsy showing the thrombi in blood vessels. Another aspect for underdiagnosis is the mishandling of blood samples leading to false negative results. Blood should be collected in tubes containing oxalate, citrate, or ethylenediaminetetraacetic acid. After collection, the blood should be stored at 37 °C until centrifuged. Then the plasma should be stored at 4 °C for 72 h. Cryofibrinogens will develop between 24 and 72 h after cooling. There are two types of the disease: essential and secondary cryofibrinogenemia. The most frequently associated disorders include malignancy, infections, inflammatory processes or thromboembolic conditions. Connective tissue diseases, such as rheumatoid arthritis, are strongly mentioned in the literature. Treatment is usually targeted at dissolving these thrombi and may include using fibrinolytic agents such as stanozolol, or immunomodulators such as glucocorticoids and cytotoxic agents. Outcomes are limited to case reports making generalized statements regarding treatment difficult.

DAPSONE INDUCED METHEMOGLOBINEMIA Likhitesh G. Jaikumar. The Cleveland Clinic foundation, Cleveland, OH. (Tracking ID #1643012)

LEARNING OBJECTIVE 1: To recognize and manage patients with drug induced methemoglobinemia.

LEARNING OBJECTIVE 2: To recognize the inadequacy of pulse oximetry and identify Saturation gap and its clinical utility in patients with methemoglobinemia.

CASE: 75 year male with known past medical history of Autoimmune encephalitis on immunosuppressive therapy, seizure disorder, Pulmonary embolism and hypothyroidism was noted to have nocturnal hypoxemia at nursing home. The patient's family also noted oxygen saturations ranging from 80 to 90 at home with associated change in his mental status from baseline. He was brought to the Emergency room for evaluation. His home medications were lamotrigine, Cellcept, Prednisone, Dapsone, Coumadin, Levothyroxine and Finasteride. In the ER his oxygen saturation improved briefly with oxygen but plateaued around 89–92, requiring about 6 l of oxygen via nasal canula. On examination his appeared drowsy without any focal neurological signs. He did not appear to be in any distress except cyanosis of his lips. His cardiac and respiratory exam was unremarkable. His initial lab work including CBC, CMP, LFTs and urine analysis were within normal limits. INR was therapeutic. Chest X-ray and Contrast infused CT per PE protocol was negative. Echocardiogram showed normal Ejection fraction, grade 1 diastolic dysfunction with normal pulmonary artery pressures. He was admitted to medicine floors with diagnosis of hypoxemia and altered mental status. A blood gas analysis revealed methemoglobin level of 13 rising to 16 over the next 6 h and then to 18. He continued to be without any distress but required high flow oxygen to maintain oxygen saturation at 90–93 %. He was admitted to the Medical ICU for observation and Dapsone was held. His methemoglobin levels rose up to 21 % and then slowly declined over a period of 3 to 4 days and did not require methylene blue for treatment.

DISCUSSION: Methemoglobinemia occurs when the iron moiety of hemoglobin is oxidized from ferrous to ferric state, forming MetHb. MetHb renders it incapable of oxygen transport; if severe it leads to tissue hypoxia. Dapsone is a well recognized drug induced etiology for methemoglobinemia. Healthy patients can tolerate low levels of methemoglobin and cyanosis is the first sign of underlying MetHb. However as MetHb levels rise symptoms of dyspnea, headache and dizziness can occur and further rise in levels can lead to arrhythmia, acidosis, seizures, coma and death. Early recognition of methemoglobinemia is vital as withdrawal of the offending agent is the first step in treatment. It is key to recognize that

saturation value by pulse oximetry becomes unresponsive to incremental supplemental oxygen and the concept of 'saturation gap' measured after a blood gas measurement will further assist as a valuable clue along with cyanosis and chocolate colored blood for the diagnosis of methemoglobinemia. Although methylene blue is a treatment option, withdrawal of the offending drug is the mainstay of treatment and clinicians caring for patients receiving Dapsone should be aware of methemoglobinemia. They should also be aware of factors that precipitate, role of co morbidities and should it happen, know how to manage it effectively.

DEADLY ACT OF VANISHING Ankit Madan; Omair Atiq; Pooja Sethi. University of Alabama Birmingham Montgomery, Montgomery, AL. (Tracking ID #1642830)

LEARNING OBJECTIVE 1: Recognize rare occurrence of vanishing bile duct syndrome has been reported in Hodgkin's lymphoma.
LEARNING OBJECTIVE 2: Discuss the importance of initiating chemo radiotherapy in achieving liver-failure free survival.
CASE: 54 year old African American male with history of hodgkin's lymphoma presented with abdominal pain and fever for 1 day. Pain was in left upper quadrant, sharp, non-radiating and associated with subjective fever and non-bloody diarrhea. Sclera was icteric. Vitals Blood pressure 119/63, heart rate 134 and temperature 103.1 F. Abdomen was tender in left upper quadrant. Bowel sounds were decreased without guarding or rigidity. Pertinent labs at admission included total and direct bilirubin 7.6 and 5.3 respectively, AST 139, ALP 305, hemoglobin 6.6, hematocrit 19 and INR 1.75. MRI abdomen revealed hepatomegaly with numerous nodular densities worrisome for diffuse infiltrative liver parenchymal disease without any intra or extra-hepatic biliary duct obstruction. Cultures were negative. Patient was placed on broad spectrum antibiotics, vasopressors and ventilator support from admission but he deteriorated. Total and direct bilirubin kept increasing and reached a maximum of 21.8 and 13.8 respectively. Platelet count decreased to 13,000 and patient needed total 13 platelet transfusions. His creatinine increased to 3.3. We were unable to obtain liver biopsy since patient was critically ill. We decided to treat him with dose modified ABVD(Adriamycin,Bleomycin,Vinblastine and Decarbazine) regimen suspecting vanishing bile duct syndrome. Patient expired the next morning.
DISCUSSION: Vanishing bile duct syndrome refers to a group of acquired disorders resulting in progressive destruction and disappearance of intrahepatic bile ducts and ultimately cholestasis. It is often associated with primary biliary cirrhosis, drugs, infections and neoplastic process. Cholestasis in Hodgkin's disease can be caused by hepatic infiltration by lymphocytes, biliary obstruction, hemolysis, viral hepatitis and toxicity from chemotherapeutic agents. However, cholestasis due to vanishing bile duct syndrome is rare. Literature comes from case reports. The exact mechanism is unknown. However, it is proposed to be due to production of cholestastic cytokines from tumor cells. Due to paucity of cases that develop vanishing bile duct syndrome, its clinical course is not well defined. Definitive diagnosis requires a liver biopsy if possible. Pathology should reveal absence or destruction of intrahepatic bile ducts. Treatment of underlying Hodgekin's lymphoma is of utmost importance if this disease process has to be reversed. This includes ABVD (Adriamycin, Bleomycin, Vinblastine and Decarbazine) or MOPP (Mustargen, Oncovin, Procarbazine and Prednisone) regimen and field radiotherapy. Since patients usually have liver failure, chemotherapy more often needs to be dose modified. There is mixed evidence regarding prognosis. Many case reports have mentioned it to be irreversible carrying a grave prognosis while other authors believe it is potentially reversible with treatment. Our patient expired after initiation of chemotherapy.

DEMENTIA WITH LEWY BODIES: A COMMON COMMONLY MISSED DIAGNOSIS Shobhit Gupta; Leena Jalota; Anthony A. Donato; Robert Freed. Reading Hospital, Reading, PA. (Tracking ID #1641972)

LEARNING OBJECTIVE 1: Recognize the clinical features of lewy body dementia in a patient with acute hallucinations
LEARNING OBJECTIVE 2: Treat a patient with lewy body dementia
CASE: A 75-year-old female on treatment for depression presented to the emergency room for an acute change in mental status initially diagnosed as hyperactive delirium. CT scan and MRI of the brain were unremarkable, and there were no acute laboratory abnormalities. The patient described very well-formed visual hallucinations that began 1 week prior to admission. She also complained of insomnia for many weeks, and her family noted that she was acting out her dreams while sleeping. Repeated mental examination throughout the day revealed significant fluctuations in both her mood and cognition. Mental status exam deficits included domains of language and praxis, but fully intact orientation. Based on this constellation of clinical symptoms she was diagnosed with DLB. A geriatric psychiatry evaluation corroborated the diagnosis. Seroquel was subsequently started, which stopped all hallucinations and stabilized her mood.
DISCUSSION: DLB accounts for 20 % of dementia diagnoses in the US. Studies suggest survival time after diagnosis is shorter for DLB than Alzheimer's disease (7.7 vs. 9.3 years). Classic clinical symptoms for DLB include visual hallucinations, parkinsonism, cognitive fluctuations, sleep disorders, and neuroleptic sensitivity. DLB is commonly misdiagnosed as acute delirium, but can be distinguished from delirium by a proper neuropsychological evaluation. Given these patients' sensitivity to older neuroleptic agents, use of behavioral modifications, cholinesterase inhibitors, and newer atypical neuroleptics in very low doses are recommended to control symptoms.

DEPRESSION AND CAPACITY? AN ETHICAL QUESTION ON AUTONOMY Brian Cruz. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640094)

LEARNING OBJECTIVE 1: Understand the nature of depression and suicidality as limitations to decision-making capacity.
LEARNING OBJECTIVE 2: Recognize the role of surrogates in patients without capacity Recognize that end-of-life wishes prior to a suicide attempt are still valid should a patient lose capacity following a suicide attempt.
CASE: A 55-year-old woman presented after being found unresponsive following a suicide attempt via ingestion of acetaminophen. She initially required intubation for airway protection and vasopressors for hypotension, but she improved over the next few days and was extubated. She expressed regret at trying to end her life. She then developed sepsis and re-intubation was recommended. She refused intubation and requested to be "Do Not Resuscitate/Do Not Intubate" status. Psychiatry was consulted and determined that she did not have capacity to make this decision based on her untreated depression and recent suicide attempt. The patient was re-intubated. The ICU and hepatology teams agreed that she had a poor prognosis and would likely develop other life-threatening conditions. Following re-intubation, she continued to express a desire to discontinue aggressive measures and transition to comfort care, despite the almost certain nature of death. Her three adult children and both parents also wanted her to have comfort care only. They affirmed that, prior to her suicide attempt, she had routinely expressed she would not want life-support. They demonstrated understanding of the medical situation, including the risks and benefits of treatment. The hospital Ethics Committee was consulted. Since her treatment course was likely to require long-standing use of life-sustaining measures with an overall high likelihood of death, it was determined that the patient's wishes in this situation, assuming her decision-making capacity was intact, would be to discontinue life-sustaining treatment and begin comfort measures. Aggressive interventions were stopped and she expired.
DISCUSSION: Decisions regarding end-of-life care are influenced by ethical considerations and legal statutes that the general internist needs to take into account. Autonomy of the individual is a cornerstone of medical ethics, which generally allows a patient to refuse medical treatment. An exception is when a patient has impaired decision-making capacity, which often occurs as a result of a mental illness or suicide attempt. These patients are treated with life-sustaining measures in acute settings, even if they object. However, loss of capacity does not mean that one forfeits autonomy. To determine what the patient's desires would be if she or he had capacity, physicians look to advanced directives or appointed surrogates. The patient in our case had neither; in these cases, states have legal statutes that grant surrogacy to the patient's family members. In the

state of Louisiana, surrogates can decide to withhold and withdraw life-sustaining measures only if the patient is diagnosed as having a terminal and irreversible condition by two physicians4. Our patient's case was not terminable and irreversible; therefore the decision of comfort care was based on what her wishes would have been if she had capacity.

DIABETES INSIPIDUS AS THE PRESENTING MANIFESTATION OF A RARE PITUITARY DISORDER Dustin T. Smith; Jenna Kay; Danielle Jones. Emory University, Atlanta, GA. (Tracking ID #1594529)

LEARNING OBJECTIVE 1: Consider lymphocytic hypophysitis in the differential diagnosis of pituitary masses and hypopituitarism, particularly in peripartum women and those with other autoimmune diseases.
LEARNING OBJECTIVE 2: Recognize that biopsy is the gold standard for diagnosis of lymphocytic hypophysitis but is not required for initiating treatment in the proper clinical context.
CASE: A 47-year-old man with a remote history of stroke presented after a mechanical fall without loss of consciousness. He reported increased thirst and urination as well as headaches without vision changes. Vital signs including orthostatics were normal and physical exam was unremarkable. Visual fields were intact and there was no thyromegaly or skin abnormalities. Laboratory studies revealed hypernatremia with the remainder of the chemistry panel normal. CT of the head showed no acute abnormalities but revealed a 10-mm suprasellar mass not seen on prior imaging. During hospitalization, the patient complained of extreme thirst and consumed up to 15 L of fluid daily. Further studies revealed a urine osmolality of 69 mOsm/kg. Prolactin was borderline elevated and testosterone was low. TSH, GH, IGF-1, cortisol, FSH, LH, and ACTH were normal. MRI of the brain showed an enlarged pituitary gland with thick infundibulum and features of lymphocytic hypophysitis. He received intranasal desmopressin and his urine output decreased. Urine osmolality and serum sodium normalized. The patient was diagnosed with central diabetes insipidus due to lymphocytic hypophysitis and hypopituitarism. Thereafter, he received desmopressin and testosterone replacement with periodic laboratory monitoring.
DISCUSSION: Sellar masses are typically caused by pituitary adenomas and less frequently by other malignant or benign tumors or physiologic enlargement of the pituitary gland. Presenting symptoms/findings include headache, vision changes, hormonal abnormalities, or incidental imaging findings. Lymphocytic hypophysitis is a rare cause of sellar masses and hypopituitarism. It is an autoimmune disorder characterized by a lymphocytic pituitary infiltrate that causes enlargement of the gland and destruction of pituitary cells. It is most often seen in peripartum women. Common symptoms include headache and visual disturbances. Over 1/2 patients have secondary hypoadrenalism. Diabetes insipidus occurs in 1/3 of patients. Concurrent autoimmune diseases such as thyroiditis or systemic lupus erythematosus are common. MRI is the standard imaging modality of the pituitary gland and reveals a pituitary mass, often indistinguishable from an adenoma. In contrast to pituitary tumors, hypophysitis is typically symmetrical and homogeneous with thickened but nondisplaced stalk. In addition, prolactinomas typically are associated with prolactin levels >200 ng/dL. Biopsy is the gold standard for diagnosis but is not required for initiating treatment in the proper clinical context. For this patient, the presentation of diabetes insipidus along with convincing imaging led the medical team to forgo definitive biopsy. In the absence of visual field disturbances, surgical therapy is withheld. Inflammation often resolves spontaneously, and the use of steroids for refractive cases is controversial. Because hypophysitis is rare, no definitive guidelines for treatment exist. Patients should receive appropriate hormonal replacement therapy and long-term serial monitoring for development of other endocrine abnormalities.

DIAGNOSING A PATIENT WITH GRANULOMATOUS DISEASE: BETTER THAN A COIN FLIP? Kimberly M. Tartaglia; Tyler Oostra. Wexner Medical Center at the Ohio State University, Columbus, OH. (Tracking ID #1631198)

LEARNING OBJECTIVE 1: Compare distinguishing characteristics and diagnostic criteria for sarcoidosis and disseminated histoplasmosis.
LEARNING OBJECTIVE 2: Review the risks of treating patients with immunosuppressant medications who have disseminated histoplasmosis.
CASE: A 44 year old man with no past medical history presented with bilateral parotid gland enlargement and xerostomia. Workup revealed cervical and mediastinal lymphadenopathy, and mediastinoscopy with lymph node biopsy showed non-necrotizing granulomas. Additionally, the patient endorsed a 30 lb weight loss over 3 months, and he was noted to have hypercalcemia (Ca=11.5) and acute kidney injury (Cr 2.8 from normal baseline.) While admitted for intravenous hydration and renal biopsy, fungal immunodiffusion showed an H band suggestive of active disseminated histoplasmosis. Renal biopsy revealed granulomatous interstitial nephritis consistent with a diagnosis of sarcoidosis. Before starting systemic steroids for sarcoid renal involvement, additional work-up for histoplasmosis was sent. Fungal blood cultures, urine Histoplasma antigen, fungal complement fixation, and Histoplasma antigen on bronchoalveolar lavage were negative. However, immunodiffusion for Histoplasma was repeatedly positive with an H band. Therefore, itraconazole was initiated prior to starting prednisone.
DISCUSSION: Sarcoidosis and disseminated histoplasmosis are both granulomatous diseases that can have similar clinical presentations and can be very difficult to distinguish in certain patients. Laboratory tests including fungal cultures, antigen testing, immunoserologic tests, and special tissue stains can all be used to help distinguish histoplasmosis from sarcoidosis. In our patient, the diagnosis of sarcoidosis was called into question by positive serologic testing. The immunodiffusion test for histoplasma has a sensitivity of 90 % and is more specific than complement fixation; however there are reports of a positive test in patients with other granulomatous diseases. A previously published case report from our institution discusses a patient with pulmonary histoplasmosis who evolved to develop sarcoidosis. Additionally, there have been numerous other case reports of patients diagnosed with sarcoidosis who have developed disseminated histoplasma infections. Whether sarcoidosis or treatment for sarcoidosis predisposes patients to histoplasma infections is unknown. Immunosuppression is the greatest risk factor for disseminated histoplasmosis; however, approximately 20 % of patients with disseminated histoplasmosis have no risk factors for the disease. Sarcoidosis has no defined etiologic agent but evidence is accumulating that there is a close relationship between histoplasmosis and sarcoidosis. Our case highlights this complex potential relationship and demonstrates the difficulty in distinguishing sarcoidosis from histoplasmosis. With the concern that sarcoidosis may be a risk factor for disseminated histoplasmosis, we recommend treatment with antifungal for patients with evidence of active Histoplasma infection prior to initiating immunosuppressant medications for sarcoidosis.

DIARRHEA IN AN EXPATRIATE: EXOTIC OR ROUTINE? Shing-Yu Lin. Emory University, Atlanta, GA. (Tracking ID #1630112)

LEARNING OBJECTIVE 1: Recognize that Clostridium difficile is a common cause of diarrhea even in unusual cases.
LEARNING OBJECTIVE 2: Understand the clinical presentation of c. difficile.
CASE: A 30 year old American expatriate living in Costa Rica for the past 6 years presents with 2 weeks of diarrhea. He reports watery, non-bloody diarrhea for 2 weeks associated with abdominal pain and fevers. He was seen at a hospital in Costa Rica and treated with Albendazole empirically. His symptoms persisted and he visited an internist who prescribed Levaquin. His temperature increased to 40 °C and came to the United States for further evaluation. Work up from Costa Rica was negative for parasites and bacterial infections including but not limited to E. Coli, Entamoeba histolytica, Giardia intestinalis, Ancylostoma duodenale, Acaris lumbricoides, Enterobius vermicularis, Strongyloides sterocoralis, Taenia saginata. Patient endorsed good food hygiene although he did report drinking from a stream and had eaten some undercooked chicken recently. Upon evaluation he was febrile with a temperature of 39.1 Celsius. Overall he was well developed and well nourished, with a benign abdominal exam. Cardiac exam revealed no murmurs, breath sounds were clear, and skin exam was unremarkable.

Laboratory studies showed WBC of 5.1, hemoglobin of 13.0 gm/dL, platelets of 240, and an unremarkable extended chemistry panel. Stool studies were repeated and negative for salmonella, giardia, campylobacter, shigella, e. coli, vibrio, yersenia, microspordium, ova and parasites. Positive findings include elevated stool lactoferrin and Clostridium difficile. He was treated with Flagyl. His fever and diarrhea subsequently improved and he was discharged home.
DISCUSSION: Clostridium difficile associated diarrhea (CDAD) is characterized by watery diarrhea. CDAD has varying degrees of severity from mild to moderate diarrhea to sepsis and death. Classically, CDAD was described in the health care setting associated with recent antibiotic use. Other risk factors include recent hospitalization, advanced age, and gastric acid suppression. However, an increasing proportion of cases of CDAD are community-associated infections. In our case, the patient presented with fever and diarrhea. The differential diagnosis of acute diarrheal illnesses in adults is broad. It includes a range of infectious processes including exotic parasitic infections, food borne illnesses, viral infections, and CDAD. Our patient's exposure to unfiltered water, undercooked meat, and living in a foreign country sparked an extensive work up to rule out both food borne bacterial infections and parasitic infections seen in a tropical locale. The patient did provided some clues in his history that suggested this diagnosis including the quality of his diarrhea, and use of antibiotics. This case illustrates that a common culprit can still be the cause of disease even in patients with a history of exotic travel and exposures. Physicians need to remember to consider all the causes of diarrhea even when the patient's history is painting a different picture.

DIFFICULTY IN BREATHING AFTER DELIVERY : IS IT SERIOUS? Nattachai Suwachittanont; Thaksa-on Wirotwan. Klaeng Hospital, Rayong, Thailand. (Tracking ID #1639203)

LEARNING OBJECTIVE 1: Recognize postpartum cardiomyopathy in a patient who presents with unexplained dyspnea during postpartum period.
LEARNING OBJECTIVE 2: Outline the management of postpartum cardiomyopathy.
CASE: A 24-year-old woman was presented to emergency department due to acute dyspnea. She was 7 days postpartum from her second pregnancy. She had no previous pulmonary or cardiovascular problem but had preeclamsia during her pregnancy. The patient reported a one-day history of febrile, cough and shortness of breath. On physical examination, she had marked respiratory distress. Her blood pressure was 141/91 mmHg, pulse rate 114 beats per minute, respiratory rate 30 breaths per minute, temperature 38 °C and the oxygen saturation 82 % when the patient was breathing ambient air. There were crakles and wheezing in both lung fields. Cardiac ausculatation demonstrated regular rapid rhythm without any murmur. Pitting edema 2+ was noted on both legs. The remainder of examination was unremarkable. Electrocardiogram showed sinus tachycardia with left ventricular hypertrophy by voltage criteria. Her chest radiograph revealed cardiomegaly, bilateral diffuse infiltration and fluid in right minor fissure. Laboratory data was normal. She was diagnosed as congestive heart failure due to postpartum cardiomyopathy after other causes had been rule out. The patient was given a non-rebreathing mask and 40 mg of furosemide intravenously at emergency department which increased her oxygen saturation up to 91 %. During admission, she received intravenous furosemide, enalapril and spironolactone. The next 4 days, her symptom was improved. Her oxygen saturation was 96 % on room air and chest radiograph showed smaller heart size and decrease pulmonary infiltration. Then she was discharged in stable condition.
DISCUSSION: Postpartum cardiomyopathy (PPCM) is a rare but fatal medical condition. It was reported 1:3,000–1:4,000 of pregnancies with 6–10 % mortality rate. Although there is no definite etiology of PCCM has been claimed, recent studies demonstrate that inflammatory processes, viral infections, autoimmunity and genetic mechanisms are leading hypotheses. Risk factors of this disease include multiparity, advanced maternal age, multifetal pregnancy and preeclampsia. Patients with PPCM usually present with shortness of breath, orthopnea and pitting edema at lower extremities. According to a high number of death rate, clinician should suspect PPCM in any postpartum patient with unexplained dyspnea. Many studies state that there is possibility to misdiagnose PCCM for other diseases like pulmonary embolism or pneumonia. Further investigations, such as chest radiograph, electrocardiogram and echocardiogram, should be obtained as soon as possible in order to make a diagnosis and start the appropriate treatment early at the emergency department. Management of PPCM is similar to that of heart failure with dilated cardiomyopathy. Effective treatment is the use of diuretics, ACEI or ARB, spironolactone and beta-blocker. Targeted therapy, pentoxifylline, intravenous immunoglobulin, immunosuppressive agents and bromocriptine, have shown some benefits but required further studies.

DILEMMA OF PLASMAPHARESIS Zakaria Almuwaqqat. saint francis hospital, Evanston, IL. (Tracking ID #1628954)

LEARNING OBJECTIVE 1: Recognize the clinical features of malignant hypertension and chronic kidney disease with end-organ damage.
LEARNING OBJECTIVE 2: Diagnose secondary thrombotic microangiopathy (TMA) and understand the specificity of low ADAMTS-13 enzyme level in TMA.
CASE: - A 34 year-old Haitian native (immigrated 10 year ago) presented to the ED with 4 weeks history of headache,nausea, vomiting, blurred vision. He reported generalized weakness, exercise intolerance, dyspnea on exertion and frequent urination for several months. PMHX: High BP in a previous screening exam several years ago. Family Hx: Hypertension in siblings Social: Non Smoker, no ETOH or illicit drugs. Meds: None Allergy: NKDA Physical Exam: - Vitals: BP; 274/169, HR; 101/min, Temp; 98 °F, RR 18 min, SpO2; 98 % (on room air), BMI 24.7 kg/m2. General: Alert, Oriented x 3, appeared ill. Lungs: Clear to auscultation bilaterally. Heart: Regular rate and rhythm, S1/S2 (normal), S4 present. Abdomen: Soft, no distention or tenderness, normoactive BS. Extremities: No pretibial edema. Skin: Turgor normal, no skin rash. Neuro: No focal neurological deficits. - Labs Cr: 24.5, BUN 138, HB 10.5, WBC 8.5, plt 80, Trop 0.25, LDH 661, peripheral smear—schistocytes, VWF (ADAMTS) protease activity 65 %. X ray chest normal, Echo : concentric LVH, LVEF 72 %, Impaired LV relaxation, trivial MR, TR. Renal US: total loss of corticomedullary differentiation bilaterally s/o medical renal disease. - In Hospital course The patient was admitted to ICU with the diagnosis of sever uncontrolled HTN, CKD and possible ESRD. BP was controlled with IV labetalol infusion, hemodialysis was initiated on the second day of admission. Initial labs were supportive of TMA; thrombocytopenia, normocytic anemia, elevated LDH and bilirubin, low haptoglobin and schistocytes on blood smear. He initially required transfusion with two units of platelets and one unit of RBC for bleeding from dialysis catheter. TMA accompanied by renal failure and low ADAMTS-13 activity (65 %) raised the suspicion of HUS/TTP and need for plasmapheresis was debated. However, with conservative treatment TMA resolved, hemoglobin and platelet count improved (200 s) the control of BP. He was discharged home with 10 days of hospital stay
DISCUSSION: - TMA(thrombotic microangiopathy) represents a final common pathway of multiorgan microvascular thrombosis; in this case report the patient developed severe hypertension and had evidence of hemolysis (MAHA) and thrombocytopenia, the overall clinical picture was supportive of TMA secondary to malignant hypertension, the robust response to platelet transfusion and BP control assisted in confirming the diagnosis. - ADAMTS-13 (von Willebrand Factor (vWF)-cleaving protease) is an enzyme responsible for degrading vWF multimeres. Severe deficiency or inhibition of this enzyme can be associated with congenital thrombotic thrombocytopenic purpura (TTP) and acquired TTP respectively. A recent study showed an association between reduced ADAMTS-13 activity and malignant hypertension, future studies should be directed toward functional characterization of this molecule and its role in TTP.

DIZZINESS IN THE ELDERLY…NOT JUST ORTHOSTASIS Abigail Gass; Anne Drabkin Schade; Tara Rickard. Medical University of South Carolina, Charleston, SC. (Tracking ID #1632484)

LEARNING OBJECTIVE 1: Presentation and diagnosis of atlantoaxial subluxation.

LEARNING OBJECTIVE 2: Differential diagnosis of dizziness in the elderly.
CASE: 73 year old AAM with PMH notable for RA, HTN, ESRD secondary to urate nephropathy and moonshine presented with a 2 month history of dizziness when standing. He was admitted to the hospital approximately 2 month prior with similar symptoms and treated for malnutrition and electrolyte abnormalities. His dialysis had been decreased by 1 kg without improvement. He reported being able to walk only a few steps before feeling like he was going to pass out. When he laid flat his symptoms resolved, but returned with sitting or standing. PE was notable for positive orthostatic hypotension, severe ulnar deviation of fingers and toes, chronic swan necking and boutonniere deformites with subluxation, chronic large tophaceous deposits on the elbows, and resorption of left 5th finger. Neuro exam was notable for normal sensorium, CN II-XII grossly intact, strength 4/5 bilateral lower extremities and 5/5 bilateral upper extremities, normal muscle tone, decreased muscle bulk in calves, 1+ reflexes throughout, normal sensation. Initial DDX included volume depletion, autonomic dysfunction, drug side effect, or structural heart abnormality. Given history of decreased oral intake and positive orthostasis, the patient was gently hydrated without significant improvement in his symptoms. CT head was performed, with subsequent MRI, indicating basilar invagination of the dens through the foramen magnum compressing the brainstem and basilar artery. There was noted to be at least 7 mm of invagination.
DISCUSSION: Atlantoaxial instability is characterized by excessive movement at the junction between the atlas (C1) and axis (C2) as a result of either bony or ligamentous abnormalities. AAI is defined as an atlantodens interval of greater than 3 mm in adults. Symptomatic AAI occurs when subluxation or dislocation causes the odontoid process or posterior arch of the atlas to impinge on the spinal cord and cause neurologic manifestations. Because it is a disease that affects synovial-lined joint, RA can manifest itself in the upper cervical spine. The rheumatoid pannus and associated inflammation can weaken the transverse ligaments, alar ligaments, and facet capsules. Neurologic manifestations include clumsiness, lack of coordination, abnormal gait, difficulty walking, easy fatigability, neck pain, limited neck mobility, upper motor neuron signs, paraplegia, and occipital headache. The earliest and most common symptom of cervical subluxation is pain radiation superiorly towards the occiput. In addition, vertebral artery insufficiency has been reported as a result of the tortuous path of the artery at the atlantoaxial articulation. Most abnormalities of C1–C2 articulation can be identified by radiography. Occult instability can be identified on flexion-extension view on standard plan film. CT and MRI can provide additional information regarding the stability of the atlantoaxial joint. Patients with cervical subluxation are treated medically and/or surgically based largely on the presence or absence of signs of spinal cord compression. Severe injury and death can result from a variety of insults including minor falls, whiplash, and intubation. Stiff cervical collars may be prescribed for stability or halo traction followed by surgery. Collars that are not rigid, and therefore more comfortable for the patient, provide little structural support and should not be used.

DOC! "I SEE MONSTERS WHEN I TRY TO SLEEP." Dhara J. Chaudhari; David Ginn. East Tennessee State University, Johnson City, TN. (Tracking ID #1642255)

LEARNING OBJECTIVE 1: To emphasis an importance of dose adjustment in patients with chronic kidney disease and on dialysis
LEARNING OBJECTIVE 2: To assess and treat valacyclovir induced neurotoxicity.
CASE: 66 year old male presented with complain of hallucination, insomnia and photosensitivity of 2 days before admission. He mentioned of insomnia secondary to "monsters coming at me" every time he closes eyes. He denied headache, fever, tingling, numbness, seizure, loss of consciousness, suicidal-homicidal ideation, interruption in dialysis regimen. Patient's spouse mentioned of patient with decrease concentration for 2–3 days. Medical history includes buerger's disease with failed renal transplant 3 years ago and was undergoing peritoneal dialysis, coronary artery disease, atrial fibrillation, Diabetes mellitus. Four days before presentation, he was seen by ophthalmologist for right eye lesion and diagnosed with herpes zoster ophthalmicus for which oral valacyclovir 1000 mg daily for 7 days with Trifluridine drops was prescribed. He is non-smoker, non-alcoholic. Besides antiviral agents, his medications were simvastatin, metoprolol, sevelamer, furosemide, glimeperide. Physical exam: Temp 98.3 F, BP 110–79, RR 20, HR 68. His pulmonary, cardiac and neurologic exam was non focal. Initial laboratory data reveal glucose 153, K 3.7, Na 138, BUN 44, Creatinine 8.0 (baseline 6.0–7.0), normal CBC. EKG: irregular rhythm with rate 68. Chest Xray: No acute abnormality. CT head without contrast: age related atrophic changes. CT head with contrast: no areas of enhancement. Wide differential diagnosis was considered including; stroke (no focal neurologic deficits, normal CT head), herpes encephalitis (afebrile, WBC normal, no enhancement on contrast CT head), Uremia (renal functions-abnormal from baseline), medication changes (added valacyclovir), mental disorder (sudden onset). Considering valacyclovir to be underlying reason, it was stopped. Valacyclovir level was ordered which was 22.20 ug/l. After 3 days of observation, hydration and regular regimen of peritoneal dialysis, his symptoms improved. Considering recommended schedule of 500 mg every other day for 7 doses in renal failure, he was deemed adequately treated.
DISCUSSION: Valacyclovir, a prodrug of acyclovir, has largely replaced acyclovir because of ease of administration and efficacy. It is metabolized in liver and excreted in urine. Although considered relatively safe, it is associated with adverse neurotoxicity. Valacyclovir associated toxicity (VAN) appears within 48–72 h of treatment. Conversion of valacyclovir to acyclovir lead to renal dysfunction secondary to interstitial nephritis or precipitation in tubular lumen. New onset or exacerbation of renal failure leads to neurotoxicity. Patients with renal failure, on peritoneal or hemodialysis, are at high risk. Symptoms of VAN are confusion, hallucination, dysarthria, disturbed consciousness with hallucination being second common presentation. Clinical dilemma appears while distinguishing VAN from organic diseases such as encephalitis, cerebral vascular event, uremic encephalopathy, mental disorder. In our case, other etiologies were ruled out, had elevated blood valacyclovir level to confirm our suspicion. VAN has been associated with higher than recommended doses. The proposed dose for patients with renal disease or on dialysis is 500 mg every other day or after dialysis; however, close monitoring of renal function and adequate hydration is a key component of management.

DON'T BE SUPRISED ! JUST NEED TO CONTROL RISK FACTORS ! Thandar Aung. St. Franscis Hospital, Evanston, IL. (Tracking ID #1600515)

LEARNING OBJECTIVE 1: Ischemic strokes in young patients (18–45 years) is relatively rare and cardiovascular risk factors are generally thought to be less important in younger patients than in older one. Dyslipidemia and elevated lipoprotein A are associated with higher incidence of ischemic stroke risk in a number of epidemiological studies.
CASE: 25 y.o male presented with right extremities weakness, right facial droop and slurring of speech. Forty hours before the admission he noticed his right leg was weak just after he woke from sleep. During the course,he also noticed his right arm was weak and he had a tendency to fall to right.He thought he was too tired from work and ignored it. Four hours before the admission, he had sudden onset of right facial droop and slurring of speech. He was diagnosed with mild hypertension and dyslipidaemia when he was 18 and was on low dose of HCTZ and statin. He was non compliance. No significant family history of hypercholesteremia. Vitals were stable. On examination, he was found to have NIHSS stroke scale of 5. Language was fluent with dysarthria and right upper seventh cranial nerve palsy. Pupils and extraocular movement and visual field were normal. Tongue was deviated to the right side. 3/5 motor strength and 4+ reflex in the right side of the body with positive right pronator drift. No sensory loss. Rt extensor plantar response. No cerebellar signs. CT head showed no acute ischemic change nor hemorrhage. MRI and MRA Brain showed acute ischemic changes in left anteromedial pons(Paramedian Basilar Infarct) and left perforator branches of basilar artery were smaller, suggestive of microvascular disease. Transesophageal echocardiogram was

negative for signs of chronic hypertension, PFO and valvular anomalies. Hypercoagulable work up, urine toxicology and HbA1c were unremarkable. Total cholesterol - 435 mg/dl, LDL - 406 mg/dl, HDL-29 mg/dl, TAG-70 mg/dl. Lipoprotein (a) - 114 mg/dl (elevated) Patient was started on ASA, statin and antihypertensive.
DISCUSSION: In young healthy adults, paramedian pontine strokes from atherosclerosis are uncommon. Embolism, arterial dissection and specific conditions of hypercoagulation rather than large or small atherosclerotic arteriopathies are thought to be the most common cause of stroke in young adults. Jukka Putaala had reported that the most frequent risk factors associated with stroke in young adults(15–49) were dyslipidemia (60 %), smoking (44 %), and hypertension (39 %). The unexpectedly high frequencies of modifiable risk factors indicate a need for aggressive management. Patients with unilateral pontine stroke can present with contralateral tongue deviation which has been shown to be associated with supranuclear CN7th Palsy,and contralateral CN lesions and hemiplegia which may pose a particular challenge on diagnosis of stroke subtype. Role of statin in primary prevention of stroke is unclear but recently Jukka Putaala reported that young patients with a first ischemic stroke of undetermined etiology who used statin poststroke had lower rates of new vascular events in long-term followup.

DOUBLY UNCOMMON Ben Ravaee. Medical College of Wisconsin, Brookfield, WI. (Tracking ID #1642758)

LEARNING OBJECTIVE 1: Recognize a rare causative agent of infective endocarditis, and review complications frequently associated with this organism.
LEARNING OBJECTIVE 2: Identify the limitations of current testing in diagnosis of endocarditis.
CASE: A 71-year-old woman with a remote history of Raynaud's syndrome presented to walk-in clinic with a one-week history of right index finger pain. She also complained of fevers, malaise, and poor appetite. At the walk-in clinic, she was noted to have a fever of 102.3 °F. Physical exam was significant for cyanosis and tenderness of the right distal phalanx and a III/VI systolic murmur that was never documented previously. She was subsequently admitted, and 3 sets of blood cultures were drawn. The patient was empirically started on vancomycin with synergistic dosing of gentamicin for concern of endocarditis. Transthoracic echocardiography did not identify any masses or vegetations, but a transesophageal echocardiogram revealed a small, serpiginous echodensity in the left atrium in continuity with the posterior leaflet. Forty-eight hours after admission, one blood culture returned positive for Fusobacterium nucleatum. With this result, the patient met Duke's criteria for endocarditis, and her antibiotic regimen was switched to ertapenem for a four-week course. At subsequent follow-up, she had improvement in her right index finger pain and resolution of her murmur.
DISCUSSION: F. nucleatum is an anaerobic Gram-negative bacillus best known for its role in causing periodontal disease. Recently, much attention has been given to a possible association between F. nucleatum and colon cancer. Out of all the oral bacteria related with periodontal disease, it is the most common organism causing infections in other body sites, particularly the chest and abdomen. Despite this, documented cases of F. nucleatum causing endocarditis are quite rare. However, many of the features of this patient's case are consistent with prior known cases. Thromboembolic phenomena, the presenting feature in this patient, have been frequently associated with F. nucleatum, with several instances of cerebral or pulmonary emboli reported. Additionally, this patient had no underlying valvular disease, which was also the case in a high proportion of previously documented cases of F. nucleatum endocarditis. As in this case, presentation of F. nucleatum bacteremia is often insidious. However, it can be fatal, especially in those patients who present in shock, lack a fever at presentation, or have underlying diseases, with overall mortality rate of F. nucleatum bacteremia quoted as high as 40.7 % in one study. Diagnosis of infective endocarditis relies heavily on the use of blood cultures and echocardiography. In this patient, a new onset murmur was the most useful tool in establishing the diagnosis, and resolution of her murmur was arguably the most specific in confirming the correct diagnosis. This case should serve as a reminder that while blood cultures and echocardiography are important, over-utilization of these tools should not serve as a substitute for a thorough history and physical examination.

DRUG RASH WITH EOSINOPHILIA AND SYSTEMIC SYMPTOMS (DRESS SYNDROME) FROM TELAPREVIR USE John Szymusiak; Reed Van Deusen. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1624104)

LEARNING OBJECTIVE 1: Diagnose DRESS Syndrome.
LEARNING OBJECTIVE 2: Recognize common causes of DRESS syndrome .
CASE: The patient is a 53 year old gentleman with a past history of cirrhosis secondary to Hepatitis C Virus (HCV) and alcohol presenting with a rash. The patient had recently started treatment for HCV with interferon, ribavarin, and telaprevir. Six weeks after initiating treatment, he began to notice a red, painful rash over his right eyebrow. The rash continued to spread down his neck, trunk, abdomen and groin. The rash began as an erythematous, itchy area which then blistered, erupted, and crusted over. The day of admission the patient became dizzy and was found to be hypotensive. His examination was significant for a diffuse, papulosquamous rash with scattered vesicles and some crusting which covered approximately 30 % of his total body surface area (TBSA). His mucous membranes were spared. Lab work revealed acute renal failure, normal liver function enzymes, and a normal WBC with 6 % eosinophils on admission. The patient's blood pressure improved with hydration; however his acute renal failure continued to worsen despite adequate fluid resuscitation. His rash continued to spread eventually covering approximately 60 % of his TBSA including his palms and genitals. He also developed fevers. His eosinophil count rose, peaking at 18 % of his total white cells on hospital day three. A punch skin biopsy showed marked spongiosis, acanthosis, and papillary dermal edema accompanied by a perivascular and interstitial infiltrate composed of lymphocytes, histiocytes, and eosinophils. This is consistent with a drug reaction/DRESS syndrome. The patient was started on oral prednisone with rapid improvement of his rash, and his creatinine began to trend back down towards his baseline. The patient was ultimately discharged on a slow prednisone taper and instructed to hold his telaprevir, which was the presumed culprit of his DRESS syndrome
DISCUSSION: Drug Rash with Eosinophilia and Systemic Symptoms (DRESS syndrome) is a severe drug reaction, which usually presents 2–6 weeks after initiation of an offending medication. Although exact diagnostic criteria are lacking, it most commonly presents clinically as an extensive rash, fever, lymphadenopathy, hematologic abnormalities with eospinophilia, and evidence of solid organ failure. The rash can vary widely. It may present as urticarial-like lesions, a maculopapular rash, vesicles, or bullae. The most common solid organ affected is the liver; however the kidneys, lungs, and heart all can be involved. Common inciting drugs include antiepileptics, allopurinol, minocycline, and antivirals (most commonly abacavir). The patient in our case presents with many of the classic features of DRESS syndrome including rash, fever, eosinophilia, and acute renal failure about 6 weeks after being started on an antiviral medication. There have been several other case reports of telaprevir associated DRESS syndrome. The syndrome can be life threatening if untreated and illustrates the importance of being aware of DRESS syndrome in patients presenting with rash on these classes of drugs.

DRUGS SMARTER THAN THE BUGS: MIRTAZAPINE AND MEFLOQUINE THERAPY FOR NON-AIDS RELATED PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY Narendranath Epperla; Steven H. Yale. Marshfield Clinic, Marshfield, WI. (Tracking ID #1643151)

LEARNING OBJECTIVE 1: 1. To report on the investigational off-labeled use of mirtazapine and mefloquine for treatment of non-AIDS related Progressive Multifocal Leukoencophalopathy (PML) 2. To review the pathophysiologic mechanisms that may account for drug effectiveness.
CASE: A 77 year-old male with chronic lymphocytic leukemia (CLL) and hypogammaglobulinemia was hospitalized for generalized seizures. Three weeks prior to admission he was found to have progressive psychomotor

slowing and decline in cognitive function. Head CT scan revealed an area of low attenuation involving the frontal lobe with effacement of the cortical sulci and anterior horn of the lateral ventricle and vasogenic edema. MRI demonstrated an abnormal signal in the left frontal lesion with edema and feathered enhancement pattern identified on post-contrast imaging. He was started on Fosphenytoin for seizures and Dexamethasone for vasogenic edema. Histopathologic evaluation of tissue biopsy from left frontal lobe lesion showed prominent reactive gliosis and frequent bizarre astrocytes. There was florid perivascular lymphocytic infiltrates spreading into the brain parenchyma. The lymphocytes were mostly small sized along with many large macrophages in the adjacent brain tissue. Immunohistochemical stains confirmed this is to be exclusively a T-cell lymphocytic infiltrate around vessels and within the parenchyma. Very few B-cells were present. John Cunningham (JC) virus in-situ hybridization study was positive. HIV was non-reactive. The patient was treated with mirtazapine 30 mg daily and mefloquine 250 mg daily for 3 days followed by 250 mg once weekly. Follow-up 13 months later showed some improvement in cognitive function. MRI of the head showed the diffusion abnormality, scant posterior contrast enhancement, and mass effect were significantly resolved.

DISCUSSION: PML invades oligodendrocytes in the central nervous system white matter causing demyelination and neurologic deficits. PML affects patients with lymphoreticular malignancy (e.g. CLL or non-Hodgkin's lymphoma), AIDS, organ transplantation and immunosuppression associated with rheumatoid arthritis, sarcoidosis, and SLE. To date, there are no satisfactory treatments for PML. Although spontaneous partial recovery and prolonged survival have been reported, the disease is invariably progressive with 80 % mortality within 9 months. Reduction or withdrawal of immunosuppressants in patients with non-AIDS PML and the use of HAART in AIDS-related PML is the only known interventions that may allow immune reconstitution and control of pathological viral activity. The 5-HT2A serotonin receptor has been found to act as a receptor for JCV in glial cells. The use of serotonin receptor blockers that are selective for the 5-HT2A receptor, such as mirtazapine and risperidone, is physiologically plausible. The anti-malarial drug mefloquine has recently been recognized to have anti-JCV activity at non-toxic concentrations within vitro culture, and passes the blood–brain barrier to achieve concentrations in the brain above the level inhibiting JCV replications in vitro The recent trial of mefloquine in 21 patients with AIDS and 3 without AIDS failed to show a reduction JC viral DNA levels in the CSF. The positive clinical response seen in our patient after the initiation of combination therapy (Mirtazapine and Mefloquine) suggest that further studies in the form of randomized controlled trials in non AIDS PML using this combination therapy is warranted.

DUAL TRAGEDY AS A LONG TERM CONSEQUENCE OF BHOPAL GAS TRAGEDY Jonathan Duong; Harris Naina. UT Southwestern, Dallas, TX. (Tracking ID #1641995)

LEARNING OBJECTIVE 1: Report development of AML and mesothelioma following Bhopal Gas Tragedy

CASE: A 67 year old Indian female presented with 1 month duration of diffuse itching. She had no other pertinent symptoms, was a non-smoker, and was otherwise in good health. She had recently moved from Indian to live here with her daughter. Her exam was largely unremarkable. On routine CBC, she was found to have 11 K WBC with 95 % peripheral blasts. Bone marrow biopsy and cytogenetics confirmed acute myeloid leukemia (AML) with del(9q). She underwent induction chemotherapy, complicated by prolonged neutropenic fever, which prompted a chest CT. On imaging, there were incidental findings of multiple subpleural nodules and a calcified breast nodule. As there was concern for a second primary, CT guided biopsy of a right upper lung mass was performed and results confirmed mesothelioma. She denies asbestos exposure and we discovered she was a survivor of the Bhopal Gas Tragedy. She was successfully induced and is planned for consolidation therapy.

DISCUSSION: The Bhopal Gas Tragedy (Dec. 3, 1984) is considered the world's most devastating industrial accident, where methyl isocyanate (MIC) gas, an intermediate to developing pesticides, was released into the air around Bhopal, India. Over the last 28 years, there have been theories of an increased risk of chromosomal abnormalities and carcinogenesis in this population, especially regarding oral, oropharynx and lung cancers. MIC is known to cause inflammation, extensive DNA damage and genomic instability in cultured IMR-90 human lung fibroblasts, but long term effects have not been defined in any study. This case presents a patient with two unrelated primaries, with the possibility of a third, which strongly suggests a direct link between MIC and cancer development. An analysis of an Indian registry compiling the types of cancers that developed in MIC exposed Bhopal residents from 2006 to 2011 found roughly 1200 separate, newly diagnosed cancers. Every organ system was found to be involved in this registry, with breast and lung cancers having the highest incidence during that time period. Of the 1200, there were only 6 new AML and no reported mesotheliomas. This report is unique in that it presents the only occurrence of mesothelioma in a MIC exposed survivor. While her lack of asbestos exposure is unverifiable, there may be a long latency period of 30 years after exposure to MIC for developing mesothelioma (comparable to asbestos). The literature has also been unable to prove that consistent genetic abnormalities develop from MIC exposure. A small study conducted 2008–2011 compared mitotic metaphases of peripheral lymphocytes in MIC exposed and non-exposed individuals and found that there was a statistically significant increase in chromosomal aberrations in the exposed group. This suggests that MIC causes chromosomal instability that persists as a long term effect, which in the later future, can cause random gene rearrangements. Unfortunately, it is unclear whether AML with del(9q), as presented here, is present across all MIC exposed AML patients. The main limitation to this case is that we cannot prove causality of MIC increasing cancer incidence or a relationship between MIC exposure leading to AML or mesothelioma. However, the development of two primary cancers, with the possibility of a third, is strongly suggestive of such and this report should promote awareness of a potential increase in incidence of mesothelioma in the coming years.

DYSARTHRIA AND RIGHT-SIDED HEMIPARESIS: METASTATIC STREPTOCOCCAL INFECTION MASQUERADING AS PONTINE STROKE Daphne T. Lo; Brandon Combs. University of Colorado School of Medicine, Denver, CO. (Tracking ID #1642307)

LEARNING OBJECTIVE 1: Question inconsistent diagnoses

LEARNING OBJECTIVE 2: Diagnose and treat Streptococcus intermedius infection

CASE: 72 yo male with a history of type 2 Diabetes Mellitus, remote tobacco use, and recent TIA presented with several days' history of progressively slurred speech and subtle right-sided weakness. Exam on admission was notable for good dentition, mild dysarthria, right-sided weakness, low-grade fever, and mild leukocytosis of 13×10^9/L. Head CT showed no acute intracranial abnormality. MRI showed an acute infarct in the left pons with a central cystic component extending superiorly and inferiorly. The patient was admitted for acute ischemic stroke and given tissue plasminogen activator. The patient's neurologic status continued to decline with progressive right sided weakness and dysarthria, new abdominal pain, and leukocytosis to 26×10^9/L with new anemia (hemoglobin 9 g/dL). A CT of his chest and abdomen showed multiple ring-enhancing low-density lesions suspicious for abscess or malignancy in his liver and posterior spleen with prominent hepatogastric and portocaval lymph nodes. Repeat MRI showed a new, ring-like enhancing lesion in the pons just left of midline with extension into the L cerebral peduncle. Blood cultures became positive for Streptococcus intermedius. Ceftriaxone 2 g IV twice daily and metronidazole 500 mg PO three times daily were initiated. Aspiration and drainage of hepatic and pontine lesions grew S. anginosus/milleri group. The patient's neurological status improved markedly after aspiration of his pontine lesion. An upper endoscopy performed to evaluate for a source for his bacteremia revealed a 3 cm ulcerated distal esophageal mass consistent with adenocarcinoma.

DISCUSSION: The patient's presenting symptoms suggestive of ischemic stroke and non-specific cranial imaging misled the diagnosis. Symptom progression despite treatment of ischemic stroke, evolving lesions on imaging, and fever prompted further investigation leading to the discovery of systemic S. intermedius infection. Streptococcus intermedius is a species of the group S. anginosus (also known as S. milleri, a subgroup of viridians streptococcus), known for causing invasive pyogenic infections. Species of the S. anginosus group are commonly found in the oropharyngeal, gastrointestinal, and urogenital tracts. Abdominal, thoracic, and central nervous system infections are commonly seen in infections by the S. anginosus group. Bacteremia is often associated with an abscess, especially in the gastrointestinal tract, and often precedes CNS infection. Treatment of S. intermedius infections can be complicated due to the natural competency of S. anginosus species leading to risk of antibiotic resistance. Studies report variable susceptibility to penicillins and cephalosporins with penicillin resistance more common in S. intermedius. Overall, S. anginosus infections respond well to penicillin G and cephalosporins, especially cefepime, cefotaxine, and ceftriaxone. Drainage of abscesses is necessary for resolution of abscesses. Once the patient's abscesses were drained and antibiotic treatment initiated with ceftriaxone and metronidazole, the patient's neurologic status improved markedly. Focusing on the common sources of S. intermedius infection indentified the source as erosive esophageal adenocarcinoma in this previous smoker.

DYSPNEA IN POLYMYOSITIS- ANTISYNTHETASE ANTIBODY IS THE CLUE Ravi Shahukhal[1]; Yagna R. Bhattrai[3]; Nirva Dube1; Madan R. Aryal[2]. [1]Queens Hospital Center, Queens, NY; [2]The Reading Health System, West Reading, PA; [3]Mercy Catholic Medical Center, Philadelphia, PA. (Tracking ID #1621951)

LEARNING OBJECTIVE 1: Recognize pulmonary involvement in patients with polymyositis
LEARNING OBJECTIVE 2: Discuss the clinical features and treatment of antisynthetase syndrome
CASE: 38 year old female with no past medical history, presented with progressive shortness of breath, dry cough and fever for 1 month. She also complained of polyarthralgia along with symmetrical weakness of her proximal muscles and Raynaud's phenomenon of fingers. On examination, her respiratory rate was 32/min and saturation was 89 % on room air. Chest examination revealed crackles at bilateral lung bases. Proximal interphalengeal, wrist and ankle joints were swollen with mild tenderness. Pertinent laboratory data included white cell count of 7600/microL, hemoglobin 8.5 gm%, platelets- 363,000/micro L, and erythrocyte sedimentation rate of 104 mm/h. Serum creatine kinase was 3257/micro L, aldolase level was 20 U/L. Thyroid function tests was normal. Chest X ray showed bibasilar opacity and patchy reticular opacity in middle lung field. She was treated for suspected atypical pneumonia, however she failed to improve. CT chest obtained was negative for pulmonary embolism and showed bilateral air space disease with interstitial prominence. Further immunological workup was carried out which were negative for antinuclear, lupus anticoagulant, antiphospholipid, anti ds DNA, Anti Ro, anti CCP and anti C- ANCA antibodies. Anti jo-1 antibody was positive in very high titer (>8, normal<1). Rheumatoid factor was 41.3 (normal 0–20). Level of C3 and C4 were normal. Echocardiogram showed ejection fraction of 65 %. Electromyography indicated findings suggestive of myopathy. Pulmonary function test showed restrictive pattern with decreased DLCO. Bronchoscopy guided biopsy of lung tissue revealed pulmonary capillaritis. Broncho alveolar sample was negative for fungal and mycobacterial infection. She was treated with high dose of methylprednisone with significant improvement in breathing, muscle strength and creatinine kinase level. She continued to improve with long term steroid treatment.
DISCUSSION: Interstitial lung disease (ILD) is a major cause of morbidity and mortality in patients with polymyositis. Anti Jo-1 antibody is positive in around 38 % in patients with ILD in polymyositis. Anti Jo 1 antibody are strongly associated with ILD, Raynaud's phenonmenon, interstitial lung disease, arthralgia, mechanics hands and constitutional symptoms like fever which are collectively known as antisynthetase syndrome. Polymyositis in our case was diagnosed with 3 out of four Bohan and Peter criterias (symmetrical proximal muscle weakness, EMG findings and elevated muscle enzymes). This in the setting of positive anti Jo antibody was suggestive of antisynthetase syndrome. Among histologial subtypes of Interstitial lung disease, non specific interstitial pneumonia (NSIP), cryptogenic organizing pneumonia (BOOP) and usual interstitial pneumonia are common. However pulmonary capillaritis, which is seen in systemic vasculitis and stemic lupus erythematosus, is very rare in polymyositis. In our case, negative C- ANCA and negative ANA further support to exclude concomitant connective tissue disease as a cause of capillaritis. Treatment is usually with high dose pulse steroid and cyclophosphamide.

DYSPNEA: DON'T SUPPRESS THE DIFFERENTIAL DIAGNOSIS Monica A. Gomberg; Harish Jasti. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1638272)

LEARNING OBJECTIVE 1: Identify sirolimus-associated toxicity in an immunosuppressed patient.
LEARNING OBJECTIVE 2: Recognize the importance of medications as potential culprits of disease processes.
CASE: A 65 year-old Caucasian male with a history of liver transplant and chronic kidney disease (CKD) presented with a 2-month history of dyspnea on exertion. He initially experienced difficulty breathing while walking uphill, which then progressed to a sensation of shortness of breath (SOB) after walking a few meters. He denied any SOB at rest, orthopnea, wheezing, chest pain or palpitations. The patient also endorsed a non-productive cough with exertion only. He was in contact with his son-in-law and grandchild, both of whom were recently treated for pneumonia. He admitted to poor oral intake over the past 2 months, leading to a 25 lb weight loss. His medications included primidone, sirolimus and propranolol. Physical exam revealed a well-appearing male in no acute distress. Vital signs were stable, with an oxygen saturation of 94 % on room air. Cardiovascular exam was unremarkable, including absence of lower extremity edema and jugular venous distention. Pulmonary exam was clear to auscultation. Laboratory work was significant for anemia of chronic disease and CKD, both of which were at his baseline. An electrocardiogram was also normal. Regadenosine single-photon emission computed tomography (SPECT) demonstrated no perfusion defects, with an ejection fraction (EF) of 40 % with diffuse hypokinesis. A transthoracic echo showed an EF of 40–45 %, mildly decreased systolic function, diastolic dysfunction, and inferior and posterior wall hypokinesis. A chest CT scan from 3 years ago revealed multiple calcified granulomas. A repeat CT scan, performed during the hospitalization, also showed the calcified granulomatous nodules, in addition to new multifocal ground-glass opacities. Pulmonary function testing revealed a moderate restrictive pattern without significant bronchodilator response, and a severely decreased diffusion capacity. His sirolimus therapy was subsequently discontinued, leading to complete resolution of his symptoms. A repeat CT scan, performed 3 months after discharge, no longer demonstrated any ground-glass opacities.
DISCUSSION: Sirolimus is a medication commonly used in patients with solid organ transplantation, particularly for its renal-sparing effects. Side effects include myelosuppression, hypertension, hyperlipidemia, glucose intolerance and infection. Pulmonary toxicity in patients on sirolimus has an incidence ranging from 2 % to 10 %. Initial symptoms include cough, fatigue, fever, and dyspnea, and can lead to conditions such as organizing pneumonia, interstitial pneumonitis, pulmonary alveolar proteinosis, focal fibrosis or alveolar hemorrhage. CT findings include reticular and ground-glass opacities and lobar consolidation. Case reports have noted that symptoms are not directly related to dosage. Once identified, most patients recover completely within 6 months after discontinuation of the medication. Given the significance of these outcomes, and the necessary cessation for resolution, it is important for the physician to consider sirolimus in their differential diagnosis in a patient presenting with pulmonary symptoms. This case also highlights the importance of doing a thorough medication review upon admission of a patient into the hospital. In our patient, identifying and discontinuing sirolimus was critical in his recovery.

EOSINOPHILIA: MORE THAN JUST ALLERGIES AND WORMS
Morgan J. Katz; Matthew N. Peters; Ardalan Minokadeh. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640375)

LEARNING OBJECTIVE 1: Recognize the diagnostic criteria for hypereosinophilic syndrome.
LEARNING OBJECTIVE 2: Understand the importance of early initiation of steroid treatment in hypereosinophilic syndrome to prevent irreversible end organ damage.
CASE: A 58 year-old woman with a history of type 2 diabetes presented with crushing sub-sternal chest pain. Review of systems was negative for pulmonary symptoms, rash, and recent changes in medications. Initial ECG revealed T-wave inversions inferiorly and laterally and initial troponin was 12.6 g/dL. Coronary arteriography demonstrated 95 % stenosis in the right coronary artery which was treated with a drug-eluting stent. Transthoracic echocardiogram revealed restrictive cardiomyopathy with a left ventricular ejection fraction of 15 %, grade 3 diastolic dysfunction, pulmonary arterial pressure of 46 mmHg and the absence of regional wall motion abnormalities. Other basic laboratory tests were within normal limits aside from a serum eosinophil count which was markedly elevated at 9400/μL (62 %). Nine months earlier her eosinophil count was also elevated at 4600/μL (34 %). Eosinophilia was confirmed with a peripheral smear, which showed numerous structurally normal eosinophils and an absence of atypical lymphocytes or blasts. The serum IgE was elevated at 802 u/mL. Her serum antinuclear antibodies and anti-neutrophil cytoplasmic antibodies were negative. She had negative stool ova and parasites, absence of BCR/ABL mutation on serum PCR, and an unremarkable travel history. The patient was diagnosed with hypereosinophilic syndrome (HS) and was treated with daily prednisone at a dose of 15 mg/kg. Three months following the initiation of therapy, the patient's eosinophil count improved to less than 1000/μL with no additional signs of end organ damage.
DISCUSSION: Hypereosinophilic syndrome is a disease that every internist should be aware. First described in 1968, HS is defined by sustained blood eosinophilia >1500/μL for at least 6 months, absence of other eosinophilia etiologies, and signs and symptoms of end organ involvement. While all organs may be affected, cardiac involvement is most common. Cardiac involvement typically begins with an early necrotic stage at 5–6 weeks, progression to a thrombotic stage, involving formation of thrombi along damaged ventricular endocardium at approximately 10 months, and finally a fibrotic stage with restrictive cardiomyopathy secondary to progressive scarring at about 2 years. Cardiac damage is caused by release of the eosinophil granule protein, major basic protein (MBP) which creates scarring and fibrosis of the endocardium via direct toxicity. An additional adverse effect of circulation of excess MBP stems from its ability to activate platelets and inhibit thrombomodulin (a cofactor in the anticoagulation pathway), predisposing to hypercoagulability and thrombus formation in the cardiac chambers and coronary arteries. Early recognition and treatment is imperative to decrease the circulation of excess eosinophils and minimize their toxic effects. Elevation of eosinophil count should not be treated as an incidental finding and patients with eosinophilia should undergo an extensive diagnostic work-up. Treatment of HS with corticosteroids is highly successful, especially in patients with elevated IgE levels, and minimizes potentially irreversible and fatal complications.

EMERGENCE OF A NEW CLASS OF RECREATIONAL DRUGS - A CASE FOR CAUTION
Vikas Khullar; Ankur Jain; Maryam Sattari. University of Florida - Shands Hospital, Gainesville, FL. (Tracking ID #1642264)

LEARNING OBJECTIVE 1: Recognize that "Bath Salts" have become an increasingly common substance of abuse.
LEARNING OBJECTIVE 2: Diagnose and manage "bath salt" ingestion appropriately.
CASE: A 20 year old Hispanic male was found running around the university campus by the police and brought to the Emergency Department for altered mental status. Police reported that he appeared to be having hallucinations with rapid speech and threatened to use a knife to harm his girlfriend. No history could be obtained from the patient at the time of admission due to his extreme agitation. On examination, the patient was afebrile, tachycardic in 120's, and mildly hypertensive at 146/99. He kept moving on and off the bed and was inattentive to questioning. Aside from shivering, the rest of the physical exam was unremarkable. Creatine Phosphokinase (CPK) level was elevated at 1151 U/L (reference range 30–170 U/L). Serum toxicology screening was negative for ethanol, acetaminophen, and salicylate. Urine drug screening was only positive for cannabinoids The rest of laboratory investigation, including complete blood count, basic metabolic panel, liver function tests, and TSH, were normal. Patient was aggressively rehydrated. Lorazepam and haloperidol were administered as needed for agitation. Over the next 24 h, CPK levels started to trend downwards. Patient became more alert, oriented, and less agitated. While he admitted to distant amphetamine use, patient only endorsed the recent use of marijuana and "bath salts". Over the next day, he was treated with both oral and intravenous hydration and was discharged to a psychiatric rehabilitation facility based on psychiatry evaluation. Of note, patient had had a similar prior presentation to our hospital. Elevated CPK at the time was attributed to cocaine use although urine and serum toxicology screenings were entirely negative.
DISCUSSION: "Bath salts" are becoming an increasingly popular form of recreational drug abuse especially amongst young adults, with many presenting to the emergency department in states of intoxication. Due to their increased abuse potential, the drug enforcement agency recently reclassified these stimulants as schedule I drugs. The primary ingredients in these novel synthetic stimulants, 3,4-methylenedioxypyrovalerone (MDPV) and 4-methylmethcathinone (mephedrone), produce a cocaine- or methamphetamine-like high. "Bath salts" can be ingested orally, intranasally, intravenously or rectally and have been associated with altered mental status (hallucinations, paranoid delusions, anxiety, violent behavior, and bizarre suicides and homicides), cardiovascular complications (tachycardia, hypertension, and chest pain), hyperthermia, rhabdomyolysis, renal failure, seizures and even deaths. Treatment is mainly supportive, focusing on hydration, sedation and symptom management. Since bath salts are not detected by conventional drug screening, clinicians should be familiar with these substances and maintain a high level of suspicion in patients who present with mental status changes, predominant sympathomimetic features, and negative toxicology screening.

EMPYEMA AS COMPLICATION OF SILENT ASPIRATIONS
Annie Chen. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1621786)

LEARNING OBJECTIVE 1: Recognize less common complications of gastroesophageal reflux disease (GERD) and hiatal hernias.
LEARNING OBJECTIVE 2: Consider age-appropriate differential diagnoses of new-onset pleural effusions.
CASE: The patient is a 75 year old man with past medical history significant only for GERD and hiatal hernia who presented to the hospital for an acute onset of intense chest pain. The pain started about 2 days before admission and was thought to be musculoskeletal pain. Despite NSAIDs, the left-sided chest pain became more intense and pleuritic in nature. He denied having any antecedent illness, weight loss, fevers, night sweats, chills, or any prolonged periods of immobility. He denied having pneumonias or aspirations. He did not have any family history of cancers, lung pathology, heart disease or autoimmune diseases. Upon presentation to the hospital, the patient was afebrile. He was hypertensive with normal heart rate. His oxygen saturation was abnormal at 92 % on room air. His exam was notable for poor inspiratory effort with short shallow breaths, crackles in the lower left lung base. His cardiac exam was normal. Initial laboratory data did not show leukocytosis. He did have elevated D-dimer and C-reactive protein levels. CT scan of the chest ruled out a pulmonary embolism but did show small left pleural effusion and questionable chronic lung changes at the bases. It also showed a moderate size hiatal hernia. Within 3 days of presentation, patient developed new onset atrial fibrillation with rapid ventricular rate and was transferred to the intensive care unit for rate control. He had also developed a new oxygen requirement. A repeat chest CT scan

found that the left loculated effusion had dramatically increased in size, necessitating surgical thoracentesis, which revealed purulent material. Over the next few days, he clinically improved with the drainage of his infection. The patient had decreased pain, decreased episodes of atrial fibrillation, and decreased oxygen requirement. Interestingly, Microaerophilic Streptococcus and Peptostreptococcus species were recovered from patient's pleural fluid.
DISCUSSION: Initially, we considered a broad differential for the patient's pleural effusion, which was later found to be an empyema. Given the acute nature and the intensity of the pain, a highly inflammatory process was at the top of the differential. More insidious causes like malignancy were considered due to his age, though much less likely due to his benign history. The most likely mechanism of patient's empyema was related to his history of moderately-sized hiatal hernia. Although patient's reflux was symptomatically well-controlled on proton pump inhibitors, he likely still had silent aspirations. He has never had a swallow study as he had no clinically important recurrent aspirations. We proposed that the oral flora caused an insidious pneumonia that eroded through the pleural space and caused the formation of the empyema. This, then, caused severe pain and irritation of the pericardial space, leading to new-onset atrial fibrillation. No other such cases have been reported; however, GERD has been associated with aspirations. As shown by this vignette, empyemas caused by silent aspirations should be considered in the differential of sudden onset of pleuritic chest pain without any other clear cause especially if patients have known GERD or a known hiatal hernia.

ENDOCARDITIS RELATED PLATYPNEA ORTHODEOXIA AND REVERSE LUTEMBACHER SYNDROME David Anwar; Nada E. Elmagboul. Penn State Hershey Medical Center, Hershey, PA. (Tracking ID #1641595)

LEARNING OBJECTIVE 1: To recognize platypnea orthodeoxia (PO) as a rare condition characterized by hypoxia in the upright position that resolves when recumbent.
LEARNING OBJECTIVE 2: To recognize the reverse Lutembacher syndrome triad of tricuspid valve (TV) stenosis elevated right atrial (RA) pressure, and right-to-left shunting.
CASE: A 35-year- old male presented with a 1 week history of fever, chills and occasional shortness of breath. Dyspnea notably worsened while standing and improved while lying flat. Patient had a past history significant for intravenous drug use associated infective endocarditis, complicated by paradoxical septic emboli to the brain with residual deficits, requiring bioprosthetic tricuspid valve replacement. On presentation, patient was septic with WBC count of 29.8, fever of 39.3 °C, blood pressure of 98/62 and sinus tachycardia of 154. While upright, patient had cyanosis, mottling and hypoxia with O2 saturation in the 80 s. These symptoms resolved within 30–60 min of laying supine. Cardiovascular exam revealed diastolic and systolic murmurs radiating throughout the pericardium. Echocardiogram showed a 3.3×2.7 cm tricuspid vegetation obstructing the tricuspid valve causing severe stenosis, severe regurgitation, and elevated right arterial pressure of 20 mmHg (normal 2–6). CT scan of Chest revealed evidence of old and new small septic emboli to the lungs. Blood cultures were positive for Streptococcus viridians. Panorex CT showed multiple dental abscesses that were subsequently extracted. Tricuspid valve replacement was performed resulting in resolution of patient's hypoxia. A repeat post-operative echocardiogram showed normal valvular function and normalization of RA pressure to a value of 3 mmHg.
DISCUSSION: Platypnea orthodeoxia (PO) is a rare condition characterized by hypoxia in the upright position that resolves when recumbent. The proposed mechanisms are intra-cardiac shunting, intra-pulmonary shunting or ventilation-perfusion (V/Q) mismatch. In addition, a physiologic driving force in the upright position must be present, as was caused by obstruction of the TV by the large vegetation in this patient's case. This condition is classically seen in hepatopulmonary syndrome, chronic lung disease or recurrent pulmonary embolism. This case also demonstrated the reverse Lutembacher syndrome as the triad of TV stenosis, elevated RA pressure, and right-to-left shunting. Although a bubble study was not performed during the echocardiogram, it was presumed that patient had a patent foramen ovale, from his previous history of paradoxical emboli. To our knowledge this is the first reported case of reverse Lutembacher syndrome due to TV stenosis from infectious endocarditis. Clinical evaluation of PO should focus on the identification of possible intra cardiac shunting, intra pulmonary shunting or V/Q mismatch. Work up includes tilt table two dimensional echo with bubble study, lung imaging and liver function test.

ENDOMETRIAL TUBERCULOSIS PRESENTING AS PRIMARY INFERTILITY: AN INTERESTING CASE Swati Choudhary; Harsha Ramchandani; David Steinberger; Randall Sternberg; Jaya Edukulla; Vijayashree Mekala. St. Mary Mercy Hospital, Farmington Hills, MI. (Tracking ID #1639416)

LEARNING OBJECTIVE 1: To illustrate an uncommon cause of infertility Tuberculosis usually involves the lungs and lymph nodes but can rarely involve genitourinary system. In males it can cause tuberculous epididymo-orchitis and in females, it can cause tuberculous endometeritis (infection of the uterus) and salpingitis (infection of the fallopian tubes).
LEARNING OBJECTIVE 2: To increase awareness among physicians of endometrial tuberculosis especially with the increasing immigration from developing countries Genital tuberculosis is a bacterial infection still frequent in less developed countries. It is becoming more common in developed nations secondary to increased immigration. The Incidence in the United States has been estimated to be less than 1 %.
CASE: We present a case of endometrial tuberculosis as a cause of infertility which was not diagnosed despite 4 years of workup; most likely due to decreased awareness. So far this is the second case ever reported in United States literature, the first case was of an African refugee. Our patient is a 30 year old healthy female with no other medical conditions. She migrated from India in 2007. According to the patient she never had any exposure to tuberculosis. Secondary to inability to conceive she started following with an infertility clinic in 2008. She and her husband went through a battery of tests, including blood tests, semen analysis, US of pelvis, and even laparoscopy. This was followed by 3 unsuccessful attempts of in-vitro fertilization. She travelled to India in 2012 where she decided to see another obstetrician for second opinion. Blood work-up came back negative again for hormonal deficiency. Finally an endometrial biopsy was done followed by histology. Although PCR of endometrial specimen came back negative, histology and culture was positive for mycobacterium tuberculosis. When we saw her in our clinic, she denied cough, low grade fever, weight loss, and any menstrual cycle disturbances. PPD test done in the clinic was negative. Chest X-ray showed no signs of active tuberculosis. As per the infectious disease specialist she will be started on anti-tuberculous treatment for the next 6 months with close monitoring.
DISCUSSION: Tuberculosis is an infectious disease caused by an acid fast bacilli, mycobacterium tuberculosis. It can affect women of any age. Women in reproductive age can present with infertility as their initial symptom. Post-menopausal women present with menorrhagia as their initial symptom. The Gold standard for diagnosis is endometrial biopsy followed by histology. Infertile women without tubal or endometrial damage given early anti-tuberculosis treatment have an excellent chance of early spontaneous conception. The recommended treatment involves 6 months of antituberculous therapy. Surgical intervention is usually only performed on women who are postmenopausal as surgery requires total abdominal hysterectomy. If not treated early, complications include development of adhesions and blocked fallopian tubes leading to permanent disability and ectopic pregnancy. Even after treatment many patients may still suffer from infertility secondary to intra-uterine scarring. For these patients the only available option could be in-vitro fertilization. Thus, in conclusion Tuberculosis should be considered in the differential diagnosis of infertility especially in patients who have migrated from developing countries.

ENIGMATIC PLEURAL EFFUSION Emily Kocurek[1,2]; Sujata Bhushan[2,1]. [1]UT Southwestern Medical Center, Dallas, TX; [2]Dallas VA Medical Center, Dallas,, TX. (Tracking ID #1642816)

LEARNING OBJECTIVE 1: Diagnose and manage an enigmatic pleural effusion. Occasionally fluid studies and cytology are unrevealing and

further measures must be taken for definitive diagnosis. Diagnosis of malignant and paramalignant effusions contributes important prognostic information. These effusions can be challenging to manage.

LEARNING OBJECTIVE 2: Recognize atypical manifestations of prostatic metastasis. Pleural effusions are rare and are often accompanied by supradiaphragmatic lymphadenopathy with extensive disease. Understand the role of lymphatic invasion in the pathophysiology of a paramalignant pleural effusion, with no direct involvement of pleura by the tumor.

CASE: 68 year old Caucasian male with past medical history of prostate cancer, treated with external beam radiation therapy and subsequent chemotherapy for biochemical recurrences and diffuse osseous metastases, was admitted with 2 week history of exertional dyspnea, associated with cough productive of whitish sputum. Chest x-ray showed a large opacity in the right lung fields. Right lateral decubitus film exhibited layering dependent fluid. He underwent large volume thoracentesis,with straw colored fluid, exudative by Light's criteria. Cultures and cytology were negative. Fluid reaccumulation prompted repeat thoracenteses. All subsequent studies were negative, including mucicarmine special stain and PSA and PAP immunohistochemical stains. Total 3480 mL of fluid was submitted for cytology, negative for malignancy. Subsequently, he underwent right video assisted thoracic surgery with full decortication, right pleural biopsy, right upper lobe wedge resection, and placement of PleurX catheter. Intraoperative bronchoscopy showed no pathologic lesions. Pleural biopsy showed organizing pleuritis but no tumor. Right upper lobe wedge resection showed metastatic poorly differentiated prostatic adenocarcinoma with extensive lymphovascular invasion.

DISCUSSION: Two types of pleural effusions are associated with malignancy, termed malignant and paramalignant. Malignant effusions are defined by the presence of tumor cells in the pleural fluid/ on pleural biopsy. If there is no evidence of tumor involvement on pleural fluid cytology or biopsy and no other cause of the effusion can be elucidated, it is termed paramalignant. Commonest mechanism for development of paramalignant pleural effusion is compromise of lymphatic drainage. Malignant effusions are mainly exudative. If cytology or percutaneous pleural biopsy are unrevealing, more invasive diagnostic procedures may be undertaken. Bronchoscopy may have low diagnostic yield and yield of CT is somewhat unclear. Therapeutic options include serial thoracentesis, chemical pleurodesis, thoracoscopy, VATS, pleural catheter, and pleuroperitoneal shunt, the choice of intervention being dependent on patient's expected survival time. The usual metastatic pattern of prostate cancer involves local lymph nodes and the axial skeleton. More atypical metastatic sites include atypical lymphadenopathy (outside the abdomen/pelvis) and metastasis to the orbit/skull, lungs, liver, and intracranial sites. Lungs and pleura are the most frequent site of atypical metastasis. Pleuroparenchymal involvement can include parenchymal nodules, pleural nodules, and more rarely lymphangtic carcinomatosis. Most pleuroparenchymal involvements have concurrent supradiaphragmatic lymphadenopathy. Our patient had a paramalignant effusion without any adenopathy, making the diagnosis difficult.

EOSINOPHILIC CARDIOMYOPATHY WITH ENDOMYOCARDIAL FIBROSIS Jason Sayanlar. [1]Georgetown University Hospital, Washington, DC; [2]National Institutes of Health, Bethesda, MD. (Tracking ID #1623491)

LEARNING OBJECTIVE 1: Recognize the clinical features of hypereosinophilic syndromes presenting with restrictive cardiomyopathy.

CASE: A 70 year-old Korean female with no significant past medical history presented to the hospital after 3 months of generalized weakness and progressively worsening lower extremity edema. She denied any shortness of breath, chest pain, fevers, chills, rashes, arthralgias, orthopnea, paroxysmal nocturnal dyspnea, syncope, or any other constitutional symptoms. She initially presented to her primary care physician 1 month prior to admission, and was started on a diuretic for her lower extremity edema. A CBC was checked, which showed a WBC of 20,000/mm3 with an absolute eosinophil count (AEC) of 19,000/mm3. At this point she was transferred to the National Institutes of Health for further evaluation of her hypereosinophilia. A peripheral smear revealed the presence of dysplastic, hypogranular eosinophils. ProBNP was elevated at 2204 (normally 0–353 pg/ml). Troponin-I peaked at 0.024. An EKG showed a prolonged QTc of 480 milliseconds. A test for the FIP1-PDGFRa mutation came back negative. Physical examination revealed a jugular venous pressure of 12, decreased breath sounds and 2+ lower extremity edema to her knees, bilaterally. On cardiac exam, she was found to have a normal rate and regular rhythm, with a 3/6 holosystolic murmur at the apex, radiating to the axilla. A transthoracic echocardiogram was done, which showed an ejection fraction of 65 %, moderate tricuspid regurgitation, severe mitral regurgitation, severe right ventricular (RV) dilatation with decreased RV function, as well as septal flattening consistent with RV overload. Her RV apex was described as thick and echodense. A cardiac MRI was also done, which noted left ventricular (LV) apical thickening (in addition to RV thickening), suggesting bilateral apical thrombi vs. endomyocardial fibrosis, thought to be secondary to eosinophilic cardiomyopathy. Treatment consisted of initiating imatinib and corticosteroids for her hypereosinophilic syndrome. Her diuretics were increased and she was started on anticoagulation for her apical thrombi, as well as an ACE-inhibitor for cardiomyopathy. One month after discharge, the patient began to report increased energy and a significant reduction in her edema. Follow-up labs also showed resolution of her eosinophilia, with a WBC of 3,650/mm3 and an AEC of 1,380/mm3.

DISCUSSION: This case illustrates eosinophilic cardiomyopathy as a rare, but clinically important, cause of restrictive heart failure. Eosinophil-mediated heart damage is characterized by three stages- 1) an acute necrotic stage, significant for direct endomyocardial infiltration and damage, 2) an intermediate phase, in which thrombi form along damaged endocardium and 3) a fibrotic stage, characterized by endomyocardial fibrosis, resulting in a restrictive cardiomyopathy. Clinicians must pay close attention to the cardiac physical examination for signs of heart failure and valvular disease, which is caused by fibrotic entrapment of chordae tendineae. Other organ systems are also frequently involved, including the skin, lungs and gastrointestinal tract, which are all characterized by eosinophilic infiltration.

EOSINOPHILIC PLEURAL EFFUSION: A WORM BY ANOTHER NAME? Jessica R. Howard-Anderson[1]; Timothy Canan[2]; Michael D. Roth[2,3]; Edward Ha[2,4]. [1]David Geffen School of Medicine at the University of California, Los Angeles, Los Angeles, CA; [2]University of California, Los Angeles, Los Angeles, CA; [3]University of California, Los Angeles, Los Angeles, CA; [4]University of California, Los Angeles, Los Angeles, CA. (Tracking ID #1642814)

LEARNING OBJECTIVE 1: Recognize the different causes of eosinophilic pleural effusions

LEARNING OBJECTIVE 2: Recognize the pulmonary manifestations of Strongyloides stercoralis infection and the dangers of misdiagnosis

CASE: A 91 year old Korean man with history of hepatitis C and recurrent pneumonias presented with 2 days of fever, productive cough and hemoptysis. In the preceding year, he had two hospital admissions for bacterial pneumonia with a persistent left loculated pleural effusion of unclear etiology. On arrival, he had a temperature of 37.9 °C, with a normal respiratory rate and oxygen saturation. He had decreased breath sounds in the left middle and lower lung fields. WBC count was 6,390 per μL with 21 % eosinophils. His IgE level was 6103 IU/mL (normal<20 IU/mL). Mycobacterium tuberculosis (MTB) quantiferon gold ELISA test was positive. A single stool ova and parasite (O&P) test was negative. A chest CT identified a complex loculated left pleural effusion with ground-glass opacities in the right upper and middle lobes. A noncalcified granuloma was noted in the right apex. Bronchoalveolar lavage was performed, and acid fast culture, MTB PCR, and O&P testing were negative. A diagnostic thoracentesis yielded 44 WBCs per mL with 24 % eosinophils, and an adenosine deaminase of 6.0 units per liter (consistent with transudative fluid). Wet prep of the pleural fluid was negative for ova and parasites. No malignant cells were identified. On the day of discharge, a second stool O&P test was obtained and eventually identified Strongyloides stercoralis larvae. Serum testing for strongyloides antibody also returned positive. He received ivermectin and had significant improvement in his symptoms and eosinophilia.

DISCUSSION: Eosinophilic pleural effusions are commonly encountered by general internists. While the most common etiologies are malignancy, idiopathic, and parapneumonic effusions, other causes including tuberculosis (TB), collagen-vascular diseases, and parasitic infections—namely Strongyloides stercoralis—must be considered in the appropriate demographics. In this case, our suspicion for active TB was high. Without acquiring a repeat O&P stool sample, more invasive diagnostic procedures for TB may have been performed. This highlights the importance of testing numerous stool samples, as the sensitivity does not approach 100 % until obtaining 7 samples. The pulmonary manifestations of Strongyloides stercoralis can include eosinophilic pleural effusions, asthma and acute respiratory failure. If undiagnosed, hyper-infection can occur, with high worm burden and disseminated disease. Specific to pulmonary disease, there have been at least three documented fatalities in patients with undiagnosed strongyloides who received corticosteroids for presumed asthma. Considering stronglyoides infection is therefore critical in patients with eosinophilic pleural effusions.

EOSINOPHILIC PNEUMONIA, RARE BUT FATAL SIDE EFFECT OF DAPTOMYCIN: A CASE REPORT Jaya Edukulla; Swati Choudhary; Alexander Glick; Derek DeSouza. St. Mary Mercy Hospital, Livonia, MI. (Tracking ID #1642282)

LEARNING OBJECTIVE 1: To increase awareness about a rare but fatal side effect of Daptomycin
LEARNING OBJECTIVE 2: To emphasize the need for early identification of eosinophilic pneumonia as a side effect of Daptomycin
CASE: 72 year old Caucasian male with history of Diabetes Mellitus type II, Hypertension, Hyperlipidemia and peripheral vascular disease was admitted for diabetic foot infection. Patient was started on vancomycin and ceftriaxone. Patient underwent angioplasty with atherectomy of left popliteal artery to promote healing. Podiatry performed cross-hatching of the wound and cultures showed gram-positive cocci. MRI Left foot was consistent with early osteomyelitis of great toe. Patient was discharged on vancomycin and ceftriaxone for 6 weeks. Vancomycin was switched to daptomycin due to worsening renal function. Fifteen days later patient was readmitted to intensive care unit secondary to hypoxic respiratory failure. Physical exam revealed bilateral diffuse crackles. Patient was started on supplemental oxygen. Chest x-ray showed patchy bilateral infiltrates. Daptomycin was discontinued because of the suspicion of EP. BAL was done which revealed numerous eosinophils, moderate neutrophils and all bacterial, viral and fungal cultures were negative. High dose corticosteroid was started, 5 days later hypoxia resolved. Shortly after the steroid taper was completed, he developed recurrent dyspnea and pulmonary infiltrates. He was restarted on steroids and autoimmune conditions were ruled out. HRCT showed extensive bilateral parenchymal abnormalities with patchy ground glass opacities as well as reticulation. Repeat BAL was negative for eosinophilia. Patient's EP improved but patient expired secondary to heart failure.
DISCUSSION: Daptomycin is a cyclic lipopeptide antibiotic active against Gram-positive bacteria including Methicillin resistant Staphylococcus aureus (MRSA) and Vancomycin resistant Enterococci (VRE). Recent case reports have shown that Daptomycin can cause serious respiratory complications including Eosinophilic pneumonia (EP). EP is characterized by pulmonary infiltrates and increased numbers of eosinophils in lung tissue or broncho-alveolar lavage (BAL) fluid, with or without increased level of eosinophils in the peripheral blood. EP is an uncommon entity most commonly associated with use of antibiotics and non-steroidal anti-inflammatory drugs. Pathophysiology involves triggering of immune response due to an offending agent, leading to eosinophilic chemotaxis and localization into the lung. EP should be considered in individuals who receive Daptomycin and develop new pulmonary infiltrates. Significant morbidity and mortality can occur if this condition remains unrecognized and not properly treated in a timely fashion. Daptomycin toxicity mechanism remains uncertain and further studies are necessary.

EVANS SYNDROME IN CHRONIC LYMPHOCYTIC LEUKEMIA Ajaykumar Kaja; Vimalkumar Veerappan Kandasamy; Khaled M. Abouelezz; Mary Tadros. Creighton University Medical Center, Omaha, NE. (Tracking ID #1642084)

LEARNING OBJECTIVE 1: Recognize the association of Evans Syndrome with Chronic Lymphocytic Leukemia.
LEARNING OBJECTIVE 2: Identify clinical manifestations,diagnostic workup and available treatments for Evans Syndrome.
CASE: 84 year old caucasian male presented with complaints of progressive fatigue,unintentional weight loss of 5 lb over 6 months and one episode of melena. Past medical history was significant for hypertension, duodenal ulcer 30 year ago, iron deficiency anemia and CLL in remission. Vital signs were unremarkable. Physical examination was negative for bruises, icterus, hepatosplenomegaly or generalized lymphadenopathy. Laboratory data showed hemoglobin of 5.9 gm/dl, platelets of 41 k/ul, white blood cell count of 10 k/ul with an absolute neutropenia. His baseline Hgb and platelet count were 11 gm/dl and 200 k/ul respectively. Other significant laboratory data include positive FOBT, indirect bilirubin of 2.3 mg/dl, reticulocyte count of 0.15 M/ul and an LDH of 600 IU/L. Peripheral smear showed smudge cells, ovalocytes and was negative for schistocytes or fragmented RBC. The patient was admitted to the ICU and received 2 units of packed red blood cells. Upper Endoscopy and Colonoscopy were negative for enteral bleed. Further workup was negative for IgM parvovirus and CMV antibodies. Direct coombs test was positive. Bone marrow biopsy was done, which showed marrow hypercellularity with erythroid and megakaryocytic hyperplasia.In light of concern of immune mediated peripheral sequestration and cellular destruction the diagnosis of Evans syndrome was made.He was then started on IV methylprednisolone. Hemoglobin and Platelet counts improved over the next 24 h.
DISCUSSION: Evans syndrome,first described in 1951, refers to a combination (either simultaneously or sequentially) of coombs positive warm AIHA, Immune thrombocytopenic purpura and less commonly autoimmune neutropenia. Only 1 % of cases present simultaneously with AIHA and ITP. Although Evans Syndrome has been considered as an "idiopathic" condition, about 50 % of cases are associated with other diseases such as SLE,lymphoproliferative disorders or primary immunodeficiencies. Immune dysregulation, decreased T4:T8 cell ratio and increased constitutive production of interleukin-10 and Interferon gamma causing activation of autoreactive antibody-producing B cells were proposed for autoantibody production. The antibodies that cause hemolysis are different from those that cause platelet destruction. Those causing RBC destruction are directed against a base protein portion of the Rh blood group, while those destroy platelets are directed against platelet GPIIb/IIIa. Clinical presentation includes features of hemolytic anemia and thrombocytopenia. Diagnostic workup for adults with newly diagnosed Evans Syndrome includes peripheral smear, serum protein and immuno electrophoresis, measurement of serum immunoglobulin concentrations and immunophenotyping of circulating B lymphocytes. Also indicated is testing for anti-dsDNA antibodies, anticardiolipin antibodies, HIV, HCV,HBV, bone marrow biopsy in diagnosing associated diseases of Evans syndrome. First line treatment is glucocorticoids and intravenous immunoglobulin. Second line treatment includes immunosuppressive agents,danazol and rituximab. Refractory cases are treated with splenectomy and stem cell transplantation. The magnitude of hemolysis and response to treatment can be serially monitored by LDH, haptoglobin, indirect bilirubin and Coombs testing.

EXERTIONAL DYSPNEA: A SYMPTOM OF INFRARENAL AORTIC OCCLUSIVE DISEASE Stacey Schott[1]; Fernanda Porto Carreiro[1]; James R. Harkness[1]; Mahmoud Malas[2]; Stephen M. Sozio[1]; Sammy Zakaria[1]. [1]Johns Hopkins University School of Medicine, Johns Hopkins Bayview Medical Center, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #1641736)

LEARNING OBJECTIVE 1: Infrarenal aortic stenosis should be considered a plausible cause of dyspnea on exertion.

LEARNING OBJECTIVE 2: Treatment of occlusive disease of the aorta may be indicated in cases where no other causes for dyspnea are found.
CASE: A 77 year old woman with a history of hypertension, hyperlipidemia and diabetes presented with 2 months of progressive exertional dyspnea and bilateral calf and buttock pain that began to interfere with performing light housework and walking farther than the length of her home. Her initial vital signs included a blood pressure of 171/71 mmHg, a pulse rate of 71 beats/min and an oxygen saturation of 99 %. Her physical examination was notable for mild sternal chest discomfort with palpation, occasional ectopic beats with cardiac auscultation and faint pulses in her bilateral femoral, dorsalis pedis and posterior tibial arteries. Her laboratory studies were within normal limits, except for elevated total cholesterol of 242 mg/dL and LDL of 152 mg/dL. An initial electrocardiogram showed normal sinus rhythm with occasional premature ventricular beats and no evidence of left ventricular hypertrophy or myocardial ischemia. She underwent a VQ scan which returned low probability for pulmonary embolism. A CT angiogram revealed diffuse coronary and aortic atherosclerosis, without evidence of pulmonary embolus or parenchymal lung disease. While hospitalized she continued to have dyspnea and fatigue with minimal ambulation. Exercise on a modified Bruce protocol treadmill stress test was limited to 7 min (4 METS) due to progressive dyspnea but otherwise showed no evidence of ischemia. An echocardiogram revealed normal left ventricular function with no diastolic dysfunction or significant valvular disease. Pulmonary function testing showed no obstruction or restriction. Coronary CTA revealed only mild luminal irregularities. MRA of the chest, abdomen, and lower extremities revealed a high-grade stenosis of the abdominal aorta 3 cm distal to the renal arteries. An abdominal CT angiogram confirmed infrarenal aortic stenosis which reduced the luminal diameter to 2 mm. Consequently, vascular surgery performed a diagnostic angiogram which revealed greater than 80 % stenosis of the infrarenal aorta. The aortic lesion was treated with angioplasty and placement of a balloon expandable stent which increased the aortic diameter to 8 mm. One day after intervention the patient's claudication symptoms completely resolved and she had noted improvement in her exertional dyspnea. Within 1 month her exertional dyspnea fully resolved and she returned to daily exercise, including 30 min bike rides, weight lifting, and frequent bowling sessions. A modified Bruce protocol stress test repeated 4 months later demonstrated a 4-minute improvement in walking time (7 METS), without reoccurrence of previous symptoms. Twelve months after intervention she remained completely asymptomatic.
DISCUSSION: Despite extensive medical testing and observation, typical causes of exertional dyspnea were not found. We postulated that aortic occlusion and renal artery stenosis could have created severe hypertension, flash pulmonary edema and shortness of breath. Another less likely explanation included dyspnea incited by metabolic acidosis. Given the distinct and lasting elimination of dyspnea following angioplasty and stenting of a near occlusive infrarenal aortic lesion we hypothesized that infrarenal aortic stenosis may be a treatable cause of exertional dyspnea.

EXUDATIVE PLEURAL EFFUSION IN A HAITIAN MAN Traci Fraser; Jordan B. Strom; Lee Park. Massachusetts General Hospital, Boston, MA. (Tracking ID #1620415)

LEARNING OBJECTIVE 1: Diagnose tuberculous pleural effusion when all cultures are negative.
LEARNING OBJECTIVE 2: Recognize the features of a tuberculous pleural effusion.
CASE: A 46-year-old previously healthy male presented with 2 weeks of subjective fevers, pleuritic chest pain, and worsened nonproductive cough with chills and night sweats. He denied hemoptysis, significant weight loss, or sick contacts. There was no significant past medical history or medications. He traveled to Haiti 6 weeks prior to presentation and reported having a purified protein derivative (PPD) 5 years prior to presentation but did not recall the results. On exam, he had firm, fixed left axillary lymphadenopathy and dullness to percussion with decreased breath sounds in the right lung base. Chest computed tomography showed new bilateral pleural effusions and mediastinal lymphadenopathy. PPD had 10 mm of induration. Pleural fluid studies revealed an exudative effusion based on a total protein 6.8 g/dL (serum total protein 8.1 g/dL) and LDH 482 IU/L (serum upper limit of normal 210 IU/L). Other pleural fluid studies included total nucleated cell count of 34,300 cells/mm3 with 41 % neutrophils and 33 % lymphocytes, pH 7.4, glucose 105 mg/dL, albumin 3.4 g/dL, and adenosine deaminase 65.2 U/L with cytology negative for malignancy. Pleural acid fast bacilli (AFB) stain and culture were negative. Sputum AFB stain and culture were negative on three repeat examinations. PET-CT showed diffuse lymphadenopathy. HIV testing was negative. Left axillary lymph node biopsy revealed reactive lymphadenopathy. Pleural biopsy could not be obtained.
DISCUSSION: Pleural effusions are commonly seen by the general internist with a wide differential. It is worthwhile for the general internist to be familiar with the features of tuberculous pleural effusion as it is the second most common manifestation of extrapulmonary tuberculosis and may be the first or only manifestation of tuberculosis in some individuals. Effusions are typically unilateral and located on the same side as the parenchymal disease. Pleural fluid is typically exudative with a protein concentration > 3.0 g/dL and LDH often greater than 500 IU/L, containing 1000 to 6000 cells/mm3 with a lymphocytic predominance. Pleural fluid cultures are positive in approximately 20 % of cases, but pleural biopsy may increase the culture yield to 90 %. An adenosine deaminase level greater than 45 U/L in pleural fluid has a 100 % sensitivity and 80–97 % specificity for the diagnosis of tuberculous pleural effusion. Neither PPD nor interferon gamma release assays are sensitive for the diagnosis of tuberculous effusion. Some features of our patient's presentation were initially suggestive of malignancy, however, once this was excluded, though AFB and culture data were negative, tuberculous pleural effusion was the most likely diagnosis and empiric therapy was started with improvement in the patient's symptoms. This case illustrates the utility of pleural fluid adenosine deaminase levels in establishing the diagnosis of tuberculous pleural effusion without positive AFB or culture data.

FACE TO FACE: UTILIZING TECHNOLOGY TO SUPPORT HOSPITALIZED PATIENTS Jane M. Shen; Rachel Kruzan. Johns Hopkins Bayview Medical Center, Baltimore, MD. (Tracking ID #1642981)

LEARNING OBJECTIVE 1: Recognize the importance of social support for hospitalized patients
LEARNING OBJECTIVE 2: Discover technological tools available to connect patients and fsupport system in meaningful way
CASE: A 51 year-old woman with granulomatous uveitis presented with 4 months of intermittent fevers, weight loss, anorexia, tachycardia, and diarrhea. She had been admitted four times prior to the current hospital admission for evaluation of fever of unknown origin. She had undergone extensive rheumatologic, oncological, and infectious work-up, including multiple CT scans, tagged WBC scan, endoscopy, colonoscopy, echocardiogram, bone marrow biopsy, skin biopsy, and PET scan, which were unrevealing. She continued to have persistent fevers and tachycardia. Labs showed hemolytic anemia requiring blood transfusions and elevated inflammatory markers. Per nuclear medicine, a gallium scan was recommended, which revealed focal intense uptake in the anterior mediastinum. She was diagnosed with diffuse large B cell lymphoma post-biopsy. Throughout the hospitalization, she became increasingly demoralized and withdrawn with minimal oral intake. However, her mood and energy improved when her family would visit, especially her daughter. Therefore, she was devastated to learn that her daughter would be unable to visit her bedside for 12 days due to the radioactivity of the gallium injection she received, as her daughter was pregnant. To continue to enable her daughter's support, we set up FaceTime sessions with our iPads, which allowed face-to-face communication between the patient and daughter. She was also able to participate in her daughter's baby shower through FaceTime.
DISCUSSION: Hospitalizations can cause significant stress for patients and their families. They may encounter fears and concerns regarding their

illness, an unfamiliar environment with little patient control, and limitations to communication with family and friends. Support systems play an important role in patient-centered care, yet there are often barriers to patients staying connected while hospitalized. These barriers include geographical distance, work constraints, functional status, and financial situation. In our case, there was a unique barrier with gadolinium precluding visits by her pregnant daughter. FaceTime allowed the patient and daughter to have face-to-face communication and stay connected. With FaceTime, her daughter would ask insightful questions about the patient's appearance or provide frequent encouragement, which left the patient with increased energy and participation in her own care. Brecher et al. in the Journal of Palliative Care found that Skype, a similar online face-to-face communication application, provided a tool for palliative care patients to communicate with family and friends, especially under circumstances in which functional status or geographic limitations precluded in-person communication. According to a literature search, this technology has also been utilized in pediatric ICUs and for intrepretation to improve quality of care. FaceTime and Skype are free applications easily accessible on computers and cell phones. Through this experience, we found that these technologies can be used with our general medicine patients to enhance patients' quality of life in the hospital, provide support through relationships, and improve patient-centered care.

FATAL INTRACRANIAL HEMORRHAGE IN SETTING OF REFRACTORY HYPERCOAGULABLE STATE: A CASE OF ATYPICAL HYPERCOAGULATION Robert L. Fogerty; Christopher Sankey. Yale School of Medicine, New Haven, CT. (Tracking ID #1612880)

LEARNING OBJECTIVE 1: Recognize intracranial hemorrhage as a fatal consequence of therapeutic anticoagulation
LEARNING OBJECTIVE 2: Recognize atypical causes of hypercoagulable states
CASE: A 56 year- old woman, recently diagnosed with heparin induced thrombocytopenia, presented with 2 weeks of worsening lower extremity pain and swelling while on anticoagulation. She denied trauma, reported complete medication adherence, took neither contraceptives nor hormones, and recently emigrated from Jamaica. On readmission, she had right leg edema from hip to toe, platelet count of 45,000, INR of 2.2, and an ultrasound demonstrating multiple thrombi, worsened from prior. Extensive cancer and hypercoagulability workup was normal. Hematology was consulted, bivalirudin was initiated, and the patient improved. The initial diagnosis was ongoing HIT. A midline intravenous catheter was placed, but she developed bleeding at the puncture site and bivalirudin was stopped. Within hours, she developed a new catheter associated clot. The midline was removed and fondaparinux restarted. She continued to improve symptomatically. Inpatient bridge to goal INR was planned. On the expected day of discharge she developed "the worst headache of my life." A computed tomography scan revealed a large left intraparenchymal and subarachnoid hemorrhage and midline shift. She clinically declined, was intubated, and transferred to Neurosurgery, where she subsequently died the next day. Autopsy was suggestive of Bush Tea Syndrome, a dietary related hypercoaguable state similar to Veno-occlusive disease.
DISCUSSION: Hypercoagulable states are commonly seen by General Internists and carry a high risk treatment, therapeutic anticoagulation, resulting in death in this case. Common causes of hypercoaguable states include malignancy, inherited disorders, and drug related etiologies. Foods can also lead to hypercoaguable states and should be considered when initial evaluation is unremarkable. The causative agent of Bush Tea Syndrome, pyrrolizidine alkaloids, are found in some concentration in 3 % of the world's flowering plants, some of which are used as traditional dietary seasonings, typically in Jamaica and South Africa. It is likely that the patient suffered from unidentified chemical ingestion via diet, resulting in a hypercoagulable state similar to Bush Tea Syndrome. Returning to our patient's history, her husband was known to frequently visit our patient, bringing traditional Jamaican foods that he prepared as a means of comfort for his wife. CONCLUSION: The morbidity and mortality associated with therapeutic anticoagulation make it incumbent upon us as medical providers to consider alternative diagnoses in cases of atypical thrombophilia. While Bush Tea Syndrome is a rare disorder, it is possible that a thorough dietary history may have changed this patient's eventual outcome by ameliorating the need for therapeutic anticoagulation.

FATIGUE AND SECOND DEGREE AV BLOCK IN A YOUNG HEALTHY MALE Ryan Nall; Paige Comstock. BIDMC, Boston, MA. (Tracking ID #1641865)

LEARNING OBJECTIVE 1: Recognize cardiac complications of lyme disease
LEARNING OBJECTIVE 2: Describe the treatment of lyme carditis
CASE: A healthy 28 y/o male presented to his PCP with a 1 month history of intermittent fevers, chills, generalized aches, dyspnea on exertion, and fatigue. The patient lives in a wooded area in Massachusetts with recent travel to North Carolina and Maine. He reports past tick exposure, however none recently. He denied rash, lymphadenopthy, chest pain, and GI symptoms. On exam, the patient was normotensive with a pulse of 45. He appeared fatigued and had a regular but bradycardic heart rhythm. He had no jaundice or rash. An EKG was obtained which showed second degree AV Type 1 heart block. The patient was started on IV ceftriaxone 2 g q24 h to emprically cover lyme carditis. Lyme serologies returned positive and western blot test was positive for IgG and IgM. The patient was continued on IV ceftriaxone and oscillated between 1st and 2nd degree hear block during hospitalization. He was also found to have anemia and transaminitis and after discharge anaplasma serology returned positive. He was then started on doxycycline. In follow up his EKG showed sinus rhythm without AV block and PR interval had returned to normal at 186 ms. Ceftriaxone was discontinued and patient completed a course of doxycycline.
DISCUSSION: Lyme disease can affect multiple systems and is caused by Borrelia burgdorferi. In the US the prevalence of carditis among patients with Lyme disease ranges from 4 % to 10 %. The most common cardiac manifestation is atrioventricular conduction block as seen in this patient. Additional reported cardiac complications include: pericarditis, myocarditis, endocarditis, myocardial infarction, pericardial effusion, coronary artery aneurysm, QT prolongation, arrhythmias, and heart failure. Cardiac manifestations usually occur about 1 month after the initial exposure. Patients with AV block can rapidly fluctuate between first, second degree and complete heart block. A PR interval greater than 300 ms places patients at higher risk for developing high degree heart block. A patient can present with conduction abnormalities as their initial presentation of lyme disease. Often patients are asymptomatic, however may have typical cardiac symptoms including chest pain, syncope, palpitaitons, dyspnea, or dizziness. Patients with higher degree heart block or with PR interval greater than 300 ms should be hospitalized for telemetry, IV antibiotics, and evaluation for temporary pacemaker. The antibiotic of choice is IV ceftriaxone. Treatment with IV antibiotics should be continued until high degree heart block has resolved and the PR interval has normalized. The patient then can be transitioned to an oral antibiotic to complete a 21–28 day course. Despite these recommendations no recent trials exist to establish the best antibiotic therapy and whether IV antibiotics are necessary. One trial in 1997 by Dattwyler et al. showed no difference between IV ceftriaxone and PO doxycycline in the treatment of early disseminated Lyme disease. In this case the patient was found to be coinfected with anaplasma, which can explain his anemia and transaminitis. A study by Steere et al. reported Anaplasma coinfection to be present in 2 % of patients infected with borrelia burgdorferi.

FEVER IN THE RETURNING TRAVELER: WHAT MAKES TYPHOID FEVER DIFFERENT Lucas Heller; Harish Jasti. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1637637)

LEARNING OBJECTIVE 1: Recognize the unique signs and symptoms of typhoid fever.

LEARNING OBJECTIVE 2: Convey post-treatment public health risks.
CASE: A 21 year-old, otherwise healthy male, returned after a 1 week trip to Nigeria with fever, chills, diarrhea, vomiting, myalgias, headache, and drenching night sweats. He presented on day 7 of his illness, at the onset of diarrhea. He had not taken any pre-travel vaccinations or chemoprophylaxis. He slept indoors, drank bottled water only, and did not eat any undercooked meat, nor did he recall any mosquito bites. His brother, who had remained in Nigeria at the time of presentation, contracted malaria and had undergone treatment. Vital signs were temperature 38.6 Celsius, heart rate of 78, blood pressure of 110/60, and respiratory rate of 16. On examination, there was no scleral icterus, rash, or hepatosplenomegaly. Mild upper quadrant abdominal tenderness was elicited with palpation. Laboratory testing for the following infectious processes was negative: malaria, dengue fever, Yellow fever, hepatitis A and West Nile virus. Subsequent blood cultures were positive for group C Salmonella paratyphi. He was placed on a 10-day course of ciprofloxacin. He then had full resolution of his symptoms.
DISCUSSION: Typhoid fever is typically caused by S. enterica serotype Typhi (formerly S. typhi). The organism enters the GI tract via contaminated food or water in endemic areas and proliferates in the small bowel, causing diarrhea. Classically, the presentation begins with fevers in the first week, followed by rose spots, abdominal pain and diarrhea. During week 3 of the illness, the patient may exhibit hepatosplenomegaly or even intestinal perforation. Our patient also exhibited Faget's sign: the classic pulse temperature dissociation seen in intracellular infections such as yellow fever and typhoid fever. Lacking in his presentation was the characteristic "rose spot" rash on his trunk. Though pre-travel immunization is recommended for all going to endemic areas, it has not been shown to be effective against paratyphoid species. Treatment is three-fold: (1) Supportive measures for hemodynamic stability following volume depletion; (2) Antimicrobials based on culture results; (3) Avoidance of contact sports for several weeks. In spite of adequate treatment, 6 % of patients may become chronic carriers. Carriage poses no overt risk to any individual but can be an infectious risk to others, especially in the setting of food preparation. This has been described in the classic case of Typhoid Mary, an Irish-American cook in early 20th century New York, who inadvertently infected over 50 people, before being quarantined by public health authorities. Our case highlights the importance of recognizing characteristic signs and symptoms of disease processes to help narrow down the differential diagnosis. For typhoid fever, these include a pulse-temperature dissociation, onset of diarrhea during the second week of illness, and rose spots, in the setting of travel to an endemic area.

FEVERS AND INTERMITTENT JAUNDICE - NOT YOUR TYPICAL GI PROBLEM Sweetheart Ador-Dionisio[1]; Stacey E. Jolly[2]; J. H. Isaacson[2]. [1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH. (Tracking ID #1637101)

LEARNING OBJECTIVE 1: To recognize the clinical manifestations of disseminated histoplasmosis.
CASE: A 64 year old female with rheumatoid arthritis on methotrexate and infliximab was admitted to an outside hospital with a 1 week history of fevers, anorexia, and generalized weakness after not improving with an outpatient antibiotics course. On admission, she was jaundiced, had right upper quadrant abdominal tenderness, clear lungs, and abnormal liver function tests (LFTs). She was started on piperacillin/tazobactam and a CT of the chest, abdomen, and pelvis showed diffuse gallbladder wall thickening; hepatobiliary scan revealed no cystic duct obstruction or cholecystitis. Despite improvement in labs, she continued to have fevers, chills, and RUQ pain. A magnetic resonance cholangiopancreatography (MRCP) showed probable primary sclerosing or ascending cholangitis. She was transferred on day 6 for endoscopic retrograde cholangiopancreatography (ERCP), but she was noted to be hypoxic, requiring 6 L oxygen by nasal cannula so ERCP was aborted. Repeat MRCP showed no intra- or extra-hepatic biliary dilation. CT chest revealed moderate centrilobular emphysema, small bilateral pleural effusions, and lower lobe predominate nodules. On day 8, azithromycin and liposomal amphotericin were added to piperacillin/tazobactam; nevertheless, her condition acutely worsened and she was transferred to ICU. Antibiotic coverage was broadened to meropenem, vancomycin and pentamidine. Despite high oxygen requirements, she did not require intubation. Blood and urine cultures were negative and rest of infectious workup was unrevealing until day 15 when Histoplasma urine antigen came back positive; antibacterials were stopped. On day 19, liposomal amphotericin was switched to itraconazole due to acute kidney injury. After 21 days, oxygen was weaned off, renal function returned to baseline, and patient was discharged home; LFTs normalized after 2 months.
DISCUSSION: Histoplasmosis is the most prevalent endemic mycosis in North America. Symptoms are usually self-limited, but about 1 in 2000 patients with acute infection develops progressive disseminated histoplasmosis (PDH). PDH typically occurs in immunocompromised individuals such as those with HIV/AIDS, primary immunodeficiency, or on immunosuppressive medications such as glucocorticoids, anti-rejection therapies, and tumor necrosis factor-alpha inhibitors. Histoplasmosis primarily affects the lungs but has various extra-pulmonary manifestations including involvement of gastrointestinal (GI) tract, skin, adrenals, central nervous system, and rarely pericarditis and endocarditis. GI involvement occurs in 70–90 % of patients but is often underdiagnosed since symptoms are typically nonspecific. GI symptoms include abdominal pain, dysphagia, gastrointestinal bleed, abnormal LFTs, and cholestatic jaundice. Given the growing number of patients taking immunosuppressant medications, it is necessary to have a heightened level of suspicion for fungal infections. Consider a disseminated fungal infection such as histoplasmosis in an immunocompromised patient with initial presentation of fevers and jaundice, if patient fails to respond to empiric antibiotic therapy and clinical picture, especially respiratory status, acutely changes.

FEVERS, RASH AND JOINT PAIN, STILL? Catherine Trimbur; Mayce Mansour. Montefiore Medical Center, Bronx, NY. (Tracking ID #1637928)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of Adult-Onset Still's Disease (AOSD)
LEARNING OBJECTIVE 2: Understand the diagnostic criteria for AOSD.
CASE: A 32 year-old woman presents with 2 weeks of intermittent fever, nonpruritic rash, and migratory polyarthritis with effusions. She initially presented with a fever of 103 F, myalgias, and erythematous, blanching rash on bilateral thighs, arms, and dorsum of feet and hands. Review of systems was positive for rhinorrhea, sore throat, hyperalgesia and migratory polyarthritis of knees, wrists and ankles. She denied insect bites or sick contacts. Initial exam was nonfocal, notably without fever, lymphadenopathy, rashes or hepatosplenomegaly. During hospitalization, she had quotidian fevers often accompanied with macular rash and migratory large-joint effusions. Laboratory workup was notable for leukocytosis of 11.3, alkaline phosphatase of 153, AST of 49, ALT of 60 (previous lab results had normal LFTs), ESR of 92 and CRP of 12.9, but negative for viral and bacterial illnesses. Imaging was negative for malignancy. Initial ferritin level was 450, but was repeated on hospital day four and found to be 991. A diagnosis of Adult-Onset Still's Disease was made and the patient was started on prednisone with resolution of fever, rash and joint pain. As an outpatient, she was tapered off of steroids due to side effects and has remained symptom free 3 months after diagnosis, with normal ferritin levels.
DISCUSSION: Adult-Onset Still's Disease (AOSD) is an inflammatory condition characterized by intermittent fevers, rash and polyarthritis. First described in 1897 by George Stills as systemic onset juvenile idiopathic arthritis, AOSD was recognized in adults that do not fit the criteria for rheumatoid arthritis but have similar clinical presentations accompanied with fever. Though pathophysiology is unclear, it has been suggested that alterations in cytokine production (particularly Th1 cytokines) play an important role in the development of AOSD, and may be triggered by various infectious agents and stress. While no specific laboratory, imaging or clinical criteria confirm the diagnosis, the Yamaguchi criteria are most widely used, with a sensitivity of 93.5 % when five features (at least two major criteria) are present. Major criteria include fever >102.2 for >1 week, arthralgias/arthritis >2 weeks, non-pruritic macular, salmon-colored rash (usually during fever), leukocytosis >10,000 (>80 % granulocytes). Minor criteria are sore throat, lymphadenopathy, hepatomegaly or splenomegaly, abnormal LFTs, negative ANA and RF. Elevated ESR and CRP are present in almost all cases, and elevated ferritin (>1000) is seen in up to 70 % of

patients. Total ferritin and glycosylated fraction can be useful in ruling out other rheumatological processes. Normally, 50–80 % of ferritin is glycosylated. In AOSD, the fraction decreases due to a saturation of glycosylation mechanisms and a glycosylated ferritin fraction <20 % has specificity of 93 % for AOSD. The clinical course of AOSD generally follows three patterns: monophasic (with complete resolution of symptoms within 1 year), intermittent (with episodic flares), and chronic (with persistently active disease often associated with destructive arthritis). Similar to other inflammatory arthritides, treatment for AOSD includes NSAIDS, glucocorticoids (required in most patients), and antirheumatic agents. DMARDS are often utilized in refractory cases, despite lack of controlled-trials demonstrating efficacy.

FINDING CONN'S, AND LIFE AFTER Irene Rahman. Boston University, Boston, MA. (Tracking ID #1642006)

LEARNING OBJECTIVE 1: Confirm a diagnosis of Conn's syndrome in the case of initial borderline workup with saline suppression test, CT imaging and adrenal vein sampling.
LEARNING OBJECTIVE 2: Recognize that despite treatment for secondary hypertension, patients may still have underlying essential hypertension.
CASE: The patient is a 62 year old man with a history of long-standing hypertension and diabetes noted to have persistent hypokalemia despite supplementation. His anti-hypertensive regimen at presentation included lisinopril 40 mg daily, labetalol 300 mg daily and amlodipine 10 mg daily, with ambulatory systolic blood pressure readings in 140–160 range. The patient reported getting leg cramps often, but otherwise ROS negative. Physical exam did not reveal any stigmata of secondary causes of hypertension. Metabolic panel showed potassium of 3.4 while on 40 mEq of supplement daily. Plasma aldosterone concentration (PAC) and plasma renin activity (PRA) were 19 and 0.17 respectively, with a ratio of 112. Saline suppression test was performed, in which the patient's aldosterone level suppressed to 6 ng/dL after 4 h of saline infusion. CT imaging revealed two 8–9 mm nodules in the left adrenal gland. Adrenal vein sampling showed aldosterone to cortisol ratio of 4.66 when comparing left side to right side. Patient was referred to surgery, and underwent a left adrenalectomy. Post-operatively, patient had systolic blood pressure in 140 range, for which amlodipine was continued.
DISCUSSION: In this patient with persistent hypokalemia and hypertension, work up for primary hyperaldosteronisim was indicated. The initial approach was to determine the plasma aldosterone concentration (PAC) and plasma renin activity (PRA). In a population with a prevalence of the disease of 20 %, the combination of PAC>20 ng/dL and PAC/PRA>30 has sensitivity and specificity of 90 % for detecting aldosterone producing adenoma, but our patient displayed only the latter feature. When the results of the initial hormone levels are ambiguous, inappropriate aldosterone secretion should be confirmed by a saline suppression test, with aldosterone level suppressed to <5 for normal patients and >10 for patients with primary hyperaldosteronism, which put our patient in the gray zone again. CT imaging was performed to visually detect and distinguish between bilateral hyperplasia (~60 % of cases) and unilateral adenomas (~35 % of cases), the most common causes of primary hyperaldosteronism. We finally pursued adrenal vein sampling for two reasons: (1) to prove biochemically that the unilateral nodules on imaging represent functional adenomas causing primary hyperaldosteronism, also known as Conn's syndrome; (2) to justify pursuing unilateral adrenalectomy of the culprit gland. Despite confirming that the patient's left adrenal was the culprit gland, he continued to have elevated blood pressures post-adrenalectomy, although requiring less anti-hypertensive treatment. It has been shown that hypokalemia is curable but residual hypertension persists in 43.8 % of patients, which likely indicates underlying essential hypertension in addition to primary hyperaldosteronism. The pathogenesis of essential hypertension is poorly understood, but many risk factors have been identified. Those present in this patient include older age, family history, and increased sodium intake. Thus, patients with an identified cause of secondary hypertension should be followed post-treatment to monitor for essential hypertension, and treated accordingly per guidelines.

FIRST DO NO HARM: CORTICOSTEROIDS AND RECURRENT PERICARDITIS Yogita Segon; Ankur Segon. Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #1619484)

LEARNING OBJECTIVE 1: Appreciate the relationship between administration of corticosteroids and development of recurrent pericarditis
LEARNING OBJECTIVE 2: Reinforce the grave consequences of inappropriate administration of oral corticosteroids
CASE: 43 y old male without any past medical history presented to urgent care clinic with cough, subjective fever and wheezing. He was diagnosed with acute bronchitis and given tapering dose of prednisone 60 mg for a week and doxycycline. He presented to another clinic about 2 weeks later with c/o substernal chest pain, fever of 100.2 F, tachypnea, tachycardia and pulsus paradoxus of 40 mmHg. His D-dimer was markedly elevated. Computed tomography scan (pulmonary embolism protocol) was ordered which suggested significant left pleural effusion, right lower atelectasis versus infiltrate and large circumferential pericardial effusion. A diagnosis of symptomatic pleura-pericarditis with effusions was made and he was started on NSAIDS, colchicine and moxifloxacin. Transthorasic echocardiogram confirmed large pericardial effusion. Thoracentesis of the left pleural effusion was performed for therapeutic and diagnostic purposes. Pleural fluid studies were consistent with a transudate. Repeat ECHO showed improvement in pericardial effusion and patient was discharged home on ibuprofen, colchicine and azithromycin. He presented to emergency room 1 week later with worsening shortness of breath. Chest x-ray showed recurrent pleural effusion and echocardiogram confirmed re-accumulation of pericardial effusion. Repeat thoracentesis was done and pigtail drain was placed in his pleural space with removal of over 1 l of fluid. He felt much better, and his respiratory status improved. At this point, corticosteroids were introduced to treat his recurrent pericardial effusion. We continued him on colchicine and ibuprofen. Autoimmune testing was equivocal (positive antinuclear antibody and anti-RNP antibody, all other antibodies negative). Hepatitis C serology was positive with normal LFTs. He was discharged on colchicine for total of 6 months. Other discharge medications included tapering doses of ibuprofen for 3 months and prednisone for 1 month.
DISCUSSION: Recurrent pericarditis is a troublesome complication of the acute pericarditis and occurs in from 15 % to 50 % of cases. Serious complications such as constrictive pericarditis and tamponade are rare sequelae of recurrent pericarditis. However, morbidity related to symptoms of pericarditis is significant. While corticosteroids have been traditionally been used to treat acute pericarditis, it is now believed that treatment with corticosteroids during the index attack is an independent risk factor for development of recurrent disease. Routine administration of corticosteroids during a first episode of acute viral pericarditis should be avoided. Other causes of recurrence include underlying autoimmune disorders and recurrent infection. Since viral pericarditis can present in conjunction with a viral bronchitis, diagnosis might not be apparent unless an echocardiogram is performed. Our case highlights the importance of not using corticosteroids for treatment of acute bronchitis which is a predominantly viral illness, especially since the patient might have associated pericarditis that might become recurrent due to corticosteroid therapy. However, corticosteroid therapy can be useful in patients with autoimmune hepatitis and uremic pericarditis. It can also be used for treatment of recurrent and refractory pericarditis.

FLESH-EATING DISEASE OF THE BREAST Marc Cerruti; Ramesh K. Gadam; Gowri Radhakrishnan; Susan Knowles. University of Nevada School of Medicine, Las Vegas, NV. (Tracking ID #1637860)

LEARNING OBJECTIVE 1: Recognize the rare disease necrotizing fasciitis of the breast.
LEARNING OBJECTIVE 2: Treat necrotizing fasciitis of the breast emergently with broad-spectrum antibiotics and early surgical debridement
CASE: Necrotizing fasciitis is a soft tissue infection that is challenging to diagnose and treat due to its rapidly progressing systemic consequences. In this case, we report the rare finding of necrotizing fasciitis involving the breast, caused by Peptostreptococcus bacteria. A 46 year old female patient with a past medical history of obesity, hypertension, and type II diabetes

mellitus presented to the emergency room with right breast pain. She was previously diagnosed with a breast abscess, for which she was treated unsuccessfully with oral antibiotics. The patient had intermittent expression of foul-smelling, purulent, and occasionally bloody discharge from her right nipple. On admission, she was afebrile, normotensive, and hemodynamically stable. On physical exam, the right breast was erythematous, swollen, warm, and exhibited peau d'orange texture. Her breast was diffusely tender to palpation, but no axillary lymph node enlargement was appreciated. The patient's laboratory data showed the following: white blood cell count 28.3×103/mm3 (78 % neutrophils), sodium 129 mmol, chloride 90 mmol, bicarbonate 19 mmol, BUN 49 mg/dL, creatinine 4.2 mg/dL, and anion gap 20. Breast ultrasound showed a soft tissue lesion with no well-defined fluid collection or mass. Computed tomography showed right breast tissue edema, fat stranding with skin thickening, and large collections of subcutaneous gas. Given the patient's clinical picture and evidence of acute kidney injury, immediate surgical debridement was performed. Pathologic examination showed inflamed and foul-smelling necrotic breast tissue with numerous white blood cells. Anaerobic wound cultures confirmed a Peptostreptococcus species bacterial infection, which was treated with tigecycline initially, and later clindamycin. After further examination, two additional surgical debridements were performed. Postoperatively, we provided local wound care every day. Our patient's renal function improved and signs of active infection resolved. She was discharged on hospital day 21 with a wound vac in place, and she was advised to return for wound closure.

DISCUSSION: This case illustrates the importance of ruling out necrotizing fasciitis when faced with a subcutaneous infection. Although seemingly stable, patients affected by necrotizing fasciitis may have potentially lethal complications, such as metabolic derangement. Necrotizing fasciitis of breast is a very rare disease with only 8 published case reports worldwide. Other than our case report, only one prior case of necrotizing fasciitis of breast has been reported to present as an abscess. While the management of this disease has been debated, here we present the successful use of both early debridement and early broad-spectrum antibiotics in treating necrotizing fasciitis of the breast.

FORGOTTEN DEMENTIA: A CASE OF WERNICKE'S ENCEPHALOPATHY Joelle Rhayem; Anthony Donato; Jessica Capasso. Reading Health System, Reading, PA. (Tracking ID #1623874)

LEARNING OBJECTIVE 1: Recognize clinical features of Wernicke's encephalopathy

LEARNING OBJECTIVE 2: Recognize Wernickes encephaloapathy as a likely etiology for altered mental status and the treatment involved.

CASE: 51-year old female with a history of long-standing alcohol abuse was brought to emergency care after being found down at home. On presentation she was noted to have a delayed response to questions, and amnesia to recent events. Physical exam by the admitting team demonstrated horizontal nystagmus, encephalopathy, and difficulty with lower extremity coordination. Polysubstance overdose was initially suspected, but urine toxic screens, osmolar gap and blood alcohol levels were negative., Thiamine therapy was initiated. Non-contrast CT and lumbar puncture results were unrevealing. An MRI was ordered which demonstrated symmetrical T2 hyperintensity in the bilateral thalami and subtle T2 hyperintensity in the gray matter around the aqueduct, third ventricle and mammillary bodies supporting the diagnosis of Wernicke's encephalopathy. She made a slow recovery over the course of 2 months, recovering all language and executive function but persisting with a profound short-term memory deficit.

DISCUSSION: Although the classic triad of Wernicke's encephalopathy, (ophthalmoplegia, ataxia, and altered mental status) is well known to most physicians, the prevalence at autopsy is much greater than the estimated clinical incidence, suggesting that the diagnosis is often overlooked. Wernicke's encephalopathy is a clinical diagnosis that requires a high degree of clinical suspicion. Presentation is often subtle, with only 10 % of patients demonstrating all components of the triad. Clinicians should have a low threshold for use of thiamine in all patients with altered mental status, given the minimal risk to this intervention and the potential harm of misdiagnosis.

FROZEN VALVE? … LYTIC THERAPY!A CASE OF PROSTHETIC VALVE THROMBOSIS Mamatha Siricilla. UAB Internal medicine, Montgomery, AL. (Tracking ID #1642544)

LEARNING OBJECTIVE 1: To recognize Complications of Prosthetic value

LEARNING OBJECTIVE 2: Learn to use appropriate diagnostic tools and treatment options to improve outcomes

CASE: 73 year old Caucasian female with PMH of Rheumatic fever, Mitral and aortic valve replacement (with St. Jude Prostheses 21 years ago) presented with sudden onset shortness of breath and Paroxysmal nocturnal dyspnea of 2 week duration. Patient denied any chest pain. Patient was hemodynamically stable. Physical examination revealed sharp S1 and S2 and faint 1–2 systolic ejection murmur at upper right and left sternal borders. Transthoracic echocardiogram (TTE) revealed mitral valve area 0.5 cm2. Transesophageal echocardiogram (TEE) showed 1 leaflet of mitral valve "frozen" in the closed position with increased transvalvular gradient. Occlusion was thought to be due to acute thrombus of the mitral valve. International Normalized Ratio (INR) was subtherapeutic at 1.20. Decision was made to proceed with thrombolytic therapy. Tenecteplase (tissue plasminogen activator) was given. Patient tolerated well with no complications. Following day TEE was repeated which showed movement of both leaflets of the prosthetic valve and decrease in transvalvular gradient. Her Coumadin dose was increased and lovenox was given for few more days. Patient had improvement in her symptoms.

DISCUSSION: Prosthetic valve thrombosis (PVT) has an incidence between 0.1 % and 6 % per patient-year of left sided valves. PVT is an infrequent but serious complication with high mortality and morbidity risk. PVT occurrence depends on the valve type and position and presence of atrial fibrillation and Left ventricular dysfunction. The most common cause is an inadequate anticoagulation therapy. Clinical Presentation is variable based on the type of PVT Obstructive (Progressive heart failure, cardiogenic shock and systemic embolism) or Non-obstructive (Stroke, Peripheral embolism, 50 % cases can be asymptomatic). Patients with thrombus formation have shorter duration of symptoms and more often inadequate anticoagulation while pannus formation is unaffected by anticoagulation. Physical examination is frequently insufficient it can reveal decreased prosthetic valve sounds, a new murmur or change in previously detected murmur. Diagnosis of PVT is established by TTE, TEE or Fluoroscopy. Doppler echocardiography is the most accurate method for detecting and quantifying the degree of transvalvular gradient increase and is useful in the follow up of patients during thrombolysis. TEE is helpful to assess thrombus size and location and aid in treatment decisions as well as differentiating Thrombus from Pannus formation and Vegetation. Management depends on the thrombus size and location, risk of surgery versus thrombolysis and patient functional status. Traditional therapy of left sided PVT is emergent surgery (Valve replacement/thrombectomy) but more recently thrombolysis has been recommended as first line treatment. Surgical treatment carries high risk of mortality and New York Heart Association (NYHA) functional class at presentation is the strongest predictor of mortality. Thrombolytic therapy has lower mortality rate but carries risk of systemic embolism, bleeding and recurrence of thrombosis. PVT can be an emergency condition with hemodynamic deterioration and high mortality. TEE plays an important role in diagnosis and guiding the optimal treatment strategy. Thrombolysis is recommended as a first line treatment unless contraindicated.

GO ASK ALICE Farah Kaiksow; Michelle M. Guidry. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640314)

LEARNING OBJECTIVE 1: Recognize methadone and other opioids as ototoxic drugs.

LEARNING OBJECTIVE 2: Appreciate the importance of obtaining an accurate medication history. Appreciate the value of "doing nothing" when faced with rare clinical findings.

CASE: A 54 year-old man presented with acute-onset bilateral hearing loss and altered mental status. He was last seen symptom-free 36 h prior to

presentation. He was able to report a history of hypertension and gout, for which he had a prescription bottle of allopurinol. He was alert and oriented to person, place, situation, and year. He was completely deaf on initial presentation; Weber and Rinne tests were not performed as he had limited ability to follow directions. He responded to simple written questions, and simple cranial nerve and neurological exams were completed through mimicry. Other than the hearing loss, his physical exam was otherwise normal. There was no evidence of acute intracranial hemorrhage or ischemia on a non-contrast CT of the head. His EKG was normal, as was his serum bicarbonate level. He had a white blood cell count of 28,000/μL, a creatinine kinase of 3, 379 units/L, a potassium of 5.5 mmol/L, an AST and ALT of 111 and 75, respectively, a blood urea nitrogen of 43 mg/dL, and creatinine of 3.4 mg/dL. His serum was negative for salicylates, acetaminophen, and alcohol, and an HIV test was negative. His serum was positive for tricyclic antidepressants and opiates. After these results were available, nursing staff examined the contents of the patient's allopurinol bottle and discovered multiple pills, one identified as amitriptyline and another as methadone. With fluid resuscitation as the only treatment, the patient's hearing, mental status, and lab values returned to normal within 36 h.

DISCUSSION: The list of common ototoxic medications that an internist should be aware of is short. Aminoglycoside antibiotics, salicylates, and diuretics are the most commonly prescribed medications causing hearing impairment. When deafness occurs suddenly, is bilateral, or is associated with changes in mental status, other less common medications should be considered. Methadone and other opioids are drugs that, when used in excess, can cause hearing impairment. Additionally, in rare cases when the symptoms are unusual and cannot be easily explained pathophysiologically, it is essential to obtain a thorough medical history. It may not be enough to ask the patient what he is taking or even to look at the prescription bottles themselves; in cases where overdose is possible, it may be beneficial to actually identify the pills themselves, as was done in this case by the emergency room nursing staff. Finally, this case reinforces the possible benefits of "watchful waiting" or "the art of doing nothing," particularly when faced with a high degree of uncertainty. Of course, we should not wait to treat an obvious and easily fixed abnormality, such as this patient's acute kidney injury; but in cases where no obvious solution or diagnosis presents itself and the patient is clinically stable, we should not hesitate to act.

GABAPENTIN RELATED NEUROTOXICITY IN HEMODIALYSIS PATIENT Shyam Patel; Rakesh Malhotra. UMDNJ-New Jersey Medical School, Newark, NJ. (Tracking ID #1643210)

LEARNING OBJECTIVE 1: Gabapentin should be renally-dosed in chronic kidney disease and/or end stage renal disease patients.

LEARNING OBJECTIVE 2: Plasma gabapentin levels should be monitored in hemodialysis patients.

CASE: We report a case of a 61-year-old hemodialysis-dependent female patient who was admitted for a seizure attack during one of her regular hemodialysis sessions. She had a history of hypertension, congestive heart failure, diabetes mellitus, end-stage renal disease, and breast cancer status-post mastectomy. Patient was reported to have jerking movement of both arms and legs during and after the hemodialysis session. On Examination, she was somnolent and unable to follow simple commands. Blood Pressure was 140/83 and heart rate was 62 beats per minute. Physical examination findings were otherwise unremarkable. Laboratory work was significant for BUN of 77 mg/dL. Chest X-ray showed signs of fluid overload. The differential diagnosis included dialysis-disequilibrium syndrome, seizure, and sepsis. Patient was admitted to Medical Intensive Care Unit for work-up of her seizure and was given IV Ativan. There was no significant improvement in mental status. Neurology was consulted and she was started on dilantin for seizure control. Review of medications revealed that patient was recently started on high doses of gabapentin. Gabapentine toxicity was considered and the medication was discontinued. Video EEG showed periodic lateralized epileptiform discharges (PLEDs), associated with gabapentin toxicity. She had improvement in mental status over next 72 h with no further seizure activity. The patient's hospital course was complicated with diabetic ketoacidosis. She was treated with an insulin drip and discharged in stable condition.

DISCUSSION: Gabapentin increases the risk of seizure and neurotoxicity in end stage renal disease patients. Common side effects of gabapentin include somnolence, tremors, ataxia, infections, acute renal failure, and, in rare cases, diabetic ketoacidosis. Gabapentin should be renally dosed based on creatinine clearance to prevent accumulation and toxicity that could potentially lead to life threatening side effects. Plasma gabapentin levels may also be frequently monitored in elderly hemodialysis or renally-impaired patients to prevent neurotoxicity.

GASTRIC MALIGNANCY IN A PATIENT WITH COMMON VARIABLE IMMUNODEFICIENCY Kah Poh Loh[1]; John P. Hunt[2]; Vaibhav Mehendiratta[3]. [1]Baystate Medical Center/Tufts University, Springfield, MA; [2]Baystate Medical Center/Tufts University, Springfield, MA; [3]Baystate Medical Center/Tufts University, Springfield, MA. (Tracking ID #1641759)

LEARNING OBJECTIVE 1: Recognize that patients with common variable immunodeficiency have higher risk of developing gastrointestinal malignancies.

LEARNING OBJECTIVE 2: Assess patients presenting with chronic gastrointestinal symptoms using the current available modalities

CASE: The patient is a 58 year old woman who presented with chronic, intermittent diarrhea and abdominal bloating. She denied any weight loss, hematochezia, hematemesis, abdominal pain, vomiting, fever or chills. The patient's past medical history was significant for common variable immune deficiency (CVID), treated with intravenous immunoglobulin (IVIg) every 3 weeks. Laboratory studies including CRP, ESR, and free T4 were normal. Colonoscopy and upper GI-small bowel follow-through were normal. A decision was made to proceed with esophagogastroduodenoscopy (EGD) to assess for celiac disease. Findings included a broad-based, multilobulated mass measuring 4 cm in the mid-gastric body. Biopsies of the mass and prepyloric antrum both exhibited high grade dysplasia. Endoscopic ultrasound showed that the mass represented a T1 N0 tumor. The patient underwent mucosal resection of the mass and mapping biopsies were performed. The endoscopic resection confirmed the diagnosis of adenocarcinoma, which invaded the submucosa (pT1). There was focal high grade dysplasia and intramucosal carcinoma at the pylorus, an endoscopically unremarkable area. Other biopsies showed chronic and focally active gastritis. Immunohistochemical studies for H. pylori were negative. A CT of the abdomen, pelvis and chest revealed thickening of the distal gastric wall, but showed no evidence of metastatic disease. The patient ultimately underwent total gastrectomy with Roux-en-Y esophagojejunostomy without complications.

DISCUSSION: This case is interesting in that it underscores the up to 47-fold increase in risk for gastric carcinoma in patients with CVID as reported in European populations. Gastric lesions are usually detected incidentally during endoscopy for non-specific dyspeptic symptoms and have been reported in patients as young as 11 years of age. To date, there are no definitive society guidelines for screening for gastric malignancy in patients with CVID. Given the high incidence of dysplasia and increased risk of gastric malignancy in these patients, physicians should have a low threshold for diagnostic endoscopy, especially if gastrointestinal symptoms persist despite therapy.

GASTRIC PNEUMATOSIS: AN UNCOMMON CAUSE OF EPIGASTRIC PAIN WITH A WIDE PROGNOSTIC AND MANAGEMENT SPECTRUM Leyda Callejas; Manuel O. Gonzalez. New York Methodist Hospital, Brooklyn, NY. (Tracking ID #1641795)

LEARNING OBJECTIVE 1: Recognize the clinical spectrum of gastric pneumatosis and tailor management accordingly

CASE: A 60 year old female presented with intermittent abdominal pain for approximately 8 months which worsened in the past 2–3 days. The pain was burning and intermittent, but not associated with food intake, nausea or vomiting. She denied trauma, alcohol ingestion or nonsteroidal anti-inflammatory medication use. Her only other complaint was loose stools.

She had been admitted 7 months ago with similar complaints, and peptic ulcer disease was diagnosed on endoscopy. Since then she has taken a proton pump inhibitor continuously. Upon examination she was afebrile and had tenderness in the epigastrium and upper quadrants. A CT scan showed a distended stomach with irregular air collections within the gastric wall; there was no evidence of bowel obstruction. Intravenous hydration and bowel rest were begun. Blood tests did not reveal leukocytosis or metabolic abnormality. As she was clinically and hemodynamically stable, conservative management was instituted. An endoscopy demonstrated moderately severe erosive gastritis within the antrum and body of the stomach. The pathology showed reactive gastropathy with no evidence of H. pylori infection. Her stool demonstrated Clostridium difficile; she was started on antibiotics and later discharged. At a follow-up visit 2 weeks later, she reported improvement of her pain.

DISCUSSION: Gastrointestinal pneumatosis is characterized by the presence of gas within the bowel wall. It is uncommon in the upper gastrointestinal tract especially in the stomach which represents about 5 % of cases. Gastric pneumatosis is a radiographic finding with a wide range of causes and outcomes. Our patient illustrates gastric pneumatosis that had a benign clinical course. There was no laboratory or imaging data that suggested bowel obstruction or ischemia. Endoscopy showed gastritis as the most likely cause of the radiographic findings. It is important to differentiate between its clinical presentations, as gastric pneumatosis can be potentially life threatening. Its mortality has been reported from less than 30 % up to 60–80 %. The condition has also been differentiated as either primary or secondary. The former is considered idiopathic, an incidental radiologic finding in an asymptomatic patient. The latter is attributed to mechanical disruption in the mucosa of the stomach secondary to trauma, instrumentation, peptic ulcer disease, distal obstruction or ischemia. In the most severe cases it can represent infection by gas-forming bacteria. The initial clinical presentation and the patient's medical history can provide us clues to its etiology. The workup must determine if there is leukocytosis, metabolic acidosis, or an elevated lactate, as these usually portend a worse outcome. Imaging, such as x-rays or CT scans, can determine the presence of pneumoperitoneum or portal gas. Other procedures such as endoscopy can be helpful in evaluating possible causes. The management can range from observation, as in our patient, to an urgent surgical intervention. Most patients are managed conservatively unless there is evidence of sepsis, perforation or peritonitis.

GIGANTIC LIPOSARCOMA MISDIAGNOSED AS IRRITABLE BOWEL SYNDROME Katherine H. Saunders; Erica Phillips. NewYork-Presbyterian Hospital, New York, NY. (Tracking ID #1626462)

LEARNING OBJECTIVE 1: To apply a cost-effective approach to differentiate between the symptoms of irritable bowel syndrome (IBS) and other conditions with similar clinical presentations

LEARNING OBJECTIVE 2: To learn about the diagnosis and treatment of liposarcomas

CASE: A 67-year-old female with hypertension, hyperlipidemia, impaired glucose tolerance, depression and a presumptive diagnosis of IBS presented to a primary care clinic for 2 months of bloating and increased abdominal girth in the setting of 2 years of intermittent constipation and gas. She had been diagnosed with IBS 1 year prior based on many months of nonspecific abdominal symptoms despite a normal transabdominal/transvaginal ultrasound, colonoscopy and routine laboratory studies. Her abdominal exam was within normal limits besides stable axillary and groin lymphadenopathy, which was first noticed 1 year prior. An outpatient abdominal ultrasound revealed "echo poor body tail junction" of the pancreas without evidence of focal mass. The radiologist noted that this finding was of uncertain clinical significance and recommended a CT or MR for further evaluation. A CT abdomen/pelvis illustrated no abnormality within the pancreas, but a 22.7 cm retroperitoneal fat density lesion containing central more solid components involving the entire right hemiabdomen and pelvis, suspicious for well-differentiated liposarcoma. The patient subsequently underwent an exploratory laparotomy during which a 2480 g, 37.2×24.3×3.1 cm retroperitoneal mass was resected. On cut section, the mass was uniformly fatty and homogenous, with small focal fibrous areas. The procedure and post-operative course were uncomplicated. The patient did not require adjuvant chemotherapy or radiation given the favorable characteristics of the tumor. Instead, she is undergoing active surveillance to evaluate for local recurrence. Her most recent CT scan revealed a 5 cm poorly defined fatty mass with scant soft tissue elements in the subcutaneous tissues of the right flank. As this mass had been visualized on previous scans, it was thought to be a stable lipoma. The patient will continue to undergo routine CT scans every three to 6 months depending on evolution of radiological findings and her symptoms.

DISCUSSION: This case illustrates the need for a thorough evaluation before making the diagnosis of IBS. Although patients may fulfill the Rome III criteria, it is important to exclude other causes of their symptoms. Abdominal ultrasound is a reasonable first step, but CT should be considered if there are more concerning findings such as lymphadenopathy, increased abdominal girth or weight loss. Liposarcomas are rare retroperitoneal soft tissue sarcomas that usually produce few symptoms until they are large enough to compress or invade surrounding structures. They are most commonly diagnosed incidentally. The preferred diagnostic test is CT scan of the abdomen and pelvis. Well differentiated (low grade) liposarcomas are the most common type of liposarcoma. These tumors have no potential to metastasize, but local recurrence is possible. The incidence of recurrence is unknown. Complete resection is the only potentially curative treatment; however, positive resection margins are not unexpected because of the anatomic complexity of the retroperitoneum.

GRANULOMATOSIS WITH POLYANGITIS: EARLY RECOGNITION AND TREATMENT KEY TO PATIENT OUTCOMES Laura Nichols; Peter-Trung Phan. Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #1643155)

LEARNING OBJECTIVE 1: Recognize the signs and symptoms of granulomatosis with polyangitis (GPA) early in the course of treatment to affect outcome

LEARNING OBJECTIVE 2: Treat GPA with cyclophosphamide versus rituximab

CASE: A 59 year-old female with a history of arthritis presented to the ED with a chief complaint of non-bloody emesis, dry cough, fatigue, and 15 lb weight loss over 3 weeks. She had been seen in urgent care twice for these symptoms and was treated for a presumed pneumonia with amoxicillin and doxycycline, which did not improve her symptoms. On review of systems the patient also noted dark urine as well as sinus congestion with occasional epistaxis. Over the 2 years prior to admission, the patient had experienced pain in her hands, which she attributed to arthritis. Physical exam revealed trace edema to the mid-lower leg and was otherwise unremarkable. On admission the patient was noted to have an elevated creatinine of 3.23 mg/dL. Urinalysis was positive for 3+ blood and 2+ protein. Leukocytosis was present with a WBC count of 15,600 cells/dL and a predominance of neutrophils. Chest radiography revealed a non-specific, mild, diffuse interstitial thickening. Renal ultrasound was unremarkable. Esophagogastroduodenoscopy was performed given the patient's recurrent emesis, which was also unremarkable. Urine microscopy revealed muddy brown casts and morphologically normal RBCs. As the patient's renal function failed to improve, renal biopsy was performed on hospital day 3 and demonstrated diffuse necrotizing and focal crescentic glomerulonephritis without detection of immunocomplex-type electron dense deposits, consistent with pauci-immue disease. Subsequent serology testing was positive for C-ANCA titer of 1:640 and proteinase 3 antibody. Anti-GBM testing was negative as were the remainder of serologies. The patient was diagnosed with granulomatosis with polyangitis and started on cyclophosphamide pulse infusion therapy. Currently she remains in remission on mycophenolate therapy.

DISCUSSION: Granulmatosis with polyangitis (GPA) is a vasculitic illness characterized clinically by a broad range of systemic symptoms and is associated with a particularly high morbidity and mortality. Prior to the introduction of cyclophosphamide, untreated patients had a mortality of

90 % at 2 years. In spite of the vast improvement with cyclophosphamide therapy, GPA is an illness that continues to cause significant morbidity and mortality both from disease and treatment, underscoring the importance of early diagnosis and the continued development of new therapies. The variety of non-specific presenting signs and symptoms in GPA can make it difficult to diagnose. Only after several urgent care visits was the patient in this case prompted to present to the emergency department, which led to her admission and subsequent diagnosis. Furthermore, as treatment with cyclophosphamide carries a high morbidity, it will be necessary to continue to search for new effective therapies with fewer side effects. Rituximab has been shown recently to be non-inferior to cyclophosphamide for inducing remission and to be superior therapy for relapse. The patient in this case was treated with traditional cyclophosphamide therapy; however, her case lends itself to a discussion of use of rituximab if relapse should occur.

GRANULOMATOUS HEPATITIS IN A PATIENT WITH CYSTIC FIBROSIS Felix H. Lui[1]; Edward W. Holt[2]; Shelley M. Gordon[1]. [1]California Pacific Medical Center, San Francisco, CA; [2]California Pacific Medical Center, San Francisco, CA. (Tracking ID #1626011)

LEARNING OBJECTIVE 1: Review the differential diagnosis and work up of granulomatous hepatitis (GH)
LEARNING OBJECTIVE 2: Evaluate the appropriate diagnostic and treatment algorithms for GH in cystic fibrosis
CASE: A 31 year-old Caucasian male with cystic fibrosis (CF) was admitted for sepsis secondary to dental and deltoid abscesses. Blood cultures grew vancomycin-resistant enterococcus, and he was treated with debridement, tooth extraction and antibiotics. On hospital day 24 he again became febrile, and blood cultures were positive for Candida glabrata, for which he was treated with caspofungin. Shortly thereafter, his alkaline phosphatase began to rise in association with elevated GGT and normal AST and ALT. Right upper quadrant ultrasound revealed only mild intrahepatic biliary ductal dilatation without evidence of cholecystitis. During this time, alkaline phosphatase reached a maximal level of 1,940 U/L, associated with daily fever spikes. Laboratory tests included a normal SPEP and UPEP, negative ANA and anti-mitochondrial antibody. His 1,25-hydroxy vitamin D was elevated, and his ACE level was elevated at 190 U/L. His HIV antibody, serologies for viral hepatitis, PPD, serum cryptococcal and histoplasma antibodies were negative. Fungitell (beta 1,3 D-glucan) was negative. MRCP showed only hepatosplenomegaly and cholethiasis. A transjugular liver biopsy revealed numerous portal-based and lobular granulomas, negative acid-fast and fungal stains and no evidence of malignancy. With no response to antifungal therapy and a negative evaluation for granulomatous diseases, a diagnosis of "idiopathic" granulomatous hepatitis was made. He completed a course of prednisone in the hospital and was discharged on a prednisone taper. On discharge, his alkaline phosphatase was 981. Two weeks later at outpatient follow up it was 481 U/L.
DISCUSSION: Granulomatous hepatitis is uncommon in patients with cystic fibrosis (CF), which made this a diagnostic challenge. In the United States, 75 % of granulomatous hepatitis is a result of sarcoidosis, mycobacterial infection, primary biliary cirrhosis, and drug-induced liver injury. Patients with sarcoidosis usually have signs and symptoms of chronic pulmonary disease, although our patient never had evidence of hilar adenopathy. Treatment of hepatic sarcoidosis is generally not recommended, though a short course of corticosteroids can be considered. Many infectious diseases are often the etiology of granulomatous hepatitis. For fungal infections, histoplasmosis and coccidioidomycosis are among the more common causes in the US. Candida glabrata hepatitis is a rare cause of granulomatous hepatitis. After an exhaustive work up, idiopathic granulomatous hepatitis is a diagnosis of exclusion and may be treated with an empiric course of corticosteroids. However, in CF patients with pancreatic insufficiency and diabetes, there is a risk of hyperglycemia secondary to glucocorticoid use. Understanding the differential diagnosis of GH in a patient with CF will allow for better diagnostic and treatment decisions. We cannot say for certain that our patient's granulomatous hepatitis was related to CF. It defied extensive diagnostic evaluation, and did not respond to a variety of anti-bacterials and anti-fungals. As the CF population lives longer, we remain alert to the possibility that we may identify additional cases similar to this one.

GRAVES DISEASE AS A DELAYED MANIFESTATION OF IMMUNE RECONSTITUTION INFLAMMATORY SYNDROME IN A HIV PATIENT Kalpana Nagarkar; Salman Azim; Anasse Souidi; Akshay Manohar; Daniel Goldsmith. Capital Health Regional Medical Center, Trenton, NJ. (Tracking ID #1643120)

LEARNING OBJECTIVE 1: The association of auto antibodies in HIV-infected patients to clinical autoimmune disease is yet to be established. With the upsurge of HAART, the incidence of autoimmune diseases liek Graves disease in HIV-infected patients is increasing and physicians need to be aware of this fact.
LEARNING OBJECTIVE 2: This phenomenon should be suspected in individuals who present with clinical deterioration and a presentation suggestive of hyperthyroidism despite good virological and immunological response to HAART
CASE: Combination retroviral therapy (cART) reduces morbidity and mortality in persons with human immunodeficiency virus-1 (HIV-1) infection. However, after treatment is commenced, some patients experience clinical deterioration caused by restoration of their capacity to mount an inflammatory immune response against both infectious and noninfectious antigens. This has been variously known as immune restoration disease (IRD), immune reconstitution syndrome/ immune recovery syndrome (IRS), or immune restoration inflammatory syndrome (IRIS). The pathogenic mechanisms are poorly understood, although awareness of these diseases is important from a clinical perspective. We report here a case of hyperthyroidism caused by Graves' disease (GD) that developed years after a patient commenced cART. A 57-year-old African American male patient was admitted to the hospital for shortness of breath, progressive dyspnea, and palpitations. He did not complain of any chest pain. Past medical history was pertinent for HIV infection and was taking antiviral medications, splenectomy secondary to trauma, COPD, and seizure disorder. Physical examination revealed a cachexic patient with an irregularly irregular pulse. Cardiac examination did not reveal any murmur, gallop or rub. Lungs were clear. X-ray chest was normal. A thyroid function test panel was obtained which revealed hyperthyroidism. Laboratory findings revealed a fully suppressed TSH. Antithyroid peroxidase antibodies and thyroglobulin antibodes were positive. The patient apparently had a progressively worsening hospitalization with suboptimally controlled ventricular rate. He became hemodynamically unstable, was intubated. He was found to be in thyroid storm. He was treated with beta blockers, diltiazem and antithyroid medications with PTU and started on hydrocortisone. The patient subsequently showed improvement and was extubated and later showed controlled ventricular rate.
DISCUSSION: Graves' disease has in recent times been described in the literature as a documented IRIS among HIV-infected patients. Graves's disease usually occurs after a rise in the CD4 T-cell count; however, its unique nature is typified by its late presentation, months after starting HAART. Our patient was diagnosed with HIV. He did not have any thyroid problems before starting the HAART therapy but did develop them after the treatment was started.

GRAVES' STORMS INTO UNCHARTERED TERRITORIES! Saraschandra Vallabhajosyula; Sri Harsha Tella; Ojas Bansal; Theresa Townley. Creighton University Medical Center, Omaha, NE. (Tracking ID #1636755)

LEARNING OBJECTIVE 1: Recognizing uncommon presentations of hyperthyroidism, that will aid in more focussed clinical evaluation and testing
LEARNING OBJECTIVE 2: Understanding the patho-physiology and management of pancytopenia secondary to hyperthyroidism
CASE: A 44 yo African-American male with no significant medical history presented with worsening tremors, palpitations, confusion and

diffuse abdominal pain of 1 day duration. Review of systems was significant for bulging of eyes, nyctalopia and unintentional weight loss of 30 lbs in 6 months. His examination was significant for tachycardia, altered mental status, diffuse thyroid enlargement and 1+ pre-tibial edema. No ocular signs of hyperthyroidism were found objectively. Admission laboratory parameters showed pancytopenia (WBC counts - 0.67 K/μL; hemoglobin - 10.8 mg/dL; platelet count - 110 K/μl) associated with elevated liver enzymes (Aspartate Transaminase - 89 IU/L, Alanine Transaminase - 77 IU/L). Thyroid function tests showed severe hyperthyroidism with TSH <0.02 mIU/L, free T3 12.7 ng/dL and free T4: >6 ng/dL. Extensive work up was done for pancytopenia, elevated liver enzymes and hyperthyroidism. Alternative diagnoses of primary hematologic illnesses, autoimmune diseases, occult malignancies and infectious causes of pancytopenia and elevated liver enzymes were ruled out. Wartofsky score of 65 was highly suggestive of thyroid storm. Work up of hyperthyroidism showed elevated Thyroglobulin and positive TSH-receptor antibodies. Thyroid ultrasound showed enlarged, hypo echoic and diffusely heterogeneous thyroid gland with marked increased vascularity, measuring 7.3×4.3×2.4 cm on the right and 8.1×3.4×3.1 cm on the left. Based on above findings a diagnosis of Grave's disease was made. Treatment with Potassium Iodide, Methimazole, Hydrocortisone and Propranolol lead to the improvement of symptoms and resolution of pancytopenia and liver enzyme elevation.

DISCUSSION: This patient's pancytopenia and elevated liver enzymes were likely manifestations of un-diagnosed and untreated Grave's disease. The potential patho-physiological mechanisms include - (a) in-effective hematopoiesis; (b) autoimmune process that induce anti-neutrophil / anti-platelet antibodies; (c) thyrotoxicosis-induced intracellular increase of 2/3 bis-phospho-glycerate causing right-shift of oxygen disassociation curve causing decreased oxygen affinity of hemoglobin; (d) direct toxicity of thyroid hormone to bone marrow stem cells and (e) relative hypoxemia in patients with elevated T3 and T4 causing peripheral acinar damage secondary to increased metabolism and subsequent elevation in liver enzymes. Pancytopenia and elevation of liver enzymes are uncommon manifestations of hyperthyroidism that respond well to the treatment of underlying disease. Patients with hyperthyroidism should be monitored closely for these complications of overt thyrotoxicosis.

GROANS, MOANS AND PSYCHIATRIC OVERTONES: WHEN IT IS NOT ONE OF THE USUAL SUSPECTS Rosy Priya Kodiyanplakkal[1,2]; Darlene LeFrancois[1,2]. [1]Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1634465)

LEARNING OBJECTIVE 1: Recognize hypercalcemia secondary to Mycobacterium Avium Intracellulare (MAI) infection as a cause of altered mental status in a patient with acquired immune deficiency syndrome (AIDS)

LEARNING OBJECTIVE 2: Explain the pathophysiology of hypercalcemia induced by granulomatous disease

CASE: A 50 year-old man with acquired immune deficiency syndrome presented with abdominal pain for 2 weeks and increasing weakness, lethargy, and hallucinations for 1 week. He was non-adherent to antiretroviral therapy and his most recent cluster of differentiation 4 count was 8. He was agitated and having visual and auditory hallucinations; talking to people not in the room. There was no fever and no neck stiffness. His abdomen was soft, but the liver was enlarged with right upper quadrant tenderness. Pertinent laboratory findings include: white blood cell count 9.8 K/ul, alkaline phosphatase 418 U/L, corrected calcium 13.6 mg/dL, intact parathyroid hormone (PTH) 1.7 pg/mL (normal>10), 25-hydroxyvitamin D (calcidiol) 16 ng/mL (normal>30), 1,25 dihydroxyvitamin D (calcitriol) 45 pg/mL (normal 20–70), angiotensin-converting enzyme-level 73 U/L (normal<50). His head computed tomography scan and subsequent lumbar puncture were entirely unremarkable. Abdominal ultrasound revealed a 22 cm liver with increased echogenicity, typical of parenchymal disease. His liver biopsy revealed nonnecrotizing granulomas mainly centered on portal tracts with numerous acid fast bacilli (AFB) seen on staining. Subsequent AFB blood cultures confirmed disseminated Mycobacterium Avium Complex infection. This patient's symptoms were thought to be a result of hypercalcemia caused by this granulomatous disease, and rapidly resolved with fluid hydration and MAI treatment.

DISCUSSION: Altered mental status in the context of AIDS is often seen by physicians, but hypercalcemia is an uncommon etiology for such presentations. Hypercalcemia can also result in lethargy, weakness, myalgias, nausea, constipation, and abdominal pain. While often caused by primary hyperparathyroidism or malignancy in general populations, hypercalcemia is also seen in association with granulomatous diseases such as sarcoidosis, fungal infections, berylliosis, Crohns' disease, tuberculosis, and other mycobacterial infections. The uncommon infectious causes of hypercalcemia are particularly important to consider in immunocompromised patients. The mechanism by which granuloma formation causes hypercalcemia is via elevated levels of calcitriol. Usually, the conversion of calcidiol to calcitriol occurs in the proximal tubules of the kidneys via a 1-alpha-hydroxylase that is regulated by PTH, phosphorus, and calcium levels. Normally, hypercalcemia suppresses the release of PTH and thereby calcitriol production. In granulomatous disease there is excessive direct production of calcitriol by macrophages from calcidiol independent of PTH. It is thought that macrophages activate extra renal 1-alpha-hydroxylase leading to calcitriol mediated, PTH independent hypercalcemia. Our patient had low PTH and calcidiol levels, but disproportionately high calcitriol levels, supporting that his hypercalcemia was a manifestation of granulomatous disease. While the definitive treatment of hypercalcemia relies on treating the underlying etiology, bisphosphonates and glucocorticoids can also play a therapeutic role.

GROUP A STREPTOCOCCUS ASSOCIATED DIGITAL ARTERIAL THROMBOSIS Michael S. Yoo; Daniel G. Heacock. Yale University School of Medicine, New Haven, CT. (Tracking ID #1635241)

LEARNING OBJECTIVE 1: Recognize the clinical features of invasive Group A Streptococcus (GAS) infections and digital arterial thrombosis.

CASE: A 41-year-old man with hypertension and hyperlipidemia presented with a painful, swollen right index finger. His symptoms progressed rapidly, extending to the forearm. He denied any injury or insect bites. He had no smoking history, diabetes, or new medications. His digit appeared necrotic, and he was subsequently transferred to our hospital. His exam was notable for fever (101.7 °F), tachycardia (100 beats per minute), and a demarcated line of necrosis on his second digit extending to the proximal interphalangeal (PIP) joint. The remainder of his exam was unremarkable. Laboratory studies revealed leukocytosis (19,800 per microliter); other tests, including creatine kinase, were normal. Empiric vancomycin, piperacillin-tazobactam, and clindamycin were started. Computerized tomographic (CT) angiography of the right upper extremity revealed arterial interruption of the second digit to the level of the PIP and metacarpophalangeal joints. Intravenous heparin was initiated. Cardioembolism was ruled out with transesophageal echocardiography. Hypercoagulability workup was negative. Surgical exploration revealed an intact flexor tendon sheath, thrombosed digital arteries, and murky subcutaneous fluid. Heparin was stopped. Intraoperative cultures grew GAS; blood cultures were negative. His cellulitis resolved completely; his necrosis did not, however, and future amputation was planned. The patient was discharged on intravenous penicillin G.

DISCUSSION: Herein we describe the first case to our knowledge of digital arterial occlusion in the setting of GAS cellulitis. The cause of our patient's thrombosis remains unclear. He had a negative workup for thromboembolic and autoimmune disease, and he reported no injury or trauma to his finger. The presence of GAS cellulitis and the absence of a clear explanation for our patient's digital occlusion raise the possibility of an association between GAS and arterial thrombus formation. We hypothesize that in light of the recent emergence and increasing virulence of invasive GAS infections, it is possible that this case may indicate evolving changes in the interactions between GAS and coagulation pathways. Future cases should be documented, and investigation into the potential association between GAS infection and thrombosis may be warranted.

GROUP G STREPTOCOCCAL ENDOCARDITIS Prashant Prasad; Sarah Moorhead; Brian Zwecker; Samir Desai. Baylor College of Medicine, Houston, TX. (Tracking ID #1634404)

LEARNING OBJECTIVE 1: Identify the most frequent sources of Group G streptococcal bacteremia
LEARNING OBJECTIVE 2: Recognize Group G streptococcus as a rare but potential cause of acute endocarditis
CASE: A 65-year-old morbidly obese male with poorly controlled diabetes mellitus and chronic venous insufficiency presented to the emergency room following a fall. At baseline, the patient was primarily bed-bound with minimal ambulation. He reported a 1 day history of chills, shortness of breath, and diffuse myalgias. On admission, the patient had a temperature of 104 °F, regular heart rate and rhythm, and no murmurs. Pitting edema in both lower extremities with several ulcerations draining purulent, foul-smelling discharge was noted. Initial lab test results included WBC 15 with neutrophilic predominance, creatine kinase 80,000, AST 688, ALT 130, BUN 24, and creatinine 2.5 (baseline 1.5). Urinalysis demonstrated the presence of large blood and granular casts. Chest x-ray revealed no significant findings. He was diagnosed with acute rhabdomyolysis and started on aggressive fluid resuscitation, as well as ceftriaxone and vancomycin for infected skin ulcers. The patient continued to have shortness of breath at rest, and repeat chest imaging showed evidence of volume overload. With diuresis and supplemental oxygen, his breathing returned to baseline over the next several days, and he was weaned off the oxygen. On hospital day 2, blood cultures drawn at admission grew Group G streptococci. A transthoracic echocardiogram revealed a focal echodense lesion on the left coronary cusp of the aortic valve, with no valvular stenosis or regurgitation. CRP and ESR were significantly elevated at 14.69 and > 100, respectively. In light of these results, the patient was continued on intravenous antibiotics, with repeat blood cultures negative after 48 h. After 2 weeks the patient was afebrile with WBC 9.5, CK 2104, ALT 53, AST 72, BUN 15, and creatinine 1.4. He was transferred to an intermediate care facility to receive 4 weeks of IV ceftriaxone and to continue physical therapy for generalized deconditioning. After 1 month, he was clinically stable with no evidence of infection.
DISCUSSION: This case describes the uncommon occurrence of Group G streptococcal bacteremia and endocarditis. In a single institutional study of 7,415 positive blood cultures over a ten-year period, Group G streptococci were isolated in 49 cases (0.66 %). In the same study, the predominant sources of infection by this organism were the skin (78 %) and pressure sores (15 %). The venous stasis ulcers on our patient's lower extremities were thought to be the site of entry in this case. Endocarditis associated with this organism is rarer yet, having only been reported in 64 cases. When it occurs, it tends to be acute in nature and quite virulent. Therefore, it is vital to identify this infection early and treat aggressively with appropriate antibiotic therapy.

GYNECOMASTIA IN AN ELDERLY MALE; IS DIGOXIN A CULPRIT? Ahmed Salman; Naba R. Mainali; Richard Alweis. Reading Health System, West Reading, PA. (Tracking ID #1621965)

LEARNING OBJECTIVE 1: To recognize gynecomastia, as a potential adverse effect of digoxin especially in elderly males.
LEARNING OBJECTIVE 2: To describe the importance of physical exam in making the diagnosis and prompt discontinuation of digoxin to reverse the condition.
CASE: Gynecomastia (GM), a benign growth of the glandular tissue of the male breast that can be unilateral as well as bilateral, is caused by an increase in the ratio of estrogen to androgen activity. Out of several causes, drug-induced GM merits deep consideration as it may account for as many as 25 % of all cases of new-onset GM in adults. Overall, approximately 4–10 % of GM is associated with the adverse effects of drugs such as spironolactone, marijuana, ketoconazole and digoxin. Even though the mechanisms through which a long list of drugs can cause GM are not fully clear, they are derived from estrogen-like activities, stimulation of testicular production of estrogens, inhibition of testosterone synthesis or blockade of androgen action. Here, we describe an interesting and relatively rare case of digoxin induced GM in an elderly male that was completely resolved after the discontinuation of digoxin. A 96-year-old male with a past medical history of coronary artery disease and atrial fibrillation was admitted in the hospital with acute decompensated systolic congestive heart failure (CHF) with diastolic dysfunction with last ejection fraction of 40 %. His chest X-ray on admission showed increased interstitial markings and pulmonary vascular congestion compatible with acute exacerbation of CHF. He was discharged on coumadin, lopressor and digoxin 0.125 mg daily for atrial fibrillation with CHF. After 4 months, he presented with complaints of chest pain and bilateral breast enlargement. He reported these complaints started shortly after discharge from the hospital 4 months earlier. After reviewing the side effects of all the medications he was taking, digoxin, being a digitalis derivative, was singled out to be most probable cause of his GM. Digoxin was discontinued and his GM resolved after 2 months.
DISCUSSION: Due to its toxicity profile and narrow therapeutic window, the use of digoxin in elderly patients is under review. In the geriatric population, digoxin has been recommended for treatment of atrial fibrillation with concurrent heart failure for rate control. The basic structure of digitalis compounds is similar to estrogen. Several studies have indicated that they show affinity to the estrogen receptor, which leads to proliferation of glandular tissue. The chronic use of digitalis derivatives therefore can lead to GM, especially in elderly men. Diagnosis is based on careful history and physical exam and is confirmed with the resolution of symptoms after discontinuation of the digoxin. Hence, the use of digoxin in elderly patients should be monitored closely and decision should be made after comparing benefits versus adverse effects.

HEYDING A DIAGNOSIS IN AORTIC STENOSIS Matthew N. Peters; Morgan J. Katz; Allison Egan; Deepa Bhatnagar. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1641469)

LEARNING OBJECTIVE 1: Recognize the association between aortic stenosis, intestinal angiodysplasia and Von Willenbrand Disease in Heyde's Syndrome
LEARNING OBJECTIVE 2: Understand the importance of push and capsule endoscopy in patients with Heyde's Syndrome and iron deficiency anemia. Recognize the role of aortic valve replacement in preventing future bleeding episodes in Heyde's Syndrome.
CASE: A 57 year-old man with a history of iron-deficiency anemia presented with a 3 week history of worsening exertional dyspnea and dizziness. The patient noted that his stools over the past few weeks had been darker than usual. Initial CBC revealed a microcytic anemia with a hemoglobin of 5.8 g/dL (previous baseline hemoglobin had been 10–12). Iron studies revealed continued iron deficiency with a serum iron of 46 μg/dL,a total iron-bidning capacity of 422 μg/dL and a serum ferritin of 18 μg/L. Upper endoscopy and colonoscopy were normal. While anemia was the suspected etiology of his exertional dyspnea and dizziness, an echo was ordered to evaluate the patient's symptoms. Trans-thoracic echocardiogram revealed critical aortic stenosis (AS) with a valve area of 0.51 cm2. Heyde Syndrome was considered and the following day the patient had a "push" endoscopy, which revealed a bleeding angioectasia in the distal duodenum. Lesion was then cauterized and injected with epinephrine. Several weeks later, the patient underwent a left heart catheterization that revealed a pressure gradient of 51 mmHg across the aortic valve, confirming severe aortic stenosis. The following month he underwent a porcine aortic valve replacement (AVR) without complication. Six months postoperatively, the patient has had no recurrence of bleeding episodes and his microcytic anemia has resolved.
DISCUSSION: Among the elderly, AS and angiodysplasia are the most common causes of acquired valvular lesions and lower gastrointestinal bleeding, respectively. First described in 1958, Heyde's Syndrome is a combination of AS, intestinal angiodysplasia, and Von Willebrand Disease (VWD). The incidence of HS is currently unknown but is likely under-recognized, due to lack of detection of AS until its later symptomatic stages and difficulty in diagnosing intestinal angiodysplasias with routine

endoscopy. Association between AS and intestinal angiodysplasia is attributed to vasodilation of intestinal vessel wall ectasia due to increased tissue hypoxia. Increased hypoxia is likely secondary to AS-associated decreased cardiac output and altered pulse waveform. VWD is caused by the degradation of Von Willebrand Factor multimers due to shear stress across a diseased aortic valve. Patients with AS and iron deficiency anemia with normal colonoscopy and upper endoscopy should be considered for either capsule or "push" endoscopy to identify angiodysplasias not seen with standard procedures. Once identified, patients with Heyde's Syndrome should undergo AVR. Patients with angiodysplasias treated surgically (including bowel resection) bleed from other sites in 95 % of cases compared to only 7 % in patients treated with AVR. Interestingly, AVR can be associated with VWD reversal as soon as 1 day postoperatively. Although VWD typically resolves following AVR, it can recur, especially in patients with prosthetic valve mismatches associated with hemodynamic turbulence. Consequently, tissue valves are recommended in Heyde's Syndrome patients to obviate the need for chronic anticoagulation (as is required with mechanical valves) in the setting of potential coagulopathy.

HIV INDUCED RHABDOMYOLYSIS Francisco Hernandez Munoz; Gregory Braden; Sarah Dreilling; Daniel Landry. Baystate Medical Center/Tufts University School of Medicine, Springfield, MA. (Tracking ID #1640847)

LEARNING OBJECTIVE 1: Recongnize Non-exertional, non-traumatic Rhabdomyolysis and its Broad Differential.
LEARNING OBJECTIVE 2: In the ICU setting Acute Kidney Injury induced by Rhabdomyolysis has an extremely high mortality rate.
CASE: 51-year-old man with past medical History of Hypothyroidism and obesity that presented with lower extremity weakness and Altered mental status in the setting of a recent viral prodrome. Patient presented to his Primary care Physician's office 2 weeks prior to admission for throat pain, subjective fevers and general malaise and was started on Bactrim. He developed an acute gastritis attributed to be a reaction to Bactrim after his first dose; Bactrim was discontinued and he was started on Amoxicillin. He finished his 10 day course of Amoxicillin with partial improvement of his symptoms. He works as a trash truck driver, no history of alcohol abuse and patient denied any illicit drug use. Three days prior to hospitalization he had severe profuse diarrhea which resolved the day before admission. He continued to feel weak and the morning of admission he was unable to stand up given lower extremity pain and stiffness. Upon evaluation his vital sings were stable; he was found to have severely contracted bilateral lower extremity muscles up to the buttocks, with severe excruciating pain to palpation and to forced ankle extension. Labwork showed Mild leukocytosis, hyperphosphatemia, hypocalcemia, severe transaminitis, negative toxic/drug screen, normal TSH, a creatinine of 13 mg/dL with a BUN of 114 mg/dL and CK that peaked at 104,000 u/L. CT scan of the Lower extremities and abdomen showed no localized site of muscle injury, no purulent abscess nor any sings of malignancy. Patient was diagnosed with non-exertional, non-traumatic rhabdomyolysis. The etiology of this was assumed to be infectious as other possibilities were ruled out. Differential diagnosis was broad and a full workup by infectious diseases team was done. Patient was found to be HIV positive with viral count of 150,00 CP/ml. Multiple other acute viral and bacterial etiologies were ruled out.
DISCUSSION: Acute Kidney Injury (AKI) secondary to Rhabdomyolysis represents about 7–10 % of all AKI cases in the US [1]. Mortality increases in patients with AKI when it is attributed as a direct complication of Rhabdomyolysis, especially in the ICU setting where mortality has been documented to be as high as 59 % [2]. Non-exertional, non-traumatic Rhabdomyolysis has broad differential including drugs, toxins, infections, electrolyte abnormalities, endocrine abnormalities, malignancy and inflammatory myopathies. Our patient had a negative lower extremity and Abdominal CT scan with a negative toxicology screen and a normal TSH. The viral like prodrome directed the differential towards an infectious etiology which included multiple microorganisms including viral etiologies like HIV. Rhabdomyolysis developed in the setting of acute HIV has been described in patients with nonspecific symptoms like myalgias and general malaise [3]. The pathophysiology mechanism of viral induced Rhabdomyolysis, even though unknown, is thought to be secondary to direct viral muscle invasion evidenced by muscle biopsies that have shown lymphocytic muscle infiltration in patients with viral induced rhabdomyolysis [4].

HORMONES AND HEARTBREAKS Ishani Pathmanathan; Varsha Somasekharan; Deepa Bhatnagar. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1641108)

LEARNING OBJECTIVE 1: Understand the cardiovascular manifestations of thyroid disease
LEARNING OBJECTIVE 2: Recognize hypothyroidism as a reversible cause of systolic heart failure. Identify relative contraindications to beta blockers in this setting.
CASE: A 58 year-old man with diabetes mellitus and a remote history of thyroid ablation presented with 2 weeks of bilateral leg and scrotal swelling. The swelling began spontaneously and was associated with dyspnea on exertion. He denied fevers, chills, recent illnesses, chest pain, palpitations, orthopnea or changes in skin, hair or temperature tolerance. He reported similar symptoms two decades ago when he was diagnosed with hyperthyroidism and heart failure that resolved after thyroid resection. On exam he had a heart rate of 61, jugular venous distention, a loud S2, and faint rales in the lung bases. He had 2+ pitting edema and a painful, edematous scrotum. Creatinine was 1.6 mg/dL, BNP 968 pg/mL, TSH 59.29 mIU/L, and free T4 less than 0.25 ng/dL. HIV and hepatitis panels were negative, as were cardiac enzymes. Transthoracic echocardiogram revealed an ejection fraction of less than 20 % and pulmonary artery pressure greater than 70 mmHg. The patient was started on levothyroxine, aspirin, lisinopril, isosorbide dinitrate, hydralazine, and spirinolactone. No beta-blocker was given because of bradycardia, and the risk of further lowering his T3 levels. Diuretics led to improved edema and kidney function and he was discharged home with close outpatient endocrine and heart failure clinic follow up and plans to schedule a cardiac catheterization when his acute kidney injury resolved.
DISCUSSION: Heart failure is an increasingly common cause of hospitalization and death. When patients present with new onset systolic failure, it's important to look for underlying causes, including ischemia, hypertension, infection, anemia and drug reactions. Thyroid abnormalities are especially important to recognize because they are one of few causes that can often be reversed. Thyroid hormones increase heart rate, cardiac contractility and overall oxygen demand. They also decrease systemic vascular resistance by dilating peripheral arterioles, causing less effective arterial filling and activation of the renin-angiotensin system. In hypothyroidism, the opposite occurs, and patients present with bradycardia, mild hypertension, narrowed pulse pressure, and increased systemic vascular resistance. Cardiac output decreases with bradycardia and decreased cardiac contractility, although it is often still adequate to meet the body's concurrently decreased metabolic needs. Also, hypothyroidism can prolong the QT interval to precipitate dangerous arrhythmias, and worsens cardiac risk by increasing serum cholesterol and atherosclerosis. Beta-blockers inhibit conversion of T4 to T3, and are therefore often contraindicated in hypothyroid cardiomyopathy even in the absence of bradycardia. Fortunately, hypothyroid-induced heart failure is frequently entirely reversible if recognized. In older patients or those with a history of angina, supplementation with thyroxine should begin at 25 % of the full replacement dose, and titrated upwards over six to eight-week intervals with close clinical follow up. TSH levels should be used to assess euthyroid status. As our patient's thyroid hormone levels normalize, it is likely that his overall cardiac contractility will improve over time, perhaps no longer necessitating evaluation for an automatic implantable cardiac defibrillator.

HEART FAILURE AFTER SINGLE DOSE OF DOXORUBICIN Swati Gulati[1]; Neha Jaswal[1]; Shweta Gupta[2]; Susan McDunn[2]. [1]John H. Stroger Jr. hospital of cook county, Chicago, IL; [2]John H. Stroger Jr. hospital of cook county, Chicago, IL. (Tracking ID #1642562)

LEARNING OBJECTIVE 1: To identify that doxorubicin can casue heart failure with a single dose.

LEARNING OBJECTIVE 2: To identify that doxorubicin cardiotoxicity can occur in young patients with no known cardiac risk factors

CASE: A 31 year old female with no significant past medical history presented with right shoulder pain and swelling, Computerized Tomography scan showed a right para-spinal and right humeral soft tissue mass with a right-sided pleural effusion. Biopsy from the para-spinal mass was consistent with spindle cell sarcoma. She was started on chemotherapy with doxorubicin and ifosfamide. Her ejection fraction prior to chemotherapy was 57 % with uniform and normal left ventricular function on a MUGA scan. She was admitted 2 weeks after chemotherapy with shortness of breath and pedal edema and developed neutropenic fever with gram-negative sepsis. She improved with medical management and her second dose of chemotherapy was postponed. She developed more shortness of breath, elevated jugular venous pressure, bilateral basal chest crackles with peripheral pitting edema of the legs up to thigh level. An echocardiogram showed Left Ventricular Ejection Fraction of 35 %, diffuse hypokinesis, a dilated right ventricle, elevated pulmonary artery pressure and moderate pericardial effusion without tamponade physiology. She improved with medical management and she received ifosfamide alone for 2 additional cycles. Two weeks after her third chemotherapy she presented with decompensated heart failure despite being compliant with beta-blockers, diuretics and ACE inhibitors. At that time she had pericardial effusion with tamponade physiology and persistent systolic dysfunction. Pericardiocentesis was done and she was referred to hospice because of progression of metastatic disease.

DISCUSSION: Adriamycin (doxorubicin) is an anti-neoplastic agent used in the management of a wide range of malignancies. The most common cardiotoxicity has been described as dilated cardiomyopathy after multiple doses of the doxorubicin. Cardiotoxicity following the infusion of doxorubicin has been described as early (1 year). Late toxicity is usually a dilated cardiomyopathy. The incidence of cardiomyopathy increases exponentially after a cumulative dose of 350–450 mg/m2. Predisposing factors are borderline cardiac compensation, cardiac risk factors and higher doses of doxorubicin. It is more common in older patients and unusual after only one dose. Early toxicities are rare and include myocarditis-pericarditis syndromes and atrial arrhythmias, which are often reversible. Cardiotoxicity of doxorubicin can usually be avoided by checking a baseline MUGA scan for cardiac function and limiting the cumulative dose to less than 350–450 mg/m2 in patients with no risk factors. Our patient is unusual because she is a very young woman with no risk factors who presented with acute dilated cardiomyopathy after a single dose of doxorubicin. Despite being rare, early doxorubicin related cardiomyopathy should be included in the differential of new heart failure occurring anytime after infusion of doxorubicin.

HEART STOPPING TICK Paras Karmacharya; Madan R. Aryal. Reading Health System, West Reading, PA. (Tracking ID #1622015)

LEARNING OBJECTIVE 1: Recognize Lyme carditis as a cause of heart block.

LEARNING OBJECTIVE 2: Discuss the importance of early treatment as it can prevent permanent pacemaker placement.

CASE: 17-year-old man presented to the Emergency Department with acute chest discomfort for 1 day. Two weeks ago, he had developed a febrile illness with headache which resolved on its own. He lives in a woody area and had a history of tick bite 5 weeks back. His physical examination was unremarkable with normal vital signs. EKG revealed sinus arrhythmia with first degree AV block with a ventricular rate of 97 beats per minute. Echocardiogram showed no evidence of structural heart disease. His complete blood count, basic metabolic panel and urine analysis were all within normal limits. Streptococcal throat swab done 2 weeks ago was normal. He was placed in observation and monitored in telemetry. In the subsequent 24 h he had first degree heart block initially followed by intermittent episodes of complete heart block with AV dissociation. EKG showed sinus tachycardia with an atrial rate in the range of 100 beats per minute with complete heart block with narrow escape beat. Empirical treatment with IV Ceftriaxone 2 g once a day was started and patient was monitored on telemetry. Further test done including peripheral smear, serology titers for ehrilichiosis, Rocky Mountain spotted fever, streptococcal throat culture, blood and urine culture were all negative. Lyme ELISA was positive. Lyme IgM through Western Blot was consistent with early infection. After 2 days he had regression of his complete heart block to first degree heart block. He was discharged on doxycycline to be taken for total of 3 weeks. He remained asymptomatic with normal EKG after 3 weeks.

DISCUSSION: Although Lyme carditis is relatively rare within 4–6 weeks of exposure, it can uncommonly present as the first sign of disseminated Lyme disease. Diagnosis requires clinical suspicion based on the history and a two step protocol with enzyme-linked immunosorbent assay (ELISA) and Western blotting has been recommended in the US. This case illustrates the importance of considering reversible causes of AV block. As in our case, the degree of heart block in Lyme disease can fluctuate rapidly from first degree to second degree to complete AV block very quickly in minutes to hours, so careful observation is prudent. Treatment with an antibiotic early in the course can revert the AV block within 48 h of therapy and can avoid the need for a permanent pacemaker insertion.

HEART OF BROKEN GLASS: A CASE OF TAKO TSUBO CARDIOMYOPATHY TRIGGERED BY SEVERE ALCOHOL WITHDRAWAL Maria G. Frank[1,2]; Jane Park[2]; Camille Ladanyi[2]; Paul Brittain[2]; Anthony Kahr[2]. [1]Denver Health Hospital Authority, Denver, CO; [2]University of Colorado, School of Medicine, Aurora, CO. (Tracking ID #1641824)

LEARNING OBJECTIVE 1: To raise awareness over association of Tako-Tsubo cardiomyopathy (TCM) and severe acute alcohol withdrawal syndrome (AAWS) through the presentation of a case.

LEARNING OBJECTIVE 2: To review the pathophysiology of both TCM and AAWS and their relationship with hyper-sympathetic states.

CASE: A 54 year-old female who was initially admitted to the medical intensive care unit was transferred to a medicine team within 12 h for further management of alcohol withdrawal syndrome, acute pancreatitis, refeeding syndrome and acute kidney injury. She had a previous history of coronary artery disease (CAD) with 3 prior stents placed to the right coronary artery (RCA), insulin-dependent diabetes mellitus, and tobacco and alcohol addiction. Exam was significant for tachycardia, tremors, and a diffusely tender abdomen. The remainder of the exam was unremarkable. Noteworthy laboratory results included hyponatremia, hypokalemia and anion gap metabolic acidosis as well as creatinine of 2.9 mg/dl. On day 4 of her hospital stay, the patient developed hallucinations and severe tremors. Later on that day, T-wave inversions and progressive QTc interval prolongation were noted on telemetry and confirmed with electrocardiogram. Trans-thoracic echocardiogram (TTE) revealed apical and anterior wall ballooning and troponins were in the indeterminate range. Cardiology was consulted and a diagnosis of TCM was made. Coronary angiography was not pursued. She was started on Metoprolol, with improvement of QT c interval, and discharged home without any evidence of heart failure.

DISCUSSION: Tako-Tsubo cardiomyopathy was first described in 1990 and named after a Japanese octopus fishing-pot. It is a transient cardiomyopathy that may mimic acute myocardial infarction (AMI). Currently, the revised Mayo criteria are used for diagnosis. It presents most often in post-menopausal women and in those individuals suffering from emotional or physical stress leading to hyper-catecholamine states. It is generally considered a reversible condition, with favorable prognosis even in patients who develop heart failure. However, fatal complications including QTc prolongation with torsade des pointes, cardiac rupture, and left-ventricular thrombus have been described. Acute alcohol withdrawal syndrome (AAWS) represents a spectrum of symptoms that may range from minor discomfort to severe disorders such as seizures, delirium tremens, halluctinations and autonomic dysfunction requiring inpatient treatment. It has been documented that sympathetic hyper-activity is responsible for the majority of these events. While studies have linked the development of TCM with hyper-catecholamine states, its association with AAWS has few citations in the literature. We present a case of presumed TCM (no angiographic confirmation) triggered by severe AAWS. Even though neither fatal arrhythmias nor acute heart failure occurred in our patient, her QTc interval prolongation reached the 600-millisecond range, exposing her to serious risk. Our case not only describes an unusual association between

TCM and AAWS, but also highlights the potential complications of a commonly treated disease-alcoholism. The clinician should be aware of this entity in patients with acute chest pain or EKG changes in the setting of severe AAWS.

HELICOBACTER PYLORI AS A POSSIBLE PRECIPITANT OF IMMUNE THROMBOCYTOPENIA PURPURA Christopher Sankey[1,2]; Carly B. Brown[2]. [1]Yale School of Medicine, New Haven, CT; [2]Yale-New Haven Hospital, New Haven, CT. (Tracking ID #1639580)

LEARNING OBJECTIVE 1: Recognize Helicobacter Pylori as a possible precipitant of immune thrombocytopenia purpura, and consider including it in the standard evaluation of individuals presenting with ITP.
CASE: A 28-year-old previously healthy Hispanic male presented for evaluation of bleeding gums and rash. Four days prior he noted mild fatigue, cough, headache, and subjective fever consistent with an upper respiratory tract infection. On presentation, vital signs were stable, and physical exam revealed petechial hemorrhages on the soft palate with bleeding gums (wet purpura), with clots visible in the oral cavity, and petechiae on his extremities, abdomen and chest. Initial labs revealed a platelet count of <1,000/μL, with other cell lines preserved and a normal chemistry panel. Peripheral blood smear was without identifiable platelets, but normal red and white blood cells. Electrocardiogram, chest radiography, and abdominal ultrasound were unremarkable. A presumptive diagnosis of immune thrombocytopenia purpura (ITP) was made, and he was started on intravenous immunoglobulin (IVIG) and prednisone. After 5 days of treatment without signs of improvement, IVIG was discontinued. Serologic testing for common ITP precipitants, including human immunodeficiency virus (HIV) and hepatitis C virus (HCV) were negative. Helicobacter pylori (H. pylori) ultimately returned positive by IgA, IgG and stool antigen. Triple therapy with pantoprazole, amoxicillin, and biaxin was initiated, after which the patient had a brisk platelet response, and was discharged 2 days later, with a platelet count of 21,000/μL. Upon outpatient follow up, after completing triple therapy, his platelet count had normalized; his repeat stool H. pylori antigen was negative.
DISCUSSION: ITP is defined as a platelet count of less than 100,000/μL with no evidence of leukopenia or anemia, recently lowered from a previous threshold of less than 150,000/μL to minimize the inclusion of otherwise healthy individuals with transient and self-limited thrombocytopenia. ITP can be divided into primary (most common) and secondary, which is related to infection resulting in molecular mimicry (often HIV, HCV, or H. pylori). These viruses contain amino acid sequences that have structural similarity to regions within platelet glycoproteins, which may allow antibodies intended for foreign pathogens to cross-react with these endogenous proteins, causing thrombocytopenia. Rates of clinical responsiveness to treatment of H. pylori vary from study to study and by clinical region, but are generally highest in Japan and Italy, and are more heterogeneous in the United States. Furthermore, the majority of patients who received triple therapy were also treated with immunosuppression, potentially confounding results, and longer follow up is needed to assess if early responsiveness persists. Given that H. pylori detection is non-invasive, relatively low cost and eradication has minimal toxicity when compared with standard ITP therapy, it should be included in the standard evaluation of individuals presenting with ITP. Eradication therapy may prove beneficial in some cases.

HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS - A ZEBRA IN THE PACK Prerna Mota[1]; Michel Bidros[3]; Hana Javaid[2]; Sara N. Dost[1]; Anat Bergner[1]; Lisa M. Chirch[2]; Trini A. Mathew[2]; Jeffrey S. Wasser[3]. [1]University Of Connecticut, Farmington, CT; [2]University Of Connecticut, Farmington, CT; [3]University Of Connecticut, Farmington, CT. (Tracking ID #1641629)

LEARNING OBJECTIVE 1: To diagnose Hemophagocytic Lymphohistiocytosis (HLH) which is a rare yet under-diagnosed and potentially fatal medical condition
LEARNING OBJECTIVE 2: To understand that pathogen-directed therapy is not sufficient to turn off the inflammatory response cascade and prevent death in EBV or CMV- related HLH.
CASE: An 18-year-old female presented with 10 days of high fever, poor oral intake, sore throat, nausea, vomiting, abdominal pain, and malaise associated with jaundice. She had travelled recently to Florida and Washington, D.C. Her past medical history included a "prolonged febrile illness" diagnosed as "cat scratch fever" at age 11. Physical exam showed an ill-appearing, tachycardic Caucasian female. She had scleral icterus with pale conjunctiva. There was no lymphadenopathy or hepatosplenomegaly. Her abdomen was mildly tender. The patient was found to have elevated liver enzymes, hyperbilirubinemia and low haptoglobin levels. Direct and indirect Coomb's tests were negative. Her blood and urine cultures remained negative. The viral serology including HIV, CMV, HSV, HHV-6 and viral hepatitis panel were negative as was the work up for babesiosis, ehrlichiosis, leptospirosis, bartonellosis, and malaria. She was found to have an acute EBV infection confirmed by serology and PCR. However, her hospital course was complicated by persistence of high-grade fevers, progressive pancytopenia and worsening liver functions. She also had hyperferritenemia and hypertriglyceridemia. A bone marrow biopsy showed extensive hemophagocytosis. Although she was started on high dose dexamethasone as per the HLH-94 protocol, administration of cytotoxic chemotherapy was delayed in preparation for fertility preservation process. At that time, her clinical condition started to improve. She was maintained on a slowly tapering dose of steroid and was seen as an outpatient. She improved, and liver enzymes as well as all other laboratory abnormalities normalized, including her anemia. Genetic testing for familial HLH was negative.
DISCUSSION: Hemophagocytic lymphohistiocytosis is an under recognized entity which can be caused by various triggers including infections, malignancies or autoimmune disorders. The clinical course is highly variable and ranges from self-limited to rapidly fatal. The diagnostic criteria include fever, splenomegaly, cytopenia involving two or more cell lines, hypertriglyceridemia or hypofibrogenemia, hemophagocytosis, hepatitis, low or absent Natural Killer cell activity, serum ferritin level > 500 ng/mL, soluble CD 25 level > 2400 unit/mL. The presence of at least 5 of the above criteria confirms the diagnosis of HLH. Our patient had 6 positive criteria (pancytopenia, splenomegaly on CT scan, increased triglycerides, hemophagocytosis on bone marrow biopsy, hepatitis and hyperferritinenemia). Still's Disease was also considered in the differential; however, the patient had a normal ANA, anti-ds-DNA, anti-Smith, anti-mitochondrial antibodies. In general, infection- triggered (non CMV or non EBV) HLH cases are usually treated with pathogen-directed therapy. Although there have been case reports of self-limited EBV or CMV- related HLH cases. Current recommendations are to begin the HLH-94 protocol as soon as the clinical picture fulfills the diagnostic criteria without delay, as mortality rate is very high. This was an unusual case of EBV-related HLH treated successfully with dexamethasone alone.

HEMOPTYSIS; AN UNUSUAL PRESENTATION OF CRYPTOGENIC ORGANIZING PNEUMONIA IN AN HIV PATIENT Yagna R. Bhattrai[1]; Madan R. Aryal[2]; Ravi Shahu[3]. [1]Mercy Catholic Medical Center, Upper Darby, PA; [2]Reading Health System, West Reading, PA; [3]Queens Hospital and Medical Center, Queens, NY. (Tracking ID #1621820)

LEARNING OBJECTIVE 1: Identify cryptogenic organizing pneumonia in the setting of unusual presentation (Hemoptysis) when usual treatment for pneumonia fails.
LEARNING OBJECTIVE 2: Discuss the work up for cryptogenic organizing pneumonia and differentiate it from chronic eosinophilic pneumonia and wegner's granulomatosis.
CASE: A 53 year old African American female with past medical history of HIV presented with cough, dyspnea, fever and hemoptysis of 1 week duration. At presentation, she was febrile and hypoxic on room air. Lung examination was remarkable for crackles in right lung bases. Chest X ray and CT revealed infiltrates concerning for pneumonia. She was treated with antibiotics twice for pneumonia within 3 months prior to this episode. Pertinent lab findings were CD4 count 532 cells/mm3, ANA screen, C-ANCA against Protineinase 3 (PR3), P-ANCA against Myeloperoxidase, anti GBM antibody were all negative. Eosinophil count was normal.

However, the infiltartes this time was migratory and this prompted us to look for further causes including crptogenic organizing penumonia. She underwent bronchoscopy which revealed blood in the trachea. Subsequently lung biopsy was considered for definite tissue diagnosis. Biopsy findings revealed non specific chronic lymphoplasmocytic inflammation, mild fibrosis and changes consistent with organizing pneumonia with recent hemorrhages. She responded very well to high dose steroid treatment. Though few cases of COP associated with HIV have been reported, hemoptysis is a rare presentation of this uncommon clinical combination. Early recognition is important as failure to do so can lead to significant morbidity and mortality.

DISCUSSION: Cryptogenic Organizing Pneumonia is an uncommon but increasingly recognized pulmonary entity that usually presents as subacute or chronic pulmonary illness that is histopathologically characterized by the presence of granulation tissue in the bronchiolar lumen, alveolar ducts and some alveoli, associated with a variable degree of interstitial and airspace inflammation. The most common features at presentation are nonproductive cough, dyspnea with exertion (2 weeks to 2 months) and weight loss of greater than 10 lb. Physical examination often reveals inspiratory crackles. Wheezing is rare and is usually present with rales, while clubbing is seen in less than 5 % of cases. Very rarely it can present with hemoptysis (as in our case), with very small quantities of blood expectorated. The clinical presentation of COP often mimics that of community-acquired pneumonia and are treated with antibiotics initially. It can also be confused with chronic eosinophilic pneumonia and interstitial pneumonitis. Hemoptysis can often complicate the clinical picture and can be difficult to differentiate from wegener's disease or lung cancer. In patients with HIV and low CD4 count, pneumocystis pneumonia should also be considered in the differentials. The definitive diagnosis is achieved by tissue biopsy. They usually respond to high dose steroids for 3 to 6 months. Our case illustrates the rare presentation of uncommon disease in association with HIV.

HEPATITIS B VIRUS AND HEPATOCELLULAR CARCINOMA: THE COMPLEXITIES OF SCREENING AND MANAGEMENT AMONG VULNERABLE PATIENTS. Madeline Sterling; Manish Patel; Sarang Kim. UMDNJ- Robert Wood Johnson Medical School, New Brunswick, NJ. (Tracking ID #1620638)

LEARNING OBJECTIVE 1: Recognize an usual presentation of Hepatocellular Carcinoma (HCC) secondary to chronic Hepatitis B Virus (HBV)

LEARNING OBJECTIVE 2: Consider the need for increased surveillance and screening for HBV among vulnerable populations.

CASE: A 38 year old male presented with a 3 week history of progressive nausea, vomiting and abdominal pain. The right upper quadrant pain was dull, without radiation and associated with emesis during meals. He reported dark urine and increasing jaundice for 1 week. He was without chest pain, dysuria, melena, hematochezia, pruritus, rashes and change in stool color. He denied weight loss, fevers and night sweats. He denied alcohol use, recent infections, previous hepatitis, blood transfusions, surgeries or use of illicit drugs. He emigrated from Mexico 6 years ago and last saw a physician in childhood. His physical was remarkable for scleral icterus and jaundice without asterixis or mental status changes. His epigastrium was diffusely tender; hepatosplenomegaly was present without shifting dullness or JVD. Lymphadenopathy, supraclavicular nodes and testicular masses were absent. Laboratory work-up revealed transaminitis and intrahepatic cholestasis with normal INR, protein and albumin. Abdominal-US was positive for a portal vein thrombosis and collaterals without ascites or biliary dilation. A Triphasic-CT revealed a nodular liver with innumerable hypo-attenuating lesions and an expansive mass invading the portal vein. An US-guided liver biopsy confirmed HCC. On serology, he was positive for HepB surface-Antigen and HepB Core-Antibody. His INR and bilirubin increased steadily and on day 7 he developed tense ascites and became markedly hypoxic. A bedside paracentesis removed 2 L of bloody fluid. He remained hypotensive despite intravenous albumin and fluid and was transfer to the ICU. He went into hemorrhagic shock, acute liver and renal failure and expired on day 9.

DISCUSSION: This case highlights the complexities of HBV disease. Unlike most end stage HCC patients, he was without cirrhosis, ascites or liver failure and maintained low HBV DNA and AFP levels. Given his unremarkable past medical history and the number of lesions found by CT, it is likely that he contracted HBV at birth and has been suffering subclinically since. The point at which the patient transitioned from being a chronic latent carrier to an active one is unknown. Hepatocellular carcinoma is the 3rd leading cause of cancer death worldwide and HBV accounts for 50 % of cases, the majority of which are transmitted perinatally. Although medical and public health interventions have decreased HBV transmission in developed nations, chronic infection persists in regions with suboptimal preventative health services. Unfortunately, epidemiological data is relatively sparse with regard to incidence and prevalence of chronic infection in non-endemic areas such as Latin America. Increased numbers of Latino patients who have had little medical care and age-appropriate screening are likely to contact the medical system as a function of healthcare reform. Clinicians must be vigilant with regard to Hepatitis screening since the identification of HBV carriers has the potential to decrease unnecessary mortality and morbidity.

HEPATITIS E VIRUS: CASE REPORT & LITERATURE REVIEW Surya N. Mulukutla; Jeffrey T. Bates. BCM, Houston, TX. (Tracking ID #1638678)

LEARNING OBJECTIVE 1: Recognize the growing clinical importance of HEV as a worldwide disease

LEARNING OBJECTIVE 2: Identify populations at risk of developing symptomatic HEV infection

CASE: A 48-year-old Caucasian male with a PMH significant for 30 years of alcohol abuse presented for alcohol detoxification. At admission, he noted 1 week of fevers and fatigue; he had no abdominal pain, hematemesis, melena, or change in stools. He had not used any medications, including over-the-counter or illegal drugs. There was no recent travel, animal exposure, or changes in diet. He was not sexually active. Physical examination revealed a pulse of 118 bpm and a fever of 38.9 °C; other vital signs were normal. He was alert and oriented to person, place, and time. He had scattered spider angiomata across his upper chest and hepatomegaly percussed at 17 cm. Initial laboratory studies revealed: AST 2410 IU/L, ALT 1419 IU/L, alkaline phosphatase 308 IU/L, total bilirubin 2.5 mg/dl, and direct bilirubin 0.7 mg/dl. Serum levels of acetaminophen and salicylates were normal. HAV IgM, HBsAg, HBc IgM, and HCV quantitative PCR were all negative. EBV IgM, CMV IgM, and an autoimmune work-up were also negative. An ultrasound did not reveal thrombi in the portal or hepatic veins. Liver biopsy confirmed cirrhosis. Eight days after admission, symptoms and LFT's had improved, and he was discharged home. One week post-discharge, hepatitis E virus (HEV) IgM and IgG antibodies returned positive. One month post-discharge, all hepatic enzyme abnormalities had resolved.

DISCUSSION: Globally, HEV infection is the most common cause of acute viral hepatitis. Though previously thought to be a problem isolated to resource-poor countries, recent data suggests an increasing number of cases in the developed world. Acute HEV infection is now more common than acute HAV infection in France, the UK, and Japan. Recent case series in both the USA and UK revealed that 3 % of patients diagnosed with drug-induced liver injury actually had HEV IgM antibody and were likely misdiagnosed. HEV subtypes 1 & 2 are found in Asia, Africa, and Latin America and typically affect men aged 15–35 years old; mortality rates range from 0.2 % to 4 % during epidemics. HEV subtypes 3 & 4 predominate in the developed world. Most infections are asymptomatic; however, non-specific symptoms can occur and extra-hepatic manifestations such as MPGN have been documented. Middle aged and elderly men who abuse alcohol are the most symptomatic; mortality rates are as high as 10 %. Seroprevalence in the USA is 21 % with an estimated annual incidence of 0.7 %. Most symptomatic infections are self-limited and last 4–6 weeks. Severe HEV infections from subtype 3 have been successfully treated with ribavirin monotherapy. Chronic HEV infection with subtype 3 has been described in solid organ transplant recipients, HIV-infected individuals, and patients undergoing chemotherapy.

HEPATOCELLULAR CARCINOMA PRESENTING WITH CERVICAL INSTABILITY Paulina Alcalan. Dallas Methodist Hospital, Dallas, TX. (Tracking ID #1641959)

LEARNING OBJECTIVE 1: Hepatocellular carcinoma may first present as cervical spine lytic lesions.
LEARNING OBJECTIVE 2: Diagnose hepatocellular carcinoma when CT is unremarkable.
CASE: A 65-year-old African American male with no past medical history except for recently diagnosed hypertension presented with neck pain and numbness in the second and third digits of the left hand. Symptoms began 1 month ago and had progressively worsened. The pain was described as constant, sharp and aggravated by neck movement. He denied trauma, loss of consciousness, spasms, gait disturbances, visual changes, seizures, weight loss, chest pain, dyspnea, abdominal pain, and dysuria. Surgical history was pertinent for an abdominal gunshot wound in 1965. He denied taking any medicines. Social history was negative for tobacco, alcohol and drug use; he had spent the last 20 years as a floor installer. Family history was negative for cancer, liver disease, diabetes and coronary artery disease. Pertinent physical exam findings included lipomas on the occipital area and posterior neck which he reported had been present for many years. He had decreased pinprick sensation in the tips of the second and third digits of the left hand. Otherwise a full exam including a neurological exam was unremarkable. CT of the neck showed a large 5 cm expansile lytic lesion involving C2 and C6. CT of the chest, abdomen and pelvis showed no evidence of malignancy, including no liver masses and no cirrhosis; but revealed an enlarged heterogeneous prostate. CBC and liver function tests were normal. Hepatitis panel revealed hepatitis C. His PSA was 5.38, CEA 5.7 and AFP 43,000. Bone scan showed no other areas of metastasis. Biopsy of the neck mass was consistent with hepatocellular carcinoma. An MRI was ordered and revealed a 1.1×1.2 cm enhancing mass in the caudate lobe of the liver that was not previously seen on CT. He was treated by neurosurgery with neck stabilization and mass resection. He was placed on Sorafenib for his advanced liver disease.
DISCUSSION: : Hepatocellular carcinoma (HCC) is the most common primary cancer of the liver. Risk factors include cirrhosis and chronic viral hepatitis B and C. Extrahepatic metastases of HCC occurs most frequently in the lungs, lymph nodes, bones, and the adrenal glands. Bone lesions comprise 6–39 % of all extrahepatic metastases and are invariably lytic. Common areas of bone metastasis include the spine, ribs, pelvis and femur. Patients with HCC usually present with hepatomegaly, right upper quadrant pain or an abdominal mass. It is rare for the initial clinical presentation to be related primarily to the presence of metastasis without overt evidence of hepatic involvement. We present a rare case in which the first clinical manifestation included neck pain and numbness to the second and third digits of the left hand with metastasis only present in the cervical spine. In reviewing the literature, only 3 other cases involving cervical metastasis have been reported. Physicians should consider hepatocellular carcinoma in the differential diagnosis when cervical osteolytic lesions are encountered.

HEPATOID ADENOCARCINOMA OF THE SMALL BOWEL - NEVER BEFORE MENTIONED MALIGNANCY IN A PATIENT WITH CROHN'S DISEASE. Tanmayee Bichile. St. Francis Hospital, Evanston, IL. (Tracking ID #1643304)

LEARNING OBJECTIVE 1: To identify hepatoid adenocarcinoma is a special type of extrahepatic alpha-fetoprotein producing adenocarcinoma, with a morphological similarity to hepatocellular carcinoma.
LEARNING OBJECTIVE 2: To recognise Chronic inflammation as a potential trigger for malignancy.
CASE: A 57 year old Caucasian female was admitted with complaints of episodic upper abdominal pain, chills, nausea, non-bloody and constipation. Her past medical history includes Crohn's disease, GERD, hypothyroidism, eczema and basal cell carcinoma excision from her face. She was discharged home recently with a diagnosis of metastatic liver disease most likely from an occult AFP producing adenocarcinoma. She received chemotherapy with FOLFOX and 5-fluorouracil. A CT scan Abdomen showed the metastatic liver disease and Crohn's colitis with microperforation. She was taken for an exploratory laparotomy with distal small bowel and cecal resection with ileoascending colostomy and wedge liver biopsy. The tissue showed findings consistent with a metastatic hepatoid adenocarcinoma. Tissue from the small bowel showed hepatoid adenocarcinoma measuring 7×4×1.2 cm, with transmural invasion into subserosal fat, perforation, serositis and adhesions with lymphovascular invasion. The same tissue showed evidence of Crohn's ileitis too. Lymph nodes were negative for tumor invasion. Additional staining tests showed this tumor to be strongly positive for Alpha fetoprotein. Genetic markers including P13K, B-RAF and K-RAS were all negative. TNM staging was done as T3N0M1 consistent with Stage IV metastatic hepatoid adenocarcinoma. The patient has however recovered well from the surgery and is currently continuing chemotherapy.
DISCUSSION: Ishikura first proposed the term 'hepatoid adenocarcinoma of the stomach' for primary gastric carcinomas characterized by both hepatoid differentiation and production of large amounts of AFP. Since then, the tumor is described in various other organs including gall bladder, lung, soft tissue, ovaries and the uterine corpus. Studies have demonstrated chronic inflammation and autoimmunity to be associated with development of malignancy. In addition immunosuppressive therapy for treatment of these diseases is an independent risk factor. The transmural chronic inflammation in patients with Crohn's disease is thought to predispose them to various malignancies. Hemminki et al. followed a Swedish cohort of nearly 22,000 patients with Crohn's disease for increased development of malignancy and higher associations were calculated for small bowel carcinoma, colon cancer and NHL. Hepatoid adenocarcinoma is an aggressive tumor with liver metastasis being the first clinical manifestation which was similar to our case. Although rare, this entity deserves clinical recognition among physicians, surgeons and pathologists to avoid potential misdiagnosis and inappropriate therapy.

HEROIN INDUCED THROMBOTIC THROMBOCYTOPENIC PURPURA Meghan Rane; Emerald Banas; Arman Khorasani-zadeh; Badal Kalamkar; Aakash Aggarwal. SUNY Upstate university hospital, Syracuse, NY. (Tracking ID #1643190)

LEARNING OBJECTIVE 1: Recognize the clinical features and laboratory findings of thrombotic thrombocytopenic purpura (TTP)
LEARNING OBJECTIVE 2: Recognize that thrombotic thrombocytopenic purpura can be heroin / drug induced
CASE: We present a 37 year old female transferred for higher level of care with opiod withdrawal, elevated troponin and platelets of 13×10^3. She complained of pain in the chest, back and abdomen. She describes the pain and stabbing in all areas, high intensity and worse on inspiration. When the foley was placed, red tinted urine was seen continuously. She stated that she was having her mensus. She was saturating well on room air, within an hour she required increased oxygen support and eventually have to be intubated and could no longer give history. As per records that arrived with her, she had recently been discharged from a drug detoxification program 1 week back and admitted to using heroin again. Two weeks prior she had been in the hospital for opiod withdrawl, there her platelets were 509×10^3. Physical Exam- vitals: temperature: 38.3C, blood pressure- 142/108 mmHg equal in both arms, pulse 139 beats per minute, respirations 26 breaths per minute and 97 % oxygen saturation on room air which eventually required 6 L oxygen then intubation. Skin- warm, moist, arms have multiple track marks, thickened sclerotic veins. Eyes: pupils dilated reactive to light, icterus present. Lungs: Clear to auscultation. Heart: tachycardic. Abdomen: soft, diffuse tenderness, no organomegaly, bowel sounds present. Genitourinary: red tinged urine without sediment. Neurological: At first was able to answer questions then became increasingly confused and agitated, had to be sedated for ventilator management. Labs- WBC-16.4×10^3 cells/ml, Hb-6.4 g/dl, platelets 13×10^3. BUN 33 mg/dl and Creatinine 1.7 mg/dl. Bicarbonate was 11. Anion Gap 25. ABG showed acidosis with low pO2 and well compensated pCO2. Cardiac enzymes were elevated. Lactic acid 7.7 meq/L. Lactic dehydrogenase >4000 IU/L. Drug screen positive for opiates only. EKG showed no ST changes. Chest x-ray- clear, no abnormalities. Patient was diagnosed with TTP secondary to heroin use and started on plasmapharesis and returned to baseline within 1 week.

DISCUSSION: The classic pentad of thrombotic thrombocytopenic purpura (TTP) include is thrombocytopenia, fever, neurologic symptoms (altered mental status, hallucinations, stroke or headache), acute kidney injury and microangiopathic hemolytic anemia (jaundice-indirect bilirubinemia, anemia, high lactate dehydrogenase). Criteria for TTP does not have to be met fully to diagnose this disorder. TTP can be drug induced, classically by classes of anti-platelet agents, immunosuppressant and chemotherapy as stated by Dlott JS and collegues; however there have been no reports which so clearly illustrate heroin induced TTP. In a patient who is unable to give history, it is possible to diagnose TTP with physical exam (fever, altered mental status) and labs (hemolytic anemia, thrombocytopenia, acute renal injury).

HMM…THAT LOOKS LIKE ARTERIAL BLOOD Neeraj Agrawal; Prathit Kulkarni; David C. Hilmers. Baylor College of Medicine, Houston, TX. (Tracking ID #1643050)

LEARNING OBJECTIVE 1: Recognize the physical signs and historical features of post-traumatic superficial temporal artery pseudoaneurysm.
LEARNING OBJECTIVE 2: Distinguish the therapeutic options for treating post-traumatic superficial temporal artery pseudoaneurysm.
CASE: A previously healthy 33-year-old Hispanic male presented with a six-week history of an enlarging, raised, painful lesion over the right temple. Approximately 8 weeks prior to presentation, the patient had suffered blunt trauma to the area when he was the victim of assault. At that time, he had a normal non-contrast computed tomographic image of the head. He did well until 2 weeks after the injury when the lesion began to develop. The pain associated with the lesion was described as constant and pulsating, with radiation down the right side of the face. The patient denied any fevers, chills, changes in hearing, otalgia, dysphagia, numbness, tingling, nausea, or vomiting. Physical examination revealed a 1.5-cm raised, mobile, tender lesion over the right temporal area. Bedside ultrasonography showed an encapsulated lesion which appeared to be a simple cyst. Aspiration was done at the bedside with the prompt return of what appeared to be arterial blood. Repeat bedside ultrasonography with Doppler analysis showed the presence of pulsatile flow, suggesting the diagnosis of superficial temporal artery (STA) pseudoaneurysm. A cerebral angiogram subsequently revealed a pseudoaneurysm of the anterior branch of the right superficial temporal artery measuring 9 mm in its largest diameter, confirming the diagnosis. There was an additional pseudoaneurysm more distal to the first that was 3 mm in its largest dimension. Both pseudoaneurysms were successfully embolized with 0.8 mL of n-butyl 2-cyanoacrylate (NBCA) using a direct puncture approach.
DISCUSSION: Post-traumatic STA pseudoaneurysm is a fairly rare diagnosis, with only a few hundred cases reported in the literature since it was first described by Thomas Bartholin in 1740. The anterior branch of the STA passes between the frontalis and temporalis muscles, above the bony ridge of the prominent superior temporal line. Trauma can lead to a contusion or transsection of the artery, creating a pseudoaneurysm. This is distinct from formation of a true aneurysm, in which all three layers of the artery wall are involved. Most patients with post-traumatic STA pseudoaneurysms are young to middle-aged males with a history of blunt trauma to the face. Patients typically present with a painless, pulsatile, compressible mass approximately 2 to 6 weeks after trauma. Diagnosis can usually be made with a careful history and physical exam. Needle aspiration of a suspicious lesion should actually be avoided because of the risk of bleeding, though it sometimes occurs because of a lack of awareness about this possible diagnosis. In the past, STA pseudoaneurysms were classically treated with surgical ligation of the afferent and efferent vessels and excision of the lesion. More recent reports have suggested a role for endovascular coil embolization; other options include endovascular embolization with NBCA, percutaneous embolization with thrombin, and ultrasound-guided compression of the lesion. NBCA is a super-glue like polymer that has been used to embolize many vascular malformations. Our case is unique because it represents one of the first reported uses of direct puncture embolization using NBCA for a case of STA pseudoaneurysm.

HOW LOW CAN YOU GO, A CASE OF ANEMIA Pooja Kumar; Raji Shameem; Robert E. Graham. Lenox Hill Hospital, New York, NY. (Tracking ID #1642387)

LEARNING OBJECTIVE 1: Anemia, viable levels of hemoglobin.
CASE: Anemia is the most common blood disorder to date. As Anemia causes decreased oxygen delivery to vital organs, the body can respond by increased cardiac output and increased tissue extraction of oxygen. The approximate normal value of Hb is defined as > 13 g/dL in men and > 12 g/dL in women, thereby lower values are defined as anemia. An 86 year old male was admitted to the MICU for lethargy and unresponsiveness. Documents from the nursing home indicated that he had a past medical history of CHF with AICD placement, CAD, Atrial Fibrillation, Dementia and that at baseline the patient was conversational. There was one episode of melena reported. Upon admission, the vitals were BP 84/51, temperature 94.6, HR 80. On physical exam, the patient was minimally responsive to sternal rub. The skin was cool with poor turgor. There was evidence of JVD, and bilateral crackles present at the lung bases. The abdomen was soft, distended and with bowel sounds. There was 3+ bilateral pitting edema present in both lower extremities. Initial CBC showed a WBC count of 17.5, Hb 1.9 g/dL, Hematocrit 6.3 %, and Platelets of seven thousand. The INR was 5.56, PT 65.7 s, and PTT 35 s. The lactic acid was 7.9. The patient was intubated, a central venous catheter was placed and over the next 7 h the patient received 5 units of pRBCs, 1 unit of platelets and 2 units of FFPs. The patient was adequately resuscitated and extubated 1 day later. The hemoglobin gradually improved to stabilize at Hb 7.5 g/dL. Further investigation revealed that the patient had a known diagnosis of myelodysplasia. One month later the patient was discharged back to the nursing home at his baseline cognitive, cardiac, and respiratory function.
DISCUSSION: There have been few reports of Hb as low as 1.9 g/dL compatible with life. In the setting of intravascular volume depletion or underlying cardiac dysfunction, studies have shown inability to maintain tissue oxygenation at Hb below 5 g/L. However, with adequate fluid resuscitation, blood product transfusions, and correction of coagulopathy, we were able to quick resuscitate this patient. Our case helps us remember that no two cases of hypovolemic shock are alike, and patients can survive Hb levels previously considered incompatible with life.

HOW TO SEE A BIG 'K' DROP! Pranathi Sundaragiri; Dhwanil Vyas; Rene H. Cuadra; Nicole S. Silverstein. University of Connecticut, Hartford, CT. (Tracking ID #1642461)

LEARNING OBJECTIVE 1: Recognize the role of hyperthyroidism in hypokalemic periodic paralysis (HPP) as management guidelines differ for familial HPP
LEARNING OBJECTIVE 2: Promote the usage of Propranolol as first-line therapy for Thyrotoxic HPP for rapid reversal of paralysis and hypokalemia
CASE: A 32-year old Hispanic male was brought to the emergency room of John Dempsey Hospital (JDH) with complaints of acute onset bilateral lower limb weakness and inability to get out of bed. While jogging, earlier that day, patient had a fall with inability to stand up. Weakness had resolved before he reached an outside hospital. Physical exam and labs at that time were unremarkable. Patient experienced similar episodes of periodic weakness off and on for the last year, which always resolved on their own. He reported no significant medical, social or family history, and no triggers or other associated symptoms. On examination at JDH, vitals were stable with isolated systolic hypertension of 146/72 mmHg. No tachycardia, lid lag, tremors of extremities, or palpable thyroid were appreciated. Neurological exam was remarkable for a 3/5 power in bilateral lower extremities. Power in bilateral upper extremities and sensory exam in all four limbs was normal. Sensorium, speech and cranial nerves were intact. No bowel or bladder incontinence was noted. Initial labs showed serum Potassium of 1.6 mEq/L and EKG showed prominent U waves. The transtubular potassium gradient was low at 2.76. Thyroid stimulating hormone was low at 0.05 uU/ml, Free T4 elevated at 5.26 ng/ml and Free T3 elevated at 12.8 pg/ml. Potassium was corrected to 4.9 mEq/L with oral and intravenous supplements and his symptoms resolved completely.

DISCUSSION: Periodic paralysis (PP) is a family of diseases manifested by episodes of painless muscle weakness. Most cases are hereditary, and acquired cases have been described in association with hyperthyroidism. Hypokalaemic PP as the first presentation of thyrotoxicosis is rare, especially in non Asian populations. The approximate incidence rate for TPP in North American population is 0.1–0.2 %, which is one tenth the rate reported for Asian populations. Exceptional cases of bulbar weakness and respiratory weakness requiring ventilatory support have been reported in TPP, as well as cases of severe, even fatal, arrhythmias (sinus arrest, second degree atrioventricular [AV] block, ventricular fibrillation, and ventricular tachycardia). Acute treatment involves potassium replacement, along with nonselective beta-blockade, the recommended initial treatment for confirmed TPP. Acetazolamide, used as prophylaxis for familial PP, a hereditary form of hypokalaemic PP without thyrotoxicosis, worsens TPP. Restoration of euthyroidism eliminates attacks of episodic weakness. Euthyroidism must be maintained for at least 6 months before a definitive treatment may be considered. Propylthiouracil bridges therapy to Iodine ablation and subtotal thyroidectomy, which are curative.

HYDROXYCHLOROQUINE INDUCED CARDIOMYOPATHY
ANITA SULTAN, MD1; SIMON P. CRASS, MD1; MATTHEW BERNSTEIN, MD2; SHERIEF N. KHALIL, MD1; VAQAR AHMED, MD1; SHAKAIB U. REHMAN, MD1 1 DEPARTMENT OF MEDICINE, MEDICAL UNIVERSITY OF SOUTH CAROLINA.2 DEPARTMENT OF PATHOLOGY, MEDICAL UNIVERSITY OF SOUTH CAROLINA
Anita Sultan[1]; Simon P. Crass[1]; Matthew Bernstein[2]; Sherief N. Khalil[1]; Vaqar Ahmed[1]; Shakaib U. Rehman[1]. [1]Medical University of South Carolina, Charleston, SC; [2]Medical University of South Carolina, Charleston, SC. (Tracking ID #1622665)

LEARNING OBJECTIVE 1: Hydroxychloroquine is commonly used to treat patients with SLE, Rheumatoid arthritis, other connective tissue diseases and malaria. Retinal toxicity is a well known complication of hydroxychloroquine; neuromyotoxicity and cardiotoxicity have also been reported in literature.
LEARNING OBJECTIVE 2: Hydroxychloroquine induced cardiomyopathy is a rare but potentially life threatening condition. Other cardiac side effects include hypotension, hypokalemia, conduction disorders, myocardial thickening, restrictive cardiomyopathy and decrease in contractility, subclinical diastolic and systolic dysfunction with chamber dilatation. The pathological findings of hydroxychloroquine induced cardiomyopathy included myocyte vacuolization with increased glycogen, lamellar lysosomal inclusion and curvilinear bodies on electron microscopy.
CASE: JD is a 32 year old African American female with past medical history significant for SLE, class III lupus nephritis (biopsy proven), tophaceous gout, and chronic kidney disease who presented with complaint of shortness of breath for 6–8 months but worsening for past few weeks. She endorses exertional dyspnea, orthopnea, lower leg swelling and chronic arthralgias. No chest pain, nausea, vomiting, sweating, palpitations or paroxysmal nocturnal dyspnea. She was recently started on diuretics for leg swelling. Lab data revealed serum creatinine of 7.7 mg/dl. Other than mild anemia, rest of her labs including LFTs, complement levels, cardiac enzymes, ds DNA antibody and urinalysis were unremarkable. Vital signs: Blood pressure 163/89, pulse 94, respiratory rate 20, temperature 97.4 and oxygen saturation 96 %. Physical examination showed a young lady with cushingoid body habitus, with multiple scars and tophi on arms, legs and abdomen. She had expiratory wheezes in the right posterior lung field. Cardiovascular examination showed regular rate and rhythm with no jugular venous distention, 3/6 systolic ejection murmur at the apex and faint S3. Patient had 2+ lower extremity edema extending to her knees. A transthoracic echocardiogram demonstrated global hypokinesis of the left ventricle and an ejection fraction of 41 %, a previous echo 4 years ago was within normal limits. There was concern for hydroxychloroquine versus lupus cardiac involvement. A right ventricular apex biopsy was performed which demonstrated mild myocyte vacuolization and few myelin figures. Based on pathology findings, the patient was diagnosed with hydroxychloroquine induced cardiomyopathy. Afterload reduction therapy with beta blocker, hydralazine, and long acting nitrate was initiated, hydroxychloroquine was discontinued, and the patient was started on azathioprine for her lupus. A repeat echocardiogram 2 months later revealed no major regional wall motion abnormalities and an ejection fraction of 70 %.
DISCUSSION: Cardiac abnormalities in SLE are not uncommon, but serious disturbances are rare. Treatment with anti malarial has shown to increase the incidence of cardiac toxicity. It is important to note that cardiac toxicity can develop in the absence of retinal toxicity. Regular eye examination has been recommended for patients on hydroxychloroquine to screen for retinal toxicity. Guidelines for the detection of cardiomyopathy in patients on chronic hydroxychloroquine therapy may be of great benefit, but none exist at this time. An annual ECG and transthoracic echocardiogram might be considered an option for the early diagnosis of hydroxychloroquine induced cardiomyopathy.

HYPERCALCEMIA OF MALIGNANCY
Andrew Mener; Sara Wikstrom. The George Washington University, Washington, DC. (Tracking ID #1641933)

LEARNING OBJECTIVE 1: Recognize the clinical features of hypercalcemia of malignancy
LEARNING OBJECTIVE 2: Manage acute hypercalcemia of malignancy
CASE: A 63 year old male with a history of coronary artery disease, peripheral artery disease, hypertension, and chronic kidney disease presented to our hospital with significant confusion and decreased oral intake of liquids and solids for a period of about 2 days. He denied dysphagia or odynophagia. He had a recent hospitalization for an exudative parapneumonic effusion that was notable for atypical cells concerning for malignancy. However, the patient did not follow-up with pulmonology after being discharged. Physical exam was significant for dry mucous membranes. On neurologic exam, the patient was oriented only to person and place. His chest x-ray revealed opacification of the right middle and right lower lobes of the lung, which was unchanged from his x-rays during his previous hospitalization. His labs were notable for a white count of 17,000, BUN of 56, Cr of 2.6, and a calcium of 15.6. The patient was admitted for altered mental status secondary to hypercalcemia and concern for a paraneoplastic syndrome. He was treated with aggressive intravenous fluid hydration. As the patient's calcium level decreased, his mental status improved. In addition to the known consolidation in the patient's lung, a CT scan of the patient's chest revealed multiple destructive appearing lucent lesions throughout multiple vertebral bodies and ribs concerning for multiple myeloma versus metastatic disease of unknown primary. A subsequent biopsy of the L2 vertebrae and a right pleural biopsy suggested primary metastatic lung adenocarcinoma. The patient was evaluated by oncology but ultimately decided to pursue hospice care.
DISCUSSION: This case emphasized the importance of recognizing the clinical features of hypercalcemia, which classically include bone pains, nephrolithiasis, abdominal pains, and altered mental status. The case also emphasized the need to maintain a high suspicion for malignancy in patients with symptomatic hypercalcemia since approximately 20 to 30 % of patients with cancer develop hypercalcemia. Patients with asymptomatic hypercalcemia or only mild symptoms often do not require immediate intervention, especially if the condition is chronic or has developed gradually over time. However, patients with calcium levels greater than 14 or those accompanied by significant symptoms, require immediate treatment. Elevated calcium levels decrease the kidney's ability to concentrate urine. When this renal defect is combined with the abdominal pains and anorexia associated with hypercalcemia, patients can become profoundly dehydrated, further reducing calcium excretion. Treatment with intravenous normal saline at a rate of 200 to 500 ml per hour is recommended to increase renal calcium excretion. Additional therapies to treat hypercalcemia include intravenous bisphosphonates (to further reduce calcium by inhibiting osteoclastic bone resorption) and dialysis. However, as with all emergent treatments for hypercalcemia, longterm treatments must be focused at the underlying malignancy. 1. New England Journal of Medicine 2005, "Hypercalcemia Associated with Cancer." Vol 352, p374-

HYPEREOSINOPHILIA AS A PARANEOPLASTIC SYNDROME
Mimi C. Tan; Lee Lu. Baylor College of Medicine, Houston, TX. (Tracking ID #1624111)

LEARNING OBJECTIVE 1: Recognize that hypereosinophilia could be a manifestation of metastatic colon cancer.
LEARNING OBJECTIVE 2: Review hypereosinophilia as a paraneoplastic syndrome of colorectal cancer.
CASE: A 74-year-old man presented with weight loss and anorexia. He had a documented 35-pound weight loss within 8 months. He was eating one meal per day due to decreased appetite and early satiety. He denied abdominal pain, diarrhea, and blood in stool. There was no history of allergies or parasitic infections. Physical exam was consistent with a soft, non-tender abdomen without hepatosplenomegaly. The rectal exam showed brown stool, although the fecal occult blood test was positive. Laboratory abnormalities consisted of leukocytosis (WBC 27,700/uL) with hypereosinophilia (absolute eosinophil count 9,100/uL) and anemia (Hgb 10 g/dL, previously 12 g/dL), consistent with iron deficiency anemia. Peripheral blood smear revealed absolute eosinophilia without dysplastic changes or blasts along with microcytic, hypochromic erythrocytes. Stool ova and parasite exam was negative. Cortisol level was normal. With the symptoms of early satiety and weight loss, an esophagogastroduodenoscopy was performed, which was normal. The abdominal and pelvic computed tomography (CT) scan, which was pursued due to the weight loss, revealed a large colonic mass and two liver hypodensitities. Serum carcinoembryonic antigen was normal at 0.61 ng/mL. Colonoscopy revealed two large, ulcerated masses in the ascending and sigmoid colon. Pathology for ascending colon mass showed poorly differentiated adenocarcinoma; sigmoid colon mass revealed moderately differentiated adenocarcinoma. The positron emission tomography (PET) scan demonstrated the liver lesions to avidly uptake fludeoxyglucose (FDG), likely representing metastatic disease. His hypereosinophilia was thought to be a paraneoplastic syndrome associated with colon cancer. He is currently undergoing neoadjuvant chemotherapy with future intent to perform subtotal hemicolectomy and portal vein embolization prior to liver resection.
DISCUSSION: Although hypereosinophilia is usually associated with allergic reactions, helminthic infections or vasculitides, colorectal malignancy should also be recognized as a potential cause. From the literature search, two previously reported cases of hypereosinophilia from widely metastatic colon adenocarcinoma showed increased levels of cytokines, particularly IL-5. Cytokine and eosinophil counts decreased after chemotherapy and rose again when the disease relapsed. In these patients, eosinophil counts can be used to monitor cancer burden. Hypereosinophilia may be associated with a worse prognosis when it presents as a paraneoplastic condition and warrants a strong suspicion for metastatic disease. Underlying malignancy, including colon cancer, causing a paraneoplastic syndrome should be considered with unexplainable hypereosinophilia.

HYPEREOSINOPHILIC SYNDROME: FISHING FOR A DIAGNOSIS
Oliver Horne. musc, Charleston, SC. (Tracking ID #1643227)

LEARNING OBJECTIVE 1: Recognize hypereosinophilia syndrome as a cause of stroke in a young, healthy patient.
LEARNING OBJECTIVE 2: Treat hypereosinophilia syndrome in the acute setting with life-threatening Loeffler endocarditis and stroke.
CASE: A 42 yo WM presented after waking with a right-sided headache and left arm and hand numbness and clumsiness. The left arm numbness started at the shoulder and extended to the fingertips. He denied other symptoms. Medical history included an ischemic stroke 4 months prior with negative carotid ultrasound and transesophageal echocardiogram. Patient was started on aspirin and dipyridamole for the previous stroke and discontinued weeks later due to thrombocytopenia. Patient had a previous 15 pack year smoking history. Family history revealed a brother with deep venous thrombosis. Patient was not taking any medications. Patient was awake, alert, and oriented. Cardiovascular exam was regular rate and rhythm. Neurologic exam revealed dysmetria of the left hand and decreased sensation to pin prick from the left shoulder to fingertips. CBC revealed 19 % eosinophils. MRI brain demonstrated multiple infarcts within the bilateral middle cerebral and left posterior cerebral artery distributions. Transthoracic echocardiogram revealed biventricular endomyocardial fibrosis, thrombus, and myocarditis consistent with Loeffler endocarditis. Cardiac MRI confirmed these findings. Patient was started on anticoagulation and 1 mg/kg oral prednisone. Molecular analysis was positive revealing 69 % of cells with FIP1L1/PDGFRalpha fusion gene. Eosinophil count did not respond to high dose prednisone so imatinib was initiated. Peripheral eosinophilia normalized within 4–5 days. Patient was discharged on imatinib, warfarin, and oral prednisone taper.
DISCUSSION: The definition of hypereosinophilic syndrome is characterized as eosinophilia ≥1500/mL present for more than 6 months, no other cause of eosinophilia such as parasitic, allergic, or other known causes of eosinophilia, and signs and/or symptoms of end-organ dysfunction such as heart failure, pulmonary fibrosis, fever, weight loss, anemia, or central nervous system abnormalities. Loeffler was first to report the associations among eosinophilia, active carditis, and multiorgan involvement in 1936. It is characterized as eosinophilic myocarditis, endomyocardial fibrosis, and clinical manifestations of thromboembolism and acute heart failure. Although eosinophilic endocardial disease is well known, myocardial and vascular involvement is rarely diagnosed during life due to its rapid fatal course. Hypereosinophilic syndrome is rare. Estimated prevalence is presumed to be 0.36–6.3 per 100,000 people. Only 10–14 % of these have associated FIP1L1/PDGFRalpha tyrosine kinase fusion protein. Testing for this mutation with FISH is now routine practice as its presence indicates response to imatinib. In patients presenting with life threatening complications, prompt empiric treatment with high dose steroids should be initiated. Imatinib is the treatment of choice for FIP1L1/PDGFRalpha positive disease and should be initiated as soon as diagnosis is made. In patients unresponsive to high-dose steroids, imatinib should be initiated early, even before FISH analysis is complete. Most patients with FIP1L1/PDGFRalpha positive disease improve clinically and hematologically within 2–4 weeks and achieve remission within 3–6 months. However, there has been no reported cure of FIP1L1/PDGFRalpha positive disease from imatinib to date.

HYPERTROPHIC CARDIOMYOPATHY AND INFECTIVE ENDOCARDITIS: RECOGNIZING THE AT-RISK PATIENT.
Sarah W. DeParis; Patrick Hart. Reading Health System, West Reading, PA. (Tracking ID #1610842)

LEARNING OBJECTIVE 1: Identify the incidence of infective endocarditis in hypertrophic cardiomyopathy (HCM).
LEARNING OBJECTIVE 2: Recognize the specific risk factors for infective endocarditis among HCM patients.
CASE: A 68-year-old woman with a history of hypertrophic cardiomyopathy presented to the emergency department complaining of intermittent fever for 1 month and severe low back pain for 2 days. Previous echocardiogram 12 years prior showed HCM with significant outflow obstruction and left atrial dilation. She denied any history of intravenous drug use. At presentation, she was afebrile and normotensive with a normal white count. Physical examination revealed tenderness to palpation over the L3 and L4 vertebrae and no focal neurologic findings. Loud systolic and diastolic murmurs were audible throughout the precordium. In addition, a 5 mm round macule was visible on the left hand, consistent with a Janeway lesion. Blood cultures were positive for Streptococcus mitis (viridans). Transthoracic echocardiogram revealed a large vegetation of the mitral valve and no evidence of heart failure. MRI of the lumbar spine increased T2 signal at L3-L4 suggestive of early osteomyelitis. She was treated with intravenous ceftriaxone to complete full six-week course, and had rapid improvement of her clinical symptoms.

DISCUSSION: Approximately three-fourths of patients with infective endocarditis have a history of underlying structural cardiac disease. Even so, infective endocarditis is a relatively rare complication of hypertrophic cardiomyopathy (HCM), with less than 40 cases reported in the literature, and an estimated incidence of only about 4 per 1000 person-years. However, HCM patients with significant outflow obstruction and left atrial dilation are at nearly two-fold greater risk for endocarditis than those with non-obstructive HCM. Antibiotic prophylaxis is no longer recommended for any HCM patients prior to dental procedures, but in patients with outflow obstruction presenting with febrile illness, a high index of suspicion for endocarditis is necessary to prevent delay in diagnosis.

HYPOKALEMIA WITH PERIODIC PARALYSIS: A CASE OF DISTAL RENAL TUBULAR ACIDOSIS Kamesh Sivagnanam[1,2]; Nili Parekh[1,2]; Hirenkumar Patel[1,2]; Terence O'Neil[2]. 1East Tennessee State University, Johnson City, TN; [2]Mountain Home Veterans Affairs Medical Center, Johnson CIty, TN. (Tracking ID #1642032)

LEARNING OBJECTIVE 1: Something as common as hypokalemia can be associated with devastating consequences and may require extensive systematic work-up.
LEARNING OBJECTIVE 2: Not all patients with hypokalemic periodic paralysis have the familial or the thyrotoxic variety. Secondary causes of hypokalemic paralysis can also be periodic.
CASE: A 41 year old veteran with past medical history of dyslipidemia, hypertension and diabetes presented with a history of recent diarrhea, vomiting, tingling sensation and weakness. His medications included metformin, glipizide, lisinorpil, bupropion and simvastatin. He had no history of substance abuse. His initial vitals were normal and examination was negative except for generalized weakness. Initial labs were only significant for potassium of 3.1 meq/dl (normal 3.5–5 meq/dl). CT scan of the head was negative. His weakness continued to progress over a few hours, eventually involving the respiratory muscles and he had to be intubated. At the time of intubation, potassium was 1.2 meq/dl, arterial blood gases showed metabolic acidosis and his diarrhea had resolved. Potassium was aggressively replaced (320 meq/22 h) with constant monitoring. With replacement, he improved to his baseline and was discharged. During the next 2 years, he had 15 more admissions involving 6 intubations with the same presentation. Negative workup for differentials during this time included a lumbar puncture (Gillian Barre syndrome), serotonin, somatostatin, gastrin, urine 5-HIAA, vasoactive intestinal polypeptide, urine anion gap (gastrointestinal loss), thyroid stimulating harmone (thyrotoxic periodic paralysis), urine diuretics panel (surreptious use), renin-aldosterone ratio, testosterone, insulin, c-peptide, epinephrine, nor-epinephrine, dopamine (transcellular shunts), heavy metal screen, urine drug screen (toxic) and a genetic test done for hypokalemic familial periodic paralysis(FPP). Bicarbonates were significantly reduced during episodes. Urine Potassium levels, urine potassium/creatinine ratio and transtubular gradients during the 2 years of monitoring ranged between 40 and 150 meq/l (>30 meq/l=renal loss), 45–120 (>1.5–2.5=renal loss), 10–50 (>3=renal loss) respectively. Several causes of renal loss were ruled out including diuretics (panel negative, not prescribed), hyperaldosteronism, hypomagnesemia and alkalosis (ruling out Bartter, Gitelman and Liddle syndromes). Urine pH was consistently greater than 5.5 ruling out a proximal renal tubular acidosis (RTA). Patient had normal anion gap metabolic acidosis, normal serum potassium in spite of high urinary losses between episodes, positive urine anion gap and an elevated urine Ph confirming the presence of a distal RTA.
DISCUSSION: Distal RTA can occur in the absence of background rheumatological conditions and can cause hypokalemia induced periodic paralysis. Periodic paralysis occurs in several settings and the diagnosis may require an extensive search for the underlying etiology since the treatment varies according to the cause. Treatment with alkali worsens FPP, but is beneficial in RTA making the distinction pivotal. Not all periodic paralysis is familial and a specific cause must be isolated to ensure appropriate treatment.

HYPONATREMIA: A COMPLICATION OF INTRA-ARTICULAR CORTICOSTEROID INJECTION Andrew J. Zane; Jingbo Huang; Shankar Bettadahalli; Sreelatha Chalasani. Marshfield Clinic/Ministry Saint Joseph's Hospital, Marshfield, WI. (Tracking ID #1642516)

LEARNING OBJECTIVE 1: Recognize adrenal insufficiency as a rare complication of intra-articular steroid injection.
LEARNING OBJECTIVE 2: Evaluation and treatment of hyponatremia in the setting of adrenal insufficiency.
CASE: A 69-year-old female presented to our facility with complaints of weakness and fatigue, progressively worsening over a 3 week duration. She denied fevers, chest pain, or dyspnea, but reported a 10 lb weight loss with occasional lightheadedness. The patient was able to ambulate without difficulty at baseline; for 4 days prior to admission, she was using a walker she had acquired from a past pelvic fracture. Two weeks prior to admission, she had seen her primary care physician and was treated for acute on chronic sinusitis and oral thrush. She was 3 days from completing a 7 day course of doxycycline and fluconazole. Her past medical history was significant for severe osteoarthritis of her knees and shoulder, hypertension, and coronary artery disease with diastolic dysfunction. The patient had received intra-articular steroid injections (100 mg of triamcinolone) to bilateral knees on 4 occasions over the past 2 years and her most recent injection was 1 month prior to presentation. Her vital signs were notable for T of 98.4 °F, HR of 66 bpm, BP of 130/67 mm Hg, and RR of 17 with oxygen saturation of 94 % on room air. Physical examination revealed a lethargic-appearing female who was alert and oriented to person, place and time. Her mucous membranes were dry and conjunctivae pale. Her heart was regular, lungs clear, and abdomen soft and non-tender. Her musculoskeletal strength was 4/5 throughout and was without any focal neurological deficits. Laboratory studies revealed sodium of 127 mmol/L, potassium 4.3 mmol/L, chloride 98 mmol/L, BUN 22 g/dL, Cr 0.8 units/L, blood osmolality 271 mOsm/L, urine osmolality 583 mOsm/kg, urine sodium 98 mmol/L, and TSH of 1.52 ng/ml. A baseline cortisol was 0.6 μg/dl. A 60-minute ACTH stimulation test revealed a cortisol of 5.1 μg/dl. Baseline ACTH was 7 pmol/L. FSH, LH, and IGF-1 were within normal limits. The patient was diagnosed with hyponatremia as a result of adrenal insufficiency secondary to intra-articular steroid injection. She was treated with hydrocortisone 100 mg IV every 8 h. Repeat serum sodium levels began to rise. Her weakness and fatigue improved. She was discharged in baseline condition and was provided a course of oral hydrocortisone and instructions for follow up.
DISCUSSION: Intra-articular steroid injections are a valuable adjunct therapy for the treatment of severe osteoarthritis. The most commonly used steroid is triamcinolone acetonide at standard dose of approximately 40 mg for larger joints, 30 mg for medium-sized joints, and 10 mg for smaller joints. Adrenal insufficiency is a recognized, but rare, complication of intra-articular corticosteroid injection secondary to hypothalamic pituitary adrenal axis suppression. Decreased cortisol levels can occur after even a single, low-dose, intra-articular corticosteroid injection. Hyponatremia in adrenal insufficiency is mediated by increased production of antidiuretic hormone, which causes water retention. Cortisol inhibits corticotrophin releasing hormone and therefore ADH. This important inhibitory effect is absent in adrenal insufficiency. Treatment of hyponatremia in adrenal insufficiency involves cortisol and volume resuscitation. Physicians should be mindful that the rise in sodium as rapid correction can cause osmotic demyelination syndrome.

HYPOTHENAR HAMMER SYNDROME EXACERBATED BY CREST SYNDROME Dereje F. Moti; Kassi S. Montgomery; Brian Weis; Mashrafi Ahmed. Texas Tech Univ Health Sciences Center, Amarillo, TX. (Tracking ID #1639769)

LEARNING OBJECTIVE 1: Diagnose the Hypothenar Hammer Syndrome
LEARNING OBJECTIVE 2: Recognize that rare rheumatological disorders like Hypothenar Hammer Syndrome may present and exacerbate together with common rheumatological diseases.

CASE: A 35 year old female presented with pain and black discoloration of left third distal finger for 1 month. The patient noticed transient discoloration in both hands, most notable in the winter months, but denied any numbness. She did not have any history of DVT, pulmonary embolism, pregnancy loss or contraceptive use. She works at a dairy farm filling bottles with milk, and a detailed occupational history revealed a 2 year history of 60 h per week of high pressured palmar compression involving only the left hand. Physical examination revealed atrophy of the hypothenar eminence of the left hand, ulceration of the third digit, and a positive Allen's test on the corresponding hand. Her Anti Centromere antibody came back positive. Digital subtraction angiogram showed occlusions of the distal radial and ulnar arteries with collateral flow to the palmar arches predominately from the distal radial collateral, and occlusion of many of the digital arteries of the hand in particular the mid to distal portion of the digital arteries of the middle finger. The patient is currently being managed for the hypothenar hammer syndrome exacerbated by CREST variant of scleroderma.
DISCUSSION: Hypothenar hammer syndrome (HHS) is a rare cause of upper-extremity ischemia. The diagnosis is often delayed due to the absence of a thorough occupational and recreational history. Importantly, it is a reversible cause of hand ischemia that, if missed, can lead to significant morbidity and even amputation. The term 'hypothenar hammer syndrome' (HHS) was suggested by Conn et al. in 1970. It is described as being the result of trauma to the ulnar artery as it courses around the hook of the hamate bone in the wrist. Such trauma leads to stenosis or occlusion of the ulnar artery, thereby affecting the blood supply to the superficial palmar arch. Ferris et al. reported the largest series (21 cases) of HHS and found that all their cases had repetitive palmar trauma. However, they also found a high incidence of bilateral abnormalities on arteriography, even in patients with unilateral symptoms. Specific jobs causing repeated trauma to the palm of the hand including mining, automobile repair, sawmill work, carpentry, butchery are the main causes. Angiography is the gold standard test to diagnose it. Treatment options are conservative or reconstructive, with exclusion of the emboligenous area. Conservative measures including intravenous heparin and prostaglandin E1 may be useful, with control of risk factors by smoking cessation, low-lipid diet and repeated venesection to reduce polycythaemia. This case reminds us that a rare clinical entity like hypothenar hammer syndrome can present along with more common rheumatological disorder like CREST syndrome and high degree of suspicion is needed to reach a proper diagnosis.

I GOT DYSPHAGIA FROM DRINKING COLD WATER! OXALIPLATIN INDUCED LARYNGOPHARYNGEAL DYSETHESIA-A RARE SIDE EFFECT Niket Sonpal; Raji Shameem; Antonio Mendoza-Ladd; Ian Yudelman. Lenox Hill Hospital, Hauppauge, NY. (Tracking ID #1624316)

LEARNING OBJECTIVE 1: The occurrence of Laryngopharyngeal Dysethesia secondary to Oxaliplatin can masquerade as an acute stroke; however a good history and physical can prevent unnecessary testing.
LEARNING OBJECTIVE 2: Patient and physician education is essential to the prevention of Laryngopharyngeal Dysethesia.
CASE: Oxaliplatin is a platinum based chemotherapeutic agent that contains diaminocyclohexane. Laryngopharyngeal dysethesia (LPD) has been seen in patients receiving oxaliplatin. This is an under recognized complication of oxaliplatin use. LPD usually occurs shortly after infusion of the drug. It is believed that LPD is induced by or exacerbated by expose to cold substances, such as cold liquids. We present a case of patient on oxaliplatin with multiple infusions who subsequently developed a sudden onset of dysphagia after drinking a glass of cold water. A 79 year old female with past medical history of colon cancer on chemotherapy presented with the complaint of weakness, difficulty swallowing, inability to speak and some blurry vision. The patient states this feeling began suddenly and was shortly have going to the bathroom. On exam the patient was found to dysarthria and difficulty handling her saliva and decreased muscle strength. A CT scan of head showed no acute infarction or or intracranial hemorrhage. An echocardiogram showed a normal left ventricle without clot or wall motion abnormalities and a carotid duplex was also within normal limits. A subsequent barium swallow demonstrated a mildly dilated mid and lower thoracic esophagus with birds beaking consistent with achalasia. The patient's condition improved after several days and she returned to her baseline. The patient had an ENG It was then discovered after lengthy discussion that the patient had before the incident ingested a cold beverage and given her oxaliplatin based regiment it was concluded that her symptoms were secondary to a rare side effect from the chemotherapeutic agent. This information combined with her rapid improvement and normal imaging studies confirmed the diagnosis.
DISCUSSION: When it comes to the management of oxaliplatin induced LPD, patient and physician education is essential. Prior to infusion one should tell the patient to be aware of the possible onset of dysphagia and to alert the physician immediately if it occurs. It is important to stop the infusion immediately and to reassure the patient. In most instances the dysphagia resolves and the patient will do well, however primary care physicians should keep this rare but importance occurrence in mind. Taking a good history is paramount as exposure to platin based chemotherapy will aid the clinician and prevent unnecessary testing.

I HAVE A DANCING HAND: A RARE PRESENTATION OF POST HERPETIC MYOCLONUS Miles Raizada; Robert B. Werner; Razi Rashid; Mashrafi Ahmed. Texas Tech University Health Sciences Center, Houston, TX. (Tracking ID #1640784)

LEARNING OBJECTIVE 1: Recognize that shingles can cause nerve damage and irritation to such an extend that it can cause myoclonus
LEARNING OBJECTIVE 2: Treat post-herpetic myoclonus with a new modality by Injecting botulinum toxin
CASE: A 70-year-old male presented to the hospital with abnormal jerking movement of the right hand 2 weeks after initially developing dermatomal pain and while still experiencing the classic dermatomal rash along the C5 dermatome. Patient was treated with acyclovir and prednisone at the time of initial presentation, but self-discontinued the medications after the pain had largely resolved. Three days after he discontinued therapy, he presented with violent myoclonic jerks of his right arm involving muscles supplied by the C5 motor nerve root. Initially the movement was constant and continuous. He was unable to rest and presented with elevation in myoglobin and creatinine kinase related to muscle breakdown from constant activation. The clinical picture of the C5 rash occurring concurrently with the myoclonus of C5 innervated muscles strongly suggests that the patient had developed a peripheral myoclonus caused by the varicella zoster reactivation. Therapy for peripheral myoclonus was initiated with benzodiazepines and Depakote without immediate success. The Patient suffered 48 h of sleep deprivation secondary to the constant, violent myoclonic jerks. We initiated neuro-chemical denervation with botox for some clinical relief. He responded to this intervention with significant resolution of the motor activity, as we continued to titrate up his oral medications.
DISCUSSION: Latent Varicella-Zoster infections can give rise to classic unilateral dermatomal shingles. It results from reactivation of endogenous latent Varicella-zoster virus infection within the sensory ganglia. Although pain due to post herpetic neuralgia is not uncommon, Herpes zoster induced myoclonic jerk is very rare presentation. Myoclonus is a brief, shock-like, involuntary movements caused by muscular contractions or inhibitions. Though the central nervous system myoclonus is more common, the peripheral myoclonus may also occur as a consequence of a peripheral nervous system lesion producing hyperactive motor discharges to its muscle. Ogata et al. presented a case of myoclonic jerk of abdominal muscles in a patient with high varicella-zoster virus (VZV) titers. Bhatia et al. also presented right upper limb segmental myoclonus following uncomplicated chicken pox without evidence of encephalitis or the opsoclonus-myoclonus syndrome. Sometimes, myoclonus may precede the skin manifestation as well. Koppel et al. encountered a patient with arm and shoulder myoclonus preceded herpes zoster involving the same segments contralaterally on two occasions. In all these cases, anticonvulsants or benzodiazepines were administered. Our patient initially failed to respond to benzodiazepine and anti-epileptic therapy and was chemically denervated with botox as a therapeutic bridge. This is the first case in the literature in which post-herpetic peripheral nerve damage has led directly to myoclonus.

IDIOPATHIC TRANSVERSE MYELITIS PRESENTING AS ACUTE QUADRIPLEGIA AND RESPIRATORY FAILURE Brielle Spataro; Farhan Zaidi; Bryan Mcverry. UPMC, Pittsburgh, PA. (Tracking ID #1630092)

LEARNING OBJECTIVE 1: Recognize the clinical features of Idiopathic Transverse Myelitis.
LEARNING OBJECTIVE 2: Treatment of Idiopathic Transverse Myelitis.
CASE: We present a case of a19 year old female who presented with acute onset respiratory failure and acute onset quadriplegia. She was in her usual state of health 2 days prior to admission. She awoke the morning of admission with neck pain and right arm paresthesias which evolved into numbness and weakness over the course of a half hour. The numbness and weakness progressed to involve her right leg and subsequently leading to quadriplegia. Her respiratory rate decreased and she was intubated for worsening respiratory status. She was then transferred to our University Hospital. On exam her extremities were flaccid and she had no rectal tone. Deep tendon reflexes were absent in the right upper extremity. The lower extremities were hyper-reflexive bilaterally, and her Babinski reflexes were normal. Sensation was absent with the exception of the face and left cervical region. Lumbar puncture revealed normal CSF. MRI of the cervical spine was markedly abnormal with cord enhancement and T2 hyper intense signal from C2 to C7. An extensive laboratory work up was negative. She was treated with parenteral corticosteroids and plasmapheresis with minimal improvement. She was subsequently treated with cyclophosphamide and 12 days later improved strength in her upper extremity and increased sensation. Her final diagnosis is Idiopathic Transverse Myelitis.
DISCUSSION: Our patient presented with acute onset quadriplegia with MRI findings consistent with Transverse Myelitis (TM) with no identifiable cause. TM is uncommon, with an approximate incidence of between 1 and 5 cases per million population annually. TM typically presents with varying degrees of weakness, sensory alterations, and autonomic dysfunction Respiratory failure is a rare presentation of TM. The diagnostic criteria for idiopathic acute TM require the development of clinical dysfunction attributable to the spinal cord with defined sensory signs in an acute period, in the absence of extra axial compressive etiology and signs of inflammation. Moreover other etiologies must be ruled out. The exact pathophysiology remains unclear but is thought to be due to an intraparenchymal or perivascular cellular influx into the spinal cord, resulting in the breakdown of the blood brain barrier and variable demyelination and neuronal injury. While patients are often treated with parenteral corticosteroid therapy, limited evidence supports that this approach alters outcomes. In one uncontrolled, retrospective study of 122 patients with idiopathic TM the greatest improvement in neurological deficits was observed in patients treated with steroids plus cyclophosphamide and plasmapheresis compared to those treated with corticosteroids alone or corticosteroids plus cyclophosphamide. Most patients with idiopathic TM have at least a partial recovery, which usually begins within 1 to 3 months. However, some degree of persistent disability is common, occurring in about 40 %. Our case demonstrates that TM should be a diagnostic consideration in anyone presenting with acute onset of quadriplegia, that TM may rarely present as acute respiratory failure, and that despite intensive therapies patients may experience minimal improvement. Further investigation is necessary to identify novel therapeutic targets for this devastating disease.

INFECTIVE ENDOCARDITIS COMPLICATED BY SEPTIC PULMONARY EMBOLI IN A CHRONIC INTRAVENOUS DRUG USER David B. Zagha; Avni S. Shah; Natalie K. Levy. NYU School of Medicine, New York City, NY. (Tracking ID #1638611)

LEARNING OBJECTIVE 1: Diagnose methicillin-resistant Staphylococcus aureus endocarditis in a chronic intravenous drug user.
LEARNING OBJECTIVE 2: Recognize pulmonary septic emboli as a complication of infectious endocarditis.
CASE: A 33-year-old man was admitted to the hospital with worsening shortness of breath over the past 2 weeks. His symptoms were associated with profuse intermittent sweating, fevers, and cough productive of pink sputum. He reported an extensive history of poly-substance abuse, including cigarettes, alcohol, crack-cocaine, and 30–40 bags of heroin injected daily. Physical exam revealed an obese, obtunded, and diaphoretic male, using accessory muscles for respiration with temperature 100.8 °F, blood pressure 110/68, pulse 118, respiratory rate 24, and oxygen saturation 85 % on room air. Exam also showed constricted pupils, tachycardia without any evident murmurs, diffuse inspiratory crackles and expiratory wheezes, and bilateral pitting edema distal to the knees. Labs were significant for a WBC of 23,900/uL with 91 % neutrophils and 6 % bands, Hb 10.1 g/dL, and platelets 56,000/uL. K was 6.6 mmol/L, BUN 206 mg/dL, and Cr 9.3 mg/dL. Two separate blood cultures grew methicillin-resistant Staphylococcus aureus (MRSA). Transthoracic echocardiogram showed a 2.4×1.7 cm vegetation on the septal tricuspid leaflet with severe tricuspid insufficiency. Chest CT revealed multiple air and fluid-filled cavitary masses, air bronchograms, and partially loculated bilateral pleural effusions.
DISCUSSION: By the Duke Criteria, our patient satisfies two major clinical criteria for definite diagnosis of endocarditis: two separate blood cultures positive for Staphylococcus aureus and echocardiographic evidence of endocarditis. The association between intravenous (IV) drug use and right-sided endocarditis is well established; studies have shown right-sided endocarditis to be responsible for up to 86 % of infective endocarditis cases seen in IV drug users. With IV drug injection, both particulate matter and common skin flora are released into circulation. The former leads to repetitive valvular endothelial damage, in particular affecting the right sided tricuspid valve, which can then be more susceptible to bacterial and fungal seeding. Staphylococcus aureus, a common skin flora, is isolated 51 % of the time in IV drug users with endocarditis as compared to 13 % of non-IV drug users with endocarditis. Septic emboli are a well known complication of infective endocarditis and are more likely to occur if the patient is an intravenous drug user (53 % vs. 35 %). Septic pulmonary emboli cause infarction of tissue distal to the occluded pulmonary vessel, thus establishing a focus for abscess formation within lung parenchyma. Given the combination of increased incidence of right-sided endocarditis and rate of embolic events in IV drug users, it is reasonable to expect preferential involvement within the pulmonary arterial system among this subgroup. Indeed, septic pulmonary emboli are found to be responsible for 38 % of embolic events in IV drug users as opposed to only 10 % in non-IV drug users. Common presenting symptoms of septic pulmonary emboli, as seen in our patient, include fever (93 %), dyspnea (36 %), cough (14 %), and hemoptysis (7 %). Common radiologic features seen on chest CT include multiple peripheral nodules (83 %), a "feeding vessel sign," described as a vessel coursing directly into a nodule (67 %), cavitary lesions (50 %), and air bronchograms within nodules (28 %).

INTRAHEPATIC PORTAL VEIN THROMBOSIS: IS GASTRIC SURGERY A RISK FACTOR? Naba R. Mainali; Madan R. Aryal; Madan Badal; Richard Alweis. Reading Health System, West Reading, PA. (Tracking ID #1621784)

LEARNING OBJECTIVE 1: Recognize the clinical features and diagnosis of Intrahepatic Portal Vein Thrombosis.
LEARNING OBJECTIVE 2: Describe the treatment and prognosis of Intrahepatic Portal Vein Thrombosis.
CASE: Portal Vein thrombosis is frequently being diagnosed these days, with life time risk of 1 % in the general population. Intrahepatic portal vein thrombosis, however, is a less common entity than extrahepatic portal vein thrombosis. Usually, intrahepatic portal vein thrombosis is associated with hepatocellular carcinoma. In adults, approximately 25 % of patients with extrahepatic portal vein thrombosis have underlying cirrhosis that might extend into intrahepatic portal veins. Other common causes of intrahepatic portal vein thrombosis include prothrombotic disorder and abdominal inflammation. It might be complicated with splenomegaly, esophageal or gastric varices, portal hypertensive gastropathy or ascites. A 38-year-old

morbidly obese female, with recent laparoscopic sleeve gastrectomy for weight control presented in the emergency department with severe abdominal pain for 2 days. Initially, the pain was crampy in nature and associated with burning sensations in the epigastric area. It was also associated with nausea and vomiting. She was passing flatus with normal bowel movements. There was no history of melena, hematochezia, hematemesis or dysuria. She denied fever, chills, chest pain and shortness of breath. In the meantime, she was being treated for left lower lobe pneumonia. Physical exam revealed mild tenderness in the mid-epigastric area but no obvious hepatosplenomegaly. Laboratory investigations revealed hemoglobin 12.1 gm/dL, WBC 7800/μL, platelets 232000/μL and normal abdominal X-ray and serum electrolytes. D-Dimer was elevated at 1000 mg/dL. Abdominal CT scan showed intrahepatic portal vein thrombosis in the left lobe of the liver. Protein C, protein S, antithrombin III were all normal and factor V Leiden, anti-cardiolipin antibodies and lupus anticoagulant antibodies were found to be negative. Anticoagulation with heparin and warfarin was initiated and she was discharged on warfarin for 6 months. On follow up exam after 6 months, she was asymptomatic without any evidence of thrombosis on the abdominal CT scan.

DISCUSSION: The patient presented with several risk factors, including recent surgery. Some studies suggest the possibility that the CO2 used for pneumoperitoneum may increase risk, but tissue damage from the surgery itself is a well-recognized risk factor for thrombophilia. Tissue damage from gastric surgery may lead to release of procoagulant products in the portal venous system eliciting portal vein thrombosis. Additionally, infection like pneumonia and obesity itself are risk factors for thrombosis. Since her pneumonia was almost resolved with treatment, negative prothrombotic work-up, recent surgery was the most likely explanation of her condition. Treatment consists of anticoagulation for at least 6 months. It is prudent to repeat the abdominal CT scan after 6 months to confirm the resolution of thrombus. It is unclear whether a follow-up D-dimer is useful in the decision to discontinue anticoagulation. Despite this increasingly common condition, there remains a paucity of studies to guide clinicians.

INTRAVASCULAR CATHETER-RELATED INFECTION WITH ACINETOBACTER BAUMANNII LEADING TO NATIVE VALVE ENDOCARDITIS Rossana Rosa; Kathreen Kraus; Rosario Colombo; Cesia M. Gallegos. Jackson Memorial Hospital-University of Miami Miller School of Medicine, Miami, FL. (Tracking ID #1642524)

LEARNING OBJECTIVE 1: Recognize the importance of Acinetobacter baumannii as an infectious agent.

LEARNING OBJECTIVE 2: Manage intravascular catheter-related infections due to Acinetobacter baumannii.

CASE: A 39-year-old female with HIV-related end-stage renal disease receiving dialysis for the past 3 months via a permanent catheter in her right subclavian vein was referred to the hospital from her dialysis center for 3 days of fever and chills. The initial physical examination had unremarkable vital signs. There was tenderness to palpation surrounding the catheter insertion site with skin blistering, but no purulent drainage or erythema. No audible murmur on cardiac auscultation. No evidence of systemic embolization. Laboratory data showed white blood cell count of 11,900/uL, hemoglobin of 7.8 g/dL, platelets 224,000/uL, BUN 39 mg/dL and creatinine 9.4 mg/dL. A chest x-ray was unremarkable. Blood cultures showed growth of Acinetobacter baumannii (2/2 bottles) and Enterococcus faecalis (2/2 bottles), both sensitive to conventional antibiotics. The dialysis catheter was removed and the tip culture showed Acinetobacter baumannii with the same sensitivity profile. A transthoracic echocardiogram showed thickened mitral valve leaflets and mild mitral regurgitation. A tunneled dialysis catheter was placed via the right internal jugular (IJ) vein. She was discharged home with a 4 week regimen of IV vancomycin and levofloxacin. Four months later the patient returned with fever, chills, nausea, and vomiting. Blood cultures showed growth of Acinetobacter baumannii (2/2 bottles) with the same sensitivity profile. A transesophageal echocardiogram (TEE) revealed moderate-sized vegetations on the anterior leaflet of the mitral valve and also attached to the tip of the dialysis catheter. The catheter was guide-wire exchanged and the patient was discharged on IV cefepime to complete 6 weeks of treatment. Two weeks later, she returned with fever, chills, nausea and vomiting. Blood cultures remained negative, but a repeat TEE re-demonstrated mitral valve vegetation. Cefepime was continued and tobramycin was added. The right IJ catheter was completely removed and the tip of the catheter, upon culture, showed growth of Acinetobacter baumannii sensitive to Colistin only. Since the patient had clinically improved, therapy with Cefepime and Tobramycin was continued for a total of 6 weeks. She has since been followed by Nephrology, and no further episodes of fever or bacteremia have been reported. Three months later a new AV fistula was created from which she is now receiving routine hemodialysis.

DISCUSSION: Acinetobacter baumannii is a gram-negative cocobacillus, of importance as an infectious agent in hospitals worldwide, and due to its ability to easily develop resistance to many classes of antibiotics. Acinetobacter baumannii leading to native valve infective endocarditis is rare, with less than 20 cases reported to date. Amongst the risk factors for infection with Acinetobacter baumannii are the use of dialysis machines, indwelling central venous catheterization and the presence of comorbidities, such as immunosuppression. The guidelines for the management of intravascular catheter-related infections recommend that the presence of gram-negative bacilli should prompt removal of catheter. Currently there is lack of data based on randomized controlled trials regarding the best antibiotic choice for infections with Acinetobacter baumannii; treatment selection is guided by in vitro sensitivity.

INVASIVE ASPERGILLOSIS: CLOSING THE TIME GAP IN ANTIFUNGAL THERAPY Anar Patel; Harish Jasti. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1643055)

LEARNING OBJECTIVE 1: Illustrate the importance of early diagnosis in the prognosis of invasive aspergillosis

LEARNING OBJECTIVE 2: Discuss the utility of galactomannan detection in the diagnosis of invasive aspergillosis

CASE: A 55 year-old male with alpha-1 antitrypsin deficiency status-post double lung transplant (7/2010), HTN, and chronic kidney disease was admitted for new-onset fatigue and dry cough. He denied nausea, vomiting, headaches, hemoptysis, abdominal pain, or rashes. He was on tacrolimus and mycophenolate mofetil for immunosuppression and azithromycin, dapsone, and acyclovir for infectious prophylaxis. Social history was significant for remote cocaine and tobacco use, and no recent travel history. Physical exam revealed a well-developed male in no acute distress. He was afebrile with an oxygen saturation of 95 % on room air. Pulmonary exam was remarkable for rhonchi in the left lower lung field. He had dry mucous membranes and tachycardia (90 bpm). Abdominal and neurologic exams were unremarkable. A CT scan of the chest revealed mild right basilar consolidation with ground-glass opacities consistent with rejection, which was unchanged from a previous scan. In addition, there was a new consolidation within the left lung base with a central area of cavitation, and consolidative nodules in the lingula and superior segment of the right lower lobe. The patient was initiated on vancomycin and piperacillin/tazobactam for community acquired pneumonia and empiric oseltamivir for influenza. After 2 days of continued fevers, levofloxacin and voriconazole were added for expanded coverage of Legionella and Aspergillus, respectively. Subsequent bronchoscopy, along with bronchoalveolar lavage (BAL), was positive for galactomannan in the fluid. A culture of the bronchial washings was positive for Aspergillus fumigatus. Treatment was started for invasive aspergillus with voriconazole and inhaled amphotericin.

DISCUSSION: Diagnosis of fungal pneumonia in immunosuppressed and critically ill patients is challenging because of a non-specific clinical presentation, lack of specificity of radiologic imaging, and delayed yield of cultures. Definitive diagnosis relies on histopathology or culture results which are often difficult to obtain. Survival can be improved if therapy is initiated prior to microbiological confirmation of the disease. Since a delayed diagnosis of invasive aspergillosis can lead to significant morbidity and mortality, early detection is critical for patient management. In addition to clinical presentation and imaging studies, a serum enzyme immunoassay that detects Aspergillus cell wall galactomannan (expressed as galactomannan index or GMI) is a useful clinical tool to help guide

antifungal therapy. Systematic reviews have shown that GMI has a sensitivity and specificity of 66 % and 90 %, respectively. The sensitivity of a serum sample is increased in patients with neutropenia, especially in those with hematologic malignancies. In non-neutropenic patients, the sensitivity of the test is higher in BAL fluid samples. False positive results can be seen with concomitant fungal infections and certain antibiotics, such as beta-lactams. False negative results may occur in patients who have received prior antifungal therapy. As our case demonstrates, galactomannan testing in serum and BAL fluid can be a valuable complement to other diagnostic tests for early detection and treatment of invasive aspergillosis.

IS SCIC MAKING THE PATIENT SICK? Kavitha Bagavathy; Hamid Habibi. University of Connecticut Health Center, Farmington, CT. (Tracking ID #1638635)

LEARNING OBJECTIVE 1: Recognize the presentation of Sickle cell intrahepatic cholestasis—a rare but potentially life threatening complication in sickle cell anemia patients.
LEARNING OBJECTIVE 2: Treat sickle cell intrahepatic cholestasis—early intervention is life saving.
CASE: We report a case of a 36 year old male with Hemoglobin SC(HbSC) disease who presented from the Department of Corrections with lower extremity pain for 1 day that responded poorly to acetaminophen. His pain began in the knees and later progressed to involve the entire extremity.He denied any abdominal pain. Past medical history was significant for avascular necrosis of the hip. Physical exam on presentation was unremarkable except for scleral icterus. Labs revealed a WBC count of 15.2, mild transaminitis,a direct bilirubin of 3.2 with no evidence of hemolysis on his peripheral blood smear.He was given intravenous hydromorphone for pain. The next day he had a temperature of 102 F,was tachycardic despite adequate pain control and his leukocytosis worsened to 22,000. His CXR, blood and urine cultures were unremarkable. Over the course of the next 5 days, he continued to spike fevers with worsening direct hyperbilirubinemia with total bilirubin of 44.9 and direct bilirubin of 27.0 and transaminitis with ALT of 145, AST 125. His alkaline phosphatase and GGT levels were elevated at 1261 and 613 respectively. MRCP showed hepatomegaly with patent biliary and pancreatic ducts. Eventually a liver biopsy was done and it showed perivenular, centrilobular fibrosis and intrahepatic cholestasis.He was hemodynamically stable and received intravenous fluids and 2 units of PRBCs to correct his borderline anemia as he was occasionally short of breath. There was a gradual but significant improvement in lab parameters and resolution of fever over the next few days prior to his discharge.
DISCUSSION: Sickle cell intrahepatic cholestasis(SCIC) is a rare but well recognized, potentially fatal complication specific to patients with sickle cell disease. The most comprehensive literature review to date reports 44 cases, including both the pediatric and adult population. Diagnosis is purely clinical and criteria include a total bilirubin greater than 13 mg/dL without evidence of extrahepatic obstruction,viral hepatitis,severe acute hemolysis or anemia.It is hypothesized that the obstruction of the hepatic sinusoids by sickled cells and the consequent hypoxia causes hepatocyte swelling resulting in intracanalicular cholestasis. The clinical course varies from a mild, self- limited form to a potentially fatal one. It can present with fever, leukocytosis and renal failure making the diagnosis challenging especially in the setting of multiple causes that can account for hyperbilirubinemia in sickle cell anemia patients. However,exchange transfusion has proven to reduce mortality in patients with severe symptoms. This patient probably had a milder course due to his HbSC disease instead of Hemoglobin SS and it is not entirely clear if the blood transfusion partially helped to avert a grim outcome by increasing the oxygen carrying capacity of the blood and decreasing blood viscosity thereby suppressing endogenous sickling. Since SCIC is essentially a cilinical diagnosis where early initiation of therapy can be life saving,it is important to consider the diagnosis in a sickle cell anemia patient presenting with hyperbilirubinemia,fever and renal failure in the absence of an infectious etiology.

IS THIS CANCER ? THINK ABOUT AUTOIMMUNE ! Thandar Aung. St. Franscis Hospital, Evanston, IL. (Tracking ID #1600504)

LEARNING OBJECTIVE 1: IgG4 related systemic disease(IgG4-RD) is increasingly recognized fibro-inflammatory condition with findings consistent with both an autoimmune disorder and allergic disorder. IgG4 related pancreatitis (autoimmune pancreatitis) is the prototypical form of IgG4-RD. IgG4 related cholangitis is the most frequent extrapancreatic manifestation.
CASE: 72 y/o chinese male with PMH of Hepatitis A, Hypertension, H.pylori gastritis and dyslipidemia presented with allergic rhinitis, abdominal discomfort, for 1 month duration associated with anorexia and 20 lb weight loss in 5 weeks, and yellowish coloration of eyes for last 4 days. He recently came back from Taiwan 2 months ago and had normal medical check up. He had strong family history of cancers. He was found to have mild icterus over conjunctiva and mild discomfort over epigastric area. His lab showed elevated total bilirubin (7 mg/dl) with direct bilirubin (4 mg/dl), elevated alkaline phosphatase (192 IU/L), AST (300 IU/L), ALT (350 IU/L), Amylase (280 IU/L), lipase (1200 IU/L) and normal wbc (4.5) with elevated eosinophil (13.4 %). MRCP showed CBD was mildly distended with no intrahepatic biliary dilatation and relatively abrupt tapering of the distal common bile duct. 1.6*1.4*2 cm peripancreatic head mass in sausage morphology. ERCP showed normal ampulla with diffusely narrowed pancreatic duct with unable to enter CBD. EUS showed entire pancreatic parenchymal abnormalities with hyperechoic strands with foci and lobularity with no lymph node enlargement. Biopsy of the ampulla showed increased IgG4 positive cells in lamina propria. Serum IgG4 was > 2 times upper limit of normal. Prednisone was started. Three months later all of his symptoms and lab findings were resolved and steroid was tapered out and stopped. Five months after completion of steroid, patient another flare of epigastric pain with lipase of 1245 IU/L .
DISCUSSION: Autoimmune pancreatitis(AIP) is an idiopathic inflammatory disease that produces pancreatic masses and ductal strictures and a benign disease which resembles pancreatic carcinoma both clinically and radiographically. Hallmarks are lymphoplasmacytic tissue infiltration with predominance of IgG4 positive plasma cells and T lymphocytes, usually accompanied by fibrosis, obliterative phlebitis and elevated levels of IgG4. Patients present with abdominal discomfort with or without frequent attacks of pancreatitis (30 %), obstructive jaundice (63 %) and diffuse enlargement of the pancreas on imaging(85 %) mimicking pancreatic cancer. Diagnostic HISORt criteria includes Histology, Imaging suggested of AIP, Serology with IgG4>2 times the upper limit of normal,Other organ involvement and Response to steroid treatment. Multiple organs can be affected simultaneously or metachronously with striking histopathologic similarities. There are conditions such as Kuttner's tumor and Mikulicz's disease are now fall within the spectrum of IgG4-RD. Relapse rate is high. Peripheral eosinophilia and allergic disorder are consistent with autoimmune mechanisms. An important part is distinguishing AIP from pancreatic cancer. Corticosteroids is mainstay of treatment.

IS YOUR ABDOMEN REALLY BENIGN? A RARE CASE OF ACUTE PANCREATITIS FROM METASTATIC BREAST CANCER! Javeria Haque; Harvey Friedman. Saint Francis Hospital, Evasnton, IL. (Tracking ID #1638627)

LEARNING OBJECTIVE 1: Acute pancreatitis from solitary metastases to the pancreas is very rare. This should be in the differential with any patient with prior neoplasm, especially breast cancer, presenting with pancreatitis.
LEARNING OBJECTIVE 2: Treatment is mainly directed towards symptom relief with goals towards cancer treatment.
CASE: A 50 year old female presented with 2 days of epigastric pain with radiation to her back. The pain was severe and sharp. It came in episodes that lasted for a couple of hours. She had some nausea but no vomiting. She did not have diarrhea. She denied having similar pain before. She had a past medical history of hypothyroidism and breast cancer. In 2008, on routine screening, a 1.5 cm speculated density was found on mammogram

in her right breast. Needle biopsy showed it was grade III infiltrative ductal carcinoma. She underwent lumpectomy and axillary dissection. Her tumor was Estrogen, Progesterone and HER 2 receptor negative. BRCA 1, 2 and other gene mutations were negative. She underwent chemotherapy followed by radiation. In 2009, another 4 cm mass was palpated in the same breast. She underwent bilateral mastectomies. She received more sessions of chemotherapy and was declared free of disease. On exam her vitals were within normal range. She had extreme epigastric tenderness with abdominal guarding but no rigidity. There was no hepatosplenomegaly. Bowel Sounds were hypoactive. Labs were essentially normal except for an elevated serum lipase (17, normal <6.0) and serum amylase. CT of the abdomen showed the pancreas was prominent in size with induration and fluid around the head. The pancreatic duct was dilated. An area of low attenuation was seen just below the pancreas. Hospital course: The patient was treated for pancreatitis with pain medications and intravenous fluids. An MRI of her abdomen showed resolution of the inflammation around the pancreas but identified a 3.4 cm mass closely related to the body of the pancreas extending anteriorly and superiorly to the stomach, with marked gastric wall thickening. The patient underwent emergent endoscopy, which revealed mucosal involvement of the stomach wall. Biopsies showed poorly differentiated ductal cell carcinoma. Bone scan and CT chest did not reveal more metastases.

DISCUSSION: Acute pancreatitis in the setting of metastases to the pancreas is fairly rare and almost unheard of in a patient with breast cancer. Our patient had elevated lipase and CT evidence of pancreatic inflammation on presentation. She had resolution of inflammation on a later MRI correlating with resolution of symptoms and normalization of serum lipase. Isolated pancreatic involvement in breast cancer is uncommon, although there are a few published series. In one study, breast cancer metastases were found to be only 8 % in all cases of isolated metastases to the pancreas, while another study showed that although isolated metastases to the pancreas are uncommon, the pancreas may be frequently involved in widely metastatic breast cancer. Breast cancer patients with pancreatic involvement usually present with jaundice, weight loss, and abdominal pain. Acute Pancreatitis is a very rare presentation in such patients.

IS ADENOSINE REALLY TO BLAME? Jerson Munoz-Mendoza[1]; Veronica A. Pinto Miranda[1]; Henry C. Quevedo[2]; Rafael F. Sequeira[3]. [1]University of Miami - Jackson Memorial Hospital, Miami, FL; [2]Tulane Heart and Vascular Institute, New Orleans, LA; [3]University of Miami, Miami, FL. (Tracking ID #1636463)

LEARNING OBJECTIVE 1: Recognize adenosine as a potential cause of coronary vasospasm during supraventricular tachyarrhythmia termination

LEARNING OBJECTIVE 2: Recognize the pathophysiology of coronary vasospasm secondary to medication

CASE: A 38-year-old male, otherwise healthy, presented to the emergency room with palpitations for 2 days and a three-hour pressure-like epigastric discomfort with radiation to the right upper quadrant. Upon arrival, he was tachycardic with a heart rate of 220 beats per minute. An electrocardiogram (ECG) showed narrow complex tachycardia. Vagal maneuvers were unsuccessful. Adenosine was then administered in two successive bolus injections of 6 and 12 mg dosages respectively with successful conversion to sinus rhythm. Right after administration of second bolus of adenosine, the patient complained of epigastric discomfort and significant ST segment elevation (STE) in the inferior leads and reciprocal changes as well as right bundle branch block were appreciated. He was emergently transported to the catheterization laboratory and shortly the STE had resolved with marked relief of his symptoms. Coronary angiography documented non-obstructive coronary disease without wall motion abnormalities. Cardiac biomarkers were elevated with a peak troponin I of 0.32. A provocation test for coronary artery spasm was not safe in these circumstances. Once clinically stable, an electrophysiological study was performed revealing a concealed left accessory pathway and he underwent successful radiofrequency ablation of the slow pathway of the atrioventricular nodal reentrant tachycardia. ECG post procedure showed normal sinus rhythm with nonspecific ST-T wave changes. He did not have recurrence of chest pain, ECG changes or arrhythmias.

DISCUSSION: Adenosine usually has a vasodilator effect in the coronary microcirculation; however this case demonstrated an unusual complication of intravenous administration of adenosine, coronary vasospasm (CV). The term CV refers to a sudden, intense vasoconstriction of an epicardial coronary artery that causes vessel occlusion or near occlusion, that could occur at the site of a stenosis or in angiographically normal coronary arteries, causing transient STE. It results from the interaction of 2 components: (1) a usually localized, but sometimes diffuse, abnormality of a coronary artery that makes it hyperreactive to vasoconstrictor stimuli, and (2) a vasoconstrictor stimulus able to induce the spasm at the level of the hyperreactive coronary segment. Adenosine is a frequently used pharmacologic stress agent in myocardial perfusion imaging and supraventricular tachyarrhythmia (SVT) termination. Its safety profile is well established, and most of its side effects are mild and transient. Cases of coronary vasospasm has been reported during or after adenosine stress test, but only one case of coronary artery vasospasm provoked by intravenous administration of adenosine for SVT has been reported. Our patient would constitute the second reported case worldwide. Adenosine usually features a safe pharmacological profile but possible mutations in the downstream signaling pathway could potentially lead to coronary artery vasospasm in a small amount of predisposed individuals.

IS IT STROKE OR HERPES VIRUS ENCEPHALITIS? Rakesh Malhotra; Shyam Patel; Amar V. Patel. UMDNJ-New Jersey Medical School, Newark, NJ. (Tracking ID #1643186)

LEARNING OBJECTIVE 1: Herpes simplex encephalitis is associated with high morbidity and mortality. The clinical presentations of herpes simplex encephalitis are varied and may be misdiagnosed for stroke, seizures, and/or non-specific delirium. Physicians should begin acyclovir therapy early on the basis of clinical suspicion.

LEARNING OBJECTIVE 2: Delay in start of treatment with acyclovir can lead to permanent neuropsychological impairment and even death in Herpes simplex encephalitis patients.

CASE: We report a case of 70-year-old female who presented with a two-week history of diffuse abdominal pain and fever. She also complained of nausea, vomiting and intermittent diarrhea. She had a history of colitis, myocardial infarction, hypertension, diabetes mellitus, and transient ischemic attack. Three weeks prior to admission, the patient received permanent pacemaker and was started on clindamycin. Physical examination revealed temperature of 100.5 °F and a pulse 74 beats/min. The initial systemic examination revealed no source of infection. Clindamycin was discontinued and patient was started on flagyl for suspected clostridium difficile. During the fifth day of hospitalization, the patient was noted to have a change in her mental status: she started making strange comments. She also had an episode of uncontrolled movements of both extremities and frothing from the mouth, requiring ativan and cerebyx. CT scans of the head showed no acute intracranial abnormality. Laboratory work was significant for chronic hyponatremia (serum sodium of 125 mEq/L). Video EEG showed right temporal sharp waves. Patient was continued on keppra and cerebyx and her hyponatremia was treated with tolvaptan. On day 9 of her illness, the patient was found to be in respiratory distress. She was given IV lasix and further intubated. The patient's seizures continued to be intractable. A repeat CT scan showed loss of the gray-white matter differentiation along the right insular cortex of the right cerebral hemisphere, as well as the occiptotemporal gyrus and mid-temporal lobe, in a vascular distribution that would reflect a right middle cerebral artery territory infarction. Patient was started on Acyclovir for possible viral encephalitis. Lumbar puncture was done with cerebrospinal fluid (CSF) analysis showing high WBC (240), 89 % lymphocyte, and a glucose of 43 mg/dL. CSF tests were negative for varicella, west nile virus, syphilis, cytomegalovirus, enterovirus, and cryptococcus. CSF serology finally revealed positive polymerase chain reaction (PCR) for Herpes simplex virus type 1 (HSV-1) (titer: 13,100). CT scan showed temporal lobe necrosis, typical of herpes virus meningoencephalitis. Video EEG also showed both right and left sided periodic lateralized epileptiform discharges (PLEDs), thus ruling out the possibility of a stroke. Patient was continued on Acyclovir therapy with no significant neurological recovery.

DISCUSSION: Herpes simplex encephalitis is associated with high morbidity and mortality. The clinical presentations of herpes simplex encephalitis are varied and may be misdiagnosed for stroke, seizures, and/or non-specific delirium. Physicians should begin acyclovir therapy early on the basis of clinical suspicion. Delay in start of treatment with acyclovir can lead to permanent neuropsychological impairment and even death.

IS THIS TRUE STEMI? Samian sulaiman; Muhammed Sherid; Husein Husein; Hani Snounou; Salih Samo; Addis Asfaw; Ana Inashvili; Alpa Vora; Nadia El Hangouche; Mehrnaz Salehidobakhshari; Shahriar Dadkhah. St. Francis Hospital. Evanston, evanston, IL. (Tracking ID #1623928)

LEARNING OBJECTIVE 1: 1- To recognize that an aVR ST elevation is a valuable indicator of the acute LMCA obstruction or proximal LAD obstruction 2- To recognize classic T waves of Wellen's syndrome which reliably suggest a high-grade stenosis of the proximal left anterior descending (LAD) coronary artery. 3- To recognize STEMI in the presence of incomplete LBBB.
CASE: A 63 year/old male presented with sudden onset, sharp, non-radiating, and retrosternal chest pain that started 1 h prior to arrival. He also was complaining of mild shortness of breath, sweating and palpitation. He reported having intermittent chest pain over the last week, but this episode was more severe and constant. Aspirin was given En route to the hospital. His Past medical history was significant for hypertension, hyperlipidemia, sleep apnea and restless leg syndrome. His medications included aspirin, simvastatin, enalapril and metoprolol. On physical examination, his BP was 214/126 mm Hg; the rest of physical examination was unremarkable. EKG showed ST elevation in leads (aVR, V1, V2) with incomplete LBBB. Chest X-ray showed a wide mediastinum. Initial labs were unremarkable. Due to the presence of incomplete LBBB and discordant ST elevation in addition to absence of an old EKG, ST elevation was considered nonspecific. First two sets of cardiac markers were negative. CT angiography of the chest did not show aortic dissection or dilatation. His chest pain was relieved temporarily with sublingual nitroglycerin. Two doses of IV metoprolol were given and Nitroglycerin drip was started. After ruling out aortic dissection a 300 mg of Plavix was given. He was admitted to the CICU for close monitoring. Two days later, a nuclear medicine stress test showed a large fixed perfusion defect in the anterior, septal and inferior walls. Patient had recurrent chest pain and an EKG at that time showed deep, inverted T waves in the precordial leads (V2-V3). On the 4th day, the patient underwent Coronary angiography, which showed 99 % ostial occlusion of the LAD. Due to the proximity of the lesion to LMCA, balloon was not inflated in order to avoid LMCA damage. Later on, the patient had off-Pump CABG with LIMA attached to LAD. Looking retrospectively, the ST elevation in leads aVR, V1, and V2 on admission was a true STEMI, and the incomplete LBBB was over-diagnosed. Two sets of cardiac markers were drawn within the first 2 h of presentation which can be falsely normal.
DISCUSSION: An aVR lead gives significant information about the right outflow tract and the basal part of septum. The latter is supplied by the first septal branch of LAD. The aVR ST elevation is a valuable indicator of the acute LMCA obstruction or proximal LAD obstruction involving the first septal branch. The classic Wellen's T-waves are described as either deeply inverted (> 2 mm) or biphasic T waves in V2-V3. Discovering Wellens' syndrome is imperative as 75 % of patients will develop acute anterior wall myocardial infarctions (MIs) within 1 week unless intervention is undertaken urgently. To diagnose STEMI in patients with incomplete LBBB, ST elevation should be in the same direction (concordant) as the QRS.

ISOLATED LEGIONELLA PERICARDITIS COMPLICATED BY LARGE PERICARDIAL EFFUSION. Mahmoud Abdelghany; Nervana Mahmoud; Saba Waseem; KM Anwar Hussain. Conemaugh Memorial Medical Center, Temple University, Johnstown, PA. (Tracking ID #1636095)

LEARNING OBJECTIVE 1: Pericarditis or pericardial effusion might be the only presentation of legionella infection.

CASE: Introduction: Since the organism was first recognized in 1976 during an outbreak at an American Legion Convention in Philadelphia, legionella has been identified as a relatively common cause of both community-acquired and hospital-acquired pneumonia. Isolated extrapulmonary disease from legionella is extremely rare; yet the most common extrapulmonary site is the heart. Few reports of pericarditis, myocarditis and even prosthetic valve endocarditis have been published. The severity of illness at presentation varies from mild, nonspecific findings to profound respiratory or multi-organ failure. Here we present an extremely rare case of a 73-year-old male patient with isolated legionella pericarditis resulting in large pericardial effusion. Case Report: The patient presented to the hospital with pleuritic type chest pain. EKG showed signs of acute pericarditis. On admission the patient had 1.2 cm pericardial effusion. He was discharged on colchicine after pain subsided. Nine days later the patient was readmitted with diarrhea and similar chest pain. More detailed history revealed recent travel with an extended stay in an air-conditioned hotel room. Repeated Echocardiography showed increased pericardial effusion to 3.2 cm with no signs of tamponade, as well as a left sided pleural effusion. Legionella infection complicated by acute pericarditis was diagnosed by urinary legionella antigen. The patient's clinical condition improved dramatically after treatment with levaquin and prednisone. Repeated Echocardiography showed decreased pericardial effusion to 2 cm following medical treatment for 2 days.
DISCUSSION: Although legionella infection usually presents with pulmonary manifestations, pericarditis or pericardial effusion might be the only presentation of legionella infection as in our case. Legionella pericarditis should be considered in the differential diagnosis of any pericarditis or pericardial effusion of uncertain origin. Urinary legionella antigen is a fast and an accurate test for legionella infection, with a high sensitivity and specificity. For our knowledge, no reported publications determined the amount of time the urinary legionella antigen needs to convert from positive to negative.

ISOLATED OSTIAL STENOSIS OF THE LEFT MAIN CORONARY ARTERY EIGHT YEARS AFTER RADIATION THERAPY Osama ALSARA; Heather Laird-Fick. Michigan State University, LANSING, MI. (Tracking ID #1642571)

LEARNING OBJECTIVE 1: Recognize the risk of coronary artery disease (CAD) with radiation therapy
LEARNING OBJECTIVE 2: Identify challenges in treatment of radiation-induced CAD, and the role of participatory decision making in management
CASE: A 60 year-old woman with a history of lung cancer currently in remission was admitted with complaints of chest pain. She has had recurrent substernal chest pain, increasing in severity, without radiation or associated symptoms during the preceding week. It usually occurs at rest and sometimes with exertion. Her pain was relieved with nitroglycerin administration. Past medical history was significant for hypertension, and stage IIIA non-small cell lung carcinoma diagnosed 8 years ago, treated with mass resection followed by chemotherapy and radiotherapy. A year later she developed a malignant pericardial effusion, treated with pericardial window, and recurrent pleural effusions, drained with pleural catheters. During the next 6 years, she was in full remission as confirmed by annual chest computed tomography (CT). Her medications included aspirin, metoprolol, iron, vitamin B12, and gefitinib. She was a nonsmoker but drinks socially. At presentation, her physical exam was benign. Cardiac biomarkers (creatine kinase, troponin) and fasting lipid panel were normal. The electrocardiogram (ECG) was also normal. Chest radiograph showed left perihilar parenchymal scars, surgical clips and postoperative changes in the chest. Other laboratory studies, including two more sets of cardiac biomarkers and fasting lipid panel were normal. She underwent an exercise nuclear stress test, which demonstrated indeterminate ECG changes with a small anteroseptal wall defect which appeared to be artifactual. Following the stress test, she developed chest pain. Repeat serum troponin level was elevated at 0.42 ug/L, and her ECG showed a new Q wave in lead III. Coronary angiography was performed and demonstrated 90 % stenosis of

the left main coronary artery ostium, without any evidence of atherosclerotic disease in other coronary arteries. Patient underwent surgical revascularization the next day. Intraoperatively she was noted to have dense adhesions surrounding the heart. She developed severe bleeding and died during surgery.
DISCUSSION: Thoracic irradiation can result in a number of cardiac complications including pericarditis, pericardial effusions, conduction disorders, pancarditis, functional valvular defects, and CAD. Histology of coronary artery tissues obtained from affected patients have demonstrated intimal thickening with minimal extracellular lipid deposits. Although ostial stenosis is typical of Radiation induced CAD, isolated ostial stenosis of the left main coronary artery following radiation therapy has been reported in only eight other cases in the literature. To our knowledge this is the first case to be reported of isolated left main CAD after radiation therapy for advanced non-small cell lung cancer. Treatment of Radiation induced CAD follows the same guidelines in management of other atherosclerotic CAD, but CABG may be more challenging due to pericardial thickening and retrosternal fibrosis. So, a multidisciplinary team approach and participatory decision making are important in such cases

ISOTRETINOIN RECHALLENGE IN A PATIENT WITH INFLAMMATORY BOWEL DISEASE Niket Sonpal; Anish Mammen; Raji Shameem; David Robbins. Lenox Hill Hospital, Hauppauge, NY. (Tracking ID #1624321)

LEARNING OBJECTIVE 1: Patients should be informed of the risk of developing inflammatory bowel disease and advised to stop the medication if abdominal symptoms occur.
LEARNING OBJECTIVE 2: Primary care physicians should be aware of this potential side effect and counsel their patients prior to the initiation of therapy.
CASE: Inflammatory bowel disease (IBD), Crohn's disease and ulcerative colitis, is a common condition affecting 70–150 cases per 100,000 individuals. It is usually diagnosed in young adults between the ages of 15 and 30 years but can present at any age. Acne vulgaris is a common skin condition affecting up to 80 % of adolescents. Isotretinoin is a medication commonly used for the treatment of acne with gastrointestinal side effects that includes colitis and ileitis. We present the convincing case of a patient who developed bloody diarrhea, fever and abdominal pain within several days after starting isotretinoin on two separate occasions. A 24-year-old male presented to our institution with bloody diarrhea, fever, and abdominal pain for the second time in approximately 18 months. The patient history was peculiar in that he had been diagnosed with ulcerative colitis a few weeks after starting isotretinoin 18 months ago. He reported no family history of IBD and no similar symptoms prior to starting isotretinoin. The medication was stopped at that time and his symptoms improved on mesalamine. However, his acne worsened so the decision was made between the patient and his dermatologist to restart the acne medication 18 months later under the close supervision of his gastroenterologist. Within 4 days of starting the acne medication for the second time, he redeveloped bloody diarrhea. The patient was passing up to 15 bloody bowel movements per day associated with moderate, crampy abdominal pain. His mesalamine was immediately increased and hydrocortisone enemas were prescribed without relief. A colonoscopy was performed that showed moderate proctosigmoiditis which did not respond to oral prednisone. His symptoms worsened with the addition of fevers so the patient was admitted. After several days of inpatient treatment with IV steroids, he improved and was discharged home and instructed to never take isotretinoin again.
DISCUSSION: Patients with pre-existing IBD should not ideally be prescribed isotretinoin. Retinoic acid affects intestinal epithelial growth, hinders cell repair and apoptosis. Retinoids also can decrease neutrophil chemotaxis. Patients should be informed of the risk of developing inflammatory bowel disease and advised to stop the medication if abdominal symptoms occur unless the acne is so severe, the risk is warranted. We now include regularly the history of acne and its treatment in all patients with IBD.

IT'S NOT REEFER MADNESS! Supreeti Behuria; Alfred Burger. Beth Israel Medical Center, New York, NY. (Tracking ID #1639680)

LEARNING OBJECTIVE 1: Distinguish between altered mental status caused by illicit drug use versus true organic causes
LEARNING OBJECTIVE 2: Understand the use of antiribosomal P protein antibody in the diagnosis of Lupus Cerebritis
CASE: A 25-year-old man, diagnosed with Systemic Lupus Erythematous (SLE) 6 months prior, and undergoing a workup for lupus nephritis, was brought to the emergency department by his family for weakness, and altered mental status, for 1 day. Per the family, the patient complained of generalized body weakness on the morning of admission. Subsequently, he stopped talking. Six days before admission he had a seizure and was started on Keppra. The family said the patient smoked marijuana daily but had no other toxic habits. On physical exam, he was afebrile, BP 189/96, HR 120, RR 18. He was awake and alert but did not respond verbally to questions or follow commands. He moved all his limbs spontaneously. He had an erythematous facial rash in the malar distribution with mild scaling. Labs showed WBC 1.5 K/UL, Platelets 109 K/UL, AST 374 U/L, ALT 231 U/L, Alkaline phosphatase 139 U/L. A CT scan of the head was negative for any infarction or intracranial hemorrhage. The patient was seen by his rheumatologist and serologies were sent. He was evaluated by neurology and had a MRI and EEG, which were negative for acute intracranial pathology or seizure-like activity. A presumptive diagnosis that the patient was experiencing the after effects of using marijuana laced with psychoactive chemicals was made, based on the negative data. On hospital day 3, the results of his rheumatological workup came back and he had an elevated antiribosomal P protein antibody of >8 AI (normal <1 AI). Based on this positive lab result, he was started on 1 g of Solumedrol IV daily for Lupus Cerebritis and after a 3 day course, his altered mental status and catatonia improved. He was discharged home soon after, doing well.
DISCUSSION: We present this case as an example of why we must avoid premature diagnostic closure in cases of altered mental status in the setting of illicit drug use, particularly if the patient concerned has a significant past medical history that could present with neuropsychiatric manifestations. In patients with SLE in the United States, nervous system involvement occurs 24–50 % of the time at some point during the course of their illness. Initially, our patient's symptoms were attributed to the use of marijuana, based on negative studies for alternative diagnoses with a normal MRI and EEG. For neuropsychiatric lupus, up to 67 % of patients will have abnormal MRI scans and EEG abnormalities are seen in 50–90 % of patients. However this leaves up to 33 % of affected patients with a negative MRI and between 10 % and 50 % with normal EEGs. Antiribosomal P protein antibody is a specific diagnostic test for Lupus Cerebritis, with specificity reported up to 80 % in some studies, and it is positive in 60 % of patients with the disease. Because the diagnosis of Lupus Cerebritis was thought about on admission, this test was sent and the result enabled the patient to be diagnosed and treated appropriately. Thus, it is important to distinguish between altered mental status caused by illicit drug use versus true organic causes in the setting of SLE. Physicians should be aware of vital diagnostic tools such as the antiribosomal P protein antibody that are available to aid in diagnosis.

JUST STICK TO BEER - A CASE OF METHANOL POISONING Anne Drabkin Schade; Abigail Gass. Medical University of South Carolina, Charleston, SC. (Tracking ID #1637135)

LEARNING OBJECTIVE 1: Diagnosing methanol toxicity
LEARNING OBJECTIVE 2: Learning how to treat methanol toxicity
CASE: Mr. S. is a 41 year-old African American male with history of schizophrenia, hypertension, diabetes and alcohol use who presented to the emergency department with confusion, agitation, blurry vision and respiratory distress. He had been off his psychiatric medication (Olanzapine) for many months prior to his admission and had been exhibiting violent behavior at home. The patient drinks 3–4 alcoholic beverages daily, smokes cigarettes and marijuana. On physical exam, the patient was hypertense (171/109 mmHg) and demonstrated disorganized

and bizarre behavior. A CT brain was within normal limits. His labs on admission showed a serum bicarbonate of 6 mmol/L, ABG was 7.24/10/134, anion gap was 24 and osmolar gap was 30. A volatile alcohol study revealed a serum methanol level of 87 mg/dl and the patient admitted to drinking windshield wiper fluid because he was unable to afford beer. No additional ingestions were seen, however his urinary drug screen was positive for cannabis. The patient was admitted to the Medical Intensive Care Unit and started immediately on fomepizole, a competitive alcohol dehydrogenase inhibitor and dialyzed for a goal methanol level <20 mg/dl and pH>7.25. For his schizophrenia, he was later started on Thorazine and transferred to the inpatient psychiatric unit.

DISCUSSION: Common causes of anion gap metabolic acidosis with an osmolar gap include methanol and ethylene glycol ingestion. Methanol ingestion is common in alcoholics as it tastes and smells more like alcohol compared to ethylene glycol, which is sweet and is practically odorless. Methanol can be found in antifreeze, windshield wiper fluid, glass cleaners, copy paints, varnishes and wood stains. Methanol breaks down via alcohol dehydrogenase to formic acid, which can cause retinal and optic-nerve toxicity, blindness and basal ganglia injury. Advanced stages of methanol toxicity can cause severe metabolic acidosis, multisystem organ failure and irreversible CNS damage. Using an alcohol dehydrogenase inhibitor such as ethanol and fomepizole allows methanol to be cleared in its nontoxic form via pulmonary and renal routes and delays its half-life. Fomepizole has fewer side effects (sedation, hypoglycemia) and a longer duration of action than ethanol. Alcohol dehydrogenase inhibitors can be used in conjunction with dialysis in the setting of methanol and elthylene glycol intoxication. Methanol toxicity has a high morbidity and mortality rate if treatment administration is delayed. In some patients with more mild intoxication, administering fompeizole can supplement the use of dialysis completely. Kruse, J. Crit Care Clin 28 (2012): 661–711 Brent, J. N Engl J Med 2009:;360: 2216–23

LACTIC ACIDOSIS DURING AN ASTHMA EXACERBATION Meghan M. Lyman. Emory, Atlanta, GA. (Tracking ID #1643065)

LEARNING OBJECTIVE 1: Identify less common causes of lactic acidosis in the setting of respiratory distress.

LEARNING OBJECTIVE 2: Recognize albuterol as a potention cause of metabolic acidosis.

CASE: 46 year old male with asthma sine he was a child and recent PFTs showing moderate obstructive defect (FEV1=55 %) presented to the ER with 2 days of worsening dyspnea and wheezing refractory to frequent inhaler use. On exam, he was tachycardic HR=130, Temp=98.8 F, BP=110/60, RR=24, pulse ox=94 % on 4 l nasal cannula. He had diffuse inspiratory and expiratory wheezing with limited air movement but no crackles. Electrolytes were normal except an anion gap of 17. Arterial blood gas on room air showed pH=7.2, pCo2=59 and pO2=47. Chest xray showed no acute process. He was treated in the ER for an asthma exacerbation with IV solumedrol, IV magnesium sulfate, and numerous albuterol nebulizer treatments. The patient was then initiated on Non-invasive Positive Pressure Ventilation (BIPAP). Repeat arterial blood gas showed that his pH had improved only minimally to 7.25 but he had significant improvement in hypercarbia and hypoxia (pCO2=44 and pO2=95). These results, including the elevated anion gap, indicated that there was an additional metabolic etiology for his acidosis separate from his respiratory issues. A serum lactic acid level was drawn and was elevated at 7.1. There was no evidence of hypoperfusion or organ ischemia at the time, therefore, his medications were reviewed to identify albuterol as a possible cause. Albuterol was withheld and he received further nebulizer therapy with only ipratropium and, after 2 h, his pH had improved to 7.36 with no associated change in pCO2 or pO2. Within 24 h, his serum lactic acid level normalized and his anion gap resolved. Even more concerning, his lactic acidosis may have worsened his respiratory status as he tried to compensate for the acidosis by further increasing his respiratory rate and increasing his risk of respiratory fatigue.

DISCUSSION: Serum Lactic acid levels are used as a marker in potentially life threatening conditions such as septic shock as well as being elevated in conditions related to metformin use, malignancy, and alcoholism. yet clinicians should be aware of other less common causes of lactic acidosis. Albuterol-induced lactic acidosis has been attributed to lactate production by overworked or inadequately oxygenated respiratory muscles and studies have shown that lactic acid levels increase within hours of inhaled beta-agonist therapy and often occur with higher doses of inhaled beta-agonists. This case illustrates the danger of using lactic acid as a diagnostic indicator of circulatory shock out of clinical context. Many patients present in respiratory distress when the etiology, infection vs reactive airway disease, is not straightforward. Lactic acid levels should be used in clinical context, along with other blood gas parameters that assess oxygenation and ventilation, to correctly determine the cause of the acidosis. Albuterol should always be considered as a possible etiology for acidosis in this setting and the medication can simply be withheld to help correct the acidosis and avoid further respiratory fatigue as the patient tries to compensate for the metabolic acidosis.

LEFT ATRIAL MYXOMA: A RARE CAUSE OF COMMON PRESENTATION Waleed Quwatli; Sarah Suliman; Joan Thomas; Deerajnath Lingutla. Unity health system, Rochester, NY. (Tracking ID #1642962)

LEARNING OBJECTIVE 1: Recognize uncommon cause of a common presentation of chest pain and shortness of breath—Left atrial myxoma

CASE: A 58 year old female with past medical history of hypertension, hyperlipidemia and meningioma who had normal coronary angiogram 2 years ago as a part of chest pain work up was presented to the emergency department with 2 weeks history of progressive dyspnea on exertion,diaphoresis and intermittent atypical left sided chest pain. On physical examination vital signs were normal. Positive findings on further systemic examination include fine bibasilar crackles on chest auscultation. Cardiovascular exam showed normal S1S2 with no murmurs or gallop, regular rhythm. Lab work up was normal except mildly elevated BNP of 163. Troponins were negative. EKG showed normal sinus rhythm withnon-specific ST-T changes in the anterior leads. Chest x-ray showed diffuse interstitial prominence suggestive of congestive heart failure. Because of the atypical features of chest pain she underwent CT angio of the chest, which was negative for pulmonary embolism, but it did show mass lesion within the left atrium measuring 4.8×3.2 cm suggestive of either a myxoma or thrombus. Subsequent echocardiogram showed normal left ventricular size with EF 55–60 %, large left atrial tissue density 5×3 cm most consistent with myxoma causing partial obstruction of the mitral flow. This mass was attached to intraatrial septum. It was mobile and crossing the mitral valve during diastole. Hence a diagnosis of left atrial myxoma was made and the case was referred to another hospital for surgical intervention. She underwent resection of the left atrium myxoma and left atrial wall with pericardial reconstruction. She recovered well from surgery with out any complications.

DISCUSSION: Cardiac myxomas are the most common primary cardiac neoplasm. More than 50 % of benign cardiac tumors are myxomas. 80 % of the myxomas originate in the left atrium and most of the remainder is found in the right atrium. Histologically, these tumors are composed of scattered cells within a mucopolysaccharide stroma. Myxomas produce vascular endothelial growth factor (VEGF), which probably contributes to the induction of angiogenesis and the early stages of tumor growth. Tumors vary widely in size, ranging from 1 to 15 cm in diameter. Symptoms range from non-specific and constitutional to sudden cardiac death. As per a published series 20 % are asymptomatic, cardiovascular symptoms are present in 67 % of the cases, mostly secondary to left sided heart failure or mitral valve damage, dizziness and syncope are present in 20 %, systemic embolization in 29 %, constitutional symptoms in 50 % which could be related to increased IL6 production, chest pain is infrequent and it could be due to coronary embolization. Once a presumptive diagnosis of myxoma has been made, prompt resection is required because of the risk of embolization or cardiovascular complications, including sudden death. The results of surgical resection are generally very good, with most series reporting an operative mortality rate under 5 %. Postoperative recovery is generally rapid. However, atrial arrhythmias or atrioventricular conduction abnormalities were present postoperatively in 26 % of patients in one series. Patients are at risk for recurrence of the myxoma suggesting the need for close follow-up. Development of a second primary myxoma may be more common in patients with a family history of myxoma.

LEGIONELLA PNEUMONIA COMPLICATED BY TRANSIENT LEFT VENTRICULAR DYSFUNCTION AND TORSADES DE POINTES Saqib Gowani1; Anupam Kumar[1]; Sabeena Arora[2]; Bimalin Lahiri[3]. [1]University Of Connecticut, Farmington, CT; [2]St. Francis Hospital, Hartford, CT; [3]St. Francis Hospital, Hartford, CT. (Tracking ID #1642293)

LEARNING OBJECTIVE 1: To consider legionella in the differential diagnosis when patients present with pneumonia with myocardial involvement
LEARNING OBJECTIVE 2: To consider torsades de pointes as a possible complication of legionella myocarditis
CASE: A 41 year old Caucasian male with no significant past medical history presented to the ED with 5 days of flu-like symptoms including non productive cough, fever and general malaise. On Examination, the patient was hypotensive with systolic in 80's, febrile and hypoxic on room air. Physical examination was significant for bronchial breath sounds in the right lower zone. Chest x-ray showed a right lower lobe pneumonia. ECG revealed sinus tachycardia with no ST-T segment changes. The patient was in septic shock and recieved fluid resuscitation without significant improvement. Cardiac enzymes at this time revealed CK of 2378 and troponin of 5.14. TTE demonstrated normal left ventricular cavity size and markedly reduced left ventricular ejection fraction of 10–20 % with global hypokinesia. The patient was treated with ceftriaxone and Azithromycin initially. All cultures were negative. The urine legionella antigen turned positive for L pneumophilia, serogroup1. During the ICU stay, the patient developed episodes of non-sustained torsades de pointes, culminating in an episode of sustained polymorphic ventricular tachycardia that deteriorated to ventricular fibrillation. The ECG obtained thereafter showed sinus bradycardia with marked QT prolongation, with a QTc of 607 ms.He was also started on isoproterenol and lidocaine for his arrythmia. His antibiotics were switched to doxycycline. The patient was extubated and continued to do well on doxycycline. A repeated echocardiographic evaluation 3 days later showed significantly improved left ventricular function with Ef of 50–55 %. His QTc at discharge was 520 ms and he was discharged on Magnesium Oxide.
DISCUSSION: Community acquired pneumonia diagnosed as legionellosis account for 12–15 % of cases in adults that require hospitalization. The most common extrapulmonary site is the heart, with numerous reports of myocarditis, pericarditis, postcardiotomy syndrome, and prosthetic-valve endocarditis. The prognosis of Legionella carditis seems to correlate with the severity of systemic involvement and patient comorbidities. Patients with extrapulmonary manifestation do well when the condition is recognized early and treated promptly with appropriate antibiotic agents. Few reports suggesting Legionella pneumonia predisposing to cardiac dysrhthmias have also been proposed. However, the patient responded well to the standard treatment protocol of torsades and no recurrences were observed once he started responding to the antibiotics. The Legionella urinary antigen is a rapid and inexpensive test that detects antigens of L. pneumophila serogroup 1 in urine. We strongly believe that Legionella should be considered in differential diagnosis and workup for patients who present with pneumonia and myocardial involvement. EKG changes and elevated troponin levels on presentation should affirm our clinical suspicion, especially if they have multiple risk factors for legionellosis. Early recognition is crucial to ensure full recovery from this form of reversible carditis, because the treatment is different from that for other forms of carditis and can be quite effective with early initiation of appropriate antibiotic medication.

LESSONS FROM THE HEART: THE ROLE OF ECHOCARDIOGRAPHY AND THROMBOLYSIS IN THE DIAGNOSIS AND TREATMENT OF PULMONARY EMBOLISM Mendel Goldfinger; Abigail Chua; Darlene LeFrancois. Montefiore Medical Center, Bronx, NY. (Tracking ID #1642528)

LEARNING OBJECTIVE 1: Recognize the role of echocardiography in diagnosis of pulmonary embolism
LEARNING OBJECTIVE 2: Identify utility of thrombolysis as treatment for atrial thrombi.
CASE: The patient is a 74 yo female, who presented with decreased exercise tolerance and new resting shortness of breath, cough, and pleuritic chest pain of 2 weeks duration. The patient, who had recent bilateral cataract surgery, also reported that she had been suffering from increased lower extremity swelling and orthopnea of 6 months duration. The patient had no personal or known familial history of coagulopathy. Vital signs were; BP 108/76, P 82, RR 20, 98 % on RA, cardiac exam was benign except for a laterally displaced PMI, lungs were clear to auscultation bilaterally. Her EKG and CXR were within normal limits, and her cardiac markers were negative. Her laboratory tests were significant for an elevated brain natriuretic peptide (BNP) 4935 and a D-Dimer of 11.70 ug/ml. CT angiogram revealed multiple bilateral extensive pulmonary emboli involving distal main pulmonary arteries, lobar pulmonary arteries and multiple segmental and subsegmental arteries. In light of her elevated BNP with no previous history of heart failure, the patient was sent for transthoracic echo which revealed multiple mobile masses with independent mobility in the right atrium, normal left ventricular wall motion and ejection fraction, moderate right ventricular hypokinesis, and moderate pulmonary hypertension. Patient was transferred to the intensive care unit and treated with tissue plasminogen activator for thrombolysis of clot, with immediate and complete resolution of symptoms. Repeat echocardiogram post thrombolysis revealed resolution of all cardiac masses.
DISCUSSION: Chest pain and dyspnea are common causes for hospital admission. Pulmonary embolism is part of the differential diagnosis for all patients with new or worsening dyspnea, chest pain, or sustained hypotension. Right atrial thrombi are a rare phenomenon. The incidence of right atrial thrombi in PE is approximately 7 %, and 18 % in those with massive pulmonary embolism. Mobile thrombi, which represent pulmonary emboli in transit, carry a risk of mortality of approximately 50 %. Multiple cases of successful IV fibrinolysis of right atrial thrombi without major complications have been documented, but fibrinolysis does pose a risk of sudden death. The management of patients with thrombi in transit includes therapeutic anticoagulation, thrombolysis, or surgical embolectomy. There is currently ongoing research assessing the utility and benefit of intravenous thrombolysis vs traditional anticoagulation in hemodynamically stable patients with right ventricular dysfunction, of which patients with thrombi in transit are a subset. Transthoracic echo is a non-invasive, portable, inexpensive and readily available diagnostic tool. Some registries have reported that only half the patients with new diagnosis of PE had echocardiography done. Although ECHO is mainly used in diagnosing PE in hemodynamically unstable patients, the case we present raises the question if it should be done in every patient with a new diagnosis of PE, as it has the potential to alter management and outcome. A prospective study is necessary to assess the optimal utility of ECHO for patients with PE who are hemodynamically stable.

LETHAL ACUTE LIVER FAILURE CASED BY MYSTERIOUS TUMOR Michinori Mayama. TOYOTA Memorial Hospital, Toyota, Japan. (Tracking ID #1639415)

LEARNING OBJECTIVE 1: Early identification of cause is indispensable in the treatment of acute liver failure
LEARNING OBJECTIVE 2: Malignancy infiltration should be considered as a cause of acute liver failure when other common causes are excluded
CASE: A 31-year-old man presented to the emergency department with nausea and vomiting. He was in his usual state of health until 1 month before admission when weakness and pain in both legs had started to develop. The weakness and the pain had worsened over time and 5 days before admission, he had difficulty walking. At this time, he had also noticed abdominal fullness. Through the course he had progressive fatigue and loss of appetite and he could not eat anything due to nausea and vomiting on the day of admission. His past medical history was unremarkable. He took Etodolac and Meloxicam for the bilateral legs pain. He smoked 10 cigarettes per day and drank alcohol occasionally. He was alert and oriented, but he looked pale. He was afebrile and his vital signs were within normal limits. The sclerae were icteric. Hepatosplenomegaly and non-tender mass in the right upper quadrant

were noted on abdominal examination. Complete blood count was significant for elevated white blood cell count of 16,900/mcL and low platelet count of 81,000/mcL. Other significant lab values were AST 6,336 IU/L, ALT 4,941 IU/L, LDH 4,546 IU/L, ALP 810 IU/L, total bilirubin 7.7 mg/dL, direct bilirubin 3.4 mg/dL, creatinine 2.0 mg/dL, and PT INR 8.73. Plain computed tomography showed moderate accumulation of ascites, hepatosplenomegaly, abdominal lymphadenopathy, and large solid tumors in the right kidney and in the pelvis. He was admitted to the hospital because of severe liver dysfunction and renal failure. Serologies for hepatitis A, B, and C, cytomegalovirus, Epstein-Barr virus, and HIV were all negative as well as autoantibody titers. Diffuse liver infiltration by malignant cells was suspected as the cause of acute liver failure since other common causes were excluded. Liver biopsy, however, could not be performed due to severe coagulation abnormalities. On day 3, his conscious level rapidly deteriorated to stage II hepatic encephalopathy and to stage IV the following day. On day 3, he met diagnostic criteria of acute liver failure, thus plasma exchange and continuous hemodiafiltration were conducted. On day 9, hemodialysis had to be discontinued due to hemodynamic instabilities. The patient died the following day. Permission for autopsy could not be obtained. Ascites, pleural effusion, percutaneous samples of the liver and the kidney were collected. Pathological examination revealed diffuse infiltration of atypical malignant lymphoma. It was positive for both T and B cell markers.

DISCUSSION: The rapid development of severe liver dysfunction and encephalopathy are characteristics of acute liver failure (ALF). Most cases are related to viral hepatitis and drugs such as acetaminophen. Infiltration by malignant cells is a rare cause of ALF and carries poor prognosis compared to other causes of ALF. ALF is usually an end-stage presentation of malignancy and the mortality rate is more than 80 %. Although liver transplantation may be considered as a treatment option for severe ALF, it is contraindicated in cases with ALF caused by malignant cell infiltration. Early diagnosis and appropriate chemotherapy is the sole way to improve such patients' outcomes. Malignancy infiltration should be considered as a cause of acute liver failure when common causes are excluded.

LEUKOCYTOCLASTIC VASCULITIS ASSOCIATED WITH COCAINE ABUSE WITH POSSIBLE LEVAMISOLE CONTAMINATION Christopher Sankey[1,3]; Lauren Wiznia[2]. [1]Yale School of Medicine, New Haven, CT; [2]Yale School of Medicine, New Haven, CT; [3]Yale-New Haven Hospital, New Haven, CT. (Tracking ID #1637289)

LEARNING OBJECTIVE 1: Recognize the entity of leukocytoclastic vasculitis associated with cocaine abuse and the possible contribution of levamisole

CASE: A 38-year-old woman with active polysubstance abuse presented with a chief complaint of diffuse joint pains of 4 days duration in the setting of a recent cocaine binge. She reported a rash over her elbows and on her lower back. She reported a fever at home to 102.9 °F, chills, rigors, nausea, and vomiting. She denied a family history of autoimmune or rheumatologic disease. Admission physical exam was most notable for 18–20 pink papules on her lower back ranging in size from 5 to 9 mm, some with pinpoint hemorrhagic crust. Similar papules were present over the bilateral extensor surfaces of her elbows. Exam of her extremities revealed tenosynovitis over elbows, hands, and wrists bilaterally. Laboratory studies were remarkable for an elevated CRP of 225. Urine toxicology was positive for cocaine, opiates, benzodiazepenes, oxycodone, and methadone. Serologic testing was negative for cryoglobulins and rheumatoid factor was <20. ANA screen was positive with a titer of 1:80 and homogenous pattern, but clinically she was felt unlikely to have a connective tissue disease. Multiple tests for various infections were negative, including gonorrhea, hepatitis B and C, HIV, EBV, and enterovirus. Skin biopsies from her left elbow and left thigh demonstrated leukocytoclastic vasculitis.

DISCUSSION: The medical complications related to cocaine use are known to most clinicians, and those associated with contaminants such as levamisole are being increasingly described. Levamisole is a veterinary antihelminthic agent with known immunomodulatory properties first reported as a contaminant in cocaine in 2001, with a steady increase in its use over time. Recent estimates of levamisole contamination of cocaine consumed in the United States is nearly 70 %. Its prevalence is likely a result of its amphetamine-like and hallucinogenic effects thought to increase those of cocaine. Cases of agranulocytosis and cutaneous vasculitis, among other toxicities, have been reported in association with levamisole. The above papular exanthem represents a presentation distinct from the purpuric retiform pattern with necrosis that has been classically associated with levamisole. Given the patient's presentation, recent history of a cocaine binge, unrevealing infectious work-up, and biopsy findings of leukocytoclastic vasculitis, we feel that her presentation was due to small vessel vasculitis secondary to cocaine, likely levamisole-contaminated. Unfortunately, testing to confirm the presence of levamisole in the urine was not available. Even in patients without the typical dermatologic presentation of vasculitis secondary to levamisole-contaminated cocaine, levamisole ought to be considered in the differential diagnosis for patients with a fitting history and presentation.

LEVITIRACETAM INDUCED PERICARDIAL EFFUSION, NOT YOUR COMMON CAUSE OF PERICARDIAL EFFUSION Madan R. Aryal; Madan Badal; Anthony Donato. The Reading Hospital and Medical Center, West Reading, PA. (Tracking ID #1619258)

LEARNING OBJECTIVE 1: Discuss the causes and work up of pericardial effusion

LEARNING OBJECTIVE 2: Recognize drug (levitiracetam) induced pericardial effuion in the absence of usual causes

CASE: 61 year old male with history of generalized seizure disorder started on levitiracetam 9 months prior to this admission presented to emergency department with increasing dyspnea and chest discomfort. His past medical history was negative for ischemic heart disease, cardiac trauma, recent surgeries and radiation treatment. His vital signs were normal. His cardiac auscultation revealed distant heart sounds, with S1, S2, and presence of S3 gallop. Compete blood count, Liver function test, renal function test, thyroid function test and cardiac enzymes were normal. Chest radiograph revealed cardiomegaly. Blood levitiracetam level was 48 mcg/mL (therapeutic range, 12 to 46 mcg/mL), and ECG demonstrated sinus tachycardia and low voltages. An echocardiogram done showed pericardial effusion without tamponade physiology. Therapeutic pericardiocentesis removed 500 mL of bloody fluid with pH 7.28; RBC count, 6,215 cells/mL; WBC count, 3,030 cells/mL (neutrophils 25 %, lymphocytes 72 %),with all bacterial, mycobacterial, viral, fungal, and cytologic studies indicated no evidence of infection or malignancy. Work up also included neagtive antinuclear antibodies, anti-double-stranded DNA, antihistone antibodies, anti-Smith autoantibody, RA factor, Anti CCP antibody, SSA and SSB and ANCA, as well as normal complement and PPD testing. Work up done to exclude other causes of pericardial effusions- viral (coxackie, echovirus, adenovirus, EBV, VZV, Influenza and HIV), lyme were all negative. Complement levels of C3, C4, CH50, and CEA level were all within normal limits. At this point, levetiracetam induced pericardial effusion was taken into consideration. He was switched to lamotrigene with no further episodes of pericardial effusion on follow up echocardiogram 3 months later.

DISCUSSION: Levitiracetam is commonly used drug for seizure; it can uncommonly cause pericardial effusion, with the reported incidence of 0.17 % in patients taking levitiracetam. Here we report a case of pericardial effusion due to levitiracetam. Although the development of cardiac tamponade is a rare complication of levitiracetam, it is reasonable to include this in the differential in the appropriate clinical setting and when other causes have been excluded. Its recognition and stopping the drug can be lifesaving in preventing future episodes.

LIFE THREATENING GASTROINTESTINAL BLEEDING IN AN AIDS PATIENT. DON'T FORGET ABOUT KAPOSI'S SARCOMA! Raji Shameem; Niket Sonpal; Pooja Kumar; Ladan Ahmadi. Lenox Hill Hospital, New York, NY. (Tracking ID #1624105)

LEARNING OBJECTIVE 1: Identify the causes of gastrointestinal bleeding in AIDS patients.

LEARNING OBJECTIVE 2: Recognize Kaposi's Sarcoma as a cause of severe gastrointestinal bleeding in AIDS patients.
CASE: A 38-year-old African American male presented to the hospital with a history of bright red bleeding per rectum. He was recently diagnosed with HIV 2 weeks prior for a hospital admission for Pneumocystis jiroveci pneumonia. HIV viral load was elevated at >200,000 and the CD4 count was 13. On admission the patient's hemoglobin was 6.2. Platelet count and coagulation tests were within normal limits. In the emergency department the patient was given 4 units of packed red blood cells and admitted to the hospital. Endoscopy and colonoscopy was performed. On colonoscopy, ulcerations were visible and biopsy of the ulcerations was positive for CMV. Subsequently, the patient was started on gancyclovir therapy. However, no active sites of bleeding were noted. Nuclear medicine imaging was negative. Mesenteric angiography revealed "blushes" in the small intestine. Due to persistent severe bleeding requiring multiple transfusions and hemodynamic instability the patient was taken for emergent exploratory laparotomy which revealed multiple reddish lesions along the wall of the small intestine with mesenteric lymphadenopathy. Ileal resection was performed. Biopsy results were consistent with Kaposi's sarcoma (KS). The patient was started on anti-retroviral therapy. After initiation of anti-retroviral therapy the patient did not have any further episodes of rectal bleeding.
DISCUSSION: Kaposi's Sarcoma is a vascular tumor caused by the human herpes virus type eight (HHV-8). One specific group of patients that are known to be susceptible to this tumor is AIDS patients. Skins lesions are the most common presentation of KS. However, there may be systemic manifestations involving the respiratory tract and the gastrointestinal tract as seen in this patient. Gastrointestinal involvement is not uncommon in Kaposi's. At times it can be the only presentation of the tumor as seen in this patient. However, it is uncommon for KS to present with such severe gastrointestinal bleeding. With endoscopy KS lesions are usually seen easily. In this case multiple imaging modalities failed to diagnose KS. Also with gastrointestinal involvement chemotherapy is usually added to the treatment regimen. In this case, the patient's symptoms improved solely with the initiation of anti-retroviral therapy.

LUCKILY IT IS NOT THE WORST CASE SCENARIO: DISSEMINATED HISTOPLASMOSIS PRESENTING AS A WASTING SYNDROME WITH HYPERCALCEMIA Monalee Patel-Chheda[1]; Miles Raizada[1]; Subhan Ahmed[2,1]; Ruba A. Halloush[3]; Faisal Khasawneh[1]. [1]Texas Tech University HSC-Amarillo, Amarillo, TX; [2]University of Oklahoma-Tulsa, Tulsa, OK; [3]Amarillo Pathology Group, Amarillo, TX. (Tracking ID #1628816)

LEARNING OBJECTIVE 1: Recognize that granulomatous diseases like sarcoidosis, tuberculosis, and disseminated fungal infections can cause severe hypercalcemia.
CASE: A 65 year-old diabetic male presented with 2-month history of constipation, polyuria and unintentional weight loss. On examination, he was cachectic without rash, lymphadenopathy or organomegaly. Labs showed hemoglobin of 10.6 g/dl, creatinine of 3.23 mg/dl and serum calcium of 12.4 mg/dl. Liver function tests, parathyroid hormone level and serum protein electrophoresis were within normal limits. Body computed tomography showed 3 brain lesions, bilateral adrenal enlargement and a lesion at the base of the tongue. Biopsies of the tongue lesion and the left adrenal gland were identical and showed non-caseating granulomas and budding yeast forms consistent with histoplasmosis. After intravenous fluid hydration and improvement in his renal function, he was started on a four-week course of liposomal amphotericin B followed by a long course of itraconazole with gradual improvement.
DISCUSSION: Histoplasmosis is the most common endemic mycosis in the country. Infection is acquired after inhaling H. capsulatum microconidia. Most infections are asymptomatic or manifest as a mild self-limiting flu-like illness. Symptomatic disease has multiple manifestations including a chronic progressive disseminated infection. In this entity, the patient is classically a middle-aged or elderly man without a known immunocompromising illness. It usually presents like a wasting syndrome suspicious for an underlying metastatic malignancy. Hypercalcemia is a very rare presentation of this infection and results from increased vitamin D production in the infectious granulomas. Diagnosis hinges on isolating the fungus on cultures, identifying its characteristic yeast forms on histopathological exam, detecting histoplasma antigen in urine or serum which carries a sensitivity of 90 % in disseminated infections or documenting a positive serology. The role of molecular methods in the diagnosis of histoplasmosis is still evolving. This infection is fatal if not treated. Cases that are mild to moderate in severity can be treated with itraconazole alone, whereas, more severe infections require an initial course of amphotericin B followed by a lengthy course of itraconazole. This case reminds Internists to consider disseminated granulomatous diseases including histoplasmosis in the differential of patients with hypercalcemia.

LUNG MASS AND PLEURAL EFFUSION - PLANNING FOR A BIOPSY? LET US TEST THE URINE BEFORE THAT! Sathish kumar Krishnan; Malav Parikh; Venu K. Ganipisetti. St. Francis Hospital, Evanston, IL. (Tracking ID #1642087)

LEARNING OBJECTIVE 1: Recognize that urine antigen testing has high sensitivity and acceptable specificity to diagnose blastomycosis.
LEARNING OBJECTIVE 2: Recognize that blastomycosis can present with large pleural effusion.
CASE: A 30 years old female presented with non-productive cough, shortness of breath on exertion, left-sided pleuritic chest pain, and an episode of hemoptysis progressively worsening for 14 days. About 10 days prior to admission, she presented to the ER with fever, non-productive cough and left-sided pleuritic chest pain. Her chest X-ray then, showed a rounded opacity in the left parahilar region and a small left pleural effusion. A CT of chest then, showed a 5.4×3.3 cm pleural-based consolidation or mass along the anterior aspect of the left upper lobe at the level of the left hilum and scattered smaller nodular opacities in the left upper lobe. She was discharged with levofloxacin, but she did not improve. Her past medical history included asthma. She emigrated from Guyana 15 years back. She had never smoked. She was a nurse. She had no family history of cancer, connective tissue disease or immunologic disease. Her vitals were stable. Her physical exam revealed decreased breath sounds in the left middle and lower lung fields. Her CXR showed a large left side pleural effusion. Thoracentesis yielded 1500 ml of clear yellow fluid. Pleural fluid analysis: LDH-127 IU/L, Glucose-103 mg/dL, protein-5.3 g/dL and WBCs-100 cu mm. Pleural fluid analysis was consistent with an exudate. Quantiferon TB gold, urine legionella and streptococcus antigens were negative. Blood culture, pleural fluid gram stain, AFB stain, KOH preparation and culture were negative. A CT-guided biopsy of the lung mass was contemplated. But, before obtaining the biopsy, urine was tested for blastomyces antigen and it was positive. The patient was treated with itraconazole. She improved clinically and a follow-up CXR in 6 weeks showed complete resolution of the mass.
DISCUSSION: Blastomycosis is a systemic pyogranulomatous infection that arises after inhalation of the conidia of the fungus, Blastomyces dermatitidis. Although it can involve any organ, lung is the most common site of infection. Pulmonary blastomycosis can cause alveolar infiltrates, fibronodular opacities and mass lesions. Although small pleural effusions are frequent, large pleural effusions are uncommon. Our patient is unique that she had a large pleural effusion. Due to the variability of the presentation and its rarity, it is important to maintain a high index of suspicion in patients with non-resolving pneumonia. Definitive diagnosis requires growth of the organism from a clinical specimen, but urine antigen detection has a sensitivity of 90 % and a specificity of 80 % and has proven useful. Urine antigen levels can be used to monitor the response to treatment. Urine antigen detection should be done before biopsy in all suspected cases, as it can preclude the need for biopsy and therefore the risk of complication, discomfort and expense associated with an invasive investigation.

LYMPHOMA PRESENTING AS COLD AGGLUTININ DISEASE Archana Satyal Chaudhary; Richard Alweis. The Reading Hospital and Medical Center, West Reading, PA. (Tracking ID #1642344)

LEARNING OBJECTIVE 1: Cold agglutinin disease (CAD) is an uncommon form of autoimmune hemolytic anemia (AIHA) accounting for

less than 15 % of AIHA. It is caused by destruction of erythrocytes by IgM autoantibodies that are directed against membrane antigens of the patients' red blood cells (RBC) and exhibit maximal reactivity at 4 °C. CAD can be idiopathic or secondary to some viral or mycoplasma infection. More commonly it is associated with lymphoproliferative malignancy.
CASE: A 85-year-old lady on chronic warfarin therapy for atrial fibrillation presented with chronic fatigue and few days of melena. She appeared pale and weak. She had few prominent firm left inguinal lymph nodes measuring 4 cm without hepatosplenomegaly. Her hemoglobin was 7.5 g/dl, lower than her baseline of 9 g/dl with normal leukocyte and platelet counts. She had hemolytic anemia with elevated reticulocytes, lactate dehydrogenase and bilirubin with undetectable haptoglobin. Peripheral blood smear revealed RBC clumps. Direct antibody test (Coombs) was positive. Blood bank had difficulty cross-matching blood due to the presence of a very strong cold agglutinin. Flow cytometry of the peripheral blood did not reveal any phenotypically abnormal cells. Her medical course was complicated by an acute arterial thrombus in the right lower extremity and was emergently taken for revascularization. An intraoperative excisional biopsy of the left groin lymph node confirmed diagnosis of an aggressive type of diffuse large B cell lymphoma. She later succumbed to the complications of acute ischemic limb.
DISCUSSION: Literature review suggests 76 % of patients with chronic CAD to have underlying lymphoma with most cases being lymphoplasmacytic lymphoma, marginal zone lymphoma and small lymphocytic lymphoma/chronic lymphocytic leukemia. It is also less commonly associated with diffuse large B cell lymphoma and suggests extra nodal disease. Hence one should strongly consider the possibility of lymphoproliferative malignancy in the presence of cold agglutinin disease and initiate appropriate work-up.

LYMPHOMA PRESENTING AS ABDOMINAL ACCESS Abhishek Singla[1,2]; Jayanth Adusumalli[1,2]; Mahmoud A. Abu Hazeem[1,2]; Nithan C. Birch[2]. [1]Creighton University Medical Center, Omaha, NE; [2]Veterans affair, Omaha, NE. (Tracking ID #1642463)

LEARNING OBJECTIVE 1: To recognize that lymphomas can present as abscess if they undergo necrosis.
LEARNING OBJECTIVE 2: To recognize that some aggressive B-cell lymphomas called "Grey Zone Lymphomas" can have features overlapping between two different types of lymphomas.
CASE: A 68 year old Caucasian male with past medical history of hypertension, paroxysmal atrial fibrillation, diabetes mellitus type 2; presented with a month history of fatigue, left upper quadrant pain, early satiety and weight loss. He reported no nausea or vomiting. Physical examination revealed tenderness in left upper quadrant and was limited by obesity. Admission labs were significant for a normocytic anemia with hemoglobin of 8.0 mg/dl. A comprehensive metabolic panel was normal. Computed tomography (CT) scan images demonstrated a large left upper quadrant abdominal mass, a 3 cm hepatic hypodense lesion in liver and diffuse abdominal lymphadenopathy. Percutanous needle Biopsy of the mass resulted in necrotic debris, which failed to demonostrate growth on bacterial, mycobecterial and fungal cultures. A biopsy of liver nodule and groin lymph node were significant for a clonal expansion of B cell lymphocytes which on immunohistochemistry stained positive for BCL2, BCL6, Mum-1, and Ki67 (100 %), which is consistent with "grey zone" lymphoma. This type of lymphoma had features that overlap between those of a diffuse large B cell and a Burkitts lymphoma. Positron Emission Tomography (PET scan) showed widely metastatic disease and bone marrow was normal. A complete remission was achieved after 8 cycles of chemotherapy with rituximab, etoposide, vincristine, doxorubicin, cyclophosphamide, and prednisone (R-EPOCH).
DISCUSSION: Rapidly proliferating lymphomas can undergo spontaneous coagulative necrosis, thereby mimicking an abscess. The diagnosis is best made based by morphology and immunophenotyping on excisional tissue biopsy, most commonly a lymph node. Some B-cell lymphoma, can have features intermediate between DLBCL and Burkitt's lymphoma lymphomas and currently designated as "Gray Zone Lymphoma"

MAGIC SYNDROME WITH VISION THREATENING KERATITIS Anil Kumar Reddy Anumandla; Lingling Du; Gaurav Kistangari. Clevaland Clinic, Cleveland, OH. (Tracking ID #1642646)

LEARNING OBJECTIVE 1: Recognize clinical features of MAGIC syndrome, an overlap of relapsing polychondritis and behcet's disease.
LEARNING OBJECTIVE 2: Manage ocular complications in MAGIC syndrome.
CASE: A 24-year-old Caucasian male presented to our hospital with ulcerative skin lesions and scleritis. He had a complex history of relapsing polychondritis diagnosed 3 years earlier, treated with various immunosuppressive regimens, well controlled for the past year with azathioprine 175 mg and prednisone 2.5 mg daily. One month prior to his current admission he developed a flare of left eye scleritis and several mucocutaneous lesions. At that time he was admitted to an outside hospital and was treated with intravenous steroids and methotrexate. During the hospital course his skin lesions worsened particularly in the areas of i.v. access sites, suggestive of pathergy. Endoscopy revealed ulcers over the left tonsil and tonsillar wall. After failure to respond, he was transferred to our hospital for further management. Upon arrival to our hospital his vital signs were: temp 36.3, BP 136/81, HR 68/min, RR 18/min. Physical examination was significant for L eye conjuctival injection and multiple diffuse ulcerated lesions over upper extremities, chest, back, buttocks and thighs. WBC was 26,000, and CRP and ESR were elevated at 13.2 and 52 respectively. Ophthalmologic evaluation revealed severe nodular scleritis and peripheral ulcerative keratitis of the left eye. Investigation for bacterial, viral, and fungal cultures was negative. Given the compelling clinical picture for new-onset of Behcet's disease, he was treated with 3 days of methylprednisolone 1 g per day with improvement of his skin lesions. After completing the pulse-dose steroids, however, he again had rapid deterioration of his keratitis with a worsening epithelial defect with a concern of corneal melt. Given the vision-threatening nature of the keratitis, the patient was started on cyclophosphamide 150 mg daily, with subsequent fluctuation in his ocular status. He proved to be sensitive not only to the dosage of steroids but also to the frequency of administration. Inflammation of the sclera and cornea finally responded to prednisone 40 mg TID and cyclophosphamide 175 mg daily. His skin lesions healed well without development of any new lesions or pathergy to phlebotomy.
DISCUSSION: MAGIC (mouth and genital ulcers with inflamed cartilage) syndrome is a rare rheumatic disease that features the concurrence of relapsing polychondritis and Behcet's disease first described by Firestein et al. in 1985, with a total of 22 cases in the world literature. We describe a patient with MAGIC syndrome and severe vision-threatening peripheral ulcerative keratitis refractory to methotrexate and azathioprine, ultimately improving with cyclophosphamide and high dose steroids. The presence of ulcerative keratitis and skin lesions in cases of relapsing polychondritis should prompt consideration of a diagnosis of MAGIC syndrome. Institution of high dose steroids in conjunction with cyclophosphamide is an effective treatment approach.

MALINGERING WITH A SECRET HELD CLOSE TO THE HEART Matthew N. Peters; Morgan J. Katz; Chad S. Miller. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1641451)

LEARNING OBJECTIVE 1: Recognize human-anti-mouse antibodies as a cause of falsely elevated troponin.
LEARNING OBJECTIVE 2: Identify medications that can create human-anti-mouse antibodies. Learn techniques to assess elevated troponin values in the presence of human-anti-mouse antibodies.
CASE: A 58 year-old man with a self-described history of coronary artery disease presented with 10/10, crushing, substernal chest pain. Initial ECG was normal and showed normal sinus rhythm at 72 beats/min. Troponin I (TnI) was found to be elevated at 27.8 g/dL. He underwent immediate coronary arteriography, which revealed only mild luminal irregularities in the left anterior descending and right coronary arteries. After the procedure, he continued to complain of chest pain and subsequent TnI measurements remained >20 g/dL. Upon further questioning, the patient stated he had been looking for a place to live for the past 2 years but had been limited by

his recurrent chest pain and multiple hospitalizations. Outside hospital records were obtained, which revealed similar coronary artery and TnI findings. A previous discharge summary revealed a remote history of Non-Hodgkins Lymphoma (NHL) which had been treated with rituximab. The discharge summary also stated that they believed that he was aware of having an "abnormal lab value that was associated with chest pain" and was malingering. Due to the potential of persistent human anti-mouse antibodies (HAMA) produced by rituximab, the TnI assay was repeated using a heterophilic antibody blocking reagent and revealed a TnI of 0.38 g/dL. The patient was informed of the results and became extremely agitated and combative before leaving against medical advice. The patient has not returned to our facility since.

DISCUSSION: In the evaluation of acute coronary syndrome, TnI has emerged as the gold standard. While elevated TnI suggests the presence of myocardial ischemia, TnI elevation can also be produced by conditions causing an increase in myocardial oxygen demand, such as severe hypertension, sepsis or a tachyarrhythmia. Other common causes include renal failure (due to decreased renal clearance) and skeletal muscle injury. A less familiar cause of falsely elevated TnI is human-anti-mouse antibody (HAMA), an immunoglobulin G (IgG), which has the ability to recognize epitopes on the Fc portion of a foreign immunoglobulin. Consequently, HAMAs can mimic circulating cardiac troponin by cross-linking detection antibodies in the troponin immunoassay and produce a falsely elevated TnI as high as 100 g/dL, which can persist for as long as 10 years following exposure. Chimeric (part mouse, part human) antibodies commonly used in clinical practice include infliximab (rheumatoid arthritis, Crohn's disease), basiliximab (renal transplant rejection prevention), rituximab (NHL) and abciximab (coagulation prevention in percutaneous coronary intervention). If HAMAs are suspected as a cause for a falsely elevated TnI, the test can be repeated using a different assay,for example, using a heterophilic antibody blocking reagent or using serial dilutions of the specimen, from which the decrease of TnI will be out of proportion to the dilution. The general internist should be alerted to medications that may cause false elevations in TnI secondary to HAMAs and understand the importance of obtaining old hospital records whenever possible.

MRI TERMINATION: THE DANGER OF DEVICE RETENTION DURING CAPSULE ENDOSCOPY Bradley Anderson; Jackson Liang; Ramona S. DeJesus. Mayo Clinic, Rochester, MN. (Tracking ID #1628068)

LEARNING OBJECTIVE 1: Recognize device retention as a potential complication during capsule endoscopy and identify common predisposing factors.

LEARNING OBJECTIVE 2: Recognize the contraindication of magnetic resonance imaging (MRI) in the setting of retained capsule endoscopy devices.

CASE: A 55 year old gentleman with a past medical history significant for primary progressive multiple sclerosis and chronic anticoagulation for a history of pulmonary embolism was hospitalized for neurologic and infectious work-up after presenting with a two-day history of hallucinations and productive cough. Following 6 days of hospitalization, the patient experienced the onset of dark stools which was accompanied by an acute drop in hemoglobin (from 9.0 to 7.4 g/dL) and positive HemoQuant (>15.6 Hb/g). The patient was subsequently transfused with one unit of packed red blood cells and an EGD was performed under sedation which detailed a normal-appearing stomach, esophagus, and duodenum without an identifiable source of bleed. CT enterography was subsequently performed which noted three subcentimeter enhancing ileal lesions which were radiographically suspicious for carcinoid. Following these findings, a colonoscopy was completed which visualized no bleeding source up to 15 cm from the ileocecal valve. To further examine the ileum for the lesions noted on CT enterography, capsule endoscopy was pursued. Three days after swallowing the capsule, the patient reported that despite passing several stools, he had not passed the capsule. An anteroposterior abdominal radiograph was completed which described a retained capsule adjacent to the proximal descending and distal transverse colon, likely contained within a colonic diverticulum. The following day, the patient developed acute right-sided lumbar radiculopathy associated with severe pain. An emergent MRI lumbar spine was performed. During performance of the MRI localizing sequence, a focal susceptibility effect was noted in the region of the pelvis. A prompt investigation was completed by the radiology staff who discovered the prior report of a retained capsule enteroscopy device. The procedure was immediately terminated without harm to the patient. A patient care assistant noted passage of the capsule two days later.

DISCUSSION: Device retention is a complication unique to capsule endoscopy. Recent studies have reported the rate of retention to be between 1.0 % and 1.7 % of patients undergoing the diagnostic procedure. Common factors which predispose individuals to device retention include Crohn's disease, neoplastic lesions, NSAID-induced enteropathy, stenosis, and adhesions. We were unable to identify a prior case report that described patient injury in the setting of retained capsules during MRI, but retained devices are considered a danger and contraindication to MRI. While this case represents a near-miss of such an event, it highlights the need for enhanced provider awareness as well as institutional safeguards against ordering MRI studies prior to the confirmed passage of an endoscopic capsule. Confirmation of device passage is quickly achieved through abdominal radiographic imaging and should be employed in circumstances where suspicion remains for retention. While emergency situations can be challenging, adequate history taking as well as education regarding this contraindication can prevent the occurrence of future events.

MAKE NO BONES ABOUT IT Hawkins Gay; Jason Higdon. Emory University School of Medicine, Atlanta, GA. (Tracking ID #1624595)

LEARNING OBJECTIVE 1: Recognize the features of hypercalcemia.

LEARNING OBJECTIVE 2: Identify the etiology of symptomatic hypercalcemia using a step-wise approach.

CASE: A 63-year-old African American man with no past medical history presented to the emergency department complaining of generalized weakness and back pain. Over the past month he had become so weak that he needed to use a walker to perform his activities of daily living. On the morning of presentation he was unable to rise from a seated position without assistance. He also described low back pain that radiated into his right leg, was worse while standing or walking, and was a 7/10 in intensity. Additional complaints included decreased appetite, constipation, nausea, increased urination and thirst, and 30 lb weight loss over this same time period. He denied any fevers, chills, diarrhea, shortness of breath, or night sweats. Physical exam was significant for bi-temporal wasting, dry mucous membranes, and a distended, tender abdomen, but was otherwise within normal limits. Initial laboratory analysis revealed a BUN of 31 mg/dl, creatinine of 1.6 mg/dl, calcium of 13.9 mg/dl, albumin of 4.4 g/dl, total protein of 13.3 g/dl, alkaline phosphatase of 82 u/l, and hemoglobin of 13.0 g/dl. Urinalysis revealed 1+ protein. An x-ray of the lumbosacral spine showed a compression abnormality of the L5 vertebra and an irregularity of the right pedicle concerning for a lytic process. Secondary labs revealed a serum ionized calcium of 13.9 g/dl, low parathyroid hormone (PTH) of 16.1 pg/ml and phosphorus of 3.3 mg/dl. A serum protein electrophoresis (SPEP) showed atypical bands in the gamma zone and immunofixation indicated monoclonal IgG. A presumptive diagnosis of multiple myeloma (MM) was made, at which time the patient was placed on normal saline and pamidronate for management of hypercalcemia. The diagnosis of MM was later confirmed by bone marrow biopsy.

DISCUSSION: Symptomatic hypercalcemia is commonly encountered and should be considered in any elderly patient presenting with symptoms of constipation, nausea, vomiting, lethargy, flank pain (kidney stones), polyuria and polydipsia, or altered mental status. The two most common causes are primary hyperparathyroidism and hypercalcemia of malignancy. The first step in approaching hypercalcemia is to confirm a truly elevated level. Roughly 45 % of calcium is bound to albumin so a rise in the serum albumin can lead to pseudohypercalcemia. Correct levels are confirmed by ordering serum ionized calcium. When elevated, the initial workup should focus on differentiating between hyperparathyroidism and malignancy. History and physical exam can determine if there are any symptoms or

findings that may be due to an underlying malignancy. Initial laboratory testing should begin with a PTH level. Normal to elevated levels would indicate primary hyperparathyroidism. If PTH levels are low (<20 pg/ml), a parathyroid hormone related peptide (PTHrP), SPEP and urine protein electrophoresis (UPEP), and/or calcitriol levels should be ordered based on clinical judgment. Therapy for mild hypercalcemia consists primarily of IV normal saline. In more severe cases or those caused by malignancy, intravenous bisphosphonates can be used to inhibit bone resorption. These may require 2-4 days before showing an effect. When more immediate treatment is needed, calcitonin may be effective in as little as 12 h.

MAKING A LIST AND CHECKING IT TWICE: THE IMPORTANCE OF ACCURATE MEDICATION RECONCILIATION IN ESTABLISHING A LIFE-THREATENING DIAGNOSIS. Thomas Radomski; Harish Jasti. University of Pittsburgh, Pittsburgh, PA. (Tracking ID #1639658)

LEARNING OBJECTIVE 1: Identify the presentation of statin-induced rhabdomyolysis.
LEARNING OBJECTIVE 2: Illustrate the importance of accurate medication reconciliation.
CASE: A 64 year-old man with a history of coronary artery disease and myocardial infarction, diabetes mellitus II, and hypothyroidism presented from an outside hospital complaining of progressive bilateral upper and lower extremity weakness. By the day of presentation, he had increasing trouble combing his hair and arising from a chair. He denied any muscle pain or stiffness, nor did he report any focal weakness, numbness or paresthesias. He did endorse chronic neck pain. The patient was unsure of his medications, and a medication list upon transfer listed aspirin, carvedilol, insulin glargine and aspart, lisinopril, metformin, and levothyroxine. The physical exam revealed a middle-aged appearing man in no distress. He was afebrile with stable vital signs. He had 4/5 strength on abduction of his upper extremities with 5/5 strength throughout the remainder of his arms. Muscle bulk was decreased bilaterally in his proximal lower extremities. Hip flexion was 3/5 bilaterally, with 4/5 strength throughout the remainder of his lower extremities. His neurologic exam was otherwise intact. He denied any tenderness to palpation throughout his muscles. Cardiac, pulmonary, and abdominal exams were otherwise unremarkable. Lab work on admission revealed a CPK of 4917 IU/L with an ESR of 52 mm/hr. Urinalysis showed 1+ blood with 1 RBC. TSH was normal and a hemoglobin A1C was 11.8 %. The patient's CPK continued to rise, peaking at 132,587 IU/L on hospital day 5. His serum creatinine rose as well, peaking at 5.8 mg/dL on hospital day 8. ANA, rheumatoid factor, and a comprehensive myositis antibody panel were negative. An EMG was performed, suggesting a toxic versus statin-induced myopathy. A muscle biopsy of the right deltoid muscle showed necrotic myofibers, major histocompatibility complex 1 up-regulation, and membrane attack complex deposition in the capillaries. All of these findings were suggestive of an autoimmune statin-induced rhabdomyolysis. Upon further review, the patient recalled he may have been on a "medication for his cholesterol." Subsequent discussion with his pharmacist revealed that he had been taking simvastatin 80 mg daily.
DISCUSSION: Statin-induced rhabdomyolysis is a relatively rare but serious complication of statin use, characterized by muscle weakness, a CPK 10 times the upper limit of normal, myopathic EMG findings, and muscle necrosis on biopsy. While 2–11 % of patients on statins may experience myalgias, only 0.5 % develop myositis or rhabdomyolysis. Multiple mechanisms of insult have been described, including increased myocyte membrane excitability, impairment of mitochondrial function and CoQ10 depletion, impaired calcium homeostasis, and induction of apoptosis. Another mechanism, whereby statins cause a necrotizing myopathy via autoantibodies directed against HMG-CoA reductase, has more recently been characterized. This was felt to be the cause in this patient given his biopsy findings. This case also illustrates the importance of a thorough medication reconciliation process, as the patient was unaware of his medications. His use of simvastatin was overlooked on multiple instances. This had major implications on arriving at an accurate diagnosis and counseling the patient to discontinue his simvastatin upon discharge.

MALIGNANT EPITHELIOID SOLITARY FIBROUS TUMOR OF THE LUNG PLEURA (SFTP) - A CASE REPORT Dania Khoulani; Zahrae Sandouk; Krishna Thavarajah. Henry Ford Health System, Detroit, MI. (Tracking ID #1625948)

LEARNING OBJECTIVE 1: Malignant SFTP are rare, with subtle presentations.
LEARNING OBJECTIVE 2: Natural history and management of malignant SFTP.
CASE: 74 yo healthy female with HTN and no history of substance use saw her PCP for left chest discomfort initially attributed to early shingles. She had work-related asbestos exposure. After 3 weeks, her discomfort had spread to her left arm without a rash. Chest X ray showed a large left upper lung mass. Further workup including percutaneous biopsies showed epithelioid variant malignant SFTP staining positive for CD34 and negative for all other biomarkers. After seeing oncology and surgery, her tumor was deemed inoperable as it was extensive and encasing major blood vessels. She underwent radiation therapy (RT) with persistently enlarging tumor, reaching the size of 12.5×10×8.5 cm. It extended towards the right, compressing her trachea and esophagus, causing worsening stridor and dysphagia. She had a tracheal stent placed. EGD revealed mechanical compression, a narrowing 2/3 the way down her esophagus with distal radiation esophagitis and a tracheo-esophageal fistula. She also developed extensive bilateral upper extremity DVT due to compression of the major thoracic veins by the tumor, treated with Lovenox. She was readmitted within a week for worsening shortness of breath and repeat CT thorax showed her tumor to be 12×9.3×9 cm. Repeat bronchoscopy revealed impinging tumor with left stent compression and a mucous mass. She was enrolled in hospice due to quickly progressing symptoms with unsuccessful RT.
DISCUSSION: SFTP is a rare mesenchymal overgrowth which was historically thought to be a form of mesothelioma. It's not related to asbestos exposure. SFTP is typically benign and surgical removal is curative; however, it is malignant in 12 % of cases. It affects both females and males in their 6th and 7th decade. Clinical presentation is typically associated with large tumor size and includes chest pain, cough or dyspnea. Patients may also develop paraneoplastic syndromes, mostly with hypoglycemia due to IGF-II production (11 % of malignant tumors, 3 % of benign tumors) and hypertrophic pulmonary osteoarthropathy due to hyaluronic acid production (20 % of tumors). Thoracic imaging typically reveals a homogenous large intrathoracic tumor, but when intra-tumor necrosis or hemorrhage is present, it appears heterogenous. Pathology reveals uniform elongated spindle cells, fibroblasts and connective tissue arranged in a pattern-less or storiform manner. Unlike mesothelioma which stains negative for CD34, vimentin, CD99 and BCL-2, SFTP stain positive for these biomarkers. SFTP staging is as follows: stage 0–1 are benign with 0 being pedunculated and 1 being sessile/inverted; stage 2–4 are malignant, with 2 being pedunculated, 3 being sessile/inverted and 4 being multiple synchronous metastatic. Complete surgical resection with large >1–2 cm tumor-free margins is the most important prognostic indicator of malignant SFTP. Even with complete surgical resection, recurrence rate can be high; however, metastatic disease typically occurs very late in the disease course. Adjuvant and neoadjuvant chemotherapy has not been effectively studied due to the rarity of the disease. There have been cases reported with postoperative RT success in possibly preventing the development of tumor recurrence, but preoperative RT has not been assessed. In our patient, it was found that preoperative RT did not help debulk a large malignant tumor in order to allow for surgical resection.

MALIGNANT TRANSFORMATION OF INTRAPULMONARY SCHWANNOMA INTO CARCINOSARCOMA IN NEUROFIBROMATOSIS-1: A CASE REPORT Sagar Mallikethi Lepakshi Reddy; Ekta Lakhani; Arshad Javed; Satish J. Bankuru; Diane L. Levine. Wayne State University/DMC, Detroit, MI. (Tracking ID #1622162)

LEARNING OBJECTIVE 1: Recognize a rare case of malignant transformation of lung schwannoma in a patient with NF-1
LEARNING OBJECTIVE 2: Recognize the possible need for screening guidelines for neoplasms in adult NF-1 patients

CASE: A 37 year-old male patient with NF-1 was found to have an incidental mass in right lung on chest X-ray. Subsequent CT-Thorax showed 6.5×5.5×3.5 cm rounded mass in right upper lung fields. A diagnosis of benign intrapulmonary schwannoma was made based on CT guided biopsy showed characteristic spindle cells, positive S-100 stain and low Ki-67 staining. Patient remained asymptomatic and was lost to follow-up. He was admitted this time 4 years after initial presentation due to worsening dyspnea, anorexia and unintentional weight loss of 20 lb over 8 weeks duration. CT-Thorax showed 12×11×7 cm mass with scattered areas of central necrosis in right upper lung and large right pleural effusion. Thoracentesis revealed hemorrhagic effusion with negative cytology. VATS-assisted biopsy of the mass was pursued. Immunohistochemical staining was positive for carcinoma markers such as CAM 5.2, AE1/AE3, CK7, and sarcoma markers such as vimentin, CD99 and actin. Nuclear atypia, high mitotic index and characteristic staining pattern, was diagnostic of lung carcinosarcoma. Patient had stage IV lung cancer and was deemed a poor surgical candidate. Currently, palliative radiotherapy is being pursued on this patient. We hypothesize that benign intrapulmonary schwannoma transformed into malignant carcinosarcoma of lung, which unfortunately carries a dismal prognosis.

DISCUSSION: Neurofibromatosis-1 (NF-1) is an inherited autosomal dominant neurocutaneous disorder with a prevalence of 1 in 2000–5000 people. As compared to general population, NF-1 patients are at 2.5 to 4-fourfold higher risk for various types of benign and malignant neoplasms. Common neoplasms in this patient population are benign neurofibromas, gliomas, malignant peripheral nerve sheath tumors, benign or malignant schwannoma, neurofibrosarcoma, rhabdomyosarcoma, pheochromocytoma, juvenile myelomonocytic leukemia, gastrointestinal stromal tumors. However, primary pulmonary malignancies have been reported rarely in these patients. Intrapulmonary schwannomas are rare and constitutes 0.2 % of all lung cancers. Malignant transformation of schwannoma is highly uncommon. Recently, a case of carcinosarcoma (a rare type of non-small cell lung cancer) was reported in NF-1. The report represents a rare case of intrapulmonary schwannoma that underwent malignant transformation into carcinosarcoma of lung in NF-1 patient. Lifetime risk of neoplasms associated with NF-1 has been reported to be 20 % by age 50. Malignancies are a major cause of morbidity, mortality in these patients. Screening guidelines are relatively well established in pediatric NF-1 population. Despite the increasing reports of various tumors and high lifetime risk for cancers, there are no established screening guidelines in adult patient population. If further studies support high lifetime risk of neoplasms, screening in such high-risk population may significantly decrease morbidity, mortality and associated healthcare costs.

MAN, MIND AND MADNESS! Kalpana Nagarkar; Akshay Manohar; Michael S. Beede; Daniel Goldsmith. Capital Health Regional Medical Center, Trenton, NJ. (Tracking ID #1628443)

LEARNING OBJECTIVE 1: Neurosyphilis must be considered in the differential diagnosis of psychiatric conditions, even in the absence of medical or other neurological findings.

LEARNING OBJECTIVE 2: This case report illustrates the usefulness of RPR testing for patients admitted to inpatient or outpatient with psychiatric symptoms.

CASE: Incidence of syphilis is once again increasing throughout the world. The disease is known as the great mimicker because of its wide range of clinical presentations. Symptomatic neurosyphilis can develop at any stage of the disease. Herein reported is a case of a 51-year-old man who initially presented with symptoms of mania mimicking schizophrenia, but was subsequently diagnosed with general paresis of the insane. A 51 year old African American man presented with acute psychosis to the emergency department. His medical history was significant only for long standing mental illness diagnosed as paranoid schizophrenia. Family history was unremarkable. During examination he was withdrawn answering only in monosyllables. Vital signs were stable. He was found to have Argyll Robertson pupils which responded to accommodation but not to light. He also had an abnormal Romberg's test. He scored a 23/30 on the MMSE scale suggestive of mild to moderate cognitive impairment. Imaging studies which included MRI of the brain and spine were negative. Initial laboratory studies were remarkable for his RPR being positive in 1:8 dilution and FTA-ABS was reactive. His treponema pallidum AB particle agglutination test was also reactive. A lumbar puncture revealed CSF that was reactive to VDRL in a 1:1 ratio. HIV testing was negative. The patient was admitted and treated with IV penicillin.

DISCUSSION: The patient described here presented with multitude of psychiatric signs and symptoms. Patients with neurosyphilis can also present with many different physical or neurologic symptoms that lead to admission or follow-up at a medical or neurology unit. What was interesting about this case was that the patient showed exclusively psychiatric manifestations, leading to direct admission to a psychiatric unit rather than a medical or neurology unit with psychiatric consultation. Clinicians—including internists and neurologists, and especially psychiatrists—need to have a high index of suspicion for neurosyphilis, which may have an exclusively psychiatric presentation and because of the increasing incidence of syphilis in recent years

MANAGEMENT DILEMMA: PROGRESSIVE THROMBOSIS IN A PATIENT WITH SARCOIDOSIS, CIRRHOSIS AND A HISTORY OF BLEEDING ESOPHAGEAL VARICES Lu Pan; Ogu Iheanyichukwu; David Desilets; Linda J. Canty. Baystate Medical Center, Springfield, MA. (Tracking ID #1619728)

LEARNING OBJECTIVE 1: Recognize the common causes of portal vein thrombosis in the setting of liver cirrhosis.

LEARNING OBJECTIVE 2: Understand the risks and benefits of anticoagulation vs. conservative management in patients with chronic portal vein thrombosis secondary to liver cirrhosis.

CASE: A 60 year old female with past medical history significant for liver cirrhosis secondary to sarcoidosis, upper GI bleeding due to esophageal varices which were subsequently banded, iron-deficiency anemia, portal vein thrombosis (PVT) and superior mesenteric vein thrombosis that was diagnosed seven months prior presented with subacute worsening of abdominal pain. The abdominal pain was severe and localized to the mid-epigastric region associated with nausea without vomiting, BRBPR or melena. On physical examination, patient had stable vital signs. Her abdomen was soft, nontender and nondistended with active bowel sounds. CT scan revealed a greater degree of thrombosis in the superior mesenteric vein and portal vein (PV) with tortuous mesenteric vessels presumably collaterals. Hypercoagulable workup revealed a mildly elevated antidcardiolipin (aCL) IgM of 19 MPL/ml, while the remainder of the antiphospholipid panel was negative. Factor V Leiden, Factor II Prothrombin, Protein S deficiency and JAK-2 mutation (screening for myeloproliferative disorder) were negative. Protein C was low at 49 % (normal range 74–151). The patient was managed conservatively with IV fluids and pain control. Her abdominal pain improved during the hospital stay.

DISCUSSION: Anticoagulation therapy was contemplated for several reasons. Anticoagulation in patients with PVT could lead to recanalization of the PV and prevent progression of PVT. The worsening thrombosis, reduced level of protein C and elevated aCL IgM were concerning for a possible underlying prothrombotic disorder contributing to the PVT. However, the lowered protein C could have been an acquired condition due to the patient's liver cirrhosis. In addition, aCL IgM has been found in 18.8 % of patients with chronic liver disease unrelated to thrombosis and was considered an epiphenomenon of chronic liver damage. Even among patients with systemic lupus erythematosus, aCL antibodies were not an independent risk factor for thrombosis-related event. Furthermore, portal vein recanalization is more likely to be achieved if anticoagulation was initiated within 6 months of diagnosis. Our patient was diagnosed with PVT seven months prior. Finally, the clinical benefits of PV recanalization in this particular patient are uncertain. Mortality benefits have only been demonstrated in individuals with PVT on the waiting list for liver transplant. Even though patients with PVT treated with anticoagulation did not have significant esophageal variceal bleeding, the risk of bleeding was taken into consideration given this patient's known prior bleeding. Finally, the PVT is likely due to reduced flow in the portal system. After careful deliberation, the decision was made not to anticoagulate. As of nine months of follow-up, no further complications have developed.

MEDICAL ERROR AND HARM AS A REAL TIME TEACHABLE MOMENT: A 52 YEAR OLD WOMAN WITH DIABETES Robert L. Fogerty. [1]Yale School of Medicine, New Haven, CT; [2]Yale-New Haven Hospital, New Haven, CT. (Tracking ID #1610294)

LEARNING OBJECTIVE 1: Recognize systems breakdowns that can occur and result in patient harm.
LEARNING OBJECTIVE 2: Recognize the importance of near miss reviews as part of teaching systems-based practices to housestaff.
CASE: A 52 year old female with a medical history notable for Type II Diabetes Mellitus, presented to our Emergency Department following a fall. She was found to have Hyperglycemic Hyperosmolar Syndrome (HHS) and was admitted. The patient arrived on the medical floor with insulin present on her IV pole, but no active order for insulin. The physician to physician report and the physician charting both described an ongoing insulin infusion. The insulin infusion was re-ordered by the medical team based on these records. The Emergency Department nursing assessment (a paper record) noted a symptomatic hypoglycemic event resulting in abrupt discontinuation of the insulin infusion. This was the only location where these events were noted. Only a careful review of the paper nursing records, outside of our Electronic Medical Record and not standard practice, resulted in the discovery of this error. The patient arrived on the medical floor without reliable intravenous access. A central venous catheter (CVC) was placed. A single view chest x-ray was desired for CVC placement confirmation. Due to confusion amongst the team members, a lateral chest x-ray was performed and suggested azygous placement of the CVC. The covering house officer believed immediate repositioning was necessary, deactivated the bed alarm and attempted repositioning. While awaiting repeat chest radiography, the patient got out of bed and fell, pulling out the CVC. The patient did not suffer any significant harm from this event, but it was identified by all involved as a 'near miss'. She recovered from her illness and was discharged home.
DISCUSSION: This case is of interest to General Internists and Physician Educators because of the growing recognition of patient safety as an important education topic. This patient's hospital course was notable for three near misses in the first 24 h of her hospital stay, each of which could have resulted in harm. Most of these were not related to clinical errors but systems-based errors. First: Poor communication between the Emergency Department and the Medical Service, an error in knowledge transfer, resulted in the ordering of a potentially dangerous drug. Second: Azygous line placement was inappropriately noted as an emergency, a knowledge deficit. Third: Deactivation of the bed alarm, a defeated defense, resulting in a fall. Further complicating the situation was the ordering of an undesired medical test, the lateral chest x-ray, a result of both a knowledge deficit and poor handoff by the medical team. The medical team subsequently dedicated an entire teaching session to these systems-based errors, including a root cause analysis that discovered the deactivation of the bed alarm. The importance of attention to non-clinical patient care issues was emphasized. Conclusions: The safe practice of medicine requires adequate medical knowledge and strong clinical skills. Non-medical knowledge and systems-based practices, such as safe patient transfer and fall prevention, also contribute to safe medical care. Real-time Root Cause Analysis can be used as a teaching tool for systems-based practices with housestaff. In this case, poor systems-based practices posed a danger to the patient and provided a teaching opportunity.

MOLLARET'S MENINGITIS IN A PATIENT WITHOUT MONONUCLEAR PREDOMINANCE SALIM HAMADEH, HARSHA RAMCHANDANI, JAMES KRUER ST MARY MERCY HOSPITAL, LIVONIA, MICHIGAN Salim Hamadeh; Harsha Ramchandani; James Kruer. St Mary Mercy Hospital, Livonia, MI. (Tracking ID #1635770)

LEARNING OBJECTIVE 1: To illustrate an uncommon yet interesting case
LEARNING OBJECTIVE 2: To learn how to approach a case of meningitis To describe CSF findings in Mollaret's meningitis
CASE: Introduction: Mollaret's Meningitis is a rare disease of benign nature. First described by French neurologist, Pierre Mollaret, in 1944, it is characterized by sudden, repeated episodes of headache, photophobia, and fever that resolve within one to seven days. The diagnosis of Mollaret's meningitis is one of exclusion and is associated with marked pleocytosis on spinal fluid analysis including mainly lymphocytes, and large mononuclear cells. Case Description: This is a 32-year-old Caucasian male with a PMH of anxiety and migraine who presented with severe headache, fever, photophobia and myalgias for 1 week duration. On admission he was afebrile and hemodynamically stable. Physical examination showed photophobia. However, there was no nuchal rigidity, no skin rash and Kernig's and brudzinski's signs were negative. Laboratory studies showed no peripheral leucocytosis. Cerebrospinal Fluid (CSF) analysis showed elevated WBC with neutrophilic predominance, high protein count, and normal glucose. CSF cultures, VDRL and comprehensive viral panel (herpes Simplex virus type 1 and 2, EBV, CMV, West Nile, HIV), streptococcal pneumonia antigen, cryptococcus antigen were negative. CT scan and MRI of the head were normal. During the hospital admission, he received IV antibiotics, corticosteroids, and acyclovir. Once CSF culture and viral PCR came negative, antibiotic and acyclovir was stopped. His symptoms improved with symptomatic treatment. The patient had a similar presentation 6 months prior, which improved after supportive treatment. CSF studies at that time also showed elevated white blood cell count with neutophil predominance, high protein count, and normal glucose. Comprehensive viral cultures and CSF culture were negative. Patient symptoms resolved within 48 h and the patient was discharged home.
DISCUSSION: Mollaret's meningitis is a rare form of recurrent, benign, aseptic meningitis and is usually associated with lymphocyte predominance on CSF, with large mononuclear cells, which disappear after the first 24 h. Chan et al. report monocytes comprising 60–70 % of CSF cells on presentation. Mollaret's Meningitis may be associated with HSV predominantly Type 2. Transient neurologic deficits such as seizures may occur in up to 50 % of patients. In our patient, CSF antibodies for Herpes Simplex Virus were negative and the patient had a low monocyte count on both episodes of meningitis. This is likely due to delay in lumbar puncture. According to the Clinical Infectious Disease Oxford journal, acyclovir is the mainstays of therapy when the cause is HSV. Indomethacin, steroids, and colchicine have also been studied. Indomethacin has been shown to reduce the duration of illness and increase the symptom free interval. It is important to consider Mollaret's meningitis in the differential diagnosis of recurrent aseptic meningitis with negative viral studies and even without lymphocytic or monocytic predominance. Timely diagnosis of this disorder may prevent repetition of extensive and costly diagnostic investigations.

MONO CAN BE YELLOW: AN UNUSUAL CAUSE OF ACUTE HEPATITIS AUTHORS: AWASTHI D, GUHA B DEPARTMENT OF INTERNAL MEDICINE, QUILLEN COLLEGE OF MEDICINE, EAST TENNESSEE STATE UNIVERSITY Disha Awasthi; Bhuvana Guha. East Tennessee State University, Johnson City, TN. (Tracking ID #1642133)

LEARNING OBJECTIVE 1: EBV hepatitis is rare cause of acute hepatitis. Early recognition of EBV as a differential in patients presenting with hepatitis, especially in the setting of fever, lymphocytosis will allow physicians to diagnose and prevent fatal fulminant hepatitis.
CASE: 37-year old female patient was admitted with complaints of fever, chills and nonproductive cough. Past medical history included history of mental retardation secondary to premature birth, epilepsy and hypothyroidism. Patient goes to an adult day care and according to her mother she had lately been weak and lethargic. On admission vitals were normal except for temperature of 101.5 F. Physical examination was normal except decreased breath sounds on the right chest and tender hepatosplenomegaly. Labs showed-WBC-5 K/ul, Hb-13.2 g/dl, Platelet-106 K/ul. Chest Xray showed a right sided infilterate. Patient was started on Rocephin and Azithromycin for possible community acquired pneumonia. She continued to have high grade fever, max-105.1 F during hospitalization. Patient developed hypotension for which she was transferred to the Intensive care unit. CT Chest showed mediastinal, hilar lymphadenopathy, hepatosplenomegaly and multiple lymph nodes along the pancreatic head. Blood, urine and sputum cultures were negative. At Day 5 Patient became icteric. Follow-up labs showed WBC-7.1 K/ul with significant

lymphocytosis, Platelet-61 K/ul, AST-271 IU/L,ALT-61 IU/L,ALK-261 IU/L,Bilirubin-3 mg/dl, PT-15.2,INR-1.2,PTT-36,D-Dimer-2090 ng/mL,LDH-326 IU/L,Ferritin-2722 ng/mL,CRP-106 mg/L. USG abdomen showed Hepatosplenomegaly, contracted gall bladder with normal bile duct. Further workup was negative except EBV IGM was positive, EBV PCR showed 900 copies. Hepatitis panel and CMV were negative. Patient continued to be febrile and lethargic. Peripheral smear showed atypical lymphocytosis and thrombocytopenia. Hemolytic anemia was ruled out. Bone marrow biopsy was done to rule out Hemophagocytic Lymphohistiocytosis, since the patient satisfied all the clinical and laboratory criteria including fever, cytopenia, splenomegaly, Hypertriglyceridemia, lymphadenopathy and elevated Ferritin. Bone marrow biopsy showed moderate hypercellular marrow with moderate megakaryocytic, erythroid hyperplasia and reactive lymphocytosis. There was no evidence of hemophagocytosis. The patient was managed supportively and her condition slowly improved. Patient was afebrile after 11th day of admission. Lymphocytosis and LFTs continued to improve. Repeat LDH and Ferritin was normal. She was discharged in a stable condition. Repeat EBV copies after 2 months were normal.

DISCUSSION: Fever, sore throat, and adenopathy are the most common clinical features of acute EBV infection, also known as Infectious Mononucleosis. We present a case of EBV induced acute hepatitis involving moderate transaminitis, jaundice and hepatosplenomegaly. EBV hepatitis generally causes a mild, self- limiting hepatitis. Symptoms of EBV hepatitis are nonspecific like anorexia, weight loss, abdominal pain, and flu- like symptoms. The diagnosis is suggested by the combination of lymphocytosis, transaminitis and splenomegaly. Clinical jaundice occurs in <5 % cases. Treatment of EBV is usually supportive and most cases of hepatitis resolve spontaneously. Fulminant hepatic failure is the main cause of death in patients with fatal EBV hepatitis.

MORE THAN SKIN DEEP: PACEMAKER ASSOCIATED ENDOCARDITIS CAUSED BY STAPHYLOCOCCUS LUGDUNENSIS Felix H. Lui; Sara L. Swenson; Shelley M. Gordon. California Pacific Medical Center, San Francisco, CA. (Tracking ID #1628925)

LEARNING OBJECTIVE 1: Highlight the clinical presentation of a rare, but aggressive, coagulase-negative staphylococcus species, Staphylococcus lugdenensis

LEARNING OBJECTIVE 2: Discuss the diagnosis and treatment of device-related endocarditis

CASE: A 25 year-old Caucasian female with a history of severe cardiomyopathy due to viral myocarditis presented with fevers and increasing dyspnea on exertion for two months. The patient underwent a pacemaker implantation in 2007 and a left ventricular epicardial lead implantation in 2008. Eight months before admission, she received a biventricular ICD. At that time her generator pocket was suspicious for infection, and coagulase negative staphylococci was cultured. This was initially dismissed as contaminant, but subsequently speciated as Staphylococcus lugdunensis. Four months before admission, another revision occurred without incident. She had felt unwell since that time. On presentation in May 2012, she was hypotensive and febrile. Cardiovascular exam revealed a normal rhythm and S1/S2 heart sounds and a 2/6 holosystolic murmur at the left sternal border. A transthoracic echocardiogram revealed a left ventricular ejection fraction of 20 % and a mobile mass on the tricuspid valve. She was started on gentamicin, rifampin, and vancomycin for endocarditis sepsis. She was transferred to our hospital two days later. Transesophageal echocardiogram revealed a dense mass on the right atrial lead. Blood cultures grew S. lugdunensis with the same antibiotic sensitivities. On hospital day 8, the pacemaker generator and 2 transvenous leads were removed. She received milrione for advanced heart failure. Due to concerns about infection of the remaining epicardial lead, she continued suppressive antibiotics until her heart transplant several months later. On transplantation, culture of the explanted lead grew S. lugdunensis.

DISCUSSION: We report a case of pacemaker-associated endocarditis caused by an interesting etiologic entity: S. lugdunensis. Coagulase-negative staphylococci (CoNS) are a major component of human skin flora. As in our patient, they are often considered contaminants when isolated, which can lead to treatment delays and adverse patient outcomes. CoNS staphylococci account for 1–5 % of cases of native valve endocarditis. Intracardiac devices represent a significant risk factor for CoNS native valve endocarditis. Thus, we should have a low threshold for obtaining blood cultures in patients with intracardiac devices, even those who present with non-specific symptoms. Treatment of pacemaker endocarditis includes appropriate antibiotic therapy and removal of the entire pacer system. Our patient's persistent infection despite extended antibiotic therapy emphasizes the need for complete hardware removal once pacemaker endocarditis is identified. Unlike other CoNS, S. lugdunensis is an aggressive pathogen which behaves similarly to S. aureus. In addition to endocarditis, it can cause osteomyelitis, skin infections, and acute, post-operative endophthalmitis. In S. lugdunensis endocarditis, valve destruction with abscess formation develops rapidly in 50 % of cases. Seventy percent of patients develop complications that necessitate surgical intervention, including systemic embolization and heart failure. With incomplete treatment, mortality rates approach 70 %, rivaling those of S. aureus endocarditis. In our patient, infection was never suspected, leading to the development of pacemaker endocarditis and delaying appropriate treatment.

MORTALITY DUE TO REACTIVATION HEPATITIS B IN AN HIV POSITIVE PATIENT Meredith Niess. University of Colorado, Aurora, CO. (Tracking ID #1629018)

LEARNING OBJECTIVE 1: Cite strengths and weaknesses of various antiviral treatments for HBV/HIV co-infected patients.

LEARNING OBJECTIVE 2: Identify high-risk patients for HBV reactivation with antiviral regimen adjustment and the utility of viral sensitivity testing to prevent this.

CASE: A 52-year-old man with chronic Hepatitis B (HBV), Fanconi Syndrome, and HIV presents to his infectious disease physician complaining of decreased energy, general malaise, and nausea for 1–2 weeks. Ill-appearing, with hypotension and scleral icterus, he is admitted. His HBV and HIV were diagnosed in 1986. His HIV and HBV viral loads have been undetectable for more than 5 years due to treatment with lopinavir/ritonavir, tenofovir, and lamivudine. Eight months prior to presentation, raltegravir replaced tenofovir in his regimen due to acute on chronic renal failure. Six months prior to presentation, his HBV and HIV viral loads remained undetectable; 4 months prior, his transaminases and bilirubin were completely normal. Labs on presentation include an undetectable HIV viral load, a CD4 count of 316 (stable), AST of 598, ALT of 736, total bilirubin of 3.3, and an HBV viral load of 784 million. Liver biopsy demonstrates hepatocyte necrosis and organizing fibrosis. Given these results, entecavir is started 48 h into his hospitalization as salvage therapy for reactivated HBV. Despite this treatment, his AST and ALT rise to 1374 and 1190, respectively and total bilirubin climbs to 18.9. Tenofovir is reinitiated, and he is transferred for transplant evaluation and continued supportive care. HBV sensitivity testing confirms resistance to lamivudine, sensitivity to tenofovir, and intermediate sensitivity to entecavir. Entecavir and tenofovir are continued, and lamivudine is stopped. Despite this optimized regimen and mild virologic response, his liver failure is fulminant. In the third week of his hospitalization, ruptured gastric varices result in transfer to the MICU and ultimately, the patient's demise.

DISCUSSION: As of 2007, nearly 10 % of HIV infected patients had concurrent HBV infection. This case illustrates the complex nature of multidrug antiviral regimens for co-infected patients. Common HBV treatments include interferon, lamivudine, adefovir, entecavir, telbivudine, and tenofovir. This patient was successfully maintained on tenofovir and lamivudine, an extremely common regimen in HIV/HBV coinfected patients. Tenofovir is a potent antiviral, effective against wild-type and lamivudine-resistant HBV, in addition to HIV. It is the staple treatment for HIV/HBV co-infected patients, and is often combined with lamivudine. Lamivudine resistance develops very easily, with mutations providing cross-resistance to entecavir and other antivirals. According to recent studies, lamivudine is a poor candidate for monotherapy. In consideration of the rising problems of multidrug resistant HBV and the associated problem of rescue therapies, monotherapy in general for HBV is increasingly discouraged. While worsening renal failure is an appropriate indication to

discontinue tenofovir, the stakes are high in the immune-compromised HIV/HBV population. Replacement of the tenofovir with another potent antiviral may have changed this patient's course. This case also raises the question of when HBV antiviral changes without HBV sensitivities first are safe practice. Indeed, in the present case, sensitivity testing may have prevented HBV reactivation, fulminant hepatic failure, and death.

MOYAMOYA DISEASE AS POTENTIAL CONTRIBUTOR TO RECURRENT STROKE IN A 57-YEAR-OLD MAN. Erin Liu[2]; Thomas Deleon[2]; Kuo-Chiang Lian[1,2]. [1]The Queen's Medical Center, Honolulu, HI; [2]John A. Burns School of Medicine at the University of Hawai'i, Honolulu, HI. (Tracking ID #1626992)

LEARNING OBJECTIVE 1: Moyamoya disease is a rare cerebrovascular disease characterized by stenosis or occlusion of the arteries around the circle of Willis with arterial collateral circulation.
LEARNING OBJECTIVE 2: Patients with Moyamoya have significant risk for brain hemorrhage. Recognition of this disease in the patient with recurrent stroke requires a high degree of clinical suspicion.
CASE: A 57-year-old man with a past history ofdiabetes, hyperlipidemia and hypertension presented to the emergency department with right-sided weakness and aphasia. A head CT on admission without contrast showed a small left frontal gyrus stroke with no acute hemorrhage and he was managed medically. Laboratory testing on admission was remarkable for elevated hemoglobin A1c and LDL cholesterol. The patient's neurologic symptoms improved initially, however on Day 3 of hospitalization, the patient developed worsening of his symptoms. Physical examination was notable for a right-sided facial droop, hemiparesis in his right upper extremity, decreased strength in lower right extremity and mixed aphasia. Repeat head CT without contrast revealed a large left middle cerebral artery infarction and CTA of the neck showed multiple intracranial stenoses, specifically occlusion of the left M1 artery and moderate stenosis of the right M1 artery. Multiple collateral vessels reconstituting M2 segments were also noted, which were suspicious for Moyamoya disease. His proximal right upper extremity weakness improved mildly, but on Day 4 the patient again developed worsening right-sided weakness and a repeat head CT showed an evolving left middle cerebral artery infarction. Other stroke workup including transthoracic echocardiogram and carotid duplex ultrasound were unremarkable. He was medically managed with aspirin, atorvastatin, lisinopril, and insulin. He continued to receive speech, occupational and physical therapy throughout his hospital stay and was transferred to an inpatient rehabilitation facility for further care after stabilization of his neurologic symptoms.
DISCUSSION: This case illustrates the clinical presentation of recurrent strokes, which is common in the context of Moyamoya disease. The diagnosis ofMoyamoya disease is made with MRA or CTA which shows significant stenosis or occlusion of the cerebral arteries with a prominent collateral circulation. It is important to consider this disease in a patient with recurrent strokes because of the progressive nature of the disease and increased risk for cerebral hemorrhage.

MULTIPLE MYELOMA MASQUERADE Kristen Dalton. Denver Health Medical Center, Denver, CO. (Tracking ID #1637496)

LEARNING OBJECTIVE 1: To expand providers' differential for hypercalcemia.
LEARNING OBJECTIVE 2: To recognize the complications of a parathyroid adenoma.
CASE: A forty-eight year female with no past medical history presented with several months of progressive fatigue, constipation, and bone pain. Initial evaluation revealed significant hypercalcemia (15.3 mg/dL), acute renal failure, and iron deficiency anemia concerning for multiple myeloma. A skeletal survey demonstrated multiple small paravertebral lesions of the skull and bone loss in left humerus and radius. SPEP revealed a mild gammaglobulinemia. A bone marrow biopsy was considered, however the patient's parathyroid hormone level was found to be significantly elevated (1815 pg/mL). A subsequent neck ultrasound demonstrated an ovoid hypoechoic and hypervascular structure in the thyroid isthmus suspicious for parathyroid adenoma versus carcinoma. The patient received acute treatment for hypercalcemia and underwent an uncomplicated parathyroidectomy. The pathology was consistent with a parathyroid adenoma.
DISCUSSION: Hypercalcemia is encountered frequently in hospital medicine. Malignancy is usually the culprit in the inpatient setting, whereas primary hyperparathyroidism is the most common etiology in outpatients. Severe primary hyperparathyroidism (PHPT) may mimic multiple myeloma with bony lesions, anemia, renal failure, and monoclonal gammopathy. The rare bony lesions are Brown tumors due to increased osteoclast activity in underlying hyperparathyroidism. These "tumors" are not true neoplasms, but can mimic them. The mechanism of anemia is uncertain and typically occurs only in severe disease. It resolved in similar cases after parathyroidectomy. Several investigators have demonstrated an association between gammopathy and PHPT. Thus, the presence of both hypercalcemia and gammopathy does not necessarily indicate malignancy. Rather, it should prompt an investigation for hyperparathyroidism. This case had many interesting diagnostic twists and turns. Initially, myeloma was thought to be the most likely etiology of her hypercalcemia, but the subsequent findings of a highly elevated parathyroid hormone and a thyroid mass were suspicious for a carcinoma. Predictors of malignancy include disease occurrence in the fourth and fifth decade of life (an average of ten years earlier than an adenoma). One would expect calcium levels to be more elevated in carcinoma (usually greater than 14 mg/dL). In addition, malignant masses are often ill-defined, highly vascular, and embedded into surrounding structures. The surgeons in this case described a well-circumscribed, noninvasive mass most consistent with adenoma. Pathology ultimately confirmed parathyroid adenoma as the culprit. The patient's hypercalcemia, bone pain, and constipation have since resolved. Her parathyroid levels dropped intraoperatively from 3420 pg/mL to 1040 pg/mL and expect further reduction over several months. Her diffuse bone loss should improve with calcium supplementation. The lesson learned in this case is that the true etiology of hypercalcemia can be unmasked if one keeps a broad differential.

NEUROSYPHILIS Matthew L. Law. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640505)

LEARNING OBJECTIVE 1: Recognize new-onset seizures as a presentation for neurosyphilis.
LEARNING OBJECTIVE 2: Recognize the barriers to diagnosing neurosyphilis. Identify the initial changing presentation of neurosyphilis.
CASE: A 41 year-old man with no past medical history and three months of altered mental status by acting strange according to his family presented with a generalized tonic clonic seizure. His pupils were equal, round, reactive to light and accommodation. Patient had no sensory or proprioception defects, or skin lesions. CT scan of the brain discovered no acute intracranial process. EEG showed diffuse slowing. Aseptic meningitis was revealed by initial lumbar tap. HIV test was negative. Later RPR of the blood and VRDL of the cerebrospinal fluid (CSF) returned positive results. On further questioning, patient admitted to multiple sexual partners over the past ten years, with inconsistent protection.
DISCUSSION: A general internist commonly encounters new-onset seizures. In conjunction with a thorough history and physical exam, an internist must consider an infectious etiology, with neurosyphilis as a possibility. The incidence of acute symptomatic seizures occurring in neurosyphilis is between 14 % and 60 %. Neurosyphilis can occur during any of the stages of syphilis, as the spirochete Treponema pallidum invades the CNS early in the course of syphilis. The diagnosis of neurosyphilis relies on many tests with the confirmatory test being a positive VRDL of the CSF. However, the VRDL of the CSF is reported as having a 25–40 % false negative rate, and this becomes one of the major barriers to diagnosing neurosyphilis. In non-HIV infected individuals where there is a suspicion of neurosyphilis a CSF lymphocyte count >5 cells/μL or a protein concentration >45 mg/dL in consistent with the diagnosis. Additionally, tabes dorsalis, a classic symptom of neurosyphilis, is one of the most affected by antibiotic therapy, and therefore is generally absent upon presentation. As a result, neurosyphilis today presents with subtle clinical signs and weakly positive serology, which can often cause a

physician to overlook neurosyphilis as a possible diagnosis in new onset seizures. Additionally, while the incidence of syphilis decreased in the latter part of the 20th century and may have lulled physicians into forgetting about this disease, syphilis is on the rise again, especially among HIV positive patients. With syphilis on the rise, physicians should investigate neurosyphilis in patients with changes in mental status, especially with new-onset seizures.

NATIVE MITRAL VALVE ENDOCARDITIS CAUSED BY STAPHYLOCOCCUS CAPITIS Rommel Del Rosario; Mohammed Bahaa Aldeen; Mashrafi Ahmed. Texas Tech University Health Sciences Center, Amarillo, TX. (Tracking ID #1639724)

LEARNING OBJECTIVE 1: Recognize that blood culture growth of skin commensal organisms should be evaluted carefully with clinical findings
LEARNING OBJECTIVE 2: Recognize that treating Staphylococcus capitis endocarditis wtih a combined medical and surgical approach may have a better outcome
CASE: A 63-year-old nursing home resident was admitted for suspected health care associated pneumonia. She has no history of IV drug use and no chronic indwelling intravenous lines. The physical examination revealed tachycardia, tachypnea, decreased breath sound and crackles on the right base of the lung and a systolic murmur heard best on the left parasternal border with radiation to left axilla. Chest x-ray showed consolidation on the right base of the lung. Blood cultures were sent and she was started on recommended triple antibiotic therapy for suspected health care associated pneumonia. Despite antibiotic treatment, she had persistent leukocytosis with fever. When her blood culture came back positive for Staphylococcus capitis on multiple sets, suspecting an infective endocarditis, a transthoracic echocardiogram was done. It showed large vegetation on the anterior mitral valve leaflet measuring about 2.5 cm in the largest diameter with severe mitral regurgitation. Antibiotic therapy was changed to vancomycin and oral rifampicin. Surgery was planned considering bulky vegetation but patient refused any surgery despite repeated counseling. She continued to deteriorate and developed acute hypoxic respiratory failure due to pulmonary edema. She adopted hospice care and died in 2 weeks.
DISCUSSION: Coagulase-negative staphylococcus is considered as normal flora on the skin. Most of the isolates reported from blood cultures are contaminants. It is rare to see this on blood cultures especially on patients with native valves, and on those with no history of IV drug use or long-term indwelling intravenous catheter. In this report, we present a case of native valve endocarditis by Staphylococcus capitis and reviewed all the published reports of similar occurrence. We found 21 case reports of Staphylococcus capitis endocarditis in Pubmed search and reviewed all of them. The age ranges from 29 to 80 years, mean - 62.5 years. Male and female were equally affected. Native valve is involved in 60 % cases. In case of prosthetic valve, bioprosthetic valve is more frequently involved than metallic one (62 % vs 12 %). Nearly in 58 % cases, vegetation and valve dehiscence with regurgitation were found and 41 % cases developed peri-valvular abscess. 55 % of cases were treated with antibiotic alone and rests were treated with antibiotic with surgical intervention. Mortality rate is 15 % and 10 % respectively among these two therapeutic groups. When antibiotic is used alone, single agent was used in 41 % cases with mortality of 20 % and combination therapy was used in 59 % cases with mortality of 42 %. Our case reminds internist to be alert for infective endocarditis when skin commensals are grown in multiple blood cultures with significant clinical and laboratorial finding.

NEURO-BEHçET'S DISEASE: AN UNUSUAL CAUSE OF HEADACHE Eric Fountain; Anjali Dhurandhar. University of Colorado School of Medicine, Denver, CO. (Tracking ID #1594886)

LEARNING OBJECTIVE 1: Identify the causes of headache in Behçet's disease and recognize when neuroimaging is appropriate
LEARNING OBJECTIVE 2: Identify the manifestations of Neuro-Behçet's disease
CASE: This is a 50 year-old woman with a 20-year history of Behçet's disease (BD) who presented to clinic with headache. The patient had awakened with the headache that morning. She had 8/10 pain located around her eyes and on top of her head and mild nausea, but no visual disturbances or focal neurological symptoms. The headache responded to ibuprofen. The patient was currently taking prednisone for painful genital ulcers. Examination was normal, except for a small oral ulcer, two large genital ulcers and tenderness over the temporal regions. Two days later, the patient was seen in the ED for persistent frontal headache of 9/10 severity for 4 days. Physical examination and non-contrast CT head were both unremarkable. The patient was sent home. Four days after her initial presentation, the patient returned to clinic with persistent headache and a new complaint of unsteady gait. Headache worsened with positional changes. She had discontinued prednisone due to her concerns of a possible infection. Physical exam noted sitting BP 138/80, then standing BP 118/78, oral ulcer and abnormalities on neurologic exam including altered mental status, left-sided dysmetria, slowed rapid alternating hand movements, and difficulty with tandem gait. The patient had intact cranial nerves, normal motor strength and deep tendon reflexes. STAT MRI/MRA/MRV were ordered. MRA and MRV were normal, but MRI demonstrated diffuse enlargement of the pons, concerning for a brainstem glioma. After discussing the patient's presentation with the neuroradiologist, the MRI was felt to be compatible with Neuro-Behçet's disease. The patient was treated with high dose corticosteroids with prompt resolution of her neurological symptoms.
DISCUSSION: Headache is one of the most common pain complaints. Differentiating primary headache from secondary headache can be challenging, particularly in patients with systemic diseases. We failed to recognize Neuro-Behçet's disease (NBD) due to our lack of awareness of this manifestation. Behçet's disease (BD) is a chronic, idiopathic vasculitis characterized by recurrent oral and genital ulcers, uveitis, and pathergy. NBD is one of the most serious sequelae. Neurological involvement in NBD often manifests as either subacute meningoencephalitis or venous sinus thrombosis. Severe headache in BD presents a diagnostic challenge as it may herald the onset of NBD, yet the decision to obtain neuroimaging for Behçet's patients presenting with isolated headache remains unclear. The prevalence of any type of headache in BD is about 70 %. Most are migraine and tension headaches. 10 % are due to non-structural headache of Behçet's that concurs with BD flares and improves with corticosteroids. Only 10 % of headaches in BD are due to NBD. While a majority of all patients with NBD present with headache, most of these patients have other findings such as focal neurological deficits or papilledema that would justify neuroimaging. The preferred diagnostic modality for NBD is T2 MRI with MRV also recommended if venous thrombosis is suspected. While imaging would not have been appropriate initially for our BD patient, greater awareness of the role of headache as a prognostic marker for NBD may have aided in diagnosis. The correct diagnosis was confirmed through rapid improvement with systemic corticosteroids.

NEW ONSET GOUT PRESENTING AS PSEUDOSEPSIS Kathyrn Veazey[1]; Mary Maher[2]. [1]University of Colorado Health Sciences Center, Denver, CO; [2]Kaiser Permanente Medical Group, Denver, CO. (Tracking ID #1640342)

LEARNING OBJECTIVE 1: Recognize that polyarticular gout can present as pseudosepsis
LEARNING OBJECTIVE 2: Recall that polyarticular gout pseudosepsis is often misdiagnosed as sepsis and treatment is with corticosteriods
CASE: A 39 year old male with a past medical history of alcohol abuse presented with alcohol withdrawal after having a seizure at home. He was initially admitted to the intensive care unit for intravenous benzodiazepines. On day 3 of hospitalization, he developed left knee pain and a fever to 39.2 with notable tachycardia and hypotension. Complete blood count showed a mild anemia with a leukocytosis of 12,800. He was worked up for infectious etiologies and treated with intravenous fluids and broad-spectrum antibiotics. Blood cultures, urine culture, chest radiography, and CT scan of the abdomen were unremarkable. Over the next few days, he

developed swelling over the left great toe, right hand, right elbow, and bilateral ankles. A radiograph of the right ankle showed soft tissue swelling and one of the left knee showed a large effusion. An arthrocentesis was performed of the left knee and the synovial fluid revealed uric acid crystals and a white blood cell count of 28,031 with 97 % neutrophils. Synovial gram stain and culture were negative. Urine chlamydia and gonorrhea as well as serum rheumatoid factor were negative. Rheumatology was consulted and felt that the presentation was consistent with pseudosepsis due to an acute polyarticular gout attack. The patient was treated with high dose corticosteroids resulting in normalization of his vital signs and a complete resolution of his symptoms

DISCUSSION: Polyarticular gout manifests as an initial gout presentation in less than 20 % of patients and an initial presentation as pseudosepsis is even more rare. Polyarticular gout flares can result in a systemic inflammatory response that mimics septic shock known as pseudosepsis. Pseudosepsis often presents with fever, leukocytosis with left shift, and hypotension. Like sepsis, it can be life threatening if not recognized early. Swan-Ganz catheters show a systemic vasodilatory response similar to sepsis. Polyarticular gout with pseudosepsis is often not considered in a differential diagnosis of the febrile and hypotensive patient. Failure to consider pseudosepsis as a diagnosis leads to unnecessary use of antibiotics and delayed diagnosis of the underlying etiology. Treatment of pseudosepsis from polyarticular gout requires hemodynamic support and use of systemic corticosteroids. This case of polyarticular gout is unique in that the patient did not have a known history of gout and his initial attack presented as a systemic inflammatory response syndrome consistent with pseudosepsis. It is important for internists to recognize that polyarticular gout can present as pseudosepsis, even in patients without known history of gout.

NON CONVULSIVE STATUS EPILEPTICUS, AN UNDER DIAGNOSED NEUROLOGICAL EMERGENCY. SUBHADRA MANDADI MD, LAKSHMI GOWDA HANUMAIAH MD, FAISAL AHMAD MD, MYRIAM EDWARDS MD, GHASSAN BACHUWA MD HURLEY MEDICAL CENTER Lakshmi Gowda Hanumaiah. Hurley Medical Center, Flint, MI. (Tracking ID #1609177)

LEARNING OBJECTIVE 1: Non convulsive status epilepticus is defined as continuous or near continuous ictal discharges on EEG with non convulsive symptoms.It is a common yet underdiagnosed cause of delirium in the elderly with underlying cerebral structural changes. It is a challenging diagnosis because of its non specific clinical presentation.

CASE: A 79 y/o Caucasian female with a history of chronic stable subdural hygroma and TIA was admitted with increasing frequency of falls. She had no significant physical findings on examination. Subsequently, she developed delirium .At that time, laboratory studies were within normal limits with no evidence of infection. The delirium could not be attributed to any secondary cause. CT head without contrast was significant for a stable left subdural hygroma with subacute bleed. Due to the worsening delirium of unclear etiology, patient was transferred to ICU. Occasional twitching of both upper extremities and face was noticed and hence EEG was ordered. EEG reported 9 seizures of left temporal onset without clinical manifestation. Parenteral ant seizure medications were initiated with an impression of aphasia/neglect syndrome secondary to partial seizures arising from the effect of subdural hygroma. A repeat EEG to monitor the response reported right Periodic Lateralized Epileptiform Discharges with low voltage delta activity, midazolam drip was added to control her ongoing seizure. Twenty-four hours video recording EEG was done considering her deteriorating mental status and it suggested bihemispheric cerebral suppression with intermittent non convulsive seizures. Patient did not show improvement despite aggressive anti epileptic medications and pressor support. Patient was transferred to another tertiary facility where she deceased after a few days.

DISCUSSION: Always suspect NCSE in an elderly patient with delirium of unknown cause. Continuous EEG monitoring is the diagnostic modality with questionable cost effectiveness. This case illustrates atypical symptomatology of NCSE with history of probable epileptic drop attacks manifested as falls, aphasia, neglect syndrome, and the importance of early diagnosis of NCSE with its significant impact on treatment and outcome. Previous history of TIA/Stroke can lead to delay in diagnosis. Aggressive management can even contribute to mortality in these cases.

NON-COMPACTION CARDIOMYOPATHY; ONE MORE DIFFERENTIAL DIAGNOSIS. Benyam G. Alemu[1]; Itzhak Kronzon[2,1]. [1]Lenox Hill Hospital, New york, NY; [2]Lenox Hill hospital, New york, NY. (Tracking ID #1623971)

LEARNING OBJECTIVE 1: Non-compaction Cardiomyopathy (NCCM) is a rare disorder that is classified as a primary-genetic Cardiomyopathy by American heart association. The purpose of this case report is to promote awareness about this rare, albeit serious disorder.

LEARNING OBJECTIVE 2: Recognize the clinical features and complications of non-compaction Cardiomyopathy

CASE: A 56 year old male patient came to our hospital with a chief complaint of recurrent syncope for the last 2 years. Patient reported palpitations and severe weakness preceding the syncopal episodes, followed by a brief loss of consciousness and rapid recovery. He denied any chest pain during those episodes. His past medical history included Hypertension, Diabetes type II and pulmonary fibrosis. His father died of 'heart attack' at the age of 66. On physical exam patient was comfortable and had no signs of respiratory distress. He had fine crackles heard on chest exam otherwise the rest of his physical was unremarkable. His initial lab work was unremarkable and EKG revealed a non-specific intra-ventricular conduction defect. Patient underwent an Electrophysiologic study and had a pacemaker placed for possible disease of bundle of His. Three days later, patient presented to the ER with another syncopal episode. Interrogation of his pacemaker revealed a sustained monomorphic ventricular tachycardia that lasted for 10 min. He was started on Amiodarone infusion and underwent coronary angiography which was normal. Echocardiography showed ejection fraction of 45 % and trabeculation around the apex of the left ventricle suggestive of isolated left ventricular non-compaction. The possibility of NCCM was strongly considered. Patient underwent pace maker explantation for a Cardiac MRI and results demonstrated mild global hypokinesis of the left ventricle and prominent left ventricular trabeculations. The diagnosis of non compaction cardiomyopathy was confirmed and patient was discharged after an automated internal cardiac defibrillator (AICD) implantation.

DISCUSSION: The incidence of NCCM has been estimated to be 0.05 % to 0.25 % per year in the general population. This disorder is caused by genetically determined disturbance of the myocardial compaction process during fetal endomyocardial morphogenesis. Both familial and non-familial cases have been described. Heart failure, ventricular tachycardia and thromboembolism are common complications of this disorder. One large cohort reported the incidence of ventricular tachycardia to be as high as 63 %. The mechanism of such arrhythmias is not completely understood but cardiac arrest and sudden death have been reported. Diagnosis is made by specific Echocardiographic criteria and Cardiac MRI can also be used for confirmation. Management involves treatment and prevention of complications such as anticoagulation and heart failure. ICD is indicated only for secondary prevention or in high risk patients. Non-compaction Cardiomyopathy is a rare disorder associated with a high incidence of cardiovascular complications. Diagnosis needs high index of suspicion and clinicians should be aware of this disorder and consider it in differential diagnosis.

NONRESOLVING RHABDOMYOLYSIS REVEALING AN OCCULT CULPRIT - A CASE REPORT OF PARASPINAL COMPARTMENT SYNDROME Taraka Vijay Gadiraju; Dhivya Sundaramurthy; Christopher R. Lachance. Baystate Medical Center/Tufts University School of Medicine, Springfield, MA. (Tracking ID #1642612)

LEARNING OBJECTIVE 1: Diagnose compartment syndrome promptly with a simple bedside investigation.

LEARNING OBJECTIVE 2: Recognize the importance of early intervention of compartment syndrome with fasciotomy to salvage muscle.

CASE: A 33-year-old man, a body builder by profession presented to our satellite location hospital with lower back pain and cola colored urine, eight hours after his rigorous weightlifting maneuvers and aerobic exercise in a Cross fit competition. He had a remote history of stable asthma, depression, uses amphetamine/dextroamphetamines for ADD and no history of back pain. Had no recent infections or antibiotic use. Denied active smoking, alcohol or drug abuse and his family history was significant for Huntington's disease. His vitals were stable and on exam, he had right loin firmness and tenderness, but no erythema, swelling, or signs of trauma. Had full ranges of motion and sensations were intact. Labs were significant for WBC18.9×100/L; creatinine 1.4 mg/dL; creatinine kinase (CK) >100,000 U/L. CT scan of the abdomen was normal and no muscle swelling. The patient was admitted for rhabdomyolysis and acute kidney injury. He was treated with bicarbonate drip and adequate hydration with intravenous saline overnight. Despite these measures, his CK remained high at >100,000 U/L and the patient was transferred to our tertiary care center. He continued to have mild right flank pain despite being on opioid analgesia. He developed mild swelling over the right paraspinal muscles with reduced sensation, without edema or erythema. With the question of persistent rhabdomyolysis and of concerns if high dose analgesia is masking the underlying pain, we had a high suspicion of an occult compartment syndrome. A Stryker instrument was passed in right paraspinal region that measured high pressure of 38-40 mmhg consistent with PCS. Patient underwent emergent surgical decompression by fasciotomy, where the paraspinal muscles appeared grayish, edematous and were bulging out on release by the incision. His other muscle groups looked viable and were salvaged from the timely intervention. This was followed by wound vac and delayed primary closure of the wound. Subsequenty his pain markedly improved, creatinine normalized, CK trended down to <2000 U/L by the time of discharge. He was able to resume his usual activities and was able to exercise again.
DISCUSSION: Paraspinal compartment syndrome (PCS) is a rare condition defined as increased pressure within a closed fibro-osseous space, resulting in reduced blood flow and tissue perfusion, causing ischemic pain and irreversible damage to the tissues, if unrecognized or left untreated. So far only 10 cases of Paraspinal Compartment syndrome have been reported in literature. Strenuous exertion was the cause in most of these cases as in our patient. Timely recognition and surgical decompression with fasciotomy is the key to salvage muscle and prevent contractures, permanent sensory deficits, infection and sepsis, worsening rhabdomyolysis, myoglobinuria and kidney injury requiring dialysis. Rhabdomyolysis can present in the absence of late complications such as neurological and vascular compromise. Physician should be vigilant in considering PCS as a possible cause of back pain in the setting of rhabdomyolysis. High dose analgesia may mask the severity of the underlying condition and simple bedside procedure, measurement of compartment pressure with a Stryker instrument could be of great help when in doubt.

NORMAL DOES NOT ALWAYS MEAN NEGATIVE! Gloria W. Li[1]; Anna Kolpakchi[2]; Lee Lu[1]. [1]Baylor College of Medicine, Houston, TX; [2]Michael E. DeBakey VA Medical Center, Houston, TX. (Tracking ID #1642509)

LEARNING OBJECTIVE 1: Review the hepatocellular carcinoma (HCC) screening guidelines for patients with chronic hepatitis C (HCV).
LEARNING OBJECTIVE 2: Recognize the limitation of the screening tools.
CASE: A 62-year-old man with HCV liver cirrhosis presented with one week history of pleuritic chest pain, shortness of breath and dyspnea on exertion. He also reported a 60 lb weight loss in the past year. He received routine HCC screening, and his last screening 6 months prior revealed a negative liver ultrasound and AFP of 5.6 ng/mL (0–9). On admission, he was tachycardia; O2 saturation was 80 % with exertion. Abdomen was mildly distended with splenomegaly. Laboratory studies were significant for platelet 70, INR 1.65, ALT/AST 53/232, total bilirubin 5.8 and albumin 2.7. AFP was 5725 ng/mL. V/Q scan showed bilateral segmental and subsegmental pulmonary emboli. Lower extremity dopplers were negative for DVT. Abdominal ultrasound showed a non-occlusive portal vein thrombosis, but no focal liver lesions. CT of the body revealed innumerable bilateral pulmonary nodules, non-occlusive main portal and occluded proximal right portal vein thrombi, and mesenteric and retroperitoneal lymphadenopathy. MRI showed a hypodense right lobe of the liver concerning for infiltrating HCC. Because of his coagulopathy and poor prognosis, liver biopsy was not performed. Given the elevated AFP, portal vein thrombosis, abdominal lymphadenopathy and hypodense lesion in the liver, the presumptive diagnosis made by oncology was metastatic infiltrative HCC. The patient wanted hospice care and expired shortly after discharge.
DISCUSSION: HCC is the fifth most common cancer in men. HCC is attributed to chronic viral (Hepatitis B or C) infection. The most common risk factor is cirrhosis; 79–90 % of HCC is diagnosed in patients with liver cirrhosis. Incidence of HCC secondary to chronic hepatitis C infection and liver cirrhosis is 2–8 %. Early detection has been shown to improve survival. Infiltrative HCC accounts for 13 % of all HCC, but it is one of the most difficult to detect on early surveillance imaging. The current guidelines for HCC screening include AFP and abdominal ultrasound every 6 months. Serum AFP has the sensitivity 40–65 % and specificity of 76–96 %. AFP elevations can be seen in non-HCC patients, especially in the presence of viral hepatitis, liver cirrhosis, and even portal vein thrombosis. The sensitivity of abdominal US for HCC screening increases from 70 % for lesions 1 cm in diameter to 90 % for those > 5 cm. The specificity varies from 48 % to 94 %. It is even less sensitive and specific in identifying infiltrating HCC, as demonstrated in our patient. The use of CT and MRI leads to more accurate HCC diagnosis with sensitivity 89 % and specificity 99 %, but exposure to radiation, cost, and the lack of evidence on survival benefits limit the utility of these tests as initial screening tools. Thus, physicians must recognize the limitation of recommended screening tools for HCC and be extremely vigilant in the evaluation of surveillance imaging in order to detect infiltrative HCC as early as possible.

NOT ALL CEREBRAL SPINAL FLUID TITERS ARE MADE EQUAL Daniel Har[1]; Mili Shum[2]; Cindy Sadikot[1]. [1]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY; [2]Weill Medical College of Cornell University, New York, NY. (Tracking ID #1622412)

LEARNING OBJECTIVE 1: Recognize when to evaluate cerebrospinal fluid (CSF) in human immunodeficiency virus (HIV) patients co-infected with syphilis
LEARNING OBJECTIVE 2: Recognize the sensitivity of CSF Venereal Disease Research Laboratory (VDRL) and the importance of clinical context for treatment
CASE: A 35 year-old man with HIV, diagnosed in 2011, with an undetectable viral load, CD4 count greater than 400, adherent with antiretroviral therapy, presented with one year of progressively worsening neurological symptoms. Following his diagnosis of HIV, the patient was diagnosed with latent syphilis, which was refractory to several courses of intramuscular (IM) penicillin and doxycycline. For the past year, he reported back pain, leg numbness, and weakness which progressed to bowel and bladder incontinence a few weeks before presentation. During this time, he also had frequent headaches, accompanied by neck pain and vomiting. The patient had a stiff neck, decreased sensitivity below T7, loss of proprioception in his toes, and a positive Romberg sign. He had a maculopapular rash on his palms and soles. His pupils accommodated, but did not constrict to light. Labs showed RPR titers of 1:16; his last set of titers changed from 1:32 to 1:8 following treatment. CT head, MRI thoracolumbar spine, and MRI brain were unremarkable. He was started empirically on intravenous (IV) penicillin for suspected neurosyphilis while lumbar puncture results were pending. By hospital day 3, the CSF VDRL returned nonreactive. Treatment was continued because his symptoms were resolving. After completing 10 days of antibiotics, he had complete resolution of his symptoms and his CSF fluorescent treponemal antibody-absorption (FTA-ABS) returned reactive.
DISCUSSION: HIV-infected patients with early syphilis are at an increased risk of developing neurosyphilis, an infection of the central nervous system by Treponema pallidum. This is critical as the incidence of

syphilis has increased 33 % from 2000 to 2004. The most common symptoms include sensory impairment (48 %), pupillary changes (43 %), and cranial nerve palsies (36 %). Early neurosyphilis affects the meninges, resulting in meningitis symptoms. Late neurosyphilis typically affects the brain parenchyma and spinal cord, causing general paresis and tabes dorsalis. In the 2010 Center for Disease Control treatment guidelines, CSF should be analyzed in all patients with serological evidence of syphilis and neurological symptoms. This is even more concerning in HIV-infected patients as they have a more rapid course and a higher risk of treatment failure, leading to permanent disability or death. Although studies have shown that HIV-infected patients with CD4 counts <350 cells/microliter have an increased risk of neurosyphilis, this case demonstrates that this diagnosis should be considered in any HIV patient with positive syphilis titers. The diagnosis of neurosyphilis requires several tests, of which the most specific is a reactive CSF-VDRL. However, CSF-VDRL has a low sensitivity of 50 % whereas the sensitivity of CSF-FTA-ABS is close to 100 %. Therefore, a nonreactive CSF-VDRL does not rule out neurosyphilis, which is why our patient's symptoms resolved. In summary, clinicians should consider prompt CSF examination in any HIV-infected patient, regardless of CD4 count, who has positive RPR titers and symptoms of neurosyphilis. In addition, it is paramount to continue neurosyphilis treatment based on clinical symptoms, and not solely on CSF-VDRL, as treatment can be life-saving.

NOT JUST ANOTHER CAUSE OF CONFUSION- A CASE OF STEROID RESPONSIVE ENCEPHALOPATHY Madan R. Aryal[1]; Ravi Shahukhal[2]; Yagna R. Bhattrai[3]; Naba R. Mainali[1]. [1]The Reading Hospital and Medical Center, Wyomissing, PA; [2]Queens Hosptial Center, Queens, NY; [3]Mercy Catholic Medical Center, Philadelphia, PA. (Tracking ID #1622026)

LEARNING OBJECTIVE 1: Recognize Hashimoto's Encephalopathy in a patient with Hashimoto's thyroiditis
LEARNING OBJECTIVE 2: Discuss the treatment of Hashimoto's Encephalopathy
CASE: 76 year old Caucasian male with past medical history of Hashimoto's thyroidits, atrial fibrillation, coronary artery disease and hypertension, presented to the emergency department with clouding of consciousness for one day. His vital signs were stable. Chest and cardiovascular examination was normal. He was admitted for further workup which revealed CBC and electrolytes to be normal normal. Urine drug screen was negative. Septic work up was negative. His ABG was normal. Serum Cortisol was normal. TSH and anti TPO antibody were elevated at 11.4 UIU/ML, and 128 IU/ML respectively. CT of the chest and MRI of the head were negative. EKG and cardiac enzymes were normal. EEG revealed continuous slow and generalized pattern. Even after 2 days he continued to be encephalopathic. Based upon history of Hashimoto's thyroiditis, raised TSH and Anti TPO antibodies and EEG findings, he was started on steroid for presumed Hashimoto's encephalopathy. He showed significant improvement. He was discharged on steroid. This case well demonstrates that early recognition of Hashimoto's encephalitis is crucial and significant improvement with steroid therapy can be achieved.
DISCUSSION: Hashimoto's encephalopathy (HE) is a rare, under recognized disorder, more common in women which presents with sub-acute onset of confusion, cognitive deterioration, psychiatric symptoms, and seizures. It can present with myoclonus, ataxia and personality changes. The precise etiology and pathophysiologic mechanisms are not known although autoimmune phenomenon has been postulated. MRI, EEG, CSF analysis are essential to exclude other causes of encephalopathy. There is no gold standard diagnostic test and serological marker for the disease. The finding of elevated anti TPO Ab or antithyroglobulin antibody in patients with compatible clinical presentation is required for the diagnosis of HE. Improvement in cognitive impairment with steroid is suggestive of diagnosis. Neurologic investigation shows diffusely abnormal nonspecific slowing of background EEG, high CSF protein level without pleocytosis and normal brain CT. The long term prognosis is favorable with steroid treatment. Immunosuppressive therapy can be useful in patients who fail to improve with steroid therapy.

NOT SO SWEET - DRUG-INDUCED HYPERSENSITIVITY REACTION PRESENTING AS ACUTE FEBRILE NEUTROPHILIC DERMATOSIS Hazem Abugrara[1]; Daniel Jenkins[2]; Faisal Khasawneh[1]. [1]Texas Tech Univ Health Sciences Center, Amarillo, TX; [2]Baptist St. Anthony's Health System, Amarillo, TX. (Tracking ID #1594190)

LEARNING OBJECTIVE 1: 1- Diagnose a rare drug-induced hypersensitivity reaction presenting with pustular rash.
LEARNING OBJECTIVE 2: 2- Remind physicians of the broad and nonspecific manifestations of hypersensitivity reactions.
CASE: A 75-year-old white male with a past medial history significant for Crohn's disease admitted with acute onset confusional state and a sepsis picture. Two weeks prior, the patient was started on azathioprine (AZA) to treat his longstanding Crohn's disease. Initially, broad-spectrum antibiotics were prescribed while infection was being ruled out. On admission, he had a maculopapular rash that involved the arms and legs. In the subsequent 2 days the rash became pustular and progressed to involve the trunk, palms and soles. Cultures were negative and a skin biopsy was done. The clinical presentation and the skin biopsy findings were consistent with azathioprine-induced hypersensitivity reaction presenting with acute febrile neutrophilic dermatosis (Sweet's syndrome). AZA was stopped and there was quick, complete resolution of the rash.
DISCUSSION: AZA hypersensitivity syndrome is a rare adverse side effect presenting with fever, variable cutaneous eruption, neutrophilic dermatosis being the most common, and inflammation of one or more internal organ including the liver, kidneys, lungs and/or heart. This syndrome is a dose independent reaction that tends to occur during the first 4 weeks of therapy. It is thought to represent a type III or IV hypersensitivity response. Most cases resolve within 2–3 days after withdrawal of the medication and may not need corticosteroids use. Re-challenge with AZA is not recommended.

NOT JUST PNEUMONIA: A "SHOCKING" TURN OF EVENTS Katarzyna Mastalerz; Mary Maher. Denver Health, Denver, CO. (Tracking ID #1640101)

LEARNING OBJECTIVE 1: Recognize myocarditis as a cause of acute-onset shock in young healthy patients
CASE: A 34-year-old previously healthy woman presented with three days of dyspnea and left sided chest pain. She was tachycardic and had left lower lung-field crackles. An ECG showed sinus tachycardia with low voltage and nonspecific T wave changes. Her chest radiograph showed a left lower lobe infiltrate and borderline cardiomegaly. Basic laboratory studies were normal, except for a positive D-dimer. A CT scan of the thorax revealed no pulmonary embolic disease. She was treated with intravenous fluids and antibiotics targeted at community-acquired pneumonia. Within hours, her tachycardia worsened and she developed bilateral pulmonary crackles, and an S3 gallop. She then became diaphoretic, tachypneic, and collapsed due to a pulseless arrest. Cardiopulmonary resuscitation was initiated, with several restorations of circulation, but was ultimately unsuccessful despite maximal efforts. The autopsy revealed severe acute myocarditis and viral pneumonia. This pathology combined with a rapidly deteriorating clinical course is consistent with fulminant viral myocarditis.
DISCUSSION: Myocarditis is found in 22 % of autopsies of young healthy adults with sudden cardiac death. Most patients present with a progressive dilated cardiomyopathy. Fulminant myocarditis is a rare subtype (estimated incidence of one case per year in the US) that presents as acute cardiogenic shock. It is typically preceded by a viral prodrome. The most common etiology is infectious (predominantly viral), but toxic and immunologic causes have been reported. Echocardiography, cardiac biomarkers, and cardiac MRI are often included as part of the evaluation, but endomyocardial biopsy is the gold standard for diagnosis. Most cases temporarily require inotropic support, intraaortic balloon pumps, or ventricular assist devices. Surprisingly, cardiac transplantation is not recommended for fulminant cases because patients who survive the initial shock recover cardiac function completely. Physicians should recognize myocarditis as a cause of acute-onset shock in young healthy patients,

particularly in those with preceding viral syndromes. Rapid recognition of this condition and referral to a heart failure center are essential as patients who are supported through the initial shock have an excellent prognosis.

OLANZAPINE INDUCED CUTANEOUS LEUKOCYTOCLASTIC VASCULITIS Paras Karmacharya; Madan R. Aryal; Anthony A. Donato. Reading Health System, West Reading, PA. (Tracking ID #1645260)

LEARNING OBJECTIVE 1: Recognize olanzapine as a cause of cutaneous leukocytoclastic vasculitis.
LEARNING OBJECTIVE 2: Discuss the management of drug induced leukocytoclastic vascultitis.
CASE: A 58-year-old female with multiple psychiatric issues including bipolar disorder presented with altered mental status and a diffuse rash. The patient was very lethargic but was able to respond to questions when aroused and was oriented to time, place and person. She had been started on olanzapine 7 days back. On exam, the patient was hemodynamically stable. A diffuse erythematous rash over the patient's trunk and proximal arms was noted. The rash was non-blanching and contained many macules. A darker erythematous petechial rash was noted over the lower extremities distal to the knees. The patient was treated with supportive management and in the absence of another explanation, olanzapine was held and her rash got significantly better. She was found to be positive for ANCA against Myeloperoxidase. However, ANCA Proteinase 3 antibody was negative and other work ups for her rash including C3/ C4 complement and cryoglobulin levels were within normal limits. She also tested negative for hepatitis B, C and HIV.
DISCUSSION: Patients with hypersensitivity vasculitis exhibit at least three of the following features: age >16, use of a possible offending drug, palpable purpura, maculopapular rash, and biopsy of a skin lesion showing neutrophils around an arteriole or venule(4 out of 5 present in our case). Cutaneous Leukocytoclastic Vasculitis only involves the skin and spares internal organs. It may be idiopathic, drug induced, or occur in association with a known disorder, such as infection eg. hepatitis C. Cutaneous leukocytoclastic vasculitis is an infrequently reported adverse drug reaction associated with olanzapine. Its pathogenic mechanism is not known exactly, but both cell-mediated and humoral immunity appear to be involved. A high index of suspicion is necessary to make a diagnosis as both idiopathic and drug induced are identical both clinically and serologically. Removal of the inciting drug usually leads to resolution of the symptoms within a period of days to a few weeks. In patients with more severe or persistent cutaneous disease, drugs such as colchicine, antihistamines, and dapsone, may be helpful. Immunosuppressive therapy with glucocorticoids or cytotoxic agents should be reserved for fulminant or progressive disease.

OPIATE ENDOCRINOPATHY: FOOD FOR THOUGHT Pratik K. Dalal; Divyashree Varma. SUNY-Upstate Medical University Hospital, Syracuse, NY. (Tracking ID #1642301)

LEARNING OBJECTIVE 1: Recognize endocrine side effects of Opiate therapy
LEARNING OBJECTIVE 2: Diagnosis and management of Opioid induced endocrine dysfunction
CASE: 44 year old female presented with syncopal events and was found to be orthostatic in the absence of a history of dehydration.A low cortisol level was discovered at 1.9 mcg/dl. Low dose ACTH stimulation test resulted in an increase to 13.6 mcg/dl suggesting adrenal insufficiency. She was started on hydrocortisone. Labs showed a low ACTH level at <5 pg/ml, normal prolactin level at 4.1 ng/ml, high FSH at 22.8 mU/ml and estradiol at 25.8 pg/ml. She was found to have oxycodone in her possession and admitted to long term abuse. Incidentally she had been evaluated 2 years ago for hyperadrenalism and suspected Cushing's syndrome when her cortisol level was noted to be 19.5 mcg/dl. Did she over treat herself with narcotics to now result in adrenal insufficiency?
DISCUSSION: Methadone related endocrine dysfunction was recognized in the 1980s. Sexual dysfunction has long been known in heroin addicts. Opiate endocrinopathy continues to be the least diagnosed consequence of chronic narcotic therapy. These effects have been attributed to μ-receptor agonism in the hypothalamus and considered a class effect for these agents. Side effects of long term opioid therapy include decreased libido, decreased muscle mass, erectile dysfunction, anemia, depression, fatigue, menstrual irregularities, osteoporosis. These stem from sex hormone deficiency and adrenal suppression secondary to Hypothalamic-Pituitary-Adrenal Axis (HPA) and Hypothalamic-Pituitary-Gonadal-Axis (HPG) suppression. Low testosterone levels have been reported in men on chronic narcotic therapy. In women alteration of the pulsatile luteinizing hormone secretion causes menstrual problems. Decreased stress cortisol response has also been shown in animal experiments. Single dose of morphine can abruptly blunt cortisol secretion. Intrathecal opioids have shown to cause hypogonadotrophic hypogonadism It should be considered in patients receiving opiates equivalent of 100 mg of morphine. Δ and κ receptors seem to be involved in ACTH control while gonadotropin secretion seems to be modulated by ε receptors. Diagnosis begins with knowledge and vigilance for symptoms and signs. In men with hypogonadism, testosterone levels should be obtained. In women, Dihydroepiandrosterone sulphate (DHEAS) may prove to be a good marker of adrenal activity. Low cortisol levels with an inappropriate rise with ACTH stimulation test may also be seen suggesting adrenal insufficiency. Testosterone remains the mainstay of therapy in men with hypogonadism. Adrenal insufficiency requires hormone supplementation. Opioid rotation with different agents may prove helpful too.

OSLER-WEBER-RENDU SYNDROME:- THE DRIPPING TRUTH! Aakash Aggarwal; Badal Kalamkar; Arman Khorasani-zadeh; Meghan Rane; Emerald Banas. SUNY Upstate Medical University, Syracuse, NY. (Tracking ID #1637581)

LEARNING OBJECTIVE 1: Review the incidence, clinical features, diagnosis and management of HHT.
LEARNING OBJECTIVE 2: Emphasize the importance of comprehensive history taking and physical examination to pick up 'zebra' diagnoses from the horses
CASE: 61 year old Caucasian male presented to the emergency room with sudden onset nausea and severe cramping abdominal pain. CT Abdomen revealed a superior mesenteric vein thrombus. The patient was started on anticoagulation with bridging with Heparin drip and then LMW Heparin and discharged to home with eventual transition to warfarin and close follow up with the anticoagulation clinic. The patient started to have significant episodes of epistaxis upto 7-10 episodes a week, and had several episodes of bleeding from the tongue as well. At this time, ENT referral was made and several vascular ectasias in his nasal cavity were found. Due to trouble with anticoagulation, a repeat CT scan of the abdomen was done which showed resolution of the superior mesenteric vein thrombus but also revealed small nodules at the base of the lung. Anticoagulation was held and a CT chest was done. CT chest showed several bilateral pulmonary nodules with vessels entering and exiting, and distinctly rounded appearance consistent with arterio-venous malformations (AVM's). CTA Head was negative for cerebral AVM's. Detailed history taking revealed that since childhood the patient had had episodes of mild epistaxis 1-2 times a month, and other family members also had similar symptoms. In fact the patient's father had been told that he was hemophiliac and the patient himself had been tested and deemed negative for hemophilia. Also the patient had been diagnosed with iron deficiency anemia, was on iron supplementation after a normal GI endoscopy and colonoscopy. Careful physical examination revealed several mucocutaneous telengectasias on the lips and tongue and several AVM's on the ear lobes. Given all of the above history and clinical symptoms a diagnosis of Hereditary hemorrhagic telengectasias(HHT) was made and patient was referred to Interventional Radiology for coil embolization of pulmonary AVM's to prevent pulmonary hemorrhage, paradoxical emboli, strokes and cerebral abcesses.
DISCUSSION: HHT or Osler-Weber syndrome, first recognized in the 19th century is an autosomal dominant vascular disorder with abnormal vascular

structures causing bleeding from the nose and GI tract. Prevalance is between 1:5000 and 1:8000 with much higher rates in certain geographical populations like Afro-Caribbean residents of Curacao and Bonaire. Epistaxis is usually the earliest sign of disease and pulmonary AVM's generally become apparent after puberty. By the age of 16 years approximately 70 % individuals will have developed some clinical sign of HHT. International consensus diagnostic criteria (Curacao criteria) are as follows- 1) Spontaneous and recurrent epistaxis 2) Multiple mucocutaneous telengectasias 3) Visceral involvement (GI,pulmonary,hepatic or cerebral AVM's) 4) 1st degree relative with HHT. These criteria define 'definite', 'suspected', and unlikely HHT when three or four, two, or zero to one of these criteria are present respectively. Management of HHT involves management of the GI bleed or epistaxis etc. similar to management as in a patient without HHT. Guidelines also recommend treating pulmonary AVM's to prevent stroke, medical management or liver transplantation for hepatic AVM's but screening for cerebral AVM's remains controversial.

POSSIBILITIES WITH VASCULITDITIES: PLEURAL EFFUSION AS THE PRESENTATION OF MICROSCOPIC POLYANGIITIS
Cady Blackey; Logan Davies. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1639852)

LEARNING OBJECTIVE 1: Review how to diagnose ANCA-positive vasculidities.
LEARNING OBJECTIVE 2: Recognize an unusual pulmonary manifestation of MPA. Identify causes of lymphocytic predominate pleural effusion.
CASE: A forty-one year-old gentleman with a history of delusional disorder and gastro-esophageal reflux disease presented to the hospital with non-bilious, non-bloody emesis for 2 weeks. He denied change in bowel habits, early satiety or abdominal pain but did report fevers and a 40-pound weight loss over 4 months. He denied sick contacts or travel. Review of systems revealed fatigue and worsening dyspnea on exertion; however, he denied chest pain, cough or palpitations. Family history was negative for malignancy or rheumatologic disease. Physical exam revealed a comfortable man with a BMI of 23. He was tachycardic, with absent breath sounds and dullness to percussion in the left posterior lung field. His abdomen was normal. He had no cyanosis, clubbing or edema. Neurologic, HEENT, skin and musculoskeletal exams were benign. Laboratory studies revealed a microcytic anemia, no leukocytosis, creatinine of 6.2, and normal LFTs. Urinanalysis revealed proteinuria and hematuria but the patient was non-oliguric. Chest x-ray illustrated a left-sided pleural effusion. Subsequent thoracentesis demonstrated a lymphocytic predominate exudate. Over the next few days, he developed hemoptysis and a new opacity on chest x-ray, consistent with diffuse alveolar hemorrhage. Further work-up revealed an atypical p-ANCA titer of 1:320 and MPO ANCA of 52. Renal biopsy showed ¬¬¬¬¬pauci-immune crescentic glomerulonephritis with focal glomerular collapse. IV cyclophosphamide was started with swift improvement in his renal and pulmonary function.
DISCUSSION: Vasculidities can overlap in their clinical presentation, often causing skin, kidney and/or lung injury. An internist often orders studies to confirm a suspicion of vasculitis. Usually, elevated p-anca is seen in MPA, though normal ANCA does not rule out the disease. If elevated, MPO-ANCA is more specific to MPA, while elevated PR3-ANCA is associated with Wegener's. Normal ANA, c-ANCA, PR3-ANCA and negative Anti-AGBM help rule out other vasculidities that present similarly. In this case, the combination of positive serology, the pleural effusion, and the renal biopsy confirm microscopic polyangiitis. MPA is a small vessel, ANCA-associated vasculitis that causes pulmonary capillariitis and glomerulonephritis. There is renal involvement in 80–100 % of MPA cases, which is confirmed by focal segmental glomerulonephritis on biopsy up to 100 % of the time. Pulmonary involvement occurs in only 25–55 % of patients with MPA, usually as hemoptysis or diffuse alveolar hemorrhage. However, a wide variety of lung disease can be seen in MPA and include the following: pleural effusion, pulmonary edema, pleuritis or interstitial fibrosis. Though a pleural effusion is a rare manifestation of MPA, pleural effusions are commonly encountered by internists. The differential for a lymphocytic predominant effusion includes only a few diseases: TB, lymphoma, sarcoidosis, chylothorax and autoimmune diseases. Vasculidities are less often seen. But clinicians should be wary of unusual presentations as significant morbidity, including dialysis and permanent lung injury, can be avoided with prompt treatment.

PTHRP INDUCED REFRACTORY MALIGNANT HYPERCALCEMIA IN A PATIENT WITH CHRONIC LYMPHOCYTIC LEUKEMIA
Ameen Salahudeen[1]; Pramod Pinnamaneni[1]; Madhuri Vusirikala[1,2]; Rob Cowan[3]; Chi Yin G. Kwong[1,2]; Harris Naina[1,2]. [1]UT Southwestern Medical Center, Dallas, TX; [2]UT Southwestern Harold C. Simmons Comprehensive Cancer Center, Dallas, TX; [3]McMaster University, Hamilton, ON, Canada. (Tracking ID #1642914)

LEARNING OBJECTIVE 1: Recognize that malignant hypercalcemia in leukemia and lymphoma can be mediated by PTHrP
LEARNING OBJECTIVE 2: Manage PTHrP induced hypercalcemia refractory to first line therapy
CASE: A 35 year old male was diagnosed with Chronic Lymphocytic Leukemia (CLL) after workup of a neck mass. He then completed 6 cycles of fludarabine, cyclophosphamide and rituximab (FCR) with complete response when he was restaged six months later. However after two months the patient's disease recurred after he presented with right hip pain and was found to have destructive bone lesions. He was also found to have malignant hypercalcemia and was effectively treated with hydration and zolendronate. Additional chemotherapy with FCR or bendamustine with rituximab did not affect the bony lesions but radiation therapy proved efficacious. A bone marrow biopsy demonstrated persistent CLL. The patient then underwent rituximab, ifosfamide, carboplatin, and etoposide (RICE) salvage therapy and was discharged. A month later, the patient was readmitted for neutropenic fever and his calcium had increased to 13 mg/dL. Antibiotics, IV fluids, calcitonin, and zolendronate were administered. The patient's calcium normalized and laboratory studies revealed Parathyroid Hormone related Protein (PTHrP) elevated at 7.1 pmol/L (normal<2 pmol/L), low PTH, and low vitamin D. A repeat bone marrow biopsy showed 90 % CLL that was positive for PTHrP on immunohistochemistry. He was initiated on alemtuzumab for refractory CLL and antibiotics were continued. Shortly thereafter the patient's hypercalcemia recurred and was treated with gallium nitrate for five days. Calcium levels improved to 10.8 mg/dL after treatment but after several days suddenly increased to 21.3 mg/dL prompting emergent dialysis. The patient also received the anti-RANK ligand agent denosumab and achieved a sustained resolution of his hypercalcemia. PTHrP at that time improved to 2.5 pmol/L. The patient was discharged to hospice after a negative infectious workup.
DISCUSSION: Malignant hypercalcemia is a common paraneoplastic process seen in solid tumors and to a lesser degree in hematological malignancies. For example, only a tenth of patients with non-Hodgkin's lymphomas develop hypercalcemia. For CLL, only a few cases have been reported. Malignant hypercalcemia occurs via bone destruction from metastatic lesions or humoral factors that increase calcium through osteoclast activation. One important signaling pathway in osteoclast activation involves the receptor activator of nuclear factor kappa-B (RANK) membrane receptors. RANK is upregulated by RANK-ligand, a cytokine secreted by stromal cells that is in turn up regulated by factors such as PTH or PTHrP. PTHrP is a peptide that plays physiological roles in tissues including smooth muscle and the pancreas. In malignancy, PTHrP is believed to promote tumor growth by inducing bone resorption around cancer cells. Management of malignant hypercalcemia consists of treating the underlying disease, hydration, anti-bone resorption agents including calcitonin and bisphosphonates. Here, a patient with a rare PTHrP secreting CLL developed remarkable hypercalcemia requiring dialysis and the anti-RANK ligand agent denosumab. Interestingly, the patient's hypercalcemia had a rapid and sustained response to denosumab that also correlated with a decrease in PTHrP levels. In CLL and other hematological malignancies with malignant hypercalcemia, PTHrP should be evaluated and denosumab may be considered for refractory cases.

PURPURA FROM PENIA, ALL PENDING PLATELET POWER Rachel Sandler. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1641565)

LEARNING OBJECTIVE 1: Recognizing the clinical presentation of Immune Thrombocytopenic Purpura
LEARNING OBJECTIVE 2: Recognizing the relationship between Antiphospholipid Antibodies and Immune Thrombocytopenic Purpura
CASE: A 46-year-old woman presented with of intermittent easy bruising. She denied any epistaxis, gingival bleeding, melena, hematochezia, hematemesis, or menorrhagia. She noted heavy vaginal bleeding after her first pregnancy, which resolved on its own with two subsequent uncomplicated pregnancies. She had no history of alcohol, drug or tobacco abuse and was originally from El Salvador. She had no family history of cancers, bleeding or clotting disorders. Her home medications included lisinopril and hydrochlorothiazide. Her physical exam revealed a pleasant woman in no distress. Her gums were without evidence of bleeding and her palate was without petechiae. Her cardiac and lung examination were within normal limits. Abdominal exam revealed mild epigastric tenderness without rebound or guarding and no hepatosplenomegaly. Extremities showed diffuse petechiae in the bilateral legs and scant bruising on the right upper thigh. Her platelet count was found to be 14×103/uL and she was mildly anemic with hemoglobin of 11.9 g/dL. White blood cell count was within normal limits. Her partial thromboplastin time was elevated at 49.9 s and was not effected with a mixing study. Her prothrombin time and INR were within normal limits. Dilute Russell viper venom and anti phospholipid antibodies were elevated with high lupus anticoagulant I. ANA, HIV, and Hepatitis Panel were negative. Peripheral blood smear showed no evidence of blast cells with few large platelets. She was treated with prednisone at 1 mg/kg with improvement in her platelet count with a gradual taper over the 2 months after hospital discharge.
DISCUSSION: Immune Thrombocytopenia Purpura (ITP) is a common hematologic disorder associated with isolated thrombocytopenia in the absence of other secondary explanations, such as HIV, antiphospholipid syndrome, or systemic lupus erythematosus that can be readily identified by the general internist. In women ages 40 to 59 to the incidence is over twice that of men, but is found equally among the genders as they age. As the name suggests, purpura are common along with petechiae and easy bruising; however, frank gastrointestinal bleeding and hematemesis are uncommon. In this case, the initial complete blood count concerning for ITP, especially in the context of negative evaluation for associated secondary causes with normal peripheral smear, negative ANA, and negative HIV. However, her isolated elevation in partial thromboplastin time merited further evaluation and lack of correction with mixing study suggested an inhibitor. Antiphospholipid antibodies, particularly anti-beta 2 glycoprotein, anticardiolipin, and antiphosphatidylserine, have been associated with exacerbations of ITP and have been found in up to 70 % of patients with ITP. In addition, the identification of antiphosholipid antibodies, particularly lupus anticoagulant, in patients with ITP may lead to increased risk of thrombosis and development of antiphospholipid syndrome. Recognition of the risk for antiphosholipid syndrome in patients with ITP who are lupus anticoagulant positive can help identify patients at risk of developing antiphospholipid syndrome.

PUTTING THE "EYE" IN SYPHILIS Sancia Ferguson; Jeff Percak. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640249)

LEARNING OBJECTIVE 1: Recognize the ocular presentations of syphilis
LEARNING OBJECTIVE 2: Understand the relationship between ocular syphilis and neurosyphilis. Interpret the different laboratory studies for diagnosing syphilis.
CASE: A 28-year old woman presented with one week of a deep aching pain in her right eye with radiation to the back of her head. The pain was exacerbated with eye movements. She also described blurred vision in the right eye over the same time period. She had a history of migraine headaches, traumatic C4 fracture three years ago and hypertension. Physical examination demonstrated visual acuity of 20/100 in the right and 20/20 in the left eye. Extra-ocular movements were intact but painful. Slit lamp examination revealed mild periorbital edema and 2+ conjunctiva and scleral injection on the right. Dilated fundus exam noted mild blurring of the disk margin nasally. Initial laboratory studies noted normal electrolytes, a negative rapid HIV, and a normal uric acid level. B scan ultrasonography was notable for posterior scleral thickening, lateral greater than medial, which was confirmed by CT scan of the orbits. She was sent home with a one-week course of prednisone and ibuprofen with a presumptive diagnosis of scleritis. Further serologies were pending. Initially, she had relief from pain and improved vision while treated with prednisone and ibuprofen. However, two weeks later these symptoms had returned. Her RPR was 1:16; treponomal pallidum partial agglutination was reactive. Her ANA was 1:80 with a speckled pattern. She was admitted for lumbar puncture and treatment of neurosyphilis with Penicillin G Benzathine. CSF revealed VDRL was non-reactive and a lymphocytic pleocytosis was noted on the cell count.
DISCUSSION: Despite a minor decrease in syphilis rates in the United States, syphilis continues to be a disease encountered by the general internist. Recognizing the uncommon manifestations of syphilis not only improves the diagnosis and treatment of syphilis, but also other sexually transmitted infections. Syphilitic-related eye disease can occur at any stage and presents in a variety of ways. Ocular manifestations include chancres of the eyelid and conjunctiva, blepharitis, scleritis, episcleritis, conjunctivitis, Argyll Robinson pupil, madarosis, neuroretinitis, and uveitis. Though data is limited, uveitis may be the most common ocular presentation in patients infected with HIV. In patients with HIV, the presentation is often bilateral, more severe, and frequently involves the posterior segment of the eye. There does not appear to be a correlation between CD4 count and the presence of ocular involvement. Ocular syphilis is treated as neurosyphilis and therefore must be treated with intravenous penicillin G. A diagnosis of ocular syphilis is made with non-treponemal tests such as an RPR or VRDL, measuring IgM and IgG to anticardiolipin cholesterol lecithin antigens. This is confirmed with a direct treponemal test such as the fluorescent treponemal antibody test (FTABS) or the microhemagglutination assay that measures antibodies to treponemal cellular components. A positive CSF VDRL or a lymphocytic pleocytosis in CSF fluid is also confirmatory. The need for CSF analysis is debated as treatment does not change, but should probably be done, especially in patients with HIV.

PALSIES AS HARBINGER: DIAGNOSIS OF ACUTE HIV IN A PATIENT WITH POLYCRANIAL NERVE PALSIES Stella Safo. Montefiore Medical Center, New york, NY. (Tracking ID #1641124)

LEARNING OBJECTIVE 1: To recognize polycranial palsy as a rare manifestation of acute HIV infection.
LEARNING OBJECTIVE 2: To review the differential diagnosis of polycranial palsy.
CASE: A 44 year-old woman presented with lymphadenopathy, fevers, decreased right-sided sensation, abnormal right-sided facial movement, and decreased hearing on right. One week prior to admission, she noted right-sided facial numbness and difficulty closing her right eye along with asymmetric smile. She reported intermittent fevers and palpable auricular nodes that increased in size over a month period. The patient reported no history of trauma and denied recent travel or camping; no insects bite. She had a negative HIV test done 5 months ago but reported recent unprotected sexual intercourse with one male partner. Her exam revealed decreased sensation in trigeminal V1-V3 distribution, decreased hearing on right and complete seventh nerve palsy on the right. She had tender lymphadenopathy in the occipital and posterior-auricular distribution. Ear exam was unremarkable. No skin rashes or tick bites were noted. No other focal neurologic deficits. An MRI brain with gadolinium was unremarkable. Lyme titers were negative. ACE level was within normal limits. Subsequent HIV testing revealed an HIV viral load of 163,774 and CD4 of 332. She was started on antiretroviral therapy along with empiric steroid treatment and had partial recovery of her neurological symptoms.

DISCUSSION: While acute HIV infection has been known to produce a viral-like syndrome with neurologic involvement potentially ranging from neuropathy to encephalopathy, polycranial nerve (CN) palsy remains a fairly rare manifestation of acute seroconversion. A review of literature offers mainly case reports of this phenomenon. One case report identified a newly infected man who presented with bilateral seventh CN palsy; workup for other infectious causes was negative and his condition was ascribed to acute HIV infection. A 2007 review of literature to identify CN palsies caused by HIV seroconversion produced 10 cases. All cases presented with facial palsies, had onset of neurologic symptoms occurring within 15 days of HIV seroconversion; many were associated with concomitant aseptic meningitis. All but one of these cases had spontaneous resolution of CN palsies. The differential diagnosis for polycranial nerve palsy includes but is not limited to sarcoidosis, bacterial infection of middle ear, cholesteatomas (tumor of middle ear), multiple sclerosis, and lyme disease. In this patient, the lack of other sarcoid features and negative ACE level makes sarcoidosis unlikely; the lack of acute ear pain and normal ear exam disqualifies bacterial ear infection; and the lack of lesions or masses on imaging made cholesteatomas and MS unlikely. The patient's lyme titers were negative, as were her lyme risk factors. In conclusion, while the literature remains scarce, it is wise to consider HIV seroconversion as a potential cause of polycranial nerve palsy in order to ensure that a thorough diagnostic work-up is undertaken from the outset.

PANCREATIC NEUROENDOCRINE TUMOR AS PRESENTATION OF MEN I SYNDROME John Szymusiak; Reed Van Deusen. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1624108)

LEARNING OBJECTIVE 1: Recognize the need to evaluate for Multiple Endocrine Neoplasia Type 1 (MEN I) in patients with Zollinger-Ellison Syndrome (ZES).
LEARNING OBJECTIVE 2: Manage the special needs of patients with known MEN I.
CASE: The patient is a 22 year old female with no past medical history who presented to the hospital with several months of weight gain and fatigue. She was found to be Cushingoid in appearance with moon facies, a buffalo hump, and abdominal striae. She had elevated urinary cortisol levels, as well as elevated adrenocorticotropic hormone (ACTH) levels which did not suppress with either low or high dose dexamethasone. A CT scan showed a liver mass and no source of her elevated ACTH. During the course of her evaluation, she developed coffee ground emesis, melena, and anemia. An EGD showed numerous duodenal ulcers concerning for ZES and the patient was found to have elevated gastrin and Chromogranin A levels. Given the concern for a neuroendocrine tumor, an endoscopic ultrasound was performed and showed a pancreatic mass. Subsequent octreotide scan and whole body PET/CT confirmed the masses in both the pancreas and liver, and biopsies of both were obtained. The pancreatic mass was found to have rare ACTH secreting cells and about 20–40 % gastrin secreting cells. It was believed that the tumor was a primary pancreatic neuroendorcine tumor which metastasized to the liver. The patient was tested for the MEN I gene mutation, which was found to be present in both her and her mother. The patient had no evidence of hyperparathyroidism as her calcium levels were within normal limits throughout her hospitalization. MRI of the head did show minimal heterogeneity of the anterior pituitary, which could represent a microtumor, but no evidence of a macroadenoma.
DISCUSSION: MEN I is an autosomal dominant genetic syndrome characterized by a predisposition to parathyroid gland, anterior pituitary, and pancreatic neuroendocrine tumors. Adenomas of the parathyroid gland are the most common tumors in this syndrome, appearing in nearly 100 % of patients by 40–50 years of age. As such, hypercalcemia is the most common presenting symptom of MEN I. However, 60–70 % of MEN I patients eventually exhibit signs of a pancreatic neuroendocrine tumor, of which ZES is the most common manifestation. It is estimated that 60 % of MEN I patients have either ZES or elevated gastrin levels, and that anywhere from 20 % to 60 % of patients with ZES will be found to have MEN I syndrome. Therefore, it is important that patients who present with ZES be tested for MEN I syndrome, as they may be at risk for further neoplasms. Patients with known MEN I should have annual calcium levels checked to screen for parathyroid adenomas. Clear consensus regarding monitoring for biochemical signs of pituitary adenomas is lacking, but patients should certainly be monitored for clinical signs of these tumors including amenorrhea, galactorrhea, and erectile dysfunction.

PANTOPRAZOLE: A REAL CAUSE OF ACUTE RENAL FAILURE Divyashree Varma; Pratik K. Dalal. SUNY-Upstate Medical University Hospital, Syracuse, NY. (Tracking ID #1642355)

LEARNING OBJECTIVE 1: Recognize Pantoprazole as a potential cause of acute interstitial nephritis
LEARNING OBJECTIVE 2: Diagnosis and treatment of acute interstitial nephritis
CASE: Patient is a 48 year old Caucasian male with the past medical history of anaplastic large T-cell lymphoma who received 3 cycles of CHOP treatment in May of 2012, but because of splenic necrosis warranted substitution of CHOP for carboplatin, ifosfamide, and etoposide (ICE) in August 2012 The patient had episodes of AKI during this time, all presumed secondary to pre-renal azotemia owing to symptomatology and improvement in renal function with isotonic volume expansion. Well after chemotherapy had ended, however, renal function began to slowly deteriorate reaching a creatinine of 6.1 mg/dL by September, 2012. Initially felt to be ATN secondary to chemotherapy, a fresh set of Nephrology "eyes" recognized the institution of pantoprazole therapy at some point during the summer of 2012. The pantoprazole was discontinued, and a renal biopsy was performed revealing an acute lymphocytic infiltrate with additional staining revealing no evidence of malignancy of infectious etiology. Owing to patient's urgent need for a hematopoietic cell transplant and the need for reasonable renal function to undergo the transplant, oral steroid therapy was added in the hope of accelerating renal recovery. Three weeks after pantoprazole cessation and two weeks after steroid initiation, the creatinine had dropped to 3.6 mg/dL.
DISCUSSION: Acute interstitial nephritis (AIN) is characterized by the presence of an inflammatory cell infiltrate in the interstitum of the kidney. It may be present in up to 15 % cases of acute renal failure. Causes of AIN include: drug hypersensitivity, infections, autoimmune, idiopathic, and glomerular disease. Malaise, nausea, vomiting, and oliguria are the commonest presenting symptoms. The gold standard for diagnosis is renal biopsy. A lesser known, but potentially important cause of AIN is pantoprazole based on its ubiquitous use, especially in the critically ill who may have pre-existing renal compromise. We present a case of a 48 year old male patient with worsening renal function that is thought to be secondary to pantoprazole wherein renal function improved following withdrawl of pantoprazole and institution of steroids. The incidence of pantoprazole induced AIN in the USA is not currently known likely due to concurrent confounding medications that may co-administered. Commonly used for stress ulcer prophylaxis in the hospital setting, it is prudent that we ensure that worsening renal failure is not secondary to drug induced AIN. Steroids are most beneficial in the acute phase of AIN. Once fibrosis has set in, stopping the offending agent is the only option. Our patient was diagnosed with pantoprazole induced AIN given the temporal correlation between the initiation of the drug and renal dysfunction. The absence of fibrosis on renal biopsy voted against chemotherapy induced AIN given the time relation again. Therefore, given AIN with active inflammatory infiltrate it was assessed that the renal injury was secondary to pantoprazole which improved with cessation and prednisone. In the end, it was a fresh set of "eyes" that may have saved the kidneys.

PEARLS IN BREAST CARE FOR THE GENERAL INTERNIST Dietlind L. Wahner-Roedler. Mayo Clinic, Rochester, MN. (Tracking ID #1632604)

LEARNING OBJECTIVE 1: To recognize that molecular breast imaging may be used as an adjunct to mammography in screening women with dense breasts.

LEARNING OBJECTIVE 2: To reinforce that atypical ductal hyperplasia on core needle biopsy requires surgical excision.
CASE: A 48 year old woman presented to the Breast Clinic for her annual breast examination and mammogram. Breast examination was normal; mammogram showed dense breasts (D4) and was read as negative. Based on her mammographic breast density the patient was invited to participate in our Molecular Breast Imaging (MBI) study. MBI showed a focal area of moderate radiotracer uptake in the 12 o'clock position of the left breast (3.2×2×2 cm). Focused ultrasound examination of this area showed an indeterminate hypoechoic focal area with posterior shadowing (1.4×0.9×0.9 cm). Ultrasound-guided core needle biopsy was performed revealing atypical ductal hyperplasia (ADH). This was followed by an excisional biopsy which showed sclerosing adenosis with scattered ductal carcinoma in situ (DCIS) over an extent of 5 cm, margins were negative. After postoperative discussion the patient requested a mastectomy. Pathology revealed an additional area of DCIS (0.7×0.6×0.5 cm).
DISCUSSION: This case illustrates 2 important breast issues: 1. MBI may serve as a valuable complementary screening imaging technique for women with mammographically dense breasts. The sensitivity of mammography to detect small lesions decreases with increased breast density. Estimates of mammographic sensitivity in women with extremely dense breasts range from 30 % to 63 %. Addition of MBI to mammography has been shown to increase the detection of node negative breast cancer in dense breasts by 7.5 per 1000 women screened. MBI, a nuclear medicine technique utilizes small semiconductor-based gamma-cameras in a mammographic configuration and provides high-resolution functional images of the breasts independent of breast density. Imaging is done after IV injection of Tc-99 m sestamibi (currently 20 mCi) with the breast lightly compressed between two detectors. Images of each breast are acquired in the craniocaudal and mediolateral oblique projections facilitating comparison with mammography. In a screening study including women with high breast density performed at Mayo Clinic the sensitivity for mammography was 27 %, and the specificity 91 %, and for MBI 82 %, and 93 % respectively. The main disadvantage of MBI is the radiation dose associated with the injection of 20 mCi Tc-99 m sestamibi: 6.5 mSv compared to 0.7–1.0 mSv for a screening mammogram. With the implementation of radiation dose reduction techniques to less than 4 mCi yielding comparable radiation exposure as screening mammography, MBI may offer an effective supplement imaging technique to the subgroup of women with dense breasts. A low dose MBI study is presently being done at the Mayo Clinic. 2. ADH noted on core needle biopsy requires surgical excision. Since ADH can coexist with a breast malignancy patients with ADH on core needle biopsy require an excisional biopsy to rule out ductal carcinoma in situ or invasive cancer. The rate of carcinoma found in subsequent excisions has been reported to range between 11 % and 62 % in different series.

PERICARDIAL FAT NECROSIS: A RARE CAUSE OF ACUTE CHEST PAIN Sarah Hess; Satya Bhupathi; Sreelatha Chalasani. Marshfield Clinic, Marshfield, WI. (Tracking ID #1642826)

LEARNING OBJECTIVE 1: Pericardial fat necrosis is a rare, yet important, cause of acute chest pain.
LEARNING OBJECTIVE 2: Pericardial fat necrosis can be diagnosed by CT scan or MRI and managed as a self-limited disease treated with NSAID therapy.
CASE: A 51-year-old obese male with a history of obstructive sleep apnea presented in the emergency room complaining of severe precordial chest pain with radiation to his neck and left arm for the past 4 days. The pain was squeezing in nature and was worse with inspiration and physical activity. Physical examination was normal. The patient had a normal complete blood count, basic metabolic panel, d-dimer, and lipid panel. He did have an elevated ESR and CRP but cardiac enzymes were negative. A pericarditis and myocarditis panel was negative. EKG showed normal sinus rhythm with T wave inversion in lead 3 and AVF. Echocardiogram showed normal left ventricular systolic function with estimated left ventricular ejection fraction greater than 65 % and no obvious regional wall motion abnormalities. Given the typical presentation of chest pain and negative cardiac enzymes, the patient underwent a regadenoson myocardial perfusion scan, which did not show any inducible ischemia. The patient continued to have severe chest pain, so a chest CT scan was ordered to further evaluate other causes. The CT scan showed the presence of prominent pericardial fat. On the left side, increased radiodensity involving the superior aspect of the left pericardial fat pad was noted and raised concerns of fat necrosis. A cardiac MRI was performed for further evaluation of the fat necrosis. A 1.6×1.5 cm focus of uncertain etiology was noted along the superior aspect of the left pericardial fat pad. The focus observed did not have a significantly increased T2 signal. Discussion with the radiologist and cardiologist determined that subacute or old pericardial fat necrosis could not be excluded. The patient was treated with NSAID therapy and responded well with cessation of chest pain.
DISCUSSION: Pericardial fat necrosis is a rare, self-limited, and benign cause of acute chest pain. Pericardial fat necrosis as a cause of acute chest pain was first reported in 1957, since that time only 26 cases have been reported in the literature. Pathogenesis is unclear, but obesity is considered a predisposing risk factor. Before the advent of CT scan, diagnosis was based on abnormal chest radiograph and surgery. Current imaging technologies allow for diagnosis by CT scan and/or MRI. MRI findings of fat necrosis may be variable depending on the pathological stage of fat necrosis. Pericardial fat necrosis is a self-limited disease and treated with NSAID therapy.

PERITONEAL MESOTHELIOMA WITH PERSENTATION OF DERMATOMYOSITIS Manivel Eswaran[1,2]; Muhammad Ansar[1]. [1]Geisinger Medical Center, Danville, PA; [2]Temple University, Philadelphia, PA. (Tracking ID #1641739)

LEARNING OBJECTIVE 1: Dermatomyositis can present with peritoneal mesothelioma
LEARNING OBJECTIVE 2: Peritoneal mesothelioma can present without significant exposure to asbestos
CASE: 64 year old woman with past medical history of hypertension presented to the clinic with rash in her chest which was spread in classic shawl like pattern. She had associated weight loss and loss of appetite. Initially it was suspected to be allergic phenomenon and was treated conservatively. It did not get better and given her associated symptoms dermatomyositis was diagnosed and underlying malignancy was suspected. This was followed with a CT abdomen given her symptoms of abdominal discomfort. CT showed mass in abdomen and it was suggestive of ovarian cancer. She was supposed to be seen by Gynecology oncology and planned for debulking surgery. Her CA 125 was elevated. In the meantime she developed symptoms of dysphagia and her symptoms got worse to the point she was not able to tolerate anything orally including liquids. Due to her inability to eat or drink she was hospitalized for hydration. She got upper gastrointestinal endoscopy and it was a normal study. Her symptoms were suspected to be from dermatomyositis and was started on high dose steroids. Also chest xray was done it was reported normal. Later on due to progression of her symptoms she was taken to operating room and got her debulking surgery with suspicion of ovarian cancer. She was planned to be started on chemotherapy for suspected ovarian cancer. Biopsy results came back soon with diagnosis of peritoneal mesothelioma. Discussions were held with her about palliative chemotherapy but she refused therapy and opted for palliative care. She was discharged home on palliative measures.
DISCUSSION: Peritoneal mesothelioma is a aggressive tumor which has poor prognosis. Only 50 % of the patients with peritoneal mesothelioma have exposure to asbestos. Due to its vague symptoms it is usually diagnosed in later stages. Paraneoplastic syndromes with peritoneal mesothelioma is rare. Description of dermatomyositis in association with peritoneal mesothelioma was limited in literature with few cases. This is one of the case with the unique presentation of dermatomyositis and dysphagia with underlying peritoneal mesothelioma. CA125 can be elevated in peritoneal mesothelioma but it is non specific. Treatment for dermatomyositis related to cancer is to treat the underlying cause. In this situation resection of tumor will offer benefit. Radical resection with intraperitoneal hyperthermic perfusion is considered the standard treatment for resectable tumor at time of diagnosis. Palliatve shemotherpay can be offered in non resectable tumors. Overall

prognosis is poor since tumor is usually diagnosed at later stages due to atypical symptoms. Our patient after the surgery chose palliative care.

PERNICIOUS ANEMIA: AN UNCOMMON CAUSE OF ERYTHEMA NODOSUM Raji Shameem; Arvind Randhawa; Niket Sonpal; Dana Shani. Lenox Hill Hospital, New York, NY. (Tracking ID #1624112)

LEARNING OBJECTIVE 1: Diagnose erythema nodosum and recognize common underlying causes.
LEARNING OBJECTIVE 2: Recognize pernicious anemia as a rare cause of erythema nodosum, which can be treated with vitamin B12 intramuscular injections.
CASE: A 34-year old female presented to the clinic with a rash over her legs of one-week duration. The onset of the skin lesion was sudden, and she denied similar lesions in the past. The rash was associated with severe pain over the affected regions. No exacerbating or relieving factors noted. The patient denied any family history of inflammatory bowel disease. She had no complaints of diarrhea, constipation, rectal bleeding, or weight loss. The patient denied the use of any home medications including oral contraceptives. On examination, 10 cm indurated nodules were noted over the anterior lower legs. There was bilateral symmetrical involvement. Nodules were deep red and violaceous in color. Lesions were warm and tender with palpation. With examination findings consistent with erythema nodosum there was investigation for an underlying cause. Workup was negative except for positive anti-parietal antibodies and anti-intrinsic factor antibodies. Also serum B12 levels were decreased. These findings were consistent with pernicious anemia. The patient was started on corticosteroids, which mildly improved the erythema nodosum lesions. She also was treated for B12 deficiency with daily B12 intramuscular injections. B12 therapy significantly improved her lesions.
DISCUSSION: Erythema Nodosum is a common type of panniculitis, with a peak incidence of 20–30 years of age. It is six times more common in females. The differential diagnosis of erythema nodosum is vast. Multiple etiologies can be culprits. They include tuberculosis, oral contraceptives, malignancies, sarcoidosis, and inflammatory bowel disease. In this patient, all of these potential causes were ruled out with appropriate testing. The only positive findings were decreased B12 levels and antibodies against intrinsic factor and parietal cells. From our research we had found only one previous case report that described an association between B12 deficiency and Erythema Nodosum. Erythema Nodosum can be treated symptomatically. However, in this case, the patient's lesions responded remarkably to B12 injection administration. A new diagnosis of pernicious anemia was made and a rare association with Erythema Nodosum was discovered.

PHEOCHROMOCYTOMA - INDEED A "GREAT MASQUERADER" Harjinder Kumar; Julia Cheringal. Walter Reed Natioinal Military Medical Center, Bethesda, MD. (Tracking ID #1624531)

LEARNING OBJECTIVE 1: Recognize an atypical presentation of advancing paraganglioma in elderly patient.
LEARNING OBJECTIVE 2: Diagnose secondary hypertension related to pheochromocytoma in late age.
CASE: Mr. S is a 77 years old male referred to the Geriatric clinic for weight loss, recurrent falls (2–3 falls daily), and persistent dizziness. He has history of smoking, hypertension, coronary artery disease with angioplasty. His health records revealed a hospitalization within the previous year due to hypertensive emergency with a recorded blood pressure of 200/140 mmHg and symptoms of dry heaves, chest pain, pounding in the chest and intermittent headache. A CT scan was performed revealing a 2.6×3.1 cm retroperitoneal abdominal mass. At that time due to overwhelming social circumstances the patient decided not to pursue further work up. Mr. S continued to lose weight, 24 lbs in one year representing 20 % loss from his baseline and returned to clinic with symptoms of intermittent palpitations, sweating and weight loss. He had an elevated blood pressure of 213/116 mmHg and complaint of intermittent sweating, continued falls and persistent lethargy with dizziness. A CT of the abdomen and pelvis during hospitalization revealed an increase in the size of the retroperitoneal mass. His plasma and urine metanephrines were profoundly elevated. Nephrectomy and resection of mass were executed. At follow up after successful rehabilitation three months later, his blood pressure was normal and he gained 24 lbs and had stopped falling. Post operative plasma and urine metanephrines were normal.
DISCUSSION: Pheochromocytoma causes excess secretion of the catecholamines, epinephrine (metanephrine) and norepinephrine (normetanephrine). Pheochrmocytomas are rare, accounting for less than 0.1 % of the hypertensive population and presents in 3rd and 4th decades. Due to its variable clinical presentation, pheochromoctoma has been termed as "the great masquerader". Some paragangliomas have grown considerable in size before symptoms develop. Retrospective studies have shown that of people with pheochromocytoma at time of autopsy, 61 % has a history of hypertension and 91 of these patients had typical symptoms which are the classic triad of headache, palpitations and sweating. Sustained or paroxysmal hypertension is present in 80–100 % of these patients. In the elderly, however, presentation can be atypical, with symptoms such as weight loss, weakness, functional decline, and recurrent falls in addition to hypertensive episodes. There are case reports of elderly patients with symptoms other than classical symptoms of pheochromocytoma. In one case report an elderly 85 years old female presented with a 6 month history of back pain, and a retroperitoneal mass incidentally discovered on a spine radiograph. A large adrenal tumor (2.3 kg) was removed found to be a pheochromocytoma. In another case report, a 67 years old male presented in heart failure, subsequently had an adrenalectomy with a 300 g tumor found. Pheochromocytoma in late age is rare and when it does occur patient can have atypical symptoms such as presented in this case report. This case illustrated that pheochromocytoma (paraganglioma) may cause not only metabolic hyperactivity and hypertensive crisis but also the rapid development of frailty and a Geriatric Syndrome (falls) if treatment is delayed. Moreover, this case illustrates that frailty can be reversed with timely treatment of pheochromocytoma/paraganglioma which is a rare occurrence in elderly.

PLESIOMONAS SHIGELLOIDES - AN UNUSUAL CAUSE OF BACTEREMIA LAKSHMI GOWDA HANUMAIAH MD, MYRIAM EDWARDS MD, GHASSAN BACHUWA MD, ELIZABETH HALE MD HURLEY MEDICAL CENTER Lakshmi Gowda Hanumaiah. Hurley Medical Center, Flint, MI. (Tracking ID #1626281)

LEARNING OBJECTIVE 1: Plesiomonas shigelloides is an anerobic gram negative bacillus found in fresh water and soil. It is known to cause intestinal and extra-intestinal diseases in humans. Intestinal manifestations can be in the form of secretory diarrhea or invasive dysenteric illness. Extraintestinal infections are frequently seen in immunocompromised hosts and include include cellulitis, bacteremia, peritonitis, meningoencephalitis, eye infections, pneumonia and abscesses.
CASE: A 91 year old African American female with a past medical history of hypertension, chronic kidney disease stage 3 and cholecystectomy presented to the ED with sharp epigastric pain present for few hours and an episode of vomiting. She denied diarrhea, constipation, subjective fever, sick contacts, cough. Her initial examination revealed fever and epigastric tenderness. Workup was normal except for elevated liver enzymes. She was started on moxifloxacin for possible pneumonia. Patient continued to have low grade fever and elevated liver enzymes. Subsequently,blood culture was positive for Gram negative rods. Hence antibiotic was changed to piperacillin-tazobactam. The organism was later identified as Plesiomonas Shigelloides and ampicillin-sulbactam was started. Plesiomonas Shigelloides infection is common in subjects with underlying hepatobiliary disease and hence she was offered further workup to look for under lying biliary tract disease. She declined it as she started feeling better and her LFT had improved.
DISCUSSION: Plesiomonas Shigelloides has been implicated in gastrointestinal infections and rarely have been recovered from extraintestinal sites. Very few cases of Plesiomonas Shigelloides with extraintestinal manifestations have been reported in the literature. Host susceptibility plays an important role in influencing the risk of

infection. Data supporting the use of antimicrobial agents is limited but more severe cases benefit from antimicrobial therapy, particularly among immunocompromised hosts, the elderly, or young children.

PNEUMOCOCCAL ENDOCARDITIS MASQUERADING AS GASTROENTERITIS Rahana Sunesara; Lee Lu. Baylor College of Medicine, Sugar Land, TX. (Tracking ID #1629543)

LEARNING OBJECTIVE 1: Recognize that Streptococcus pneumoniae endocarditis may present with a myriad of symptoms, including gastrointestinal complaints.
LEARNING OBJECTIVE 2: Realize the aggressive nature of Streptococcus pneumoniae endocarditis associated with high mortality and a combined medical-surgical approach improves outcome.
CASE: A 41-year-old healthy male presented with 11 days of generalized myalgia, fatigue, anorexia, and non-bloody diarrhea and vomiting. Patient was treated seven days earlier for similar symptoms with metronidazole and ciprofloxacin for a presumptive gastroenteritis. Three weeks prior, he had a dental procedure for a broken tooth. He was a cocaine user but denied IV drug use or alcohol abuse. On admission, he was afebrile but was tachycardic and tachypneic with rigors; a systolic ejection murmur was heard at the apex. Abdominal exam was unremarkable. WBC was 14.9 with neutrophil predominance. CXR was normal. Blood cultures grew S. pneumoniae with intermediate susceptibility to penicillin but susceptible to ceftriaxone. On hospital day 2, patient became hypoxic; repeat CXR showed pulmonary edema. An echocardiogram revealed large vegetation on the mitral valve and perforation of anterior leaflet with resultant severe mitral regurgitation. Subsequently, he developed acute left leg coldness and numbness, and a thrombus was identified in the left femoral artery. Thrombectomy was performed emergently. Due to the rapid progression of patient's heart failure and thromboembolic event, patient underwent successful mitral valve replacement. Intraoperatively, it was noted that all mitral valve leaflets were destroyed with extension into the myocardium. He was treated with intravenous ceftriaxone for four weeks and discharged in stable condition.
DISCUSSION: Prior to the discovery of penicillin, the triad of pneumococcal endocarditis, pneumonia and meningitis, also known as Osler's triad, was well recognized with high mortality. S. pneumoniae is an infrequent cause of bacterial endocarditis and now attributed to <3 % of all endocarditis cases since discovery of penicillin. A review of 197 cases in the penicillin era was studied and the predisposing risk factors were alcoholism (28.1 %) and valvular disease (13.3 %). The portal of entry was identified mainly from lungs (47 %), sinus (4.7 %), and oral cavity (<1 %). Our patient did not have a known predisposing risk factor but did have a dental procedure three weeks prior to admission. Unlike other bacterial endocarditides, pneumococcal endocarditis is very aggressive and can cause valve destruction, especially mitral and aortic valves. The most common complications are congestive heart failure and embolization. Even with availability of penicillin, mortality rates range from 28 % to 60 %, with higher mortality associated with CHF due to valve destruction and perforation. In the cases for which outcomes were available, 37 patients were managed with medical-surgical approach with the resultant mortality rate of 32 % as compared to 62 % in 91 patients who were managed with antibiotics alone. Multiple case studies over the decades have shown that a two-pronged approach, which includes surgery and antibiotics, improves mortality. Thus, S. pneumoniae endocarditis, although rare, needs to be diagnosed promptly and treated aggressively to improve outcome.

PNEUMONIA IN AN IMMUNOSUPPRESSED PATIENT WITHOUT HIV: INITIAL CONSIDERATIONS AND PROPHYLAXIS Michael J. Plakke; Leena Jalota; Benjamin Lloyd. Reading Health System, West Reading, PA. (Tracking ID #1642361)

LEARNING OBJECTIVE 1: Develop a broad differential diagnosis for respiratory infections in patients on chronic immunosuppressive therapy.
LEARNING OBJECTIVE 2: Identify patients who should be considered for Pneumocystis jirovecii pneumonia (PCP) prophylaxis.
CASE: A 56-year-old male presented with fever and dyspnea. He had a history of membranoproliferative glomerulonephritis, which was treated with 60 mg of prednisone and mycophenolate mofetil daily for several months. His immunosuppressive regimen was stopped one week prior to admission with a plan to initiate hemodialysis soon. He was HIV-negative. His temperature was 39.3 °C; pulse 94; respiratory rate 24; BP 179/95; and SpO2 96 % on room air. He appeared ill but not in respiratory distress. He had fine bilateral crackles on pulmonary exam. There was an infiltrate noted on chest radiography; therefore, he was admitted for sepsis due to pneumonia and started on empiric antibiotics. Despite extension to broad-spectrum antibiotics, he did not improve. He had daily fever spikes, no new lung findings on chest radiography, and cultures remained negative. High-resolution CT scan of his chest showed diffuse ground-glass opacifications. On day six of hospital admission, his respiratory status rapidly declined; arterial partial pressure of oxygen was low at 57 mmHg (75–90 mmHg). After minimal improvement using bi-level positive airway pressure, he was intubated and transferred to the intensive care unit (ICU) for acute hypoxemic respiratory failure. While in the ICU, bronchoalveolar lavage (BAL) confirmed the presence of Pneumocystis jirovecii. The patient was initially started on high-dose intravenous trimethoprim-sulfamethoxazole (TMP-SMX) and intravenous corticosteroids. Five days later, he was successfully weaned off mechanical ventilation and converted to oral medications. He was discharged after his respiratory status returned to baseline with the recommendation to continue TMP-SMX for 21 days. He has had no complications to date.
DISCUSSION: Patients on chronic immunosuppressive therapy, especially those taking high doses of corticosteroids in combination with another T-cell modulating agent, should be managed differently than those with community-acquired pneumonia. Corticosteroids decrease the number of CD4+ lymphocytes and leave these patients susceptible to opportunistic respiratory pathogens such as Mycobacteria, Nocardia, cytomegalovirus, and herpes virus. Fungal organisms such as Aspergillus and Cryptococcus and the parasites Strongyloides, Ascaris, and Toxoplasma should also be considered. Pneumocystis jirovecii has traditionally been thought of as an AIDS-defining illness, but the incidence of PCP in patients without HIV is increasing, mostly due to iatrogenic immune system defects related to chronic immunosuppressive therapy. Surprisingly, compared to HIV-positive patients, HIV-negative patients with PCP have significantly worse outcomes. This includes higher rates of hospitalization, respiratory failure, ICU admission, and mechanical ventilation. Recent recommendations state that HIV-negative patients taking 20 mg or more of prednisone for one month or more should be considered for PCP prophylaxis, especially if they are taking other cytotoxic drugs. In hindsight, our patient would have benefitted from this suggestion. Due to significant risk of morbidity, non-HIV patients on chronic immunosuppressive therapy should be identified early and treated properly to avoid the need for intensive care and prolonged hospitalization.

POLYOMA BK VIRUS, AN ONCOGENIC VIRUS Ayad Alkhatib; Ibrahim Abdullah; Qasim L. Shakeel; Syed Hassan; Waqas Qureshi. Henry Ford Hospital, Detroit, MI. (Tracking ID #1629663)

LEARNING OBJECTIVE 1: Recognize the potential of latent viral infection to reactivate post kidney transplant
LEARNING OBJECTIVE 2: Recognize the potential of a latent viral infection to contribute to a malignancy especially in immunocompromised patients
CASE: A 65 year old African American gentleman with a history of hypertension, schizophrenia, and end stage renal disease secondary to hypertensive nephropathy and lithium toxicity received a deceased donor kidney transplant eleven years ago. He immediately regained his renal function with adequate urine output. He was put on tacrolimus, steroids and mycophenolate and followed up in the transplant clinic every month for the first year. Six months later, he was found to have elevated BUN and serum Cr., also his blood tested positive for BK

viremia with a constant elevated viral load on two occasions four weeks apart. His immunosuppression was immediately reduced; his serum creatinine and PCR test for BK viral DNA was closely monitored. Inspite of best efforts four years later, the transplanted kidney failed secondary to BK virus nephropathy. It was confirmed by histopathology and immunohistochemical staining. The patient was then put back on hemodialysis and transplant list. He was followed by his primary care physician every six months for his other chronic medical conditions. During one of his visits, he complained of hematuria at the beginning of micturition. Originally thought to be due to ongoing chronic rejection, and was started on low dose steroids. A UA was significant for RBC's. Ultrasound of the kidney ruled out any hydronephrosis or inflammation of the transplanted kidney. Following which a retrograde pyelography revealed a medium, sessile tumour on the posterior wall of the bladder and a transurethral resection of the tumour was performed. Histopathology confirmed a high grade, adenocarcinoma in-situ of the bladder which was not invading into the muscularis propria. CT scan of the abdomen and pelvis ruled out any metastasis. Esophagogastroduodenoscopy and colonoscopy ruled out GIST (gastrointestinal stromal tumour). He had a 6 months follow up with urology and a repeat cystoscopy with retrograde pyelography showed no residual tumour. Biopsy of the bladder wall showed normal urothelium. The patient continues to follow up with urology every year and is waiting for another kidney transplant

DISCUSSION: BK virus is a member of polyomavirus family which is found ubiquitous in the human body. However clinically relevant and life threatening infections are limited to immunocompromised host as seen in transplant recipients. BK virus is incriminated in several case studies for causing bladder and prostrate carcinoma, Kaposi sarcoma, bone and brain tumours. Bladder carcinoma was also reported in a patient who underwent simultaneous kidney and pancreas transplant. The oncogenic potential is mediated through its ability to bind p53 tumour suppressor gene disrupting the cell cycle and hindering repair of damaged DNA. In our case, bladder carcinoma was found in an immunocompromised host, who was noted to have high levels of BK viremia in blood. This is similar to other cases reported in literature were high levels of BK viral DNA were expressed both in the primary and the metastatic tumors. However, BK virus role in development of human malignancies is still controversial. Indeed one needs to have high index of suspicion for a potential bladder malignancy in light of hematuria in immunocompromised host who has positive BK viremia.

POSITIONAL HYPOTENSION AND ACUTE LIMB ISCHEMIA DUE TO MITRAL VALVE FIBROELASTOMA: A DIAGNOSTIC DILEMMA NABA RAJ MAINALI, MD; MADAN BADAL, MD; MADAN RAJ ARYAL, MD; RICHARD ALWEIS, MD READING HEALTH SYSTEM, WEST READING, PA 19611 Naba R. Mainali; Madan Badal; Madan R. Aryal; Richard Alweis. Reading Health System, West Reading, PA. (Tracking ID #1618113)

LEARNING OBJECTIVE 1: To recognize the clinical presentation and acute complications of fibroelastoma of the heart.
LEARNING OBJECTIVE 2: To describe the diagnosis and management of fibroelastoma of the heart.
CASE: Papillary fibroelastoma are histologically benign neoplasm of the heart that can develop either on valve or endothelial surface of the heart. Although it is a rare tumor, it stands as second most common tumor of the heart after atrial myxoma. It has multiple papillary fronds resembling sea anemones and is extremely fragile in nature. It usually presents with emobolic complications including myocardial infarction, stroke, pulmonary embolism, acute limb ischemia. Fragile papillary fronds or fibrin aggregations on the tumor is a main cause for systemic embolization. Here, we report an unusual presentation of mitral valve fibroelastoma presenting with acute limb ischemia secondary to embolization and positional hypotension, posing diagnostic dilemma with atrial myxoma. A 68-year-old woman with recent history of acute embolic right lower extremity ischemia status post right above knee amputation after failure of multiple trials of endovascular revascularization with local rTPA thrombolysis, was referred by her primary care physician for hypotension with systolic blood pressure consistently variable between 80 and 100 mm of Hg. She was symptomatic with dizziness at most of the time. Physical exam revealed normal findings except variable systolic blood pressure. She underwent various tests, including cosyntropin stimulation test to rule out addison's disease, which were negative. A suspicion of autonomic instability was then made and treatment with TED stockings and midodrine were started without significant improvement. Careful examination revealed variation of 20 mm of Hg between supine and left lateral position indicating some obstructing lesion on the left atrium. Transthoracic echocardiogram showed mild to moderate enlargement of left atrium close to the posterior mitral valve annulus, consistent with fibroelastoma without the evidence of mitral valve obstruction but slightly impaired filling of the left ventricle in left lateral position. This was confirmed with transoesophageal echocardiography and the patient underwent surgery for the resection of the mass on the anterior leaflet of mitral valve. Histology of the resected mass confirmed papillary fibroelastoma on left atrial surface. After surgery, her blood pressure readings were consistently similar on supine and left lateral position. At three months follow up visit, her blood pressure recordings were found to be consistently normal without variability with the position.
DISCUSSION: Echocardiography remains the gold standard of diagnosis for papillary fibroelastoma, trans- esophageal echocardiography being superior in differentiating it from the vegetation, atrial myxoma or thrombus. Many of them remain undiagnosed until autopsy report after Sudden Cardiac Death. Due to potential embolization, it is recommended that such fibroelastomas be excised, even if the patient is asymptomatic. Though it is not entirely clear, positional hypotension in our case was probably secondary to the location and size of the tumor causing drop in cardiac output leading to hypotension and dizziness. The optimal treatment modality includes valve sparing resection with thorough inspection of all areas during primary surgeries. Prophylactic anticoagulation therapy should be initiated in order to guard against thrombi while awaiting surgery.

POSITIONAL HYPOXEMIA SECONDARY TO A PATENT FORAMEN OVALE Jane Njeru; Murali Duggirala. Mayo Clinic, Rochester, Rochester, MN. (Tracking ID #1636164)

LEARNING OBJECTIVE 1: Recognize secondary erythrocytosis
LEARNING OBJECTIVE 2: Diagnose patent foramen ovale as a cause of secondary erythrocytosis
CASE: A 79 year old woman, non-smoker, was seen in the General Internal Medicine Clinic for chronic musculoskeletal back pain. History was significant for osteoporosis. Her medications included Ibandronate, calcium and vitamin D, tramadol and acetaminophen for back pain. Review of systems was notable for some decline in exercise tolerance over the previous year. She had no known cardiac disease, but had some positional snoring. Her BP was 120/69 mmHg, heart rate 72/min, and oxygen saturation 93 % seated, on room air. BMI was 30. General condition was good, with no mucosal pallor, cyanosis, digital clubbing or peripheral edema. Cardiopulmonary examination revealed normal jugular venous pressure, and normal auscultation. Abdominal examination was normal. Hemoglobin was 17.1 g/dL (normal range 12.0 to 15.5); erythrocyte count - 6.01×1012 /L (3.9 to 5.03), hematocrit - 51.7 % (34.9 to 44.5). Peripheral smear was normal. Serum erythropoietin level was unremarkable at 6.1 mIU/mL (2.6 to 18.5). Peripheral blood JAK2 V617F mutation analysis was negative, ruling out Polycythemia Vera. There was no evidence of sleep disordered breathing on polysomnography, but she had position dependent hypoxemia, without hypoventilation. A trans-esophageal echocardiogram revealed a patent foramen ovale (PFO), 5–6 mm in size, with large, spontaneous atrial level right-to-left shunt. She then underwent right heart catheterization, which also revealed a significant right-to-left shunt through the PFO. Supplemental oxygen did not improve her oxygenation. Interestingly, she had normal right and left sided cardiac filling pressures, pulmonary pressures and cardiac output. It was thus concluded that the hypoxia was secondary to the PFO. She underwent

successful PFO closure with Amplatzer device, with improvement in her oxygenation and exercise tolerance.
DISCUSSION: Our patient presented with declining exercise tolerance over a year, and progressive erythrocytosis. The echocardiogram and right heart catheterization helped identify and confirm the diagnosis. Patent foramen ovale is a common condition, affecting 25 to 30 % of all adults. However, only a small percentage of affected persons present with symptoms, the most common being cryptogenic stroke, migraine headaches, decompression sickness and the rare platypnea-orthodeoxia syndrome. Our patient did not describe typical position dependent symptoms as are noted in platypnea-orthodeoxia syndrome, but during her sleep study and cardiac catheterization, she clearly had position dependent hypoxemia. Her hypoxemia occurred when she was recumbent, in contrast to the platypnea-orthodeoxia syndrome, where right-to-left shunting across a defect at the atrial level occurs in the upright posture and resolves in the recumbent position. The reasons for these phenomena are unclear, but may be related to the fact that our patient lacked a functional cardiac abnormality that would result in increased right atrial pressures promoting right-to-left shunting, a phenomenon that is crucial for the platypnea-orthodeoxia syndrome. Although she had normal cardiac pressures on catheterization, she had a significant right-to-left shunt, associated with hypoxemia. Correction of this defect resulted in resolution of her symptoms. This case outlines the work up of erythrocytosis, and the patho-physiologic correlates in this patient with a PFO.

POSTPARTUM REVERSIBLE VASOCONSTRICTION SYNDROME Harith Baharith; Amy Zarrin. New York Methodist Hospital, Brooklyn, NY. (Tracking ID #1617975)

LEARNING OBJECTIVE 1: Postpartum cerebral vasoconstriction is one of the rare, reversible cerebral vasoconstriction syndromes (RCVS). We report a patient with headache and focal neurological deficits that occurred one week after delivery, with segmental narrowing of cerebral arteries on angiography.
CASE: A 35 year old woman (gravida 10, para 11) presented with throbbing headache beginning five days after Caesarean section. Ten days after delivery, she developed decreased right sided sensation, tingling and weakness, with right facial droop, tongue heaviness and difficulty speaking. The patient denied past medical problems, but had a long history of chewing khat (methcathinone, a methyl derivative of cathinone, an ephedrine amphetamine-like stimulant) and a 5-year smoking history (tobacco). During the Caesarean section, she received 4 units of packed red blood cells. Physical examination showed right lower facial droop, and diminished power (2/5) of the right arm and (3/5) leg. Her brain computerized tomography (CT) scan showed acute left middle cerebral artery infarction. On day 2, magnetic resonance angiography (MRA) showed vasoconstriction of the middle and anterior cerebral arteries. On day 3, head CT angiography showed diffuse vasoconstriction of medium and small vessels. The blood count, chemistry panel, sedimentation rate, C-reactive protein, autoimmune studies, hypercoaguability testing, electroencephalogram and echocardiogram were all unremarkable. Hepatitis B, hepatitis C and syphilis antibodies were negative. She received verapamil for relieving vasoconstriction and levetiracetam for seizure prophylaxis. Head MRA on day 6 showed significant resolution of her vasoconstriction. Follow up revealed clinical resolution.
DISCUSSION: Strokes in pregnant and postpartum women are generally caused by: cerebral venous thrombosis, preeclampsia/eclampsia or RCVS. Postpartum strokes incidence ranges from 4.3 to 210 per 100,000 deliveries with unknown RCVS incidence. Most strokes occur in the third trimester and postpartum period, when physiological changes affect cerebrovascular tone. Postpartum cerebral vasoconstriction is often underdiagnosed, but recently disease recognition is increasing. This disorder has various precipitating factors such as vasoactive substances, blood transfusion or can occur spontaneously postpartum. The disorder may last for a short period of time or may become persistent with poor outcome if severe vasoconstriction leads to brain ischemia or hemorrhage. The clinical presentation includes thunderclap headache, focal neurological deficits and seizures which are usually reversible within a 3 month period. Angiography usually shows segmental narrowing of cerebral arteries that resolves completely or near-completely within 3 months. Our patient developed initial symptoms within the first week after delivery and recovered completely. She had a history of two possible precipitating factors: chewing khat and blood transfusion. Her repeat head MRA showed significant resolution of cerebral vasoconstriction 2 weeks after her initial symptomatic presentation. Treatment consists of eliminating any precipitating agents, verapamil and levetiracetam. Most patients recover completely with few having residual deficits.

PRE-OPERATIVE CHEST RADIOGRAPHY: OLD HABITS DIE HARD Meredith Niess. University of Colorado, Aurora, CO. (Tracking ID #1621961)

LEARNING OBJECTIVE 1: Outline and criticize existing research on pre-operative chest x-ray use.
LEARNING OBJECTIVE 2: Identify the negative ramifications of pre-operative chest x-ray overuse.
CASE: A 54-year-old veteran with mild intermittent asthma, anxiety, and depression presents to his general surgeon for pre-op evaluation. His umbilical hernia has become more painful in the past 3 months. After documenting a normal cardiopulmonary exam and labs, the surgeon orders a chest radiograph (CXR) with the indication as "pre-operative work-up, over 55, history of asthma". The CXR reveals a 7 mm left parahilar lung nodule, for which "CT of the chest for further evaluation" is recommended. Surgery is delayed. Four weeks later, the patient arrives in my clinic to review the results of his CT: "1. No pulmonary nodule. 2. Circumscribed homogenous right adrenal nodule." An adrenal CT is ordered; three weeks later, benign adrenal adenoma is confirmed. Finally, the patient undergoes uneventful ventral hernia repair.
DISCUSSION: In the 1980s, researchers began examining the utility of pre-op CXRs, attempting to create algorithms and categories to curb overtesting. (1–8) More recently, the Choosing Wisely campaign identified preoperative CXR as a priority area to raise patient awareness of rampant overtesting.(9) Assessing the utility of this screening method requires estimating what fraction of the total number of CXRs ordered have unexpected results that prove useful in management. Our best estimates of these numbers do not support screening CXR: In a meta-analysis by Archer et al., only 10 % of 14,390 subjects had abnormalities. 1.3 % of those screened had an unexpected abnormality, and 0.1 % (0 to 0.6 %) had CXRs that changed management.(10) This same analysis calculated that every "useful" CXR came at a cost of $23,000, taking into account only the cost of the CXR itself (in 1993) and no follow-up tests. CXR results change management when they delay or cancel surgery or result in a change in anesthesia management. There are no randomized controlled studies on anesthesia management changes, and reviews of the topic consistently cite the same few non-blinded, non-randomized—and often retrospective—studies. Silvestri et al. conducted the largest multi-center study to date (n=6111). Results showed that pre-op CXR changed anesthesia management anywhere from 0 % to 44 % of the time depending on the anesthesiologist questioned,(11) illustrating the subjectivity of this outcome. Given the non-blinded retrospective format of the survey, this may be a true measure of change in management, or may simply reflect evaluator bias. Importantly, no studies address whether these changes, much less surgical cancellation or delay, affect patient outcomes. In 2001 the American Society of Anesthesiologists (ASA) recommendations on pre-operative CXR stated, "[the ASA] does not believe that extremes of age, smoking, stable COPD, stable cardiac disease, or resolved recent upper respiratory infection should be considered unequivocal indications for chest radiography;"(12) This is a poignant recommendation in the context of this case. The veteran experienced continued pain due to his delayed surgery, unnecessary costs and radiation exposure, and anxiety over multiple false positive findings. The present case is familiar to nearly all clinicians: an image ordered for unclear reasons leading to a cascade of time-consuming, anxiety-provoking and expensive follow-up tests with no measurable benefit.

PRESENTATION OF ZINC DEFICIENCY AS A PERIANAL ULCERATIVE RASH IN AN ALCOHOLIC MAN. Yasmin Raza[1]; Yelena Averbukh[2]. [1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, Bronx, NY. (Tracking ID #1638498)

LEARNING OBJECTIVE 1: To consider zinc deficiency as a cause of perianal rash in adults.
LEARNING OBJECTIVE 2: To recognize pathognomonic signs, symptoms and associated laboratory findings in zinc deficiency syndromes for timely diagnosis and treatment.
CASE: A 54-year-old alcoholic homeless man was brought to the hospital by EMS after being found intoxicated on the street. Of interest, the patient used adult diapers in lieu of underwear while homeless. His past medical history was significant for TB treated 1 year prior to admission and he adhered to a multidrug regimen for 6 months. On exam he was thin, disheveled and smelled strongly of alcohol. His skin was notable for confluent patches of an erythematous, ulcerative rash covering the buttocks and perineum. Laboratory studies were remarkable for chronically low to low normal alkaline phosphatase of 51–58 U/L and hemoglobin of 8.4–10.4 g/dL. Due to the unusual distribution of the rash, a zinc level was checked and came back to be 36 μg/dL (normal range 60–130 μg/dL), altogether leading to a diagnosis of zinc deficiency. Treatment with zinc supplements was initiated with great improvement of the patient's rash over several weeks.
DISCUSSION: : Zinc deficiency is a global health issue affecting up to 2 billion people. Acrodermatitis enteropathica is a rare autosomal recessive disorder characterized by an impairment of zinc absorption. Acquired zinc deficiency may be due to decreased absorption of zinc in conditions such as inflammatory bowel disease, cystic fibrosis, and malabsorption syndromes; increased renal excretion as in nephrotic syndrome or alcoholism; inadequate dietary intake as seen in anorexia nervosa and total parenteral nutrition; or in increased demand states such as pregnancy and lactation. Cutaneous presentation ranges from annular and psoriasiform plaques or lichenoid lesions in mild deficiency to scald-like erythema, fissuring and eczematous lesions with bullae in severe cases. The lesions develop acutely around orifices and on dependent areas. Plasma zinc levels may not correlate with zinc status; however, given the lack of other biomarkers, low plasma levels remain the gold standard for detecting zinc deficiency. Additionally, serum levels of alkaline phosphatase, a zinc-dependent enzyme, can be measured as they correspond to zinc status. Treatment is with zinc by enteral or parenteral replacement depending on the cause of the deficiency, leading to rapid clinical improvement. Conclusions: Zinc deficiency has been recognized as an important nutritional deficiency for decades, yet much of the focus was on the pediatric population due to its association with diarrhea, dermatitis and overall childhood morbidity and mortality. Zinc deficiency in adults has a similar presentation and should not be overlooked. This case demonstrates zinc deficiency should be included in the differential for adult patients presenting with an ulcerative rash in the diaper distribution area, especially in the context of active alcoholism, recent treatment with isoniazid associated with atrophic gastritis or the presence of other malabsorptive states.

PREVENTING HARM: SUICIDE PREVENTION IN A NONPATIENT FAMILY MEMBER: A CLINICAL ETHICS VIGNETTE Nora Segar; Julie R. Rosenbaum. Yale University School of Medicine, New Haven, CT. (Tracking ID #1643184)

LEARNING OBJECTIVE 1: Describe ethical considerations when a non-patient family member threatens suicide.
LEARNING OBJECTIVE 2: Effectively weigh autonomy, nonmaleficence, confidentiality, and the importance of maintaining relationships during clinical care.
CASE: Mr. V, a 68-year-old man with history of end-stage Huntington's disease, presented to our hospital with shortness of breath and was diagnosed with an empyema. His course was complicated by bilateral pulmonary embolism, gastrointestinal bleed, and hypoxic respiratory failure. His wife, who had uncontrolled diabetes and hypertension, did not take her medications, shower, or leave the hospital for 41 days. As Mr. V declined, Mrs. V became increasingly distraught, eventually disclosing her intention for suicide to the house-staff. She threatened to take a bottle of lorazepam when Mr. V died, requesting that we not tell anyone. We ultimately disclosed her threat to the attending physician, her primary physician, and the hospital ethics committee. They met with Mrs. V, but they did not mention her previous threats, and she did not reveal the extent of her psychological distress. Two days later, Mr. V declined further and we admitted him to the Intensive Care Unit. While Mr. V was in the ICU, Mrs. V sustained a myocardial infarction and ischemic stroke at his bedside. She was admitted to the hospital under our care, receiving treatment for depression in addition to her other medical conditions.
DISCUSSION: We feel this case illustrates a variety of ethical challenges pertinent to the general internist. First, although this situation may be periodically encountered, the existing medical ethics literature has not extensively explored the physician's obligation when patient's family member threatens suicide. If a patient threatens harm against herself, there is a nonmaleficence-based ethical justification for action and possible disclosure to others to prevent harm that potentially outweighs confidentiality. However, if a family member or non-patient makes a suicide threat, this obligation is less well-established. We exercised our "Samaritan-benefit claim" in an effort to minimize harm for Mrs. V, but it was only when she transitioned from family member to patient that she received psychiatric care. In hindsight, her refusal to engage in self-care may have been a form of passive suicidality, but without the obligations of the patient-physician relationship, we could not formally intervene and treat her against her will. Second, we also questioned whether Mrs. V. could act as her husband's power of attorney given her need for medical and psychiatric attention. Our team and the ethics committee determined that her depression did not cloud her capacity sufficiently to remove her from this role. She remained the primary decision maker for her husband until his death. Finally, though we were not bound by patient-doctor confidentiality prior to her admission, we did weigh her confidentiality against our obligation to prevent harm. Perhaps her myocardial infarction and stroke could have been prevented, but we felt that her autonomy and the preservation of our relationship outweighed the need for acute intervention for her threat. As a result, she was able to stay at her husband's bedside, her relationship with her doctors remained intact, and she eventually received the psychiatric attention she required.

PROCEED WITH CAUTION! David Burkland[1]; Lee Lu[1]; Anna Kolpakchi[2]; Ikedieze Chukwu[2]. [1]Baylor College of Medicine, Houston, TX; [2]Michael E. DeBakey VAMC Houston, Houston, TX. (Tracking ID #1635394)

LEARNING OBJECTIVE 1: Recognize that intra-articular corticosteroid injection (IACI) can alter glucose metabolism.
LEARNING OBJECTIVE 2: Realize that IACI can cause diabetic ketoacidosis (DKA).
CASE: A 74-year-old man with history of diet-controlled diabetes mellitus with last hgbA1c 6.6 %, HTN, chronic kidney disease, and osteoarthritis of bilateral shoulders presented with complaints of sudden onset of fatigue, malaise, polyuria, polydipsia, and blurry vision for 4 days. One day prior to onset of symptoms, patient underwent IACI with triamcinolone acetonide (TA, Kenalog) 40 mg in each shoulder. Patient denied fever, chills, cough, nausea, vomiting, abdominal pain and dysuria. His medications included amlodipine and nortriptyline. On admission, patient was afebrile, BP 155/92, and P 79. Physical exam was unremarkable except for dry mucous membranes. Abnormal laboratory studies revealed serum glucose 839 mg/dL, bicarbonate 21, with anion gap 14, creatinine 2.2 (baseline 1.8), BUN 55 (baseline 30), negative serume and urine ketones, and B-hydroxybutyrate (BOHB) 8.3 (0.0–3.0). Despite negative ketones, patient was diagnosed with DKA due to the elevated BOHB, which is the predominant ketone present in severe DKA and cannot be detected by a conventional ketone laboratory measurement. He was treated with intravenous fluids and insulin drip with rapid correction of hyperglycemia and closure of anion gap. Evaluations for cardiac ischemia and infection

were all negative. Patient was discharged on detemir 20 units twice daily and 10 units premeal aspart. Several days after discharge, patient developed symptomatic hypoglycemia with blood sugars down to 50 mg/dL and self discontinued insulin. His fasting blood glucose has remained less than 130 mg/dL off insulin.

DISCUSSION: Intra-articular corticosteroid injection (IACI) is a very popular therapeutic modality for local treatment of painful joints. While the effects of oral and intravenous corticosteroids are well known, an understanding of systemic manifestations of IACI is still actively developing. What has been clearly demonstrated in the literature is a significant proportion of injected corticosteroids will be absorbed resulting in significant measurable serum corticosteroid levels varying based on the formulation, quantity, and number of joints injected. Clinical effects include but are not limited to a significant decrease in inflammatory markers, suppression of hypothalamic-pituitary-adrenal axis with maximal effect at 24–48 h with full recovery after 1–4 weeks, and Cushing syndrome in some cases of repetitive injections. But only recently have studies demonstrated a clear transient increase in blood glucose levels in response to IACI. On comprehensive literature review, there has only been one case of hyperglycemic hyperosmolar non-ketotic state caused by IACI; however, the case is confounded by the concurrent use of ritonavir, which dramatically decreases clearance of corticosteroids. We did not find another case report of hyperglycemic crisis resulting from IACI in the literature. Most likely, injections of bilateral large joints, large dose of steroids and older age contributed to an exaggerated systemic response in our patient. Thus, hyperglycemia should be listed as one the side effects of IACI, and diabetic patients should be advised to monitor their blood sugar closely after IACI.

PROLONGED EVOLVING SYMPTOMATOLOGY IN A PATIENT WITH DAPSONE HYPERSENSITIVITY Noa Schwartz[1,2]; Darlene LeFrancois[1,2]. [1]Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1641944)

LEARNING OBJECTIVE 1: Describe the clinical presentation of the Dapsone Hypersensitivity Syndrome (DHS), its similarity to the presentation of Pneumocystis Carinii Pneumonia (PCP), and its life-threatening potential

LEARNING OBJECTIVE 2: Identify that DHS can continue to evolve even weeks after the triggering drug is discontinued

CASE: A 61 year-old man with AIDS presented with 3 weeks of weight loss, fever, and productive cough. His recent CD4 count was 42, and he was not on anti-retroviral therapy. His symptoms began after dapsone was initiated for PCP prophylaxis, due to a history of trimethoprim/sulfamethoxazole allergy. The patient developed a pruritic rash on his chest, progressively worsening cough productive of white sputum, malaise and fever, as well as numbness on the bottom of his feet. He stopped taking the dapsone after 2 weeks, but as his symptoms did not subside, he came to the emergency room. On arrival, he was febrile to 103, with desaturation on exertion from 96 % to 86 % in room air. His exam was notable for mild bibasilar crackles, and a fine maculopapular rash on his chest. Laboratory values were significant for eosinophilia of 18 %, and elevated AST and ALT (227 and 129, respectively). An infectious work up, including blood and respiratory cultures, acid-fast bacilli stains, and PCP smears, was negative. Chest X-ray did not reveal any focal infiltrates, CT scan and bronchoscopy were nonspecific. The patient was empirically treated for PCP and community-acquired pneumonia, but continued spiking fevers. On hospital day 6 he seemed clinically improved, afebrile and with resolution of pulmonary symptoms. Although his liver function tests and eosinophils remained elevated, he was discharged to outpatient follow up on hospital day 10. Within 4 days he developed a dusky, desquamating rash involving his oropharynx, trunk, and genitalia. He was started on Prednisone 100 mg, but a day later was re-admitted. Punch biopsy of his skin lesion was consistent with erythema multiforme, and he was diagnosed with toxic epidermal necrolysis (TEN). He healed over the next few weeks with supportive treatment, without apparent sequelae.

DISCUSSION: Cutaneous drug reactions are thought to be prevalent in the HIV patient population. As the use of dapsone is common in this population, it is important to recognize the Dapsone Hypersensitivity Syndrome (DHS). DHS is thought to be a severe form of the drug reaction with eosinophilia and systemic symptoms, or DRESS syndrome. It is characterized by the onset of fever, skin eruption and internal organ involvement. It commonly presents with prominent hepato-pulmonary manifestations, including interstitial pneumonitis that can mimic the presentation of PCP. The skin manifestations can in severe cases progress to Stevens-Johnson Syndrome/TEN. DHS may also present with hematologic, renal, and neurologic manifestations, ranging from hemolytic anemia to peripheral neuropathy. The incidence of DHS is estimated to be 0.01–3 %; it is idiosyncratic, and usually occurs within 8 weeks of starting the drug. It is thought that the syndrome is triggered by antibody formation to dapsone metabolites, which can linger in the patient's serum for up to 35 days. The persistence of the toxic metabolites can explain our case, in which the syndrome continued to evolve weeks after the withdrawal of the offending drug. The mortality from severe DHS is 12–23 %, thus requiring careful monitoring of all patients on dapsone therapy for symptoms and signs suggesting the complication.

PULMONARY MUCORMYCOSIS AND ACUTE LYMPHOBLASTIC LEUKEMIA-SIBLINGS BEFORE CHEMOTHERAPY Nikhil Kapila[1]; Poojita Shivamurthy[1]; Prerna Mota[1]; Saqib Gowani[1]; Michael Lawlor[2]. [1]University of Connecticut Health Center, Farmington, CT; [2]Hartford Hospital, Hartford, CT. (Tracking ID #1642436)

LEARNING OBJECTIVE 1: To have a high index of suspicion for hematological malignancies in patients presenting with pulmonary mucormycosis

LEARNING OBJECTIVE 2: Less invasive methods, with increased sensitivity, are needed to diagnose mucormycosis in order to expedite antifungal therapy

CASE: A 30 year old male presented with a 4 week history of fevers,chills,generalized fatigue, and progressive dyspnea on exertion. Past medical history and family history were non-contributory.On examination,he had a temperature of 101.4 F,sinus tachycardia,a BP of 120/76 mmHg,respiratory rate of 24–28,and saturating 96 % on room air.He had dry mucous membranes,grade 2/6 systolic ejection murmur at the left upper sternal border,and decreased breath sounds in the left upper and left lower lung fields with crackles.No lymphadenopathy was appreciated. His laboratory data showed a WBC count of 0.5 with 92 % lymphocytes, 5.8 % neutrophils,ANC of 0.3,hematocrit of 20,and platelets of 246,000. Additional laboratory data revealed a transaminitis,ferritin of 3668,and LDH of 251. Peripheral smear showed polymorphous lymphocytes and tear drop cells. HIV by ELISA was negative.CT scan of the chest showed multiple bilateral lung nodules,the largest being 2.7 cm in diameter.It also showed an ill defined infiltrative soft tissue mass in the anterior mediastinum, as well as hilar,subcarinal,and axillary lymphadenopathy. Pleural fluid analysis showed numerous monomorphic lymphocytes. Biopsy from the dominant pulmonary nodule showed broad aseptate hyphae in the background of necrosis,and Gomori's methenamine silver stain was positive for rhizomucor. Flow cytometry showed blasts with T-lineage differentiation,and bone marrow biopsy confirmed acute lymphoblastic leukemia of a mixed phenotype. Our patient presented with pulmonary mucormycosis concomitantly with acute lymphoblastic leukemia.He was treated with liposomal amphotericin B and posaconazole. Considering the extensive multilobar nature of his infection,he was a poor surgical candidate. Chemotherapy was held because of the potential for developing further neutropenia and worsening the infection.

DISCUSSION: Although mucormycosis is the most common mold in patients with hematological malignancies,it is uncommon as the initial presentation in leukemic patients. Studies demonstrate the prevalence of mucormycosis to be less than 1 % in those with hematological malignancies. Leukemic patients are most susceptible to pulmonary mucormycosis in the aplastic post chemotherapy period or while receiving high dose steroids post bone marrow transplantation. Pulmonary

mucormycosis is associated with poor outcomes and some studies suggest a mortality rate as high as 87 %.In addition, the diagnosis of pulmonary mucormycosis is challenging due to the poor sensitivity of diagnostic imaging. However,even BAL and sputum samples are unreliable diagnostic modalities. These points reinforce the need for physicians to maintain a high degree of suspicion when treating neutropenic patients in the setting of hematological malignancies. Since our patient was not a surgical candidate,he was immediately initiated on liposomal amphotericin B and posaconazole. Newer modalities of treatment include amphotericin B and capsofungin but more randomized controlled trials are required prior to their implementation. Considering that early initiation of therapy is associated with markedly better outcomes,it is essential to develop a sensitive,yet cost-effective means to diagnose mucormycosis in a timely fashion.

PURULENT BACTERIAL PERICARDITIS IN A PATIENT WITH PNEUMOCOCCAL PNEUMONIA Emily Horvath; Amanda M. O'Connor; John D. Rogers. University of Illinois College of Medicine at Peoria, Peoria, IL. (Tracking ID #1624106)

LEARNING OBJECTIVE 1: Recognize that purulent pericarditis is an infrequent complication of pneumococcal pneumonia which must be identified early to avoid significant morbidity and mortality.
CASE: Purulent bacterial pericarditis is an increasingly rare cause of pericardial inflammation that is associated with significant morbidity and mortality. Pneumococcus is a particularly infrequent inciting pathogen of purulent pericarditis in this post-antibiotic era, making a high index of suspicion critical to making the diagnosis. A 55 year old African-American male presented to the Emergency Department with complaints of cough, progressive dyspnea, and extreme fatigue for over 1 week. He endorsed no chest pain or abdominal symptoms, but was noted to have had periods of altered mental status prior to presentation. Past medical history was significant for heavy daily alcohol use but no other known medical problems. On physical examination the patient was afebrile, tachycardic, and tachypneic. He was lethargic and in mild respiratory distress. He had decreased breath sounds in the right lower and mid lung fields, markedly decreased heart sounds, but no evidence of jugular venous distension or pericardial friction rub. A 12 lead electrocardiogram revealed diffuse ST segment elevation. Laboratory data revealed a leukocyte count of $57\times103/\mu l$. CXR revealed right middle lobe consolidation and collapse with an enlarged cardiac silhouette, and subsequent chest CT delineated the presence of a moderate pericardial effusion. Further clinical examination revealed a pulsus paradoxus with drop in blood pressure of 20 mmHg upon inspiration. Echocardiogram demonstrated a moderate pericardial effusion without RV collapse but with respiratory variation of cardiac inflow consistent with early tamponade physiology. The patient's respiratory status and hemodynamics quickly deteriorated and he required vasopressor support, intubation, and transfer to the intensive care unit. He underwent bronchoscopy which did not reveal any obstructing endobronchial lesion. A pericardiocentesis was performed which produced distinctly purulent fluid. A pericardial drain was then placed and over the next 24 h his hemodynamics improved. Gram stains of bronchoalveolar lavage, blood, and pericardial fluid demonstrated the presence of gram positive cocci which was subsequently cultured and identified as Streptococcus pneumoniae. The patient was started on IV penicillin therapy and his pericardial drain was removed after 7 days. He ultimately required a pericardial window but did well and was discharged after a 4 week hospital course.
DISCUSSION: This case presents an increasingly uncommon cause of acute pericarditis and illustrates the challenge of diagnosing and treating purulent pericarditis, in part due to the absence of typical clinical features. Without aggressive treatment including pericardial drainage and selective antibiotic therapy, the mortality rate of purulent pericarditis nears 100 %. Maintaining a heightened awareness of this rare entity is critical in the timely initiation of appropriate treatment and subsequent minimization of patient morbidity.

PUS, THROMBOSIS AND FUSOBACTERIUM NECROPHORUM INFECTION: A RECURRENT THEME. Zahrae Sandouk; Dora Montezuma; Abdul Kareem Uduman; Allison Weinmann. Henry Ford Hospital, Detroit, MI. (Tracking ID #1617893)

LEARNING OBJECTIVE 1: Recognize Fusobacterium necrophorum infection as a possible etiology for portal vein thrombosis.
LEARNING OBJECTIVE 2: Manage Fusobacterium necrophorum infection and its complications: thromboembolic events, abscess and sepsis.
CASE: A 56 years old man with history of heavy alcohol use, presented to the hospital with complaints of weight loss, right upper quadrant pain and night sweats for 1 month. His laboratory findings were normal except for normocytic anemia. Hepatitis panel, HIV, blood and urine cultures were negative. Tuberculosis was ruled out. Ultrasound of the abdomen revealed right portal vein thrombosis without liver or gallbladder abnormalities. Anticoagulation was started and malignancy work up was performed, including CT chest, abdomen and pelvis, endoscopy and colonoscopy. No suspicious masses or lymph nodes were detected. Thrombotic work up was negative. The patient did not have any recorded fever while in the hospital, was stable and discharged with warfarin. He returns a month later with the same complaints. Work up included blood, urine and fungal cultures (fungitell, galactoman, and urine for histoplasma) all of which were negative. A repeat CT abdomen reveals interval development of an abscess within the right hepatic lobe measuring 8.8×6.8 cm. He was started on empiric ceftriaxone and metronidazole. One hundred milliliters of white purulent fluid was aspirated. Gram stain of the fluid was negative as were aerobic cultures, but the anaerobic culture grew Fusobacterium necrophorum. Hospital course was complicated by septic shock and development of right sided empyema attributed to contiguous spread of infection from the liver, requiring video assisted thoracoscopy with decortication. Due to the size of the hepatic abscess complete drainage was not feasible, it was decided to treat with oral metronidazole for several weeks, with planned reevaluation by CT as outpatient.
DISCUSSION: Fusobacterium necrophorum is an anaerobic gram-negative bacillus that belongs to the normal oropharyngeal flora. It is associated with septic venous thrombosis, Lemierre's disease, in which thrombosis of the internal jugular vein is precipitated by an upper respiratory infection. Primary foci of F. necrophorum infection in sites other than the head are uncommon, but can occur in the urogenital or gastrointestinal tracts. Clinical features include fever, dyspnea, malaise, and night sweats. The infection is most often recognized with isolation of the bacteria from a sterile body site (blood or abscesses). Compared with Lemierre's syndrome, illness due to primary foci caudal to the head carries a higher mortality rate. Complications include abscesses and septicemia. Metronidazole has been found to be the drug of choice, with duration of treatment from 3 to 6 weeks. Response to antibiotics is slow because of the endovascular nature of the infection. Our patient is responding slower than expected with planned longer duration of antimicrobials in the setting of an undrainable abscess. Therapeutic anticoagulation to prevent thromboembolic complications is controversial. It is used most frequently for patients with an underlying thrombophilia, a cerebral infarct, cavernous sinus thrombosis, and refractory disease. The most beneficial role of surgery is associated with drainage of the abscess within the neck, lung or liver. Finally, it is important to exclude underlying malignancy with non-head primary foci as up to 69 % of patients have underlying malignancies of the affected system.

PYOGENIC LIVER ABSCESS: IMAGING OF THE ABDOMEN IN A PATIENT WITH PNEUMONIA LIKE SYMPTOMS Tatiana McKenna; Dhruti Patel; Ronnie Mantilla; Anasse Souidi. Capital Helath Regional Medical Center, Hopewell, NJ. (Tracking ID #1641790)

LEARNING OBJECTIVE 1: Pyogenic liver abscess can be easily mistaken as another more common diagnosis, and requires a high index of suspicion to identify.

CASE: A 62 year old African American male with past medical history of gastroesophageal reflux disease, gastric ulcer, and benign prostatic hypertrophy presented to emergency room with right sided pleuritic chest pain, dyspnea, fever, cough with greenish sputum, and night sweats. He also reported symptoms of dysuria, with frequency and urgency for a few days. For the past 3 months, patient reported several trips to two different hospitals for recurrent fever, generalized malaise, constipation, early satiety and unintentional weight loss of 30 lbs. During one of these visits, he was hospitalized for 2 weeks, where he was diagnosed with a gastric ulcer, treated and discharged. On physical examination, patient had right sided lower chest wall tenderness, right upper quadrant tenderness, severely distended abdomen, and costovertebral angle tenderness on the right side. He was afebrile, but had leukocytosis of 17.4×10^9/L, creatinine of 3.88 mg/dL, blood urea nitrogen of 57 mg/dL, and glomerular filtration rate of 20. Chest radiograph showed significant elevation of right sided hemidiaphragm and cardiomegaly, but no infiltrates or consolidation. Patient was started on intravenous ceftriaxone for empirical treatment of possible pneumonia. Ultrasound of the abdomen revealed normal kidneys, and identified multiple liver masses. For further work up of these liver lesions, CT abdomen with contrast showed three hypodense masses (measuring approximately 6.6 cm, 5 cm, and 9.1 cm) within the right lobe of the liver. CT guided biopsy was performed and one abscess was drained. The patient's condition significantly improved after this procedure. Wound and blood cultures were positive for Streptococcus Intermedius. Patient underwent 4 weeks of intensive therapy with intravenous antibiotics (ceftriaxone and metronidazole) and was discharged home. Follow up CT abdomen showed radiological improvement of liver lesions.
DISCUSSION: Identification of PLA is especially challenging, since it has subtle onset and there are no specific symptoms. Symptoms and findings may mimic other more common diagnoses such as pneumonia, and patients may have more than one diagnosis, as in this case with a proven gastric ulcer. For single abscess with a diameter ≤5 cm, either percutaneous catheter drainage or needle aspiration is acceptable. For percutaneous management of single abscesses with diameter > 5 cm, catheter drainage is preferred over needle aspiration. Surgical drainage is warranted in multiple or loculated abscesses, when viscous contents obstruct the drainage catheter, and when there is inadequate response to percutaneous drainage within 7 days.

PYOGENIC LIVER ABSCESSES: MANIFESTATIONS AND MANAGEMENT OF AN EVOLVING PATHOGEN Atena Lodhi; Diana Purushotham; Michael A. Kron; Sumanta Chaudhuri. MCWAH, Wauwatosa, WI. (Tracking ID #1643046)

LEARNING OBJECTIVE 1: 1. Increasing awareness of an evolving pathogen in which early diagnosis and management is critical
LEARNING OBJECTIVE 2: 2. Discuss management goals in the hyperviscous variants of Klebsiella pneumonia, which is often not amenable to percutaneous drainage and inhibits penetration of appropriate antibiotics.
CASE: A 60-year-old male with no significant past medical history was admitted with a 5 day history of right upper quadrant pain and fevers. The patient recently came to the US from northern China. He reported a sharp, non-radiating 8 of out 10 right upper quadrant pain associated with mild nausea. The patient was not on any medications and denied melena, hematochezia, or changes in stool. He worked as a crane operator, and had no family history of colon cancer but had never had a colonoscopy. Admission laboratory studies showed no leukocytosis and a normal complete metabolic panel. Right upper quadrant ultrasound and an abdominal CT revealed multiple hypodense liver lesions suspicious for hepatic abscesses versus metastatic disease. Blood cultures obtained in the emergency room showed no growth over 3 weeks. Serologies for hepatitis B and C; stool ova and parasite; E. Histolytica antibody; Ameobiasis Ag stool test; and cultures for enteric pathogens were all negative. He was empirically started on piperacillin/tazobactam but continued to have intermittent fevers up to 103 °F so Vancomycin was added. Ultrasound guided percutaneous drainage of the suspected liver abscess/tumor was attempted multiple times without apparent success since gram stain and cytology of the scanty material obtained demonstrated no leukocytes. Culture of that material nonetheless grew 1+ pansensitive hypermucoid Klebsiella pneumonia. Despite 14 days of antibiotic treatment MRI revealed that the abscesses were increasing in size. Therefore laparoscopic drainage of the multiloculated abscess cavities was performed. Intraoperative cultures of the copious mucoid material grew 3+ pansensitive K. pneumonia. Postoperatively the patient did very well, and completed a four-week course of IV ertapenem with complete resolution of his liver abscesses.
DISCUSSION: The hyperviscous subtype of Klebsiella pneumonia in Asia emerged in the 1980s and has since expanded to the US. The capsular K1 serotype of K. pneumonia, has virulence genes magA, rmpA, and aerobactin, conferring resistance to neutrophil phagocytosis and serum complement killing. Primary liver abscesses can be further complicated with metastatic infection developing in 10–12 % of patients, with metastasis primarily involving the ocular or central nervous system. The surgical literature recommends percutaneous drainage and antibiotics in small (<3 cm) or unilocular abscesses. However, in the case of liver abscesses with mucoid K. pneumonia medical management often fails. Identification of hypermucoid K. pneumonia abscess should be a strong indicator for early surgical intervention.

RAISING AWARENESS FOR CHRONIC MESENTERIC ISCHEMIA: AN OFT-HIDDEN DIAGNOSIS Kristen M. Meier; Doyun Park; Geeta Laud. Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1635137)

LEARNING OBJECTIVE 1: Diagnose CMI based on clinical presentation
LEARNING OBJECTIVE 2: Understand the morbidity and mortality associated with late diagnosis of disease
CASE: An 86-year-old female with a history of HTN, T2DM, and CKD presented with a 6 month history of intermittent post-prandial abdominal pain, nonbloody diarrhea and weight loss. She had been hospitalized five times with the same complaint and treated with multiple courses of antibiotics. She underwent an EGD, colonoscopy, and EUS, with inconclusive results. An outpatient CT scan performed 1 week prior revealed mild ascending and transverse colits for which she was being treated with ciprofloxacin and metronidazole. Vital signs were stable and physical exam was notable for hyperactive bowel sounds and tenderness in the right and left upper quadrants. Laboratory studies showed hypokalemia, hypomagnesemia and leukocytosis of 21. She was empirically started on treatment with oral vancomycin for presumed C difficile colitis as well as ciprofloxacin and metronidazole. Workup for C difficile was negative and vancomycin was discontinued. Despite improvement in leukocytosis, patient continued to have intractable diarrhea, abdominal pain and electrolyte abnormalities prompting CTA of her abdomen, which revealed atherosclerotic changes in the abdominal aorta and its branches, the most notable being significant atherosclerotic disease of the celiac artery and SMA. Patient was evaluated by the vascular team for possible intervention, but was discharged to follow-up as an outpatient without a plan due to the need for operative risk assessment.
DISCUSSION: CMI is an indolent condition, often going underdiagnosed as patients usually present with nonspecific abdominal symptoms. CMI generally presents in patients older than 60 years and is three times more frequent in women. It is not as devastating as it acute counterpart, but it has debilitating consequences such as

recurrent postprandial abdominal pain, anorexia and weight loss averaging 25 lb. Major risk factors include CAD, HLD, smoking history and T2DM. Due to its insidious progression, collateral formation usually occurs between the three major arteries-celiac, SMA, IMA. Thus, symptomatic disease reflects significant blockage in two or more of the arteries. Less commonly, CMI can result from venous thrombosis secondary to hereditary thrombophilias, portal hypertension, inflammatory bowel disease and malignancies. The gold standard of diagnosis is intravascular arteriography as it allows for simultaneous therapeutic intervention. However, several noninvasive imaging modalities are readily available. Duplex sonography can detect turbulence of flow in arteries whereas CTA and MRA offer excellent sensitivity and specificity and combine 3D imaging to identify multivessel stenoses. Elective surgery-either vascular bypass or endarterectomy-is the standard of therapy for CMI but may not be a viable option for those with high postoperative risks. Percutaneous angioplasty and endovascular stenting have reduced morbidity but stents have been associated with higher recurrence of restenosis. For CMI due to venous thrombosis, anticoagulation or antiplatelet therapy should be considered. While working up a patient with recurrent postprandial pain, diarrhea, and nonspecific GI symptoms, it may be worthwhile to pursue CTA or MRA early on, especially in elderly patients with multiple risk factors for atherosclerosis and in those with active malignancy and inflammatory bowel disease.

RARE COMPLICATIONS OF SINUSITIS WITH NEW DIAGNOSIS OF HIV Emily Privette; Nirali Desai. Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA. (Tracking ID #1643134)

LEARNING OBJECTIVE 1: Assess the possible complications of severe sinusitis
LEARNING OBJECTIVE 2: Diagnose and treat cavernous sinus thrombosis
CASE: A 51 year-old male with no significant medical history presented to the ED with complaints of congestion, fever, and left-sided headache. On initial exam, he had nuchal rigidity and left-sided ptosis. CT scan of the head and neck showed complete opacification of the left sphenoid, maxillary, frontal sinuses, and ethmoid air cells. LP showed elevated protein and 58 white blood cells with a PMN predominance, but normal glucose and no organisms. Blood cultures from the day of admission grew out Strep constellatus, but CSF cultures were negative. Blood cultures cleared on day two of vancomycin and ceftriaxone, but the patient remained febrile. MRI of the brain obtained on day four showed enhancement of the Clivus, suspicious for osteomyelitis, as well as inflammation of deep cervical muscles on the right side. The patient remained febrile and Flagyl was added to vancomycin and ceftriaxone to cover a poly-microbial sinus infection. He defervesced on this combination of antibiotics. Flagyl was stopped, and the patient continued IV vancomycin and ceftriaxone for a six-week course. The MRI also raised concern for cavernous sinus thrombosis, and this was confirmed on CT scan. Thus, the patient was started on Heparin for therapeutic anticoagulation and discharged on Coumadin for 3 months. Prior to discharge, the patient was taken to the OR for sinus drainage and washout. Given the multitude of sinus complications, the patient was tested for HIV antibodies and found to be positive; confirmed by Western blot, with a CD4 count of 497
DISCUSSION: Cavernous sinus thrombosis, osteomyelitis, Horner's syndrome, and bacteremia are rare complications of sinusitis. Though the rarity of these complications create a diagnostic challenge, it is critical to suspect and begin treating these conditions early. This case illustrates multiple complications of sinusitis and underscores that diagnosis of cavernous sinus thrombosis is aided by recognizing clinical features attributable to sepsis and involvement of cranial nerves within the cavernous sinus. Furthermore, this case illustrates that an underlying immunodeficiency, such as HIV, can play a role in exacerbating common infections like sinusitis. Additionally, HIV may manifest as a state of hypercoagulability, which increases the risk of developing cavernous sinus thrombosis.

RECOGNITION & INITIAL WORK-UP OF INTERSTITIAL LUNG DISEASE IN THE PRIMARY CARE SETTING Russell G. Buhr[1]; John Charalambopoulos[2]; Katherine B. Komis[1]; Christopher B. Walsh[2]. [1]MedStar Georgetown University Hospital, Washington, DC; [2]Virginia Hospital Center, Arlington, VA. (Tracking ID #1638014)

LEARNING OBJECTIVE 1: Recognize interstitial lung disease as a cause of chronic cough
LEARNING OBJECTIVE 2: Execute initial work-up of interstitial lung disease
CASE: A 71-year-old Caucasian man presented with non-productive cough for 6 months and exertional dyspnea. His coronary artery disease, hypertension, and CKD-3 were well-controlled with aspirin, atenolol, HCTZ, lisinopril, atorvastatin & fenofibrate. Neither stopping lisinopril nor a trial of omeprazole improved the cough. He was a 20 pack-year smoker who quit 15 years ago. He denied atopy, asthma, COPD, or occupational exposures. He previously visited the ED and was diagnosed with pneumonia after chest x-ray showed interstitial & alveolar infiltrates. He took levofloxacin without improvement. He saw a pulmonologist, where spirometry showed moderate restrictive disease and was given an ipratroprium-albuterol MDI without change. An echocardiogram showed normal LVEF of 55 %, diastolic dysfunction, and no significant valvular disease. When he returned with unresolved cough, examination was significant for bibasilar inspiratory crackles and clubbing and was negative for hypoxia or signs of connective tissue disease. A CXR demonstrated increased interstitial markings, suggesting ILD. We ordered full pulmonary function tests that showed moderate restrictive & diffusion defects. A high-resolution chest CT showed advanced ILD with pattern suggestive of idiopathic pulmonary fibrosis (IPF). Connective tissue serologies were sent and are pending. He was referred back to pulmonology for further management.
DISCUSSION: ILD encompasses a group of over 160 distinct entities with varying etiologies & clinical courses. In this case, CT appearance and epidemiology favor IPF. The American Thoracic Society 2011 guidelines outline criteria for diagnosis including ruling out other known causes of ILD (e.g., occupational and drug exposures), typical CT appearance, and optional open lung biopsy. Serologies may elucidate a specific etiology due to connective tissue disease or hypersensitivity. We opted against biopsy due to patient preference and because his underlying CAD and advanced age would preclude transplant. Some ILD etiologies are steroid-responsive. Without clear-cut evidence of IPF, there is support for a defined trial of steroids to assess for improvement. More advanced therapies including steroid-sparing agents, should only be undertaken under expert consultation, and Pneumocystis prophylaxis should be considered in patients receiving more than 20 mg prednisone/day. Notably, the ongoing PANTHER-IPF trial has indicated against the use of azathioprine, prednisone, and n-acetylcysteine (NAC) triple therapy in IPF due to increased mortality, while the NAC monotherapy arm is in progress. Early recognition of ILD is key to diagnose & treat any reversible inflammatory processes prior to progression to incurable fibrosis. Internists may expedite work-up by ordering simple connective tissue screening serologies, PFTs, and a high-resolution CT if suspicion is high and CXR suggests interstitial disease. Quality of life is frequently improved by enrollment in pulmonary rehabilitation, as well. Advanced directive counseling is crucial in progressive disease. In summary, the evaluation of ILD requires a multimodal approach, but can easily be started in the primary care clinic with a thorough history and physical examination, basic studies, and early referral for expert opinion and possible enrollment in clinical trials, which are ongoing for novel therapies.

RECOGNIZING LESS COMMON PRESENTATIONS OF CELIAC DISEASE Maryam Mahmood; Benjamin Lloyd. Reading Health System, Reading, PA. (Tracking ID #1624145)

LEARNING OBJECTIVE 1: Recognize extraintestinal manifestations of celiac disease

CASE: Celiac disease (CD) is associated with many extraintestinal manifestations. These can involve almost any system including liver, kidney, blood, endocrine, nervous, skin, skeletal and muscular. Older patients in particular tend to present with extraintestinal rather than gastrointestinal complaints. We present a case of an older woman with celiac disease who presented with bone pain, hypocalcemia, liver involvement and nephrotic range proteinuria. A 72-year-old woman with a background of celiac disease diagnosed 10 years ago presented with bilateral lower extremity bone pain, abdominal distension and a 10 lb weight loss over 2 months. She had not been adherent to a low gluten diet. Investigations noted significant hypocalcemia (ionized calcium 0.93 mmol/L), elevated serum alkaline phosphatase (368 IU/L) and low serum total vitamin D (<7 ng/mL). Additionally elevated transaminases (AST 72 IU/L, ALT 62 IU/L), elevated INR of 1.9 and low serum albumin (2.7 g/d) were noted. The urine TP/Cr ratio was 4.8 with normal creatinine (0.43) and anti-gliadin IgA was elevated (>142 EU/ml). In the hospital, her calcium and vitamin D were repleted and INR corrected with one dose of vitamin K. Her bone pain resolved and she was discharged after counseling on the importance of low gluten diet adherence.

DISCUSSION: Calcium and vitamin D malabsorption in CD can manifest with hypocalcemia, hypophosphatemia, secondary hyperparathyroidism, bone pain, tetany and osteopenia. Additionally magnesium and zinc deficiencies, as well as chronic intestinal inflammation have been linked with reduced bone mineral density. The most common hepatic complication of CD is a mild chronic transaminitis, reported in about 40 % of patients with untreated CD. In some cases it is the only clinical sign of CD. The underlying cause is poorly understood; increased intestinal permeability in CD may facilitate the entry of toxins, inflammatory cytokines, and antigens into the portal circulation contributing to hepatic involvement. The presence of tissue transglutaminase antibodies in the liver also raises the possibility of humoral-mediated liver injury. Additionally CD is linked with primary sclerosing cholangitis, primary biliary cirrhosis and autoimmune hepatitis. CD is linked with an increase of renal diseases; the most common is IgA nephropathy which occurs in 3 % of CD patients It is thought that there is shared autoimmune pathogenesis with these disease processes as 22–77 % of patients with IgA nephropathy have circulating IgA anti-tissue transglutaminase antibodies, and 3–4 % of these have CD. Awareness of the potential extraintestinal manifestations and complications of CD is important in management of CD patients. Strict adherence of a low gluten diet has been demonstrated to resolve abnormalities of calcium and vitamin D, transaminitis, and proteinuria.

RECOGNIZING THE HOOF BEATS OF A ZEBRA Jessica H. Voit[2]; Daniel R. Zeve[2]; Blake R. Barker[1]. [1]UT Southwestern Medical Center at Dallas, Dallas, TX; [2]UT Southwestern Medical School, Dallas, TX. (Tracking ID #1643248)

LEARNING OBJECTIVE 1: Recognize the risk of anchoring errors in medical decision-making

LEARNING OBJECTIVE 2: Recognize pheochromocytoma as a cause of chest pain

CASE: A 54 year-old male with a past medical history of poorly-controlled hypertension, diabetes, hyperlipidemia and CHF (diagnosed at an outside hospital) presented with 9 months of intermittent left-sided chest pain of increasing frequency. The pain lasted 10 min, worsened with exertion and diminished with rest. It was associated with palpitations, dyspnea, diaphoresis and nausea. He denied any abdominal pain, weight change or new neurologic or psychiatric symptoms. Home medications included atenolol, Tribenzor (olmesartan-amlodipine-hydrochlorothiazide), metformin. On admission, he was afebrile with a blood pressure of 140/89. His lungs were clear to auscultation bilaterally. His cardiac examination was notable for a regular rate and rhythm with no murmurs or gallops, normal jugular venous pulsations, and no peripheral edema. Neurological exam was within normal limits. During the hospitalization, he experienced intermittent hypertension and tachycardia. His work-up was notable for normal serial cardiac enzymes, normal echocardiography and a vasodilator myocardial perfusion study with no evidence of ischemia. Therefore, CT angiography was performed to assess for pulmonary emboli (PE). There was no evidence of PE, but it revealed an incompletely visualized 5 cm mass either in the pancreatic tail or left adrenal gland. Subsequent abdominal CT confirmed a left adrenal mass. Plasma metanephrines and 24-hour urine metanephrines were elevated, consistent with pheochromocytoma (pheo). He was initiated on pheoxybenzamine and metoprolol until a left adrenalectomy could be performed several months later. Pathology confirmed pheo. Post-operatively, 2 sets of metanephrine and normetanephine levels were normal, confirming cure.

DISCUSSION: Pheochromocytoma is a catecholamine-producing tumor derived from chromaffin cells, typically from the adrenal medulla. The periodic release of hormones leads to a variety of clinical manifestations including episodes of tachycardia, palpitations, chest pain and hypertension. These symptoms mimic more common conditions, including acute coronary syndrome (ACS). Diagnosis is often delayed or missed by anchoring error as clinicians cling to an initial impression despite the accumulation of conflicting data. On admission, we began evaluating for ACS because of his multiple risk factors, a reported history of CHF, and the common nature of ACS. However, as the labs and imaging indicated normal cardiac function and perfusion, we broadened our differential and ordered a CT angiography to evaluate for PE. This led to the incidental discovery of the abdominal mass that, in the setting of his symptoms, was suspicious for a pheo and ultimately confirmed by elevated plasma metanephrines and 24-hour urine. This case illustrates that when presented with the constellation of episodic tachycardia, dyspnea, hypertension, and chest pain, clinicians must first evaluate for common etiologies, especially those that require immediate intervention. But to avoid the trap of anchoring error, one must reconsider the initial impression and consider other less common etiologies, such as a pheochromocytoma. When hearing hoof beats, think horses; just don't forget the possibility of zebras.

RECURRENT ASPIRATION PNEUMONIA IN A PATIENT WITH GASTRIC BANDING Vikram Sengupta; Cristina M. Gonzalez; Manuela Calvo. Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY, NY. (Tracking ID #1643139)

LEARNING OBJECTIVE 1: Recognize recurrent aspiration pneumonia as a complication of laparoscopic adjustable gastric banding (LAGB).

LEARNING OBJECTIVE 2: Identify alarm symptoms of LAGB complications.

CASE: A 48 year-old man presented with 5 months of worsening productive cough and subjective fever. His symptoms had failed outpatient therapy for upper respiratory tract infection and he had subsequently been admitted, diagnosed with multi-lobar pneumonia and discharged on a course of antibiotics. Despite completing the course of antibiotics, his cough recurred which prompted re-admission. His past medical history was significant for diabetes mellitus and morbid obesity treated with laparoscopic adjustable gastric band placement in 2005. Physical examination revealed a temperature of 102.8, a pulse of 130, a respiratory rate of 36 and an oxygen

saturation of 80 % on room air. There were diffuse rhonchi and crackles in the right lung field. Blood tests revealed a white cell count of 10,600 cells/uL. Arterial blood gas was significant for pH 7.38, pCO2 48.8 and pO2 42.2. During intubation, copious gastric secretions were noted in his oropharynx. Chest computed tomography ruled out pulmonary embolus but revealed opacities in the right lung field and a dilated esophagus, which caused concern for pseudoachalasia as a consequence of laparoscopic gastric band hyperinflation. This finding prompted minimally invasive surgery to completely deflate the laparoscopic band. The patient's cough subsequently resolved. He was discharged and has been asymptomatic since that time.

DISCUSSION: Obesity and its co-morbid disorders are an increasingly common challenge to the general internist in the United States. Laparoscopic adjustable gastric banding procedures have become the leading surgical intervention for the treatment of morbid obesity worldwide. These interventions, however, are associated with significant morbidity and mortality, which often occurs months to years after surgery. The most common complication of LAGB is aspiration pneumonia, which occurs as a consequence of partial or complete esophageal obstruction. Often the patient will report recent tightening of the gastric band. Band slippage may also restrict the lower esophageal sphincter. Esophageal obstruction leading to aspiration underlies all other pulmonary complications, which include hemoptysis, abscess, bronchiectasis and interstitial lung disease. Common alarm symptoms are cough, dyspepsia, dysphagia and regurgitation after meals. These symptoms place patients at risk for aspiration and will be reported to the general internist long after surgery. In this case, the patient's first alarm symptom began 7 years after surgery. He complained of cough for 6 months, was hospitalized twice with aspiration pneumonia and went into respiratory failure before the diagnosis was made. On further questioning, he recalled having dyspepsia, dysphagia and regurgitation in the same time period but had not associated them with his cough. In summary, the general internist must identify symptoms and intervene early to prevent aspiration pneumonia in patients with LAGB. These patients should be asked about reflux, cough, fever and other alarm symptoms during every follow-up visit. Recent tightening of the gastric band or respiratory cultures suggestive of aspiration pneumonia should also arouse suspicion. Total deflation of the ring is recommended if recurrent aspiration pneumonia is suspected.

RED FLAGS OF ACUTE LOW BACK PAIN SIGNAL INFECTIOUS COMPLICATIONS OF BACILLUS CALMETTE-GUERIN (BCG) THERAPY David R. Linz; Harish Jasti. University of Pittsburgh School of Medicine, Pittsburgh, PA. (Tracking ID #1638669)

LEARNING OBJECTIVE 1: To recognize back pain caused by infectious complications of Bacillus Calmette-Guerin therapy

LEARNING OBJECTIVE 2: To identify red flags of acute low back pain in order to guide higher quality and more cost effective care

CASE: An 85 year-old gentleman presented to his primary care physician with 2 months of severe, progressive low back pain associated with malaise, functional impairment, and a 15 lb weight loss. His symptoms had worsened despite physical therapy, steroid joint injections, and analgesia with narcotics and neurotransmitter modulators. He denied any fevers, chills, sweats, or exposure to tuberculosis. His medical history included diet controlled type 2 diabetes, chronic low back pain secondary to spinal stenosis at L5-S1 diagnosed 8 months prior by MRI, and superficial bladder cancer treated with transurethral resection of the bladder and adjuvant intravesicular Bacillus Calmette-Guerin (BCG) therapy. Examination was notable for spinal tenderness over the lumbar spine, marked weakness of the lower extremities, and bilateral radiculopathy. Laboratory analysis showed normocytic anemia, normal WBC, elevated ESR (74 mm/hr; nl<23), and elevated high sensitivity CRP (4.1 mg/dL; nl<0.7). A repeat MRI of the thoracic and lumbar spine revealed T12-L1 discitis-osteomyelitis and bilateral psoas abscesses. A needle biopsy sample was positive for Mycobacterium bovis.

DISCUSSION: Bladder cancer is the sixth most common human malignancy in the United States and immunotherapy with intravesical BCG, a live attenuated strain of Mycobacterium bovis, is a common adjunctive therapy. Although BCG therapy is well tolerated, it has been associated with localized and systemic complications, such as hematuria, urinary frequency, cystitis, sepsis, and osteomyelitis. Infection involving the spine may present with back pain, motor weakness, and elevated inflammatory markers as it did with this patient. Risk factors for systemic infection include age ≥70, pelvic radiation, immunosuppresion, and disruption of the bladder, prostate, or urethra. Diagnosis can be made radiographically and confirmed by biopsy. Recognition of the complications of BCG therapy is important for physicians who must carefully weigh the benefits and harms of routine imaging for low back pain. Red flags of serious underlying conditions, such as infection, cancer, cauda equina syndrome or symptomatic spinal stenosis, should be identified in order to practice high quality care and conscientious use of finite clinical resources. This patient presented with 5 of the 10 red flags outlined by the American College of Radiology's appropriateness criteria for acute low back pain: unexplained weight loss, history of cancer, age >70, disabling symptoms, and duration >6 weeks. Additional red flags include recent trauma, unexplained fever, immunosuppresion, IV drug use, and prolonged corticosteroid use/osteoporosis. According to one of the top 5 recommendations from the Promoting Good Stewardship in Clinical Practice initiative of the National Physicians Alliance, abstaining from imaging for low back pain within the first 6 weeks unless red flags are present will improve care, reduce harm, and decrease overall medical costs.

RED HERRING SYNCOPE AND A BIT OF EXTRA STORAGE: A NOVEL ALLELIC FORM OF GAUCHER DISEASE David M. Levine; Andrew A. Chang. New York University Medical Center, New York, NY. (Tracking ID #1635562)

LEARNING OBJECTIVE 1: Formulate a differential diagnosis for splenomegaly and thrombocytopenia

LEARNING OBJECTIVE 2: Recognize and diagnose Gaucher Disease

CASE: A 46 year-old incarcerated man with history of hypertension and hip replacement was admitted for two unwitnessed episodes of syncope. During both episodes, the patient described lying in his intensely hot cell when he began to experience weakness and dyspnea, until he lost consciousness for an unknown period of time. He denied preceding palpitations or post-episode confusion, focal deficits, or loss of bowel/bladder function. Upon waking, he noted sharp non-radiating substernal pleuritic chest pain. CXR, ECG, troponins, TTE, and stress test were unremarkable. Unexpectedly, laboratory analysis revealed thrombocytopenia (41) and transaminitis (AST 45, ALT 44). Abdominal ultrasound demonstrated hepatosplenomegaly with poorly marginated echogenic splenic masses. CT found multiple low attenuation splenic lesions with likely reactive porta hepatic lymph nodes. Subsequent MRI demonstrated T1 and T2 hypointense enhancing splenic lesions, less likely hemangioma or lymphoma. FNA of an enlarged submandibular lymph node was negative for malignancy. Delayed collateral from the patient's mother cited a childhood diagnosis of "bone disease." The patient refused bone marrow biopsy. Further testing demonstrated highly elevated ACE and ferritin levels and heterozygosity for the N370S Gaucher Disease (GD) mutation. Upon DNA analysis, a novel mutation in the second disease allele: R48W (exon 3) in cis with R120W was discovered. Given our patient's comorbidities, he was offered enzyme replacement therapy with recombinant glucocerebrosidases.

DISCUSSION: Our case highlights the pivotal role an in-depth history can possess in shaping workup and emphasizes the importance of formulating a broad differential for splenomegaly and thrombocytopenia. After workup of syncope and chest pain, we ruled out the major causes of splenomegaly: congestion (cirrhosis, portal/hepatic/splenic thrombosis, heart failure), malignancy (lymphoma, leukemia), infection (HIV, EBV, CMV, viral hepatitis, TB, MAC, endocarditis, malaria), inflammation (lupus, sarcoid), and hypersplenism (hemolytic anemias, use of G-CSF). The remaining cause involved infiltration: lysosomal

storage disease ([LSD]; GD, Niemann Pick Type B, cholesterol ester storage disease), amyloidosis, and others. Given the initial ACE and ferritin levels, youthful hip replacement, and childhood "bone disease," further glucocerebrosidase activity and DNA analysis was warranted. The most common LSD, GD is an autosomal recessive disorder caused by mutations in glucocerebrosidase, which dysregulate cellular glycolipid recycling and cause accumulation of lipid-laden macrophages in the spleen and elsewhere. Type 1, 2, and 3 GD are characterized by their degree of neuronopathic involvement: absent, acute, and chronic, respectively. Type 1 GD (GD1) is characterized by anemia, thrombocytopenia, hepatosplenomegaly, marrow infiltration, lung disease, and bone abnormalities. Its course is extremely variable, with some patients remaining asymptomatic throughout life. The N370S allele is pathognomonic for GD1. Both of our patient's alleles have been previously reported, but never on one chromosome. In retrospect, the patient's syncope was likely a function of a blistering prison cell. The constellation of findings that initially appeared disconnected, ultimately proved entirely unifying for the diagnosis of a novel allelic form of GD1.

RENAL FAILURE HERALDING A DEEPER ABNORMALITY Paavani Komanduri; Harish Jasti. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1641893)

LEARNING OBJECTIVE 1: Describe the diagnostic evaluation for renal failure
LEARNING OBJECTIVE 2: Discuss the treatment options for amyloidosis
CASE: A 42 year-old woman, with a history of hypertension, presented with severe abdominal pain which started 2 months prior to presentation and was initially alleviated with ibuprofen. It progressively worsened and she developed dyspnea on exertion. On review of systems, she endorsed polyuria and a 15-lb weight gain. She denied any associated fevers, chest pain, orthopnea, nausea, vomiting, or dysuria. Her medications included lisinopril and hydrochlorothiazide (HCTZ). Physical exam revealed a well-appearing female in mild distress. She was afebrile with a blood pressure of 185/95. Her cardiac and pulmonary exams were unremarkable. Abdominal exam was significant for epigastric tenderness without rebound. She had 2+ pitting edema up to her knees. Initial labs were remarkable for a Cr of 6.4, BUN of 47, and hemoglobin of 10. Baseline Cr 6 months prior was 1.3. Subsequent evaluation revealed a fractional excretion of urea of 74, suggestive of acute tubular necrosis (ATN) secondary to the use of ibuprofen, lisinopril and HCTZ. Renal ultrasound demonstrated no hydronephrosis or renal artery stenosis. A 24-hour urine collection revealed 14 g/day of protein. Additional testing for ANA, ANCA, hepatitis B and C, and complement levels, were all negative. Due to progression of her renal failure, she underwent a renal biopsy which showed ibuprofen induced ATN, along with prominent Congo-red staining, indicating a diagnosis of renal amyloidosis. Subsequent bone marrow biopsy revealed 8 % plasma cells, which was consistent with a diagnosis of amyloid light-chain (AL) amyloidosis.
DISCUSSION: Amyloidosis constitutes a spectrum of diseases characterized by deposition of insoluble beta pleated sheets into tissue, causing organ dysfunction. AL amyloidosis is the most common systemic form of amyloidosis in the United States. It is associated with amyloid production due to plasma cell dyscrasia and included under the classification of multiple myeloma. Since amyloidosis is a systemic disease, any organ system can be affected, with the liver, kidney and heart being the most common. Cardiac amyloid manifests as a restrictive cardiomyopathy, along with arrhythmias and complete heart block due to infiltration of the conduction system. Treatment is targeted at preventing progression of disease since amyloid proteins cannot be removed after deposition. With respect to AL amyloidosis associated with multiple myeloma, definitive treatment is autologous stem cell transplant (SCT). This results in 25–67 % of patients achieving complete remission. Successful transplantation can also lead to improvement in renal function, including a 50 % reduction in proteinuria and >25 % increase in GFR. It is especially effective in patients without persistent plasma cell dyscrasia (71 % vs. 11 %). In patients unable to tolerate chemotherapy, systemic bortezemib with dexamethasone can be used as an alternative therapy, with a hematologic response rate of 44 %. In cases of cardiac involvement, pre-SCT heart transplantation may be required depending upon the degree of cardiac involvement. Survival is typically 12 months (6 months with cardiac involvement) vs. 4.5 years with treatment. Our case demonstrates that it is important to consider AL amyloidosis in the differential diagnosis of patients who present with nephrotic-range proteinuria, unexplained nonischemic cardiomyopathy, or atypical multiple myeloma.

RENAL TAMPONADE SYNDROME WITH BILATERAL KIDNEYS: A CASE OF SUB-CAPSULAR HEMATOMA INDUCED ACUTE KIDNEY INJURY Vaidehi S. Patel[1]; Kamesh Sivagnanam[1]; Martin Q. Tran[2]. [1]ETSU, Jonesborough, TN; [2]JCMC, Johnson City, TN. (Tracking ID #1642111)

LEARNING OBJECTIVE 1: Conclusion: Renal tamponade syndrome must be considered as a differential by hospitalists for patients who present with AKI after biopsy. The presence of two kidneys does not exclude the condition.
CASE: Case report: A 46 year old lady with hypertension, diabetes, chronic kidney disease (baseline creatinine 1.3 mg/dl) and tobacco abuse, with a recent history of renal biopsy, presented with non-specific complaints including generalized body aches, weakness and nausea for 3–4 days. Medications included furosemide, lisinopril and insulin. Examination was significant for tachycardia and diffuse abdominal and extremity tenderness. Initial labs showed leukocytosis(11.2*10^3/ml), hyperkalemia(7.2 meq/dl), elevated creatinine(7.7 mg/dl) and acidosis(co2-12 meq/dl,ABG-metabolic acidosis). An EKG and CXR were normal. CT scan of the abdomen and pelvis showed a circumferential hematoma of the left kidney (1.5 cm largest thickness). The right kidney had trace hydronephrosis and dilated ureters but no definite stones. Patient was admitted to intensive care and hyperkalemia was corrected with bicarbonates, insulin, D5normal saline and sodium polystyrene. Furosemide and lisinopril were stopped. Patient was started on fluids and received empirical antibiotics. With the above treatment, hyperkalemia resolved, but her acidosis required a continuous bicarbonate infusion for management. On day3, all electrolyte abnormalities resolved and the patient was moved to the floor, but her creatinine was still above baseline. Patient was doing well except for nausea that was managed symptomatically. Her biopsy came back at this time and was suggestive of diabetic nephropathy. Patient was discharged home with stable symptoms and improving renal function.
DISCUSSION: Introduction: Approximately 47 % of renal biopsies result in subcapsular hematomas. 8.7–10 % of these hematomas are large (>1 cm thickness) and can cause pressure effect(tamponade) induced acute kidney injury(AKI). This is mostly described in patients with solitary kidneys as they don't have an additional Kidney to compensate for the loss of function. We present a patient with bilateral kidneys who developed acute on chronic renal failure secondary to biopsy related renal tamponade.
DISCUSSION: Renal tamponade syndrome should be considered in patients with subcapsular hematomas and AKI. Patients with bilateral kidneys who undergo renal biopsy may still manifest the syndrome in the setting of functional compromise of the contralateral kidney. In the patient described, while renal tamponade affected one kidney, the function of the contralateral kidney was possibly affected secondary to the underlying diabetic nephropathy and ischemia induced activation of the renin-angiotensin system. Of note, the population that is most likely to get a renal biopsy is the same group that is likely to have functional impairment of the contralateral kidney. Like cardiac tamponade, the hematoma's size as well as the time taken for it to develop are important factors affecting severity. Therefore, a small tamponade must not be dismissed as clinically irrelevant. Management is usually conservative. Surgical intervention is for large hematomas or persistent symptoms.

REPEATED EPISODES OF NEUROLOGICAL SYMPTOMS AND SEVERE HYPOCALCEMIA, THINKING BEYOND THE USUAL CAUSES Madan R. Aryal[1]; Naba R. Mainali[1]; Ravi Shahukhal[3]; Yagna R. Bhattrai[2]. [1]Reading Health System, West Reading, PA; [2]Mercy Catholic Medical Center, Philadelphia, PA; [3]Queens Hospital Center, Queens, NY. (Tracking ID #1622107)

LEARNING OBJECTIVE 1: Although uncommon to be presenting in the elderly population, recognize Di George Syndrome in the setting of repeated neurological symptoms and hypocalcemia.
LEARNING OBJECTIVE 2: Discuss the management of Di George Syndrome
CASE: A 61 year old Caucasian male with history hypoparathyroidism, recently diagonosed VSD, right aortic arch, Atrial fibrillation, Personality disorder and seizure due to hypocalcemia presented to us with confusion, irritability and lethargy. He denied any focal neurological deficit, tingling and numbness, speech abnormality or drooping of face. His symptoms were initially confused with stroke, however his brain MRI was negative. When he was first diagnosed with seizure due to hypocalcemia 6 years ago he was started on calcium and has been on it since then. Formal evaluation for his low calcium was also done in the past which revealed low PTH. Vitamin D and magnesium were normal. He denied parathyroid surgery, symptoms of malabsorption, family history of calcium disorder and diuretic intake. On further lab testing it was found that calcium was 6.5 mg/dl, magnesium 1.9 mg/dl, phosphorous 5.7 mg/dl, albumin 3.2 g/dl, ionized calcium 0.90 mg/dl and corrected calcium of 7.3 mg/dl. MRI brain was normal. His cardiac anomaly, low calcium and low PTH level prompted us to do genetic analysis for Di George syndrome which was positive. Immunological test showed CD3+ T cells of 454/mm3. Our patient had multiple admissions with neurological complaints which were attributed to low calcium level. He also had atrial fibrillation that was not well controlled most likely due to hypocalcemia.
DISCUSSION: Diagnosis of DGS requires reduced number of CD3+ T cells, along with either demonstrated deletion in the chromosome 22q11.2 or typical clinical findings. Management of DGS requires multidisciplinary approach. Sinopulmonary infections are common and aggressive antibiotic therapy is instituted early. Hypocalcemia is treated with calcium supplementation after the measurement of serum calcium and PTH level. Involvement of psychiatrist is required for the proper treatment of schizophrenia and major depression.

REVERSE BROKEN HEART SYNDROME. IS THE BETA-2 AGONIST A CULPRIT? Raji Shameem; Niket Sonpal; Zakaria Majeed; Robert E. Graham. Lenox Hill Hospital, New York, NY. (Tracking ID #1624109)

LEARNING OBJECTIVE 1: Diagnose reverse takotsubo cardiomyopathy as an uncommon variant of the well documented stress induced phenomenon.
LEARNING OBJECTIVE 2: Recognize Beta-2 agonist therapy as a potential cause of reverse takotsubo cardiomyopathy.
CASE: 59-year-old female with a past history of well-controlled asthma without the need for rescue therapy presented to the hospital with shortness of breath for a duration of 1 week. The patient had no previous history of cardiac disease The patient went to a local urgent care center the previous day where she was diagnosed with an asthma exacerbation and prescribed an albuterol inhaler. The patient reported administering frequent treatments of the albuterol inhaler with the use of a spacer and estimated to have taken 70–80 puffs of her inhaler between the times she started using the inhaler and the time she presented to the Emergency Department. In the emergency department the patient was found to be in respiratory distress. On examination she was found to have poor air entry with diffuse wheezing on expiration. The patient was immediately started on nebulizer treatments with albuterol and given high dose glucocorticoids intravenously. Given her worsening respiratory status after nebulizer treatments with albuterol, the decision was made to intubate the patient and admit to the ICU. Of interest, the patients EKG just prior to intubation revealed ST depression in the inferior leads (II, III, avF) and lateral leads (V4,V5,V6). Labs drawn upon arrival to the ED and post intubation revealed elevated Troponin at 0.179 and 0.424 respectively. Echocardiographic imaging obtained while the patient was intubated revealed basal inferior wall akinesis and hyper-dynamic apical segments. Left ventricle ejection fraction was estimated to be 35 %. A diagnosis of reverse takotsubo cardiomyopathy was made.
DISCUSSION: Reverse takotsubo cardiomyopathy is characterized to be a transient impairment in cardiac systolic function. Unlike the typical variant, there is basal wall akinesis and a hyper-dynamic apex. The pathophysiology of this condition is thought to be caused by stress induced catecholamine surge that leads to supraphysiologic activation of beta adrenoreceptors in human myocardium, for this reason it is also referred to as stress induced cardiomyopathy. Studies have further postulated the particular roles of B1 and B2 adrenoreceptors in stress cardiomyopathy. At normal physiologic levels, epinephrine binds Beta-adrenoreceptors and activates G-stimulatory protein resulting in increased cardiac inotropic effects. At supra physiologic levels, epinephrine binding to the Beta-adrenoreceptors is thought to have a negative inotropic effect on myocardium via activation of G-inhibitory protein instead of its normal physiologic activation of G-stimulatory protein, a process referred to a signal trafficking. It is, therefore, not difficult to postulate how a catecholamine surge lead by epinephrine could result in stunning and aknesis of myocardium densely populated with B2-adrenoreceptors. In this case, it was likely the excessive B2 stimulation by albuterol therapy that precipitated the transient cardiomyopathy.

RIGHT ATRIAL THROMBUS ASSOCIATED WITH INDWELLING DIALYSIS CATHETERS Jasmine K. Ahuja. Capital heatlh regional medical center, Trenton, NJ. (Tracking ID #1642424)

LEARNING OBJECTIVE 1: Right atrial thrombus (RAT) associated with indwelling dialysis catheters may be successfully managed conservatively.
CASE: Case 1: A 43 year old African American male with ESRD secondary to interstitial nephritis and diabetic nephropathy presented with fever, chills, and generalized malaise. Blood cultures were positive for Staphylococcus epidermidis and Streptococcus agalactaciae. The source of bacteremia was identified as the right internal jugular dialysis catheter placed 5 months earlier. Transthoracic echocardiogram showed a large mass within the right atrium. The CT chest confirmed a low density mass within the right atrium adjacent to the catheter tip measuring 2.5×1.0×2.0 cm. Intravenous heparin was bridged to warfarin, the catheter was exchanged, and repeat transthoracic echocardiogram 2 months later showed no mass in the right atrium. Antibiotics were continued for 6 weeks. Case 2: A 73 year old African American female with ESRD secondary to diabetic and hypertensive nephropathy presented with rapid atrial fibrillation and sepsis. Blood cultures grew Staphylococcus epidermidis and Staphylococcus capitis. Transthoracic echocardiogram showed dilated right and left atria with a large mobile echogenic density in the right atrium measuring 1.9×1.6 cm. Transesophageal echocardiogram showed a multi-lobed mass within the right atrium attached to the inferior vena cava and the right atrial wall with a catheter in the right atrium. The patient refused surgical thrombectomy and the catheter was not exchanged due to conern for thromboembolism. Intravenous heparin was bridged to warfarin, and repeat transthoracic echocardiogram 2 months later showed no right atrial mass and patient now has a functional AV fistula used for HD. Antibiotics were continued for 6 weeks.
DISCUSSION: The optimal management of dialysis catheter-associated RAT is unclear. Thrombectomy has been reported to be associated with a lower mortality compared with conservative management with anticoagulation and antibiotics. However, some patients may refuse or are poor candidates for surgery. All ESRD patients require stable dialysis access which complicates the decision process. Literature has advocated conservative approach to clots less than 2 cm, and thrombectomy for larger clots, however our experience suggests larger clots may be successfully managed conservatively.

RIGHT ATRIAL THROMBUS: A HANGING QUESTION Sarah Apgar[1]; Christopher Hoimes[2]. [1]Yale-New Haven Hospital, New Haven, CT; [2]Yale School of Medicine, New Haven, CT. (Tracking ID #1640445)

LEARNING OBJECTIVE 1: Recognize the clinical features of right heart thromboemboli, a rare and potentially life-threatening form of venous thromboembolic disease.
LEARNING OBJECTIVE 2: Emphasize the controversial management options for right heart thromboemboli and the need for a multidisciplinary approach to tailor therapy to a specific patient.
CASE: A 34 year-old woman with a stage IV infiltrative ductal breast carcinoma being treated with capecitabine and goserelin was admitted for management of a right atrial thrombus incidentally found on restaging contrast enhanced computerized tomography (CT) 4 days prior to admission. Results revealed a possible defect in the inferior vena cava (IVC) concerning for thrombus without evidence of pulmonary emboli (PE). On the day of admission, the patient underwent an echocardiogram which confirmed a mobile echodensity in the right atrium which appeared to originate from the IVC. The echodensity was noted to move to and fro across the tricuspid valve. Right ventricular function was normal. Upon evaluation, she denied any chest pain, shortness of breath, leg pain or swelling. Her blood pressure was 129/83 mm Hg and pulse was 73 beats per minute. She was obese (BMI 46 kg/m2) and breathing comfortably. Cardiac examination demonstrated a regular rhythm with no murmurs, gallops, or plops. There was no lower extremity swelling or calf tenderness. She had no indwelling lines. Blood work revealed a troponin of <0.01 ng/mL and pro-B-type natriuretic peptide of 17 pg/mL. There was no right heart strain on electrocardiogram. Bilateral lower extremity ultrasound examination was without thrombus. A heparin infusion was begun for treatment. Repeat echocardiogram 2 days later showed no change in the echodensity. On hospital day 4, the patient complained of a brief episode of left sided pleuritic chest pain that resolved spontaneously. Her vitals remained stable. On hospital day 7, a repeat echocardiogram showed no evidence of thrombus. A PE protocol CT chest prior to discharge confirmed a pulmonary embolus in the distal left pulmonary artery and posterior basal right lower lobe. The patient was discharged in stable condition on low molecular weight heparin.
DISCUSSION: Right heart thromboemboli (RHTE), often referred to as "thrombi-in-transit", represent a rare form of venous thromboembolic disease (VTE). Presentation can vary from hemodynamic instability to an insidious onset as was the case with this patient. RHTE are most often discovered by echocardiogram done during the evaluation of PE. Management options include anticoagulation alone, thrombolysis, interventional percutaneous thrombus retrieval or surgical thrombectomy. As this is a rare clinical event, no prospective randomized trials are available and there is no consensus on the ideal treatment option. Case series have shown conflicting results with significant mortality between 20 % and 60 % regardless of the treatment chosen. In this case, a multidisciplinary approach was employed with consultants from hematology, thoracic surgery, interventional radiology and pulmonology. As the patient was stable with good cardiopulmonary reserve, anticoagulation alone was chosen with a low threshold to provide thrombolytics if clinical deterioration occurred. Ultimately she developed a pulmonary embolism, but it was well tolerated.

RING-ENHANCING BRAIN LESION IN A YOUNG ADULT: WORK YOUR MAGIC, DOCTOR Michael J. Plakke; Sarah H. Van Tassel; Khan K. Chaichana; Benjamin Lloyd. Reading Health System, West Reading, PA. (Tracking ID #1642464)

LEARNING OBJECTIVE 1: Develop a broad differential diagnosis for a ring-enhancing brain lesion in a young adult
LEARNING OBJECTIVE 2: Manage a young adult presenting with a ring-enhancing brain lesion
CASE: An 18-year-old previously healthy female presented to the emergency department for the second time in 1 month complaining of possible seizure-like activity, unrelenting headache, and dizziness upon standing. Upon questioning, she described multiple episodes of nystagmoid eye movements unaccompanied by loss of consciousness or neurologic deficit. Her headache was constant and only relieved by massaging the back of her head, neck, and shoulders. She denied fever, visual disturbances, cognitive impairment, nausea, and vomiting. She had no history of recent travel or exposure to animals. Her mother has multiple sclerosis. Her vital signs were stable, and physical exam revealed no abnormalities. Laboratory workup, including complete blood count and chemistry studies, was unremarkable. Magnetic resonance imaging (MRI) with contrast showed a 1.0-cm ring-enhancing lesion in the left occipital lobe. Further investigations, including lumbar puncture and electroencephalogram were negative. She was discharged from the hospital on levetiracetam for seizure prophylaxis and instructed to obtain a follow-up MRI in 3 months. Her follow-up MRI showed a stable ring-enhancing lesion. Due to continued symptoms and the favorable location of the mass for surgical intervention, craniotomy with wedge resection was performed. Pathology confirmed the diagnosis of a low-grade oligodendroglioma. She did not receive any postoperative chemotherapy or adjuvant radiation. At a recent 1-month follow-up appointment, she was symptom-free.
DISCUSSION: The differential diagnosis for a ring-enhancing brain lesion includes metastasis, abscess, glioma, infarct, contusion, demyelination, and radiation scarring. A helpful mnemonic for recalling this differential diagnosis is "MAGIC DR." Lymphoma and toxoplasmosis are additional diagnoses to consider in immunocompromised patients. In young adults without known risk factors for central nervous system (CNS) infection or history of malignancy, primary neoplasms and demyelinating processes should top the list of possible diagnoses. In our 18-year-old patient, our differential focused on glioma and multiple sclerosis (MS). We strongly favored glioma, since MS very rarely presents with headache or seizure, but it was important to rule out demyelination given her nystagmus and positive family history. Initial management of a ring-enhancing lesion in these patients depends on clinical manifestations and location of the mass. If headache or seizure predominates, it is reasonable to treat conservatively (with seizure prophylaxis if indicated) and obtain follow-up imaging in 3–4 months. For patients with focal deficits or mass effect, biopsy or resection should be immediately considered. Most primary brain tumors in young adults are low-grade gliomas; the two most common types are astrocytomas and oligodendrogliomas. If biopsy suggests a low-grade glioma, total resection is favored if possible, as removal may be curative. Tumors that recur or progress may require radiation or chemotherapy. Fortunately our patient has done well thus far, but she will require careful monitoring and lifelong follow-up.

ROCKY MOUNTAIN "SPOTLESS" FEVER Moise Jean. Emory University School of Medicine, Atlanta, GA. (Tracking ID #1637810)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of Rocky Mountain Spotted Fever.
LEARNING OBJECTIVE 2: Appreciate the importance of history taking and high clinical suspicion for Rocky Mountain Spotted Fever, in febrile patient without rash.
CASE: A 68 year old male presents with 3 days of persistent fevers to 1030. The patient reported a 2 week history of malaise, athralgias, myalgias, frontal headache, chills and fevers. Past medical history was unremarkable. He had no sick contacts of recent travel. He was pine wood farmer in South Georgia. One month prior, while working outside he did notice a tick on his skin which he quickly removed with his fingers. On presentation he was febrile with a temperature of 38.60. He had no skin rashes, nuchal rigidity, joint effusions, and no signs of local infection on exam. Laboratories revealed leukopenia with white blood cells count of 1700/mcL, with 13 % monocytes, and thrombocytopenia with platelet count of 59000/mcL. Alanine aminotransferase, and Aspartate amintransferase were within normal limits. He was empirically treated for sepsis with Vancomycin and Levoquin. Doxycycline was added for tick borne illness given his exposure. On hospital day 2, he defervesced and vancomycin and levoquin were discontinued. Leukopenia and thrombocytopenia resolved. He was continued on doxycycline with a presumptive diagnosis of tick-borne illness. Several weeks later serology was positive for Rocky

Mountain Spotted Fever. Lyme and Ehrlichia serologies were negative.
DISCUSSION: Rocky Mountain spotted fever is a tick borne illness caused by Rickettsia rickettsii, spread to humans by Dermacentor ticks. Cases of RMSF are most common during spring and summer months in the southeastern regions of the United States but can be seen in other months from Mexico to Canada. Clues such as risk factors for tick exposure or a report of a tick bite should raise suspicion for tick-borne illness. Typically, RMSF presents with the triad of fever, rash and headache. The classic rash begins as blanching erythematous macules around the wrists and ankles that then spread centripetally and become petechial. Less commonly, RMSF without dermatologic manfestations, or "spotless RMSF" can occur. 15 % of patients with RMSF have no rash on presentation and 10 % of patients never develop a rash during their illness. Unfortunately, the absence of the rash presents a diagnostic challenge because of the nonspecific nature of the presentation. Spotless RMSF may be misdiagnosed as Erlichiosis and some patients may be dually infected with R. rickettssii and erlichia. However, treatment with doxycycline is the same. Serological testing is the mainstay modality in confirmation of diagnosis of RMSF, however the results may take days to weeks. The Weil-Felix test has fallen out of favor as it lacks sufficient sensitivity and specificity. "Spotless" RMSF often leads to delay in diagnosis and proper treatment. Treatment must be initiated as soon as infection is suspected, as the mortality rate increases from 6.5 % to more than 20 % when treatment is initiated more than 5 days after onset. Given this, physicians should consider the possibility of RMSF in patients with nonspecific febrile illnesses even without the classic rash. As in this case, the absence of a rash does preclude the diagnosis of RMSF. Physicians need to be aware of both the likelihood of "spotless RMSF" and the potential risk of failing to recognize this condition.

ROUTINE COLONOSCOPY, NOT SO ROUTINE AFTER ALL: SERRATED POLYPOSIS SYNDROME (SPS) Dhruti Patel; Daniel Goldsmith; Joseph DeAntonio; Joshua Cantor; Jyoti Bhatia; Armen Simonian; Akshay Manohar. Capital Health Regional Medical Center, Trenton, NJ. (Tracking ID #1641999)

LEARNING OBJECTIVE 1: Recognize new developments in Colorectal Cancer Screening in relation to SPS
CASE: Case 1: A 66-year-old Caucasian female underwent a routine colonoscopy. She had no symptoms such as bleeding, weight loss, change in bowel habits or abdominal pain. She did have mild anemia with hemoglobin 11.7 g/dL and MCV of 90.5 fl. Pertinent past medical history included Grade I Astrocytoma (well differentiated), obstructive sleep apnea, hypertension, transient ischemic attack, and dyslipedemia. She occasionally used alcohol, but not tobacco or drugs. She denied family history of malignancy. The colonoscopy demonstrated 30 polyps varying from 0.5 cm to 2–3 cm throughout the colon. Biopsies revealed "sessile serrated" adenomas, characterized by prominent histological serrations, distorted and dilated bases of crypts with aberrant branching, without dysplasia. The results met criteria for diagnosis of SPS. The patient elected for surveillance colonoscopy at 1 year instead of surgical intervention. Case 2: A 47-year-old female underwent a colonoscopy due to family history of adenomatous polyps in her mother. She had no prior colonoscopies or symptoms. Her hemoglobin was 13.3 g/dL, with an MCV of 103 fl. Her medical history was significant for hypertension and polysubstance abuse, mainly alcohol and cocaine. Family history was significant for adenomatous polyps in her mother at age 75. Colonoscopy demonstrated several polyps ranging from 5 mm to 1.5 cm with similar histopathological findings as in Case 1. Due to poor preparation, colonoscopy will be repeated in 6 months. Case 3: A 47-year-old female with a history of colon polyps underwent a follow up colonoscopy. The patient complained of no symptoms. Pertinent past medical history include coronary artery bypass graft, pyloric stenosis at birth, Hodgkin's lymphoma at age 3, gall bladder polyp, chronic hepatitis C without cirrhosis, inflammatory bowel syndrome, hypertension and asthma. Two prior colonoscopies were performed. The first was performed due to history of iron deficiency anemia without any symptoms and a normal EGD. Benign hyperplastic polyps were found incidentally. The second follow up colonoscopy, performed 8 years later, showed several serrated adenomas. The third repeat colonoscopy showed even more sessile serrated adenomas. Currently, future management, whether it includes surveillance colonoscopy or surgery, is under discussion with the patient.
DISCUSSION: Traditionally colorectal adenoma is considered the main precursor lesion to colorectal cancer; however, over the past decade, "serrated" polyps are being recognized as premalignant lesions and markers for synchronous and metachronous colorectal neoplasia. They are associated with an increased risk of colorectal cancer by 25 to 40 %, and an increased risk for developing colorectal cancer between otherwise normal screening intervals. SPS is defined by one of the following criteria: 1) At least 5 serrated polyps proximal to sigmoid, with 2 or more ≥ 10 mm 2) Any serrated polyps proximal to sigmoid with family history of SPS 3) > 20 serrated polyps of any size throughout the colon.

SUGAR AND SPICE: NOT SO NICE Morgan J. Katz; Matthew N. Peters; John Wysocki; Chayan Chakraborti. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640487)

LEARNING OBJECTIVE 1: Understand the importance of taking a detailed history of ingestion of over the counter herbal supplements.
LEARNING OBJECTIVE 2: Recognize the association between acute hepatitis and ingestion of over the counter cinnamon supplement.
CASE: A 42 year-old man with history of diabetes mellitus presented with a 2-day history of 9/10 throbbing abdominal pain, nausea and diarrhea. The pain was initially localized to the peri-umbilical region but later migrated to the right upper quadrant. He denied prior diagnosis of hepatitis, intravenous drug or acetaminophen use, but acknowledged occasional alcohol intake. His only medication was 1000 mg of twice daily metformin and he had no family history of autoimmune disease. Upon further questioning, he reported a two-week consumption of the over the counter herbal cinnamon pills "to help" with his diabetes. He had right upper quadrant tenderness with a palpable liver edge 5 cm below the right costal margin. Abnormal admission labs included an AST of 969 U/L, an ALT of 724 U/L, an alkaline phosphatase (ALP) of 155 U/L and a total bilirubin of 1.3 mg/dL. Other laboratory values including amylase, lipase, antinuclear antibodies and INR were within normal limits and an acute viral hepatitis panel and HIV test were negative. Abdominal ultrasound revealed hepatomegaly with fatty infiltration. He was advised to discontinue the herbal cinnamon supplements and by hospital day 4 his abdominal pain had resolved with AST/ALT and ALP levels decreasing to 319, 447 and 99 U/L, respectively. Three weeks later, liver enzymes returned to normal (AST 40, ALT 40, ALP 65 U/L) and a repeat hepatitis panel was non-reactive. A repeat abdominal ultrasound showed diminished hepatomegaly with resolution of the fatty infiltrates.
DISCUSSION: The general internist should be aware that the use of over the counter herbal supplements has rapidly grown in popularity during recent years. Use of cinnamon, in particular, has risen amid recent reports of its ability to decrease blood glucose, serum triglyceride and low-density lipoprotein levels. While the benefit of cinnamon supplementation may be real, unfortunately many herbal supplements are not composed of pure cinnamon. Rather they contain cassia cinnamon, which is known to have substantially larger quantities of a potentially toxic substance, coumarin. Whereas regular cinnamon contains low levels of coumarin (0.5 % and under), cassia cinnamon can contain up to 5 % coumarin. Approximately 20 cases of coumarin-induced hepatitis have been documented in the past 20 years, with occurrence following both long term (>2 years) and short term (<3 weeks) ingestion. Resolution of hepatitis with a return to normal transaminase levels has been reported to occur within 4–8 weeks following discontinuation of cinnamon supplementation. As herbal

supplements and other "organic" substances become increasingly popular, the importance of obtaining a detailed history of over-the counter medication use cannot be overstated. It is important to keep in mind that "natural" does not necessarily mean "harmless."

SAME OLD PNEUMONIA OR IS IT? Rajan Garg; Mher Onanyan; Syed Asghar. CAPITAL HEALTH REGIONAL MEDICAL CENTER, Trenton, NJ. (Tracking ID #1641868)

LEARNING OBJECTIVE 1: Early consideration of Idiopathic Interstitial Pneumonias in differential diagosis of patients presenting with signs and symptoms of lower respiratory tract infections
LEARNING OBJECTIVE 2: Diagnostic studies including Procalcitonin level, HRCT, and BAL with possible trans-bronchial biopsy and high dose steroid therapy should be considered early in patients with suspected Idiopathic Interstitial Pneumonia.
CASE: Patient is a 63 year old white male with history of DM, Hypertension, and Atrial Fibrillation who presented to the ED with 2–3 days history of productive cough, chills, generalized weakness, and a choking spell while eating recently. Patient is a lifetime non-smoker and reported no chemical exposure. Patient had no fever, acute respiratory distress, but had bilateral coarse breath sounds on examination. Initial chest x-ray showed bilateral lower lobe infiltrates and patient had mild leukocytosis. Patient was admitted for possible community acquired/aspiration pneumonia and started on appropriate antibiotics. Patient continued to deteriorate over next 2 weeks despite aggressive empirical antibiotics, IV steroids, and supportive care with non-invasive positive pressure ventilation. Bilateral lung infiltrates worsened and HRCT obtained showed extensive bilateral ground glass opacities with interstitial fibrosis, without bronchiectasis. Echocardiogram done showed normal cardiac function. All lab studies including blood, sputum cultures and autoimmune antibodies were reported negative. Due to worsening condition, patient was electively intubated for scheduled lung biopsy for further diagnosis but he became unstable during procedure and it was aborted. Due to patient's worsening medical condition and poor overall prognosis, patient was terminally extubated as per his wishes and patient passed away the same day. Limited lung autopsy obtained as per family's wishes reported diffuse alveolar damage with foamy macrophages consistent with idiopathic interstitial pneumonia.
DISCUSSION: Pneumonia is a common condition that we, as physicians, encounter on a regular basis. Although most of the pneumonias are infectious in origin, suspicion for Idiopathic Interstitial Pneumonias including Acute Interstitial, Cryptogenic Organizing Pneumonia, Lymphoid, Desquamative types, to name a few, should be high if patient doesn't show signs of recovery with antibiotic therapy. Diagnostic studies including Procalcitonin level, HRCT, and BAL with possible trans-bronchial biopsy should be considered early in appropriate patient population for further diagnosis. High dose steroids and Macrolide antibiotics are the only therapeutic measures shown to improve survival in patients with suspected idiopathic interstitial pneumonias.

SATISFYING AN ITCH FROM THE INSIDE OUT Matthew N. Peters; Morgan J. Katz; Allison Egan; Deepa Bhatnagar. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1641319)

LEARNING OBJECTIVE 1: Review the diagnoses associated with chronic urticaria.
LEARNING OBJECTIVE 2: Recognize the association between Helicobacter pylori infection and chronic urticaria and the potential for improved patient comfort with Helicobacter pylori eradication.
CASE: A 34 year-old woman with a 4 year history of intermittent chronic hives and gastroesopheal reflux disease (GERD) presented with a 4 day history of worsening urticaria. She had undergone multiple non-revealing skin and allergen tests, and described a typical outbreak as a sudden appearance of itchy and burning red marks across her chest, abdomen and bilateral thighs and buttocks. The outbreaks occurred several times a month. She was unable to identify exacerbating factors and had tried multiple over the counter topical creams and ointments without relief. She also had a 3 year history of acid reflux and abdominal discomfort. Home medications included hydroxyzine and esomeprazole. Family history was notable for systemic lupus erythematosus (SLE) in her mother. Despite persistent itching and burning, physical exam failed to detect any skin lesions. She had pictures of an outbreak from the previous day, revealing multiple round, circumscribed, raised erythematous plaques across her abdomen and thighs. Baseline laboratory testing was unremarkable and an extensive panel of autoiummune tests was negative; skin biopsy was not performed due to lack of visible lesions. Helicobacter pylori (H. pylori) IgG and IgM serology were both positive. Subsequent upper endoscopy showed multiple superficial erosions in the gastric body and antrum. Biopsy of these erosions revealed the presence of H. pylori. Patient was started on twice daily 600 mg Clarithromycin and 1 g Amoxicillin in addition to twice daily 20 mg omeprazole for 14 days. Three months following completion of therapy the patient has noted complete resolution of urticarial symptoms; her longest symptom-free interval since her initial onset 4 years ago.
DISCUSSION: Affecting up to 1 % of the population, chronic urticaria (CU) is a common and frustrating condition for patients and physicians. Despite being typically managed by dermatologists, general internists are confronted with the task of identifying potential exogenous causes of CU. While finding an underlying cause of CU is daunting (successful in 20 % of cases), unmasking an underlying systemic disease may improve CU-associated symptoms and prevent future morbidity and mortality. Common associated conditions include H. pylori, Sjogrens syndrome, SLE, rheumatoid arthritis, cryoglobulinemia and hypothyroidism. Due to the ubiquitous occurrence of H. Pylori, (25 % of the population in industrialized countries and higher in developing areas), the link between H. pylori and CU is of particular interest. Due to a lack of large clinical trials, the association between CU and H. pylori is still controversial. H. pylori has been found to occur 2–3 times more frequently in patients with CU and subsequent eradication has demonstrated a 2-fold increase in remission, compared to untreated H. pylori positive patients. The most commonly speculated mechanism of H. pylori-associated CU is chronic infection leading to increased gastric acid and pepsin release; this prompts recruitment of inflammatory cells (mainly lymphocytes and neutrophils), subsequently inducing mast cell degranulation and histamine release. Recognition of H.pylori-associated urticaria may lead to improved urticarial symptoms and earlier identification and eradication of H.pylori.

SAVE ME FROM MYSELF: EBV-ASSOCIATED HEMOPHAGOCYTOSIS IN AN ADULT Jacqueline Pflaum; Sean Drake; Gregory Buran. Henry Ford Hospital, Detroit, MI. (Tracking ID #1623737)

LEARNING OBJECTIVE 1: Diagnose HLH using published criteria and recognize early diagnosis as key in initiating therapy and lowering risk of mortality
LEARNING OBJECTIVE 2: Identify this recovery without initiation of HLH 94 protocol as unique
CASE: A 27 year-old female was transferred to our teaching institution from an outside hospital with a fever of unknown etiology, lymphadenopathy, hepatosplenomegaly, jaundice and a maculopapular rash. Two weeks prior she had been seen at an urgent care clinic for subjective fevers and cough, and was discharged under the diagnosis of viral illness. The following week, she continued to have fevers with malaise and presented to an outside ED. At that time, she was presumed to have pneumonia and treated with amoxicillin/clavulanate and discharged home. Two days after initiation of the antibiotic, the patient presented to her PCP's office with jaundice and was switched to cefuroxime; she then developed a maculopapular rash and was

admitted to the hospital. At the outside hospital she was discovered to have elevated liver enzymes, thrombocytopenia, anemia, leukocytopenia and hepatomegaly with EBV positive IgM and IgG. CMV and viral hepatitis panels were negative. The patient was transferred to our hospital for evaluation of acute liver failure. Upon arrival, she was jaundiced with a maculopapular rash and a rapid rise in AST/ALT levels. Due to a suspicion for Hemophagocytic Lymphohistiocytosis (HLH), triglyceride and ferritin levels were drawn and came back extremely elevated, peaking at 723 mg/dL and 36,151 respectively. She remained febrile and was transferred to the ICU for more intensive monitoring; there she received IV dexamethasone and several platelet and PRBC transfusions. Bone biopsy was performed with inconclusive, but highly suspicious results, showing an increase in phagocytic macrophages and a granulocytic shift with marked toxic changes. At that time, liver enzymes were improving and fever had resolved, and HLH-94 treatment protocol was held due to clinical improvement with steroids alone. She was discharged on day #16 after liver enzymes normalized and coagulopathy, rash, jaundice and thrombocytopenia resolved.

DISCUSSION: There are two forms of HLH: inherited, which typically occurs in the pediatric population, and sporadic, which is most frequently associated with EBV but has been associated with other viruses. Due to higher prevalence of these viruses in Asia, most virus-associated case studies come out of that area. Very few cases of adult EBV-associated HLH have been reported in the US. The diagnosis can be elusive, and is typically defined via the following set of criteria: fever >38.5 for 7 or more days, splenomegaly >3 cm, cytopenia involving two or more cell lines, hypertriglyceridemia or hyperfibrinogenemia, and hemophagocytosis on bone marrow biopsy. The exact mechanism of disease is not clearly understood, but it is believed to be uncontrolled proliferation of cytotoxic T-cells and malfunctioning NK cells. Successful treatment usually involves initiation of the HLH-94 protocol (etopiside, dexamethasone and cyclosporine A followed by a stem cell transplant) within 2 weeks of diagnosis; however, the drugs can have long-term neurotoxic and cytotoxic side effects, making the decision to treat difficult but crucial.

SCEDO-SEIZURES Priti Dangayach; Himabindu Kadiyala. Baylor College of Medicine, Houston, TX. (Tracking ID #1638096)

LEARNING OBJECTIVE 1: Recognize scedosporium apiospermum as a rare fungal organism that affects the immunocompromised

LEARNING OBJECTIVE 2: Recognize the importance of culture to distinguish between aspergillis and scedosporium

CASE: A 64-year-old man with an orthotopic liver transplantation on chronic immunosuppressive medication presented with diarrhea of 3 weeks duration. The patient had a history of hepatitis C and alcoholic cirrhosis; he subsequently developed hepatocellular carcinoma. On presentation, he reported non-bloody, watery bowel movements, five to six times daily for 3 weeks. He complained of midepigastric cramping, anorexia, 10 lb of weight loss, intermittent fevers to Tmax 102 F, but no nausea or vomiting. On examination, he was afebrile. He was non-toxic appearing, anicteric, with dry mucous membranes. His abdomen was soft, nontender, and nondistended with bowel sounds. No abdominal masses were palpated. A rectal fissure was noted. During his hospitalization, he remained NPO, given fluids, and started empirically on vancomycin and piperacillin/tazobactam. His blood, stool, and urine cultures all remained negative. His diarrhea did not improve with cessation of eating or with loperamide. Home medications including magnesium oxide, ursodiol, tacrolimus, and mycophenolate mofetil were all held given persistence of diarrhea and acute renal failure. EGD and flexible sigmoidoscopy was performed and showed multiple large, shallow ulcerations throughout the colon. He was then started empirically on IV ganciclovir for possible CMV colitis, again without improvement. Repeat colonoscopy showed persistent multiple ulcerations throughout the colon and biopsies revealed acute inflammation without evidence of malignancy and immune-histochemical stains and PCR were negative for HSV or CMV. Despite continued treatment with IV ganciclovir, 2 weeks into his hospitalization, his diarrhea had not improved. He then developed new generalized tonic clonic seizures. A head MRI revealed a ring-enhancing left frontal lobe mass. Brain biopsy showed necrosis and acute inflammation with septate branching fungal hyphae, confirmed by silver stain. He was started on IV voriconazole with concern for neuroinvasive aspergillosis. His repeat MRI after 1 week showed worsening of the brain abscess cavity, and he underwent left frontal lobectomy. Biopsy revealed fungal organisms on H&E and PAS stains. Culture identified these as Scedosporium apiospermum, which appears morphologically similar to aspergillis. PAS stains were performed on his colonic biopsies, which revealed fungal hyphae, and he was diagnosed with disseminated disease with scedosporium. After several weeks on voriconazole, his repeat colonoscopy showed healing of the ulcers and his symptoms improved.

DISCUSSION: This case highlights the importance of suspecting opportunistic fungal pathogens such as Scedosporium apiospermum in immunocompromised patients. Scedosporium species is found ubiquitously in the environment. Both scedosporium and aspergillis are septate, non-pigmented hyphae, branching at 45° angle. They are distinguished by culture. Based on case reports, treatment with voriconazole, alone or in combination with another antifungal agent is favored given ability to cross the blood–brain barrier. It is important to distinguish between these two pathogens as scedosporium is resistant to amphotericin B, most azoles, and echinocandins. Overall, there is an extremely poor prognosis.

SEASONAL RECURRENT MYOPERICARDITIS Laura Divoky; Rex Wilford. Summa Health System, Akron, OH. (Tracking ID #1642291)

LEARNING OBJECTIVE 1: Recognize the clinical features of recurrent myopericarditis

LEARNING OBJECTIVE 2: Manage cases of recurrent myopericarditis

CASE: Myopericarditis occurs in up to 15 % of patient with pericarditis. Recurrent myopericarditis occurs in 15–30 % of patients after partial or complete recovery from acute myopericarditis. Relapse occurs most often within 1 month of initial episode. We present a case of seasonal recurrent myopericarditis. An African American male presented to the emergency department with chest pain in November 2010, 2011 and 2012. The first occurrence was November 2010 when at age 32 he presented with a 3 day history of a dull, aching left sided chest pain that was exacerbated when laying supine. The chest pain radiated to the center of his chest and down his right arm. His past medical history was herpes labialis and chronic hepatitis B. Past surgical history and family medical history were noncontributory. Medication was acyclovir for herpes labialis suppression. He had no know drug allergies, a 13-pack year smoking history, drank alcohol socially and smoked 3 marijuana cigarettes per day. Vitals were significant for a temperature of 101.3 and heart rate 110. Physical exam was only significant for anterior chest wall tenderness and heart was tachycardic, but no friction rub was heard. Significant lab work included a mildly elevated monocyte count, ESR of 33 mm/hr and CRP of 17.20 mg/dL. Troponin was elevated at 10.99 ng/mL, with no change at repeat checks. Hepatitis B surface antigen was positive, other viral testing including HIV screen was negative. Autoimmune work-up was negative. EKG had subtle upward sloping T-wave in anterior precordial leads and subtle PR depression in the inferior leads. A left cardiac catheterization showed no evidence of significant coronary artery disease and an ejection fraction of 55 %. Echocardiogram had mild concentric left ventricular hypertrophy with normal left ventricular function. He was treated with high dose NSAIDS and colchicine and discharged home on NSAIDs as he was unable to afford colchicine. He presented in November 2011 and in November 2012 with very similar clinical courses and symptoms which responded to NSAIDs.

DISCUSSION: The etiology of myopericarditis is divided into: infectious, non-infectious, and immune-mediated. Hepatitis B is a reported cause of myopericarditis. This could be a component of his recurrent myopericarditis, although it is interesting at the three-year seasonal recurrence in November. The standard of care is initial treatment with non-steroidal anti-inflammatory drugs for duration of 10–14 days. Colchicine for 3 to 6 months can be administered for resistant chest pain due to myopericarditis. Extensive review of the literature shows no other case reports of seasonal recurrent myopericarditis. The question posed in an individual with apparent seasonal myopericarditis 3 years in a row in November: is there a role for seasonal prophylactic treatment? Given the severe chest pain requiring hospitalization it may prove beneficial in individuals with seasonal recurrent myopericarditis to start NSAIDS or colchicine prior to symptom occurrence.

SEPTIC THROMBOPHLEBITIS AND OSTEOMYELITIS IN A PATIENT WITH MYCOSIS FUNGOIDES Jeffrey J. Hsu. University of California, San Francisco, San Francisco, CA. (Tracking ID #1642117)

LEARNING OBJECTIVE 1: Recognize bacteremia as one of the major complications of mycosis fungoides
CASE: The patient is a 64-year-old man with a history of mycosis fungoides (MF) who presented with a chief complaint of debilitating back pain for the previous 10 days. Six years prior, he developed bouts of pruritic rashes on his limbs and torso. Initial biopsies suggested a spongiotic dermatitis, and he was treated with topical and systemic corticosteroids. His symptoms progressively worsened over the ensuing years, and a subsequent biopsy revealed MF. He underwent a chemotherapy regimen of cyclophosphamide, doxorubicin, vincristine and prednisone (CHOP) through a Port-a-cath in his left chest. CHOP was discontinued after two cycles due to erythroderma, and he was started on methotrexate 9 months prior to his presentation. On examination, he was afebrile, normotensive and tachycardic. His cardiac, pulmonary and neurological exams were otherwise normal. He had a diffusely tender, erythematous and flaky skin rash, worse over his upper extremities and chest, and his left arm was markedly edematous. An ultrasound of his left arm revealed a deep venous thrombosis of his left internal jugular and subclavian veins, and his Port-a-cath was subsequently removed. An MRI of his neck revealed inflammation around his left internal jugular vein, suggesting septic thrombophlebitis. An MRI of his spine suggested osteomyelitis of his T8 vertebral body with extensive phlegmonous changes in the prevertebral space extending from the cervical to thoracic spine. A CT angiogram of his chest did not reveal any pulmonary emboli, and a transthoracic echocardiogram did not show any valvular abnormalities. Peripheral blood cultures drawn on admission, as well as a culture of the catheter tip, grew methicillin-sensitive Staphylococcus aureus (MSSA). Repeat blood cultures were also positive for MSSA. He was treated with enoxaparin anticoagulation and a planned six-week course of intravenous nafcillin, and his blood cultures did not clear until hospital day 6. Topical steroids were applied to his skin rash with slight improvement. He was discharged home on hospital day 15 with scheduled follow-up with Oncology and Dermatology.
DISCUSSION: Cutaneous T cell lymphoma (CTCL) is the most common primary lymphoma of the skin and has an annual incidence of 6.4 per million persons in the United States. The most common variant of CTCL is MF, which presents cutaneously as patches, infiltrated plaques, tumors or generalized erythroderma. These lesions are commonly initially diagnosed as a benign dermatitis, leading to a delay in the diagnosis of MF; the median time from symptom onset to the diagnosis of MF is 3–4 years. Because of their disrupted protective skin barrier and the potential immunosuppression that can occur from systemic lymphoma, patients with CTCL are at increased risk of bacterial infection, which is the major cause of morbidity and mortality in this population. In one retrospective study, bacteremia had an incidence of 2.1 per 100 patient-years, with S. aureus as the predominant pathogen, and was a major cause of death in these patients. In the case above, the indwelling catheter itself clearly increased the patient's risk of septic thrombophlebitis. Yet his risk was likely compounded by his MF and its tendency to predispose patients to bacteremia. Thus, in patients with MF, it is especially crucial to be vigilant in monitoring for infection and minimizing the presence of intravascular lines.

SEVERE MITRAL STENOSIS IN THE SETTING OF MULTIVESSEL CORONARY ARTERY DISEASE, PULMONARY HYPERTENSION, AND TRICUSPID REGURGITATION Vu Hoang; Don Pham; Anita Deswal. Baylor College of Medicine, Houston, TX. (Tracking ID #1642230)

LEARNING OBJECTIVE 1: Diagnose mitral stenosis when echocardiographic data is unclear or conflicting
LEARNING OBJECTIVE 2: Evaluate and manage mitral stenosis in the setting of atrial fibrillation, pulmonary hypertension, multivessel coronary artery disease, and multivalvular disorder
CASE: This is a 64 year old man with history of coronary artery disease with previous coronary artery bypass graft surgery, atrial fibrillation on anticoagulation therapy, moderate calcific mitral stenosis, left ventricular dysfunction, and pulmonary hypertension who presented with progressive shortness of breath, cough, and fatigue. Six months ago, patient was able to walk about 1 block before getting short of breath, however now just moving around in his bed caused him to be short of breath. Vital signs were significant for blood pressure of 105/57, heart rate of 99, and pulse oximetry of 95 % on 2 l of oxygen. Physical examination was noted elevated jugular venous distention to mid-neck, irregularly irregular rhythm, bilateral rales, and 1+ bilateral lower extremity edema. He was treated with warfarin, metoprolol, digoxin, valsartan, amlodipine, and intravenous bumetanide. Due to persistent symptoms despite maximum medical therapy, patient was referred for further imaging evaluation. Transthoracic echocardiogram demonstrated left ventricular ejection fraction between 55 % and 60 %, flattened septum, and severe left atrial enlargement. Furthermore, there was severe mitral annular calcification, extending to the base of the posterior mitral valve leaflet. There was severe tricuspid regurgitation and pulmonary artery pressure was between 69 and 74 mmHg. Left heart catheterization findings showed native vessels with three-vessel disease, 100 % complete total occlusion of the distal LAD, 90 % stenosis of the distal circumflex and 100 % complete total occlusion of the proximal RCA. Bypass grafts findings had 50 % stenosis of SVG and atretic LIMA. Right heart catheterization showed right atrial pressure of 22 mmHg, pulmonary artery pressure of 66/37 mmHg, and mean of 46 with heart rate of 80. Pulmonary wedge pressure was 37 mmHg. Mitral valve study showed mean gradient of 10.53 mmHg, valve area of 1.4 cm2 with severe stenosis.
DISCUSSION: Mitral annular calcification (MAC) is usually not a common cause of severe mitral stenosis. However when it occurs in the presence of severe coronary artery disease, pulmonary hypertension and multi-valvular disease, there can be a dilemma in management. There is no strong evidence regarding the timing of surgical intervention for mitral stenosis. It is reasonable to intervene once symptoms are more than mild and ideally before pulmonary hypertension develop. However, in the presence of multi-vessel disease, patient would need to be optimized first. Aortic regurgitation and tricuspid regurgitation both frequently accompany mitral stenosis. Double and triple valve replacement significantly increases risk of mortality. However, if mitral stenosis is deemed the only correctable pathology, then mortality rate should not be prohibitive. Pulmonary hypertension is usually reversible after mitral stenosis is relieved.

SEVERING YOUR LIFELINE Jerson Munoz-Mendoza[1]; Veronica A. Pinto Miranda[1]; Amit Badiye[2]; Sandra V. Chaparro[2]. [1]University of Miami - Jackson Memorial Medical Center, Miami, FL; [2]University of Miami, Miami, FL. (Tracking ID #1636506)

LEARNING OBJECTIVE 1: Recognize the importance of regular psychological monitoring and support before and after LVAD implantation
LEARNING OBJECTIVE 2: Recognize unrecognized/untreated psychiatric disease as potential cause of failure of the therapy
CASE: A 47-year-old female with end-stage non-ischemic dilated cardiomyopathy underwent HeartMate-II LVAD implant 3 years ago at outside hospital. She had chronic infection of the driveline exit site post-operatively and suffered a left middle cerebral artery ischemic stroke with residual right sided paralysis and mild Broca's aphasia. Subsequently she became more bipolar, non-compliant and started smoking again. She presented to the ER requesting for dressing change. On exam the driveline was found to be cut and was protruding from abdomen with erythema and foul smelling pus. On further interview, patient said she intentionally cut it a week ago as "she was fed up of it and knew she didn't need it". She had stable vital signs despite the non-functioning LVAD. TEE revealed no flow in the inflow and outflow conduit. Ejection fraction was severely reduced to 15 %. Her noncompliance may have led to the clotting of entire conduit. This proved advantageous when she cut her driveline preventing significant backflow. Psychosocial evaluation revealed lack of decision making capacity and psychosis. She was treated conservatively and subsequently suffered multi-organ failure at another hospital.
DISCUSSION: Left ventricular Assist Devices (LVADs) are an effective form of therapy in patients with end-stage heart failure, according to the results of the landmark REMATCH trial. We present a unique case of an adverse outcome, where psychosocial problems dominated the post-implant care and lead to a grave decision by the patient. This is the first reported case where a patient, who developed psychosis 3 years after LVAD implantation, cut the LVAD driveline or "life line", threatening her life, fortunately the entire LVAD conduit was clotted already at the time when the driveline was cut. This case highlights the need of in-depth psychosocial evaluation of these patients who require complex decision making by a multi-disciplinary team not only regarding candidacy for LVAD, but the need for regular and long term psychological support after LVAD implantation, as psychological or psychiatric conditions may worsen or occur de novo in this unique patient population. Failure to address these variables is associated with increase morbidity and mortality post LVADs implantation.

SEXUALLY TRANSMITTED PROCTITIS Elena Lebduska. Montefiore Medical Center, Bronx, NY. (Tracking ID #1642560)

LEARNING OBJECTIVE 1: Identify the differential diagnosis of acute proctitis in men who have sex with men
LEARNING OBJECTIVE 2: Recognize the clinical presentations of proctitis caused by different chlamydial serovars
CASE: A 49 year-old male with HIV (on anti-retrovirals, undetectable viral load) presented with 1 week of rectal pain. He noted some white drainage from his rectum occasionally streaked with blood, constipation, and pain with defecation. On examination he had no external rectal or genital lesions, but he did have pain with digital rectal examination, and inguinal lymphadenopathy was noted. He reported being treated for syphilis in the past, but denied a history of any other sexually transmitted diseases. He endorsed being sexually active with men only. Radiography of his pelvis revealed marked mural thickening of the rectum with perirectal lymphadenopathy. On subsequent sigmoidoscopy multiple rectal ulcers with white exudates were seen, consistent with a diagnosis of proctitis. Pathologic examination of the biopsied ulcers reveled colonic mucosa with ulceration, while immunostains for cytomegalovirus and herpes simplex virus were negative. Pcr probe of rectal discharge was positive for chlamydia, but negative for gonorrhea. The patient was started on doxycycline with improvement in his symptoms by day 4.
DISCUSSION: Acute proctitis in men who have sex with men is usually sexually acquired. The most common sexually transmitted infections causing proctitis are: N. gonorrhoeae, C. trachomatis, T. pallidum, and herpes simplex virus. The majority of chlamydial infections in men are asymptomatic. Symptomatic infections usually cause urethritis and epidemitis. Chlamydial proctitis is relatively uncommon and occurs almost exclusively in men who have sex with men. The clinical presentations of this illness depends on the infecting chlamydial serovars. Serovars D-K are usually asymptomatic but may cause a mild proctitis. Alternatively, chlamydial serovars L1, L2, and L3 cause the disease known as lymphogranuloma venereum. In contrast to mild proctitis, rectal inoculation with these serovars can cause significant rectal pain, tenesmus, bleeding, and constipation. Anocsopy usually reveals internal friable lesions, ulcers, and exudates. Untreated these strains can cause rectal fistulas and strictures, and can even be mistaken for inflammatory bowl disease. Outbreaks of lymphogranuloma venereum among men who have sex with men occurred in North America and Europe in the mid 2000s. Concern for rapid identification and treatment of this disease among high risk populations is of importance for the generalist, since the rectal lesions associated with infection increase the likelihood of HIV transmission. Serovar testing is not widely available, and high clinical suspicion should prompt early treatment and monitoring for clinical improvement. Doxycycline 100 mg twice a day for 3 weeks is the current standard of care.

SHORT OF BREATH? CALL THE NEUROSURGEON. Rupel Dedhia; Daniela Uebelhart. Rush University Med Center, Chicago, IL. (Tracking ID #1619837)

LEARNING OBJECTIVE 1: Review the main causes of unilateral diaphragmatic paralysis
LEARNING OBJECTIVE 2: Discuss current treatment options for patients with unilateral diaphragmatic paralysis
CASE: 75 year-old female with history of COPD, right lung nodule, obesity, HTN, CAD, cervical spine osteoarthritis who presented with a two-month history of worsening shortness of breath with associated productive cough. She denied fever, chills, chest pain, orthopnea, or lower extremity edema. Patient had received two courses of steroid therapy for possible COPD exacerbations without symptomatic improvement. Pulmonary exam revealed decreased breath sounds in the left lung base without rales or wheezing. Chest x-ray revealed new elevation of the left hemidiaphragm. An Ultrasound Sniff test revealed minimal downward movement of the left hemidiaphragm, suggesting left diaphragm paralysis. Chest CT showed stable right lung base nodule and new left base atelectasis with left hemidiaphragm elevation. Patient had known moderate spinal canal stenosis in C3–C4 and bilateral foraminal stenosis at C4–C5 possibly contributing to this patient's UDP. Patient has been evaluated by Neurosurgery; however, surgery has been deferred at this time due to her medical co-morbidities. Patient has been medically optimized on her therapy for COPD and is closely followed in the General Medicine and Pulmonary Clinic.
DISCUSSION: The diaphragm is the chief muscle of inspiration. It is innervated by the phrenic nerve, which arises from the nerve roots C3–C5. The differential diagnosis of diaphragm paralysis (DP) is therefore broad and includes compressive, traumatic, neurogenic, myopathic, and inflammatory conditions. UDP is more common than bilateral diaphragm paralysis (BDP). While asymptomatic in healthy individuals, UDP can cause significant compromise in patients with underlying lung disease. The most prevalent symptoms include dyspnea and diminished exercise tolerance. Diagnosis of UDP is

strongly suggested by the presence of an elevated hemidiaphragm on chest radiograph. A sniff test, wherein diaphragmatic motion is recorded by fluoroscopy, is frequently used for confirmation. Ultrasonography has been recently described as a method of diagnosis, through evaluation of diaphragm thickness. Once UDP is confirmed, it is important to exclude major intra-thoracic pathologies such as malignancies or infections. Observation is recommended for asymptomatic patients with a negative workup. In symptomatic patients, surgical plication of the diaphragm is the most common treatment. When cervical spondylosis is the causative mechanism, reports suggest that laminectomy may be effective. Diaphragmatic pacemakers can be used to stimulate contraction in patients with an intact phrenic nerve and has mainly been used in ventilator dependent patients. Repair of the phrenic nerve has been reported and its benefits are yet to be elucidated.

SHOSHIN BERIBERI IN A YOUNG MAN LIVING ON JAPANESE RICE BALLS Chiaki Murase; Naomi Otowa; Jintetsu Minami; Yoshitomo Nishikawa; Hiroshi Miyake; Hisashi Umeda; Mitsunori Iwase. TOYOTA Memorial Hospital, Toyota, Japan. (Tracking ID #1626158)

LEARNING OBJECTIVE 1: Review clinical features of wet beriberi.
LEARNING OBJECTIVE 2: Note that fatal vitamin deficiency could occur as a result of an unbalanced diet.
CASE: A 24-year-old single man was in his usual state of health until 3 days before admission when he noticed chest pain and shortness of breath. On the day of admission, he called for an ambulance for his worsening dyspnea. En route to the hospital, the patient went into cardiopulmonary arrest and resuscitation was provided. Fortunately, his pulse came back in 4 min. On arrival, the patient was disoriented and was unable to provide history. Vital signs were; BT 35.2 °C, BP 70/15 mmHg, HR 75 beats/min, RR 30 breaths/min. On physical exam, he had systemic edema, central cyanosis and hyporeflexia. Serum albumin level was 4.0 g/dL and BNP was 2,305 pg/mL. Arterial blood gas showed marked lactic acidosis with pH 6.80, pCO2 23.4 mmHg, pO2 397.0 mmHg, HCO3- 3.4 mmol/L, and lactate 26.4 mmol/L. He was intubated and catecholamines were administered. An electrocardiogram showed complete right bundle branch block and flat T-wave in the inferior leads. A chest radiograph revealed prominent pulmonary trunk and moderate cardiomegaly, although a contrast-enhanced CT of the chest was negative for pulmonary embolism. An echocardiogram showed enlarged right ventricle with intraventricular septal flattening and tricuspid regurgitation. The cardiac index was 9.8 L/min/m2, suggesting high cardiac output state, and the mixed venous oxygen saturation was 91.7 %. From these findings, thiamine deficiency was suspected as one of differential diagnosis and thiamine was administered. His hemodynamic parameters improved dramatically in only 3 h after the administration of thiamine. Within a few days, hemodynamical findings returned to normal. Systemic edema had also subsided and his BMI at this point was 17.4. His pre-treatment thiamine level was as low as 17 ng/mL (normal: 24–66 ng/mL), and the patient was diagnosed with "Shoshin" beriberi. A thorough history was obtained after he had regained consciousness. He had no significant past medical history and was not taking any medications, drank alcohol on social occasions, had never smoked tobacco or used illicit drugs. The patient lived alone and due to his financial problems, he had been subsisting on rice balls made of only polished rice for the preceding 4 years. On the 23rd day of admission, he was discharged home in excellent general condition without any residual symptoms.
DISCUSSION: A fulminant form of wet beriberi is called "Shoshin" beriberi and is characterized by hypotension, tachycardia, and lactic acidosis. If left untreated, patients may die from cardiopulmonary collapse within hours after the onset of symptoms. Due to the complexity of the clinical presentation and the lack of rapid diagnostic tests, thiamine deficiency is still being underrecognised, especially among young non-alcoholic patients. In our patient, we first suspected pulmonary embolism from the echocardiographic findings but it was ruled-out by the contrast-enhanced CT. Remarkable hypotension with a wide pulse pressure suggested decreased vascular resistance in a high-output state. It is essential that we do not miss the opportunity for early intervention and thiamine should be administered as soon as clinical suspicion for thiamine deficiency arises.

SILENT SQUEEZE: ABDOMINAL OBSTRUCTION FROM REPEATED PERICENTESIS Omar Ahmad. Capital Health Regional Medical Center, Somerset, NJ. (Tracking ID #1643217)

LEARNING OBJECTIVE 1: Improvement in the assessment and management of an atypical cause of intestinal obstruction in an End Stage Liver Disease(ESLD) patient with past history of multiple paracentesis.
CASE: A 55 year-old African American male was admitted with complaints of diffuse abdominal pain and diarrhea for 2 days. Past medical history included end stage liver disease secondary to alcohol abuse, and refractory ascites treated with multiple paracentesis and medication such as spirinolactone, propranolol and furosemide. Physical exam revealed a tender distended abdomen with ascites. A computed tomogram (CT) of the abdomen demonstrated a complex loculated cyst in the anterior abdominal wall with ascending and descending colon wall thickening. After ruling out spontaneous bacterial peritonitis, a follow up ultrasound of the abdomen demonstrated a small pocket of fluid with multiple loculations and septations in the anterior abdomen. Later, the patient developed symptoms of obstruction. Despite nasogastric tube placement for decompression, his obstructive symptoms persisted. An obstructive series and a repeat abdominal CT scan showed dilated small bowel loops, suggestive of small bowel obstruction without any prominent lymphadenopathy suggesting cancer. A decision was made for an emergent exploratory laparotomy during which small bowel loops were found encased in a thick whitish membrane. The patient became too unstable to completely dissect the fibrous tissue. Microscopy of the specimen showed a fibrocollagenous tissue consistent with encapsulating peritoneal sclerosis. The Patient did not respond to steroids while in the ICU and remained on mechanical ventilation. With no clinical improvement the patient was made comfort measures and terminally extubated.
DISCUSSION: Intestinal obstruction normally is a result of adhesions from prior surgery, past intrabdominal or pelvic trauma or an encroaching neoplastic mass. In an ESLD patient that presented with abdominal pain and obstruction, infection and neoplasm first comes to mind. It has been hypothesized that repeated paracentesis can alter the peritoneal membrane structure in a similar manner as peritoneal dialysis which can result in gross interstitial thickening of the membrane with fibrotic changes and loss of mesothelial cells due to repeated irritating stimuli. This fibrous change of the serous membrane of the peritoneum resulting in diffuse adhesions can lead to obstruction. This condition is known as encapsulating peritoneal sclerosis (EPS) or cocoon syndrome. Patients with ESLD with a history of multiple paracentesis presenting with abdominal obstruction after ruling out more common causes should be evaluated for EPS. Patients at risk of this condition are already in a fragile state. Successful treatment depends on recognizing key past historical events with clinical symptoms and imaging. Early surgical intervention and the use of tamoxifen with corticosteroids have been postulated to improve outcome.

SIXTH CRANIAL NERVE PALSY AS AN UNUSUAL PRESENTING SYMPTOM OF IPILIMUMAB-INDUCED HYPOPHYSITIS David Burgess; Kah Poh Loh; Shin Yin Lee; Syed Ali. Baystate Medical Center, Springfield, MA. (Tracking ID #1645144)

LEARNING OBJECTIVE 1: Recognize ipilimumab as a recently approved drug for the treatment of metastatic melanoma
LEARNING OBJECTIVE 2: Recognize hypophysitis as a common immunological side-effect of ipilimumab
CASE: A 72-year-old man presented with progressively worsening diplopia, associated with headache and fatigue. He denied any associated focal neurological weakness, parasthesias, facial droop, aphasia, fever, neck stiffness, nausea, or vomiting. Physical examination revealed medial deviation of his right eye. The rest of his neurological exam was unremarkable. No orbital swelling or erythema was noted. His medical history was notable for stage IIB malignant melanoma which was resected with sentinel lymph node biopsy. Due to high risk of recurrence, he was enrolled in the ECOG 1609 trial and was randomized to ipilimumab therapy. He had completed 3 cycles of therapy prior to admission. On admission his vitals were within normal limits. Laboratory investigations revealed evidence of hypopituitarism; he had significant hyponatremia, subclinical hypothyroidism, hypoprolactinemia, and low ACTH, LH and cortisol. MRI of the brain showed an asymmetrically enlarged pituitary gland without any evidence of extraocular pathology, suggesting cranial nerve compression as the cause of his diplopia. The patient was subsequently given IV corticosteroids, with rapid improvement of his diplopia, headache and hyponatremia.
DISCUSSION: Until recently, dacarbazine and high-dose interleukin-2 were the only therapies approved by the US Food and Drug Administration (FDA) for metastatic melanoma. However, in March of 2011, ipilimumab became the newest agent for this indication and is the only drug that has shown a clear survival benefit in clinical trials. This case is interesting in that it underscores the atypical presentation of ipilimumab-induced hypophysitis. Ipilimumab is a human monoclonal antibody directed against the cytotoxic T-lymphocyte antigen-4 receptor, thus enhancing T-cell activation and amplifying T-cell-mediated immunity. The most common side effects are autoimmune and include hypophysitis, dermatitis and colitis. Hypophysitis usually manifests as headache and/or symptoms of pituitary hormone deficiency. Ocular side effects are much less common, although there have been reports of extraocular muscle deficits associated with ipilimumab due to orbital myositis. In our patient, there was no evidence of extraocular myositis. His unusual presentation with diplopia was caused by compression of his sixth cranial nerve as it ran laterally to the enlarged pituitary gland; a direct result of ipilimumab-induced hypophysitis.

SLOW POISON Tanvir Haque. University of North Carolina, Chapel Hill, NC. (Tracking ID #1637278)

LEARNING OBJECTIVE 1: Identify risk factors for lead poisoning
LEARNING OBJECTIVE 2: Distinguish indications for treatment of lead toxicity
CASE: A 49 year old woman presented with a 1 month history of abdominal pain, bloating and fatigue. She reported no melena or hematochezia, while the pain was described as crampy. She had conjunctival pallor as well as bluish-grey discoloration of her lower gingival border. She had mild tenderness in the right upper quadrant without any peritoneal signs. She also had normal strength, reflexes and sensation. Basic laboratory data showed a hemoglobin of 6.8 g/dL with mean corpuscular volume of 104, aspartate aminotransferase of 185 U/L, alanine aminotransferase of 36 U/L, total bilirubin of 1.0 mg/dL. Anemia studies showed a folate of 2.0 ng/mL. Blood smear was significant only for hypersegmented neutrophils and macrocytosis. Ultrasound revealed a liver measuring 22 cm, cholelithiasis, but no biliary distention or choleducolithiasis. The patient did admit to significant use of moonshine, consuming 3–5 cups a day for the last year, and was supplied by an independent distiller. Given her history of heavy moonshine use, a lead level was checked, and was found to be elevated at 25 μg/dL. The use of chelation therapy was ultimately decided against given her mild symptoms and lead level less than 50 μg/dL.
DISCUSSION: This case is an example of the association of lead toxicity with the regular use of moonshine. While the majority of cases of lead poisoning in the United States stems from occupational exposures, namely manufacturing, construction and mining sectors, nonoccupational sources, such as contaminated food and liquids, still contribute a significant proportion of elevated blood lead levels in the US. The incorporation of lead into the alcohol stems from the distillation process, as often times car radiators or lead-soldered vessels are used for makeshift condensers. The contamination of moonshine with lead is particularly common in illicitly produced moonshine. In 2004, The US Bureau of Alcohol, Tobacco, and Firearms studied 115 samples of illicitly produced moonshine in the Eastern United States, and found that the median lead level was 44.0 μg/dL, with 28.7 % of samples containing lead levels >300 μg/dL, the limit defined as potentially hazardous by the Food and Drug Administration. Diagnosis is often pursued by clinical suspicion; in this case, the presence of lead lines in conjunction with her moonshine use and nonspecific symptoms of fatigue and abdominal pain influenced her testing. Treatment centers on elimination of the environmental source of lead, in this case, abstinence from further moonshine use. Regarding chelation therapy, it is generally recommended that therapy begin at lead levels of >50 μg/dL in symptomatic patients, and >80 μg/dL in asymptomatic individuals. As this case illustrates, screening for lead toxicity in patients who abuse moonshine is warranted, especially since symptoms can be very subtle and nonspecific. If left ignored, chronic lead exposure can often times lead to hypertension, anemia, chronic kidney disease, neuropathy, and neurobehavioral impairments.

SO BASIC! Harman S. Kular. Baylor college of medicine, Houston, TX. (Tracking ID #1642407)

LEARNING OBJECTIVE 1: Understand that Bulimia Nervosa can lead to severe electrolyte defencies and ultimately cardiac arrest.
LEARNING OBJECTIVE 2: Recognize the importance of screening tools for eating disorders in the primary care setting.
CASE: A 27-year-old woman presented with weakness, nausea, and vomiting for 4 weeks. Exam was significant for a thin female with pallor, dry mucous membranes, and erosion of her upper molars. She denied history of an eating disorder. While in the ER, she had a witnessed myoclonic seizure and was noted to have ventricular tachycardia. She was cardioverted to normal sinus rhythm and emergently intubated. A few minutes later, patient developed pulseless ventricular tachycardia; ACLS protocol was initiated. During this arrest, she had multiple arrhythmias, including torsades de pointes and ventricular bigeminy and eventually returned to a normal sinus rhythm. Initial labs revealed Na 109 mmol/L, K 2.1 mmol/L, Cl <50 mmol/L with arterial blood gas showing pH of 7.89, pCO2 32, and HCO3 61.3. Upon transfer to the ICU, she went into pulseless ventricular tachycardia again. After 16 min of resuscitation, including defibrillation a total of six times, the patient regained a pulse and was in normal sinus rhythm. A hydrochloric acid drip was started for her profound alkalosis. She also received intravenous drips of lidocaine, levophed, and hypertonic saline. A transthoracic echocardiogram showed an ejection fraction (EF) of 15 % and apical ballooning consistent with a stress cardiomyopathy. By hospital day 3, she was extubated. She later admitted to a 2 year history of bulimia and alcohol abuse. After 8 days, she recovered and was discharged in stable condition with a psychiatric follow up. A repeat echocardiogram at discharge revealed a normal EF.

DISCUSSION: Primary care physicians are well trained to screen and treat obesity; however, bulimia nervosa and eating disorders are infrequently recognized until patients present with severe complications. The estimated prevalence of bulimia nervosa is 3 % to 10 % of adolescent and college age women in the United States. Complications include electrolyte imbalances (e.g. hyponatremia, hypokalemia, and hypochloremic metabolic alkalosis), arrhythmias, and increased incidence of drug and alcohol abuse. From our literature review, this is the first case report of severe alkalosis with a pH 7.89 caused by bulimia. In severe alkalosis, intravenous infusion of dilute hydrochloric acid is indicated. In a recent meta-analysis of 12 studies, the mortality rate of bulimia is estimated to be 1.74 per 1,000 person-years, meaning 0.17 % patients die. Early recognition and intervention may prevent this fatality. The SCOFF questionnaire as a screening tool has been shown to have 100 % sensitivity and 87.5 % specificity. Currently, there is no standard guideline for screening, and it is essential for primary care physicians to screen high risk patients.

SPIRALING FUTILITY: A CASE OF EUCALCEMIC HYPERVITAMINOSIS D Charles D. Magee. Uniformed Services University of the Health Sciences, Bethesda, MD. (Tracking ID #1642741)

LEARNING OBJECTIVE 1: Diagnose Hypervitaminosis D
LEARNING OBJECTIVE 2: Recognize that surreptitious use of over-the-counter (OTC) supplements poses risk for toxicity
CASE: CC: 74 year old male with fatigue, malaise and headache for several weeks HPI: The patient reports slight fatigue and malaise and occasional headaches for approximately 3 weeks. The fatigue was progressive, and non-exertional. The malaise led to a reduction in performing pleasurable activities. He also endorsed mild, self-remitting non-focal headaches most days of the past week. Review of systems was negative for fevers, weight changes, cough, dyspnea or chest pain, gastrointestinal pain or change in diet or normal bowel habits, new urinary complaints, hematuria or flank pain. He denied new muscle weakness or joint pain and reported no depressive or suicidal thoughts. PMH: Atrial flutter, hypertension, hyperlipidemia, obstructive sleep apnea, benign prostatic hypertrophy, chronic sinusitis and gastroesophageal reflux, osteoarthritis, and spinal stenosis. SHx: He is a non-smoker, non-drinker, physically-active retired officer from the Public Health Service. FHx: non-contributory. Medications: losartan 50 mg, rosuvastatin 20 mg, aspirin 81 mg, alfuzosin 10 mg, guiafenesin 600 mg twice daily, esomeprazole 40 mg, and celecoxib 200 mg. Supplements: Eucalyptus/peppermint emollient cream, stannous fluoride 0.4 % dental gel, Co-enzyme Q10 300 mg, testosterone powder, SAMe, Hyaluronic acid, DMSO, and saw palmetto. Vitals: HR 62 (sinus) BP 131/68 (left arm, seated) RR 16T 97.8oF Ht 73″ BMI 32 Physical Exam: The patient was obese, alert and oriented with appropriate affect. He had normal cardiopulmonary auscultation and a soft, nontender abdomen without organomegaly or reduced bowel sounds. Extremities were without edema, clubbing or cyanosis and no dermatologic lesions identified. Neuro exam was without focal sensory or motor deficits and demonstrated normal deep tendon reflexes. Cranial nerve examination was unremarkable. Diagnostic Studies: Initial labs identified a normal CBC, TSH and Liver associated enzymes. The 25-OH D3 level was >150 ng/mL (<10 deficiency; 10–30 insufficiency; 30–100 sufficient; >100 toxicity) and last baseline from September 2007 was 42.30 ng/mL. -During follow up the patient disclosed surreptitious OTC vitamin D supplement use for > 6 months, taking 10,000 IU of vitamin D3 daily, with upward titration to 40,000 IU for several weeks. Patient stopped vitamin D supplement and performed confirmatory testing 10 days later: Additional Studies: labs 10 days later confirmed normal serum calcium and creatinine. Repeat 25-OH D3 remained >150 ng/mL. Additionally, PTH was 9.0 pg/mL (15–65), 1,25OH D3 43 pg/mL (18–72) and 1,25OH D2 <8 pg/mL (16–55.6).
DISCUSSION: This is a unique case of eucalcemic hypervitaminosis D following surreptitious use of an OTC vitamin D supplement. Vitamin D intoxication (VDI), defined as serum 25OH D3 levels >150 ng/mL, remains rare in adults, yet case reports are increasing worldwide due to increases in supplement use. Though hypercalcemia is the most common sequelae of hypervitaminosis D in reported cases, it is not requisite for diagnosis. Vitamin D recommended daily intake (RDI) for adults is between 600 and 800 IU. Five cases have been linked to improper labeling of supplements in recent years. Mislabeling and lack of regulatory oversight of OTC supplements generates unnecessary risk for toxicity to patients. References available by request.

SPONTANEOUS IDIOPATHIC PNEUMOPERITONEUM: A CASE REPORT Ayesha Godil; Aslam Godil; Jeffrey Frost. Sierra Nevada Gastroenterology Medical Associates, Inc., Grass Valley, CA. (Tracking ID #1642851)

LEARNING OBJECTIVE 1: Recognize different causes of spontaneous pneumoperitoneum and importance of conservative management in the treatment of spontaneous idiopathic pneumoperitoneum.
CASE: An 86-yr old Caucasian male has presented with recurrent chronic abdominal bloating and dyspepsia since the late 1990s. He had a non-diagnostic colonoscopy and endoscopy in June 2001 for his evaluation. The patient underwent a CT scan of the Abd/pelvis in August 2001. Free air was noted in the splenic flexure region. Although patient had no abdominal pain, he was advised to report to the emergency room as a caution. Plain abdominal films confirmed air under the diaphragm. The patient's abdominal exam was completely benign; he was afebrile with a normal white blood cell count. His past medical history was unremarkable. The patient was admitted for observation on the surgical floor. The next day the patient remained asymptomatic, tolerated his meal and was discharged for home. The patient remained fairly stable for the next several years and it was not until August 2006 when he was reevaluated for recurrent gas and bloating. Another CT Abd/pelvis was done which again showed intraperitoneal free air. He was sent to the emergency room for evaluation. His ER workup was again negative, including barium small bowel follow through. A repeat CT scan was performed in October 2006 to follow up on the pneumoperitoneum. This time, there was no evidence of the condition. In June 2007 patient was evaluated again for gas and bloating. A lactose-free diet was instituted, to which patient showed some improvement. During his September 2008 visit, he was significantly better. The patient presented again to his primary care physician's office with abdominal bloating and distention in October 2011. Another CT Abd/pelvis was performed which revealed massive pneumoperitoneum. This was patient's third abdominal CT that had shown pneumoperitoneum over the course of a 10 year period. Around this time, patient was also dealing with a progressively advancing dementia. After discussing with the family, a decision was made to avoid further testing. To date, the patient is still living comfortably in an assisted living as he deals with his progressive dementia.
DISCUSSION: Over 90 % of cases of pneumoperitoneum are the result of perforation of an intra-abdominal viscus. In 5–10 % of cases, the condition does not reflect perforation and results from another source that does not require emergency surgery. Causes of spontaneous pneumoperitoneum include postoperative, thoracic, abdominal, gynecologic, and idiopathic. This case is unique in that no etiology could be identified. This patient has been followed for over a twelve-year period with no clinical consequences. Conservative treatment should always be considered as the preferred treatment in patients with spontaneous idiopathic pneumoperitoneum.

SPONTANEOUS INTRACRANIAL HYPOTENSION: AN UNUSUAL CAUSE OF HEADACHE Riddhi Shah[1]; Beth Ryan1; Ekta Kapoor[2]. [1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN. (Tracking ID #1613029)

LEARNING OBJECTIVE 1: 1. Identify spontaneous intracranial hypotension as an important cause of orthostatic headache

CASE: A 48-year-old Caucasian female presented to her local emergency department with acute onset of severe bifrontal headache associated with severe nausea and retching. The headache was exacerbated on standing up and completely resolved on lying flat. A CT scan of her head was unremarkable, and she was discharged home on analgesics. She continued to have daily severe headaches, and presented to our hospital. Her past medical history was significant for multiple previous shoulder dislocations and hyperflexible joints. On physical examination, her vital signs were normal. She did not have any nuchal rigidity, and Kernig's sign was negative. Her neurological examination including cranial nerve exam was unremarkable. Her acute spontaneous orthostatic headache, coupled with her history of possible connective tissue disorder, was most likely consistent with spontaneous dural tear resulting in intracranial hypotension. Magnetic resonance imaging (MRI) of her spine showed extensive extrathecal fluid consistent with cerebrospinal fluid (CSF) leak beginning in the cervical spine, extending throughout the thoracic spine, and up to the L2 level. She was treated with caffeine tablets, intravenous fluids and strict bed rest. After 4 days, a high volume (50 ml) autologous blood patch was placed which led to complete resolution of symptoms. At a follow-up visit 1 month later, the patient was doing very well.

DISCUSSION: Spontaneous intracranial hypotension (SIH), also known as Schaltenbrand syndrome or spontaneous aliquorrhea, was initially described in 1935 and is characterized by the spontaneous onset of orthostatic headache. Typically, the headache worsens on assuming an upright posture, is relieved with recumbency, and is not preceded by a lumbar puncture. The precise etiology of spontaneous spinal leaks is not entirely known. However, an underlying structural weakness of the meninges is generally implicated. Indeed, a number of connective tissue disorders including Marfan syndrome, Ehlers-Danlos syndrome and isolated joint hypermobility, among others, have been described in patients with SIH. The key MRI findings in patients with SIH include meningeal enhancement, subdural fluid collections, engorgement of the venous structures, pituitary hyperemia, and sagging of the brain. Conservative measures such as bed rest, adequate oral hydration and abdominal binder generally lead to resolution of symptoms. Other interventions such as administration of intravenous caffeine, steroids or theophylline have all been tried with varying degrees of success. Placement of an autologous blood epidural patch remains the most important and effective method of treatment in patients who fail to respond to conservative measures. About 10 to 20 ml of blood is generally sufficient; however in some patients, a large-volume patch (up to 100 ml) may be necessary to effectively act as a dural tamponade. Surgical treatment is reserved for patients who do not respond to high-volume blood patch, or those who have a focal CSF leak identified. The vast majority of patients experience spontaneous improvement in their neuroimaging findings within days to weeks. Our case report underscores the importance of considering spontaneous intracranial hypotension as a cause of orthostatic headache. Prompt recognition and timely intervention could lead to improved outcomes for these patients.

SPONTANEOUS HEALING OF A SEVERE (F-TYPE) CORONARY ARTERY DISSECTION Waseem Chaudhry. New York Methodist Hospital, Brooklyn, NY. (Tracking ID #1645358)

LEARNING OBJECTIVE 1: Feasibility of spontaneous healing of severe coronary artery dissection managed conservatively when CABG and PCI are not an option

CASE: Iatrogenic severe coronary artery dissection is a rare complication of percutaneous transluminal coronary angioplasty (<1 %), and spontaneous healing is rare. We report a patient whose catheter-induced dissection caused acute vessel closure and myocardial infarction (MI) that healed completely after conservative management. Case Presentation: A 70-year-old man with 2-vessel coronary artery disease (CAD), hypertension, diastolic heart failure and chronic obstructive pulmonary disease presented with leg edema and dyspnea on exertion. Acute decompensated congestive heart failure was diagnosed clinically and medical therapy was begun. His Pro-BNP was 4505 pg/ml, and an echocardiogram revealed left ventricular ejection fraction (LVEF) of 60 %, without wall motion abnormality, dilated right ventricle (RV) with markedly reduced systolic function and a peak pressure of 70 mm Hg. His heart failure symptoms did not improve and he was evaluated for revascularization. Left heart catheterization revealed 2-vessel CAD, 80 % stenosis of mid left-anterior-descending artery proximal to the previous stent, and 80 % calcified stenosis of the proximal right coronary artery (RCA). After the RCA lesion was crossed with the wire during balloon angioplasty, a 100 % residual stenosis became evident and attempts at re-wiring the lumen were unsuccessful. The patient remained hemodynamically stable after transfer to the coronary care unit. Cardiac magnetic resonance imaging revealed an LVEF of 45 % with significant RV dysfunction with transmural infarct in the anteroseptum and apical septum. Because of severe RV dysfunction and pulmonary hypertension, he was treated medically for the MI and discharged. An angiogram repeated 4 months later revealed complete resolution of the RCA dissection.

DISCUSSION: Discussion: According to the National Heart Lung and Blood Institute classification, coronary dissections are graded A-F based on their angiographic appearance and occlusion characteristics. Type-F dissections lead to total luminal occlusion without distal antegrade flow. In the pre-stent era, such closure affected 11 % of cases but the rate is now <1 %. Studies antedating the stenting era defined the important relationship between the dissection class and clinical outcome. Several studies reported spontaneous healing of mild to moderate dissection (Type-A-D) in 63–95 % of cases. It is recommended that Type-A-B dissections should be managed conservatively with adjunctive glycoprotein IIb/IIIa inhibitor use. Type-C-F are managed with stenting or coronary-artery bypass graft (CABG) depending on ability to wire the true lumen and patient's clinical status. The strategy consisting of primary attempt to stent with back-up CABG when needed has resulted in an overall survival rate of 94.4 %. The spontaneous healing of our patient's type F dissection with periprocedural MI establishes the feasibility of conservative management of a severe coronary dissection when stenting and CABG are not an option.

STEROID REFRACTORY DRUG REACTION: TIME TO READDRESS Lena K. Makaroun; Yunwen Chiu; Bliss Temple; Anna Haemel; Phuoc Le. University of California, San Francisco, San Francisco, CA. (Tracking ID #1633441)

LEARNING OBJECTIVE 1: Recognize the potential for direct organ toxicity such as neprhitis, pneumonitis and myocarditis resulting from marked eosinophilia in DRESS syndrome.

LEARNING OBJECTIVE 2: Consider initiaitng second line immunosuppressives in critically ill patients with drug reactions when eosinophilia does not respond to steroids alone.

CASE: A 58 year-old African American male presented to our hospital with confusion, diffuse morbiliform rash, facial edema, fever to 41.1 C, leukocytosis with eosinophilia, acute kidney injury, transaminitis and elevated creatinine kinase. Extensive evaluation for possible infection, including urine, blood and CSF cultures, was negative. Six weeks prior to admission the patient had been started on phenytoin at a skilled nursing facility. Dermatology was consulted for high clinical suspicion of drug reaction with eosinophilia and systemic symptoms (DRESS) syndrome. The patient was given a 3 day pulse of methylprednisolone 1 g daily. His eosinophil count continued to rise, peaking at 17,000 (total WBC count 47,000) on hospital day 6. On this day he also became hypoxemic. Chest CT showed bilateral upper lobe pulmonary infiltrates thought to represent eosinophilic pneumonia. Transthoracic echo to assess for eosinophilic mycocarditis was normal. Skin biopsy showed a dermo-epidermal interface process with lymphocytic and eosinophilic infiltrate consistent with a drug reaction. Testing for viral reactivation, including HHV6/7, EBV, CMV, and HIV

was unrevealing. Ultimately, DRESS refractory to steroids continued as the presumed diagnosis, and cyclosporine 5 mg/kg divided BID was started in addition to a second pulse of methylprednisolone. After cyclosporine initiation the eosinophil count began to drop within 24 h and eventually normalized. The patient's overall clinical picture concurrently improved with stabilization of hemodynamics, resolution of renal failure and improvement in respiratory status. Three months after discharge, cyclosporine was tapered to off, and the patient continued to do well on a slow taper of prednisone. Four months after discharge, the patient's prednisone was tapered down to 10 mg/d and his eosinophilia then recurred, peaking at 800. He was placed back on 80 mg of prednisone with good control, and hydroxyurea was added as a steroid sparing agent.
DISCUSSION: Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) syndrome is a distinct severe adverse drug reaction characterized by skin rash, fever and internal organ involvement. The marked eosinophilia that accompanies the disease can lead to life-threatening organ toxicity such as interstitial nephritis, pneumonitis and myocarditis. The cornerstones of treatment are removal of the offending agent as well as prompt initiation of steroids. However, as seen in this case the decline in eosinophils can lag behind the initiation of appropriate treatment. Furthermore, there are a small subset of cases of DRESS syndrome that appear to be refractory to steroids alone. When the patient's clinical condition continues to deteriorate despite appropriate treatment with steroids, additional immunomodulators should be considered.

STILL'S DISEASE PRESENTING WITH MYOPERICARDITIS Jonathan S. Kurman. Froedtert & The Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #1638423)

LEARNING OBJECTIVE 1: Recognize that adult-onset Still's disease may present with myopericarditis.
LEARNING OBJECTIVE 2: Review the diagnostic criteria for adult-onset Still's disease.
CASE: A 35-year-old male with a past medical history of juvenile idiopathic arthritis presented with 2 days of sharp, positional, substernal chest pain preceded by 3 days of pharyngitis, fever, and myalgia. Physical examination was remarkable for tachycardia, tachypnea, and proximal muscle weakness. Initial diagnostic studies showed a leukocytosis of 13,000/uL, elevated aminotransferase levels, an elevated troponin level, and diffuse ST segment elevation along with PR segment depression in the inferior leads on electrocardiogram. A transthoracic echocardiogram demonstrated preserved left and right ventricular function, no significant valvular disease, and minimal pericardial effusion. Colchicine and aspirin were initiated for suspected myopericarditis, which was subsequently confirmed by cardiac magnetic resonance imaging showing subepicardial delayed enhancement in the basal inferolateral wall of the left ventricle. Over the next few days, the chest pain dissipated. Multiple urine, respiratory, and blood cultures were persistently negative. An extensive infectious disease evaluation, including tests for human immunodeficiency virus, parvovirus B19, coxsackie A and B viruses, cytomegalovirus, and hepatitis A and B, was completely negative. The leukocytosis persisted, and he continued to spike high fevers each night even after resolution of the chest pain. Given the persistent nocturnal high fevers, leukocytosis, and otherwise negative comprehensive evaluation, the patient was diagnosed with adult-onset Still's disease.
DISCUSSION: Adult-onset Still's disease (ASD) is an inflammatory disorder typically characterized by high daily fevers, arthralgia, and an evanescent rash. It is a rare condition, occurring in less than 1 per 100,000 people with a bimodal age distribution peaking between ages 15–25 and ages 36–46. Although an infectious origin is suspected, the etiology remains unproven. There is no definitive test or laboratory value to diagnose ASD. Several sets of criteria have been established to aid in the diagnosis, the most sensitive of which is the Yamaguchi criteria. The four major criteria include persistent high fever, leukocytosis, arthritis or arthralgia, and a skin rash that is usually present during the febrile episodes. The minor criteria include a sore throat, organomegaly, elevated liver function tests, lymphadenopathy, and normal antinuclear antibody and rheumatoid factor. In order to make the diagnosis, five of these features must be present, including two of the major criteria. Several treatment options are available, including nonsteroidal anti-inflammatory drugs, glucocorticoids, disease-modifying antirheumatic drugs, and biologic immunomodulatory agents. The disease can follow a variable time course, and the prognosis is generally favorable with only a small subset of patients suffering long-term complications. In conclusion, adult-onset Still's disease is an uncommon condition that in rare cases can present with myopericarditis.

STREPTOCOCCUS CONSTELLATUS BACTEREMIA ASSOCIATED WITH COMPLEX PULMONARY AND HEPATIC INFECTIONS FOLLOWING PERFORATED APPENDICITIS IN A PATIENT TAKING ADALIMUMAB Anita Bhagavath; Malka Krupka; Rebecca Calabrese. Beth Israel Medical Center, New York, NY. (Tracking ID #1641811)

LEARNING OBJECTIVE 1: Recognize the infectious complications of adalimumab therapy
LEARNING OBJECTIVE 2: Diagnose and manage Streptococcus Constellatus bacteremia
CASE: A 41-year-old male with a history of chronic plaque psoriasis and an appendectomy 3 months prior presented to our hospital with malaise, dyspnea, fever and a productive cough for 1 week. On arrival, the patient was hypotensive and in respiratory distress, with a multifocal pneumonia on chest x-ray. He was admitted to the medical ICU for severe sepsis with hypoxic respiratory failure and was started on Azithromycin, Ceftriaxone and Vancomycin. On hospital day 3, the patient spiked a fever of 102 F. Further questioning into his past medical history revealed that he had received adalimumab injections for 6 months due to chronic plaque psoriasis. His last injection was 3 months prior, shortly before he was admitted to a hospital in London with ruptured appendicitis, complicated by peritonitis, requiring 3 weeks of antibiotic therapy. Despite initial improvement, he noted that after discharge he experienced intermittent subjective fevers, poor PO intake and night sweats, culminating in his presentation to our hospital. Blood cultures from this admission grew Streptococcus Constellatus in 1 of 4 bottles. HIV testing was negative. Repeat chest x-ray revealed a pleural effusion, which was too small to drain. A chest CT was performed and incidentally demonstrated a hypogenicity in the liver. A right upper quadrant ultrasound confirmed the presence of a small liver abscess, unable to be drained. Metronidazole was added for anaerobic coverage. The patient began to improve clinically, and repeat blood cultures were negative. He was successfully discharged from the hospital on a four-week course of Ceftriaxone and Metronidazole.
DISCUSSION: S. constellatus is part of the S. Milleri group, a subgroup of viridans streptococci. It is part of the normal flora of the oral cavity and GI tract. It is important to properly interpret positive blood cultures for these organisms because, unlike other viridans strep, they are rarely contaminants. Local infection with this organism is relatively common and well defined in clinical practice. However, bacteremia is less frequent. Systemic infections, including appendicitis, brain and liver abscesses, and sepsis have been demonstrated in children, cystic fibrosis patients, diabetics, organ transplant recipients and cancer patients. In our case, we suspect that this patient's adalimumab use left him immunocompromised and susceptible to S. Constellatus bacteremia. In our case, a young man with a history of adalimumab use presented 3 months after prompt medical therapy for perforated appendicitis with sepsis due to S. Constellatus, with a multifocal pneumonia and a liver abscess. The progression and spread of S. Constellatus infection despite medical therapy and discontinuation of the immunosuppressant should serve as caution to providers treating the infectious complications of adalimumab therapy.

SUBACUTE BACTERIAL ENDOCARDITIS MASQUERADING AS AN AUTOIMMUNE VASCULITIS Arshia Ali. University of Cincinnati, Cincinnati, OH. (Tracking ID #1641911)

LEARNING OBJECTIVE 1: Recognize the different causes of anti-neutrophil cytoplasmic antibodies.
LEARNING OBJECTIVE 2: Distinguish between autoimmune and infectious etiologies of endocarditis.

CASE: A 26 year old female presented with 6 months of malaise, thirty pound weight loss, night sweats, pleuritic chest pain and dyspnea. Past medical history included chronic sinusitis. Social history was significant for heroin use. On exam, she was ill-appearing, afebrile, tachycardic at 120 bpm, with hepatomegaly, bilateral pitting ankle edema with few petechiae. Notable laboratory findings were a platelet count of 17,000, ESR of 56 (mm/hr), CRP of 40.4 (mg/dL), and numerous RBCs on urinalysis. Chest CT showed multiple bilateral and predominantly apical pulmonary nodules with cavitary lesions as well as pulmonary emboli. A vasculitic disorder was suspected and a rheumatologic panel was positive for cANCA (>1:640) and PR3 (8.5 U/mL). Later the patient became febrile to 102.7 °F. A transthoracic echocardiogram showed a large (22×29 mm), heterogeneous, multilobulated, mobile vegetation on the tricuspid valve and blood cultures grew Pseudomonas aeruginosa. The patient was treated with antibiotics and was anticoagulated. Her edema, dyspnea, and thrombocytopenia resolved. She is doing well on outpatient follow up with rheumatology.
DISCUSSION: A positive cANCA is commonly seen in Wegener's granulomatosis and several other vasculitic disorders such as Churg-Strauss syndrome and microscopic polyangiitis. Other autoimmune diseases may also have a positive ANCA such as autoimmune hepatitis, rheumatoid arthritis and systemic lupus erythematosus. Several prescription medications as well as cocaine and heroin can cause a positive ANCA. Interestingly, as in our case, a positive ANCA can also be seen with infectious diseases including malaria, acute parvovirus B19, acute mononucleosis and subacute bacterial endocarditis (SBE). A comprehensive literature search revealed less than two dozen cases of SBE with cANCA positivity. The culprit organisms were primarily Streptococcus with rare reports of E. coli and indolent bacteria (Propionibacterium, Gemella, and Bartonella). Our case seems to be the first reported Pseudomonal SBE with cANCA and PR3 positivity. This also appears to be the first case in which the right heart was involved resulting in septic pulmonary emboli and a chest CT that was indistinguishable from pulmonary vasculitis. The clinical picture of SBE and Wegener's granulomatosis can present very similarly. Furthermore, ANCA associated vasculitis may present with non-infective endocarditis with detectable vegetations on echocardiography. Autoimmune and infectious diseases frequently co-exist in the differential diagnosis of multi-organ system disease. The clinician should be aware that a positive cANCA is not 100 % specific for autoimmune disease. The misdiagnosis of an infectious disease as an autoimmune process and the administration of immunosuppressive therapy could lead to increased morbidity and mortality.

SUCCESSFUL COMBINATION THERAPY OF CORTICOSTEROIDS, PLASMA EXCHANGE AND INTRAVENOUS IMMUNOGLOBULIN FOR SEVERE TOXIC EPIDERMAL NECROLYSIS. Takashi Watari[1]; Joel Branch[1]; Shuku Sato[1]; Haruki Uojima[2]; Daimu Tutumi[3]; Izumi Kitagawa[1]; Sumi Hidaka[4]; Takayasu Ohtake[3]; Shuzo Kobayashi[3]. [1]Shonan Kamakura General Hospital, Kamakura, Japan; [2]Shonan Kamakura General Hospital, Kamakura, Japan; [3]Shonan Kamakura General Hospital, Kamakura, Japan; [4]Shonan Kamakura General Hospital, Kamakura, Japan. (Tracking ID #1636243)

LEARNING OBJECTIVE 1: Toxic epidermal necrolysis (TEN) is a rare life-threatening disorder with a mortality rate of approximately 30 %. Although treatment is not standardised due to the unknown pathogenesis and lack of randomized clinical trials, high dose of systemic corticosteroids, immunoglobulins (IVIG) and immunosuppressive drugs such as cyclophosphamide have been used in the treatment of TEN with success. Because of increased risk of infections via exfoliated skin and GI bleeding, and the masking of sepsis, many physicians hesitate to adopt corticosteroids. We present a patients with severe TEN treated successfully with high dose corticosteroids followed by plasma exchange.
CASE: A 37-year-old, Japanese female with a high intake of over-the-counter (OTC) medications was admitted to our hospital with several days history of subacute high fever, pharyngeal pain, painful eyes, dry cough, generalized skin erythema and irregularly shaped purpuric macules. She was diagnosed with Steven-Johnsons syndrome in addition to drug-induced interstitial pneumonia. She underwent skin biopsy and was then commenced on methyl prednisolone 500 mg/day. After 3 days, there was no remarkable improvement with conventional corticosteroid treatment, with extensive epidermal exfoliation covering over 30 % of her body surface area, and worsening respiratory failure. In view of the lack of response to corticosteroid therapy, plasma exchange was commenced for 3 days for treatment of TEN, and she was intubated and ventilated. Remarkably after three plasma exchanges, exfoliation stopped and extensive reepithealization occurred by day 9. IVIG (0.3 mg/kg/day) was added for 3 days for exacerbation of respiratory failure. The patient made a full and uneventful recovery. Drug-induced lymphocyte stimulation test was undertaken at 20 days after admission and the result was positive for an OTC medicine containing wood creosote (Seirogan®).
DISCUSSION: Drug induced toxic epidermal necrolysis (TEN) is a rare but frequently lethal disease of the skin and mucous membranes of unknown etiology. Standard therapy has been established which includes meticulous wound care, fluid replacement, and nutritional support in and intensive care setting. Conversely, systemic corticosteroids and IVIG are not well established due to the unknown pathogenesis and lack of randomized clinical trials. However, there is common agreement which considers TEN as a manifestation of a deregulated immune reaction against epithelial cells. During the first stages of TEN, apoptosis mediates keratinocyte death with a pivotal role of the activated cytotoxic mediators such as Fas/FasL, granulysin and, TNF-alpha. Use of plasma exchange is a safe intervention in the more severe form of TEN, because the above inflammatory cytokines, autoantibodies, immune complexes or other unknown toxic substances cannot be removed by dialysis. Although expensive and requiring venous access, it is efficacious rapid cessation of of dermal necrolysis.

SUGAR, SUGAR, HOW'D YOU GET SO HIGH? Ishani Pathmanathan; Varsha Somasekharan. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640726)

LEARNING OBJECTIVE 1: Recognize potential side effects of second-generation antipsychotics
LEARNING OBJECTIVE 2: Understand screening for metabolic complications of second-generation antipsychotics
CASE: A 53 year-old man with a history of non-insulin dependent diabetes mellitus, hypertension and depression presented with 2 days of nausea, vomiting, polyuria and polydipsia. Previously, his diabetes had been well controlled on metformin. He denied fevers or recent illness. He had been adherent to his medication regimen. On exam, his heart rate was 113 with dry mucus membranes; he had a slightly distended but non-tender abdomen. Initial glucose was 452 and anion gap was 25. Arterial blood gas revealed a pH of 7.2. Urinalysis yielded greater than 1000 glucose and 150 ketones. He was admitted to the intensive care unit and treated with an insulin drip. After resolution of his ketoacidosis, capillary glucoses remained uncharacteristically high, requiring eventual discharge on 48 units of daily insulin. Strikingly, his hemoglobin A1C was found to be 14.2 %, although documented at 7.4 % 6 weeks earlier. Further history revealed that his quetiapine dose had been doubled from 300 to 600 mg at that time. His quetiapine was decreased to 200 mg daily, with plans to taper it off fully as an outpatient in exchange for another anti-depressant.
DISCUSSION: Second-generation antipsychotics are essential pharmacologic tools for psychiatrists and internists alike. The newer generation of drugs has fewer extrapyramidal side effects than their predecessors, but they are not without complications. Most significantly, they are linked to weight gain, insulin resistance, and lipid dysregulation. For some patients, starting or escalating therapy can precipitate acute diabetic decompensation, although the mechanism is poorly understood. Clozapine and olanzapine are most notorious for causing metabolic derangements, while aripiprazole and ziprasidone are the least frequent offenders. Risperidol and quetiapine have mixed results in the literature; both cause weight gain, but there is evidence that quetiapine may be worse at exacerbating diabetes. The FDA MedWatch Drug Surveillance System found 46 cases of quetiapine-associated hyperglycemia, of which 21 had diabetic ketoacidosis and 11 died. While second-generation antipsychotics are useful in treating psychiatric illness, their serious side effect profile

warrants concern. The American Diabetes Association consensus guidelines for weight, glucose and lipid screening are available to prescribers. It is important for internists to be mindful of the propensity of second-generation antipsychotics to exacerbate metabolic syndromes and to implement appropriate screening to detect potential side effects before they become life-threatening or irreversible.

SWISS CHEESE MRI FINDINGS IN A PATIENT WITH HYPERLEUKOCYTOSIS Saveri Bhattacharya[1]; Roy E. Smith[2]; Victor Okwiya[3]. [1]University of Pittsburgh Medical Center Shadyside, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]University of Pittsburgh Shadyside, Pittsburgh, PA. (Tracking ID #1637044)

LEARNING OBJECTIVE 1: To recognize the clinical symptoms of leukostasis and the associated radiological findings.
LEARNING OBJECTIVE 2: To recognize the high mortality associated with leukostasis and treatment options
CASE: Our patient is an 84-year-old male with history of Myelodysplastic Syndrome who presented to an outside hospital with a white blood cell count of 65,000 and severe metabolic acidosis thought to be secondary to tumor lysis syndrome. One day prior to admission, the patient received Filgrastim and his hyperleukocytosis was attributed to this medication. On day 2 of admission, his white blood cell count was 221,000 and he acutely decompensated. He was hypotensive and bradycardic and was resuscitated with CPR, epinephrine and atropine, when he developed agonal respirations and was emergently intubated and was transferred to our institution. A CT scan of the head on the day of arrest was normal. On admission to our institution, the patient's white blood cell count was 130,000 and peripheral smear showed 3 % blasts. On Day 2 after transfer, the patient was successfully extubated. He denied neurological symptoms and was mildly delirious, but comprehensible. Physical examination was unremarkable. However, on day 3 he was suddenly found obtunded and emergently intubated. His white blood cell count was 89,000 and an emergent CT of his head, obtained 5 days after his previous normal CT, revealed numerous bilateral supra- and infra-tentorial hyperdense nodules/masses. Further investigation with an MRI of the brain revealed innumerable hypodense hemorrhagic lesions in the supra- and infra-tentorial regions with surrounding edema on T2-weighted images, giving the patient's brain a "swiss cheese" like appearance. Due to innumerable hemorrhagic lesions in the brainstem, the patient had no chance for meaningful recovery. The patient's family decided that he should be made comfortable and he subsequently passed away. The family declined an autopsy.
DISCUSSION: Leukostasis is defined as hyperleukocytosis in a patient with leukemia who presents with symptoms of respiratory or neurological distress. It is considered an oncological emergency and the mortality associated with it is as high as 40 % (Percu et al., 2000). Leukostasis is a pathological diagnosis in which the white blood cells sludge the microvasculature leading to tissue hypoxia. However, it usually occurs when the white blood cell count is greater than 100,000. Common neurological symptoms include confusion, ataxia, headache, blurred vision, somnolence, delirium, and coma. Imaging of the brain usually reveals intracranial hemorrhage. Respiratory symptoms include shortness of breath and physical examination will reveal tachypnea and rales. Additionally, a chest X-ray usually reveals bilateral interstitial or alveolar infiltrates. The pathophysiology of leukostasis is not clear. In one theory, the elevated white blood cell count leads to increased blood viscosity and blasts occlude the microvasculature. However, in our case leukostasis occurred without hyperleukocytosis, suggesting that there are other factors influencing leukostasis occurrence. There is some evidence that the interaction between blasts and surface endothelial cells might lead to the aggregation of blasts in circulation (Mahjail et al., 2004). Emergent treatment is imperative. Usually treatment is initiated if the white blood cell count is greater than 100,000. Management includes cytoreduction by leukopheresis, aggressive fluid hydration and possible hydroxyurea.

SYMPTOMATIC HYPERCALCEMIA INDUCED BY DIFFUSE LARGE B-CELL LYMPHOMA Gliciria Kalathas; Anthony A. Donato. The Reading Health System, West Reading, PA. (Tracking ID #1638308)

LEARNING OBJECTIVE 1: 1. Recognize the causes of hypercalcemia of malignancy
LEARNING OBJECTIVE 2: 2. Interpret and manage laboratory tests suggestive of hypercalcemia of malignancy
CASE: Hypercalcemia is a common finding in asymptomatic patients, seen in 0.6 % of healthy adults and 1.9 % of those on thiazide diuretics. However, symptomatic hypercalcemia requiring acute hospitalization is a life-threatening problem, most often caused by disordered calcium homeostasis as the result of malignancy. We present a case with an unusual cause of this condition. An 89 year-old male was brought to emergency care with altered mental status, cachexia and ambulatory dysfunction. Hospital records noted a new diagnosis of diffuse large B-cell lymphoma identified 2 weeks prior, at which time he had a normal serum calcium (10.6 mg/dl) and renal function (0.89 mg/dl, normal: 0.50–1.50 mg/dl). On examination, he was found to have a blood pressure of 113/55 mmHg, heart rate of 61, disorientation, abulia, and signs of significant hypovolemia. Laboratory examination found a Calcium level of 13.3-mg/dl (normal 8.5–10.5 mg/dl), Phosphate 1.4 mg/dl (normal 2.5–4.6 mg/dl) and new acute renal failure with a creatinine of 2.3 mg/dl. Metabolic tests revealed low PTH (3 pg/ml, normal: 15–88 pg/ml) and elevated PTH-related peptide (PTH-rp) (2.6 pmol/L, normal: <2.0 pmol/L), confirming the diagnosis of hypercalcemia of malignancy. A course of aggressive IV hydration was pursued, as well as 60 mg IV Pamidronate, resulting in complete recovery of his mental status and renal function, and serum calcium level by his fourth day of admission. He was referred to a hematologist for outpatient chemotherapy.
DISCUSSION: PTH-rp is a peptide produced by malignant cells, most commonly lung and breast carcinoma, that results in life-threatening hypercalcemia. Calcium-induced diuresis can induce symptomatic hypovolemia, as was seen in this case. PTH-rp induced hypercalcemia in diffuse large B cell lymphoma is unusual, reported in 7.1 % of cases in which PTH-rp is seen and is associated with a poor prognosis. Early recognition and prompt management of symptomatic hypercalcemia is critical for hospital physicians.

SYNTHETIC MARIJUANA: A DIFFERENT BREED OF WEED Amitpal S. Nat; Shraddha Goyal; Amritpal S. Nat; Luke Yuhico; Arman Khorasani-zadeh; Bhargav Mudda; Amit Sharma; Amit Sharma; Michael C. Iannuzzi. SUNY Upstate, Syracuse, NY. (Tracking ID #1642927)

LEARNING OBJECTIVE 1: Recognize the severe complications of synthetic marijuana.
LEARNING OBJECTIVE 2: Distinguishing synthetic marijuana from organic marijuana.
CASE: A 45 y/o male presented with 1 week history of worsening dyspnea and right-sided pleuritic chest pain. There was no history of trauma or recent illness as per the patient. He denied fever, night sweats, weight loss, hemoptysis, cough, wheezing, orthopnea, paroxysmal nocturnal dyspnea, rash, arthralgias, tuberculosis exposure, asbestos exposure, or recent travel. He had a 20 pack year tobacco smoking history and quit cocaine use 10 years prior. He has been smoking a synthetic marijuana, called K2, for the past 1.5 years. Physical exam revealed a hemodynamically stable, well built African American male in slight distress. Respirations were shallow and restricted secondary to pain, which was appreciated upon inspiration. On lung auscultation, bilateral air entry was appreciated but decreased breath sounds at the right base. Rest of the exam was unremarkable. Ancillary testing was pertinent for eosinophilia of 7.2 % and an elevated D-dimer at 4,190 ng/mL. CBC, BMP, LFT's, BNP, PT/PTT/INR, P-anca, C-anca, rheumatoid factor, ANA and stool for ova/parasites were unremarkable. CXR and CTA revealed a large right lower lobe pleural effusion, mediastinal lymphadenopathy, two small pulmonary nodules, and was negative for pulmonary embolism. Thoracentesis revealed 550 cc of orange turbid fluid, consistent with an exudative effusion, showing 45 % eosinophils, 5,055 nucleated cells, and 10,284 RBC's. TB, fungal, and bacterial cultures, and cytology were unremarkable. Pathology showed reactive mesothelial cells and numerous eosinophils.

DISCUSSION: In 1995, Dr. John Huffman used synthetic compounds for research on neurogenic cannabinoid effects. After his publication, nationwide use increased rapidly, posing extreme cardiopulmonary risks toward users with minimal knowledge of the drug. We present a healthy male who developed respiratory compromise with eosinophilic pleural effusion secondary to synthetic marijuana. With limited public awareness about severe complications of synthetic marijuana, it's imperative that physicians educate patients and colleagues of the potential dangers of the drug. The past 3 years have demonstrated an exponential boom in cannabinoid use, exemplified by 6,955 calls received regarding harmful exposure last year, compared to just 15 in 2009. With now 17 states and D.C. having allowed legalization of medical marijuana, there is a public misconception that both the organic and its synthetic counterpart are similar and harmless. Despite some similarities in smell, synthetic marijuana however can be up to 100 times stronger and has been described to lead to life-threatening complications such as respiratory failure requiring mechanical ventilation and ecmo, myocardial infarction, status epilepticus, suicide, hypertensive crises, or in our case, respiratory compromise secondary to large eosinophilic pleural effusion. Dr. Huffman, himself, stated: "These things are dangerous—anybody who uses them is playing Russian roulette. We never intended them for human consumption." In this report, we describe yet another significant respiratory complication of the use of synthetic marijuana and the public's lack of awareness of the significant dangers of the drug.

TAKING AWAY MORE THAN YOU BARGAINED FOR Morgan J. Katz; Matthew N. Peters; John Wysocki; Chayan Chakraborti. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640473)

LEARNING OBJECTIVE 1: Identify delayed hemoperitoneum as a complication of large volume paracentesis.
LEARNING OBJECTIVE 2: Recognize renal insufficiency as a risk factor for hemorrhage
CASE: A 55 year-old man with end-stage congestive heart failure and chronic kidney disease presented with massive abdominal ascites and pitting edema of his lower extremities. Initial hemoglobin was 8.9 g/dL and platelet counts were 432/μL. He was diuresed with intravenous furosemide with minimal reduction of ascites. Ultrasound-guided paracentesis removed 5 l of straw-colored fluid with immediate symptomatic relief. Three days later, he complained of abdominal pain. Hemoglobin levels precipitously dropped to 6.9 g/dL. He was a Jehovah's Witness and refused transfusion of blood products. Hemoglobin continued to drop daily to 5.0 g/dL and then to 2.9 g/dL. Diagnostic paracentesis yielded 10 cc of blood-tinged fluid. Emergent upper endoscopy demonstrated no evidence of bleeding but revealed a bluish hue in the stomach suggestive of an intraperitoneal bleed. CT scan of the abdomen demonstrated hemoperitoneum. Inferior epigastric and gastroduodenal angiogram revealed no evidence of active bleeding. Following a discussion with him, he was discharged to hospice.
DISCUSSION: Bleeding following paracentesis is typically acute and related to puncture of abdominal wall vessels or internal organs. However, hemoperitoneum is a rare complication of paracentesis and occurs 3–7 days after procedure. Mortality from this complication is as high as 70 %. Patients with advanced liver failure and portal hypertension are at risk. A sudden drop in pressure caused by removal of >4 l of ascitic fluid can increase the pressure gradient across the wall of mesenteric varices, causing eventual rupture and hemorrhage into the abdominal cavity. Diagnosis is challenging due to slow onset and unrevealing imaging studies; however, suspicion should be high in patients with abdominal pain, decreasing hemoglobin levels and evidence of hypovolemia. Initial evaluation should include diagnostic paracentesis to detect intraperitoneal blood and serial blood counts. Further imaging studies are usually non-diagnostic and not recommended. Preventive measures against this complication include slower drainage of ascitic fluid (<4 l at a time) and concurrent albumin infusion. While low platelet counts and elevated INR typically increase bleeding risk, they have not been demonstrated to increase the risk of delayed hemoperitoneum. In contrast, patients with concurrent advanced renal disease have an increased bleeding risk (likely due to underlying platelet dysfunction), and prophylactic administration of fresh frozen plasma prior to the procedure should be considered in these groups.

TB MENINGITIS-AN UPRISING OR A FALSE ALARM? Saraschandra Vallabhajosyula[1]; Renuga Vivekanandan[1,2]; Laurel Preheim[1,2]. [1]Creighton University Medical Center, Omaha, NE; [2]Creighton University Medical Center, Omaha, NE. (Tracking ID #1641922)

LEARNING OBJECTIVE 1: Assessing laboratory parameters judiciously in a patient with no clinical features suggestive of tuberculosis
LEARNING OBJECTIVE 2: Recognizing recent spate of false-positive TB cases in the Mid-West due to laboratory contamination
CASE: 72 yo Caucasian man with type-2 diabetes mellitus, hypertension, hyperlipidemia, obesity and permanent atrial fibrillation on chronic anticoagulation presented with acute altered mental status (AMS) of 3 days duration associated with low grade fevers, inappropriate speech and disorientation. No history of recent travel/incarceration/illicit drugs. However, he did report a recent tick removal from his beard. Examination was remarkable for a combative patient in AMS with stable vitals and temperature of 103 F. Systemic and neurological examinations were otherwise unremarkable. Peripheral blood count showed leukocytosis with left shift. Cerebral spinal fluid (CSF) was clear and colorless with 12/cu.mm erythrocytes, 16/uL leucocytes (52 % neutrophils, 37 % lymphocytes), glucose 99 mg/dl and protein 65 mg/dl. CSF gram stain, Acid fast bacilli (AFB) stain and cultures were negative. Chest, cardiac and cerebral imaging was unremarkable. Extensive infectious workup for bacterial and viral etiologies of AMS was negative. Patient was empirically started on Ceftriaxone & Doxycycline for tick-borne infection. Mental status returned to baseline in 3–4 days after treatment. One month later, patient's CSF-AFB culture and TB-genoprobe become positive. Patient was completely asymptomatic with normal lab parameters. Repeat CSF was colorless with 10/cu.mm erythrocytes, 2/uL leucocytes (98 % lymphocytes), glucose 75 mg/dl and protein 44 mg/dl. Serum serology was positive for Rickettsia typhi antibodies—IgG 1:256, IgM 1:64 which may explain the finding a month prior. The patient's overall clinical picture remained inconsistent with TB meningitis 1 month later. We hypothesized that this was a false-positive culture due to laboratory contamination and did not advocate treatment for TB at this point in time.
DISCUSSION: EPTB gold-standard for diagnosis involves direct smear and culture identification which has the limitations of non-rapid diagnosis, poor sensitivity and long incubation period (4–8 weeks). Recent molecular-based methods include Polymerase Chain Reaction (PCR) assays that target hup-B gene with a 90.32 % sensitivity and 94.48 % specificity. As defined by CDC, a false-positive TB testing has the following criteria: (a) if all 3 genotyping methods show a match with the presumed source of the false-positive culture; (b) suspect isolates were processed at the same time or collected in the same location or with the same instrument; (c) no other likely explanation for findings and (d) misdiagnosed patient does not have a clinical picture consistent with TB. These parameters were true in our patient, thus validating the superiority of the clinical picture over laboratory findings and preventing our patient from being exposed to unnecessary medications. Currently, two other similar cases have been reported from the same diagnostic microbiology lab. Center for Disease Control and Prevention (CDC) confirmed that all three TB isolates had the same genotype, thus validating our hypothesis of laboratory contamination.

TB OR NOT TB Mallory Otto. New York Presbyterian-Cornell, New York, NY. (Tracking ID #1642265)

LEARNING OBJECTIVE 1: Review a diagnostic tool for ruling out TB with acid fast bacilli on culture in emergent scenarios
CASE: A 28 year old woman presented to her primary care physician with 1 month of facial swelling and a left sided neck mass. She had no fevers, night sweats, or cough. Ultrasonography of the neck mass demonstrated

necrotic lymph nodes. Further evaluation with CT demonstrated a 15 cm anterior mediastinal mass encasing the great vessels, invading and completely occluding the SVC with supraclavicular and bilateral axillary lymphadenopathy and surrounding fat stranding. The lungs were clear. A PET CT demonstrated the mediastinal mass had an SUV of 13.6. A biopsy was obtained from the L neck mass and demonstrated mostly necrotic tissue without evidence of malignancy but with rare acid-fast organisms; unfortunately a culture had not been obtained. A PPD and a quantiferon gold were negative. A neck dissection was performed to obtain a definitive diagnosis and demostrated lymph nodes positive for Reed Sternberg cells consistent with Hodgkin's lymphoma. In addition few acid-fast bacilli were visualized on the concomitant culture that were negative by nucleaic acid amplification for TB, which notably is approved for use in sputum only. The mycobacteria is undergoing sequency for further identification, and the patient tolerated her first several rounds of chemotherapy without mycobacterial treatment.

DISCUSSION: Nucleic acid amplification (NAA) has been approved by the Centers of Disease Control and Prevention (CDC) for use to detect tuberculois (TB) in respiratory specimens only. The positive predictive value (PPV) is >95 % when used in acid fast bacillus (AFB) positive respiratory specimens with high clinical suspicion. The PPV is <50 % for NAA testing in scenarios with low clinical suspicion for TB and is not recommended. In AFB negative specimens the sensitivity is lower around 50–80 % and thus a negative NAA is not sufficient to exclude TB if the clinical suspicion is high. NAA testing can be useful for early confirmation of TB however should not replace the gold standard of the traditional culture. In respiratory specimens, however, the CDC does recommend treating AFB + and NAA + respiratory sample with anti-TB treatment while awaiting definitive culture results. When an AFB smear is positive but the NAA is negative it is possible that in 3–7 % of cases sputum specimens could contain inhibitors that prevent amplification and may cause false negative results. Such inhibitors can be tested for and the CDC recommends doing so and treating for TB if inhibitors are present. Evidence is sparse on the utility of NAA testing in non-sputum specimens. Of the data that exists it appears that commercially available NAA testing such as the MTD have a relatively high specificity (~95 %) but lower sensitivity (~79 %) for non-sputum samples, and lower especially for non-liquid samples (1). While a positive result can be helpful in ruling in disease a negative one cannot be relied on to rule it out (2). Clinical suspicion remains of upmost importance in decisions regarding treatment of extrapulmonary TB. 1. Dinnes J, Deeks J, Kunst H, Gibson A, Cummins E, Waugh N, Drobniewski F, Lalvani A. A systematic review of rapid diagnostic tests for the detection of tuberculosis infection. Health Technol Assess. 2007 Jan;11(3):1–196. 2. TB OR NOT TB: A CASE OF TUBERCULOSIS PYOMYOSITIS Matthew A. Joseph; Vikram Krishnasamy; Harish Jasti. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1642153)

LEARNING OBJECTIVE 1: Recognize the presentation and stages of pyomyositis

LEARNING OBJECTIVE 2: Identify the common organisms that cause pyomyositis

CASE: The patient is a 53 year old Caucasian female with a history of sarcoidosis and pulmonary fibrosis on chronic glucocorticoids, who presented to the hospital with a 6–8 month history of progressive pain, erythema, and edema on the left scapula, biceps, and groin. She also endorsed subjective fevers and chills. The symptoms were unresponsive to a course of vancomycin, meropenem, and doxycycline during a previous hospitalization. She denied any travel history, tick bites, or exposure to tuberculosis and other sick contacts. On physical exam, her vital signs were stable, afebrile, on 4 l baseline home oxygen. She was toxic appearing and in pain. On her left upper back, she had a well-defined boggy area of tissue which was mildly erythematous and tender to palpation. Within the boggy area was a 5 mm hollow circular crater, without fluctuance or expressible purulence. On her left arm, she had erythema, purpura, induration, and was painful to palpation. On her left leg, she had 2+ pitting edema and erythema extending from the groin to the foot. Labs were notable for a WBC count of 22, with 88 % polys and 10 % bands. A CT scan revealed multiple subcutaneous and intramuscular abscesses in the left shoulder, left arm, and left chest wall, along with a 12 cm intramuscular abscess in the anterior compartment of the left thigh. There were also ground glass opacities in the right upper lung and bilateral lower lungs, centrilobular nodules, a right upper lobe calcified granuloma, and prominent paratracheal lymph nodes. She was diagnosed with pyomyositis, and was started on vancomycin, ceftriaxone, and metronidazole. Aspiration and examination of the left groin fluid collection revealed acid-fast bacilli on smear, which was confirmed as mycobacterium tuberculosis on culture. Bronchoalveolar lavage of the ground-glass opacities also revealed mycobacterium tuberculosis.

DISCUSSION: Pyomyositis is an acute intramuscular infection that is the result of hematogenous spread. The pathogenesis is not clearly understood, but predisposing factors may include muscle trauma, strain or vigorous exercise. Pyomyositis occurs both in the tropics and temperate environments. In the latter setting, the patients usually have severe underlying comorbidities or are immunocompromised. The most common organisms are Staphylococcus aureus, including MRSA, and Group A streptococci. Less common organisms include non-group A streptococci, gram negative bacilli, pneumococci, and mycobacteria. The infection consists of three stages. Stage 1 is characterized by a low grade fever, muscle pain, and swelling. Abscesses may not be apparent in this stage. Stage 2 is the most common presentation and occurs 10–21 days after the beginning of the initial symptoms. It is characterized by fever, muscle tenderness, and leukocytosis. Aspiration of the affected muscle will yield purulent material. Stage 3 is the most severe and is characterized by a large amount of pus, significant fluctuance, systemic toxicity, and possible sepsis. Despite having no identifiable risk factors for TB, she presented with a case of TB pyomyositis. Consider pyomyositis in the differential diagnosis of patients with painful, deep skin lesions, and associated fevers and chills. Obtaining cultures prove vital in guiding appropriate antimicrobial therapy.

THE BEST PART OF WAKING UP Naomi Karlen; Ardalan Minokadeh; Morgan J. Katz. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640352)

LEARNING OBJECTIVE 1: Recognize that unusual practices, even if they have support from a health care source, can cause disastrous consequences.

LEARNING OBJECTIVE 2: Highlight the importance of asking about patients' social history: including personal practices.

CASE: A 39 year-old woman with no past medical history presented with acute altered mental status after alerting her roommate to call EMS. She was found drinking water directly from the bathtub faucet. She complained of loss of awareness and tunnel vision. She was alert and oriented to person, place, and time, had no abnormal physical findings and neurologic exam demonstrated no abnormalities: grossly intact cranial nerves 2 through 12, intact sensation to light tough and temperature, no cerebellar findings, and demonstrated appropriate strength and deep tendon reflexes in all extremities. Sodium was 121 mmol/L, potassium 2.5 mmol/L, chloride 91 mmol/L, phosphorus 1.6 mg/dL, and magnesium 1.4 mg/dL with urine osmolality 74 mOsm/L, urine sodium 21 mEq/L, and urine creatinine less than 10 mg/dL. CT head revealed no acute findings or cerebral edema, chest radiograph was revealed clear lungs and normal cardiac silhouette, EKG showed mild PR prolongation, occasional u waves, and mild T wave inversion. Upon further questioning, she revealed that she had recently started performing one to two coffee enemas daily for the last few weeks. In addition to her enemas that morning, her spiritual guidance led her to believe that she needed to consume large amounts of water to "cleanse" herself. She felt in control of her water intake, consuming an immeasurable amount of water from the faucet until she alerted her roommate to feeling unwell.

DISCUSSION: While practicing Shamanism, this patient's spiritual guidance had led her to undergo "body cleansing" and "detoxification procedures." Initially, that manifested in dietary changes with elimination of preservatives, gluten, and processed sugars. This eventually also included daily coffee enema(s). While seemingly unconventional, there have been multiple healthcare providers who promote the use of coffee enemas on a regular basis in treating cancer patients. One theory supports the use of coffee enemas to help the body detoxify from tumor cell metabolites. Risks of coffee enemas have a wide range of consequences including bowel injury, fluid overload, severe electrolyte deficiencies, potential septicemia, and two documented deaths. In the case of this patient, the electrolyte imbalances were additionally exacerbated by consumption of large amounts of water, which she was driven to drink under the direction of her spiritual guides. In this case, the patient suffered from a brief period of purposeful polydipsia more than psychogenic polydipsia. As exotic lifestyle preferences become increasingly popular, personal ideas regarding maintenance of health and wellness similarly expand. While it is important for health care providers to keep an open mind regarding such practices, it behooves internists to help these patients to maintain an appropriate balance between their personal beliefs and evidence based medicine in addition to taking an extensive history.

THE FINAL INSULT: A CASE OF ACUTE-ON-CHRONIC BUDD-CHIARI SYNDROME Jianhua A. Tau; John Lin; Jeffrey T. Bates. Baylor College Of Medicine, Houston, TX. (Tracking ID #1643195)

LEARNING OBJECTIVE 1: Diagnose the Budd-Chiari Syndrome in a patient with acute-onset jaundice and history of thromboembolic disease.
LEARNING OBJECTIVE 2: Recognize that the majority of cases have underlying hypercoagulable states that require anticoagulation to prevent severe complications.
CASE: A 61-year-old female was admitted with acute jaundice. She was in her usual state of health until 2 weeks prior to admission, when she developed progressive jaundice, dull right upper quadrant pain, and lower extremity edema. Her PMH included a deep venous thrombosis while taking oral contraceptives and a pulmonary embolism after a surgery. Physical examination revealed icteric sclera and jaundiced skin. She was alert, but oriented to only person and place. She had mild right upper quadrant pain with palpation; she did not have hepatomegaly or ascites. Asterixis and 2+ lower extremity edema were present. Laboratory studies showed a total bilirubin of 6.3 mg/dl, a direct bilirubin of 4.7 mg/dl, AST of 487 mg/dl, ALT of 336 mg/dl, and an INR of 1.9; other liver function tests, chemistries, and CBC were normal. Serologies for Hepatitis A, B, and C and EBV, HSV, and CMV were negative. An abdominal MRI demonstrated an atrophied left hepatic lobe; associated biliary ducts and vasculature were atretic. Hepatic venogram revealed an acute short-length right hepatic vein thrombosis partially involving the inferior vena cava, as well as chronic occlusion of all other outflow segments. Acute-on-chronic Budd-Chiari syndrome was diagnosed. A stent was placed in the right hepatic vein. Jaundice, edema, and pain improved, but her coagulopathy did not resolve. She was anticoagulated with warfarin and placed on the liver transplant waiting list.
DISCUSSION: Budd-Chiari syndrome is rare, with an estimated incidence of less than 1 case per million individuals per year. It is diagnosed when hepatic outflow obstruction occurs anywhere between the hepatic veins and the terminal IVC. An underlying hypercoagulable state is identified in 75 % of cases; primary myeloproliferative disorders are most commonly identified. Other causes include paroxysmal nocturnal hemoglobinuria, antiphospholipid antibody syndrome, oral contraceptive use, and inherited deficiencies of protein C, protein S, or antithrombin III. Clinical manifestations do not appear until at least two hepatic veins are occluded; if obstruction occurs slowly and is accompanied by extensive collateral development, the patient may remain asymptomatic. In this case, the severely atrophied left hepatic lobe suggests a slow thrombosis of the left hepatic vein, resulting in asymptomatic necrosis as collateral vessels developed. The damage was clinically undetectable until the final thrombotic insult occurred. This acute-on-chronic presentation of the Budd-Chiari syndrome carries a relatively poor prognosis.

TOO FAT TO FILTER: OBESITY-RELATED GLOMERULOPATHY Jane Andrews; Chad S. Miller. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1639697)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of new acute on chronic renal failure secondary to obesity
LEARNING OBJECTIVE 2: Identify the differential of focal segmental glomerular sclerosis Understand the pathophysiology of obesity-related glomerulopathy
CASE: A 28 year-old healthy woman presented with 4 weeks of worsening nausea and vomiting. She has also noticed foul-smelling urine and generalized pruritus. She had an upper respiratory infection 2 weeks prior to presentation. Vitals signs were remarkable for a heart rate of 90 beats per minute and a blood pressure of 178/102 mmHg. Physical exam was significant for a morbidly obese woman with a body mass index (BMI) of 55. She had excessive facial hair on her chin and several 1 cm excoriations on her arms. Laboratory studies were notable for a urine specific gravity of 1.010, 5–10 WBC per high-powered field, 3+ leukocyte esterase, 3+ protein, 1+ blood. Hemoglobin was 6.1 gm/dL with a normal mean corpuscular volume. BUN was elevated at 186 mg/dL while creatinine was 31 mg/dL. Total Protein was 8.8 gm/dL and albumin was 3.2 gm/dL. Total cholesterol was 76 mg/dL, HDL was 28 mg/dL, and LDL was 38 mg/dL. Kidneys were sonographically unremarkable. Urine protein-to-creatinine ratio measured 5.8, suggestive of nephrotic-range proteinuria.
DISCUSSION: Chronic renal failure and obesity are common diagnoses for the internist, frequently co-existing in the same patient. Recent studies have described the association between severe obesity and secondary focal segmental glomerular sclerosis (FSGS), specifically obesity-related glomerulopathy. These findings are independent of the relationship between renal failure and hypertension or diabetes. Signs of obesity-related glomerulopathy include a BMI of 30 or above, nephrotic-range proteinuria and worsening renal insufficiency. Obesity-related glomerulopathy is distinct from idiopathic FSGS with less proteinuria, a milder course, and less foot process fusion seen on pathology. Obesity-related glomerulopathy begins with the increase in glomerular size that correlates closely with body mass index. This hypertrophy causes podocyte injury, which leads to glomerular scarring and renal failure. Patients with obesity-related glomerulopathy who lost significant weight were able to reduce their levels of proteinuria. Some studies have demonstrated complete reversal of obesity-related glomerulopathy by treating concurrent sleep apnea. Considering potential for reversal of kidney disease, internists should consider translating new science surrounding obesity-related glomerulopathy into aggressive counseling on body mass index.

THE ART OF DECREASING CANCER IN THE HOSPITABLE HOST Michal Gross; Julie Lorton; Marina Shcherba; Mark A. Menegus. Montefiore Medical Center, Bronx, NY. (Tracking ID #1643156)

LEARNING OBJECTIVE 1: Recognize lymphoma as part of the differential diagnosis of a cardiac tumor in AIDS.
LEARNING OBJECTIVE 2: Assess the likelihood of certain AIDS-defining malignancies based on the CD4 count.
CASE: A 35 year-old man with HIV/AIDS (CD4 158, VL >4 million) presents with 2 weeks of progressive severe shortness of breath. His shortness of breath is confined to the supine position, without a decrease in exercise tolerance. He endorses anorexia, unintentional weight loss, low-grade fevers, and fatigue. His review of systems is otherwise negative. The patient was diagnosed HIV+10 years prior, but did not opt for treatment. On admission the patient was afebrile and normotensive but tachycardic to 130 and tachypneic to 24, with oxygen saturation 97 % on room air. Bilateral upper extremity edema and bilateral basal ronchi were noted. Chest X-ray showed bilateral pleural effusions. Echocardiogram showed pericardial effusion with tamponade physiology. CT thorax showed mediastinal adenopathy and a right atrial mass extending into the superior vena cava. The pericardial effusion was drained and the mass endovascularly biopsied. Pericardial fluid cytology and biopsy were positive for non-Hodgkin's Lymphoma (NHL), specifically Large B Cell

Lymphoma. The diagnosis of Primary Effusion Lymphoma (PEL) was made based on the findings of pericardial effusion with HHV8+ immunoblastic B cell phenotype in an AIDS patient. Immediately after diagnosis, the patient began chemotherapy and has been clinically responsive thus far, with decreased shortness of breath and radiographic evidence of decreasing mass size.

DISCUSSION: AIDS-defining malignancies including Kaposi's Sarcoma, non-Hodgkin's lymphoma and invasive cervical carcinoma were commonly seen in the pre-Antiretroviral Therapy (ART) era. The incidence of these malignancies has declined since the advent of ART and the consequent rise in patients' CD4 counts, suggesting an inverse relationship between malignancy risk and CD4 count. Lymphoma subtypes found almost exclusively in AIDS are frequently associated with viruses, such as HHV8, which causes Primary Effusion Lymphoma. The reason for the high incidence of these infectious-driven cancers in HIV/immunodeficiency is thought to be the unchecked proliferation of HHV8 infected lymphocytes in the setting of T-cell deficiency. PEL is defined as an immunoblastic HHV8+ B-cell lymphoma that presents as a pleural, peritoneal or pericardial effusion, traditionally without a coexisting solid tumor. Our patient presented with HHV8+ B cell lymphoma, PEL solid variant subtype, which is a recently recognized subtype, similar to traditional PEL, but associated with a mass. This is the second reported case of PEL presenting as a cardiac tumor and is the first reported case of PEL presenting as a right atrial tumor. The differential for our patient's right atrial tumor was broad; atrial myxoma, metastasis, primary cardiac tumor, and thrombus were all considered given the location and clinical context. Although the prevalence of AIDS-defining Non-Hodgkin's lymphoma has decreased in the era of HAART, it is important to keep PEL on the differential of a cardiac tumor in an HIV + patient, particularly one with uncontrolled AIDS or HAART non-compliance. PEL generally has a poor prognosis; however the two reported cases of cardiac tumor PEL, including this case, improved rapidly with chemotherapy, rendering diagnosis very important.

THE ASSOCIATION OF PARVOVIRUS B19 AND TYPE I CRYOGLOBULINEMIA Narendranath Epperla; Steven H. Yale. Marshfield Clinic, Marshfield, WI. (Tracking ID #1643189)

LEARNING OBJECTIVE 1: 1. To recognize the association of parvovirus B 19 with Type I cryoglobulinemia. 2. To understand the appropriate treatment of Type I cryoglobulinemia associated with Parvo B 19 and low grade lymphoproliferative disorder.

CASE: A 62 year-old male with a history of exposure to his grandchild diagnosed with erythema infectiosum presented with a 1 week history of fever, peripheral polyarthralgias and myalgias. Evaluation revealed a platelet count of 68,000 and hemoglobin 15.7. Computed Tomography scan showed splenomegaly and intra-abdominal lymphadenopathy. He presented 2 day later and was hospitalized for generalized urticaria, pruritus and lightheadedness. Platelet count at that time was 17,000×103 and hemoglobin 7.2 g/dl and reticulocyte count of 18.3 % (index 0.68). Laboratory studies were negative for Lyme and Ehrlichia serology. Peripheral blood film examination showed thrombocytopenia, areas of red cell agglutination, very rare schistocytes, and LDH >900 (units). The activated partial thromboplastin time, prothrombin time, and fibrinogen levels were normal. Direct-antiglobulin test was positive for IgG only and serologic tests (enzyme-linked immunosorbent and immunofluorescence assays) for B19 were positive for IgM and IgG antibodies. Viral studies (HBV, HCV, HIV and CMV) and autoimmune panel (ANA, ANCA and anti-GBM) were normal. On hospital day five he developed acute renal failure requiring hemodialysis. Renal biopsy showed thrombotic microangiopathy and cortical necrosis and ADAMTS13 was 57 %. Flow cytometry showed CD5+ CD23+ CD20+ and FMC7+ consistent with low grade lymphoproliferative disorder [LPD]. Other significant laboratory studies included a serum protein electrophoresis with an M spike in gamma region. Immunofixation (IF) showed a monoclonal IgG Kappa with serum free light chains with high K/L ratio and low C3 and C4. On hospital day seven he developed a diffuse painful macularpapular rash involving sparing his back and intertriginous areas and oral mucosa with areas of necrosis. CG was positive (CG-3 % and IF shows Type-I cryoglobulinemia) and skin biopsy revealed findings were consistent with cryoglobulinemia. He was started on high dose IV steroids and plasmapheresis. Bone-marrow biopsy was significant for 20 % small lymphocytes and <5 % plasma cells c/w LPD. He was treated with 4 doses of rituximab with clinical resolution of symptoms.

DISCUSSION: We report an unusual case of a patient with Type I CG and Parvovirus infection with overlapping clinical and laboratory features. Immune-mediated autoimmune hemolytic anemia, thrombocytopenia and neutropenia of the IgG type as well as CG have been reported to occur in both of these conditions. In patients with PB-19 infection autoimmune antibodies may be induced due to the presence of proinflammatory cytokines or shared antigenic epitopes between viral and host cells. Type I GC is typically found in patients with lymphoproliferative disorders or multiple myeloma while Type II is typically associated with viral infections and autoimmune disorders. Patients with type I CG, as found in our patient, may rarely develop renal disease as a result of thrombotic disease. We speculate that immune stimulation and lymphoproliferation due to the Parvoviruses infection may have accounted for the pathogenic CG response.

THE CHICKEN OR THE EGG: PARVOVIRUS B19 OR ANTIPHOSPHOLIPID ANTIBODY? Kartika Reddy; Samina Sarwar; Erin Sullivan. Lenox HIll Hospital- NSLIJ, New York, NY. (Tracking ID #1624071)

LEARNING OBJECTIVE 1: To understand a common presentation of Parvovirus B19 and an uncommon association with the presentation

CASE: A 44 year-old woman with a history of three previous spontaneous abortions presented with a 3 day history of headache, neck stiffness and cervical lymphadenopathy. She developed a macular rash that involved all extremities and spread centrally. She denied fevers or recent travel. She has had three healthy children with uncomplicated pregnancies. The patient reports she had close contact with a child infected with mononucleosis and an adult with influenza 2 days prior to onset of symptoms. The patient had left posterior cervical lymphadenopathy, a confluent macular rash on her extremities and torso. Laboratory studies revealed WBC 3,200 mm3 and a platelet count 141,000 mm3. Rapid HIV testing was negative. A lumbar puncture revealed no leucocytes and gram stain was negative. The patient was discharged home but returned 2 days later with new symmetric joint pain that was tender to palpation in her knees, ankles, wrists, interphalangeal joints. No joint swelling or gross joint abnormalities were noted. Monospot, rheumatoid factor and EBV IgM were all negative. EBV IgG was positive. Double-stranded DNA, ANA, throat culture and ASO were negative. A blood smear was unrevealing. All symptoms resolved in 48 h and the patient was discharged home. Post-discharge parvovirus B19 IgM and IgG came back positive. IgM was positive with a value of 6.4 (<0.9). Her phospholipid Ab IgM was positive with a level of 100 MPL (negative <10) and her phospholipid Ab IgG was elevated at 17 GPL (negative <10).

DISCUSSION: General internists encounter patients with flu-like symptoms on a daily basis. Parvovirus B19 is a single-stranded DNA virus that can cause a wide spectrum of manifestations, including fifth disease, arthropothy, transient aplastic crisis, anemia, spontaneous abortions and hydrops fetalis in pregnant women. Parvovirus has been known to mimic or trigger autoimmune diseases. The development of antiphospholipid antibodies can be transiently increased with Parvovirus B19 infection. However, in the majority of cases, no thrombotic episodes have been reported. Thus none of the patients were reported of having clinical manifestations of antiphospholipid syndrome. Our patient had an atypical presentation of three healthy pregnancies coupled with subsequent spontaneous abortions. The acute parvovirus infection warranted further investigation revealing the underlying antiphospholipid syndrome.

THE DIAGNOSIS IN RED Angela Beckert. University of Chicago, Chicago, IL. (Tracking ID #1643153)

LEARNING OBJECTIVE 1: Describe the multiple manifestations of systemic amyloidosis and the difficulties in diagnosis.
CASE: Fifty-seven year old man presents with complaint of nausea, vomiting, weight loss, leg numbness, and dizziness/syncope for 1 year. Patient reports extensive medical work up without unifying diagnosis before being referred to tertiary care center. Soon after initial clinic visit, patient admitted to hospital for treatment of preserved EF heart failure. During hospitalization patient stabilized and work up yielded diagnoses of gastroparesis, orthostatic hypotension secondary to autonomic dysfunction, and peripheral neuropathy. Outpatient differential diagnosis focused on causes of autonomic and peripheral nervous system dysfunction. Patient had an extensive malignancy work up, MRI spine, paraneoplastic panel, heavy metal levels, HIV test, A1C, and rheumatologic work up that was unremarkable. In the following months, patient developed chronic diarrhea. Patient underwent a repeat CT abdomen and pelvis revealing significant colitis. Repeat colonoscopy was performed and biopsies revealed amyloidosis.
DISCUSSION: Amyloidosis involves the extracellular deposition of insoluble proteins with a beta-fibrillar structure. Symptoms are dependent on organ involvement with AL (primary) amyloid most commonly affecting the kidney and heart. Our patient had evidence of cardiac, GI, and nervous system involvement. Classification is based on type of precursor protein and includes AL (primary) amyloidosis composed of monoclonal immunoglobulin light chains, AA (secondary) amyloidosis, a response to chronic inflammatory process, ATTR (familial) amyloidosis, other heritable causes, senile amyloidosis, and dialysis induced amyloidosis. Primary amyloidosis accounts for the majority of cases. Prognosis is poor (avg 13.2 mo), likely related to delay in diagnosis. Diagnosis requires biopsy proven disease. Biopsies are typically done on affected organ or surrogate site such as abdominal fat pad. In our patient, three colonic biopsies were performed before diagnosis, though retrospectively a prior biopsy also revealed amyloidosis. Pathologically it is not always apparent with H&E stain and requires clinical guidance and suspicion. After tissue diagnosis, must focus on elucidating type of amyloid. First evaluate for plasma cell dyscrasia. SPEP/UPEP with immunofixation detects 90 % of monoclonal immunoglobulins or light chains. Serum free light chain analysis can increase sensitivity, and bone marrow biopsy with immunohistochemical staining may also reveal predominance of clonal plasma cells. If no evidence of plasma cell dyscrasia, genetic analysis can be performed to look for hereditary causes. In our patient, no monoclonal spike was identified though lambda light chain was elevated. Bone marrow biopsy revealed plasma cell dyscrasia. Patient underwent once cycle of bortezomib and cyclophosphamide, but passed in his sleep shortly after treatment.

THE DIFFICULTY IN DIFFERENTIATING INFECTIVE ENDOCARDITIS (IE) FROM NONBACTERIAL THROMBOTIC ENDOCARDITIS (NBTE) Ryoji Ito; Takashi Watari; Joel Branch; Izumi Kitagawa. Shonan Kamakura General Hospital, Kamakura, Japan. (Tracking ID #1636250)

LEARNING OBJECTIVE 1: Both IE and NBTE show similar physical examination findings, and echocardiography features. However, it is imperative to diagnose IE from NBTE, because the therapy of these diseases is different. In the case of IE, treatment consists of antibiotics or if severe, replacement of cardiac valves. Conversely, in cases of NBTE, identification of an underlying non-infectious cause, for example malignancy, is undertaken and treatment is by surgery, chemotherapy and anticoagulation. Such treatment for NBTE can be dangerous in IE, because chemotherapy results in immunosuppression and worsening of infection and anticoagulation may lead to dissemination of an infectious vegetation.
CASE: An otherwise fit and healthy 35-year-old woman had been undergoing fertility treatment with in vitro fertilization and hormone replacement for the preceding 2 years. One week prior to admission, she was diagnosed with a missed abortion. This was followed several days later with pain felt in her finger tips. The next day, she underwent outpatient dilatation and curettage and she was prescribed oral fosfomycin post-procedure antibiotics. On the day of admission, she developed right lower quadrant pain and she consequently visited this hospital. Blood pressure was 117/51 mmHg, heart rate was 51 beats per minute and temperature was 98.06 °F (36.7 °C). Physical examination revealed a systolic murmur at the second left sternal border radiating to the apex position in addition to splinter hemorrhages in the nail beds. Leukocyte count was 13,800/μl, D-Dimer was 17.0 μg/ml and autoimmune examinations were negative. Abdominal ultrasound scan revealed ascites and an ovarian cystoma. Brain magnetic resonance imaging (MRI) showed an asymptomatic right frontal lobe infarct. Abdominal computed tomography (CT) scanning demonstrated infarctions of the kidneys and spleen in addition to a pelvic tumor. Transthoracic echocardiography demonstrated a vegetation on the aortic valve. In view of these clinical features, infective endocarditis (IE) was highly suspected, and antimicrobial therapy was commenced with ceftriaxone, vancomycin and gentamicin. Three weeks after admission, the vegetation was visualised oscillating on the aortic valve and it had enlarged from 11×9 mm to 15×7 mm. As a result, emergent aortic valve replacement was performed successfully. Almost 2 months after admission, surgical removal of an ovary carcinoma was performed. Several days later, a repeat transthoracic echocardiogram revealed a vegetation on the mitral valve. Because of the lack of response to antimicrobial agents, negative blood cultures, the presence of a carcinoma and valve histology showing non-destructive changes with adherent thrombus, we considered the diagnosis of NBTE and the patient was subsequently anticoagulated. Despite this, she developed multiple new cerebral infarcts and,the patient eventually succumbed to multiple organ failure.
DISCUSSION: IE is more common than NBTE and clinical features are similar. The lack of risk factors for IE, negative blood cultures and the presence of a carcinoma increased the likelihood of NBTE. Treatment of NBTE is different and potentially dangerous in IE. Physicians should have a strong clinical suspicion of NBTE when there is inadequate response to therapy for IE

THE FORGOTTEN DISEASE: A CASE OF LEMIERRE'S SYNDROME Leena Jalota; Shobhit Gupta; Naba R. Mainali; Richard Alweis. Reading Health System, West Reading, PA. (Tracking ID #1635047)

LEARNING OBJECTIVE 1: Identify patients who should be considered for the diagnosis of Lemierres syndrome
LEARNING OBJECTIVE 2: Be familiar with the classic presentation, pathophysiology, complications and treatment strategy of Lemierres syndrome.
CASE: A 17-year-old previously healthy female presented to her pediatrician with cough and sore throat. She was initially diagnosed with infectious mononucleosis and treated with steroids for 3 days. Her condition did not improve and she presented to the emergency room with severe shortness of breath, left shoulder and chest pain. Examination at this time was significant for tonsillar enlargement, oropharyngeal erythema and enlarged anterior cervical lymph nodes. She was transferred to the intensive care unit for progressive respiratory distress requiring BIPAP support. Laboratory tests were significant for thrombocytopenia of 44,000/μL, a leukocytosis of 24,000/μL and a lactic acidosis of 3 mmol/L. A CT scan of the chest revealed multifocal consolidation and multiple nodules consistent with an atypical infection. A CT scan of the neck was ordered to rule out epiglottitis but instead revealed a clot within the left internal jugular vein. On day four of admission, blood cultures grew Fusobacterium necrophorum. With a constellation of symptoms including mononucleosis, internal jugular vein clot, septic pulmonary emboli and cultures consistent with Fusobacterium, a diagnosis of Lemierre's syndrome was made. She was subsequently started on ampicillin-sulbactum for a total duration of 4 weeks. Prior to discharge on day 19, her symptoms improved considerably and a follow up CT scan of the chest and neck showed significant decrease in size of consolidative changes and no progression of the prior noted internal jugular vein thrombus.

DISCUSSION: Lemierre's syndrome was once called the forgotten disease because of its rarity but increasing antibiotic resistance patterns worldwide has led to a resurgence in number of cases reported. Despite the classic pattern of sore throat, internal jugular vein thrombosis, and isolation of anerobic organisms, many cases go undiagnosed. This syndrome carries an overall mortality rate of 5 %, so prompt recognition is crucial to prevent fatal outcome. The syndrome typically manifests in healthy teenagers and young adults and spreads via a septic thrombophlebitis of the tonsillar vein and internal jugular vein. The ensuing bacteremia is complicated by septic emboli to a range of sites such as lung, joints, and bones. Although rare, there is evidence of resurgence in the condition in recent years, postulated to be due to reduced use of antibiotic therapy for sore throats and increased resistance patterns of antibiotics worldwide. Lemierre's syndrome should be suspected in the setting of antecedent pharyngitis, septic pulmonary emboli, and persistent fever despite antimicrobial therapy. Treatment consists of beta lactamase resistant beta lactam antibiotics for 4 to 6 weeks. The decision to anticoagulate is subjective as data on this issue is still controversial. Early recognition of this syndrome is essential to prevent associated morbidity and mortality and to keep a once forgotten disease at bay.

THE GREAT IMITATOR STRIKES AGAIN Joshua K. Sabari; Anna Platovsky; Matthew Shaines. Montefiore Medical Center, Bronx, NY. (Tracking ID #1631361)

LEARNING OBJECTIVE 1: Recognize the signs, symptoms, and pathophysiology of gastrointestinal sarcoidosis.
LEARNING OBJECTIVE 2: Understand testing characteristics of CA-19.9
CASE: A 53 year-old woman presented with abdominal pain and 30 pound weight loss over 3 months. Pain was dull, epigastric, with associated nausea and vomiting worse with oral intake. Cancer screening was up to date. An outpatient workup included an endoscopy, which showed mild atrophic gastritis, and a benign colonoscopy. She denied fever, dyspnea, cough, and chest pain. Vital signs were within normal limits, she appeared comfortable, and had mild diffuse epigastric tenderness. Labs revealed a hemoglobin of 10.5 G/dL, platelet count 440 K/uL, corrected calcium of 11.5 mg/dL, direct bilirubin 1.2 mg/dL, SGOT 78 U/L, SGPT 59 U/L, and alkaline phosphate of 546 U/L. Computed tomography revealed multiple bilateral pulmonary nodules, and innumerable small hypodense lesions measuring 1 cm scattered throughout the liver, pancreas, and spleen. Differential diagnosis at the time included metastatic disease, primary pancreatic malignancy, lymphoma, or inflammatory process such as sarcoidosis. Due to concern for malignancy, tumor markers were ordered and CA-19.9 was elevated at 357 U/mL (normal <35 U/mL). Ultrasound guided liver biopsy was performed. Pathology showed non-necrotizing granulomas, negative for AFB, consistent with a diagnosis of gastrointestinal sarcoidosis.
DISCUSSION: Sarcoidosis is a multi-system granulomatous disorder of unknown etiology, with the pathologic hallmark of non-caseating granulomas. The prevalence is 20 per 100,000 people per year. It is thought to arise from an exaggerated cellular immune response to self-antigens and subsequent accumulation of mononuclear inflammatory cells. Sacroid is a systemic disorder involving multiple organ systems. Ninety percent of patients have pulmonary involvement and present with cough, dyspnea, and classically have bilateral hilar adenopathy on chest xray. Common extrapulmonary manifestations include skin (erythema nodosum), eye (uveitis), and joint involvement. Gastrointestinal (GI) manifestations of sarcoid are rare and occur in only 0.5 % of patients. When there is GI involvement, the stomach is the most commonly involved organ; patients present with epigastric pain, vomiting, and weight loss. Hepatic involvement is less common and usually asymptomatic, with differing case series reporting 20–95 % incidence. Pancreatic involvement is rare and is often misidentified as pancreatic malignancy. Sarcoid, known as the "Great Imitator," is often initially misidentified as malignancy and tumor markers ordered during the initial workup are frequently falsely elevated. CA19.9, a tumor marker elevated in GI cancers (pancreatic, hepatobillary, gastric), is thought to be elevated in our patient due to chronic inflammation. CA19.9 has low sensitivity (80), specificity (85) and positive predictive value (72), and guidelines recommend against its use for cancer screening. Pancreatic sarcoidosis carries a good prognosis, with greater than 80 % improvement in symptoms either spontaneously or with steroids, compared to the dismal prognosis of pancreatic cancer which carries a 1 year survival rate of 15–20 %. This case of GI sarcoid, initially thought to be pancreatic cancer based on an elevated CA19.9 value, demonstrates that one should use caution in ordering tumor markers prior to having a tissue diagnosis.

THE MALIGNANT TRUTH ABOUT HYPERCALCEMIA
Vikas Khullar; Ankur Jain; Margaret C. Lo. University of Florida-Shands Hospital, Gainesville, FL. (Tracking ID #1614828)

LEARNING OBJECTIVE 1: Assess the role of PTHrp, skeletal scintigraphy, and targeted CT-scans in the diagnostic evaluation of hypercalcemia of malignancy, especially from cutaneous squamous cell carcinoma (cSCC).
LEARNING OBJECTIVE 2: Recognize the risk factors and poor prognostic factors associated with hypercalcemia of malignancy in the setting of chronic nonhealing skin ulcers.
CASE: A 52 year-old Black female presented with 2 days of confusion, abdominal pain, anorexia, and dehydration, after recent discharge for hypercalcemia (14.2 mg/dL) secondary to severe dehydration. At that admission, patient had a nondiagnostic hypercalcemia workup including normal PTHrp, intact PTH, SPEP/UPEP, Vitamin D 25-OH levels. Medical history included steroid-dependent Crohn's disease and chronic Stage IV sacral decubitus ulcer complicated with cSCC and osteomyelitis s/p sacrectomy and wide local excision with negative margins. Physical exam exhibited a cachectic, confused female with dry mucosa, skin tenting, diffuse abdominal tenderness but clean sacral ulcer. Lab values revealed severe hypercalcemia (17 mg/dL), mild anemia, thrombocytosis, and hypoalbuminemia. Repeat hypercalcemia workup demonstrated normal values of PTHrp, intact PTH, and Vitamin D 1,25-OH. Head CT, 2 V-CXR, and KUB were nondiagnostic. Occult malignancy was suspected, despite normal PTHrp values. A skeletal scintigraphy was negative for bony metastases, showing only specific uptake in the upper sacrum, consistent with destructive changes from chronic sacral ulcer as seen on abdominal/pelvis CT-scans 6 months ago. However, repeat full-body CT-scan revealed T4 vertebral lytic lesions, necrotic left inguinal lymphadenopathy, and metastases to the pelvis, liver, and lungs. Brain MRI showed metastases to the skull marrow space but no masses. Inguinal lymph node cytopathology confirmed the diagnosis of metastatic, moderately-differentiated cSCC. Patient responded to IV fluids, calcitonin, and zolendronate. Given poor prognosis from diffuse metastases and malnutrition, she was discharged under hospice care.
DISCUSSION: This case illustrates cSCC's obscure potential to induce hypercalcemia via bony metastases, independent of well-known PTHrp mediation. Literature cites cases of PTH-independent hypercalcemia of cSCC correlating with the susceptibility to develop metastases. The metastatic potential of cSCC arising from chronic skin ulcers (30 %) is greater than that of cSCC arising in normal skin (3 %). These rare malignant Marjolin skin ulcers develop into aggressive cSCC with higher mortality than other skin cancers. Other poor prognostic factors of hypercalcemia of malignancy include presence of liver metastases, hypoalbuminemia, and calcium >11.83 mg/dL, all present in our patient. Skeletal scintigraphy is the preferred initial imaging modality for detection of bony metastases in cancer-induced hypercalcemia; yet its diagnostic value is poor for lytic metastases (sensitivity 62–100 %, specificity 78–100 %). Experts recommend targeted CT-scans or PET/CT-scans to detect both lytic and blastic bony metastases in high risk cases. Clinicians must vigilantly assess the diagnostic dilemma from normal PTHrp and skeletal scintigraphy before excluding hypercalcemia from cSCC, especially in Marjolin skin ulcers, malnutrition, and severe hypercalcemia. Recognition of such risk factors and the need for CT imaging to detect bony metastases in cSCC-induced hypercalcemia will prevent extensive testing and patient morbidity of this aggressive disease.

THE METASTATIC HIATAL HERNIA SAC: AN UNUSUAL PRESENTATION OF RECURRENT OVARIAN CANCER Raji Shameem; Solaiman Futuri; Stephen Machnicki; Dana Shani. Lenox Hill Hospital, New York, NY. (Tracking ID #1624117)

LEARNING OBJECTIVE 1: Recognize that recurrent ovarian cancer can present with metastasis to a hiatal hernia sac.
LEARNING OBJECTIVE 2: Recognize imaging modalities that can be used to diagnose hiatal hernia sac metastasis.
CASE: An 87-year-old female presented to the clinic with non-specific symptoms of lower abdominal and back pain. Past medical history included Stage II ovarian cancer diagnosed 3 years ago and treated with systemic chemotherapy. The patient had a positive family history of a sister diagnosed with breast cancer at the age of 40. The lower abdominal and back pain had an insidious onset. The patient denied any symptoms of general malaise or weight loss. Examination, including pelvic exam was grossly unremarkable. Given the patients compelling malignancy history computerized tomography of the abdomen was performed which revealed masses within a hiatal hernia. For further evaluation, an endoscopic ultrasound was performed to obtain a sample of the hernia sac contents for biopsy. Hernia sac biopsy pathology results were consistent with ovarian cystadenocarcinoma.
DISCUSSION: Ovarian carcinoma still remains to be a prevalent malignancy with severe morbidity and mortality. In the United States it is a common gynecological malignancy and the number one cause of death in women with gynecological malignancies. The patient risk factors for ovarian cancer included breast cancer in a first-degree relative and late menopause. Other risk factors for ovarian cancer are nulliparity, early menarche, polycystic ovarian disease, and history of ovarian cancer in a first-degree relative. When ovarian cancer metastasizes it has a predilection to spread to the nearby peritoneum. However, no previous case reports have described the metastasis of ovarian cancer to a hiatal hernia sac. This unusual presentation was clearly visible on imaging and confirmed with biopsy results. In addition, there is no literature that comments on the prognosis for patients with such a unique presentation.

THE SISTER MARY JOSEPH NODULE AS PRESENTATION OF ADVANCED MALIGNANT PERITONEAL MESOTHELIOMA Christopher Sankey[2,3]; Ke Zhang[1]. [1]Yale School of Medicine, New Haven, CT; [2]Yale School of Medicine, New Haven, CT; [3]Yale-New Haven Hospital, New Haven, CT. (Tracking ID #1637233)

LEARNING OBJECTIVE 1: Understand the significance of the Sister Mary Joseph nodule in the diagnosis of new abdominal malignancy.
LEARNING OBJECTIVE 2: Explore the typical malignancies associated with Sister Mary Joseph nodules.
CASE: A 63-year-old Puerto Rican male with history of benign prostatic hyperplasia, HTN, and chronic kidney disease presented with sudden onset of difficulty urinating and high blood pressure. On the day of presentation, the patient noticed difficulty urinating associated with penile swelling and discomfort. His left leg is chronically swollen, but was noted to have increased in size in the 2–3 days prior to admission. Upon admission, the patient was afebrile and hypertensive. On exam, patient was noted to have an "irreducible umbilical hernia," firm and nodular, measuring 4.3 cm. Labs were most notable for a creatinine of 5.9, far above his baseline. Retroperitoneal ultrasound demonstrated severe hydronephrosis. Abdominal CT revealed a 10 cm mass posterior to the bladder, a 5 cm mass in the inguinal canal, a 5.2 cm mass inferior to the right hepatic lobe, and a 3.3 cm mass in the retroperitoneum. Biopsy of the umbilical nodule was consistent with malignant peritoneal mesothelioma (MPM). Chemotherapy was initiated, but the patient ultimately elected to pursue further treatments near family in Puerto Rico, and was discharged from our care.
DISCUSSION: The umbilical lesion with which the patient presented was a so-called Sister Mary Joseph (SMJ) nodule, indicative of underlying abdominal malignancy. Named for Sister Mary Joseph, the first assistant for Dr. William Mayo at the Mayo Clinic in the early 1900's, these umbilical nodules were often noted to be associated with advanced abdominal malignancies. Primary malignant nodules in the umbilical area are extremely rare. SMJ nodules are generally metastatic and are seen in 1–3 % of all intra-abdominal and pelvic malignancies; they are the first and only sign of an underlying neoplasm in up to 30 % of cases. The site of origin of malignancy remains unknown in over 30 % of cases as well. SMJ nodules are mainly adenocarcinomas, with half of the cases stemming from GI cancers such as the stomach, colon, or pancreas. An umbilical nodule from metastatic mesothelioma is exceedingly rare, and to our knowledge there are only two case reports of a primary localized malignant mesothelioma in the umbilical area. Approximately 10 % of mesotheliomas are found in the abdomen, but rarely do they involve the umbilicus. In the United States, only about 400 cases are diagnosed annually. We were not able to determine whether the umbilical nodule in our patient was the primary source, as further biopsies of his other abdominal tumors were deferred. The Sister Mary Joseph nodule is important to recognize as heralding previously undiagnosed advanced abdominal malignancy.

THE STRAW THAT BROKE THE ONCOGENIC BACK-OCCURRENCE OF LARGE B CELL LYMPHOMA AFTER HEPATITIS C TREATMENT Niket Sonpal; Raji Shameem; Ilan Weisberg. Lenox Hill Hospital, Hauppauge, NY. (Tracking ID #1624318)

LEARNING OBJECTIVE 1: Indolent lymphoma can potentially be unmasked at the onset of Hepatitis C treatment.
LEARNING OBJECTIVE 2: Clinicians need to be aware of the important association between HCV infection and NHL and this potential complication of antiviral therapy
CASE: The risk of hepatocellular carcinoma with chronic hepatitis C virus (HCV) infection is well recognized while the association between HCV and B-cell non-Hodgkin's lymphoma (NHL) is under appreciated. Lymphoma is thought to arise from chronic B-cell stimulation resulting in malignant monoclonal proliferation. Case series suggest that treatment of HCV infection may lead to regression of lymphoma in select patients. However, there is also a concern for the development of malignancy as a secondary outcome to interferon therapy. We present a patient who developed large B-Cell lymphoma shortly after initiation of HCV treatment. A 60 year-old man with treatment naïve, genotype 1b chronic HCV infection (baseline viral load 7.7 million IU) was referred to our institution for treatment. He contracted the virus in 1969 after blood transfusion for a bleeding duodenal ulcer. There were no radiographic or clinical signs of cirrhosis, portal hypertension, or decompensation. He had no lymphadenopathy on physical exam. After a 4 week lead-in with pegylated interferon alpha and ribavirin, boceprevir was added. He was interferon responsive, evidenced by a 4-log decline in viral load at treatment week 4. Shortly thereafter, he developed a sore throat and painless swelling in the left neck. On exam, a palpable 3 cm lymph node was identified. CT of the neck showed a level 2A lymph node measuring 3.6 cm with associated tracheal deviation and a smaller level 2B lymph node measuring 1.5 cm. The patient underwent ultrasound guided FNA biopsy, which confirmed a diffuse large B cell lymphoma. Due to the rapid presentation, all HCV therapy was discontinued and he was started on R-CHOP (rituximab-cyclophosphamide, doxorubicin, vincristine, and prednisone). Treatment was complicated by mild transaminitis but led to complete regression of his lymphoma. Reattempt at HCV treatment is planned.
DISCUSSION: While antiviral therapy may lead to regression of lymphoma in some patients with chronic HCV infection, the immunostimulating properties of interferon seem to have unmasked an occult lymphoma in our patient. Clinicians need to be aware of the important association between HCV infection and NHL and this potential complication of antiviral therapy.

THE GREAT RADICULAR ARTERY OF ADAMKIEWICZ Eunice Y. Chuang; Indumathy Varadarajan. Mount Auburn Hospital, Cambridge, MA. (Tracking ID #1642384)

LEARNING OBJECTIVE 1: To recognize the presentation of anterior spinal cord infarction.
LEARNING OBJECTIVE 2: To recognize the distribution of the arterial supply of the spinal cord and to clinically correlate the neurological deficit in the presence of an anterior spinal cord infarct.
CASE: 94-year-old female with hypertension, hyperlipidemia and coronary artery disease developed sudden onset of 10/10 belt like pain across

her chest and abdomen when bending forward. It lasted 15 min and was associated with nausea. This was followed by persistent weakness in her legs, hence presented to the ED. Vital signs were stable; physical examination revealed marked bilateral lower limb weakness, more so in the left leg with a power of 3/5, reflexes 1+ at the patellar tendons, Achilles reflexes were absent bilaterally, Babinski sign was present on the left side; temperature and pinprick sensation was lost bilaterally from the T4 level. Rectal sensation was preserved but the tone was decreased. CT chest/abdomen was negative for dissection, but showed a new burst fracture of the T10 vertebra with 5 mm retropulsion of a portion of the posterior vertebral body into the spinal canal. She was started on dexamethasone, advised bed rest and a foley was placed. MRI of the upper thoracic and cervical spine confirmed compression fracture of T10 with retropulsed fragment in the canal but no cord deformity or compression. However there were diffusion changes in anterior spinal cord from T2-T7 more to the left consistent with spinal cord infarct despite the absence of any compressive lesions. Steroids were discontinued. She got a brace for potentially unstable T10 fracture. Patient was discharged to rehab with some improvement of her weakness.

DISCUSSION: A single anterior and 2 posterior spinal arteries supply the spinal cord. The anterior spinal artery (ASA) supplies the anterior 2/3 of the cord. The posterior spinal arteries (PSA) primarily supply the dorsal columns. The ASA and PSA arise from the vertebral arteries in the neck and descend from the base of the skull. Various radicular arteries branch off the thoracic and abdominal aorta to provide additional blood supply to the spinal arteries. The largest and most consistently present of these radicular branches is the artery of Adamkiewicz, which supplies the ASA. This artery enters the spinal cord anywhere between T5 and L1. The PSAs are supported by a greater number of radicular arteries than the ASA, therefore the anterior spinal cord is more vulnerable to infarction in the lower thoracic region. Spinal cord infarction is a relatively rare disorder and account for 1 % of all strokes. It is characterized by sudden motor and sensory loss below the level of the spinal-cord injury. In our case, the T10 burst fracture likely compressed the artery of Adamkiewicz leading to the patient's symptoms. We have described a classical case of thoracic anterior spinal cord infarction, with upper motor neuron lesion signs including paraparesis, extensor plantar response, incontinence and loss of spinothalamic sensation with preservation of dorsal column sensation. Acute pain of spinal belt-like or radicular irradiating character typically precedes or accompanies the presentation of neurological deficit. The di¬agnosis of spinal-cord infarction depends on clinical symp¬toms and MRI findings. Treatment and prognosis depend on the level and extend of the infarction, which includes physiotherapy and psychological counseling.

THE PATH OF LEAST RESISTANCE: A LESSON IN KEEPING A BROAD DIFFERENTIAL Gretchen Snoeyenbos; Robin Klein. Emory University School of Medicine, Atlanta, GA. (Tracking ID #1641832)

LEARNING OBJECTIVE 1: Appreciate the growing incidence of HIV infection in older patients and understand the interplay of age and other confounding factors on the decision to include older patients in HIV testing at all levels of health care.

LEARNING OBJECTIVE 2: Review the broad-based HIV testing recommendations for patients 13 to 64 in all health care settings.

CASE: A 62 year old African American male with a 50+ pack year smoking history presents with progressive dyspnea, cough and cachexia. On admission, he was not hypoxic or tachypneic. Exam revealed was cachexia and glossitis. Laboratories studies revealed a sodium of 126 mEq/L and osmolarity of 254 mOsm/L. CT imaging of the chest revealed mild septal thickening. He was treated for presumptive COPD. Unfortunately, his symptoms worsened. He was no longer able to work due to dyspnea. Three months later, he came to the ED with dyspnea, productive cough, and weight loss. Chest X-Ray showed no focal infiltrate. His room air saturation was 91 %. At that visit, he was diagnosed with bronchitis, given nebulizer treatments, prescribed a course of azithromycin, and instructed to follow up in primary care. His cough worsened and his dyspnea progressed until present at rest. One week later, he returned to the hospital. He was hypoxic and tachypneic. Exam revealed marked cachexia as he has lost 30lbs. His PaO2 was 37 mmHg and A-a gradient was over 80 mmHg. CT imaging showed bilateral reticular ground glass opacities concerning for Pneumocystis pneumonia. Laboratories revealed a positive HIV test with a CD4+ count of 33.

DISCUSSION: A growing number of older people now have HIV. Those over 50 represent a quarter of all people with HIV in the US. Most commonly diagnosed in younger patients, 1,983 cases were diagnoses in patients 60 years and older in 2010. Many are unaware of their diagnosis due to a general underappreciation of HIV rates in older patients. Since 2006, the Center for Disease Control has recommended broad-based HIV testing for patients 13 to 64 in all health care settings. Efforts were made to reduce requirements for separate consent procedures and pretest counseling to facilitate testing at all levels of health care even the acute care setting. Some argue that a broad testing strategy could facilitate earlier diagnosis, expedite treatment, and reduce opportunistic infections. Rapid HIV tests are available with comparable sensitivity, specificity, and negative predictive value for screening at the HIV prevalence observed in most US testing sites. Our patient accessed health care environments on three separate occasions prior to being tested for HIV. An HIV test was performed at initial presentation would have facilitated earlier diagnosis of his underlying opportunistic infection. In retrospect, our patient displayed may of the typical signs and symptoms of pneumocystis including progressive dyspnea, weight loss, hypoxia, and bilateral ground glass opacities. His symptoms were attributed to different etiologies on different occasions. This case highlights the importance of thinking comprehensively about a patient's symptoms and the importance of a broad-based HIV testing strategy. Physicians need to recognize that new HIV diagnoses do occur in older patients and that age should not preclude these patients from inclusion in HIV testing at all levels of health care.

THE TRIAD: DIABETIC KETOACIDOSIS, SEVERE HYPERTRIGLYCERIDEMIA AND ACUTE PANCREATITIS Eunice Y. Chuang; Indumathy Varadarajan. Mount Auburn Hospital, Cambridge, MA. (Tracking ID #1642607)

LEARNING OBJECTIVE 1: To recognize the association between Diabetic ketoacidosis (DKA), severe hypertriglyceridemia (HTG) and acute pancreatitis (AP)

LEARNING OBJECTIVE 2: To manage AP in the setting of DKA and severe HTG.

CASE: A 48-year-old man with no significant past medical history presented with lethargy, nausea and abdominal pain for 2 weeks. He reported a 14 pound weight loss, polyuria, and polydipsia for 1 month. No fever, diarrhea or alcohol consumption. No family history of hyperlipidemia or diabetes type 2; but his brother has diabetes type 1. On physical exam, temperature 99.7 F, heart rate 100/min, BP 130/70 mmHg and oxygen saturation was 95 % on room air, BMI of 26; there were no skin discoloration or xanthomas. Laboratory data showed sodium 130 mmol/L, potassium 4.0 mmol/L, chloride 92 mmol/L, bicarbonate 16.0 mmol/L, anion gap 22.0, glucose 511 mg/dL, HbA1C 15 %, BUN 10, creatinine 0.8 mg/dL, triglycerides 5,940 mg/dL, hematocrit 38 %, WBC 8.29, platelets 225, lipase 12,064 U/L, Albumin 3.8 g/dL, total Bilirubin 1.1 mg/dL, Alkaline Phosphatase 171 U/L, ALT 19 U/L, AST 20 U/L. Urinalysis showed 3+ glucose, 2+ ketones. Abdominal ultrasound showed enlarged pancreas with ill defined areas of hypoechogenicity, likely secondary to pancreatitis, increased liver echogenicity consistent with hepatic steatosis. He was started on an insulin drip with IV fluids and admitted to ICU. After 24 h, Triglycerides was 969 mg/dL and anion gap was closed. The patient was started on gemfibrozil therapy for hpertriglyceridemia and transitioned to Insulin glargine and lispro. GAD 65 antibodies and islet cell antibodies were negative. Patient was discharged home on gemfibrozil and insulin.

DISCUSSION: The combination of severe HTG, DKA and AP is rare. It is not clear which entity is causative in this triad. One hypothesis is that in DKA, the deficiency of insulin activates lipolysis in adipose tissue releasing increased free fatty acid (FFA), which accelerates formation of VLDL in the liver. In addition, reduced activity of lipoprotein lipase (LPL) in peripheral tissue decreases removal of VLDL from the plasma, resulting in HTG. HTG is an

uncommon cause of acute pancreatitis accounting for 1–4 % of cases, especially when the serum TG level exceeds 1,000 mg/dL. Severe HTG can occur in deficiency of LPL in genetic disorders; or relative LPL deficiency in diabetes, hypothyroidism and medications. Treatment of pancreatitis with HTG and DKA include limiting fat intake and rapid removal of chylomicrons and TG. In the present case, HTG was controlled with insulin without lipid lowering agents. However, in severe hypertriglyceridemia not responding to insulin, the application of plasma exchange should be considered to avoid complications, such as necrotizing pancreatitis. IV heparin is a proposed treatment which is still controversial.

THE USUAL SUSPECT … DOG, OR IS HUMAN THE CULPRIT? CAPNOCYTOPHAGA ENDOCARDITIS IN A NEWLY DIAGNOSED CASE OF MULTIPLE MYELOMA Navid Mehraban; Michael Sheffield; Zakir Shaikh. Methodist Dallas Medical center, Dallas, TX. (Tracking ID #1624635)

LEARNING OBJECTIVE 1: Capnocytophaga, a facultative anaerobic gram-negative bacilli, is often times a normal inhabitant of the human mouth. It can present as an opportunistic infection in immunocompromised patients. Capnocytophaga canimorsus species is found in normal oral flora of dogs and cats and can be transmitted to humans by close contact (bite, scratch, etc.). It is a rare infection that can affect cancer patients particularly those with hematologic malignancies. Other reported risk factors include alcoholism and asplenia. We report a patient with pathologic fracture of the femur due to multiple myeloma who was diagnosed with Capnocytophaga endocarditis during her initial presentation

CASE: A 53 year old African-American female with a past medical history of bipolar disorder and hypertension was admitted to our critical care unit for altered mental status and a pathologic fracture of her left femur sustained after a fall. She was found to have severe hypercalcemia, and acute kidney injury,. and was diagnosed with multiple myeloma. She received aggressive fluid resuscitation, pamidronate, and calcitonin. Upon hospitalization, she was noted to be afebrile, with poor dentition, and normal white blood cell count. However, 1 day into her admission she developed a fever of 38.5 C. Blood cultures were sent and empiric Ceftriaxone was initiated. After 3 days her blood cultures grew Capnocytophaga species. Transesophageal echocardiogram done to evaluate a new murmur identified vegetation on her tricuspid valve. At that time, upon further questioning, she admitted to having close contact with her dogs and being exposed to their saliva. The patient successfully underwent right femur stabilization and was started on chemotherapy. She was treated with ceftriaxone for a total of 42 days and her repeat blood cultures remained negative.

DISCUSSION: Capnocytophaga is a fastidious bacterium that is found in dog saliva and can be transmitted to humans via contact with dogs. This genus can cause severe systemic infection, including sepsis, septic arthritis, meningitis, and endocarditis. Capnocytophaga species can be difficult to diagnose due to its slow-growing nature and need for special culture media. There are limited literature reports of this organism as a cause for endocarditis. Sandoe et al. described 12 cases of endocarditis with C. canimorsus reported between 1977 and 2002. Contact with dogs was noted in 66 % of those patients and 33 % had underlying cardiac risk factors. Martino et al. reported a series of 28 cancer patients with Capnocytophaga bacteremia of which two patients had multiple myeloma. Penicillin is the treatment of choice for Capnocytophaga infection but response to other antibiotics, including third generation cephalosporins, has also been reported. Our patient had poor mucosal barrier, close contact with dogs, and newly diagnosed multiple myeloma,all of which could have increased her predisposition to the Capnocytophagainfection. Question as to whether it may have originated from her own oral flora or was transmitted through her dog's saliva, likely will remain unanswered!

THIS LEAK NEEDS MORE THAN A PLUMBER Ishani Pathmanathan; Neil Shah. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1641144)

LEARNING OBJECTIVE 1: Rapidly recognize signs and symptoms of impending cardiogenic shock.

LEARNING OBJECTIVE 2: Understand complications associated with mechanical valves. Identify the need for acute surgical intervention for prosthetic valvular dehiscence.

CASE: A 58 year old woman presented to the emergency room with shortness of breath, increasing lower extremity edema, weight gain, dyspnea on exertion and disorientation. She had a history of atrial fibrillation, sick sinus syndrome status-post pacemaker, and mechanical mitral valve replacement 5 years prior. She was afebrile with an irregular heart rate in the 110's, blood pressure of 100/70, and respiratory rate of 20. She was oriented only to person and asterixis was present but appeared otherwise alert and comfortable. She had a 3/6 left sternal border systolic murmur, a 2/4 diastolic murmur and a loud mid-systolic click, as well as jugular venous distention, hepatojugular reflux, a pulsatile liver, 3+ bilateral pitting edema and cool extremities. Bicarbonate was 20, creatinine 2.2, AST 55, total bilirubin 4.9 and direct bilirubin 2.1. She had a normocytic anemia but no leukocytosis or thrombocytopenia. LDH was 976 and haptoglobin undetectable. Troponin was 0.53 with atrial fibrillation and non-specific ST-segment changes diffusely on electrocardiogram. Pro-BNP was 1,791 and lactic acid was 6.5. Chest X-ray showed an enlarged cardiac silhouette with pulmonary venous congestion. Transthoracic echocardiogram (TTE) demonstrated a paravalvular mitral valve leak, hyperdynamic left ventricle, left atrial and severe right ventricular enlargement and pulmonary hypertension. Within a few hours she deteriorated, despite intubation, ionotropic and vasopressor support. Further imaging with a trans-esophageal echocardiogram (TEE) revealed posterior suture dehiscence of the mechanical valve prosthesis. An Impella device was placed emergently for circulatory support and preparations were made for surgical intervention.

DISCUSSION: Shortness of breath is a common presenting symptom and we must recognize a declining clinical course despite initial stability. In this case we had to synthesize the many worsening symptoms and recognize prosthetic valve dehiscence as the cause of worsening cardiogenic shock. Prosthetic valve replacements are increasingly common, with serious complications in about 3 % including structural malfunctions, thromboses, bleeding, endocarditis and hemolytic anemias. Mechanical valves are at lower risk of structural failure than bioprosthetics, but when paravalvular leaks occur their clinical implications can be severe, if months or years post-operatively. Suture valve dehiscence is particularly common in mitral valves at the posterior suture line. Our patient presented with shortness of breath that quickly escalated into multi-organ failure. Prosthetic valve dehiscence caused mitral regurgitation, left atrial strain, increasing pulmonary vascular pressures, and right-sided heart failure. Resulting cardiogenic shock precipitated a rapid ventricular rate leading to poor renal, cardiac and hepatic perfusion. The combined result of pulmonary hypertension, encephalopathy and hemolytic anemia from traumatic shearing of erythrocytes contributed to the patient's hypoxia, subsequent intubation and rapid clinical deterioration. Recognition by the hospitalist of suture dehiscence as a possible complication of her prosthetic valve and precipitant of acute heart failure allowed for timely diagnosis and appropriate surgical intervention.

THREE HOLES IN THE HEAD Jerson Munoz-Mendoza[1]; Veronica A. Pinto Miranda[1]; Shivashanker Balasingham[2]; Karlo J. Lizarraga[3]; Gio J. Baracco[4]. [1]University of Miami-Jackson Memorial Medical Center, Miami, FL; [2]University of Miami-Jackson Memorial Hospital, Miami, FL; [3]University of Miami, Miami, FL; [4]Miami Veterans Affairs Healthcare System, Miami, FL. (Tracking ID #1636410)

LEARNING OBJECTIVE 1: Diagnose osteomyelitis in patients with HIV/AIDS

LEARNING OBJECTIVE 2: Recognize Salmonella enteritidis as etiology of osteomyelitis in patients with HIV/AIDS

CASE: A 64-year-old man with history of HIV/AIDS infection, whose last CD4 was 4 cell/mm3 and viral load was 47, 848 copies/ml, poorly adherent to antiretroviral therapy and to prophylaxis against opportunistic pathogens

presented to the emergency department complaining of progressively worsening headache and general malaise over the last 3 weeks. He also complained of urinary frequency and dysuria. Physical examination was normal except for low grade fever and a 5 cm by 5 cm subcutaneous fluctuant mass over the left parieto-occipital region of the cranium, which was slightly tender to palpation. The overlying skin was warm but not erythematous. Laboratory data showed a hemoglobin level of 11 g/dL, the white blood cell count was 5,800 cell/mm3, the platelet count was 217, 000/mm3. Urinalysis showed 54 leukocytes per high power field, nitrates positive. Cerebrospinal fluid analysis showed 0 cells/mm3, 25 mg/dL of protein, glucose 57 mg/dl. A CT scan of the head revealed three large osteolytic lesions in the cranial vault, two in the left frontal bone, measuring 3 cm each and one in the left parietal bone of 2.7 cm with mild intracranial extension of extraosseous soft tissue. MRI of the brain showed the parietal one had superimposed central fluid extending from the subgaleal scalp to the epidural space, without brain parenchymal invasion or edema. Needle aspiration of the large subcutaneous collection yielded purulent fluid. The isolate on the cultures plates was identified as S. enteritidis. The same organism also grew in the urine culture but neither in the blood culture nor in the cerebrospinal culture. Blood and CSF cultures were negative. Cytology of the aspirate was negative for malignancy. Therapy with ceftriaxone was begun, resulting in improvement in the patient's condition however after 2 weeks of therapy he developed a generalized itchiness and the antibiotic was switched to oral ciprofloxacin. Antiretroviral therapy was also initiated and he had two repeat aspirations of the posterior mass. Another brain MRI 1 month after therapy showed improvement of the calvarial lesions; therefore he was discharged with instructions to complete a course of ciprofloxacin for 6 weeks and would follow with infectious disease and neurosurgery as outpatient.

DISCUSSION: Non-typhoid salmonella infection is a common occurrence among HIV-infected patients. Salmonella infection in the setting of AIDS usually present as bacteremia, however localized infection, such as osteomyelitis, is very rare. We report a unique case of an HIV-infected patient with multiple foci of cranial osteomyelitis with concomitant epidural abscess and urinary tract infection caused by enteritidis. This case describes an uncommon presentation of Salmonella enteritidis infection in a patient with AIDS. This case provides also evidence to consider non-typhoid salmonella infections in the differential diagnosis of HIV patients with osteomyelitis. Clinicians caring for HIV-infected individuals should take that into account since prompt diagnosis, prolonged antibiotic therapy, and in some cases surgical drainage, will result in full recovery from infection.

THROMBOPHILIA: A RISK FACTOR FOR HEPATOPORTAL SCLEROSIS Hamid Habibi[1]; Kavitha Bagavathy[1]; Deepika Devuni[2]. [1]University of Connecticut, Farmington, CT; [2]University of Connecticut, Farmington, CT. (Tracking ID #1638520)

LEARNING OBJECTIVE 1: To explain the different causes of hepatoportal sclerosis

LEARNING OBJECTIVE 2: The explain the association of hepatoportal sclerosis with thrombophilia

CASE: A 69-year-old male presented to the gastroenterology clinic for an evaluation of abnormal liver function tests. His past medical history was significant for hypertension, coronary artery disease, Factor VIII thrombophilia and pulmonary thomboembolus. He denied any symptoms suggestive of liver disease. His risk factors for transaminitis included history of blood transfusion,statin and alcohol use (3–4 beers a day). On exam, he had scleral icterus with bilateral arcus senilis. His abdomen was soft with an enlarged liver, but no clinically evident splenomegaly or ascites. Lab tests included liver function tests were as follows: ALP: 247U/L, AST: 26U/L, ALT, 19U/L, Indirect Bilirubin 3 mg/dL, Direct Bilirubin: 4.4 mg/dL, Platelets: 127, INR 1.5. Viral hepatitis serologies were negative. An antibody panel, which included anti smooth-muscle, alpha-1antitrypsin, anti-mitochondrial,anti LKM-1, ANA screen, ceruloplasmin, cardiolipin, homocysteine, celiac markers and iron studies were all unremarkable. A factor VIII assay was elevated at 210 %. An abdominal ultrasound with doppler showed evidence of ascites, with patent portal veins, splenomegaly and cholelithiasis without biliary ductal dilatation. In the absence of a clear etiology, the patient underwent a transjugular liver biopsy, which showed marked dilatation of portal veins with sclerosis and no evidence of cirrhosis. The findings were consistent with non-cirrhotic portal hypertension and hepatoportal sclerosis (HPS).

DISCUSSION: Hepatoportal sclerosis also known by other names including Banti syndrome, tropical splenomegaly, idiopathic portal hypertension and nodular regenerative hyperplasia is a rare but known cause of noncirrhotic liver disease. The cause is unknown but manifests with an enlarged spleen and portal hypertension. Many authors have linked chronic or recurrent infections of the digestive tract, toxic exposure to arsenic, vinyl chloride or pharmacologic agents such as azathioprine,methotrexate and 6-mercaptopurine to HPS. Some studies suggest that an underlying autoimmune process, connective tissue disorder, HIV and a prothrombotic state may increase portal venule obstruction. The clinical presentation is related to symptoms and complications of portal hypertension. Although commonly misdiagnosed as cirrhosis, pathologically, the distribution of fibrosis confined to the portal tracts differentiates it from the former. Patency of the hepatic and portal veins is also needed for a correct diagnosis. Unlike cirrhosis, HPS is generally non-progressive with a better prognosis, especially if the raised portal pressure is reduced by shunt surgery or other procedures. Although a non-cirrhotic hepatopathy, in rare cases it can progress to end-stage liver disease needing liver transplantation.In our patient, his likely risk factor for HPS was his thrombotic state of Factor VIII coagulation factors. A suspicion of HPS should prompt a clinical evaluation and correlation including a thrombophilia workup.

THROMBOTIC STORM- 'WOLF AT THE DOOR'-A RARE CASE OF ARTERIOVENOUS CLOTS Madan Badal; Paras Karmacharya; Naba R. Mainali; Madan Badal. Reading Hospital, Wyomissing, PA. (Tracking ID #1609805)

LEARNING OBJECTIVE 1: Thrombotic storm presents as multiple clots in arterial and venous system in short span of time with negatve thrombophilia workup.

LEARNING OBJECTIVE 2: Early anticoagulation is the key in the management of this catasrophic phenomenon.

CASE: Thrombotic Storm presents as a serial thrombotic events that escalates rapidly involving multiple sites. Here we report a case of thrombotic storm in a young pregnant lady successfully treated with anticoagulation. 24 years old pregnant (25 week) female with history of nephrotic syndrome was admitted for diabetic ketoacidosis and pneumonia. On day 4, she delivered non-viable fetus which was followed by flash pulmonary edema due to inferior wall MI. Cardiac catheterization was suggestive of right coronary artery embolus. On day 8, she developed left upper quadrant abdominal pain and was found to have splenic infarct and bilateral iliac vein thrombi. Personal and family history of coagulation disorder was negative. She was then started on heparin infusion. During the course she developed progressive thrombocytopenia and worsening renal failure. However, liver function tests were normal. Blood, urine and sputum cultures were sterile. Lupus anticoagulant, anticardiolipin antibody, beta 2 glycoprotein, heparin induced platelet antibody, hemolytic and DIC panel were negative.CD 55/CD 59 assays, homocysteine, anti-thrombin III, protein C and protein S were non-revelaing. Prothrombin gene and factor V Leiden mutation were also negative. On day 15, her course was further complicated by multiple embolic stroke as seen on CT scan. Continued anticoagulation for 3 months lead to recovery of her symptoms with minimal residual neurological deficit.

DISCUSSION: Thrombotic storm, progresses rapidly within a short period of time with clots affecting multiple organ systems. Catastrophic anti-phospholipid syndrome, Heparin induced thrombocytopenia and Paroxysmal Nocturnal Hemoglobinuria should be excluded before making the diagnosis. Usual triggers of thrombotic storm include pregnancy, infammation, trauma, surgery, and infection. It is often lethal if not detected and treated quickly. Continued anticoagulation therapy usually controls thrombotic storm.

THYROTOXICOSIS AND ABDOMINAL SYMPTOMS—A DIAGNOSTIC CHALLENGE David Kim[1]; Sonya Gupta[2]; Supratik Rayamajhi[3]. [1]Michigan State University, East Lansing, MI; [2]Michigan State University, East Lansing, MI; [3]Michigan State University, East Lansing, MI. (Tracking ID #1643124)

LEARNING OBJECTIVE 1: Recognize uncommon presentations of hyperthyroidism
LEARNING OBJECTIVE 2: Distinguish between an acute surgical and thyrotoxic medical abdomen
CASE: JB is a healthy 46 year old Caucasian male with no prior medical history. He presented to the Emergency department for 1 week duration of persisting vomiting, subjective fevers, worsening left lower quadrant pain radiating to the left flank, and diarrhea associated with occasional hematochezia. He admitted to eating seafood at a restaurant prior to symptom onset and to drinking alcohol excessively for the last 6 months. Initial evaluation revealed that the patient was diaphoretic with low grade temperature and tachycardia. Physical exam revealed guarding of the left lower quadrant with mild rebound, left CVA tenderness, and hypoactive bowel sounds. Examination of the skin, thyroid, and eyes were unremarkable. Significant lab abnormalities were an elevated ESR of 29, mild elevations in CRP and Lipase but normal LFTs. Urine analysis was unremarkable. Initial CT scan was without contrast and negative for nephrolithiasis. Patient was admitted and worked up for possible infectious versus ischemic etiology for his symptoms. Stool studies were obtained and he was started on empiric Cipro and Flagyl. Repeat CT scan with contrast was negative for diverticulitis, colitis, or pancreatitis. Colonoscopy was negative for colitis and biopsy samples were taken which were later interpreted as unremarkable. Pt had a TSH level of <0.01 mIU/ml, obtained shortly after admission due to his symptoms of anxiousness and tachycardia, and a free T4 level of 8.2 ng/dL that confirmed thyrotoxicosis. A thyroid ultrasound was negative. Elevated levels of Thyrotropin receptor antibody levels of 40 IU/L and thyroid stimulating immunoglobulin of 4.6 confirmed Graves disease. The patient was started on methimazole and Propranolol and by hospital day number four, the patient's symptoms dramatically improved. At 2 week follow up, his abdominal pain resolved and Free T4 levels normalized. The risks and benefits of I131 therapy was discussed with the patient.
DISCUSSION: Thyrotoxicosis is a systemic syndrome caused by exposure to excessive levels of thyroid hormone. Graves disease is the most common cause of thyrotoxicosis and occurs in 2 % of the female population, with a female to male ratio of 7–8:1. Classic signs and symptoms include opthalmopathy, dermopathy, goiter, palpitations, diaphoresis, nervousness, and weight loss. However, it remains a "great masquerader" due to its unrecognized presentations. Hyperthyroidism presenting as acute abdomen, diarrhea, and vomiting have been described in the literature but are considered to be unusual and rare manifestations. On review of the literature, a retrospective study conducted on 25 patients hospitalized with acute thyrotoxicosis by Dr. Harper revealed that up to 36 % of patients complained of abdominal symptoms. The diagnosis of Graves disease was delayed in this case due to nonspecific abdominal symptoms despite the presence of some classic signs. Moreover, this case emphasizes the significance of a good history and physical exam and also the possibility of missed diagnosis, more invasive testing, and increased risk for morbidity/mortality in such presentations. Our case demonstrates the importance of keeping a broad differential diagnosis of the causes of an apparent acute abdomen.

TIGECYCLINE: CAUTIONARY TALE Dhara J. Chaudhari; Samit Bhatheja; Wael Zakaria. East Tennessee State University, Johnson City, TN. (Tracking ID #1638406)

LEARNING OBJECTIVE 1: To recognize adverse effects of Tigecycline
LEARNING OBJECTIVE 2: To heighten awareness and emphasis high index of caution with tigecycline, and vigilance with symptom monitoring.
CASE: 86 year old male presented to hospital with complains of nausea, vomiting, abdominal pain, and loose stools of 2–3 days duration. Abdominal pain was dull, non-radiating. He denied dysphagia, hemetemesis, fever, or sick contact. His medical history includes recent hospital admission for recurrent bilateral lower extremity cellulitis for which he was discharged home with Intravenous Tigecycline for total of 15 days, coronary artery disease, obstructive lung disease. He had cholecystectomy done few years ago. He was non-smoker, non-alcohol drinker. His Physical exam was significant for BP 164/92, Temp 96.4, tenderness in epigastrium, diffuse red and scaly bilateral lower extremity. Initial laboratory evaluation revealed lipase 562, amylase 81, WBC 16.2, normal chemistry panel, fasting triglyceride 302 (10 days ago 198). Patient was kept nothing by mouth, given IV fluids with bowel rest. CT Abdomen/pelvis revealed sever pancreatic inflammation with early necrosis (Balthazar score-D), no evidence of gall stone. other causes of pancreatitis such as hypertryglyeridemia, gallstones were ruled out. Only plausible medication was tigecycline. His tigecycline was stopped and He was started on IV Imipenem. Patient continued to do well over next few days and tolerated oral diet. His lipase returned to normal value. He was discharged home with change in his antibiotics.
DISCUSSION: Tigecycline, 9-t-butylglycylamido semi-synthetic derivative of minocycline, developed to overcome two mechanisms of tetracycline resistance ribosomal and efflux pump. It has in vitro activity against Gram positive, gram negative, anaerobes. It is indicated for skin and soft tissue infections, intra-abdominal infection. Acute drug induced pancreatitis is considered when pancreatitis develops during administration of culprit drug, exclusion other causes, symptom improvement with discontinuation of drug. Although exact mechanism of pancreatitis is unknown, postulated hypothesis regarding tetracycline induced pancreatitis exits in literature. Tetracycline induced block in protein synthesis lead to accumulation of defective protein with in the hepatocytes. It inhibits release of triglyceride, and causes retention of triglyceride and precipitation of pancreatitis. tetracycline and tigecycline has 4 ring structure making this hypothesis plausible for tigecycline as well. Phase 3 trails on tigecycline used in skin and soft tissue infections had documented incidence of 3.3 % as compared to control group. Acording to the published cases in literature, patient present with nausea, abdominal pain within 6–14 days of initiation of treatment. Amylase and lipase were reported to be elevated up to 2 to more than 5 times upper limit of normal with variation in recovery time. Tigecycline induced pancreatitis is a rare phenomena requiring strong emphasis on cautious use of tigecycline, monitor symptoms of abdominal pain, and evaluate with amylase-lipase if clinical presentation demands.

TIME TO BRING STEROIDS IN THE MANAGEMENT OF LEVAMISOLE INDUCED VASCULOPATHY? Arshad A. Javed1; Rohit Gupta1; Sri B. Yadlapalli1; Muhammad A. Shahzad1; Shabnam Ali1; Rajaie Namas2. 1WSU/DMC, Detroit, MI; 2WSU/DMC, Detroit, MI. (Tracking ID #1626207)

LEARNING OBJECTIVE 1: Recognize the need for high dose steroid therapy in levamisole induced vasculitis
LEARNING OBJECTIVE 2: Diagnose case of levamisole vasculitis in cocaine abusers
CASE: A 45 year old woman was admitted to the MICU with mental status changes, hypotension, fever, renal failure, acidosis and intubated for respiratory failure. She had history of heavy alcohol, cocaine and tobacco use. She was hypotensive, tachycardic, febrile and in severe pain, crying when awake but otherwise, delirious. There was violaceous discoloration on all extremities with bullae especially on lower extremities, arms and hands along with impending gangrene of the fingertips and bilateral necrotic patches on cheeks with necrotic eroded nasal cartilage. Urine showed cocaine and levamisole. ANCA was positive. Skin biopsy showed superficial and mid dermal angiocenteric infiltrates of mixed inflammatory associated with multiple fibrin thrombi in the lumen of vessels. Another 42 year old woman presented with joint pain, fatigue and painful skin rash mostly on the right upper and lower extremities that was attributed to her lupus history. There was diffuse macular ecchymotic rash most prominent on the patient's buttock and thighs but also extending down to the legs and on the arms; large ecchymotic lesions of approximately 10 cm diameter on legs that

appeared to be nonblanching but exquisitely tender. She denied drug abuse but urine was positive for cocaine. ANCA was positive. Skin biopsy showed multiple intraluminal thrombi in small vessels of superficial and deep dermis without vasculitis. Both the patients were started on treatment with high dose intravenous methylprednisone ('pulsed'), showed dramatic improvement in symptoms and later on it was switched to oral steroids.
DISCUSSION: Now that cocaine-levamisole has been associated with a severe vasculitis and described in medical literature repeatedly, there is a need to treat the condition in a better way. Conservative approach (wound care and antibiotics) with or without corticosteroids and surgical modalities either with skin grafting or with amputation have been the cornerstones of management so far. There have been questions regarding the efficacy of corticosteroids. Another question is whether the response to steroids depends on the pathological findings which range from vasculitic to thrombotic to a mixed picture. Both of our patients responded very well to high dose IV steroids. We hope that results like this will encourage further research to reach the best management option.

TITLE: AN UNUSUAL CAUSE OF PARALYSIS Patrick Quinlan. Reading Hospital, Wyomissing, PA. (Tracking ID #1621532)

LEARNING OBJECTIVE 1: To recognize severe hypokalemia as a potential side effect of tenofovir therapy.
LEARNING OBJECTIVE 2: To understand the mechanism involved in tenofovir induced hypokalemia.
CASE: A 51 year old female with a long standing history of HIV on tenofovir therapy for about 1 year presented with profound weakness of the upper and lower extremities. On initial presentation, serum potassium was measured to be 1.1 mEq/L, serum phosphate was found to be 1.2 mg/dl, and a non-anion gap metabolic acidosis was also present. A complete neurological workup, including MRI of the brain, MRA of the head and neck, CT scan of the head and neck, EMG and nerve conduction studies were performed and found to be unrevealing. The patient's profound weakness was attributed to severe hypokalemia and hypophosphatemia. After excluding other potential causes of hypokalemia (absence of GI symptoms, normal thyroid functions studies, absence of other medication causes), her low potassium, low phosphorus, and metabolic acidosis were attributed to her longstanding treatment with tenofovir. After aggressive IV and PO potassium and phosphorous replacement, the patient recovered her former strength and walked out of the hospital.
DISCUSSION: Although rarely resulting in profound hypokalemia, proximal renal tubular dysfunction is a known complication of tenofovir therapy. There are only several case reports of tenofovir induced hypokalemia resulting in profound weakness or paralysis. The mechanism is thought to be due to nephrotoxicity affecting the proximal tubular cells of the nephron which results in Fanconi Syndrome and potassium wasting, which manifests as hypokalemia, hypophosphatemia, proteinuria, glucosuria, and non-gapped metabolic acidosis. Rarely, tenofovir can cause profound hypokalemia. Periodic (every 6 months) measurement of renal function and potassium levels should be performed in patients on tenofovir therapy. Therefore, beware of the potential for severe hypokalemia and non-anion gap metabolic acidosis in patients on tenofovir therapy.

TITLE: CONGENITAL INFERIOR VENA CAVA MALFORMATION AS A RISK FACTOR FOR DEEP VENOUS THROMBOSIS INTRODUCTION: ANOMALIES OF THE INFERIOR VENA CAVA HAVE BEEN RECOGNIZED AS A POSSIBLE RISK FACTOR FOR PROXIMAL DVT. WITH RESPECT TO THE PATHOPHYSIOLOGY OF DEEP VEIN THROMBOSIS IN INDIVIDUALS WITH AN ANOMALY OF THE INFERIOR VENA CAVA, BLOOD RETURN MAY BE INADEQUATE DESPITE OF PROMINENT COLLATERALS. THIS INADEQUATE BLOOD RETURN MAY INCREASE THE BLOOD PRESSURE IN THE VEINS OF THE LOWER EXTREMITIES, WITH ENSUING VENOUS STASIS AND SUBSEQUENT DEEP VEIN THROMBOSIS, WHICH IS BILATERAL IN MORE THAN 50 % OF SUCH PATIENTS Foroozan Famoori; Saba A. Hasan. CAPITAL HEALTH REGIONAL MEDICAL CENTER, Trenton, NJ. (Tracking ID #1641830)

LEARNING OBJECTIVE 1: 1- Anomaly of the inferior vena cava should be considered in young patients who present with deep vein thrombosis especially proximal and bilateral. 2- Consider lifetime anticoagulation for IVC vasculature anomalies in patients who cannot have reconstructive vascular surgery. 3- Physicians should investigate underlying causes of DVT before stopping anti-coagulants for patients with unusual presentations of DVT.
CASE: The patient was a 26-year-old male without significant past medical history who was admitted with back pain. The back pain progressed, and he began having leg pain and swelling. Venous duplex showed lower extremity DVT. Further evaluation showed an extensive IVC thrombus which was completely occluded. CT scan showed a retroperitoneal fusiform soft tissue swelling at the level of kidneys as well as bilateral renal vein thrombus. The contrast-enhanced CT Scan revealed anomalous vasculature with an incomplete and hypoplastic IVC. There was no direct connection between the IVC and the right atrium. He underwent systemic thrombolysis and thrombectomy, and was placed on warfarin at discharge. Warfarin was stopped after 3 years of therapy. Six months after stopping warfarin, the patient came back to the hospital with left leg discomfort. Doppler ultrasound again showed bilateral common femoral vein thrombosis. The patient underwent lower extremity venography and thrombolysis, and thrombectomy of the IVC. Venacavagraphy of common iliac veins revealed stasis of flow within the inferior vena cava at the level of the L2 vertebral body. Pt was started again on warfarin this time for lifetime, and patient was advised to wear elastic stockings.
DISCUSSION: Sonography is usually the first imaging modality in the evaluation of patients with deep vein thrombosis, but anomalies of the inferior vena cava may be missed on sonography. Therefore physicians must consider contrast enhanced CT scan and venogram in spontaneous unprovoked bilateral deep vein thrombosis in a young patient without any past medical history.

TITLE: SYSTEMIC MASTOCYTOSIS- AN INTRODUCTION TO A RARE HEMATOLOGICAL DISORDER REQUIRING CAREFUL DIAGNOSTIC PLANNING Misako Nagasaka; Hirokazu Ban; Masayuki Nigo; Efat Azizi; Alfred Burger; Ilan Shapira. Beth Israel Medical Center, New York, NY. (Tracking ID #1644733)

LEARNING OBJECTIVE 1: Recognize systemic mastocytosis (SM) as a rare yet morbid differential which may mimic the presentation of leukemia/lymphoma.
LEARNING OBJECTIVE 2: Diagnose SM while safely managing the potential sequelae of life-threatening mediator-related events.
CASE: A 66 year-old man without any past medical history presented with fatigue, weight loss and generalized abdominal pain for 3 months. Physical exam was positive for splenomegaly. The patient's labs revealed an hemoglobin of 8.0 g/dl and platelets of 79 K/ul. CAT scan of the abdomen showed splenomegaly and diffuse lymph node (LN) enlargement. An endoscopic biopsy of the porta hepatis LN was performed. A few hours after endoscopy, the patient complained of sudden rigor, became unresponsive and a medical code was called. Monitor showed ventricular fibrillation. The patient was successfully resuscitated after four defibrillations. As the prior LN biopsy was inconclusive, a bone marrow (BM) biopsy was performed. This revealed mastocytes infiltration; peritrabecular spindle cell infiltrates positive for CD117, weakly positive for CD45 and CD43 which was consistent with systemic mastocytosis (SM). Serum tryptase, a marker for mastocytosis activity, was elevated to 835 ng/ml (nl 5–10 ng/ml). This decreased to 457 ng/ml after treatment with imatinib mesylate. One month after the diagnosis, the patient developed abdominal distension and his hemoglobin acutely declined. A repeat abdominal CAT scan showed new splenic hemorrhage with massive ascites. Splenic embolization was performed. Paracentesis was positive for hemorrhagic ascites, and spontaneous bacterial peritonitis. Broad spectrum antibiotics were administered. Despite treatment, the patient continued to deteriorate and expired approximately 2 months after the diagnosis of SM.
DISCUSSION: Mastocytosis is a rare hematologic disorder with an unknown incidence. There are two types, cutaneous and systemic.

Systemic mastocytosis (SM) is where neoplastic mastocytes accumulate in multiple organs such as the skin, spleen, BM and LN, whereas cutaneous mastocytosis presents with skin findings as urticaria. As in our case, patients with SM present with generalized symptoms from organ impairment due to mastocyte infiltration. Clinical presentation may mimic those of lymphoma/leukemia. The World Health Organization SM diagnostic criteria require one major-criterion and one minor-criterion or at least three minor-criteria. The major-criterion is the multifocal infiltrates of mastocytes in the BM and/or other organs based on biopsy results. Minor-criteria include; more than 25 % of mastocytes having spindle-shaped or atypical morphology, point mutation at codon816(KIT), mastocytes expressing CD2 and/or CD25 with normal mastocyte markers and serum tryptase exceeding 20 ng/mL. The danger in SM is that during biopsy, mediator-related events may occur. Mediator release may be triggered by any physical/emotional stress or drugs; general anesthesia is of particularly high risk. This can also be precipitated by insect bites or snake venoms. Close communication between the primary medical team, anesthesiologists and surgeons is essential. Obtaining tryptase prior to procedures while considering telemetry monitoring of tryptase positive patients peri/post-diagnostic procedures with bedside preparation of epinephrine, H1/H2 blockers and steroids may also be advised. This case highlights the need for careful diagnostic planning to prevent the sequelae of life-threatening mediator-related events.

TO BE OR NOT TO BE-THAT IS THE QUESTION-ATRIAL MYXOMA OR COUMADIN RIDGE? Aiman Shokr; Christopher Gully; Hazem Abugrara; Mashrafi Ahmed. Texas Tech Univ Health Sciences Center, AMARILLO, TX. (Tracking ID #1639870)

LEARNING OBJECTIVE 1: Diagnose atrial myxoma as a rare cause of ischemic stroke
LEARNING OBJECTIVE 2: Recognize that rare anatomical variants in heart like coumadin ridge may mimic a myxoma or thrombus and add to the diagnostic dilemma
CASE: Left atrial myxoma can cause ischemic stroke due to embolism. Occasionally, rare variants of cardiac anatomical structure like Coumadin ridge can mimic left atrial myxoma or thrombi and warrants unnecessary procedures and treatment. In this report, we present two cases of ischemic stroke with similar clinical picture with one having left atrial myxoma and the other with Coumadin ridge. In the first case, a 40 year-old female presented with right sided weakness and global aphasia. She had no past medical illness other than occasional right arm pain. CT scan and MRI of the brain confirmed Lt Internal carotid artery and Lt middle cerebral artery (MCA) thrombosis with Lt MCA territory stroke. Transthoracic echocardiogram showed a globular structure attached just below anterior leaflet of mitral valve and later a transesophageal echocardiogram confirmed it as a myxoma. The 3×2 cm myxoma was excised successfully. In the second case, a 56 year-old male presented to the hospital with slurred speech and right-sided weakness. A CT scan of the brain showed infarction at the left paramedian aspect of the pons and the MRI reconfirmed that. Transthoracic echocardiogramshowed a mass in the left atrium. Considering a thrombi or myxoma, the patient was started on heparin drip and cardiothoracic surgeon was consulted but a transesophageal echocardiogram designated it as a Coumadin ridge.
DISCUSSION: Atrial myxoma is the most common benign cardiac tumor. It can be a source of emboli to the central nervous system and elsewhere in the vascular tree. It is found more commonly in young adults with stroke or TIA. The annual incidence is 0.5 per million with 75 % of cases occurring in the left atrium. There is a 2:1 female preponderance and the age of onset is usually between 30 and 60 years. Although atrial myxoma is mostly sporadic, at least 7 % of cases are familial. Strokes are often recurrent. The presentation ranges from progressive multi-infarct dementia to massive embolic stroke causing death. Because tumor fragments or adherent thrombus may embolise, anticoagulation may not be protective. On the other hand, the Coumadin ridge has been described from echocardiographic studies as a ridge of atrial tissue separating the left atrial appendage from the left upper pulmonary vein. It can present as a linear structure or even sometimes as a nodular mass that protrudes into the left atrium. This 'mass' can undulate with cardiac motion and appears similar to a thrombus or atrial myxoma. In the past, this structure was often mistaken for thrombus and resulted in patient being prescribed anticoagulation therapy with warfarin (Coumadin) and it is from here that it derives its name. Transesophageal echocardiogram and Cardiac MRI are more helpful to differentiate it from myxoma or thrombus.

TO BLEED AND NOT TO BLEED: ACUTE HEMATOMA AND ACUTE VENOUS THROMBOSIS ON WARFARIN THERAPY Akshay Manohar; Nadereh Nasserhelali; Emily Chen; Dhruti Patel. Capital Health Regional Medical Center, Trenton, NJ. (Tracking ID #1642241)

LEARNING OBJECTIVE 1: A therapeutic or supratherapeutic INR may not prevent venous thrombosis in the setting of significant pro-coagulant factors.
CASE: A 60-year-old Caucasian male came to the emergency room with bilateral knee swelling and pain that worsened with exertion. Apart from hypertension, Insulin dependent Type-2 Diabetes and a history of esophageal ulcers, he had a long history of multiple hospitalizations for deep vein thrombosis (DVT) treated with an inferior vena caval (IVC) filter and warfarin. The patient's records indicated that he had often been noncompliant with medication. However on this occasion, his International Normalized Ratio (INR) was 6.9. His INR 9 days prior was 3.3 and 2 weeks before that was 1.8. The patient said he had been taking his medicine recently, and the above INRs seem to validate this. His liver function tests were normal and a fecal occult blood test was initially negative. A venous doppler of his lower extremities showed chronic scarring and despite his supratherapeutic INR, demonstrated acute thrombosis in both femoral veins, left popliteal vein and the origin of the left profunda vein. After clotting through his supratherapeutic INR, the patient developed a large hematoma and gastrointestinal bleeding the next day. He was given Vitamin K and fresh frozen plasma to lower his INR to around 2. A planned thrombectomy by interventional radiology was cancelled as the patient's creatinine was elevated. He was intended to be started on enoxaparin, however, because of financial reasons, he was restarted on warfarin with closer monitoring.
DISCUSSION: An elevated INR usually indicates relative anti-coagulation and bleeding risk, however some clinical scenarios can result in clotting despite therapeutic or even supratherapeutic INR. The physiologic process of coagulation is maintained by over 50 pro- and anticoagulants that constantly counter each other to maintain balance. While there are many causes for thrombogenesis, the three primary influences are endothelial injury, abnormal blood flow and hypercoagulability. Of the three, endothelial injury and abnormal flow can enhance each other's effects contributing to thrombosis. In our patient, we can hypothesize that abnormal flow of blood in his chronically scarred deep veins have provoked and worsened his multiple DVT's. Also, the (Prevention du Risque d'Embolie Pulmonaire par Interruption Cave (PREPIC) Study which followed up patients with permanent IVC filters showed that IVC filters, while decreasing the risk of pulmonary embolism, did increase the risk of DVT. The patient's IVC filter may have also played a role in his venous thrombosis.

TOO MANY CYSTS IN THE LUNG WITH AN UNCOMMON CULPRIT Veronica A. Pinto Miranda[1]; Jerson Munoz-Mendoza[1]; Jodi Renner-Carmona[2]. [1]University of Miami-Jackson Memorial Hospital, Miami, FL; [2]University of Miami-Jackson Memorial Hospital, Miami, FL. (Tracking ID #1636359)

LEARNING OBJECTIVE 1: Recognize metastatic lung disease as cause of diffuse cystic lung disease.
LEARNING OBJECTIVE 2: Assess diffuse cystic lung disease with a thorough diagnostic workup
CASE: A 22-year-old man with multiple sclerosis and no history of tobacco use presented with 2 days of a non-productive cough and fever. He also endorsed a 20-pound weight loss over 6 months. His physical exam revealed a thin man in no acute distress with normal vital signs and lungs clear to auscultation. On his

upper back, he had an 8×5 cm rubbery, erythematous and mildly tender mobile mass that had been present for weeks but seemed to be increasing in size. Initial laboratory testing was normal except mildly elevated ESR. His chest x-ray, which was normal 18 months prior, was significant for diffuse bilateral cysts and a reticulonodular pattern. A noncontrast chest CT showed cysts, cavities, and nodules too numerous to count involving all lobes of the lung. Additional tests including HIV, alfa-1-antitrypsin, ANA, ANCA, C3/C4, AFB sputum smear were all normal. Pulmonary function test showed mixed obstructive/restrictive changes and severely reduced diffusion capacity. The patient had a bronchoscopy that revealed no endobronchial lesions, and video-assisted thoracoscopic surgery wedge resection of the right upper and middle lobes. Pathology showed monomorphic, spindle cells, arranged in storiform/herringbone pattern, positive for CD34 and CD99, negative for keratin, consistent with metastatic dermatofibrosarcoma protuberans. Upon further questioning, the patient stated he had his back lesion debrided 2 years prior, but did not follow-up with his care. His past medical records were obtained and revealed that the back lesion was dermatofibrosarcoma protuberans. He was referred to oncology for follow-up of his metastatic sarcoma.

DISCUSSION: This case shows an uncommon cause of diffuse cystic lung disease. Diffuse cystic lung disease is present in a limited number of pulmonary conditions which include Langerhans histiocytosis, lymphangioleiomyomatosis, honeycomb lung, advanced sarcoidosis, and rarely, metastatic disease. Typically, metastatic lesions to the lung present as focal nodules that may later cavitate. The primary tumor, dermatofibrosarcoma protuberans is a rare cutaneous tumor of low malignant grade that metastasizes in less than 5 % of cases, but has a high propensity to metastasize to the lungs. This case highlights the importance of considering metastatic disease as the etiology of diffuse cystic lung disease when other causes after a thorough diagnostic workup have been ruled out.

TOPICAL STEROIDS: NOT SO QUICK WITH THAT PRESCRIPTION PAD. IT CAN BE TOO MUCH OF A GOOD THING Kehinde Odedosu. UTSW, Dallas, TX. (Tracking ID #1635727)

LEARNING OBJECTIVE 1: Clinicians must recognize the dangers of prescribing topical steroids particularly highly potent steroids.

LEARNING OBJECTIVE 2: Recognize when to re-evaluate a previous diagnosis and treatment plan if treatment is not effective

CASE: A 48 year old male with a 1 year history of generalized pruritic rash presented with lethargy. Temperature 99° Fahrenheit, pulse 80, blood pressure 141/99. Exam revealed a regular heart beat, clear lung exam and a benign abdominal exam. His exam was also notable for dry skin with scattered erythematous maculopapular rash on face, chest, abdomen, upper and lower extremities. The rash spared mucosal membranes, palms and soles. Laboratory data was notable for sodium of 113. Evaluation for the cause of his hyponatremia revealed a low morning cortisol level (<1 mcg/dL). On further questioning, patient revealed he was given a diagnosis of severe eczema a year ago. He saw multiple physicians in the last year about his underlying skin condition and was prescribed Clobetasol 0.05 % ointment. Patient admitted to applying Clobetasol three to four times a day to his entire body for the last 6 months as it provided relief for his severe pruritis however the rash never fully resolved. He stated he ran out of Clobetasol a few weeks prior to admission. A diagnosis of Adrenal Insufficiency secondary to topical steroids was made.

DISCUSSION: Adrenal insufficiency is caused by decrease production of glucocorticoids. The most likely cause of this patient's adrenal insufficiency is the use of topical steroids three to four times a day over a large surface area of his body and the abrupt withdrawal. He was initiated on hypertonic saline solution for his symptomatic hyponatremia and his sodium and his mental status improved over the next few days. He was initiated on oral hydrocortisone for adrenal insufficiency and an outpatient dermatology referral was placed. Topical steroids are a rare but plausible cause of adrenal insufficiency. It is important that clinicians are aware of this when they prescribe topical steroids particularly highly potent steroids as Clobetasol (Class 1). If this patient had only one provider, his misuse of Clobetasol would have been discovered earlier and possibly prevent the development of adrenal insufficiency. I am guilty in my clinical practice of refilling a topical steroid prescription, although not as potent as Clobetasol, at the request of my patients for "my eczema flaring up" without thinking twice about it. This case illustrates the possible danger of that practice. In this patient, a discussion of how he was applying the steroids might have prevented the development of adrenal insufficiency and a sooner referral to a dermatologist to discuss 1) re-evaluation of his diagnosis of eczema 2) discussion of steroid-sparing agents.

TRAUMA LEADING TO THE DISCOVERY OF DIFFUSE LYMPHADENOPATHY AND A COLONIC MASS Hillary Dunlevy; Joshua Metlay. University of Pennsylvania, Philadelphia, PA. (Tracking ID #1641895)

LEARNING OBJECTIVE 1: Establish the etiology of diffuse lymphadenopathy in a presentation of advanced HIV

LEARNING OBJECTIVE 2: Recognize the possible presentation of multiple malignancies in advanced HIV

CASE: A 55 year old male without significant past medical history was evaluated in the emergency department after his son assaulted him. During the trauma evaluation, physical examination revealed a thin male with diffuse lymphadenopathy. Though there was no sign of excessive acute bleeding, he was found to be anemic, hemoglobin of 6.3 g/dL, later confirmed as iron deficiency anemia. Computed Tomography of the chest, abdomen and pelvis demonstrated diffuse lymphadenopathy, notably in the inguinal, axillary and mesenteric nodes. Additionally, the CT revealed a transverse colonic thickening, suspicious for malignancy. Further questioning exposed a 6 month history of epigastric abdominal pain, fatigue, early satiety and weight loss of ten pounds. Given this history, an HIV test was sent and later returned positive with a CD4 of 77 per μL and HIV RNA of 179,858 copies/mL. His reported risk factors included sex with multiple partners of both genders, though he reported consistent barrier protection. Endoscopy revealed a dysplastic gastric polyp, which was removed, and a near obstructive colonic mass. The colonic mass biopsies demonstrated neoplastic epithelial cells, likely invasive adenocarcinoma. Given the colonic malignancy and the diagnosis of AIDS, an axillary lymph node fine needle aspirate was performed to distinguish metastatic disease from a separate HIV associated process. The lymph node biopsy demonstrated a population of surface immunoglobulin-negative CD10+ B-cells with a monoclonal immunoglobulin heavy chain mutation, concerning but not diagnostic for lymphoma. The patient was referred for excisional lymph node biopsy as an outpatient to further clarify the diagnosis. Additionally, he was scheduled for follow-up with colorectal surgery for excision of the colonic mass as well as oncology, infectious diseases and primary care.

DISCUSSION: This patient presented with advanced HIV and had several possible etiologies for his diffuse lymphadenopathy. The fine needle aspirate showed nothing to support the initial concerns for metastatic colon cancer. Other possibilities for adenopathy in the setting of AIDS are lymphoma, mycobacteria or hyperplasia. The results of the flow cytometry and immunoglobulin heavy chain mutation testing raised concerns for lymphoma or a more benign diagnosis of follicular hyperplasia. The fine needle aspirate identified atypical cells, though not the architecture of the lymph node, which will be necessary for final diagnosis with excisional biopsy. Importantly, though the initially identified colonic mass could have explained the patient's presenting symptoms, he had multiple diagnoses found on further investigation, including HIV/AIDS. While there is some conflicting evidence regarding the risk of adenocarcinoma of the colon in HIV, a prospective cohort study using sigmoidoscopy showed higher odds of colonic neoplasms in the HIV population. The same study suggested increased odds in patients with lower CD4 count and longer duration of HIV infection, such as this patient. Additionally, his epigastric pain with early satiety prompted an EGD, revealing a dysplastic gastric polyp. Finally, further investigation including excisional biopsy will have to be performed to evaluate for lymphoma, due to his higher risk of lymphoma with HIV.

TREATING HYPONATREMIA-NO WIN SITUATION Vishal Goyal. Allegheny General Hospital, Pittsburgh, PA. (Tracking ID #1644939)

LEARNING OBJECTIVE 1: Alcoholics, malnourished patients with low sodium at presentation and chronic hyponatremic patients are at high risk of developing CPM even if their sodium is corrected slowly.

CASE: Forty-eight year old male with past medical history of COPD, GERD and hypertension was admitted to hospital with chief complaint of nausea, vomiting and an episode of syncope on day of admission. His medications include Lisinopril, Hydrocholrothiazide and bronchodilators. He has been drinking vodka mixed with orange juice for past several years. BMP showed sodium of 110 mmol/l. He received one liter of normal saline and sodium decreased to 107 mmol/l. Serum osmolality was 234 mosm/kg. Urine osmolality was 222 mosm/kg and urine sodium was 22 mmmol/l. It was determined that hypernatremia was due to poor salt intake in presence of excess water intake. He also had a state of increased ADH secretion due to continuous vomiting. Therefore, he was put on fluid restriction as we improved his dietary intake. His sodium never corrected more than 7 mmol/l in 24 h period. His symptoms improved and sodium corrected to 135 mmol/l in 7 days. He was discharged home. Patient presented to ED 5 days after discharge with tremors and ataxia. MRI of brain showed central pontine myelinolysis(CPM)

DISCUSSION: The osmotic demyelination syndrome is a complication of treatment of patients with profound, life threatening hyponatraemia. It occurs as a consequence of a rapid rise in serum tonicity in individuals with chronic severe hyponatraemia who have made intracellular adaptations to the prevailing hypotonicity. Elevation in serum sodium is the overwhelming contributor to the rise in tonicity, but potassium elevation may contribute. The prognosis of the osmotic demyelination syndrome has long been regarded as bleak, primarily because before CT/MRI this was a postmortem diagnosis. The most recent recommendation for rate of correction of sodium is not in excess of 8 mmol/l/day. Some suggest stabilising the patient in a mild hyponatraemic state after the initial correction. Laureno and Karp suggest that "it may be impossible to define a level of correction that is always completely free of risk". This problem is compounded as the treating physician has only indirect control over the rate of Na + rise which may correct faster despite their best intentions. This case illustrates that alcoholics, malnourished, patients with low sodium at presentation and chronic hyponatremic patients are at high risk of developing CPM even if their sodium is corrected slowly. It is also important to consider not only the rate of correction but amount of correction of sodium. It also raises the question that if we should correct sodium to normal level in patients with chronic hyponatremia or not?

TRICUSPID REGURGITATION: VALVULAR DYSFUNCTION ON THE RISE Atena Lodhi; Sherrill Gutierrez; Michael Curley. MCWAH, Wauwatosa, WI. (Tracking ID #1643039)

LEARNING OBJECTIVE 1: Recognize valvular complications related to pacemakers and implantable defibrillators.

LEARNING OBJECTIVE 2: Describe the diagnosis and treatment of lead-related tricuspid regurgitation.

CASE: A 75-year-old male with a history of hypertension, hyperlipidemia, diabetes mellitus, coronary artery disease, congestive heart failure and second-degree atrioventricular heart block treated with pacemaker placement presented from an outside hospital with a chief complaint of progressive weight gain and abdominal girth. The patient stated that he had been gaining weight over the last year and more acutely over the last 2 weeks with increasing abdominal girth. He denied shortness of breath, alcohol use, drug use and recent travels. At the outside hospital, liver function tests showed a mildly elevated AST, ALT, and alkaline phosphate with a normal bilirubin, INR and albumin. The patient was also noted to have acute kidney injury and thrombocytopenia. The remainder of the complete blood count and a complete metabolic panel were normal. Abdominal ultrasound revealed findings consistent with cirrhosis with portal hypertension, including a small to moderate amount of ascites and bidirectional flow within the portal vein. On admission to our hospital, viral serologies for hepatitis were negative. His pacemaker was interrogated and revealed evidence of newly developed atrial fibrillation. A repeat echocardiogram showed a left ventricular ejection fraction of 45–50 %, normal right ventricular function, severe biatrial dilation and pinning of the posterior leaflet of the tricuspid valve by the pacemaker lead with wide-open tricuspid regurgitation. The pulmonary artery systolic pressure was normal. Patient was aggressively diuresed and amiodarone was started for his atrial fibrillation. On day three he was cardioverted with restoration of sinus rhythm. Patient diuresed greater than 20 l with significant reduction in his ascites and peripheral edema. In addition, his acute kidney injury and thrombocytopenia improved. The plan at that time was to continue diuresis, with outpatient follow-up with cardiology for a repeat echocardiogram to reevaluate his tricuspid regurgitation.

DISCUSSION: Pacemakers and implantable cardioverter-defibrillators (ICDs) are important medical devices used in the treatment of a variety of cardiac diseases. With the aging population and an increase in life expectancy, the utilization of these devices is expected to continue to rise. As such, it is important that general internists appreciate not only the indications for these devices, but also the complications that can occur secondary to them. Tricuspid regurgitation is one such known but under-appreciated complication. While heart failure and fluid overload have a host of potential etiologies, in a patient with a right ventricular pacemaker or defibrillator lead, tricuspid valve dysfunction must be included in the differential. Limited data on the frequency of tricuspid regurgitation related to endocardial lead implantation is conflicting, but the importance and clinical impact is not. Severe tricuspid regurgitation is known to be associated with right heart failure and increased mortality. Early diagnosis of and intervention for lead-related tricuspid regurgitation is critical for addressing an iatrogenic cause of valvular dysfunction.

TRIMETHOPRIM-SULFAMETHOXAZOLE INDUCED HEPATOTOXICITY Tajdeep Dhindsa[1]; Carina Jackman[2]; Andrew Wuenstel[3]. [1]Medical College of Wisconsin, Milwaukee, WI; [2]Wheaton Franciscon Healthcare-St Joseph Program, Milwaukee, WI; [3]Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #1638434)

LEARNING OBJECTIVE 1: Present a case of Trimethoprim-Sulfamethoxazole induced hepatotoxicity

LEARNING OBJECTIVE 2: Consider a wide differential for etiology of hepatotoxicity

CASE: A 66 year-old male presented with malaise, insomnia, nausea, reduced appetite, and abdominal pain for 5 days. Two weeks prior to presentation, he was treated for a presumed urinary tract infection with amoxicillin. Five days prior to admission, his antibiotic was switched to trimethoprim/sulfamethoxazole when his symptoms of dysuria did not improve and his initial urine cultures grew amoxicillin resistant Escherischia coli. His past medical history included atrial fibrillation, MV replacement and prostate cancer and his current medications included digoxin, amiodarone, and warfarin. Upon admission he was noted to be febrile with a temperature of 102.2 F, but otherwise hemodynamically stable. On exam, he had scleral icterus and diffuse jaundice. Initial lab studies were remarkable for an INR of 10, total bilirubin 9.6, direct bilirubin 6.4,normal white blood count with 13 % bands, platelet count 87,000, AST 137, ALT 173, and alkaline phosphatase 180. Other infectious etiologies, including HIV and viral hepatitis, were excluded. Imaging included a normal abdominal US and chest x ray. Abdominal CT showed a renal calculus and perinephric stranding concerning for pyelonephritis. He was initially treated with ceftriaxone, but urine culture showed no growth, and the patient denied urinary symptoms. With the complete picture of elevated hepatic enzymes, coagulopathy, and thrombocytopenia, he was diagnosed with drug- induced liver injury due to trimethoprim/sulfamethoxazole. All antibiotics were discontinued, supportive care provided and lab values normalized. He was discharged on oral course of cephalexin because of slight increase in his white count, although no overt signs or symptoms of an infection.

DISCUSSION: Drug-induced liver injury (DILI) is a serious, although rare adverse effect of trimethoprim/sulfamethoxazole. It is usually an idiosyncratic reaction; it is dose-independent with an unpredictable course that occurs after a latent period. Severity ranges from benign elevation in aminotransferases to fulminant liver failure with multi-organ dysfunction. Risk factors include alcoholism, obesity, liver disease, malnutrition and certain medications. DILI can manifest as a hypersensitivity reaction consisting of fevers, eosinophilia, rash and abdominal pain. Most commonly there is a cholestatic injury pattern manifesting with jaundice

and pruritis. Drug classes that are known to cause DILI include antibiotics, various dietary supplements, NSAIDS and anti-epileptics. Among antibiotics, amoxicillin-clavulanate is most commonly associated with DILI. The most effective treatment strategy is withdrawal of the agent and supportive care. Prednisone may be helpful when a hypersensitivity reaction with features such as fever, rash or arthralgias is predominant.

TUBERCULOUS EFFUSION: A COMMON ENTITY WITH A COMPLEX DIAGNOSIS Shira Eytan; Sarah B. Fleisig; Robert E. Graham. Lenox Hill Hospital, new york, NY. (Tracking ID #1622227)

LEARNING OBJECTIVE 1: To recognize the difficulty in diagnosing tuberculous effusion.
LEARNING OBJECTIVE 2: To recognize the importance in treating TB if clinical suspicion is high, even if cultures are not yet positive.
CASE: A 61-year-old female hospital employee with infrequent health care presented with dry cough, chest discomfort, fatigue, and unintended 20-lb. weight loss. PPD performed due to risk of occupational TB exposure was positive and the patient was placed on airborne isolation precautions. CT abdomen/pelvis performed in the Emergency Department revealed a large loculated pleural effusion. Thoracentesis yielded exudative fluid negative for AFB and malignant cells. VATS performed for the loculated effusion yielded bronchial washings, pleural fluid, and pleural biopsy; however, all specimens obtained by hospital day 7—three pleural fluid aspirates, two intrapleural cultures, six bronchial washings, and several sputum cultures—were AFB negative by stain and culture. Pleural biopsy was negative for granulomatous change. The patient had cough and intermittent fevers throughout hospitalization. Due to positive PPD and symptoms suggestive of active TB, quadruple-agent therapy [rifampin, isoniazid, pyrazinamide, and ethambutol (RIPE)] with pyridoxine. For confirmatory evidence, further bronchial washings and pleural biopsies were obtained via bronchoscopy. Pathology, revealing necrotizing granulomatous inflammation of the recently-biopsied pleura, first confirmed the tuberculous effusion on hospital day 19. Over the next week, acid-fast bacilli grew in bronchial washings that were collected over hospital days 7–14. After 2 weeks of treatment, isolation precautions were lifted by the New York State Department of Health and the patient was discharged for 6 months of outpatient therapy.
DISCUSSION: Tuberculous effusion is the second most common form of extrapulmonary tuberculosis (TB) after tuberculous lymphadenitis. Despite its frequency, tuberculous effusion can be a diagnostic challenge given the low sensitivity of available tests. The effusion, an immune-mediated process, is typically exudative and lymphocyte-predominant. Cultures for acid-fast bacilli (AFB), therefore, are positive in only 20–30 % of pleural fluid samples and in 50–80 % of pleural biopsies. Here we present a case of tuberculous effusion as the first manifestation of active TB infection in an immunocompetent host. Diagnosis of tuberculous effusion may be missed if treatment is held for positive culture; therefore, physicians must suspect TB in patients with lymphocytic effusions and initiate treatment based on clinical suspicion.

TYPE B INSULIN RESISTANCE SYNDROME: A RARE TYPE OF DIABETES MELLITUS Glynda Caga-anan[1,2]; Iris De Castro[1,2]; Jeffrey T. Bates[2]; Morali Sharma[1]. [1]Baylor College of Medicine, Houston, TX; [2]Michael E. DeBakey VA Medical Center, Houston, TX. (Tracking ID #1642465)

LEARNING OBJECTIVE 1: Recognize the clinical and diagnostic features of Type B Insulin Resistance.
LEARNING OBJECTIVE 2: Manage Type B Insulin resistance with immunosuppressive therapy.
CASE: The patient is a 27-year-old Asian male, with recent diagnoses or SLE and a mixed connective tissue disorder, who presented to his primary care physician complaining of a 2 month history of polydipsia, polyuria, a 20-pound weight loss, and darkening of the skin on his posterior neck, back, and axilla. There was no family history of diabetes. He was diagnosed with type II diabetes mellitus and treated with maximum doses of metformin, pioglitazone and glipizide with no improvement of his HgbA1c. Eight months after his diagnosis, he was seen by an endocrinologist who noted the severe acanthosis nigricans and started the patient on insulin, again with no improvement in his glycemic control. Laboratory studies revealed HgbA1c of 9.7 %, fasting glucose >300 mg/dl, WBC 2.6 K/ml, insulin level of 187 uIU/mL (normal <17), and insulin antibody level of 4 U/ml (normal<0.5). Anti-GAD and anti-IA2 antibodies were negative. The patient's serum was sent to the University of Cambridge and confirmed to have a strongly positive antibody against the insulin receptor, and he was subsequently diagnosed with type B insulin resistance. Over the next 9 months, the patient was treated with rituximab, cyclophosphamide, and pulse dose steroids per a National Institutes of Health (NIH) protocol. Repeat laboratory studies showed HgbA1c 6.8 %, fasting glucose of 64 mg/dl, and resolution of his leukopenia. Six months after the end of immunosuppressive therapy, he was no longer taking any medications, his HgA1c was 5.4 %, his insulin level had normalized to 4 uIU/mL, he had regained all his weight, and his acanthosis nigricans had nearly resolved.
DISCUSSION: In contrast to the usual mechanism of type II diabetes mellitus, which results from a complex interaction among many genes and environmental factors, type B insulin resistance syndrome results from autoantibodies formed against the insulin receptor. Although its exact prevalence is unknown, its diagnosis remains rare. Our patient presented with typical features of this syndrome: extreme insulin resistance (insulin level >200 uU/ml), hyperglycemia refractory to massive doses of insulin (average dose 5100units/day), dramatic weight loss (average 43±26 pounds), severe hyperandrogenism, and unusually widespread acanthosis nigricans. The disorder commonly occurs in the background of a rheumatologic illness or other autoimmune disorders. The presence of autoantibodies is confirmed by immunoprecipitation of recombinant human insulin receptors. Recognition of this syndrome remains important, as it affects both treatment and prognosis. Treatment of the syndrome is aimed not only at correcting the metabolic derangements but also controlling the production of autoantibodies. The National Institutes of Health published a treatment protocol in 2010, consisting of rituximab, cyclophosphamide, and steroids; azathioprine or cyclosporine can be utilized for maintenance once the patient is in remission. The mortality rate in this syndrome is high, but it appears to be largely determined by the severity of the other underlying systemic diseases. Our patient responded well to the immunosuppressive regimen, with recovery to euglycemia without any anti-diabetic medications and resolution of severe insulin resistance and its metabolic consequences.

TYPICAL PRESENTATION OF AN UNCOMMON CAUSE OF BACK PAIN Gurkaran Garcha; Priti Dangayach; Himabindu Kadiyala. Baylor College of Medicine, Houston, TX. (Tracking ID #1631227)

LEARNING OBJECTIVE 1: Recognize the clinical features of a psoas abscess
LEARNING OBJECTIVE 2: Review the appropriate diagnostic and therapeutic measures for management of a psoas abscess.
CASE: A 57 year old male presented to the Emergency Room with gradual onset right sided back/flank pain and fevers. It started as a dull ache and progressed to 10/10 pain that was achy and relentless. The pain was worse with movement especially getting out of bed and was controlled when he lay still. There was no history of trauma, dysuria, diarrhea, or constipation. No history of intravenous drug use. No changes in bowel or bladder function. The physical exam was significant for a Temperature of 1020 F, right costovertebral angle tenderness, and worsening pain with active hip flexion and passive hip extension. A CT scan of the abdomen and pelvis without contrast was normal. Blood cultures were positive for methicillin susceptible S.aureus. A Subsequent MRI of the Lumbar spine showed ill-defined focal edema with enhancement present in the right psoas muscle anteriorly at the level of L-3 measuring 4×1.5×1.5 cm in size, no drainable fluid was present. A TEE was negative for vegetations. The patient was

treated with 6 weeks of intravenous nafcillin. Subsequent blood cultures were negative. The patient made a full recovery after this treatment course and repeat MRI 8 weeks after treatment showed resolution of the psoas abscess.

DISCUSSION: Psoas abscess is a relatively rare pathology with some large tertiary care centers reporting 5–12 cases per year. A primary psoas abscess occurs as a result of hematogenous or lymphatic seeding from a distant site whereas a secondary psoas abscess occurs as a result of direct spread of infection to the psoas muscle from an adjacent structure. Intravenous drug use is the most commonly reported risk factor for a primary abscess. Recent abdominal or retroperitoneal surgery and inflammatory bowel disease are the most common risk factors for secondary abscesses in the U.S. S. aureus is widely reported to be the most common pathogen recovered in primary psoas abscesses. S.aureus is also a frequent cause of vertebral osteomyelitis leading to secondary psoas abscesses. Secondary abscesses are generally considered to be caused by enteric organisms. The treatment is centered around drainage of the abscess and parenteral antibiotics. Traditionally, extra-peritoneal surgical drainage was considered to be the treatment of choice. However, more recently CT guided percutaneous catheter drainage is has reported>95 % success rate in several case series and is now thought to be the first line treatment. Surgical drainage is still considered first line treatment by some authors when the cause is inflammatory bowel disease. There is also limited retrospective data showing successful treatment of abscesses<2 cm with antibiotics alone, however, this practice is not routine. Our patient presented with the classic clinical signs of expected with a psoas abscess. This case also highlights that repeat imaging may be necessary to confirm the diagnosis of this evolving pathology, especially when the initial results are inconsistent with the overall clinical picture.

UNEXPANDABLE LUNG SECONDARY TO SPONTANEOUS BACTERIAL PLEURITIS WITH RESOLUTION AFTER LIVER TRANSPLANTATION Zahrae Sandouk; Dania Khoulani; Ghassan Bandak; Alan Betensley. Henry Ford Hospital, Detroit, MI. (Tracking ID #1617890)

LEARNING OBJECTIVE 1: Diagnose spontaneous bacterial pleuritis in the setting of liver disease.

LEARNING OBJECTIVE 2: Recognize unexpandable lung as a complication of spontaneous bacterial pleuritis

CASE: 60 years old man with ulcerative colitis and end stage liver disease secondary to primary sclerosing cholangitis, a candidate on the transplant list, was admitted to the hospital with acute renal failure and spontaneous bacterial peritonitis diagnosed after one of his weekly sessions of paracentesis. He had been complaining of weakness, loss of appetite, reduced urine output and significant shortness of breath 2 weeks prior. His labs revealed elevated white blood count, creatinine and potassium. He was started on dialysis for uncontrolled hyperkalemia and ceftriaxone for his peritonitis. His chest X ray on admission revealed complete opacification of the left hemithorax. Multiple thoracocenteses were performed removing a total of 5.6 l of cloudy non bloody fluid until no more fluid could be aspirated. Pleural fluid analysis revealed a transudative pattern with elevated ANC of 554 cells/mm, negative culture, gram stain and cytology. He was continued on ceftriaxone. The patient's shortness of breath improved significantly, however repeat chest X-rays continued to show unchanged left sided opacification. Despite the large volume removed, his lung did not fully expand. On day 9 of hospitalization, he underwent liver transplant successfully. He was followed for two more weeks prior to discharge. Surveillance chest Xrays were performed every day and he had full re-expansion of his left lung prior to discharge, without further thoracocentesis following his surgery.

DISCUSSION: Patients with end stage liver disease often develop lung pathologies. Pleural effusions, also called hepatic hydrothorax, are reported in 5–6 % of patients with end stage liver disease. They are mainly right sided or bilateral and less commonly left sided. Spontaneous bacterial pleuritis is uncommon complication. There is limited data defining pleural fluid analysis, echocardiographic characteristics, or CT imaging in patients with spontaneous bacterial pleuritis. It is usually diagnosed clinically after excluding primary pulmonary or cardiac causes. Patients may be asymptomatic or may present with dyspnea, cough, or hypoxemia. They are prone to recurrent bouts of spontaneous bacterial pleuritis with or without concurrent spontaneous bacterial peritonitis. Pleural fluid analysis have a transudative pattern in 63 % of cases with spontaneous bacterial pleuritis, and positive gram stain and cultures only in 29–33 % of cases. Most importantly a pleural absolute neutrophil count above >500 cells/mL is the earliest and most reliable marker for spontaneous bacterial pleuritis. This infection can cause inflammation of the pleural space resulting in unexpandable lung. The common feature is the presence of a visceral pleural peel. The pleural peel does not allow the lung to achieve its characteristic shape, completely filling the chest cavity, after attempted evacuation of the pleural space. Other etiologies for unexpandable lung include malignancy or non-specific inflammation such as cardiac surgery, uremic and rheumatoid effusions. Treatment includes managing the underlying condition, and most unexpandable lungs resolve on their own. Our patient had full left lung re-expansion 2 weeks after his liver transplant with resolution of his ascites and hepatic hydrothorax without any further interventions.

UNUSUAL CAUSE FOR IRON DEFICIENCY ANEMIA Yaser Alkhatib[1]; Philip Kuriakose[2]; Tameem Al-aqtash[1]. [1]Henry Ford Hospital, Detroit, MI; [2]Henry Ford Hospital, Detroit, MI. (Tracking ID #1624077)

LEARNING OBJECTIVE 1: Negative colonoscopy in a clinical settings suggestive of GI bleed like a positive stool for occult blood should prompt the physician to pursue further testing to rule out bleeding from the remaining of the GI tract

LEARNING OBJECTIVE 2: Intestinal melanoma can present with iron deficiency anemia

CASE: A 69 year-old Caucasian male presented to his primary care physician with a new onset dizziness and recurrent episodes of near syncope for 1 month prior to presentation. His past medical history was significant for a cough variant asthma and tubular adenoma, and he was only on albuterol inhaler as needed. He was non smoker, didn't drink alcohol or use any drugs. Physical examination was remarkable for conjunctival pallor. Complete blood count showed microcytic anemia. Stool was positive for occult blood and Iron studies confirmed the presence of iron deficiency anemia. Colonoscopy was negative for masses, polyps or diverticulosis. Esophagogastroduodenoscopy was unremarkable. Subsequently, a capsule endoscopy was performed, which showed a moderate-sized, frond-like, semi-circumferential mass in the jejunum with areas of ulceration and mild active oozing of fresh blood. CT scan of the abdomen and pelvis revealed a small bowel mass in the distal jejunum with adjacent enlarged lymph nodes suspicious for metastatic disease. Exploratory laparotomy was done with resection of the mass in the jejunum. The biopsy was consistent with malignant melanoma, with a histopathology positive for BRAF V600K gene mutation but three negative nodes for metastasis. Patient was evaluated by Dermatology with no dysplastic nevi on full skin evaluation. Ophthalmologic evaluation didn't find any evidence for ocular melanoma. MRI of brain showed only chronic ischemic white matter changes with no radiological finding of metastasis. Post surgical PET-CT was suggestive of hypermetabolism in small bowel at the surgical site, representing normal evolution of postsurgical changes. There was no evidence of residual or recurrent disease.

DISCUSSION: Iron deficiency anemia is the most common cause of anemia. While there are a variety of etiologies for iron deficiency anemia, chronic blood loss should always be on top of the differential diagnosis list. Gastrointestinal tract as a source for blood loss should be always considered, and the need to rule out colorectal cancer is a priority, especially in the appropriate age group. In highly suspicious clinical settings like with a positive stool occult blood, a negative colonoscopy should prompt the physician to pursue further testing to rule out bleeding from the remaining of the GI tract. Mucosal melanoma can originate from the melanocytes of mucosal epithelium of respiratory, gastrointestinal, or genitourinary tracts, unrelated to skin involvement. Isolated intestinal

melanoma is a rare type of melanoma that has different presentations. Herein we present a patient in whom an iron deficiency anemia led to a diagnosis of primary intestinal melanoma.

UNUSUAL PRESENTATION OF MULTIPLE MYELOMA AS VERTEBRAL ARTERY DISSECTION Pahul Singh; Navneet Kaur. SUNY Upstate Medical University, Syracuse, NY. (Tracking ID #1627916)

LEARNING OBJECTIVE 1: Recognize unusual presentation of Multiple Myeloma.
LEARNING OBJECTIVE 2: Treat vertebral artery dissection in an early and prompt manner.
CASE: A 50-year-old female was admitted to our institution for sudden onset of headache, vertigo and left sided neck pain for 2 h duration. Examination revealed normal vital signs, tenderness over the neck posteriorly and horizontal nystagmus to right in both eyes .CT head was unremarkable. CTA head and neck revealed multiple lytic lesions causing acute pathological fracture of C1 cervical vertebra and vertebral artery dissection at that level. MRI brain showed acute cerebellar infarct. Laboratory values showed normocytic normochromic anaemia on complete blood count, total protein of 11.6 (g/dL) and elevated erythrocyte sedimentation rate. Serum protein electrophoresis showed monoclonal band in gamma region. Bone marrow biopsy showed 34 % plasma cells consistent with multiple myeloma. Patient was started on warfarin for anticoagulation and vincristine, doxorubicin and dexamethasone and she has been doing well in last 1 year of follow up.
DISCUSSION: Multiple Myeloma is characterized by malignant clonal proliferation of immunoglobulin secreting differentiated B-lymphocytes and plasma cells. Pathological fracture of cervical spine due to multiple myeloma is rare. Vertebral artery is susceptible to injury or occlusion at the level of C5 and C6 cervical vertebra, atlanto-axial joint and atlanto-occipital joint secondary to stretching or tearing of intima or compression of the artery following cervical fracture or dislocation. Intimal tear can trigger platelet aggregation and clot formation which can lead to embolic stroke. MRI and MRA are non-invasive diagnostic techniques that can be used to evaluate vertebral artery dissection. Angiography is reserved for cases in which MRA is not diagnostic. Treatment with anticoagulation is recommended for 6 months in patients who have neurological symptoms caused by extracranial dissection. For patients with recurrent ischemic events despite adequate antithrombotic therapy, stent placement or surgical treatment may be considered. In summary, vertebral artery dissection is a potentially morbid complication which needs prompt diagnosis to initiate therapy in a timely fashion.

UNUSUAL ASSOCIATION OF IDIOPATHIC THROMBOCYTOPENIC PURPURA AND SARCOIDOSIS- A CASE REPORT Leena Jalota; Shashank Jain. The Reading Heath System, West Reading, PA. (Tracking ID #1642430)

LEARNING OBJECTIVE 1: Recognize that thrombocytopenia can be associated with Sarcoidosis
LEARNING OBJECTIVE 2: Recognize the underlying mechanisms and treatment options for ITP associated with sarcoidosis
CASE: A 39 year old dairy farmer with past medical history of sarcoidosis-currently under no treatment, presented with purpura. On examination there was a significant finding of wet purpura in the oral mucosa and petechiae present all over his body with no evidence of splenomegaly. Platelets on admission were 5,000. Hematology was consulted and the patient was initiated on treatment with standard IVIG and steroids. In addition he was given platelet transfusions in an attempt to increase his platelet count to prevent spontaneous hemorrhage. Over the next 48 h, despite the above lined treatment, his platelet count dropped to a 0. Rituximab was then added to the treatment regimen with no beneficial response. Given the patient's refractory thrombocytopenia, a decision of giving Romiplostim (Nplate) was made to which he thankfully responded. At the time of discharge his platelet count had increased to 81,000 and he was discharged on a tapering dose of dexamethasone and outpatient Romiplostim with an appropriate hematology follow up.
DISCUSSION: Sarcoidosis is a systemic disease of unknown cause characterized by the formation of granulomatous lesions in various organs with a predilection for the lower respiratory tract. Sarcoidosis mostly presents with thoracic involvement. Common extra-thoracic presentations include skin, liver, lymphatics, ocular, upper respiratory, spleen, calcium regulation as well as renal disease. Severe refractory thrombocytopenia associated with sarcoidosis has been infrequently reported in literature. When reported this has been noted to be severe, symptomatic and associated with increased morbidity. It has also been found to be very difficult to treat, with frequent use of 2nd and 3rd line treatment options. Thrombocytopenia can stem from 3 main mechanisms during sarcoidosis: hypersplenism, bone marrow infiltration, and immune thrombocytopenia (ITP), with this later mechanism accounting for majority of cases. In our case our patient's thrombocytopenia was thought to be secondary to ITP. His successful treatment entailed use of Romiplostim, which to our knowledge is being reported for the first time in this setting. It's imperative that clinicians anticipate this rare complication of sarcoidosis, its underlying mechanisms, and be ready to treat it aggressively if need be.

UNUSUAL PRESENTATION OF A RARE DISORDER Yogita Segon; Ankur Segon. Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #1609464)

LEARNING OBJECTIVE 1: Review an unusal presentation of rapidly progressive glomerulonephritis due to anti-glomerular basement membrane disease
LEARNING OBJECTIVE 2: Know the differential diagnosis and management of pauci-immune glomerulonephritis
CASE: Forty-four year old African-American male with presented with 3 weeks of persistent nausea, vomiting and decreased urine output. He was found to be anemic with hemoglobin of 7.6 gm/dL and serum creatinine of 5.76 mg/dL. Urine-analysis showed proteinuria with marked microscopic hematuria. Kidney biopsy showed rapidly progressive glomerulonephritis with crescent formation in 65 % of all glomeruli. Immunofluorescence was negative for IgA, IgG or IgM. There was no clinical or radiographic evidence of pulmonary involvement. He was started on pulse dose steroids and cyclophosphamide for pauci-immune crescentic glomerulonephritis. His renal function continued to decline and he was treated with 7 sessions of plasma exchange. ANA, ANCA and complement level returned negative. Anti-glomerular basement membrane (anti-GBM) antibody eventually returned strongly positive (152 units, normal 0–20 units). His creatinine peaked at 7.69 mg/dl and then down-trended to 3.95 mg/dl. Dialysis was not required. He was discharged on cyclophosphamide and steroid taper. His kidney function returned to normal after 7 months of treatment while his anti-GBM antibody level declined to 5 units after 4 months of treatment.
DISCUSSION: Patients who develop auto-antibodies directed against glomerular basement antigens frequently develop a glomerulonephritis termed anti-glomerular basement membrane (anti-GBM) disease. When they present with lung hemorrhage and glomerulonephritis, they have a pulmonary-renal syndrome called Goodpasture's syndrome. The performance of an urgent kidney biopsy is important in suspected to confirm the diagnosis and assess prognosis. Anti-glomerular basement disease is a rare disorder that affects 1 in one million patients. Caucasians are the most frequently affected racial group. Peak incidence is seen in the third, sixth and seventh decades. Lung involvement is seen in two-third of patients. Immunofluorescence shows pathognomonic IgG linear deposition along glomerular capillaries. Patients with more than 30 % crescents on renal biopsy, an initial creatinine greater than 3 mg/dL and need for dialysis within 72 h of presentation are more likely to require long term dialysis and renal transplantation. Our patient with anti-GBM disease had several atypical features. While anti-GBM disease can present at any age and in all racial groups, presentation in an African American male in the fourth decade is less common. Pauci-immune crescentic glomerulonephritis is typically secondary to ANCA-associated vasculitis. Absence of immunoglob-

ulins on immunoflorescence in anti-GBM disease is virtually unknown. Finally, our patient had a good response to plasma exchange and immunosuppression inspite of having 65 % crescents on renal biopsy and an initial creatinine of 5.7 mg/dl.

UNUSUAL PROGRESSION OF WEST NILE VIRUS POLIOMYELITIS Arvind Kalyan Sundaram[1]; Vibha Inamdar[2]; Patrick L. Gordan[1]; Greg Lipshutz[1]. [1]Mount Auburn Hospital, Cambridge, MA; [2]Boston VA healthcare, West Roxbury, MA. (Tracking ID #1642819)

LEARNING OBJECTIVE 1: Recognize the presentation and progression in a patient with West Nile Virus poliomyelitis
LEARNING OBJECTIVE 2: Prognosis of WNV poliomyelitis does not always correlate with MRI findings.
CASE: Seventy Year old Caucasian woman with past medical history significant for ITP, Hypothyroidism, Hypertension and Hyperlipidemia presented after a fall while getting out of bed following days of rapidly progressing bilateral lower extremity weakness preceded by rash and fever a week before presentation. The rash was described as generalized, non-pruritic, red papules more on the arms and legs compared to the torso. The fever was intermittent with peak temperature of up to 102 ° F associated with vomiting and loose stools. She was initially treated as a viral syndrome with supportive care. Over several days, her rash markedly improved but she developed significant weakness in her lower extremities, which gradually involved the upper extremities. Physical exam was remarkable for bilateral 2/5 strength in Iliopsoas, 2/5 in the quadriceps, dorsiflexors and plantar flexors, 4/5 strength in upper extremity, diminished vibratory sense in MTP joint and absent reflexes in the lower extremity. Lumbar puncture showed CSF pleocytosis with WBC 210, RBC 3 and protein 88. Her serology study came back positive for West Nile virus. A spinal MRI showed abnormal T2 signal in C3-C6 level preferentially involving the grey matter of the cervical ventral horns. She was monitored with serial neurological checks and NIF's for her respiratory function status. She was initially started empirically with Ceftriaxone, Doxycycline and Acyclovir but later discontinued based on her serological and clinical findings. After 2 days, patient showed rapid improvement in her symptoms and was later referred to a rehabilitation center for regaining her baseline physical status.
DISCUSSION: WNV is the most common cause for viral encephalitis in the United States. Neuroinvasive disease caused by WNV involves only around 1 % of the affected population. Among the various presentations, acute WNV poliomyelitis is extremely rare. Our patient uniquely recovered from the flaccid paresis within days while patients with typical neuroinvasive diease usually tend to have a prolonged recovery period taking months. Another interesting finding in our case was the MRI imaging in which according to known literature increased T2WI signal intensity involving the spinal cord indicates poorer prognosis while our patient had successively regained her strength in days. In summary, our patient is an atypical case of WNV presenting as flaccid paresis with rapid recovery of strength spontaneously and contradicts the correlation with the MRI findings.

UPPER EXTREMITY VENOUS THROMBOSIS-CALM BEFORE THE STORM Ankit Madan; Pooja Sethi; Kavita Tripathi. University of Alabama Birmingham Montgomery, Montgomery, AL. (Tracking ID #1642865)

LEARNING OBJECTIVE 1: Recognize that idiopathic upper extremity vein thrombosis is rare but can occur secondary to an underlying malignancy.
LEARNING OBJECTIVE 2: Initiate appropriate investigations promptly once malignancy is suspected in the absence of underlying head and neck pathology or a hematological disorder.
CASE: 23 year old Caucasian female presented with of swelling of left upper extremity for 3 days. She denied pain, fever, chills, night sweats, trauma, insect bite, weight loss, smoking or medication use. No significant past medical or family history. On examination, she was a well-built female with stable vital signs. There was swelling and tenderness of left side of neck and left arm. There was no palpable cervical, axillary, supraclavicular or inguinal lymphadenopathy. Rest of the examination was normal. All her initial lab work was normal except D-dimer which was 6.14 mg/L (high). Protein C, protein S and anti-thrombin level were normal. Chest x-ray was normal. Doppler ultrasonography of left upper extremity revealed left internal jugular vein thrombosis. CT angiogram of left upper extremity revealed thrombosis and non-visualization of left subclavian vein. CT angiogram of chest revealed anterior mediastinal mass measuring 3.7 and 7.4 cm in dimensions. Subsequent biopsy of the mediastinal mass revealed large B cell lymphoma with strong expression of CD 20 and CD 45 on immunohistochemical staining. Patient was discharged on low molecular weight heparin for anticoagulation and right internal jugular vein infusion port was placed for chemotherapy to be received as an outpatient.
DISCUSSION: There is 3 to 19-fold increase in idiopathic venous thromboembolic events in presence of an underlying malignancy. This is due to tumor cells activation of coagulation cascade by directly stimulating thrombin formation or induction of mononuclear cells to synthesize procoagulants like tissue factors, prothrombin and factor 5 activators. Internal jugular vein thrombosis can also occur as part of superior vena cava syndrome which mostly occurs secondary to malignancy. Other causes of upper extremity vein thrombosis include central venous catheters, thrombophilic states, congestive heart failure, renal failure, intravenous drug abuse, deep neck infections and use of contraceptives. The cause in our case is either underlying hypercoagulability or compression of the vein by the mass causing blood stasis and ensuing thrombosis. It presents as pain and swelling in the neck and can lead to complications like pulmonary embolism, septic emboli, facial swelling, increased intracranial pressure and even loss of vision. Doppler ultrasonography is an excellent way of diagnosing venous thrombosis with a sensitivity of 97 %. Computed tomography and magnetic resonance imaging can be used to delineate an overlying mass or an underlying malignancy. Internal jugular vein thrombosis can propagate in the absence of anticoagulation and cause pulmonary embolism. Treatment must be individualized. It includes anticoagulation with low-molecular weight heparin and warfarin or rivaroxaban. Superior vena cava filters are used rarely in patients with contraindications to anticoagulation or at increased risk of bleeding. Definite treatment and prognosis depends on the underlying cause.

VITAMIN E N-E-U-R-O-P-A-T-H-Y Dana Ellis; Neal Viradia; Deepa Bhatnagar. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640197)

LEARNING OBJECTIVE 1: Identify the differential diagnosis of neurological symptoms in post-gastrectomy patients
LEARNING OBJECTIVE 2: Recognize nutritional and metabolic deficiencies in bariatric surgery patients and the optimal treatment
CASE: A 37-year-old African American woman had an out-of-country gastric sleeve procedure 3 months prior to presentation. The surgery resulted in intractable nausea, vomiting and a 90-pound weight loss. Upon presentation the patient complained of 2 weeks of numbness and tingling in her bilateral lower extremities, which lead to numerous falls. She denied any bladder or bowel incontinence. The patient's home medications included a multivitamin with iron, folate at 1 mg daily, weekly vitamin B12 injections, potassium chloride at 20 mEq daily, promethazine for nausea and omeprazole for gastric reflux. On neurological exam, mental status and speech were appropriate, and cranial nerves II through XII were intact bilaterally. The patient had 5/5 strength in the upper and lower extremities bilaterally. She was responsive to light touch over her lower back, torso and bilateral lower extremities and had intact proprioception when the great toe was moved up and down with the eyes closed. She had slightly diminished sensation to temperature above the level of the mid-calf, and she had decreased pinprick sensation above the level of the mid-calf and below the level of L2. Vibration sensation was diminished over the medial malleoli bilaterally. MRI showed no evidence of spinal cord compression and transverse myelitis. We obtained ferritin, vitamin B12 and methylmalonic acid, homocysteine, 1,25-dihydroxyvitamin D and vitamin E (alpha-tocopherol) levels; thyroid stimulating hormone; HIV; RPR; hemoglobin A1C; along with serum ceruloplasmin and selenium levels. All

of her labs came back within normal limits, except for her level of vitamin E, which was low at 4.0 mg/L (normal=5.5–18.0 mg/L).
DISCUSSION: Neurologic complications following bariatric surgery are most commonly associated with nutritional deficiencies in vitamins and minerals such as thiamine (B1), B12, folate, and copper. The associated complications can involve many areas of the nervous system and include encephalopathy, optic neuropathy, myelopathy, polyradiculoneuropathy, and polyneuropathy. Vitamin E deficiency is very rare in all forms of bariatric surgery. The most common findings of low vitamin E levels include loss of deep tendon reflexes, truncal and limb ataxia, diminished perception of vibration and position, ophthalmoplegia, muscle weakness, ptosis, and dysarthria. Low vitamin E levels have been found 6–12 months after surgery but symptoms may not appear for 5–10 years. Guidelines suggest that post-bariatric surgery patients take multivitamins that contain folate, calcium citrate, vitamin D, elemental iron, and vitamin B12. Because of the rarity of vitamin E deficiency following bariatric surgery, there are no set guidelines suggesting these patients take vitamin E supplements. However vitamin E neuropathy and myopathy are often treatable. In this case, the recommended daily dose of vitamin E is 400 IU. Differential diagnosis of neurological symptoms in post-gastrectomy patients should always include hypovitaminosis E, and a vitamin E level should be obtained. Early detection could lead to earlier resolution of symptoms.In order to prevent post-surgical vitamin E deficiency and associated neurological complications, perhaps guidelines should include a standard multivitamin formulation rich in vitamin E.

VARIATIONS ON A THEME: ATYPICAL HEMOLYTIC UREMIC SYNDROME IN A PATIENT WITH ADULT-ONSET STILL'S DISEASE Shail Rawal[1]; Katerina Pavenski[3]; Louise Perlin[2]; Laurence Rubin[2]; Martina Trinkhaus[3]; Yael Einbinder[4]. [1]University of Toronto, Toronto, ON, Canada; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]St. Michael's Hospital, Toronto, ON, Canada; [4]St. Michael's Hospital, Toronto, ON, Canada. (Tracking ID #1628512)

LEARNING OBJECTIVE 1: Recognize the clinical features of atypical hemolytic uremic syndrome.
LEARNING OBJECTIVE 2: Describe the pathogenesis of atypical hemolytic uremic syndrome and its treatment.
CASE: A previously healthy 26 year-old woman was admitted to a peripheral hospital following a several month history of rash, myalgias, serositis and fevers. Complications in hospital included peritonitis requiring laparotomy with no pathology identified, and acute left-sided vision loss with a diagnosis of an acute retinal artery occlusion. A diagnosis of Adult-Onset Still's Disease (AOSD) was made on the basis of her rash, serositis (peritonitis, pericarditis, pleuritis), fever, granulocytosis, and a ferritin of > 1,500 nmol/L. Therapy with oral prednisone was initiated and her symptoms improved. The etiology of her retinal artery occlusion remained unclear, and she was discharged home with Rheumatology and Ophthalmology follow-up. In the weeks following discharge, she developed shortness of breath, generalized weakness, and progressive vision loss. Investigations were consistent with a thrombotic microangiopathy (TMA) and acute kidney injury. A presumptive diagnosis of TTP/HUS was made, and she was transferred to St. Michael's Hospital in Toronto for plasmapheresis (PLEX) and hemodialysis. Her clinical condition improved with plasmapheresis and pulsed corticosteroids, and she was discharged home on oral prednisone with hemodialysis. Within days of discontinuing her PLEX, she developed headache, vision loss, malignant hypertension and an altered level of consciousness/seizure. Investigations showed recurrence of her thrombotic microangiopathy. Genetic testing performed through the Hospital for Sick Children in Toronto revealed an activating mutation in C3 in the complement pathway. Therapy with eculuzimab (Soliris) was initiated for atypical hemolytic uremic syndrome (HUS). Markers of hemolysis normalized within 12 h of commencing therapy and hemodialysis was no longer required. The patient was discharged home 1 week later on oral prednisone and a plan to continue eculizumab.
DISCUSSION: Fifteen cases of TMA occurring in patients with AOSD are described in the literature. TMA typically occurs early in the disease course and is associated with an altered level of consciousness/seizures, acute kidney injury and vision loss. To our knowledge, this is the first case report to describe atypical HUS in a patient with AOSD. Ten percent of HUS cases are classified as atypical as they are not precipitated by Shiga-like toxin. Rather, atypical HUS is a disease of uncontrolled complement activation that is either familial or sporadic and is associated with a high mortality rate. Eculizumab is a humanized monoclonal antibody against C5 that inhibits terminal complement activity and has recently received FDA approval for atypical HUS. Our case adds to the growing body of evidence that suggests that eculizumab may be used to successfully treat atypical HUS in adult patients.

VENTRICULAR SEPTAL RUPTUREA AS A RARE IMMEDIATE COMPLICATION OF ACUTE MYOCARDIAL INFARCTION Abhilash Akinapelli; Jaya S. Gupta; Showri Karnam; Andrew G. De Nazareth; Susan M. Schima. Creighton University Medical centre, Omaha, NE. (Tracking ID #1643279)

LEARNING OBJECTIVE 1: To be aware that ventricular septal rupture can also occur as an immediate complication of an acute myocardial infarction.
LEARNING OBJECTIVE 2: Physical exam plays a key role in early identification of these patients at risk to enable prompt life saving treatment.
CASE: A 78 year old woman was transferred from an outreach hospital with an acute anterior ST elevation myocardial infarction. She presented with acute onset substernal chest pain of 20 min duration that was accompanied by dyspnea, nausea, and diaphoresis. Thrombokinase was administered and she was transferred to our coronary care unit within 2 h. Upon arrival, exam revealed grade III/VI pansystolic murmur best heard at left sternal border and jugular venous distention. Immediate bedside transthoracic echocardiogram (TTE) was performed which revealed ventricular septal defect (VSD). She immediately underwent coronary angiography, which showed single vessel disease, a 99 % stenosis of the distal left anterior descending artery. Stent deployment was not possible secondary to extensive calcification of the vessel, however balloon angioplasty provided TIMI III flow. Left ventriculogram confirmed VSD. An intra-aortic balloon pump was placed to help decrease afterload. Patient underwent VSD repair the following morning. Intraoperatively, she was found to have a hemorrhagic septum, and a large area of septum was removed and patched. Her postoperative course was complicated by cardiogenic shock and oliguria. On the fourth postoperative day she became hypotensive, bradycardic, and suffered cardiac arrest. Despite sustained efforts, she was unable to be resuscitated.
DISCUSSION: Ventricular septal rupture, before the thrombolytic era, complicated 1–2 % of acute myocardial infarctions. Reperfusion therapy decreased the incidence of septal rupture to 0.2 %. It typically occurs 2–8 days after an acute myocardial infarction. In patients undergoing thrombolysis for acute myocardial infarction, the risk factors for septal rupture include advanced age, female sex, hypertension, extensive myocardial infarction and absence of smoking. Incidence of rupture is increased in those with single vessel disease, who have less evidence of collateral circulation. Prior angina or infarction may lead to myocardial preconditioning with development of collateral circulation, both of which reduce the likelihood of developing septal rupture. The median time from the onset of infarction to rupture is comparatively shorter at 24 h in patients receiving thrombolysis. Typical presentation of ventricular septal rupture includes clinical deterioration of a patient with recent myocardial infarction. Signs may include increasing dyspnea, chest pain, and cardiogenic shock. Clinical evidence on exam of a harsh pansystolic VSD murmur along the left lower sternal border should raise suspicion. Doppler Echocardiography is usually diagnostic. The sensitivity and specificity has been reported to be as high as 100 %. In current practice, ventricular septal rupture is considered a surgical emergency. Current guidelines from the American College of Cardiology-Americal Heart Association recommend immediate operative intervention in patients with septal rupture. Long term survival is improved in patients who undergo

prompt surgey. Further benefit is seen in those patients who undergo concurrent coronary artery bypass grafting surgery, if clinically indicated.

VERTEBRAL OSTEOMYELITIS PRESENTING AS ATYPICAL CHEST PAIN Janine Adamczyk; Aaron Fox. montefiore medical center, Bronx, NY. (Tracking ID #1642271)

LEARNING OBJECTIVE 1: Recognize vertebral osteomyelitis as an uncommon cause of chest pain or back pain
LEARNING OBJECTIVE 2: Review the pathogenesis, diagnosis and treatment of the disease
CASE: A 58 year-old female presented with worsening chest pain for 1 month. The pain was constant, 8/10 in severity, worsening with deep inspiration and physical activity and located substernally with bilateral radiation below her breasts. Three months ago, she had started physical therapy for new-onset low back pain (which had resolved) and initially attributed the chest pain to a muscle strain. She was afebrile, had clear lungs and a regular heart rate and rhythm without murmurs. Tenderness was reproducible in a band-like distribution over her sternum, ribs and medial thoracic vertebrae. Her chest X-ray was clear and her laboratory showed negative cardiac enzymes, no leukocytosis, hemoglobin 10.9 g/dL and erythrocyte sedimentation rate of 120 mm/h. Magnetic resonance imaging (MRI) revealed multi-level discitis /osteomyelitis of the thoracic spine (T6/T7), the cervical spine (C6/C7) and lumbar spine (L3/L4) with kyphotic angulation and compression of the thecal sac. The patient denied any neurologic symptoms, any drug use or dental procedures. Several blood cultures grew methicillin-sensitive staphylococcus aureus (MSSA). She was started on a six-week course of antibiotic therapy with nafcillin, fitted a spinal brace and ruled out for endocarditis by negative transesophageal echocardiogram.
DISCUSSION: Complaints of chest pain or low back pain are frequently encountered in the primary care office. Imaging for low back pain is not recommended within 6 weeks of symptom onset unless "red flags" are present (i.e. neurological symptoms or suspicion of osteomyelitis). Osteomyelitis of the vertebrae and disc space most commonly occurs due to hematogenous spread from a distant site of infection (e.g. intravenous catheters, endocarditis or dental infections) and due to local instrumentation or an adjacent soft tissue infection. Given increasing rates of nosocomial bacteremia, an aging population and injection drug use, the incidence of the disease is rising (1:145 000) and it primarily affects men over 50 years of age. Staphylococcus aureus accounts for more than 50 % of cases. Gram negative bacilli, pseudomonas and mycobacteria are other important pathogens. Clinically, it manifests as progressive back or neck pain and less than 50 % of patients are febrile. As plain X-rays are often normal, an MRI is recommended for diagnosis and has a sensitivity of 91 % within the first 2 weeks of symptoms and of 96 % thereafter. Most commonly, vertebral osteomyelitis responds to antimicrobial therapy (at least 6 weeks) which is usually withhold till the causative organism is identified. If blood cultures are negative, a computed tomography-guided needle biopsy of the spine needs to be performed. Surgery is indicated in threatened cord compression, spinal instability or progression despite medical therapy. Vertebral osteomyelitis has a 5 % mortality rate and, given an often delayed diagnosis, up to 7 % of patients experience permanent neurologic complications. Early diagnosis of the disease led to a complete recovery in our patient.

VINEGAR CAUSING CHEMICAL PNEUMONITIS AND SUBSEQUENT BROKEN HEART: A RARE CASE OF ACCIDENTAL VINEGAR INHALATION RESULTING IN TAKOTSUBO CARDIOMYOPATHY Soujanya Sodavarapu; Amanada Scott; Richard Belkin; Thomas D. Watson. Santa Barbara Cottage Hospital, Santa Barbara, CA. (Tracking ID #1624593)

LEARNING OBJECTIVE 1: Stress induced (Takotsubo) cardiomyopathy has been classically attributed to an intense emotional or physical stress, therefore it has also been known as broken heart syndrome. It is thought that during such an intense state, excessive serum catecholamine levels cause apical hypokinesis and therefore diminished left ventricular systolic function. This case illustrates an interesting and largely unseen cause of Takotsubo syndrome secondary to accidental inhalation of household vinegar. Most reported cases of vinegar inhalation are related to industrial accidents and result in chemical pneumonitis. This is the first reported case of household vinegar inhalation inducing not only chemical pneumonitis, but also Takotsubo syndrome.
CASE: A 77-year-old female with a history of controlled hypertension was doing a daily sinus treatment at home when she accidentally used distilled vinegar instead of distilled water. She began the sinus rinse and immediately realized her mistake, however she had already inhaled a small amount of the vinegar. Soon she developed severe shortness of breath and was brought to the emergency department (ED) by her family. In the ED she required 100 % oxygen via a bag valved mask with an oxygen saturation of only 66 %; she was therefore intubated for acute respiratory hypoxemic failure. An EKG obtained in the ED showed fairly diffuse S-T segment elevation, which was most marked in the inferior and lateral leads. The patient was quickly taken to cardiac catheterization which demonstrated patent coronary arteries as well as the typical findings of Takotsubo syndrome. An echocardiogram showed an ejection fraction of 30–35 % with apical, septal, anteroseptal, anterior, inferior, posterior, and lateral wall motion hypokinesis. The patient was then transferred to the medical intensive care unit where she required aggressive diuresis and had repeated bouts of respiratory failure, necessitating intubation a total of two additional times. She developed recurrent episodes of pulmonary edema in the setting of atrial fibrillation. Medical management included the use of amiodarone, coreg, lisinopril and lasix. Her condition slowly improved over the course of her week-long admission and prior to discharge she was saturating well on room air. She was discharged with pulmonary and cardiology follow up. A follow up echocardiogram in 1 month showed normalization of her global hypokinesis and ejection fraction.
DISCUSSION: The etiology of Takotsubo cardiomyopathy remains uncertain and it is likely that the cause is multifactorial. One mechanism that has been proposed is that this syndrome is the result of high levels of catecholamines and stress-related neuropeptides. In this case, a generally healthy elderly female developed chemical pneumonitis after vinegar inhalation; this stress likely resulted an excess release of catecholamines. There could also be a direct affect of vinegar on her cardiac function which is unknown. This is the first reported case in which chemical pneumonitis from inhaled household vinegar acted.

VIRAL MENINGITIS FROM HERPES SIMPLEX VIRUS TYPE-2 Brienne Miner. Yale New Haven Hospital, New Haven, CT. (Tracking ID #1645055)

LEARNING OBJECTIVE 1: Recognize HSV-2 as a common cause of viral meningitis.
LEARNING OBJECTIVE 2: Recognize a possible link between HSV-2 meningitis and spinal steroid injection.
CASE: A 66-year-old woman with chronic low back pain despite previous lumbar spinal fusion presented with nausea, vomiting, headache, photophobia and neck stiffness. The headache began after a spinal epidural steroid injection for back pain 3 weeks prior to presentation. It persisted despite treatment with pain relievers consisting of butalbital, acetaminophen and caffeine. She denied any history of similar symptoms in the past. In the emergency room the patient had a fever of 104° Fahrenheit. A lumbar puncture showed the following results: opening pressure 39 cmH20, protein 310 mg/dL, glucose 48, 1,200 white blood cells with 86 % lymphocytes, and 2 red blood cells. The results of the PCR from the cerebrospinal fluid showed HSV-2. She had no genital lesions at the time of presentation, had not been sexually active for over 20 years, and denied a history of genital herpes infection or meningitis in the past. The patient received IV acyclovir and supportive therapy. Her symptoms gradually improved and she was discharge from the hospital 5 days after admission on PO acyclovir for a total of 14 days.

DISCUSSION: HSV-1 is a common cause of viral encephalitis. While we often associate HSV-2 with genital herpes, it is also the most common cause of viral meningitis (1). HSV-2 can present as a primary CNS infection with fever and meningeal signs, and can also lead to recurrent episodes of meningitis. With the advent of a PCR test for HSV, we now know that HSV-2 is the most common etiology for Mollaret's meningitis, also known as benign recurrent lymphocytic meningitis (2). Episodes of meningoencephalitis have been noted in the past, though this presentation is less common (3). Previous studies have noted, as we did with this case, that patients with HSV-2 meningitis often have no history of genital herpes and have no herpetic lesions of the genitalia at the time of presentation (2, 3). The proximity of this patient's presentation to a recent spinal steroid injection is a connection that has been noted previously. In a retrospective observational study of 23 patients with HSV-2-positive cerebrospinal fluid, the authors noted two celibate women who developed HSV-2 associated meningitis and meningoencephalitis after lumbar steroid injection for spinal stenosis (3). The appropriate treatment of uncomplicated HSV-2 meningitis has not been firmly established. Despite the recognition that recurrent lymphocytic meningitis is a benign syndrome that usually resolves spontaneously (4), most patients receive antiviral therapy. The route of administration and duration of this therapy are highly variable and there is no controlled trial data to support the efficacy of antiviral therapy in these patients. WAILINGS & WELLENS' Kate Hust; Anjali Niyogi. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640305)

LEARNING OBJECTIVE 1: Recognize Wellens' sign on EKG tracing.
LEARNING OBJECTIVE 2: Understand implications of Wellens' sign. Identify appropriate work-up and intervention in patient with Wellens' syndrome
CASE: A 42-year-old woman with no known medical history presents complaining of episodic, sub-sternal chest pain for 5 months. Episodes last 20–30 min each and are increasing in frequency and intensity (10/10). No clear pattern of exertional or radiating pain is discernible. Pain is not associated with food. The patient denies orthopnea and paroxysmal nocturnal dyspnea but does endorse non-specific dyspnea on exertion which slows her at times but does not prevent activity. Vital signs are normal. Previously the patient had received morphine and a GI cocktail, both of which temporarily improved her pain. She is screaming loudly and beating her chest in pain. Her chest is tender to palpation, but exam is otherwise unremarkable. Brain natriuretic peptide is normal, and the troponin is <0.01 ng/mL on two occasions, 6 h apart. First and second EKGs show inverted T-waves in leads 1, avL, V1 and V2, with the deepest inversion, including a biphasic component, in V2. Third EKG shows extension of inverted T-waves to V3 and V4.
DISCUSSION: Chest pain is a ubiquitous complaint investigated by internists, and cardiac causes must be quickly investigated. Ischemic etiologies of chest pain are often supported by EKG findings, such as ST-elevation in an acute myocardial infarction. In the absence of ST-elevation and Q-waves, ischemia indicated by Wellens' sign is manifested by deeply inverted t-waves (type A) or biphasic t-waves (type B) in the pre-cordial leads, especially V2 and V3.1 These findings indicate occlusion of the proximal left anterior descending artery (LAD), and extension of the t-wave inversions along the pre-cordial leads suggests an increasingly proximal stenosis. Early recognition of Wellens' sign on EKG is even more critical because it often occurs in the absence of elevated serum cardiac markers, meaning reliance upon a rising troponin will fail to efficiently identify ischemia. Stress testing is avoided in this case as it may provoke an acute myocardial infarction.2 Instead, the LAD stenosis represented by Wellens' sign should trigger urgent revascularization as these EKG findings often herald near total occlusion of the proximal LAD. In an original study, 75 % of cases failed to respond to medical therapy alone and developed an anterior wall myocardial infarction within a few weeks.3 Early recognition of Wellens' sign by internists is critical as its associated ischemia requires immediate attention and intervention.

WHAT'S GOING ON IN THIS MAN'S HEAD? Brian Cruz; Sancia Ferguson. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1640114)

LEARNING OBJECTIVE 1: Recognize corticosteroid use and malignancy as risk factors for Nocardia infection
LEARNING OBJECTIVE 2: Describe the clinical diagnosis of Nocardiosis. Identify treatment options for immunocompetent and immunocompromised patients.
CASE: A 63-year-old man presented with 2 weeks of cough productive of pink sputum and dyspnea on exertion. He was febrile, hypoxic, tachycardic, and had diffuse expiratory wheezes in the mid lung fields and bibasilar crackles. Two months prior he had visual field deficits and right leg weakness, subjective fevers, chills, night sweats, and weight loss. MRI demonstrated 3 enhancing lesions in the left cerebral hemisphere. He was started on dexamethasone for suspected metastatic lung cancer with subsequent improvement in his neurological symptoms. CT angiography of the chest revealed numerous nodular opacities in both lung fields (some with cavitation), a paravertebral mass in the right lower lung, and bilateral consolidation in the lower lobes. Bronchoscopy showed yellowish inflammatory secretions but no evidence of malignancy. Cultures from blood and alveolar lavage were positive for Nocardia species and he was diagnosed with disseminated nocardiosis. Intravenous trimethoprim-sulfamethoxazole and impenem-cilastatin were started. Amikacin was added to the regimen after repeat CT demonstrated progressive disease. Despite initial improvement his mental status declined. Enlarging lesions in left cerebral hemisphere with midline shift were noted on CT scan. Biopsy of the brain yielded poorly-differentiated adenocarcinoma of the lung.
DISCUSSION: The general internist increasingly recognize Nocardia species as causes of localized and systemic infections. Nocardiae are gram-positive, branching, filamentous bacteria that are ubiquitous in soil. While infection can occur in immunocompetent hosts, it is often encountered as an opportunistic pathogen in immunocompromised patients. The most important risk factor for nocardiosis is systemic corticosteroid administration, seen in as many as 62 % of patients. The presence of an underlying solid organ or hematologic malignancy was found in 11 % of nocardiosis patients. Diagnosis of nocardiosis requires a high clinical suspicion. Symptoms such as fever, cough, and pleuritic chest pain are non-specific, their presence in an immunocompromised patient warrants consideration of Nocardia. The organism reproduces slowly on commonly used culture media, often requiring 5–21 days before exhibiting growth. If suspected, special tests and growth media can be employed to isolate the organism and accelerate diagnosis. Skin manifestations may aid in diagnosis and can include cellulitis or subcutaneous nodules. Nocardia brain abscesses are radiographically difficult to distinguish from metastases and may require biopsy. Combination drug therapy is generally used as initial treatment for nocardiosis until susceptibility patterns are identified. Trimethoprim-sulfamethoxazole is the cornerstone of treatment with ceftriaxone, amikacin, imipenem, linezolid, and minocycline also effective against most isolates. Agents with good CNS penetration include TMP-SMX and ceftriaxone. Though Nocardia can successfully be treated in 6–12 months in immunocompetent patients, immunocompromised patients with CNS involvement require 12 months or more of therapy. Successfully treated immunocompromied patients should receive prophylaxis with TMP-SMX, though new data suggest that traditional tri-weekly dosing may be insufficient to prevent recurrence.

WHEN HAVING A BIG HEART CAN BE DANGEROUS Rachel Sandler. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1641539)

LEARNING OBJECTIVE 1: Recognize risks for hemopericardium after cardiothoracic surgery
LEARNING OBJECTIVE 2: Recognize the clinical presentation of cardiac tamponade Identify the classic findings of cardiac tamponade on imaging
CASE: A 32-year-old woman with a history of rheumatic heart disease presented with worsening abdominal pain for 1 day. She also noted palpitations and shortness of breath. Three weeks prior, she underwent mitral valve replacement with St. Jude bileaflet valve and tricuspid valve repair. Two weeks prior, her INR was therapeutic at 2.7. She was in moderate distress with a pulse of 173 and blood pressure of 112/84. Jugular venous pulse was present 4 cm above the sternal angle. Heart sounds were muffled. Epigastrium was diffusely tender to palpation. EKG showed atrial flutter with 2:1 AV conduction. Lactic acid was normal. Her INR was found to be 7.7. Chest x-ray showed a globular heart with increased size from prior films. Bedside echocardiogram revealed a large pericardial effusion. She was taken emergently for pericardiocentesis and 1.6 l of grossly bloody fluid were removed. She underwent subsequent cardioversion.
DISCUSSION: Warfarin is a widely prescribed medication. General internists should be largely familiar with its potential for toxicity given its narrow therapeutic index. Patients started on full-dose anticoagulation with warfarin in the perioperative period have an increased risk for a pericardial effusion. These patients are also more likely to develop larger effusions, putting them at greater risk for cardiac tamponade. Accumulation of the fluid may be seen as late as 30 days after surgery. The recognition of cardiac tamponade is essential in order to quickly treat this condition. Patients in cardiac tamponade are likely to present with symptoms of dyspnea, chest pain and abdominal fullness. Abdominal pain can occur from direct compression of the esophagus by the heart or indirectly from hepatic congestion. Common physical exam findings include tachycardia, hypotension, pulsus paradoxus, and elevated jugular venous pulse. These findings are a result of the increased pericardial fluid limiting diastolic filling pressures and decreasing cardiac output. Chest x-ray with a globular and enlarged cardiac silhouette is highly suggestive of an effusion. Through direct visualization of the heart on echocardiogram at the bedside, a hypoechoic border can be seen around the heart to suggest potential pericardial fluid. In patients who have recently undergone valve replacement surgery on warfarin, the diagnosis of cardiac tamponade must be considered as a potentially life threatening cause of abdominal pain.

WHEN IN DOUBT, SCOPE IT OUT Cady Blackey; Deepa Bhatnagar. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1639858)

LEARNING OBJECTIVE 1: Recognize signs and symptoms of upper gastrointestinal bleeding
LEARNING OBJECTIVE 2: Review a complication of ERCP
CASE: A 62 year-old woman with end stage renal disease presented to the ER with a one-day history of nausea and non-bloody, non-bilious emesis. She complained of constipation. She denied nausea, abdominal pain, hematemasis, melena or hematochezia. One week prior, she was hospitalized for abdominal pain and cholestasis and underwent ERCP with sphincterotomy. Stent was placed in the common bile duct stent for a stricture. Upon presentation, her conjunctivae were pale but anicteric. Her abdomen was soft; no tenderness or organomegaly as palpated. Rectal exam revealed brown stool in the rectal vault. At discharge 3 days prior, her hemoglobin was 8.3 g/dL. On readmission, hemoglobin was 5.6 g/dL. LDH and haptoglobin were normal. Total bilirubin level was normal. Abdominal CT showed gallstones, noted previously, with no hematoma. Nasogastric tube aspirate was negative for blood. She required 4 units of packed red blood cells to maintain her hemoglobin and remained constipated. On the fourth night of readmission, she developed melena on exam. Endoscopic retrograde cholangionpancreatography (ERCP) revealed a bleeding ulcer at the site of the common bile duct stent that was treated with epinephrine, cautery and clipping.
DISCUSSION: In this case, lack of clinical evidence of gastrointestinal (GI) bleeding made the diagnosis challenging. Often internists evaluate for an upper GI bleed based on a history of melena (Likelihood Ratio (LR): 5.1–5.9), melena on exam (LR: 25), or a nasogastric tube aspirate with a bloody or coffee ground appearance (LR: 9.3). These signs and symptoms are all highly suggestive upper GI bleed as cause for acute drop in hemoglobin. However, the findings of melena on rectal exam (sensitivity 49 %) and a bloody or coffee ground aspirate (sensitivity 44 %) are associated with a low sensitivity. Lacking these signs is not sufficient to rule out an upper GI bleed. ERCP has become the preferred method for diagnosis of biliary disease but carries potential for significant complications. While pancreatitis is more common, bleeding due to sphincterotomy may also be seen. Tagged RBC scan or CT angiography may reveal bleeding, but repeat ERCP allows for definitive diagnosis and treatment. Five risk factors for bleeding after ERCP have been identified and include coagulopathy, cholangitis, anticoagulant therapy within 3 days, endoscopist inexperience, and bleeding during the procedure. While this case highlights an uncommon complication of ERCP, internists must be prepared to handle the consequences of biliary tract manipulation.

WHERE HAVE ALL THE MYCOBACTERIA GONE? Rachel Sandler; Kyle Widmer. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1641583)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of pleural tuberculosis
LEARNING OBJECTIVE 2: Identify key laboratory studies consistent with a diagnosis of pleural tuberculosis Recognize nonsurgical approaches to the treatment of pleural tuberculosis
CASE: A 27-year old man from Honduras presented with 2 weeks of worsening dyspnea on exertion. He also noted pleuritic chest pain, sore throat, and night sweats. He was treated 1 week ago with amoxicillin, without improvement. He appeared thin and fatigued. He was breathing 16 times per minute and his oxygen saturation was 97 % on room air. Dullness to percussion persisted up to the third rib along the posterior lung fields with decreased tactile fremitus. His breath sounds were decreased throughout the entire right lung fields, while lungs on the left side were clear to auscultation. Chest radiograph revealed near complete opacification of the right hemithorax. Chest computerized tomography showed a large loculated pleural effusion with surrounding atelectasis. Thoracentesis was performed and revealed an exudative fluid with lymphocytic predominance. Bacterial, fungal and acid fast bacterial cultures of the fluid were negative. Adenosine deaminase of the pleural fluid was elevated to 58, over twice the upper limit of normal. HIV test was negative. PPD was positive to 20 mm. The patient was started on rifampin, isoniazid, pyrimethamine, and ethambutol with resolution of his symptoms.
DISCUSSION: While pleural tuberculosis had previously been a rare cause of exudative pleural effusions in the developed world, the general internist must continue to consider this diagnosis. With the HIV epidemic and global migration, pleural tuberculosis rates are increasingly common. The most common symptoms include pleuritic chest pain, high-grade fever above 38° Celsius, and nonproductive cough. Nonspecific symptoms such as fatigue, night sweats, and weakness may develop acutely with up to two-thirds of patients. The effusion tends to be unilateral and moderate in size. In patients with suspected pleural tuberculosis, definitive diagnosis requires isolation of Mycobacterium tuberculosis from the sputum, pleural biopsy or pleural fluid. Pleural biopsy, although often high yield for mycobacteria, is highly invasive and largely avoided in diagnosis as most clinicians opt for pleural fluid analysis. However, pleural fluid cultures are only positive in approximately 10 % of cases. Pleural fluid analysis suggestive of tuberculosis is exudative with lymphocyte predominance. Adjunct pleural fluid analyses with biomarkers like elevated adenosine deaminase and interferon γ can be used in clinical context. Tuberculin skin testing can also be a useful adjunct in diagnosis. Patients may undergo chest tube placement and video-assisted thoracic surgery procedures in cases of loculated effusions; however, these procedures are often unnecessary if rifampin, isoniazid, ethambutol, and pyrazinamide are promptly started. Within 6 weeks of initiating treatment, most effusions have completed

resolved. The majority of tuberculosis pleural effusions resolve spontaneously; however, the majority of these infections can later develop into active tuberculosis if untreated.

WAITING FOR A LIVER AND SMOKING MARIJUANA: STUCK IN THE WEEDS Megan S. Lemay; William Becker; Jeanette M. Tetrault. Yale-New Haven Hospital, New Haven, CT. (Tracking ID #1634932)

LEARNING OBJECTIVE 1: Recognize the impact of new laws regarding marijuana use on current liver transplant policies
LEARNING OBJECTIVE 2: Identify potential risks of marijuana use related to liver transplantation
CASE: MG was a 47 year old man suffering from decompensated cirrhosis secondary to primary sclerosing cholangitis. Mr. G was admitted to the inpatient liver service in August 2011 with nausea and altered mental status. A urinary toxicology screen on admission was positive for cannabinoids, and he reported recreational marijuana use three times weekly. He denied use of other illicit substances and his last reported use of alcohol was in 2008. Exam was notable for grade 2 encephalopathy, jaundice, and tense ascites. His Model for End-Stage Liver Disease (MELD) score was 22. MG's case was discussed at the Recipient Review Committee for Liver Transplantation. It was determined that MG would need to complete 6 months of rehabilitation for marijuana use and document negative urine toxicology before being considered for transplantation. In the next 2 months, MG developed further complications of cirrhosis including variceal bleeding, worsening encephalopathy, and hepatorenal syndrome. Following his family's decision to withdraw medical care, MG died in November, 2011. His MELD score at the time of his death was 50.
DISCUSSION: Over 16,000 people are awaiting liver transplantation in the US. Currently, 18 states have legalized the use of medical marijuana, and two states recently voted to legalize recreational marijuana. This makes it increasingly likely that transplant programs will be evaluating patients who use marijuana. Controversy surrounds whether marijuana use should impact transplantation listing. On one hand, there are no data suggesting worse outcomes among marijuana users undergoing liver transplantation. In one retrospective cohort study of patients with cirrhosis being considered for transplantation, there was no difference in mortality between marijuana-smokers and non-marijuana smokers. Furthermore, marijuana use has been shown to improve symptoms often experienced by patients with cirrhosis, such as anorexia, nausea, and pain. On the other hand, cannabis use is correlated with use of other illicit drugs and alcohol. Additionally, although adverse effects of smoking marijuana may not be equivalent to cigarette smoking, there is evidence of increased morbidity and mortality among post-transplant cigarette smokers. Overall, no evidence exists that recreational or medical marijuana use has a negative impact on patients with cirrhosis being considered for transplantation. As marijuana becomes increasingly legally available, consideration should be given to whether marijuana use should contraindicate or delay transplant listing.

WAS IT SOMETHING I ATE? A CASE OF THE REFEEDING SYNDROME AS A CAUSE OF NEUROLOGIC AND RESPIRATORY FAILURE David Weir[1]; Parth Rali[1]; William Fleischman[2]. [1]Mount Sinai, New York, NY; [2]Mount Sinai, New York, NY. (Tracking ID #1594699)

LEARNING OBJECTIVE 1: Review the pathophysiology and treatment of the refeeding syndrome.
LEARNING OBJECTIVE 2: Recognize risk factors for the development of the refeeding syndrome in hospitalized patients.
CASE: A 31 year-old man with a history of alcohol abuse presented to our ER with abdominal pain for 3 days. His physical exam was remarkable for visual hallucinations and mild abdominal tenderness. A Wernicke's encephalopathy was suspected and he was started on high-dose thiamine. The following day he developed paresthesias in the upper and lower extremities, as well as horizontal and vertical nystagmus. He quickly developed a progressive generalized weakness with dysphagia and hypoxic respiratory failure requiring intubation. On admission to the Intensive Care Unit his phosphate level was undetectable at less than 0.5 mg/dL. Other serum electrolyte abnormalities were significant for a sodium level of 119 mEq/L, potassium of 2.3 mEq/L, and a chloride level of 74 mEq/L. Electromyography revealed a peripheral polyneuropathy with axonal dysfunction, demyelination, and myopathy. Both an MRI of the brain with gadolinium and lumbar puncture were normal. He was treated with aggressive intravenous phosphate and electrolyte supplementation with gradually increasing caloric support. Over the course of 2 weeks he made a full neurologic recovery.
DISCUSSION: The refeeding syndrome (RFS) is a diagnosis that is often overlooked in hospitalized patients. This syndrome can manifest as a spectrum of disease, from the asymptomatic to cardiac arrhythmias or respiratory failure with multi-organ dysfunction and death. The hallmark of RFS is the development of severe hypophosphatemia after feeding a patient following a period of prolonged malnutrition. Clinical signs and symptoms of the refeeding syndrome appear in patients who begin feeding after a period of malnutrition. It was first described after World War II in prisoners of war who developed heart failure and neurological complications after undergoing prolonged periods of starvation. Hypophosphatemia is the predominant feature of RFS, but other features include fluid-balance and electrolyte abnormalities, altered glucose metabolism and vitamin deficiencies. While the incidence has been reported to be approximately 0.43 % of all hospitalized patients, it may be present in up to 34 % of patients who have been admitted to the ICU. Because of phosphate's crucial role in a number of physiological processes including muscle myocyte and nerve conduction, phosphate depletion can lead to heart failure, arrhythmias, seizures, paresthesias, and a generalized progressive weakness. This generalized weakness can mimic the Guillain-Barre syndrome including diaphragmatic weakness requiring mechanical ventilation as in our patient. The RFS is most commonly seen in patients with anorexia nervosa, alcoholism, inadequate nutrition for greater than 5 days, and post-operative patients. The management of RFS should begin with appropriate repletion of electrolytes with thiamine and vitamin supplementation. Caloric support should begin at 5–20 Kcal/Kg/day, and increase by 10–25 % per day once serum electrolytes have normalized. In patients at risk for RFS, the diagnosis can be made by clinical history and biochemical data, with the predominant feature being hypophosphatemia. While RFS is relatively uncommon in hospitalized patients, this case highlights the importance of physicians being mindful of patients at risk and the severe complications associated with this syndrome.

WEAK LEG, COLD ARM, CLOT IN THE LUNG, HOLE IN THE HEART Mandy Stull; Anthony Donato. The Reading Hospital Health System, West Reading, PA. (Tracking ID #1628399)

LEARNING OBJECTIVE 1: Recognize clinical features suggestive of a paradoxical embolism in the setting of acute cerebrovascular accident.
CASE: 78-year-old male with a history of hypertension and hypercholesterolemia was found minimally responsive, lying on the bathroom floor. Upon initial evaluation, he was found to have a hyperdense right MCA sign, which was compatible with cerebrovascular stroke. The patient's physical exam findings of left hemiparesis, dysarthria, dysphagia, and right gaze preference were also consistent with this diagnosis. MRI of the brain was performed, which identified acute ischemia in the right basal ganglia, internal capsule, and corona radiata. Due to the large size of the stroke, anticoagulation was withheld and an IVC filter was placed. Interestingly, computed tomography imaging also revealed filling defects in the right main pulmonary artery and lower lobe branches compatible with acute pulmonary embolism. However, the patient did not have any signs of tachypnea, tachycardia, or hypoxia, and he was not symptomatic. Further work-up included an ultrasound of his bilateral lower extremities, which was

negative for deep vein thrombus, a carotid ultrasound, which showed 16 % to 49 % stenosis in left and right internal carotid arteries, and a transthoracic echocardiogram, which showed an ejection fraction 66 %. There were no regional wall motion abnormalities and no obvious clot mass. The patient remained in normal sinus rhythm during the hospital course and had normal PTT and platelet studies with no recent administration of heparin. The following day, the patient was noted to have a cold, pulseless right arm. Arterial embolization was suspected in the setting of ischemic right upper extremity. A right brachial and axillary embolectomy retrieved two segments of clot measuring up to 7 cm. Given a high clinical suspicion for patent foramen ovale in the setting of multiple emboli suggestive of both venous and arterial origin, a transesophageal echocardiogram with contrast was performed. A transesophageal echocardiogram subsequently revealed a PFO with right to left shunt on bubble study during valsalva maneuver.
DISCUSSION: Stroke is the leading cause of serious, long-term disability in the United States. Paradoxical embolism via a patent foramen ovale account for 5.5 % of all ischemic strokes. Our patient presented after toileting with an embolic ischemic stroke as well as concurrent pulmonary emboli and right brachial emboli. This constellation of findings led to the discovery of a PFO as a conduit for a paradoxical embolus. Both valsalva maneuver preceding onset of focal neurological deficits and evidence of concurrent venous and arterial emboli are important features of paradoxical embolism. In light of a negative transthoracic echocardiogram, a transesophageal echocardiogram must be pursued to establish the etiology when there is a high index of suspicion for a patent foramen ovale.

WEIL'S DISEASE (ICTERIC LEPTOSPIROSIS) CONTRACTED ON A CARIBBEAN CRUISE Deepa Rani Nandiwada; Aaron Smith. NYU Langone Medical Center, New York, NY. (Tracking ID #1620667)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of leptospirosis
LEARNING OBJECTIVE 2: Understand the diagnosis and treatment of leptospirosis
CASE: A 54 year old man presented with worsening lower extremity pain, headache and fever for 4 days. The patient had no significant past medical history. Fourteen days prior to admission, while on a Caribbean cruise, he suffered a superficial abrasion on his left leg on a rainforest hike. Four days prior to admission he noted a severe, retro-orbital headache, chills, and fever up to 103 F. The fever dissipated after 3 days, followed by the onset of intense, bilateral thigh pain. Patient came to the hospital because of inability to walk due to severe muscle pain. On physical exam his vital signs were significant for tachycardia. He had severe lower extremity weakness. Lung exam was clear to auscultation bilaterally. Abdominal exam was not significant. A complete blood count revealed a white blood cell count of 10,000 k/mm2, a hemoglobin of 14 g/dl and platelets of 45,000 k/mm2. AST and ALT were 130 IU/L and 80 IU/L, total bilirubin 2 mg/dl and a creatine kinase of 8,000 U/L. A chest x-ray revealed mild interstitial infiltrates. The patient became jaundiced with total bilirubin peaking at 45.8 mg/dL, and AST of 432 IU/L. He became anemic and required two units of packed red blood cells. Thrombocytopenia persisted. Worsening renal function and hypotension improved with aggressive intravenous hydration. Initial tests were negative for viral hepatitis, HIV, Lyme disease, West Nile virus, Legionella, dengue virus, and leptospirosis. He was treated with intravenous penicillin for leptospirosis and azithromycin for disseminated legionella. One week later, repeat testing for Leptospira antibodies returned positive at a concentration of 1:400. He was discharged home on oral penicillin.
DISCUSSION: Leptospirosis, caused by the spirochete Leptospira, is the most common zoonotic infection worldwide. It is transmitted through contact with urine from infected animals or contaminated fresh water. The prevalence in developing countries has spread, especially with the rising popularity of adventure tourism. Leptospirosis should be considered in any traveler who returns from an endemic region with any combination of fever, retro-orbital headache, severe myalgias, photophobia, and vomiting. The incubation period ranges from 10 days to 3 weeks. Infection is usually self-limited, however 5–10 % of cases will progress to Weil's disease (icteric leptospirosis). This is manifested by jaundice, acute renal failure, and hemorrhage. Pulmonary involvement, thrombocytopenia, and rhabdomyolysis may occur. Distinguishing between Weil's Syndrome and Dengue hemorrhagic fever can be challenging. Our patient's laboratory values and presentation had features that were classic for both diseases. Thrombocytopenia, bilateral interstitial infiltrates and increased liver enzymes are more consistent with Dengue hemorrhagic fever. However, patients with Weil's syndrome can have significant thrombocytopenia and develop liver failure with hyperbilirubinemia. Diagnosis of leptospirosis is made with the microscopic agglutination test. It can take up to 4 weeks for this result to become positive and so initial titers may be negative. Standard treatment is penicillin or doxycycline.

WELL KNOWN, BUT LEAST SUSPECTED—A CASE OF FUROSEMIDE-INDUCED PANCREATITIS Sathish kumar Krishnan; Dima Dandachi; Malav Parikh; Harvey Friedman. St. Francis Hospital, Evanston, IL. (Tracking ID #1642031)

LEARNING OBJECTIVE 1: Consider furosemide-induced pancreatitis in the differential diagnosis whenever elderly patients, taking furosemide present with epigastric pain.
LEARNING OBJECTIVE 2: Recognize that furosemide can cause pancreatitis, even when prescribed at lower dose and for shorter duration.
CASE: A 81 years old Mexican female presented for epigastric pain and nausea for 1 day. Her past medical history was significant for coronary artery disease with stent placement, hyperlipidemia, hypertension, hypothyroidism, osteoporosis and pancreatitis due to hypertriglyceridemia. She was taking aspirin, clopidogrel, amlodipine, ezetimibe, niacin, levothyroxine, pantoprazole, risedronate and cholecalciferol. She had completed taking furosemide 40 mg/day for about a week. It was prescribed for her leg swelling. She was not a smoker and did not drink alcohol. She had no trauma or any family history of autoimmune disease. Her physical exam was positive for epigastric tenderness. Investigations were as follows. Cardiac biomarkers: unremarkable, EKG: no acute ischemic changes, amylase: 527 IU/L (25–125 IU/L), lipase: 219 IU/L (0–6 IU/L), LFT: unremarkable, serum calcium: 8.6 mg/dL (8.5–10.5 mg/dL), Triglycerides: 46 mg/dL (<150 mg/dL). An US of abdomen was done, which did not show any gall stone, biliary sludge or biliary duct dilatation. A CT scan of abdomen showed the head of pancreas to be mildly hypodense, suggestive of pancreatitis. She was treated with supportive care including pain control and intravenous fluids. The pancreatitis was considered idiopathic. The patient improved and was discharged on the 5th day. Two months later, she presented with epigastric pain, nausea and vomiting. On examination, she had mild epigastric tenderness and bilateral pedal edema. Her amylase and lipase levels were elevated. LFT, lipid level, serum calcium level and US abdomen were unremarkable. A MRCP did not show any biliary duct obstruction or dilatation. After careful questioning, she revealed that she was taking furosemide 40 mg daily on the previous 3 days for her leg swelling. Furosemide was withheld and she was treated with supportive care. Upon discharge, the patient was educated not to take furosemide in future.
DISCUSSION: The true incidence of furosemide-induced pancreatitis is unknown, as the evidence is derived mainly from random case reports. Suggested pathogeneses include a direct toxicity to pancreas, furosemide-induced stimulation of pancreatic secretion, and ischemia. Diagnosis is considered definite, if other causes are ruled out, if there is recovery after drug withdrawal, and if pancreatitis recurs with reintroduction of furosemide. Among the adverse drug reactions of furosemide, pancreatitis is often ignored and under- reported because of the difficulty in implicating the drug as its cause. There are case reports of furosemide-induced pancreatitis with a shorter latency (pancreatitis occurring within days of taking furosemide). But in those instances, the patients were taking higher dose (about 750 mg/day). Our patient is unique that she developed pancreatitis with a shorter latency and at much lower dose(40 mg/day). The physician should have a high index of suspicion for this condition, especially in geriatric patients, HIV + patients, cancer patients, and patients receiving immunomodulating agents. The mainstay of preventing further episodes is avoiding future use of furosemide in those patients.

WHAT WALKS LIKE CELLULITIS, AND TALKS LIKE CELLULITIS, BUT ISN'T CELLULITIS? Susanna A. Curtis; Manuela Calvo. Montefiore, Bronx, NY. (Tracking ID #1641980)

LEARNING OBJECTIVE 1: Recognize alternative diagnoses other than infectious cellulitis in patients presenting with skin erythema, edema and warmth.
LEARNING OBJECTIVE 2: Diagnose pseudocellulitis as a possible side effect of gemcitabine.
CASE: A 39 year-old man presented with right lower extremity erythema, edema, and tenderness for 1 day. He had a history of metastatic perivascular sarcoma of the pelvis with consequent obstructive uropathy and intermittent lower extremity edema due to lymphatic obstruction. His vital signs were within normal limits. On physical exam, his right lower extremity had 3+ pitting edema up to the knee with associated erythema, warmth, and tenderness to palpation. His left lower extremity was not erythematous or edematous but was tender to palpation There were palpable lymph nodes in the left inguinal region. White cell count was 5,000 cells/uL, blood cultures were negative, and lower extremity dopplers revealed no deep vein thrombosis. He received one dose of Vancomycin therapy for presumed cellulitis. The following day his edema, erythema, and tenderness improved drastically, faster than expected for cellulitis. On further questioning he revealed that 5 days prior he had finished the third week of his first cycle of a gemcitabine based chemotherapy. Pseudocellulitis due to gemcitabine was suspected and all antibiotics were stopped. Within 48 h all lower extremity symptoms resolved and the patient was discharged home without antibiotics. He received no further chemotherapy treatments and his symptoms did not recur.
DISCUSSION: Cellulitis is a common admitting diagnosis. Importantly, there are many causes of cutaneous inflammation, and distinguishing noninfectious etiologies from cellulitis can be challenging. Chemotherapy in particular is associated with a variety of dermatologic manifestations such as rash, alopecia, and pruritus. Gemcitabine pseudocellulitis is most commonly a radiation recall reaction that presents as dermatitis in the area of previous radiation days to weeks after induction of chemotherapy. Areas of lymphedema, regardless of radiation exposure, are also at risk though this is far less common. Our review of current literature revealed only 7 cases of gemcitabine pseudocellulitis without prior radiation therapy. Patient's present afebrile, without neutrophilia and with negative blood cultures. Treatment is corticosteroids, though use of NSAIDs and diphenhydramine has also been described. Our patient had no radiation exposure but his large pelvic mass caused pelvic outlet obstruction resulting in persistent edema in his lower extremities. It is hypothesized that chemotherapeutic drugs permeate the lymphatic fluid allowing drug to accumulate in chronically edematous areas thus making them more prone to related drug reactions. Gemcitabine in particular is metabolized primarily in the large organs, therefore the drug is unable to be metabolized and remains active longer when it has accumulated in areas of lymph edema. In summary, when a diagnosis of cellulitis is being considered, noninfectious etiologies of inflammation should also be entertained. Pseudocellulitis should be suspected in patients who are afebrile, culture negative, and whose physical exam findings improve faster than expected. Chemotherapy related drug reactions are an important consideration in a select population, and the appreciation of this diagnosis may dissuade against the inappropriate use of antibiotics.

WHEN ADDING SPICE CAN THREATEN LIFE Robert B. Werner; Nazrul Chowdhury; Roger D. Smalligan. Texas Tech Univ Health Sciences Center, Amarillo, TX. (Tracking ID #1628364)

LEARNING OBJECTIVE 1: To recognize that smoking synthetic marijuana can cause ST Elevation myocardial infarction.
LEARNING OBJECTIVE 2: To recognize that synthetic cannabinoid like K2 ("Spice") may be more likely to cause myocardial infarction than other cannabinoids.
CASE: A 26-year-old male was taken to the emergency department complaining of severe substernal chest pain radiating to the left jaw, associated with palpitations, diaphoresis and dizziness. His mother had a myocardial infarction in her 50s. The patient reported smoking 1 pack of cigarettes per day, consuming moderate amounts of alcohol, and smoking K2, a synthetic cannabinoid. His past medical history was otherwise unremarkable. On physical exam his vital signs included a blood pressure of 124/87, heart rate of 100/min, respiratory rate 23/min, temperature of 99 °F, and an oxygen saturation of 98 % on room air. Laboratory data showed a troponin level of 16.5 and creatine kinase MB fraction of 27 (normal<5), and lipid panel within normal range. EKG showed ST elevation in the inferolateral leads and chest x-ray did not show pneumonia or other pathology. Cardiac catheterization showed patent coronary arteries. The patient was treated with standard acute coronary syndrome therapy and made a full recovery.
DISCUSSION: K2, or as it is known on the streets, "Spice," is a mixture of herbs that have been sprayed with a synthetic compound similar in chemical makeup to 9-tetrahydrocannabinol (THC), the active ingredient in marijuana. It has until recently been available to the public and is a popular drug of abuse among young people. It is the second most popular illicit drug of abuse behind marijuana. Coronary artery spasm has been reported in the literature in association with the use of 12 different illicit substances in young adults, including cocaine, marijuana, alcohol, butane and amphetamines. Smoking cannabis has also been reported as a rare trigger of acute myocardial infarction in teenagers, presumably by this same coronary spasm mechanism. Such cases have shown thrombus formation involving the left coronary artery with no atherosclerotic lesions. Due to the increasing use of K2, its widespread availability, and its mimicry of THC, it is important to understand its effects on the body. Our case illustrates that K2 usage may well cause similar coronary spasm and myocardial infarction and can therefore be life-threatening in young people. Presumably K2 could be even more dangerous in older people with pre-existing atherosclerotic lesions or other coronary artery disease risk factors. Synthetic cannabinoids are not detected on routine urine toxicology tests, making obtaining an accurate history of illicit drug use by these patients of paramount importance. Recently, the DEA has declared synthetic cannabinoids as Schedule I controlled substances. This case reminds physicians to educate their patients regarding the important risks associated with their use and to keep K2 abuse in the differential of patients presenting with acute coronary syndrome or acute myocardial infarction without other obvious risk factors.

WHEN BLOOD DOESN'T HELP Joshua K. Sabari; Matthew Shaines. Montefiore Medical Center, Bronx, NY. (Tracking ID #1629625)

LEARNING OBJECTIVE 1: Recognize the signs and symptoms of Delayed Hemolytic Transfusion Reaction
LEARNING OBJECTIVE 2: Understand the indications for transfusion and possible adverse outcomes in a patient with Sickle Cell Disease.
CASE: A 30 year-old woman with a history of Sickle Cell Disease (Hemoglobin SS), complicated by monthly vasoocclusive crisis (VOC), presented with acute onset chest pain. She described the pain as a "typical" VOC. On presentation she was febrile, tachycardic, tachypnic, hypoxic, and was noted to have scleral icterus and moderate respiratory distress. Laboratory studies revealed a hemoglobin (Hb) of 4.9 G/dL, (baseline Hb 7 G/dL), reticulocytes 24 %, lactate dehydrogenase (LDH) 1,400 U/L (600 during prior crisis), and an indirect bilirubin of 2.6 mg/dl. Chest xray was significant for a left lower lobe infiltrate. Given the presumed diagnosis of acute chest syndrome, and the significant drop in Hb from baseline, an urgent blood transfusion was ordered. Type and screen was drawn prior to transfusion and she was emergently transfused one unit of type O negative blood, with the goal to increase Hb to a safer level prior to exchange transfusion. Repeat Hb post-transfusion decreased to 4.2 G/dL and LDH increased to 1,900 U/L. Subsequently, type and screen drawn prior to transfusion was noted to be positive for Anti-Jkb antibody. After review of the electronic medical record it was noted that the patient was seen in the ED 2 weeks prior to the current admission for VOC and was transfused 2U PRBCs. Type and screen prior to transfusion at that time was negative for autoantibodies. A diagnosis of Delayed Hemolytic Transfusion Reaction was made. The patient was started on high dose methylprednisolone,

epoetin and iron infusion. Hb trended upward to 6.5 g/dL without receiving further blood products, with complete resolution of her presenting symptoms.
DISCUSSION: Sickle cell disease is a common disorder seen by general internists. These patients often receive blood transfusions during inpatient hospitalizations, although they are not always evidence based. It is critical to understand the risks and benefits of transfusion; including the indications for transfusion. We report a case of delayed hemolytic transfusion reaction (DHTR). Indications for transfusion in a patient with sickle cell disease include acute stroke, acute chest syndrome, acute multi-organ failure, acute symptomatic anemia, and reticulopneia (e.g. parvo-B19 induced). The adverse risks of transfusion include febrile non-hemolytic reaction, acute hemolytic reaction, anaphylaxis, transfusion associated acute lung injury, and DHTR. The incidence of DHTR occurs in 1:5,000–10,000 units packed red blood cells transfused; often 3–21 days post transfusion. DHTR is clinically characterized by hemolysis, fever, a positive antiglobulin on Coombs test, and a new positive antibody screen. DHTR is a primary immune response where the recipient generates non-complement binding antibodies that coat donor red blood cells (RBC) leading to extravascular hemolysis. DHTRs are often mild and do not require treatment. On rare occasions hyperhemolysis may occur, requiring symptomatic management. It is important to consider the diagnosis of DHTR as further transfusions often worsen DHTRs or lead to a hyperhemolysis syndrome due to re-exposure to foreign RBC antigens. Treatment is often supportive with steroids to ameliorate immune response and erythropoietin with iron transfusion in an effort to increase hemoglobin production.

WHEN YOU CANNOT BREATH AFTER HEAD TRAUMA: A CASE OF INTRACRANIAL BLEED AND NEUROGENIC PULMONARY EDEMA Mihir S. Shah; Harvey Friedman; Pakhadi Buddhadev. St. Francis Hospital, Evanston, IL. (Tracking ID #1642578)

LEARNING OBJECTIVE 1: Neurogenic Pulmonary Edema (NPE) is a rare disorder where the patient develops pulmonary edema due to an acute intracranial event like hemorrhage, head injury or epilepsy. It occurs due to an autonomic storm which follows minutes to hours after the intracranial event. It usually has a good prognosis with improvement once the neurologic insult is addressed. It is one of the rare complications of intracranial bleed where the patient requires supplemental oxygen and can be fatal if not treated early.
CASE: An 18 y/o male presented to the ER with a mechanical fall and altered mental status. The patient had taken an unknown drug pill prior to the presentation. The patient was hypotensive and tachycardic, with physical examination remarkable for bilateral crackles. The patient's labs were normal on admission and the urine toxicology screen was positive for cannabinoids. His CT scan revealed large intraparenchymal bleed. The patient underwent emergent craniectomy to evacuate the bleed. The patient had an echocardiogram which showed global hypokinesia with an Ejection Fraction of 20 %. The patient was maintained on mechanical ventilation after the surgery and his saturations were <70 % despite maximum FIO2. He was eventually sedated and paralyzed in order to oxygenate him adequately. He was also put on mannitol to control his intracranial pressure. He improved over the next few days and was eventually extubated. A repeat echocardiogram was done, which showed improvement in the left ventricular function with an Ejection Fraction of 60 %.
DISCUSSION: Neurogenic Pulmonary Edema (NPE) is a condition in which there is autonomic nervous system overactivity due to an acute intracranial event. This leads to increased pressure in pulmonary veins which in turn leads to extravasation of fluid into the alveoli leading to pulmonary edema. The medulla oblongata is considered a vital structure in the pathogenesis of this condition. The hypothesis behind NPE is the left ventricular function deteriorates due to systemic hypertension, negative inotropic effect due to excessive vagal discharge and increased venous return. The outcome of these patients is determined by the course of the neurologic insult rather than the neurogenic pulmonary edema. The treatment is usually supportive therapy. These patients may require mechanical ventilation. High PEEP which can increase the intracranial pressure must be avoided. Permissive hypercapnia which can also increase the intracranial pressure by intracranial vasodilation must be avoided as well. Most of the episodes of NPE are well tolerated and resolve in 48–72 h. Our case illustrates the important diagnostic and management issues in the treatment of Neurogenic Pulmonary Edema.

WHY VITAL SIGNS ARE VITAL: TACHYCARDIA AS A SIGN OF SOMETHING MORE INSIDIOUS Joseph T. Knapper; Bhavin Adhyaru. Emory University, Atlanta, GA. (Tracking ID #1625721)

LEARNING OBJECTIVE 1: Recognize tachycardia as a manifestation of systemic disease and, in certain cases, underlying infection.
LEARNING OBJECTIVE 2: Diagnose and treat prostate abscess.
CASE: A 64 year old male with a history of type 2 diabetes and benign prostatic hyperplasia presented to clinic with a few days of fevers, dysuria, hematuria, and increased urinary frequency. His exam was significant for tachycardia and scrotal swelling. Urinalysis on that visit showed 3+ leukocyte esterase, and cultures eventually grew E. coli. Initial testicular ultrasound showed no evidence of torsion. The patient was diagnosed with a urinary tract infection (UTI) and prescribed 7 days of ciprofloxacin. Because he had persistent symptoms a week later, he presented for re-evaluation. He remained tachycardic on exam, and was prescribed an additional 7 days of ciprofloxacin for a complicated UTI. After completing 14 days of antibiotics, the patient returned to clinic reporting no improvement in symptoms. Further, he reported worsening urinary retention that required self-catheterization. On exam, he was afebrile but still tachycardic. The scrotum was full with palpable masses in the right and left spermatic cords and no penile discharge. Prostate exam revealed no masses or tenderness. ECG showed sinus tachycardia and his white blood cell count was slightly elevated at 9.7. Repeat urinalysis was positive for bacteria, trace leukocyte esterase, 11–25 red blood cells, and 26–50 white blood cells. The patient was admitted for further workup of sepsis. On admission, blood and urine cultures were drawn and the patient was placed on IV ceftriaxone due to concern for ciprofloxacin-resistant UTI. Blood and urine cultures came back negative, but the patient continued to have fevers, tachycardia, hematuria, and dysuria. In search of a source for his sepsis, a CT scan of the pelvis was ordered and showed two large prostatic abscesses. The urology team drained the abscesses and injected ceftriaxone into the prostatic tissue. After further treatment with broad-spectrum antibiotics, the patient's symptoms finally improved and his tachycardia resolved. He continued to be symptom free at his 1 month follow up visit.
DISCUSSION: The present case demonstrates the importance of vital signs in the evaluation of patients in outpatient practice. Our patient's tachycardia was overlooked on multiple consecutive clinic visits. The persistence of tachycardia despite antibiotic therapy should have raised suspicion of an inappropriate antibiotic choice or a more serious infectious etiology. When tachycardia persisted on this patient's initial follow-up visit, a change in antibiotic regimen may have prevented this abscess formation. This case also illustrates that clinicians must maintain a high index of suspicion for prostate abscess in males with UTIs or prostatitis who do not respond to standard therapy, as signs and symptoms of prostate abscess are generally non-specific. Fever, chills, and leukocytosis are frequently absent and patients often have a normal prostate exam. Risk factors such as diabetes, prostatic hyperplasia, and urinary catheterization, as seen in our patient, can heighten suspicion. Although a CT was done in this case, transrectal ultrasonography is preferred if prostate abscess is strongly suspected. Once the diagnosis is made, drainage and broad-spectrum antibiotics are the standard of care. Mortality rates are low with appropriate therapy, and outcomes are generally good.

WHY WOULD A YOUNG HEART CAUSE PALPITATION? Samian sulaiman; Muhammed Sherid; Husein Husein; Hani Snounou; Salih Samo; Addis Asfaw; Ana Inashvili; Derya Mahmutoglu; Nadia El Hangouche; Mehrnaz Salehidobakhshari; Samaneh Dowlatshahi; Mohamad Albsheri; Shahriar Dadkhah. St. Francis Hospital. Evanston, evanston, IL. (Tracking ID #1623956)

LEARNING OBJECTIVE 1:—To recognize that most wide complex tachycardias (WCT) are ventricular tachycardias, even in the absence of apparent structural heart disease—Diagnostic algorithms of WCT are imperfect, so Electrophysiologic study is the only way for definitive diagnosis.—Idiopathic VT often responds to antiarrhythmic drugs that would be unhelpful or even contraindicated in VT occurring in the setting of coronary heart disease.

CASE: A 20 year-old male presented with a chief complaint of recurrent palpitation. One year ago the patient started having shortness of breath and palpitation while he was resting in his room. The palpitation lasted for about 10 min and resolved before his arrival at ED. Few months later, he had a similar episode and an EKG done in ED showed a WCT with a heart rate of 180, RBBB morphology and upward QRS axis. Patient was hemodynamically stable. The arrhythmia was treated as an SVT with aberrancy. Adenosine was initially infused which failed to terminate the Arrhythmia. He was then given intravenous diltiazem which terminated the Arrhythmia successfully. The Patient was admitted to the hospital for 3 days. During his stay, no further episodes of arrhythmia were noticed on cardiac monitor. The arrhythmia was attributed to his increased intake of caffeinated drinks and was advised to decrease his intake of such drinks. After his third visit to ED for a similar episode, patient was admitted to the hospital and an electrophysiology study was planned. His past medical history was significant for bipolar disorder and mild mental retardation. His medications included valproic acid, risperidone and venlafaxine. Physical exam including vital signs was unremarkable. Further work up revealed normal labs including electrolytes, normal echocardiography and a normal CXR. Electophysiologic mapping revealed idiopathic LV ventricular tachycardia involving the left posterior fascicle. The origin of the ventricular tachycardia was localized to the left inferior septal region which explains the RBBB-Like morphology and the upward axis of QRS complex. Electrogram-guided ablation and empiric anatomic ablation were performed. Aspirin and verapamil were added to his medications. Patient was discharged uneventfully. Patient was free of symptoms for the 3 months after the ablation procedure.

DISCUSSION: Ventricular tachycardia (VT) that occurs in the absence of apparent heart disease is referred to as idiopathic. Idiopathic VT has accounted for approximately 10 % all patients referred for evaluation of VT. Most idiopathic VT originate from the Right ventricle, while LV origin is much less common. Idiopathic LV Tachycardia (ILVT) is often confused with supraventricular tachycardia because of its response to verapamil. The typical patient with ILVT presents at age 20 to 40. Verapamil is effective in the treatment of ILVT, both for the termination of acute episodes and the prevention of recurrence.

YOU ARE TOO BRASH IF YOU IGNORE THE RASH Madan R. Aryal[1]; Madan Badal[1]; Anup Subedee[2]. [1]Reading Health System, Wyomissing, PA; [2]Tulane University, New Orleans, LA. (Tracking ID #1624072)

LEARNING OBJECTIVE 1: Diagnose Syphilitic meningitis in patients presenting with features of meningitis and palmar rash.

LEARNING OBJECTIVE 2: Discuss workup and treatment of syphilitic meningitis

CASE: A 42-year old homosexual male with history of HIV/AIDS and non-compliance with antiretroviral therapy presented with history of intermittent headache, neck-pain, malaise, fever and night sweats for 2 months, and new bilateral palmoplantar rash for 2 weeks. On exam, temperature of 39.6 ° C and neck stiffness were noted. Maculopapular rash with some scaling was present in bilateral distal extremities, especially in the palmar and plantar surfaces. Genital lesions were absent. Complete blood count was unremarkable. CD4 cell count was 287/uL. Cerebrospinal fluid analysis showed WBC 141CMM with lymphocytic predominance, protein 230 mg/dL and glucose 14 mg/dL. Gram-stain, acid-fast stain, India ink stain, cryptococcal antigen, PCR for herpes simplex and toxoplasma antibody tests in cerebrospinal fluid were non-revealing. MRI of brain was unremarkable. Given the palmoplantar rash and the cerebrospinal fluid findings, serologic tests for syphilis were also ordered. Serum RPR was reactive at titer 1:1,024 and FTA-ABS was positive. VDRL in cerebrospinal fluid was reactive at titer 1:32. The patient was started on a two-week course of intravenous aqueous penicillin and had rapid symptomatic improvement over several days.

DISCUSSION: Neurosyphilis may present with widely variable presentations in different stages of syphilis and can be missed if non-neurological symptoms or signs of syphilis, "the great impostor", are not recognized. We here reported a case of syphilitic meningitis in an HIV patient diagnosed due to the presence of palmoplantar rash.It is important to recognize that meningitis can appear in early secondary syphilis, as it did in our case, as the earliest presentation of neurosyphilis. Diagnosis is confirmed with demonstration of VDRL or FTA-ABS titer in cerebrospinal fluid. .A high index of suspicion as well as correlation with non-neurologic symptoms or signs such as palmoplantar rash or epitrochlear lymph node enlargement which can be highly suggestive of syphilis would facilitate early diagnosis and treatment.

"DOC, JUST CUT MY ARM OFF!" Sweetheart Ador-Dionisio[1]; Stacey E. Jolly[2]. [1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH. (Tracking ID #1637160)

LEARNING OBJECTIVE 1: To recognize and distinguish Complex Regional Pain Syndrome (CRPS) from other musculoskeletal, vascular, neurologic, and chronic pain disorders.

CASE: 49 year old male with a history of diabetes, hypertension, hyperlipidemia, and viral pericarditis, presented to clinic complaining of left upper extremity (LUE) pain and swelling for 1 month. Previously, he was evaluated by a cardiologist for possible pericardiocentesis complications as he had intermittent left chest wall pain and swelling. However, given concern for statin-induced myositis, his statin was discontinued. At the visit, he described constant LUE swelling and throbbing pain, associated with tingling in his fingers, exacerbated by movement, with no alleviating factors. He denied trauma, LUE weakness, weight loss, or fevers. On exam, his left chest wall and shoulder were tender to palpation, with visible swelling of the entire LUE, inability to abduct the arm more than 90° due to pain, normal radial pulses, and both left arm and chest felt cool and clammy. X-ray of chest and left shoulder were normal. LUE ultrasound was negative for deep venous thrombosis. CT chest showed no pulmonary disease or chest wall abnormality. Left arm venogram was negative for thoracic outlet syndrome. EMG showed bilateral mild median neuropathies consistent with carpal tunnel syndrome but no evidence of brachial plexopathy or cervical radiculopathy. MRI of the left shoulder and LUE showed full thickness supraspinatus and infraspinatus tears but no evidence of soft tissue swelling or LUE abnormality. Orthopedic and hand surgeons recommended against surgery given his multiple co-morbidities and pain out of proportion to those diagnoses. His pain persisted despite treatment by a rheumatologist and pain specialist.

DISCUSSION: CRPS is the umbrella term that includes reflex sympathetic dystrophy and Sudeck's atrophy. The mechanism of CRPS is unclear but often begins after an inciting event such as soft tissue injury, fracture, myocardial infarction, or stroke. In some cases, no trigger is identified. CRPS is a debilitating disease in which pain triggers repeated cycles of pain and swelling. Diagnosis is made based on clinical presentation but is often underdiagnosed since symptoms are nonspecific, including significant pain, edema, and skin changes. MRI and 3 phase bone scan can be helpful if positive but do not preclude diagnosis if unrevealing. Treatment includes a multidisciplinary approach involving rehabilitation and pain management. Pain is treated in a stepwise approach where pregabalin, NSAIDs, and opioids are initially used, followed by bisphosphonates and a trial of steroids if pain persists. More invasive therapies include nerve blocks, neurostimulation, and rarely sympathectomy as last resort. Consider chronic pain syndrome such as CRPS in a patient with pain out of proportion to injury, local swelling, skin changes, and vasomotor instability, who does not respond to conventional pain management and has no alternative diagnosis to explain the degree of pain and dysfunction in the affected extremity.

"IS IT OR ISN'T IT LUPUS?": A CASE OF NEWLY DIAGNOSED SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) POSTPARTUM Irem Nasir. greenwich hospital, Greenwich, CT. (Tracking ID #1642283)

LEARNING OBJECTIVE 1: To recognize a new diagnosis of SLE postpartum.
LEARNING OBJECTIVE 2: To distinguish an acute presentation of SLE from preeclampsia.
CASE: A 23 year old female G1P1001 with no prior history was vaginally induced at 36 weeks gestation after a diagnosis of severe preeclampsia, and discharged after magnesium IV and labetalol was initiated the week prior. She returned with dyspnea, fatigue, and poor po intake x5 days. She denied fevers, abdominal or chest pain, cough, nausea, vomiting, arthralgias, headaches, or blurry vision. She also noted a petechial rash on both lower extremities. There was no personal or family history of autoimmune or hypercoagulable disorders. She was afebrile. On vitals, sbp 170–180, HR 70, and 94 % RA. There were decreased breath sounds bibasilar, no wheezing, no murmurs. There was no joint swelling or tenderness. She had trace pitting edema and a petechial rash on B lower extremities. Despite increasing labetalol, in addition to nifedipine and hydrochlorthiazide, sbp were persistently elevated. WBC was 6, hemoglobin and platelets were both low at 7.8 and 83, respectively. Cr was elevated at 1.8, from a baseline of 0.9, 4 weeks prior. There was 3+ proteinuria and 3+ hematuria on urinalysis. There were no schistocytes on peripheral blood smear. LDH, liver function tests, and INR were normal. ESR was elevated at 128. On CXR was a globular heart and moderate B pleural effusions. Echo showed an EF 60 %, normal valves, and a small pericardial effusion. On day 4 of admission, a new vasculitic rash was noted on her L foot. ANA was positive at a titer of 1:320. ANCA panel and RF were neg. Anti dsDNA was positive at 1:300 and Anti Ro Ab was positive at >1:8. Both C3 and C4 were low at 23 and 2.3, respectively. HIV ELISA was neg. A new diagnosis of SLE was made postpartum. Prednisone and hydroxychloroquine were initiated. Over the next few days, her dyspnea and vasculitic rash resolved and SBP improved to 120's. Hemoglobin and platelets increased to 9 and 153, respectively. C3 and C4 normalized. Her renal function continued to improve back to baseline, a few weeks later.
DISCUSSION: SLE, an autoimmune disorder primarily affecting women in their childbearing years, is thought to be due to an increase in endogenous estrogens, resulting in an increase in autoreactive B cells. Lupus flares occur at any time during pregnancy, as well as several months after delivery. Skin, joint, and constitutional symptoms are the most common. Hematologic disease, like thrombocytopenia and anemia, range from 10 to 40 % and lupus nephritis from 4 to 30 % peripartum. There are only a few case reports in which a new diagnosis of SLE is made postpartum, as is the case with our patient. An initial diagnosis of severe preeclampsia was made, with sbp 170's and 3+ proteinuria, prompting the induction of delivery. However, she remained persistently hypertensive with acute renal failure, thrombocytopenia, serositis, and a new vasculitic rash. Our case demonstrates that, in the diagnosis of preeclampsia, SLE should be excluded, even in cases of low prevalence, since the treatment of these two conditions is different. Preeclampsia remits with delivery and active SLE requires immunosuppression. Clinicians must maintain a high index of suspicion in the setting of persistently elevated SBP after delivery, accompanied by proteinuric acute renal failure and thrombocytopenia, since acute SLE is an imitator of severe preeclampsia and only an early, accurate diagnosis can prevent irreversible organ damage.

"MY THROAT IS KILLING ME"—MOVING BEYOND INFECTIOUS CAUSES OF THROAT PAIN Lori Randall; Stacy Higgins. Emory University School of Medicine, Atlanta, GA. (Tracking ID #1600402)

LEARNING OBJECTIVE 1: 1. Create a differential diagnosis for persistent oropharyngeal pain.
LEARNING OBJECTIVE 2: 2. Describe clinical features and treatment of oral pemphigus vulgaris.
CASE: A 64-year-old African-American female presented with severe throat pain for 6 months, worsening for 3 days with difficulty swallowing, a white tongue coating, hoarseness, nausea, difficulty clearing secretions, and cough. She had had multiple negative throat cultures and been treated unsuccessfully with antibiotics. ENT performed laryngoscopy showing inflammation and recommended tonsillectomy, but she became worse and came to the ER. Her admission medications included hydrocodone-acetaminophen, liquid ibuprofen, insulin, metformin, gabapentin, lisinopril, metoprolol, hydrochlorothiazide, amlodipine, fluticasone, ipratropium, albuterol, montelukast, rosuvastatin, omeprazole, ranitidine, ondansetron, and promethazine. On exam, she had profuse oral secretions, with easily scraped grayish tongue plaque, cracked lips, and excoriation of her inflamed oropharynx. HIV, RPR, monospot, and hepatitis panels were negative. HSV-1 and HSV-2 IgG were positive, but Tzanck smear was negative. She was treated empirically for candidiasis with IV fluconazole, then with liquid acyclovir for HSV, without improvement. Dermatology was consulted. Lower lip biopsy revealed absent superficial and mid epidermis with a broad suprabasilar bulla in the remaining epidermis, consistent with pemphigus vulgaris; ELISA was positive for desmoglein 3.
DISCUSSION: Pharyngeal pain is a common complaint. Physicians often assume infectious cause. Bacterial causes include groups A, B, and C streptococcus, Mycoplasma pneumoniae, Chlamydophila pneumoniae, Neisseria gonorrhoeae, Arcanobacterium haemolyticum, Fusobacterium necrophorum (Fn), and Corynebacterium diphtheriae. Viral causes include influenza, parainfluenza, coronavirus, rhinovirus, adenovirus, enterovirus, RSV, metapneumovirus, HSV, EBV, and HIV. Immunocompromised patients or those recently on antibiotics may have candidiasis. However, beyond infection, persistent throat pain can indicate laryngopharyngeal reflux, allergic rhinitis, recurrent aphthous stomatitis, Behcet's disease, malignancy, or an autoimmune disorder such as pemphigus vulgaris (PV). PV initially affects the mouth in ~50 % of cases. Skin blistering often comes later, causes poor quality of life, and can even be life threatening. PV has unclear etiology but has been associated with certain ethnic groups (Ashkenazi Jews and Mediterraneans), HLA Class II alleles (DRBI*0402 and DQBI*0503), and drugs (including captopril, penicillamine, and rifampicin). In blistering disorders, autoantibodies attack the desmosomes, which bind cells; in PV, this occurs intraepidermally, with autoantibodies against desmoglein 3. Treatment for PV consists of systemic corticosteroids or other immune suppression, even for oral disease. With steroids, mortality has decreased from 30 % to 6 %. Our patient was initiated on high-dose glucocorticoids with significant improvement. Outpatient, she is on mycophenolate mofetil 1,000 mg BID and prednisone 30 mg daily and doing well. PV and other autoimmune diseases are important to keep on the differential for patients with varied presentations not responding to empiric management. When mucosal or skin lesions are involved, biopsies can be extremely helpful, as can consultants for common complaints that do not resolve easily.

"ROUTINE" DENTAL CARE? A CASE OF PNEUMOME DIASTINUM DURING A DENTAL CAVITY REPAIR Shobhit Gupta; Robert Freed; Anthony A. Donato. Reading Hospital, Reading, PA. (Tracking ID #1642009)

LEARNING OBJECTIVE 1: Recognize that routine dental procedures can cause pneumomediastinum
LEARNING OBJECTIVE 2: Recognize clinical features of pneumomediastinum to prevent respiratory collapse
CASE: A 46 year-old female presented to the ED with complaints of headache and left-sided facial swelling hours after a dental filling using an air-turbine drill. During the procedure the patient had acute onset of left jaw pain, for which the filling was aborted and patient directed to the ED. She was found to have facial crepitus but specifically denied chest pain, shortness of breath or dysphagia. Chest X-ray was normal and she was sent home with oral amoxicillin. She returned 2 days later with severe left-sided pleuritic chest pain and was found on CT scan to have pneumomediastinum with extensive subcutaneous air in her neck, extending to her maxilla and pre-orbital region. She was admitted with a diagnosis of traumatic dental filling complicated by pneumomediastinum and begun on broad-spectrum antibiotics to prevent mediastinitis. For the next 2 days she remained hemodynamically stable and did not require surgical intervention. She was discharged with oral amoxicillin and close follow-up.

DISCUSSION: Pneumomediastinum is a well-recognized entity associated with trauma or surgical procedures of the respiratory or alimentary tract. Pneumomediastinum after routine dental procedures, however, is a rare but equally destructive phenomenon. The use of high pressure pneumatic drills is increasingly being used by dentists as an alternative to standard rotary drills. However, this procedure has been associated with subcutaneous and mediastinal emphysema. An exact mechanism is postulated to be air dissection through cervical facial planes via the submandibular space, resulting in mediastinal emphysema, infection, pneumothorax, pneumopericardium and air embolism. Delay in recognition can lead to complete cardiovascular and respiratory collapse requiring surgical intervention. If promptly recognized, supplemental oxygen and antibiotics may prevent the potentially life-threatening complications of pneumomediastinum.

CLINICAL PRACTICE INNOVATIONS (CPI) A CHECKLIST TO OPTIMIZE TRANSITIONAL CARE MANAGEMENT BETWEEN HOSPITALISTS AND A PATIENT CENTERED MEDICAL HOME

Scott Joy[1]; Katie Arvidson[3]; Kelly Griffey[3]; Sharon Khan-Khan[3,2]; Jonathan Manheim[1,2]; Erin Marcum[1,2]. [1]The Colorado Health Foundation, Denver, CO; [2]Presbyterian/St. Luke's Medical Center, Denver, CO; [3]HCA/HealthONE, Denver, CO. (Tracking ID #1639916)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): What are critical data items necessary to communicate between hospitalist and outpatient providers to deliver comprehensive care team management for patients being discharged from a hospital to a Patient Centered Medical Home?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Identify the critical items necessary to communicate between the hospital and outpatient team to optimize patient care during the transition of care period Simplify the documentation process for the critical items to improve communication and efficiency between hospitalists and the outpatient care team Integrate this information into the electronic health record

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In the 2013 Physician Fee Schedule Rule, CMS released guidelines for Transitional Care Management Services. To optimize the service provided to patients after discharge, clear communication must take place between the hospitalists and the outpatient team in the transition of care (TOC) period. We sought to identify these critical pieces of information to allow our team to proactively address patients needs before their TOC face-to-face visit. Checklists have been shown to be effective at communicating critical needs and improving quality of care. In Fall 2012, a group consisting of hospitalists, primary care physicians, practice administrators, clinical nurses, social workers and electronic medical record analysts was convened to determine best practice for communication, workflow and integration of data in the TOC period. The intended strategy was to develop a one page TOC document to be completed by the hospitalist and then to fax/scan the completed document into the EHR for review by the outpatient team.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Create a single document in checklist format to communicate critical data from the inpatient to outpatient setting necessary to optimize TOC Integrate the data into the EHR to allow the data to be pushed to and shared by relevent team members

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): A single page document was created in checklist format as below, followed by Yes or No checkboxes and areas to write in additional detail. 1. Inpatient Care Team: (Name of Hospitalists, contact number) 2. Patient Information (name, DOB, best phone contact #, e-mail address, insurance status) 3. Scheduling Needs: -moderate complexity (schedule within 14 d) -high complexity (schedule within 7 d) -special needs(vision, hearing, translation, disability) 4. Critical Clinical Information: -Discharge Diagnosis? -Outstanding Diagnostic Testing Results Pending? -Critical Follow-up Testing Needed? -High Risk Medication prescribed (warfarin, insulin, narcotics)? -Infection Control Precautions? -Advanced Directive? 5. Social Work/Behavioral Health Needs: Rx assistance, home O2, DME, Home Health, PT/OT, Transportation, Mental Health/Substance Abuse: 6. Discharge Summary Completed? 7. Medication List included?

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A checklist on a single sheet of paper can be created to communicate critical data required to optimize TOC between hospitalists and a Patient Centered Medical Home The checklist allows the care team to prioritize issues and optimize pre-visit time prior to the patients follow-up TOC appointment. This document can be integrated into existing EHR systems to allow for electronic flow and sharing of the information to relevant team members in an outpatient clinic setting.

A MULTIDISCIPLINARY APPROACH TO IMPROVE GLOBAL IMMUNIZATION FOR INPATIENTS

Thomas K. Spain[1]; John Starmer[2]; Asli O. Weitkamp[2]; Christine A. Kennedy[3]; Audrey H. Kuntz[4]; Neesha N. Choma[5]. [1]Vanderbilt University School of Medicine, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Vanderbilt University Medical Center, Nashville, TN; [5]Vanderbilt University Medical Center, Nashville, TN. (Tracking ID #1642346)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Expansion of The Center for Medicare and Medicaid Services (CMS) immunization core measure on January 1, 2012 significantly increased the volume of eligible inpatients who require screening for influenza and pneumococcal vaccination while hospitalized.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Develop a standardized and sustainable process to screen and administer vaccines to all eligible inpatients in a large quarternary academic medical center.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): To address the new CMS measure, a multidisciplinary committee was formed in August 2011 including physician, nursing, pharmacy, quality, and informatics representation. A new screening process was implemented in two phases. Phase I consisted of a provider-driven "exit check" integrating a vaccine advisor into the computerized discharge order process. The advisor was triggered by a decision support algorithm utilizing age, vaccine history, time of year, and comorbid diagnoses, giving providers the choice to either order appropriate vaccine(s) stat at discharge or document a reason for patient decline or exclusion. Phase II consisted of a nurse-driven protocol which screened all patients for immunizations during the routine admission assessment. Modifications to the existing electronic history form allowed nurses to document declinations, recognized exclusions, and vaccines received elsewhere. A nurse-protocol vaccine order was generated, if appropriate, to be given at 8 am on hospital day two. Patients who had received vaccines based on the admission protocol or per the electronic immunization record did not trigger the exit check, which ultimately serves as a safety net prior to discharge. Phases I and II were piloted in Fall 2011 on adult inpatients with pneumonia, and expanded on January 1, 2012 to include all eligible inpatients. Barriers addressed during implementation included institutional culture around importance of global immunizations, nurse vs. physician driven orders, provider concerns about vaccinating select patient populations (e.g. transplant and ICU patients), pharmacy processes affecting vaccine delivery, cost and wastage, and interoperability of clinical informatics systems.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The primary measure was the percentage of eligible inpatients who received influenza or pneumococcal vaccine screening during their hospital stay. Data was obtained from chart

abstraction of a random subset of charts selected for CMS core measure reporting.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): The rate of influenza vaccine screening during the first calendar quarter of 2012 was 94 %. Initial data from the current season shows a sustained screening rate of 93 % in October 2012. Although there is no true baseline comparator prior to this newest core measure, our rate of influenza vaccine screening for adult inpatients with pneumonia was 84 % during the fourth quarter of 2011. The rates of pneumococcal vaccine screening during the first, second, and third quarters of 2012 were 87 %, 88 %, and 96 % respectively. A trend towards improved screening rates over the course of 2012 has mirrored ongoing efforts to identify specific process failures and iteratively improve them.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): An approach to inpatient vaccine screening efforts integrating a nurse-driven protocol, a provider-driven exit check, and informatics decision-support into existing workflow shows promise as a comprehensive and sustainable strategy for improving hospital vaccine screening practices.

A QUALITY IMPROVEMENT APPROACH TO IMPROVING OPIATE PRESCRIBING IN OUTPATIENT PRACTICE Constance van Eeghen; Charles D. MacLean; Amanda G. Kennedy; Mark Pasanen. University of Vermont, Burlington, VT. (Tracking ID #1643297)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The epidemic of prescription drug abuse has had an important impact in primary care due to both the complexity of caring for opiate dependent patients and the practice management issues that often arise.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): While most states have implemented Prescription Drug Monitoring Programs (PDMPs) and other public health measures, less attention has been paid to improving primary care office systems around opiate prescribing. In this study we developed and implemented a quality improvement (QI) process for best practice opiate management. The objective of this study is to describe the implementation process, and the barriers and enablers to adoption in 10 outpatient practices in Vermont.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We used a LEAN QI approach to assist practice teams analyze office workflow and select/implement from among 14 best practice strategies. The LEAN QI approach was characterized by short cycle time for implementation planning (8 h of meeting time for multi-disciplinary teams that ranged from 3 members to 8), direct involvement of front line providers and staff, and a tightly structured problem-solving approach. The study subjects were the practice members, all of whom were affected by office system changes, with a subset participating directly on teams to select and plan those changes. Of these practices, 1 was Internal Medicine, 6 Family Medicine, 2 were a combination of both, and 1 Orthopedic. Practice size ranged from 2 providers to 20. Teams collected information through their meetings to produce system diagrams that measured delays and errors in office processes, which were used both to plan changes and guide qualitative data collection. Each team's workflow analysis resulted in the selection of strategies and led to discussions with the team that identified barriers and enablers to implementation. We used a consensus approach among the project staff to categorize barriers and enablers.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): All 10 practices completed the workflow analysis. Each practice planned to adopt between 2 and 10 of the 14 strategies offered. These included systematic use of the PDMP (100 %), agreement across all providers to use the same office systems processes (90 %), use of a risk assessment screening tool as part of the assessment of patients receiving opioids (90 %), and systematic use of drug screening as part of the monitoring process (90 %). One of the most important determinants of successful implementation was leadership and support from an influential provider in the practice, including resource support for team meetings, liaison to foster uptake by colleagues in the practice, and role modeling best practice behaviors. Important barriers included finding time for office teams to convene, distractions of day to day work, and heterogeneity of individual prescriber attitude regarding optimal approach to managing opiates.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): LEAN QI techniques can help improve opioid prescription management in varied office settings. Strategies for managing opiates that include pre-treatment risk assessment and systematic ongoing monitoring for misuse are most favored by busy clinicians in the practices studied. Implementation of such strategies depends on a commitment from practice leadership to support adoption of innovation through specific roles and actions.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This QI approach to improving opiate prescribing may be adaptable to other settings.

A QUALITY IMPROVEMENT PROJECT TO REDUCE EMERGENCY DEPARTMENT DELAYS WITH THE ELECTRONIC MEDICAL RECORD Changwan Ryu[1,2]; Teresa M. Michel[1]; Stacey Gonzalez[1]; Dinesh John[1]; Joan Mitchell[1]. [1]Syracuse VA Medical Center, Syracuse, NY; [2]SUNY Upstate Medical University, Syracuse, NY. (Tracking ID #1624350)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Our emergency department (ED) experiences significant delays in patient care, as measured by the number of visits lasting >6 h and total hours of diversion, resulting in countless missed opportunities for the care of our veterans.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Streamline patient flow from the ED to the hospital wards by improving the electronic medical record admission process. 2. Improve ED performance by reducing the number of visits lasting >6 h and total hours of diversion.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Collaborating with our colleagues from business and clinical applications, we created a flow-map of the admission process. It revealed that completion of admission orders by the admitting service was a rate-limiting step for ED flow because patients cannot be transferred to the wards without them. We identified our bottleneck as the inefficient need for completing both paper and electronic orders. After the ED physician notifies the admitting service, the resident completes a paper order that contains the diagnosis, status, service, and need for telemetry, and physically hands it to the clerk. All other treatment orders are electronic and cannot be submitted until the clerk has processed the paper order. After the clerk inputs the paper order, the clerk hands it to the nurse for admission notification, and then the nurse hands it to administration. We changed this by creating an electronic order set to replace the paper order, and instituted a system of computer alerts to automatically facilitate communication. This ensured physicians and staff would not have to waste time physically delivering paper orders. We successfully performed a trial with our Internal Medicine (IM) residents, and then proceeded to meet with leaders from multiple departments for widespread implementation.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Our primary outcome will compare admission order completion times between paper and electronic orders because this was the rate-limiting step in the admission process. We will collect the times from 400 paper orders and 400 electronic orders and conduct an independent sample t-test for significance. Additionally, we will construct control charts on ED visits >6 h and total hours of diversion to evaluate the effectiveness of our intervention on delays.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Presently, 95 % of our admissions utilize our electronic order set. We continue to seek out feedback and adjust our order set as needed. For our primary measure, preliminary data from 100 admissions using electronic orders showed a time of 43 min, vastly improved from the 111 min it took with paper orders. We will continue to collect data on admission order times, the number of ED visits >6 h, and total hours of diversion.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The trial with our IM residents provided an opportunity to conduct a PDSA cycle prior to implementation. After formulating a plan with our IM department, we did a trial with our residents and studied the results by examining admission order times and immediate feedback. This proved to be instrumental in our act of transitioning to our new admission process. Our multidisciplinary approach enabled us to gather insight from multiple points of view on our admission process, which was vital for completing our flow-map and enlisting the support of ancillary services. Through this collaboration, we were able to develop an efficacious and sustainable quality improvement project.

A SHARED MEDICAL VISIT MODEL FOR WEIGHT LOSS: A PILOT STUDY Ingrid Lobo; Brandy Deffenbacher; Carmen Faust. University of Colorado, Denver School of Medicine, Aurora, CO. (Tracking ID #1637792)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can the group visit approach be applied to weight loss management in the ambulatory clinic setting?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): objective 1:To pilot test within an academic primary care setting a weight loss visit program that operates during regular clinic hours and is integrated into existing clinic routines. objective 2:To gauge success and sustainability through assessments of program-associated patient participation, process measures, work productivity and patient and provider satisfaction.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Three medical providers at three different outpatient clinic sites each assumed leadership of a group visit series. In each group, 15 English-speaking adults with a BMI >30 m/kg were invited to participate. Groups met monthly for 6 months for a total of 6 visits. The shared medical visit took the place of a normal morning or afternoon clinic session for the provider, pre-empting usual one-on-one patient appointments for that day. The group visit model combined a group educational segment and then patients were seen individually if needed. This could be for blood pressure control, medication titration or any acute issue. A medical assistant checked patient in, started an electronic visit note, and escorted patients to a conference room for the shared portion of the visit. The main focus of the group visits were weight loss. Topics covered included nutrition, food shopping, eating out, exercise, mood and sustaining weight loss. Services were billed using standard Evaluation and Management (E&M) codes.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Measures of success included patient's interest and completion of the 6 month course and a smooth integration of the group model into the ambulatory clinic setting. Process measures included the number of patients who lost weight, % weight loss, and maintenance of weight loss. Patient and provider satisfaction were measured through survey data. Provider productivity, measured in work-related value units, was compared to a typical clinic morning or afternoon for that provider where patients were seen one-on-one.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Weight loss group visits were successfully integrated into regular clinic hours with minimal disruption to existing clinic routines. Attendance has been high, with 34 patients attending at least 3 of the 6 visits. Attrition reached 26 % by the fourth session. Patient feedback has been positive. 96 % indicated "group visits are better for managing my weight loss than my usual care alone" and "group visits presented useful information." Providers seem to like this type of health care delivery. After completion of the program, 79 % of patients lost weight with 2.37 % weight loss. Provider productivity, measured in work-related value units, was 16 % greater during group visits as compared to one-on-one clinic sessions.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The group visit model is potentially a successful way to tackle weight loss management in the ambulatory clinic setting. The program filled and was integrated into a typical clinic day. The pilot suggests that although weight loss was achieved, it was not significant. However, patients and providers seem to like this type of health care delivery. With further development of the curriculum, continued patient feedback, and a close look at financial sustainability, this could be a successful method to approach obesity in the ambulatory clinic setting.

A POPULATION MANAGEMENT SYSTEM FOR IMPROVING COLORECTAL SCREENING RATES IN A PRIMARY CARE SETTING Charlotte A. Wu[1,2]; Amara L. Mulder[3]; Manuela V. Costa[3]; Adrian Zai[4]; Lori Tishler[3]; John R. Saltzman[5]; Asaf Bitton[3,6]; Andrew L. Ellner[1,7]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]Massachusetts General Hospital, Boston, MA; [5]Brigham and Women's Hospital, Boston, MA; [6]Harvard Medical School, Boston, MA; [7]Harvard Medical School, Boston, MA. (Tracking ID #1641764)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Provision of colorectal cancer (CRC) screening in primary care is currently suboptimal because of uncoordinated care systems and poor patient-provider communication.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Our goal was to optimize adherence to evidence-based guidelines for CRC screening in a large hospital-based academic primary care clinic by shifting non-visit-based health maintenance tasks from a physician-dependent to team-based model using an interactive IT registry tool (TopCare-PIMS).

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): TopCare-PIMS is an automated, closed-loop network of 5 inter-related registries that monitor and track patients overdue for CRC screening at the Phyllis Jen Center at Brigham and Women's Hospital. This system is rooted in a population-based, rather than visit-based, workflow and empowers providers to utilize non-clinical support staff to perform tasks, including:—contacting patients via mail and phone—obtaining and scanning outside records—systematically documenting patient decline after discussion of risks and benefits—deferring patients from screening for specified periods of time—excluding patients permanently from screening Provider training in TopCare-PIMS was performed in 5 suites, with plans to expand to 3 remaining suites, representing approximately 2400 total overdue patients. LEAN/six sigma quality improvement principles and process mapping guided implementation.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): First, we conducted semi-structured interviews and observations with providers to understand barriers to registry use and task delegation to other team members. Second, we began extracting monthly data from TopCare-PIMS to provide real-time trends in physician compliance with CRC screening. Reasons for patient non-participation were obtained to guide future interventions to increase screening rates.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): During Phase 1 implementation in the first two suites, 19 of 31 physicians received 1:1 training while

the rest were trained via written materials. Prior to implementation, 445 patients were overdue for colonoscopy out of a total of 1,050 patients. The screening rate improved from 58 % to 68 % over 9 months. The overall rate of adherence to the evidence-based algorithm (including documented deferred tests, as well as outside tests) increased to 83 %. Among 445 overdue patients: 44 new colonoscopies were ordered via the TopCare-PIMS, 164 patients were deferred, and 88 outside colonoscopies were documented. After system optimization based on Phase 1, including integrating a real-time algorithm for PCP-patient linkage and improving capture of outside colonoscopy record entry from our EMR, we began Phase 2 implementation to 3 additional suites in 12/2012.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We have begun to successfully implement a population management system that uses closed loop communication to improve CRC screening rates.—Well-designed IT systems can enable sharing of patient care responsibilities and allow physicians to practice at the top of their license.—Process mapping helped us understand deficiencies in the current siloed screening process and helped us build a safer, more efficient process.—Interdepartmental collaboration with the endoscopy team was crucial for project success.—Implementing population management systems present novel opportunities for working across institutions and departments in the evolving "medical neighborhood."

AN ANALYSIS OF TIME COST OF THE COMMON PRECEPTING MODEL IN AN OUTPATIENT INTERNAL MEDICINE RESIDENCY TRAINING CLINIC Eric Martin[1,2]; Scott Joy[1,2]. [1]University of Colorado Denver, Denver, CO; [2]High Street Internal Medicine, Denver, CO. (Tracking ID #1642259)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The time cost of the common precepting model in outpatient internal medicine residency training has not been quantified, resulting in unknown amounts of unaccompanied patient time, and an unclear impact on resident-patient counseling.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Emphasize the time cost of the common precepting model in a residency training program 2. Quantify unaccompanied patient time, and resident-patient counseling time 3. Generate consideration of systems that optimize UPT, and improve RPC

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The traditional teaching model in outpatient residency training involves a resident-patient encounter, followed by senior faculty staffing, and ends with resident-patient counseling. This model results in an unknown amount of unaccompanied patient time (UPT), and an unclear impact on resident-patient counseling (RPC). A literature search for relevant MeSH and non-MeSH terms revealed no similar studies. We have quantified these time periods in hopes of implementing alternative models that minimize UPT, and as a consequence, improve patient satisfaction, maximize resident and patient education, and improve clinic efficiency.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): At a primary care residency training program in Denver, Colorado, between December 18, 2012 and January 7, 2013, a resident physician and a medical assistant served as time recorders. Times of resident exam room entry and exit were recorded into an excel spread sheet. Initial Encounter Time (IET) was defined as resident entry to resident exit time for staffing. UPT was defined as resident exit for staffing to resident return for counseling. RCT was defined as resident entry time for counseling, to resident exit for visit conclusion. Not all encounters during the aforementioned time period were included in data analysis due to observer absence, or atypical patient encounter and/or needs. Pertinent details regarding each encounter were noted and were taken into consideration at data analysis.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): After atypical record exclusion, averages of IET, UPT and RPC were attained for all participants, with resident categorization by post-graduate year level. IET, UPT, and RPC averages were summed to provide average total time. Forty-four encounters were included in data analysis. Notable results demonstrated UPT that was stable across all training levels, averaging 12:25. RPC decreased steadily as PGY increased, with PGY3's averaging 6:10, and PGY1's averaging 9:17. Total Times decreased from a PGY1 mean of 1:02:36, to a PGY3 mean of 59:54.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): While the traditional precepting model provides valuable education to the resident, the opportunity cost of UPT cannot be ignored, particularly in regards to providing better patient specific education at the point of care. Interestingly, our data demonstrates a stable UPT across training levels, and a trend towards decreased RPC time from PGY1 to PGY3. Next steps for our clinic are to design systems that optimize UPT. UPT alternatives being explored include computer or print based patient-specific education to be reviewed by the patient during UPT, use of instant messaging (IM) between junior/senior residents and attending physicians to reduce UPT, and electronic solutions such as a web-based, clinic specific "virtual preceptor" that a resident can access during IET that provides attending answers and algorithms to the most common clinical questions encountered in primary care settings.

ANTIBIOTIC TIMEOUT PROGRAM: IMPLEMENTING A HOSPITAL STEWARDSHIP INTERVENTION Kimberly M. Tartaglia; Curt Walker; Allison Heacock; Ivy Kuofie; Beth Liston; Jessica West; Kurt Stevenson. Wexner Medical Center at the Ohio State University, Columbus, OH. (Tracking ID #1631248)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Excessive antibiotic use has been associated with occurrences of Clostridium difficile infections, increasing bacterial resistance, adverse drug reactions, and is a driver of rising healthcare costs.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Modeled on a national initiative by the Centers for Disease Control and Prevention (CDC) entitled 'Get Smart for Healthcare', the Antibiotic Timeout (ATO) program is a quality improvement effort designed to optimize use of antimicrobials. Our objective was to introduce the concept of an antibiotic time-out to all inpatient general medicine services as purposeful review of a patient's antibiotics 48–72 h after admission with the goal of determining the indication, dose, and duration for any necessary antibiotics.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The ATO program is a patient safety initiative championed by the division of hospital medicine in collaboration with the Antimicrobial Stewardship Program at our institution. The program and rationale was introduced to hospital medicine physicians in May 2012. After introduction of the program, we developed a template that facilitated progress note documentation of participation in an antibiotic time-out with specific information on antibiotic dose, indication, and planned duration of treatment. We then worked to integrate the initiative into routine work practice through weekly reminders to physicians on service that included education on the program and feedback on current performance.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): To measure the impact of our program, we tracked participation in the antibiotic time-out through physician documentation in our electronic health record from May to December 2012. Outcome measures for our program include antibiotic use and cost data as well as occurrences of hospital-acquired C. difficile infections both before and after implementation of the program.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): For the resident supported general medicine services, physician compliance with documentation was 1 % at baseline

(May 2012) and increased to 45 % documentation for inpatients on antibiotics by week 30 (December 2012.) For attending only services, documentation of an antibiotic time-out was 1 % at baseline and increased to 28 % documentation by week 30 of our initiative.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Clinician participation in and documentation of the ATO program increased with weekly reminder messages with feedback on current performance targeted to the current physicians on service. Next steps in the program are evaluating the program's impact on antibiotic usage and cost data as well as continued monitoring of C. difficile infections within the institution.

BUILDING SYSTEMS OF CARE: DOES A MULTI-FACETED DIABETES IMPROVEMENT PROJECT CHANGE CLINIC STAFF ASSESSMENT OF THE CARE SYSTEM? Debra Maltby; Yue Gao; Anna P. Goddu; Tonya Roberson; Marshall Chin; Monica E. Peek. University of Chicago, Chicago, IL. (Tracking ID #1641918)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Does a multifaceted intervention improve specific components of a diabetes care system?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The objectives of the "Improving Diabetes Care and Outcomes on the South Side of Chicago" initiative are to: 1) build and strengthen community partnerships and the medical neighborhood to improve diabetes resources and quality of care, 2) empower patients to take ownership of their health, and 3) redesign the health center delivery system through planned visits, care coordination, shared decision making, provider education and care coordination.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The initiative is a multi-year, multi-faceted project that addresses the high prevalence of diabetes on the South Side of Chicago and serves primarily African American patients who lack access to healthcare. Interventions correspond to many elements of the Chronic Care Model (CCM). The most visible and effective interventions include developing successful community partnerships in underserved neighborhoods, designing patient education classes specifically tailored to the area's unique culture and creating provider workshops emphasizing culturally based communication and shared decision making. The six participating health centers have quality improvement teams that extend and reinforce the work of the initiative with clinic redesign efforts including group visits, patient outreach, peer mentoring, referral tracking for behavioral health, nutrition and diabetes education. The clinics are starting to focus on expanding care coordination and customizing newly implemented electronic health records to foster chronic disease information systems, registries and clinical decision support.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Six health center teams completed self-evaluation using a modified version of the Assessment of Chronic Illness Care (ACIC) specific to diabetes. The ACIC is a validated tool addressing improving chronic illness care at the community, organization, practice and patient level. The seven components (organization of the healthcare delivery system, community linkages, self-management support, decision support, delivery system design, clinical information systems and integration of CCM components) are scored from zero to ten and correspond to the elements of the CCM. Health center teams completed the evaluation every 6 months for a total of six measurement points in time. Data from the ACIC survey was analyzed using Page's L test to examine trends with a small number of observations.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Participants' ratings showed significant ($p<0.05$) improvements in four of the ACIC domains; community linkages (First 4.0, Last 5.0, Range 3.8 to 6.0), diabetes self-management (First 6.1, Last 6.2, Range 6.1 to 7.8), diabetes delivery system design (First 5.4, Last 5.8, Range 4.9 to 7.1) and integration of CCM (First 4.3, Last 5.4, Range 4.3 to 6.1) The overall average also improved significantly (First 5.2, Last 5.8, Range 5.0 to 6.7). Significant improvement was not found in the other domains of the ACIC.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): An initiative to improve diabetes care tailored to the needs of a specific community has had positive impacts. Health center evaluations of diabetes care management systems showed significant positive change on elements of the CCM most closely matching the diabetes initiative's most successful interventions.

COMMUNITY-BASED CARE COORDINATION TO OVERCOME FRAGMENTATION OF SERVICES IN AURORA, COLORADO Joseph D. Johnson[1,2]; Maisha Pollard[2]. [1]University of Colorado Denver, Aurora, CO; [2]The Fields Foundation, Aurora, CO. (Tracking ID #1642210)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In North Central Aurora, 45 % of women over 20 lack a high school education and 15 % of children are born to mothers under 20, unfortunate facts given the myriad of independent medical and social health providers servicing the area.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The Fields Foundation's Clinical Community Coordination Program's primary objective is to help these young families and at-risk youth to access existing services and overcome the burdens of poor health literacy, lack of awareness of this support structure, and lack of coordination amongst providers. Secondary objectives are to improve sexual health literacy and reduce pregnancy rates amongst youth.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The program is administered by an independent community organization and revolves around a community-based nurse care coordinator overseeing 2 tiers of community health workers (CHWs). Tier 1 is a broadly available "street team" available in person or via social media to provide intermittent education and service coordination to a large pool of potential patients. Tier 2 is based upon continuous family-based care relationships, with CHWs and care coordinator navigating and interfacing with multiple providers to ensure care access, understanding of care goals, and appropriate service utilization. We have developed a family-based documentation technique that reflects our holistic recognition that a person's chief complaint is not always a medical issue, but may rather involve domestic issues, food insecurity, legal trouble, etc. In lieu of the complexity of the community's health and social welfare systems, this intervention must be grassroots-led, rather than connected to any one institution or provider network. Our partners, including the Piton Foundation, Colorado Children's Health Access Program, and the University of Colorado School of Public Health and Departments of General Internal Medicine and Community Pediatrics, support this approach. Tier 1 CHWs have already begun providing care, and we are currently developing a problem-based learning curriculum to train Tier 2 CHWs, with a goal to begin enrolling continuity patients in autumn 2013.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Our metrics include utilization data, health indicators including pregnancy rates, and markers of financial and social well-being. We will compare these metrics to those of nearby control communities, similar to the approach employed assessing the Earth Institute's Millennium Villages Project. Metrics are coordinated with our partner institutions and organizations.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): To date, we have completed a full needs assessment in the form of a PhotoVoice project, as well as a survey of sexual health knowledge and attitudes amongst local high school students. These assessments identify a need for holistic care coordination, as well as a strong community and political will to implement such a design.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our results will be generalizable to other

communities lacking an inclusive safety net care structure, demonstrating that community-based care coordination provides cost-effective, culturally appropriate care that improves both health utilization and outcomes. This evidence will ultimately support the policy goal of primary care reimbursement reform by the Colorado Department of Health Care Policy and Financing. Finally, this project provides educational benefit, demonstrating the potential for community-based participatory research within a primary care medicine residency program.

CREATING A CHECKLIST TO USE DURING TEAM HUDDLE TIMES TO OPTIMIZE PRACTICE EFFICIENCY AND CARE MANAGEMENT IN AN ACADEMIC PATIENT CENTERED MEDICAL HOME Scott Joy[1]; Eric Martin[3]; Carly Byrne[2]; Gerardo Caldero Rosales[2]; Oswaldo Hernandez[2]; Lucy Llamas[2]. [1]The Colorado Health Foundation, Denver, CO; [2]HCA/HealthONE, Denver, CO; [3]University of Colorado Health System, Denver, CO. (Tracking ID #1640050)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): How can we maximize the content discussed during team huddle to optimize review of the medical record, standardize and improve team communication, and improve the quality of care for patients scheduled for a clinic visit in a primary care setting?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Create a simple checklist to use during team huddle to standardize team communication with the intent to optimize visit efficiency and quality of care Measure the time required to complete a huddle session between medical assistants and providers using this checklist

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Excellent communication and coordination among the members of the team has been found to be a critical feature of successful patient-centered practices, and is a must pass factor for NCQA certification as a Patient Centered Medical Home, in that the practice must participate in team meetings, particularly huddles. There are no specific guidelines for what huddles need to consist of, other than it being a team meeting to discuss patients on the day's schedule and involve a communication process that may include regular e-mail exchanges, tasks or messages about a patient in the medical record. Our practice has internal medicine residents that rotate in our clinic either in the AM or PM, and our huddles occur twice a day. To standardize the effort and time required to huddle, we sought to create a checklist that would cover critical issues necessary to optimize the visit time for the patient and the skill sets of the schedulers, medical assistants, and providers (including behavioral health and social work), focus on quality measures necessary for the delivery of high quality primary care, and to review messaging from previous notes from providers or clinical staff.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Create a single checklist to use during each huddle between providers and medical assistants to create an efficient and reproducible mechanism for team communication Measure the time it takes for provider/MA to huddle prior to clinic session

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Our checklist consisted of the following questions: 1. Is this a New or Established Patient? 2. What is Reason for Visit? 3. Review Grey box (this is a section in our electronic medical record (eCW) that alerts the team to outstanding items,such as Labs, Diagnostic Imaging, Referrals, Actions, Telephone Encounters, Web Encounters, Documents and P2P communication) 4. Any outstanding Actions and/or Alerts for the patient? 5. What is current status of age appropriate vaccinations for this patient? 6. What information do you need to make this visit most efficient and effective? (asked by MA to provider) By following this checklist, we have found that It takes an average of 4:07 min (range 1:00 to 7:04, SD 0.07) to complete the huddle per provider schedule

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A simple, standardized set of questions can improve communication between medical assistants and providers in a PCMH This set of questions can be used to identify outstanding items necessary for the patients care, help to develop an optimal plan for the face-to-face visit, and takes less than 5 min to complete This checklist provides a standard mechanism within a primary care practice to optimize vaccinations for patient in a PCMH

CREATING A NEW HABIT: IMPROVING PHYSICIAN COMPLIANCE IN HIV SCREENING Marelle Yehuda; Valentina Rodriquez; Robert E. Graham; Ladan Ahmadi. Lenox Hill, New York, NY. (Tracking ID #1642500)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The objective of the study was to determine the rates of HIV screening at our New York City hospital and to make systems based improvements, based on data from a survey of resident physicians, to improve our rate of screening.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To evaluate rate of HIV screening after the implementation of a resident education initiative, the addition of a reminder to screen for HIV to the admission form and facilitation and clarification of the order entry for HIV screening on our EHR.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In September 2010 New York State legislation amended the public health law to require that HIV testing be offered to all patients, ages 13 to 64, in primary care settings, emergency departments and inpatient settings. Barriers to HIV screening include lack of physician knowledge about the mandate, work load, and difficulty discussing the topic of HIV with patients. This study aimed to determine if physician education, work flow improvement and clarification of HIV screening law would improve the rates of screening at our New York City Hospital.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The first 134 medical records of all patients admitted to the department of medicine at Lenox Hill Hospital in June 2011, were reviewed for the presence or absence of a rapid HIV antibody test or documentation of offering HIV screening. Patients with known HIV infection, admitted for routine chemotherapy, requiring ICU or ICU step down admission or having a terminal end stage disease were excluded. Three interventions were instituted to improve inpatient HIV screening based on a resident survey which identified barriers to HIV screening. These included a resident education initiative, the addition of a reminder to screen for HIV to the admission form and facilitation and clarification of the order entry for HIV on our EHR. We then reviewed the first 135 medical records of patients admitted after the interventions were put in place, using the same exclusion criteria, for documentation of HIV screening or offering of screening.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Prior to the implementation of our intervention program, 8/87, or 9.1 % (CI 4–15 %), of qualifying patients admitted to the department of medicine were offered or screened for HIV. Repeat chart review after implementation of our program found that of 85 qualifying patients 13 had been screened or offered screening for HIV, or 15.3 % (CI 8.4–24.7 %) P=0.32.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Interventions attempted based on survey information from residents failed to improve the rate of HIV screening at our New York City Hospital indicating that bad habits are hard to break. As seen in our resident survey the stigma associated with the disease and physicians' comfort with offering testing continue to be major barriers to wide spread screening. We will continue to offer the educational intervention quarterly

in hopes of changing physician habit and incorporating HIV screening into routine admission to the hospital.

CREATING AN INTENSIVE CARE MANAGEMENT TEAM AND IDENTIFYING HIGH RISK PATIENTS IN AN ACADEMIC GENERAL INTERNAL MEDICINE PRACTICE Scott Joy[1,3]; Leanne Clark[1]; Lynn Haley[1]; A. Meghan Hayes[3]; Gretchen Hubner[4]; Michael Masse[4]; Katey Morris[2]; Steve Mack[3]; Alyssa Nash[3]. [1]The Colorado Health Foundation, Denver, CO; [2]Walgreens, Denver, CO; [3]University of Colorado Health System, Denver, CO; [4]HCA/HealthOne, Denver, CO. (Tracking ID #1639919)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): How can an academic General Internal Medicine practice create an intensive care management (ICM) team, identify patients at high risk for overutilization, understand current utilization of hospital/ER services for this group of patients, and identify medication adherence issues?
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Identify patients who historically have been high utilizers of ER/hospital services and determine the frequency of ER visits/hospitalizations over a 12 month period Create a registry of these patients in an electronic health record (EHR) and an electronic method for team/PCP communication Build a relationship with local pharmacy to identify patients with medication adherence issues
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Patients were identified as being high utilizers of ER/Hospital services by PCP, Hospitalist or case management referral, or data from a health risk assessment completed by patients in our office. A patient-specific alert (Intensive Care Management) was created in our EHR that allowed this group to be queried and alert other providers of patients co-managed by the ICM team. A multidisciplinary team (attending/resident physicians, clinical psychologist, social worker, medical/administrative assistant, pharmacist) was created and meets weekly for up to 90 min to review each patient. Team conversations are documented in a specific "Notes" section in the EHR. If the team decided an action needed to be taken during that review (vaccination due, f/u testing, records review), an electronic notification was created for the PCP to review during huddle at next patient visit. ICM patients filling their prescriptions at our collaborating pharmacy were reviewed by pharmacy systems to identify gaps in medication adherence.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Form clinical team to evaluate and provide additional oversight of high risk patients Identify high risk patients within our practice Determine ER/Hospital visits from 1/1/2012 to 12/31/2012 to establish baseline of utilization Create notifications, alerts and specific area for documentation of team review and care plan within our EHR Improve communication between pharmacy and primary care practice to proactively screen for medication adherence issues
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Number of high risk patients identified: 12 Total number of ER visits/Hospital Admissions for this group: 114 (average 9.5 visits/patient; range 0 to 37 visits, ER visits 94, Hospitalizations 20) Months with highest numbers of ER/Hospitalizations: August (19), October (14), September (13) Number of patients followed by collaborating pharmacy as documented in e-prescribing system: 5 (42 % of group) Number of patients in this group identified as having potential adherence issues: 1 (20 %)
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A multidisciplinary team can be formed within an academic General Internal Medicine clinic and workflows can be developed within the EHR that allow the team to communicate with one another and with the PCP. Utilization for this group was not constant throughout the year, spiking in late Summer/early Fall. For patients that fill their medications with our collaborating pharmacy, a mechanism can be developed to proactively track medication adherence. Now that a process and baseline measurements have been established for this group, interventions can be developed with the intent to reduce the overutilization of services, particularly ER visits.

CREATION AND EVALUATION OF A MULTI-DISCIPLINARY HOSPITAL FOLLOW-UP CLINIC IN AN ACADEMIC GENERAL INTERNAL MEDICINE CLINIC Shana Ratner; Christine D. Jones; Jamie Cavanaugh; Katy K. Tsai; Genevieve G. Embree; Brooke B. McGuirt; Robin H. Roche; Thomas M. Miller; Betsy B. Shilliday; Darren A. DeWalt. University of North Carolina, Chapel Hill, NC. (Tracking ID #1624771)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Most initiatives to reduce hospital readmission focus on discharge and care management and do not optimize the outpatient settings that receive patients.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) To create a standardized approach to primary care follow-up after hospitalization using a clinical pharmacist, care manager, and physician 2) To improve access to primary care for the recently discharged patient 3) To reduce 30-day readmissions for the Internal Medicine population
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The UNC Internal Medicine Clinic is an academic general internal medicine practice with 13,958 patients. Approximately 200 of these patients are discharged monthly from UNC Hospitals, and 15–20 % are readmitted within 30 days. Prior to our innovation, primary care follow-up was determined by inpatient teams, access was often obtained in our embedded urgent care, and content of the follow-up visit was not standardized. We developed a quality improvement team including leadership from inpatient and outpatient settings. The team set the aim to reduce UNC readmissions by 20 % in our practice population. Using best practices identified by the Care Transitions Program® and the IHI STAAR Guide, we designed a standardized visit process for a clinical pharmacist practitioner and physician team. We first created a hospital discharge database with real-time display of daily discharges stratified by readmission risk (low, medium, or high). A care manager tested several methods of outreach to schedule and guide patients to a hospital follow-up appointment. Using the Model for Improvement, we tested the visits with selected patients and refined the approach. To fill the demand of moderate and high risk patients, we increased access with 108 hospital follow-up appointments monthly.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Run charts and control charts are used to monitor the new processes. Before expanding capacity to accommodate all moderate and high risk patients, we conducted a retrospective cohort study to compare 30 and 90-day readmission rates for patients seen in the special hospital follow-up clinic versus usual care (using risk-matched controls). Other intermediate outcomes include time to follow up, access to urgent care services for other conditions, no-show rates, and visit duration.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): The first 48 patients seen in the hospital follow-up clinic who met inclusion criteria were compared to a risk-matched control group. Age, length of stay, and comorbidities were similar between the two groups. Patients seen in hospital follow up clinic were seen sooner than those in the usual care group (median time to internal medicine clinic follow-up 7 vs 14 days, $p=0.0005$). There was a trend toward fewer 30-day readmissions in the hospital follow-up group 6/48 (12.5 %) vs usual care 12/48 (25.0 %), $p=0.117$. There was a statistically significant difference in 90-day readmissions between the two

groups; hospital follow-up clinic 10/48 (20.8 %) and usual care 21/48 (43.8 %), p=0.016.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): As the healthcare system works to reduce 30-day readmissions, primary care clinics can be successful in improving access and standardizing content of visits. Within 6 months, we implemented a multidisciplinary program utilizing a clinical pharmacist, social worker, and physician. This method is showing promise in reducing 30 and 90-day readmissions.

DECREASING FOLEY CATHETER UTILIZATION ON THE YALE NEW HAVEN HOSPITALIST SERVICE Jose Salvana. Yale New Haven Hospital, New Haven, CT. (Tracking ID #1642916)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The Yale New Haven Hospitalist service (HS) has expanded over the last 10 years from being responsible for less than 10 % to covering over 60 % of the internal medicine inpatient census and are in a position to impact inpatient catheter associated urinary tract infections.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To decrease unnecessary use of foley catheters on the Hospitalist Service.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Yale New Haven Hospital adapted the Sunrise Clinical Manager (SCM) as its primary Electronic Medical Record (EMR) in 2007. The Hospitalist Service (HS) created an Access database: LISTMAKER in September 2008 to generate worksheets for patient assignments. The worksheets are distributed to HS medical providers at the start of each workday. The worksheet was developed into a quality improvement tool identifying the performance improvement priorities set by the HS. Functionality was added to the worksheets by leveraging embedded SCM order filters to create a column identifying active FC orders and day counts. Baseline data was collected for a month starting November 15, 2009. The electronically generated FC order reminders were incorporated into the worksheets on December 15, 2009. Foley catheters that were maintained >14 days were excluded from the study.An in-service reviewing the IDSA Guidelines: Diagnosis, Prevention and Treatment of Catheter Associated Urinary Tract Infections in Adults, 2009. was held at the start of the project cycle and updates were reviewed annually. A physician champion was identified to track FC utilization. Periodic reviews of the metrics were undertaken during monthly quality and performance improvement meetings. The need for evidence based indications for FC use was stressed during each educational session

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): FC utilization is defined via two metrics: (1) the percentage of the daily census with an FC order (Daily Prevalence) and (2) number of days the catheter orders are maintained (FC Days).

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): The HS had 41,474 unique discharges during the study period. The daily prevalence of FC use decreased from 16.6 +/− 3.28 % to 11.27 +/− 3.15 % (p<0.001). The mean FC Days decreased from 2.73 +/− 0.97 days to 2.24 +/− 0.8 days (p< 0.001). The decrease in Foley catheter utilization has been sustained over last 3 years with a daily prevalence of 10.8 +/− 2.5 % and means FC Days of 2.0 +/− 0.58 days in the last quarter of 2012.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The HS was successful in decreasing overall FC utilization 32 % through the use electronically generated daily reminders, by developing the infrastructure for periodic review of metrics and by identifying a physician champion to promote evidence based best practices. The infrastructure we created leverages functionality already available on the EMR and the implementation of the program had little incremental cost to the system.

DEVELOPMENT OF A HEPATITIS C TESTING AND TREATMENT LINKAGE PROGRAM IN AN URBAN PRIMARY CARE CENTER Zachary Rosner[1,2]; Alain H. Litwin[1,2]; Meredith Steinman[1]; Angela Jeffers[1]; Laura J. Guderian[1,2]. [1]Montefiore Medical Center, New York, NY; [2]Albert Einstein College of Medicine, New York, NY. (Tracking ID #1642671)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): New treatments are available for treatment of chronic hepatitis C (HCV) infection, yet many patients face barriers to accessing treatment in specialty clinics and may benefit from hepatitis C services located within a community health care center.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) To increase HCV testing and linkage to care for a high-risk patients. 2) To provide HCV treatment in an accessible primary care setting.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Setting: In order to increase testing and treatment for chronic HCV, services were initiated through an academic community health center which also provides substance abuse treatment. The health center and affiliated outreach locations are all in an urban setting. Testing started in September 2012 and results are presented through early January 2013. Staff: A patient care navigator helps coordinate outreach and testing programs. An infectious disease trained primary care provider oversees the medical evaluation and treatment of eligible patients. Supervision is provided by an experienced hepatitis C provider and support by a program coordinator and with resident physician participation. Program: Outreach efforts include poster placement and recruitment in clinic waiting areas, participation in health fairs, and collaboration with community organizations. Testing is performed in multiple settings with high-risk populations. Chronically infected patients are referred to the physician for further management. A patient navigator assists patients throughout the process. Tasks performed by the patient navigator include initial antibody testing, ensuring follow-up viral load testing after a positive antibody test, assisting patients with insurance or housing, referring for additional social support services, patient teaching, and helping to coordinate medical care by obtaining prior authorization and ensuring delivery of HCV antiviral medications. All activities are done in conjunction with the medical provider and a dedicated weekly clinic session allows the physician and patient navigator to see patients and coordinate care as a team.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We evaluated the program by number of tests done, number of patients with chronic infection, the number linked to care and those lost to follow-up at any stage.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): A total of 498 participants have been tested between the start of testing in September and early January 2012. Antibody testing was positive for 130 (26 %) participants. Ninety-two patients (18 % of all tested) were found to have detectable viral load tests. To date, 83 chronically infected patients (90 % of those identified) have been linked with care. Ten (2 %) patients were lost to follow-up, seven prior to receiving viral load testing and three after.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Efforts targeting at risk populations in an urban setting can successfully link patients to care for hepatitis C within a primary care setting. A patient navigator can help guide patients through the testing process and initiation of treatment. Early results suggest that placement of HCV services in a primary care setting may help improve linkage to care and avoid significant loss to follow-up.

DEVELOPMENT OF A STUDENT-FACULTY COLLABORATIVE CLINIC WITH A SPECIAL FOCUS ON SERVING POST-INCARCERATED PATIENTS Kimberly Sue[1,2]; Rachel E. Simon[1,2]; Gabriel Sneh[1,2]; Mihir J. Chaudhary[1,2]; Jessica Zeidman[2]; Marya J. Cohen[2]. [1]Harvard Medical School, Boston, MA; [2]MGH-Chelsea, Chelsea, MA. (Tracking ID #1634482)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Individuals released from jail/prison have high rates of chronic medical conditions, mental health and social service needs, but tend to have low engagement in primary care; can a student-faculty clinic attend to the complex needs of patients who have been recently incarcerated?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The initial weeks following release from prison and jail represent a key period during which health providers can intervene to improve the outcomes of this population. A student-faculty collaborative clinic—the Crimson Care Collaborative (CCC) Clinic at MGH Chelsea—was established in 2010 in large part to address the needs of the post-incarceration population. The objectives are:—Conduct a systematic review of the clinic's formerly incarcerated patients to assess their health and social services needs—Develop and pilot a qualitative instrument that will be administered to post-incarcerated patients to allow us to better understand how incarceration has affected their health—Use the above data to develop a post-incarceration health program that will better meet the needs of post-incarcerated patients most effectively

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Chelsea, MA is the smallest city in the state (pop. ~ 40,000). The city is mainly Latino and a hub for immigrants; roughly 25 % of inhabitants live below the poverty line. It is estimated that 4–6 people are released per week from prison/jail into the Chelsea area. The CCC-Clinic is located in Adult Medicine at MGH Chelsea. The clinic established relationships with several area prisons and jails and began receiving referrals for individuals returning to greater Chelsea. The goal is to schedule patients within 2 weeks of release. The clinic also has a team of students that conduct outreach to relevant social service/advocacy agencies.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Enhanced access to healthcare system for post-incarcerated patients. Improved patient satisfaction with post-incarceration healthcare.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): The preliminary data from our chart review show that the post-incarcerated patients (n=17) are predominantly older men with high rates of chronic disease (e.g. type II diabetes, hypertension and COPD) as well as infectious disease (HIV, Hepatitis C). 13/17 patients reported at least one mental health diagnosis (9 reporting depression and/or anxiety) and several reported physical trauma and/or PTSD symptoms. 6/17 reported housing instability and/or homelessness. 14 reported histories of substance use, primarily alcohol, cocaine and heroin. Only 3/17 are employed. There were high rates of missed appointments among this group.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):—Individuals returning to the community from prison or jail have significant co-morbidities, including chronic disease, infectious disease, mental health and substance abuse.—These patients have unique and complex social services needs, including vocational training and access to stable housing. The clinic should ensure access to job training, housing specialists and mental health care. The high no-show rate suggests that health care providers must engage these patients earlier/more intensively, perhaps even while they are incarcerated.—Students are an essential part of providing high-quality primary care with an intensive focus on social services for this population; this clinic is an ideal place to engage students with health disparities and social medicine.

DEVELOPMENT OF AN INTERACTIVE, WEB-BASED COMPREHENSIVE PERFORMANCE DASHBOARD FOR USE IN PRIMARY CARE PRACTICE NETWORKS Charlotte E. Ward; Wei He; Jeffrey M. Ashburner; Steven J. Atlas. Massachusetts General Hospital, Boston, MA. (Tracking ID #1641544)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Improving care and containing costs, a key goal of health care reform, requires measuring performance across a broad range of outcomes and delivering data that is informative and actionable.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To develop and implement a novel performance reporting system that provides outcome measures, patient demographic information, and productivity information to providers, and practice and network leaders.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Primary Care Performance Report (PCPR) interface was designed with input from local physician and administrative focus groups. It was developed in collaboration with a business IT team that used an existing software system to meet design goals. Reports were created and tailored to whether the user is an individual provider or a practice/network leader. Reports covered three domains in distinct sections at the level of the provider/practice: 1) patient demographics, 2) visit-based and panel productivity, and 3) outcome measures (including quality of care and patient survey composite measures, and resource utilization). All outcome measures are located within the same tab and divided into separate tables that can be viewed on a single page and are designed to give an overview of quality measures across the three domains. Users can then drill down into each category of data by: 1) reviewing individual components that drive composite performance and 2) viewing their performance in relation to other providers in their practice, or their own practice to other practices within the network. These elements allow users to identify areas needing improvement and to identify those in their practice or network that are excelling. National benchmarks are also displayed for measures when available in order to compare results to external high performers. Dissemination of the PCPR employed the use of a 'Train-the-Trainer' model to promote local, graduated dissemination. Our team demonstrated the use and application of the PCPR to network and practice leaders, who received their practice reports first. They then reviewed practice-level reports with physicians at team meetings. After this meeting, individual providers were sent emails that provided embedded links to their own reports for review.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Measures of system usage, utilization and ultimately, tracking changes in outcome measures over time.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Out of 45 users that were sent an invitation to view the primary care performance report in the Fall of 2012 as part of a preliminary roll-out, 24 users had done so within the first week of going live. The report had been viewed 154 unique times by these 24 users. Results from the full dissemination effort are pending.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A comprehensive quality reporting system can be successfully developed and implemented to better inform providers and practice leaders about performance measures. However, in order to guide innovation and change, users will need to learn to incorporate such data into local and network level quality improvement initiatives. Understanding how to disseminate such information to busy providers to prevent them from being overwhelmed by the quantity and complexity of the data will determine whether such PCPRs promote practice innovation or not.

DIABETIC GROUP VISIT IN A SAFETY NET AMBULATORY HEALTH CENTER Melanie Gordon[1]; Renee E. Walker[2]. [1]Stroger Cook County Hospital, Chicago, IL; [2]University of Wisconsin- Milwaukee, Milwaukee, WI. (Tracking ID #1641137)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Insufficient time for clinic visits in safety net systems can lead to ineffective communication between patient and provider, thus decreasing quality of patient-centered care; can maximizing the clinician- patient time improve care delivered to patients with type 2 diabetes?
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Enhance comprehension of diabetes in patients within a safety net community by maximizing time with their personal primary care physician. The goal would be to strengthen the patient/provider relationship, as well as empower patients to self-manage their disease.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A physician led diabetic group visit was implemented in a health center that serves a low income, uninsured population. This innovative approach required the provider to see several patients simultaneously to manage their diabetes. Fifteen patients with type 2 diabetes attended monthly, three-hour group sessions for 6 months with their personal primary care physician (PCP). Each session was an informal round table discussion centered on a topic chosen by group consensus. Examples of topics include: 1) what is diabetes? 2) healthy eating and 3) increasing your physical activity. Patients and PCP discussed questions, misconceptions, barriers, and solutions related to topics. The physician provided information regarding community resources available to patients that would assist with lifestyle modifications. A pre and post test was administered at the first (baseline) and last session (6 months) to assess knowledge of diabetes. Brief Individual patient visits were completed each month with medication adjustment and concerns addressed.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): To measure quality improvement, quantitative and qualitative analyses were conducted. First, assessment in improvements of scores (pre versus post-test) were analyzed. Second, assessment of knowledge, skills, and attitudes regarding techniques for improving patient-provider communication, and diabetes self-management were conducted using semi-structured interviews.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Preliminary findings show an improvement in post-test scores, suggesting increased comprehension and enhanced communication with the PCP. Patients also expressed feeling more empowered to self-manage their diabetes. While we are cautious in our interpretation of the data due to a small sample size (n=15), we are triangulating the data with qualitative analyses, which are pending.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Self-management is important in patients with chronic disease. Lack of resources in some clinics prevents adequate education to assist patients with this endeavor. Through group visits, a provider can simultaneously educate patients while addressing barriers and concerns relevant to them. Using topics chosen by the group and developing solutions based on patients needs or resources keeps the visit patient centered and strengthens the relationship between patient and provider. This novel approach was found to increased patients' comprehension of diabetes and serves as a tool to disseminate information about access to care and community resources available to patients. Many patients showed initiative by joining community wellness groups for further education on lifestyle modifications after the group visit ended, a display of empowerment. Using this format to deliver care could serve as a model for other chronic diseases and allow physicians to maximize their time while improving delivery of patient centered care.

ESTABLISHING ATTENDING PHYSICIAN SAFETY AND QUALITY METRICS: SELECTION AND PILOTING OF NATIONAL PERFORMANCE MEASURES FOR INDIVIDUAL HOSPITALISTS

Henry J. Michtalik[1,2]; Peter J. Pronovost[2,1]; Redonda G. Miller1; Jill A. Marsteller[3,2]; Joanne E. Spetz[4]; Daniel Brotman[1]; Daniel E. Ford[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Armstrong Institute for Patient Safety and Quality, Baltimore, MD; [3]Bloomberg School of Public Health, Baltimore, MD; [4]Philip R. Lee Institute for Health Policy Studies, San Francisco, CA. (Tracking ID #1638916)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Performance measures are increasingly being used to rank physicians and determine reimbursement through pay-for-performance programs and value-based purchasing; however, systematic methods to identify quality measures attributable to individual hospitalists have been limited.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Determine criteria for selecting measures that can be attributed to individual hospitalists. 2. Apply these criteria to currently collected and reported quality and safety measures to generate attending-physician-level metrics. 3. Assess the distribution and variability of these metrics to compare individual hospitalist providers and programs.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We used a mixed-methods approach to evaluate and select inpatient performance measures. First, we used a series of interviews to perform a multi-stakeholder analysis with 2 hospitalists, 3 hospital administrators, and 2 quality improvement experts to determine qualitative criteria for selecting appropriate attending-physician-level measures. Next, we applied these criteria to 64 mandated, publicly reported Maryland Potentially Preventable Complications (PPCs) and 50 Joint Commission Core measures to determine a set of quality metrics. Finally, we examined both metric distribution and variability. For the PPCs, we examined the number of events from 2011 to 12 in 4 hospitalist programs within our network; for the Core measures, we compared 45 Maryland hospitals during a performance period (2010–11) against a baseline period (2008–9) and scored each measure on achievement of benchmarks and improvement to determine a final performance score ranging from 0 to 100.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): To minimize cost and resource utilization we examined standardized, commonly reported performance measures. For the qualitative criteria used in the selection of metrics, we sought and achieved consensus amongst the stakeholders. For the quantitative evaluation of the selected metrics, we examined distribution and variability to distinguish both between hospitalist programs and individual providers.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Stakeholders reached consensus that measures should be actionable, attributable, and accountable. Actionable was defined as a measure which could be actively intervened upon during a single hospital admission or a preventable adverse event. Attributable was defined as measures associated with, or under the supervision of, an attending physician. Accountability was defined as being within the direct or indirect responsibility of an attending physician. Thirty-four of the 64 Maryland PPCs and 19 of the 50 Joint Commission Core measures reviewed met all three criteria. Regional review of PPCs over time showed variation both between and within 4 hospitalist programs in our network, with a range of 0 to 54 events per month. Statewide examination of the Core measures showed a near normal distribution with a performance score ranging from 18 to 100, indicating good discrimination amongst hospitals.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our analysis identified criteria to assign commonly collected, standardized quality and safety measures to individual hospitalists. Regional and statewide analysis of these measures suggests adequate variation to assess quality. These measures may be used in the future to compare individual hospitalists and programs both within and between institutions.

FOOD RX: MOBILIZING OUTPATIENT CLINICS TO PRESCRIBE HEALTHY FOOD FOR UNDERSERVED PATIENTS
Anna P. Goddu[1]; Tonya Roberson[1]; Katie Raffel[2]; Marshall Chin[1]; Monica E. Peek1. [1]University of Chicago, Chicago, IL; [2]University of Chicago, Chicago, IL. (Tracking ID #1641685)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Patients living with diabetes in underserved communities face significant challenges to eating healthy; to support them, clinics should integrate community nutrition resources into diabetes care.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To develop a program integrating community nutrition resources into diabetes care, in collaboration with clinics, a local farmers market, and a national retail pharmacy. 2. To assess the feasibility of using a provider's prescription to offer financial incentives for healthy food, raise awareness of local food resources, and provide nutrition education to underserved patients. 3. To increase utilization of community resources for fruits, vegetables and other healthy food by patients with diabetes living on the South Side of Chicago.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Food Rx leverages a novel platform—the prescription—to link clinics with nutrition resources on the South Side of Chicago, a food desert. Food Rx was collaboratively and iteratively developed by the clinics, community partners, and research team. Primary care providers and endocrinologists prescribe Food Rx to diabetes patients at six practices: four federally-qualified health centers, an academic primary care center, and an academic endocrinology clinic. Food Rx includes a behavioral prescription, a nutrition education handout, a map of local food partners, and a coupon for healthy food. The coupon is redeemable at a local farmers market and nine participating Walgreens stores expanded to sell healthy food.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We have regular calls and in-person check-ins with the clinics, Walgreens, and Farmers Market and save all anecdotal feedback (e.g. emails, re-stock requests). We are identifying purchasing trends among our patients via coupon redemption data and qualitatively exploring barriers/facilitators to Rx utilization via in-depth interviews.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Anecdotal evidence suggests that Food Rx may be a powerful tool to promote healthy food as part of diabetes treatment: providers prescribing Food Rx report that it is "empowering," and patients report that the educational handout is useful and the coupon helpful. Integrating Food Rx into the clinics can be challenging, especially because physicians may not remember to use it. Visually highlighting the Rx (e.g. colorful shelves in workrooms) is helpful, and involving staff with more time to counsel patients (e.g. nutritionists) and/or familiarity with the community (e.g. medical assistants) holds promise to improve integration with care. The value of the Rx—both the voucher amount and any minimum purchase required—is a strong determinant of its use. The convenience of redemption sites and patients' existing use of those retail locations (e.g. for medication refills) are key to facilitating use of the Rx.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The collaborative process of designing Food Rx, as well as the diversity of the coordinating team, enabled us to meet the demands of clinic workflow, research methodology, and organizational priorities of our partners, a major national corporation and a small, local non-profit organization. The coordinating team was also able to balance standardizing the intervention with adapting components to each clinic. Involving non-physician staff at the clinics may be critical to dissemination of the Rx. Although implementation is in early stages, Food Rx shows promise as a model for integrating community resources into clinical care of underserved patients.

HEALTH CARE ADVOCACY FOR SURVIVORS OF DOMESTIC VIOLENCE
Arash Nafisi; Hillary Kunins. Montefiore Medical Center, Bronx, NY. (Tracking ID #1635005)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Survivors of domestic violence face numerous health risks and encounter many barriers to accessing health care, potentially compromising their quality of health.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To assess the needs and barriers to care for survivors of domestic violence with the goal of developing a sustainable model for care that effectively addresses this population's medical needs.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We established a collaboration between an academic federally qualified health center and the Family Justice Center (FJC), an umbrella domestic violence service organization providing comprehensive services, including legal, counseling and social service support to clients affected by domestic violence. We developed on-site medical office hours at the FJC, where a medical resident met with survivors, ascertained medical needs and facilitated prompt access to primary care via on-the-spot medical appointments for interested survivors. Survivors' needs and ability to access health care were demonstrated via a voluntary medical needs assessment, an 11 question paper survey available in English and Spanish, adapted from a New York City Department of Health questionnaire.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1) Identifying medical needs and barriers to care via a medical needs assessment and informal feedback. 2) Quantifying the number of clients able to attend a medical appointment.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): 23 survivors completed the medical needs assessment. 16 of 23 (70 %) rated their overall physical health from very poor to average on a five point scale. 13 of 19 (68 %) experienced somatic symptoms within the past 30 days. 15 of 18 (83 %) stated they needed to see a physician in the past year but were unable to do so. 18 of 22 (82 %) were currently interested in seeing a medical provider. Of the 11 survivors who were prescribed medications, five ran out of or stopped taking them. Moreover, of the 20 survivors who had previously seen a physician, 14 had not discussed their relationship issues with their doctor. Of the 12 survivors seen during medical office hours at the FJC, six were interested in and were provided with primary care appointments; four of six attended their initial primary care visit. Upon subsequent follow up, survivors reported to FJC staff appreciation for an initial medical visit in a neutral space outside the medical establishment. However, they reported significant hardships in accessing care, including mistrust of the health care system, trouble accessing providers due to improper documentation and privacy/safety concerns in the waiting room.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Collaboration between physicians and advocates for survivors of domestic violence can facilitate better access to health care for this cohort. In this small sample, survivors had medication lapses and difficulty accessing primary care, yet had health conditions and symptoms requiring medical attention. Though domestic violence survivors may have competing demands such as concern for safety, financial insecurity and housing instability, this study found that survivors identified primary care as a need and were able to attend a primary care visit. To improve the health status of domestic violence survivors, medical collaboration with domestic violence organizations may be one avenue to promote primary care access and utilization. Though preliminary results from this study are compelling, more work must be done to identify and address barriers to care to facilitate easier access to medical care for survivors of domestic violence.

HOSPITAL AT HOME AS AN INTERAGENCY COLLABORATIVE AT THE PHILADELPHIA VA MEDICAL CENTER Elizabeth A. Mann[1]; Bruce Kinsosian[1,2]; Rachel K. Miller[1,2]; Haggerty Mary-Ann[2]; James Hammond[2]; Ariel Feinberg[2]. [1]University of Pennsylvania, Philadelphia, PA; [2]Philadelphia VA Medical Center, Philadelphia, PA. (Tracking ID #1643764)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can hospital-level services be delivered safely and inexpensively in the home by a team of home care practitioners and community home health agency staff?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Create an interdisciplinary and interagency team to deliver in-home care 2. Demonstrate Hospital at Home as a safe and effective alternative to hospital admission 3. Provide cost-savings to the VA health system

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Prior studies of Hospital at Home programs have shown in-home care to be safe, effective, and reduce costs by 30 %. We adapted the traditional model, which uses only VA staff, by forming a team comprised of community health agency employees and VA home care providers. Patients were enrolled from the Philadelphia VA Medical Center emergency department, clinics and inpatient medicine wards. Patients received daily physician and nursing visits, parenteral therapy, necessary laboratory and radiology testing and allied services in their homes. At the completion of therapy, patients were discharged back to the care of their primary care physician. Funding was supplied by the Hospital at Home Fund, which was credited with the direct variable costs for an equivalent DRG at the Philadelphia VA.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Clinical data included diagnoses, length of stay, prior hospitalizations and readmissions. Financial data included direct variable costs and costs of hospitalization for those transferred to Hospital at Home from an inpatient ward. Qualitative data regarding patient experience in the program will also be collected.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Hospital at Home admitted 17 veterans 25 times during the first two quarters. Two patients comprised 28 % of admissions. There were 33 hospital admissions in the 6 months prior to initiation of the program. 56 % of Hospital at Home admissions were CHF exacerbations. Additional admission diagnoses were UTI, asthma exacerbation, pneumonia, upper GI bleed and uncontrolled diabetes. The average length of stay was 5.2 days. 11 patients were transferred from the inpatient wards; their mean pre-transfer length of stay was 1.6 days. There was 1 readmission within 30 days and there were 25 readmissions within 180 days. The median time to post-discharge contact with a PCP was 4.5 days and the median time to follow-up PCP appointment was 23.5 days. The Hospital at Home Fund was credited with $192,402 at the start of the program. The fund had a net balance of $63,716 at the end of the year, representing 32 % savings of the direct variable costs for equivalent DRGs and 60 % savings after excluding transfer costs of $87,164 due to hospitalization. Direct costs for in-home services averaged $240/day.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our program demonstrates that high quality medical care can safely be provided in the home by VA practitioners teaming with community home health agency staff. Compared with the traditional model, this integrated model is simpler to implement and can provide additional cost-savings. Costs may also be reduced by identifying eligible patients prior to hospital admission. This program benefits integrated payer systems such as the VA network, but may also benefit traditional health systems facing the financial costs of Medicare readmissions. Future directions of our program include improving primary care follow-up time and educating VA staff on early identification of potential participants.

IDENTIFICATION OF FACILITATORS AND BARRIERS TO IMPLEMENTATION OF E-CONSULTS USING THE CONSOLIDATED FRAMEWORK FOR IMPLEMENTATION RESEARCH Leah M. Haverhals[1]; George Sayre[2]; Christian Helfrich[2]; Susan Kirsh[3]; David Aron[3]; Michael Ho[1]; Julie Lowery[4]. [1]Department of Veterans Affairs, Denver, CO; [2]Department of Veterans Affairs, Seattle, WA; [3]Department of Veterans Affairs, Cleveland, OH; [4]Department of Veterans Affairs, Ann Arbor, MI. (Tracking ID #1641113)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In 2011 the Veterans Health Administration (VHA) began implementation of electronic consults (E-Consults) as an alternative to in-person visits with specialists in order to improve access and reduce travel burdens for patients.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The purpose of this evaluation was to identify barriers and facilitators to implementation of E-Consults in order to improve dissemination.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): E-Consults allow primary care providers to obtain specialty care advice by submitting consults about specific patients via the VA's electronic health record. Specialists can respond with advice and/or recommend that the patient be seen in-person at the specialty care clinic. A new E-Consult program was piloted at 24 facilities in 14 specialties or conditions, such as rheumatology and diabetes.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We conducted semi-structured interviews with clinical leaders, primary care providers, specialists, and support staff at E-Consults pilot sites. Sites were selected based on variation in implementation success, defined as the ratio of E-consults to all consults for a specific specialty of focus, and the ratio of E-consults for patients from outlying clinics relative to medical center-based clinics. Interview data were coded deductively using constructs from the Consolidated Framework for Implementation Research (CFIR), and rated according to their role in implementation (positive or negative, weak or strong). We looked for CFIR constructs consistently associated with implementation across sites, and based recommendations on best practices from more successful sites, or surmountable barriers at less successful sites.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Interviews were conducted with 37 participants at four low and four high implementation sites. Five themes distinguished high implementation sites, and suggested potential recommendations to improve subsequent dissemination of E-Consults: 1) Adaptability: Conduct a trial, with the explicit agreement to revise the approach if it doesn't work. 2) Compatibility: Disseminate the benefits (using actual data) of E-Consults for patients and for workflow to participating providers. 3) Networks and Communications: Specialists must reach out to primary care providers to engage them. 4) Training: Include one-on-one, hands-on demonstrations. 5) Access to Knowledge and Information: Provide more guidance and details for implementation, including a better infrastructure for program roll-out—e.g., a standardized template for scheduling, tracking, and recording workload and a timetable for implementation.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The systematic and data-driven identification of factors affecting implementation success is critical for improving dissemination of new initiatives. A deductive coding and rating process using the CFIR provides such an approach and identifies those areas on which organizations should focus their implementation efforts.

IMPLEMENTATION OF A STRUCTURED, ELECTRONIC REFERRAL SYSTEM TO SUPPORT THE PRINCIPLES OF THE PCMH-NEIGHBORHOOD Jennifer J. Monacelli; Nathaniel Gleason; Chanda Ho; Michael Wang; Don Collado; Ralph Gonzales. UCSF, San Francisco, CA. (Tracking ID #1642240)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Referrals often lack a clear clinical question, key clinical data, and the referring provider's expectations regarding duration of specialty care and co-management roles, all of which may lead to inefficient care that is not patient-centered.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES):—To develop a set of structured referral templates that communicate specialist recommendations regarding the diagnostic data needed to optimize the initial specialty visit.—To integrate the referral templates into the electronic health record (EHR), and point-of-care workflow, in a manner that maximizes usability and acceptability.—To improve communication regarding expected duration of specialty care, and allocation of co-management responsibilities, through the use of Care Coordination Agreements (CCAs).
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Structured referral templates were developed with formal input from specialists and PCPs. Eight medicine subspecialty practices, and all primary care practices, across a single academic institution were included. The templates elicit the consultative question, convey information about referral appropriateness, list optimum pre-referral diagnostic studies, and auto-populate relevant diagnostic data. Three CCA options are offered: Consultation Only; Co-Management—PCP is First Call; and Co-Management—Specialist is First Call. We introduced "First Call" as short hand for the provider with primary management responsibility (e.g. urgent patient concerns, and medication titration).
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Process evaluation was based on chart abstraction of all referrals sent to participating subspecialties during the 2nd and 8th months following implementation. Uptake measures included the proportion of referrals using a template, and the distribution across PCPs and primary care practice sites. Adoption measures included the proportion of referrals 1) containing a consultative question, and 2) submitted with all recommended tests. For patients missing≥1 diagnostic test at the time of referral, we determined if the PCP ordered those tests after viewing the template.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): We developed templates for 68 diagnoses across 8 specialties. In the 2nd month of implementation, PCPs used a template in 136 referrals (82 % of referrals to participating specialties). Of these, 96 % contained a consultative question, 68 % contained all recommended tests, and 86 % included a CCA. In the 8th month, PCPs used the template in 181 referrals (78 %). Of these, 98 % contained a consultative question, 79 % contained all tests, and 82 % included a CCA. After combining both study sample months, 68 % (n=271) of referrals employed a template that recommended specific tests. Of these, 25 % (n=67) were missing ≥1 test at the time of referral. After viewing the referral template, 21 % (n=14) of PCPs ordered all missing tests, 18 % (n=12) ordered some of the missing tests, and 61 % (n=41) ordered none of the missing tests. The distribution of Care Coordination Agreement selection was 58 % Consultation Only, 26 % PCP First Call, and 15 % Specialist First Call.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Nearly all referrals placed using a structured template included a consultative question (prior studies show up to 24 % of referrals lack a question). Template use appears to increase the ordering of key pre-referral diagnostic tests for some patients. Over half of PCPs requested brief consultation followed by return to primary care for management.

IMPLEMENTATION OF A WEB-BASED PATIENT PORTAL TO IMPROVE TEST RESULT NOTIFICATION IN A COMMUNITY-BASED PEDIATRIC PRIMARY CARE PRACTICE Nive Maniam[1,2]; Garrett M. Chinn[3,2]; Lynn A. Volk[1,2]; Deborah H. Williams[1]; David W. Bates[2,1]; Steven R. Simon[3,2]. [1]Partners HealthCare, Wellesley, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]VA Boston Healthcare System, Boston, MA. (Tracking ID #1642933)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Timely notification of test results is an element of CMS's meaningful use criteria and a JCAHO Patient Safety Goal; however, little is known about the adoption of web-based patient portals to communicate test results in community practices.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Examine how test result notification changes with implementation of a patient portal. Evaluate the timeliness of test result notification before and after portal adoption.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We studied the timing and method of test result notification before and after adoption of a patient portal in a pediatric practice. Before the portal, physicians utilized in-person (follow-up visit), telephone, letter, or regular email message encounters. The patient portal enabled physicians to post results to the portal, generating a portal email. We extracted automated data from the electronic health record, including date of physician review of test results, date of patient notification, and notification method. We compared the timing and method of notification in the 6 months before portal adoption (pre-adoption), the 6-month period beginning 4 months after portal launch (early post-adoption) and the 6-month period beginning 1 year after portal launch (late post-adoption).
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The primary outcome measure was the percent of results communicated within 30 days by each notification method per time period. Secondary outcome measures included the average time to notification after physician review by notification method.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): 2,055 results reviewed: 711 pre-adoption, 643 early post-adoption, and 701 late post-adoption. Pre-adoption: clinicians notified patients of 54 % of test results within 30 days, primarily by telephone (74 %) but also in-person (17 %) and rarely by postal mail (1 %) or email (2 %). [10 % of tests notified by unspecified methods, 4 % notified by more than one method] Early post-adoption: clinicians notified patients of 62 % of test results within 30 days, primarily by telephone (49 %) and portal email (30 %) but also in-person (13 %) and rarely by postal mail (2 %). [9 % of tests notified by unspecified methods, 3 % notified by more than one method] Late post-adoption: clinicians notified patients of 63 % of test results within 30 days, primarily by telephone (72 %), but also through portal emails (17 %) and in-person (11 %). [5 % of tests notified by unspecified methods, 5 % notified by more than one method] Average time to notification of in-person and telephone encounters increased between pre and post portal adoption. Average time to notification using patient portal emails decreased from 5.3 days in early post-adoption to 3.0 days in late post-adoption.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): After patient portal implementation, more patients are notified of test results within 30 days. In-person encounters as a notification method declined. Telephone encounters decreased after the initial adoption of the patient portal but increased in the late adoption period. Portal emails decreased in the late adoption period with overall time to notification decreasing by 2.3 days. These data suggest that a majority of patients may prefer to have their results communicated by telephone even though they may receive notification more quickly through a patient portal. When implementing a patient portal, physicians should assess patient preferences for a preferred method of result notification.

IMPROVING ADULT PNEUMOCOCCAL VACCINATION COVERAGE IN PRIMARY CARE CLINICS IN NEW HAMPSHIRE: CONTEXT MATTERS Antonia Altomare[1,2]; Ellen Eisenberg[1,3]; Auden McClure[1,3]; John N. Mecchella[1,2]. [1]Dartmouth Hitchcock Medical Center, Lebanon, NH; [2]The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH; [3]Geisel School of Medicine at Dartmouth, Hanover, NH. (Tracking ID #1632574)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): National coverage of pneumococcal vaccination in adults 65 years of age and older is 60 % despite strong evidence supporting the efficacy of pneumococcal vaccination against invasive pneumococcal disease and a target coverage goal of 90 %.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Improve adult pneumococcal vaccination coverage to 90 %. 2. Provide clinic-specific immunization data and engage clinics in the quality improvement process. 3. Assess the effectiveness of a new electronic health record (EHR) clinic workflow.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We utilized a microsystems approach to analyze three primary care clinics within an academic institution. Data regarding pneumococcal vaccination coverage was queried from the Dartmouth-Hitchcock Data Trust. All three clinics were provided with their baseline vaccination data displayed in statistical process control charts and analysis of means charts (by visit type and by provider). Meetings were held with clinic staff to update them on current vaccination guidelines and to introduce a new vaccination EHR workflow that included prospectively identifying patients coming to clinic who were not up-to-date and preparing a vaccination order for the visit provider.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The absolute number of pneumococcal vaccines administered per month and the percentage of all eligible patient visits in which a patient was brought up-to-date per month were measured before and after our site visits.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): We analyzed 59,239 office visits for a total of 51,404 patients over the age of 65 between January 2010 and August 2012. All three clinics had a statistically significant improvement in the average number of vaccines administered per month: Clinic A 9.2 vs 23.6, Clinic B 8.6 vs 19.8, and Clinic C 4.9 vs 21.0; and the average percentage of patients brought up-to-date on pneumococcal vaccination per month: Clinic A 35.2 % vs 52.3 %, Clinic B 13.3 % vs 24.4 %, and Clinic C 13.8 % vs 40.6 % (all $p<0.01$ using two sample t-tests and proportional t-tests). Adoption of the new EHR workflow varied by clinic. Making individual clinic data available for review was identified as a primary source of motivation that guided successful change across clinics. In addition, Clinic A engaged support staff who were empowered to create system change and utilize the EHR workflow. Clinic B only started using the EHR workflow after a local champion was identified and led the improvement initiative. Clinic C chose to implement an alternative EHR workflow that involved a vaccination reminder at the time of scheduling eligible patient appointments.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Improving pneumococcal vaccination coverage has significant implications for population health and is possible through context specific interventions. Improving vaccination coverage requires knowledge of the barriers, understanding of the local context, and motivation to change. This study supports the effectiveness of the EHR as a quality improvement tool that may affect change; however, its use alone is not sufficient. Sustainable change requires multifaceted context specific interventions and engagement of key stakeholders.

IMPROVING PROVIDER EXPERIENCE AND INTERDISCIPLINARY COLLABORATION IN THE COMPLEX CARE MANAGEMENT PROGRAM AT THE GENERAL MEDICINE CLINIC AT SAN FRANCISCO GENERAL HOSPITAL Anneliese Johnson[1]; Julia Janssen[1]; Fern Ebeling[2]; Lisa Tang[2]; Lindsay Evans[2]; Claire Horton[1]; Reena Gupta[1]; Elizabeth Davis[1]. [1]University of California-San Francisco, San Francisco, CA; [2]San Francisco General Hospital, San Francisco, CA. (Tracking ID #1642742)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): It is often difficult for members of a care management team managing medically and socially complex patients to communicate and collaborate with busy primary care providers in an academic clinic.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): This intervention aims to 1) improve provider satisfaction with the General Medicine Clinic Care Management Program and 2) to determine optimal methods of communication between the care management team and providers.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Complex Care Management Program (CCMP) is an interdisciplinary team embedded in San Francisco General Hospital's General Medicine Clinic focused on improving care for frequently admitted high risk patients. The CCMP seeks to achieve its aims through collaboration with primary care providers and patients, and in the process improve providers' experiences caring for complex patients. The first step in this project was to meet with providers and the care management team informally to elicit feedback about communication needs and optimal methods for communication. We then created guidelines for charting and email communication between both groups. When the clinic launched huddles before every shift, the care management team joined the huddles to enhance in-person communication. We also conducted care management educational sessions during resident pre-clinic conferences. We conducted preliminary surveys of providers whose patients were entering the program and shared this information with the care management team to inform program design. We are also conducting follow up provider surveys and will design our next improvement steps based on these results.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Providers who have patients enrolled in the CCMP are asked to complete an anonymous survey at time of enrollment, 6 months, and 1 year. Specific areas that the survey addresses include 1) physician satisfaction with chronic care, 2) time spent managing complex patients and 3) knowledge of patients' clinical characteristics.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Currently, results from 6 month surveys showed: 1) 53 % increase of providers rating quality of care as 'very good' or 'excellent' compared to time of enrollment, 2) 50 % increase of providers reporting 'yes' when asked if they knew all the meds that their patient was prescribed and taking and 3) overall improved satisfaction in communication with patients and family members, coordination of care, monitoring chronic conditions, referrals to community resources and efficiency of office visits. When asked to compare the care the patient received before and after enrollment in CCMP, all providers responded that the care was 'better' or 'much better'. Since start of the program in February 2012, 23 providers have had patients enrolled in the program. Currently, 10 providers have completed the initial enrollment survey and 7 providers completed the 6-month follow-up survey. Over the next several months, we will focus on increasing survey response rates.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Complex care management can improve provider experience and perceived quality of care. Email guidelines and huddles are helpful tools for optimizing communication between interdisciplinary teams and primary care providers. Ongoing evaluation of provider experience informally and through surveys helps to foster collaboration between providers and other care team members.

INCREASING EFFECTIVE SMOKING CESSATION INTERVENTIONS IN AN ACADEMIC INTERNAL MEDICINE CLINIC Shana Ratner; Stephanie Flecksteiner; Douglas Friedman; Hongxen Nguyen; William A. Wolf; Brooke B. McGuirt; Thomas M. Miller; Michael Pignone. UNC Chapel Hill, Chapel Hill, NC. (Tracking ID #1632590)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The University of North Carolina Internal Medicine Clinic was underutilizing effective smoking cessation interventions for patients with tobacco abuse.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) To determine the prevalence of tobacco abuse in our clinic population 2) To simplify the North Carolina Quitline referral process and improve our referral rates 3) To assess efficacy of Quitline referrals for our patients

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The UNC Internal Medicine practice is a Level 3 Patient Centered Medical Home with 13,958 active patients and 103 mostly part-time providers (68 residents, 24 faculty, and 11 midlevel providers). From January–April 2012, we sought to improve the quality of our smoking cessation services with four intern Quality Improvement projects. The first project determined the prevalence of smokers in our clinic, mapped the care process (including methods of assessment and intervention, particularly referrals to the NC Quitline), and performed chart reviews to determine frequency of intervention. The second project surveyed residents about their knowledge base, used this information to revise our tobacco abuse educational curriculum, created clinical tools for medication dosing and motivational interviewing, and piloted a reminder to ensure that providers reviewed nurse documentation of smoking status. The third project simplified the process of Quitline referral creating a single step for provider ordering. Fourth, an intern called patients referred to the Quitline to assess patient satisfaction and cessation outcomes.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We performed chart reviews to measure nurse documentation (smoking status, readiness to quit) and provider documentation (smoking cessation interventions). We developed run charts to track monthly the number of current smokers in the practice, proportion expressing readiness to quit, number of Quitline referrals, and feedback from the Quitline. Patient satisfaction with the Quitline was also assessed by phone interview. We looked at quit rates (1 visit as current smoker followed by at least 2 visits in a row as former smoker) before, during, and after our interventions.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): At baseline, 19 % (2,659/13,958) of patients were current smokers and 32 % (857/2,659) of smokers reported readiness to quit. Nurses documented smoking status at 98 % of visits, but among patients ready to quit, providers only mentioned smoking 45 % of the time. After implementing the smoking cessation curriculum, there was an increase in Quitline referrals from a mean of 0.33 (range 0–1) to 9 (range 4–18) per month. After changing to a single step process for Quitline referral, referrals increased from 9 to 22 (range 15–34) per month. Of 16 patients contacted for feedback about Quitline referral (31 attempted, 16 reached), all 16 reported cutting back, 14 found the service helpful, and 2/16 had quit smoking. During 2011 (before our interventions) 62/2,659 smokers quit, whereas in 2012 (during and after our interventions), 55/2,669 smokers quit.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Intern quality improvement projects were effective in improving smoking cessation processes in our practice. Interventions included physician prompting, simplifying process, resident education, and tracking patient level outcomes. Physician prompting and simplifying the process drastically increased the number of Quitline referrals made.

INNOVATIVE MULTIMEDIA METHODS TO ENHANCE PATIENT-CENTERED CARE IN UNDERSERVED POPULATIONS

Pamela S. Ganschow[2]; Elizabeth A. Hahn[1]; Elizabeth A. Jacobs[3]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Rush University Medical Cemter and Stroger Hospital of Cook County, Chicago, IL; [3]University of Wisonsin School of Medicine and Public Health, Madison, WI. (Tracking ID #1641256)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The strategic use of health information technology has the potential to enhance patient-centered care for diabetes patients with low literacy, computer, and/or English language skills.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To test whether a bilingual, low literacy, multimedia information and assessment system used in daily clinical practice increases the impact of diabetes-specific patient educational guides, enhances patient-centered care, and improves patient outcomes. 2. To evaluate the relationships between patient characteristics, resources, needs, health behaviors and health outcomes using the Behavioral Model for Vulnerable Populations. 3. To determine the short-term cost-effectiveness of the multimedia system and to develop a budget impact model to assess the affordability of the system.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We developed the DiabetesHelp-Talking Touchscreen (TT) as an integrated software system for patient education and assessment. It delivers educational information on diabetes medication, enables patients to self-administer patient-reported outcomes questionnaires, and can create an individually tailored list of concerns to share with health care providers. The user-friendly software is designed to be accessible to patients across the spectrum of computer and literacy skills. There is minimal screen text and it will read text aloud on-demand. Strategies to include the use of simple and familiar words, providing definitions for technical or unfamiliar words, and reinforcing the written messages with visual images were implemented to enhance the ease of use. We are conducting a randomized controlled trial with 151 English- and 152 Spanish-speaking adult patients with Type 2 diabetes. Participants assigned to the DiabetesHelp-TT intervention have access to the multimedia patient education program on a kiosk in the clinic waiting room. They receive a CD-ROM to take home and can print out information. Participants assigned to the Control arm receive the same educational material in written booklets. All participants complete a comprehension measure and a battery of self-report measures on the TT at baseline and 1 month later.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The primary endpoints are: satisfaction with the method of information delivery, comprehension of educational information, knowledge about diabetes, and satisfaction with health care communication. The secondary endpoints are: adherence, self-efficacy and health status. Additional measures include: health literacy, health beliefs, patient preference for decision-making, and evaluation and use of DiabetesHelp-TT.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): 25 % of English- and 75 % of Spanish-speaking participants have less than a High School education. Mean number of correct health literacy responses was 9 in english and 8 in Spanish (out of 16 items). Mean age is 55 years (range: 23–80); 44 % are on pills only, 20 % are on insulin only, and 36 % are on both. The majority of partipants in the intervention arm, regardless of prior computer experience, rated the overall design of DiabetesHelp-TT as very good (39 %) or excellent (40 %), and reported that it was very easy (38 %) or easy (61 %) to use.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The TT is a practical, user-friendly method for delivery of educational health information. This novel multimedia system increases access of underserved populations to new technologies, and contributes information about the experiences of diverse populations with new technologies.

INTER-PROFESSIONAL "COMMUNITY OF PRACTICE" TO IMPLEMENT "UNIVERSAL PRECAUTIONS" FOR OPIOID SAFETY WITHIN THE PATIENT CENTERED MEDICAL HOME

Michael Saenger[1,2]; Ingrid M. Duva[1]; Corrine Abraham[1]; Roeina Porter, RN[2]; Veronica D'Antignac[2]. [1]VA National Quality Scholars Program, Atlanta, GA; [2]Grady Health System, Atlanta, GA. (Tracking ID #1643849)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In the face of a prescription opioid overdose death epidemic, provider-centric care slows "Universal Precautions" implementation for safer opioid use in chronic non-cancer pain (CNCP).
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): By emphasizing an Inter-Professional (IP) Community of Learning and Practice (CoP) within the Patient Centered Medical Home (PMCH), this quality intervention aims to increase safety for both patients with CNCP on chronic opioid therapy and the public at large. The IP CoP is hypothesized to facilitate: 1)implementing potential harm assessment with "Universal Precaution's" (UP) Medication Agreements (MA) and Urine Drug Screening (UDS); and 2) learning and self-regulating to promote continuous improvement beyond lagging guidelines.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Contexts: first pilot in urban, Internal Medicine resident continuity clinic; second trial in VA community clinic new to PCMH (Teams of one each provider, RN, LPN, and Clerk; Teams see their patients once or twice a year) but knew 2010 VA opioid guidelines. Caring but mutually exasperated Nursing staff and an internist started urban pilot. Diverse Task Force (TF) developed which: surveyed literature; updated MA; crafted tracking documents; standardized institutional policy; and became CoP. Prior to TF, Nurses documented Pain Numeric Rating Scale (NRS), which providers ignored while refilling opioids; after IP CoP the Nursing staff facilitated UP for each CNCP patient on opioids. VA pilot initiated Team-level QI through IP champions consisting of two RNs and two MDs. IP role models led four monthly 90 min CoP sessions: team forming/storming/norming; QI "fishbone" of barriers to good CNCP care; bio-psychosocial approach to complex pain; and opioid pros/cons/UP. Future CoP sessions include: UDS interpretation; and feedback of audited measures for analysis by Teams.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Safety measures-Team-level, percentages of: MA<360 days; UDS<90 days; and morphine equivalent daily dosages<100 mg. Each measure will use Weissman et. al. "Achievable Benchmarks of Care" for continuously improving target. Balancing measures will be: longitudinally tracked subset of individual patients' NRS; and qualitative analysis of CoP/Team functioning by surveys and focus groups.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): First pilot (urban clinic) demonstrated 30 % decrease in monthly opioid refills. The second implementation (VA clinic), shows rapid UP uptake with opportunity for dramatic decrease in unsafe opioid refills. Responsibility for UP now shared amongst IP Team: RN triages refill requests and provides pain management self-care education; LPN collects UDS and reinforces bio-psychosocial care; Clerk scans MA and assists in scheduled follow-up rather than walk-in appointments. One Team's improvements in<4 months: MA up from 13 to 38 % of patients on chronic opioids; recent UDS up from 16 to 41 %, with 75 % of the additional UDS uncovering aberrant behavior.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): As Mary Dixon-Wood noted in the Michigan ICU project, two different CoPs exceeded UP standards faster than a checklist or changing institutional policy. IP CoP involves the whole healthcare team, keeps the patient at the center with sustainable and continuous improvement.

KEEPING THE PRIMARY CARE PRACTICE AT THE CENTER OF POST-HOSPITALIZATION CARE TRANSITION Ning Tang; Jeffrey Fujimoto; Leah Karliner. UCSF, San Francisco, CA. (Tracking ID #1634592)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Post-hospitalization phone calls have traditionally been made by hospital-based nurses; can shifting these calls to primary care practice-based nurses improve care coordination and prevent medical mishaps?
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Improve care coordination and patient education around follow-up appointments, medication changes and adherence, and home care needs. Identify early symptoms of worsening disease with the goal of assisting Primary Care Physicians (PCPs) to intervene quickly.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): From July to December 2012, two nurses integrated in the General Internal Medicine (GIM) practice called all patients discharged home from the Medicine Service at UCSF Medical Center within 72 h of discharge. Nurses used a standardized call script to review all key post-discharge issues, including follow-up appointments, medication reconciliation, home care needs, durable medical equipment needs, new symptoms, and how to access urgent clinical assistance. Nurses documented their calls using a template in our electronic medical record (EMR). Gaps in care were immediately handled at the time of the call by forwarding the EMR note to the PCP, schedulers, social workers, and other clinic staff with highlighted action items.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Measures of success included GIM appointment scheduling for patients discharged without an appointment; identification and resolution of medication-related problems, need for home care, in-home assistance, durable medical equipment, or referrals to social work; and, identification of patients with new or worsening symptoms that required immediate PCP attention.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): To date, 268 of 482 (56 %) total discharged patients had follow-up phone calls completed on average 2.6 days after discharge. Our nurses found that 29 % of patients did not have a follow-up appointment scheduled, 19 % had unmet home care needs, 17 % described new symptoms, 16 % needed medication refills, 13 % needed referrals, 10 % had equipment problems, 6 % were unaware of their follow-up appointment times, and 2 % had medication errors. Nurses provided education about how to get care urgently to 87 % of contacted patients. Additional education about follow-up appointments, medications, symptom management, and diet was provided for 81 %, 53 %, 51 %, and 8 % of contacted patients, respectively. Of the remaining 214 patients without completed calls: 44 had already been seen in follow-up or called by their PCP, 25 had been readmitted, 3 were in the ED at the time of the call, 6 calls were deferred for PCP feedback, 1 refused, 1 ended the call prematurely, 7 were not called due to staffing issues, and 127 were unreachable despite multiple attempts.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our program has demonstrated immediate benefits of relocating post-discharge nurse phone calls to the primary care practice. Clinic nurses had easy access to clinic schedulers to arrange follow-up appointments; they knew how to quickly access PCPs to troubleshoot clinical problems or obtain orders for needed medications, home care, or equipment. We continue to fine-tune the program, including finding ways to contact patients who are difficult to reach, increasing the efficiency of the nurses' time spent on each patient call—for example bringing patients in for an in-person nursing visit when medication reconciliation is too difficult over the phone, and better identifying patients who benefit the most from this program.

LETTING PATIENTS DECIDE: A NOVEL STRATEGY FOR INCREASING USE OF PATIENT DECISION AIDS IN PRIMARY CARE Leigh H. Simmons[1]; Karen R. Sepucha[2]; Lauren Leavitt[1,2]. [1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA. (Tracking ID #1642563)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Patient decision aids have been shown to help inform and engage patients in decision making, however, implementation of decision aids in primary

care has had limited success. A significant barrier is the identification of eligible patients for decision aids. We have tested an intervention of patient self-ordering of decision aids.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Design an intervention that allows patients to self-order decision aids 2. Identify differences in ordering patterns of patient-triggered versus physician-initiated decision aid ordering 3. Identify areas of unmet need for decision support based on patient ordering patterns of decision aids

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our intervention was conducted in an internal medicine primary care clinic that has a well-established program in which physicians can order DVD and booklet decision aids for patients through the electronic medical record. Most of these orders take place during the office visit and patients view programs after the visit. We created an order sheet to be included with the mailed reminder letter for the annual visit. The sheet listed 14 commonly-used decision aids and patients were instructed to select up to two decision aids of interest. Medical assistants processed the returned forms and the decision aids were mailed to patients prior to the annual visit.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We analyzed information on ordering patient gender and age, and number and types of decision aid orders by patients and providers (data follows). We are also surveying patients who have received decision aids on their knowledge about the target conditions and their decision-making process. We will also be measuring office staff and provider satisfaction with the distribution process and enhanced use of the decision aids.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): We analyzed information on gender, age, and decision aid orders by patients and providers during a three-month period. From Sept–Nov 2012, 54/767 (7 %) patients returned the order form, 57 % were female and the average age was 60. Patients ordered 121 decision aids, an average of 2.2 decision aids each. The top three programs ordered by patients were advance directives (n=18), anxiety (n=16) and insomnia (n=15). During that same time period, physicians in the practice ordered 83 decision aids. The top three programs ordered by physicians were prostate cancer screening (n=20), advance directives (n=14) and insomnia (n=11). The ordering process was well-received by patients and by office staff. Medical assistants and front desk staff became engaged in the decision aid program and were integral to project design. The project successfully introduced a new workflow to a practice that had previously relied solely on physician-driven ordering of decision aids.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Engaging patients in self-ordering of decision aids has the potential to significantly increase the use of the tools. There appears to be an unmet need given the level of interest patients have in ordering these programs. Patients ordered programs on chronic symptomatic conditions (e.g. insomnia and anxiety) at a higher rate than did physicians, who ordered more programs on cancer screening options and advance directives planning. Further research is needed to determine whether the programs have a different impact when patients self-select programs versus receive them from physician prescription. The program continues with full engagement of office staff and physicians.

LONG TERM PATIENT CARE BENEFITS ASSOCIATED WITH RESIDENT-LED DECISION SUPPORT HUDDLES IN AN OUTPATIENT CLINIC Laura Divoky[1,2]; Tho Luong[1,2]; David B. Sweet[1,2]; Lynn Clough[1,2]. [1]Summa Health System, Akron, OH; [2]Northeastern Ohio Medical University, Rootstown, OH. (Tracking ID #1641668)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Clinical inertia can lead to less intensification of care than would be advisable for patients with chronic diseases such as diabetes mellitus (DM).

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): For patients with DM: 1. Increase intensification of care to reach ADA recommended glycemic, blood pressure (BP) and lipid targets (A1c<7.0, BP<130/80, LDL<100) 2. Increase the percentage of patients reaching ADA recommended targets and improve overall levels

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In this Quality Improvement project, clinic sessions during the 4th quarter of 2011 began with resident-led huddles lasting <10 min in which residents discussed current A1c, LDL and BP levels of patients with DM scheduled to see their primary care physician (PCP) during that session and also presented fellow residents and faculty with a paper copy of this information. The intervention took place only during this quarter. These indicators along with decision support prompts continued to be presented in the Electronic Health Record (EHR) as they had been previously.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Between Oct 2011 and Sept 2012 rates of intensification of care for patients seen by their PCP who were not at goal for the three quality indicators were monitored and compared with those of historical controls seen between Jan 2010 and Sept 2011. Mean BP, LDL and A1c results and percent of patients at goal for a Static group of patients with at least one clinic visit during 2010, 2011 and the first 3 quarters of 2012 were determined.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): After introduction of peer huddles intensification of BP care at PCP visits increased from 46.7 % to 49.6 % (p=0.036); glycemic control intensification increased from 67.3 % to 75.0 % (p<0.001) and lipid control intensification was unchanged. In the Static patient group of 781 patients rates of BP control improved with introduction of huddles from 39.2 % to 44.5 % (p=0.019), with systolic BP decreasing from 133.5 to 130.7 (p<0.001) and diastolic BP from 77.3 to 75.7 (p<0.001). Glycemic control worsened slightly—the number of patients with glycemic control declined from 41.4 % to 37.7 % (p=0.02) and A1c levels increased from 7.8 to 7.9 (p=0.02). Lipid control (65.0 % and 66.9 %), LDL levels (91.6 and 89.9) and the percent of patients reaching all 3 targets showed non-significant improvement (12.3 % and 12.8 %).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Resident-led presentation of decision support information for patients with DM was associated with increased intensification of care and improvement in BP control up to 9 months after the intervention was completed. The patient results utilized in the huddles were already being presented in the EHR and only needed to be reconfigured to make them available for the huddles. The major change was peer presentation and discussion of the quality indicators. Longer term use of the intervention is planned to see if it will lead to improvement in A1c and LDL outcomes. The brief time required for the intervention and the associated improvement in BP control make it a potentially beneficial intervention for other residency programs.

MULTIDISCIPLINARY GROUP EDUCATION SESSIONS TEACHING PATIENT SELF-MANAGEMENT SKILLS IMPROVES OUTCOMES FOR LOW-INCOME, LOW-LITERACY PATIENTS IN AN URBAN SETTING Stacie Schmidt[1]; Amber Knight[2]; Lesley Miller[1]; Shelly-Ann Fluker[1]; David Levitch[2]; Jada C. Bussey-Jones[1]; Mary Katherine Brown[2]; Kristi Quairoli[2]; Michael Fost[3]. [1]Emory University, Atlanta, GA; [2]Grady Memorial Hospital, Atlanta, GA; [3]Georgia State University, Atlanta, GA. (Tracking ID #1639428)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In an urban outpatient setting serving large numbers of low-income, low-

literacy patients, do multidisciplinary group sessions for obesity improve patient (1) perceptions of overall health, (2) perceptions of healthcare delivery, and (3) outcomes in weight loss?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): (1) Develop a multidisciplinary group education class aimed at enhancing patient/provider interaction, as compared to a standard clinical encounter (2) Deliver patient-centered information in a manner that promotes autonomous decision-making and enhances patient self-efficacy regarding healthy diet and exercise choices, in keeping with PCMH principles (3) Demonstrate that the program improves (1) patient outcomes related to perceptions of health and healthcare delivery and (2) clinical parameters, such as weight

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Grady Primary Care Center (PCC) is an urban outpatient clinic located in Atlanta, Georgia with ~70,000 visits annually. Mostly patients have low-literacy and are uninsured. Approximately 60 % are obese, often with other related chronic illnesses. Due to time constraints and lack of provider knowledge, little time is spent empowering patients to make healthy choices related to diet and exercise. Investigators conducted a pre-post intervention study among obese adults in the PCC with at least one other chronic condition. Enrollees attended group sessions teaching self-management skills for making healthy behavioral choices related to diet and exercise. A team of healthcare providers (physician, pharmacist, nutritionist, and nurse) lead sessions twice per month. Patients were invited to attend five sessions in total. We treated three groups of patients, with each group conducted in successive quarters over the year.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Patients completed pre and post intervention surveys: Short Form 36 (SF 36) Health Survey assessing perceptions of overall health, and the Patient Assessment of Chronic Illness Care (PACIC) Survey assessing patient activation, goal setting, and problem-solving in line with the chronic care model. We measured pre- and post-survey scores using matched pairs t-tests.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Fourteen patients completed pre- and post-surveys. Significant differences in overall scores for both the PACIC [t=−2.42, p=0.04, CI (−2.056, −0.048)] and SF-36 [t=3.52, p=0.01, CI (2.509, 14.004) were observed. There was no significant difference in overall mean arterial pressure pre- and post-intervention. Weight loss did reach a statistically significant change [t=−2.48, p=0.02, CI (−9.542, −0.752), mean of the differences=−5.147], although this did not meet clinical significance (defined as >5 % weight loss).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): In our urban outpatient clinic serving low-income, low-literacy patients, group classes teaching self-management skills related to diet and exercise improved obese patients' perceptions of overall health, as well as their satisfaction with healthcare delivery in line with PCMH principles and the chronic care model. A larger sample size is needed for definitive analysis and should be followed over time to determine if outcomes persist.

MULTIDISCIPLINARY LONGITUDINAL APPROACH TOWARD PATIENTS WITH HIGH ADMISSION RATES Anunta Virapongse; June Ree; Wendy Daisley; Erin Sullivan; Caridad Aguirre-Pellicer; Michael Greenblatt; Diane Ackroyd; Nicole Lapinel; Kathleen Kane; Miriam Raport; Mary McGinn. Lenox Hill Hospital, New York, NY. (Tracking ID #1624270)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): To identify high-volume users and develop a process for creating longitudinal care plans that would be implemented at the time of Emergency Department (ED) arrival so as to optimize care and decrease readmissions.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Create a multidisciplinary committee (Complex Care Committee or CCC) to review identified patients and determine and fix gaps in care. 2. Develop brief care plans that can be placed into the ED record to help assist providers in decision making regarding admission and care. 3. Improve transitions in care and ultimately reduce readmission rates.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Patients were selected for review if they had greater than 3 admissions over 3 months, or if they were designated by case management as a good candidate forintervention. At each biweekly meeting, the charts for the last few hospital stays are pulled for each patient. Input is obtained from committee members and the primary care physician regarding the medical and social history, baseline vitals and medications, therapeutic interventions and key consultants. Following discussion, a care plan is created and placed on a password protected share drive. Because the ED has an electronic medical record (EMR) and is independent of the hospital system, which lacks an EMR, key components from the care plan are placed into the ED record for reference by providers. Some interventions for these patients include designating the same hospitalist across all visits, predetermined pain regimens, and prepaid patient phones at time of discharge. At each CCC meeting, updates on all CCC patients are discussed and care plans are modified accordingly.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The primary success outcome was a reduction in the number of admissions to less than 1 hospital admission per month. This was calculated by rate of admissions per month prior and after care plan development. Secondary outcomes were the rate of ED visits and length of stay prior and after care plan development.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): From August 2011 to August 2012, we reviewed 61 patients. For purposes of data analysis, we excluded patients with a diagnosis of sickle cell disease, patients which we had discussed less than 3 months ago, and patients that did not have a care plan placed into the ED medical record. In the remaining population (n=31), after creation of a care plan we decreased the hospitalizations by 49 % (p=.004) and overall acute care visits (ED and hospital visits) by 30 % (p=0.19). We also saw a slight decrease in ED visits in this population by 2 % (p=.954).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): By examining high volume, high utilizing patients in this manner, organizations can design a targeted approach that encompasses both the medical aspect and the socioeconomic difficulties that face these patients. Using this methodology, organizations can start to think of each hospitalization almost as a 'clinic visit', with the ultimate goal of achieving good outpatient follow-up and care. Providers will also become more aware of surrounding community resources that were previously underutilized, as well as gaps in the hospital and community safety net.

PALLIATIVE CARE CONSULTS IN THE INTENSIVE CARE UNIT: A QUALITY IMPROVEMENT TRIGGER PROJECT Sarah Nickoloff[1,2]; Katherine Recka[1,2]; Sean Marks[1,2]. [1]Medical College of Wisconsin, Milwaukee, WI; [2]Zablocki VA Medical Center, Milwaukee, WI. (Tracking ID #1596683)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The Zablocki Veteran Affairs Medical Center (VAMC) has a high proportion of deaths in the intensive care unit (ICU), a late referral pattern for palliative care (PC) consults, and considerable moral distress among staff regarding the care provided for veterans in the VAMC ICU.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Increase number of appropriate PC assessments in the ICU 2. Reduce moral distress for nursing and physician staff

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): One quarter of all US hospital deaths occur in the ICU. Identifying unmet PC needs at admission and throughout hospital course is therefore important. Studies show increased patient and family satisfaction and decreased length of ICU stay for patients who receive PC consultation. The literature does not address whether PC consultation decreases moral distress among ICU physician and non-physician staff. To address this moral distress, a nursing screening trigger was piloted for veterans in the ICU who met specific clinical criteria which generated a PC screening assessment. A 5 question screening was performed on admission and every third day thereafter, and included questions about the patient's prognosis, care requirements, symptoms, goals of care and staff beliefs about the patient's care.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Number of appropriate PC assessments in the ICU 2. Feedback from physician and non-physician staff 3. Awareness of PC and implementation of primary PC by the ICU team

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Nine ICU PC consults were placed compared to three consults in the 2 weeks prior to the project, and four consults during the same 2 weeks the previous year. Nursing staff gave overwhelmingly positive feedback about the screening tool, and felt that it helped to mitigate moral distress surrounding the care of certain veterans in the ICU. Physician staff was less receptive to the project, and none of the consults were generated specifically through the protocol. There appeared to be an increase in primary PC after initiating the project, as evidenced by an increase in family meetings held by primary teams. Although the project was clearly set up to initiate a PC "assessment" and not a consult, many nursing providers were frustrated and confused when a formal PC consult was not generated. The PC team felt that ICU nurses were not directly communicating concerns for unmet PC needs to ICU attendings, instead communicating them to a third party (PC team) who often was not directly involved in the patient's care.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Nurse led ICU triggers to generate PC assessments hold promise in assuring uniform access to excellent patient care among all ICU patients as well as reducing moral distress in the ICU. The screening tool may have been more effective as a tool for ICU nurses to have a standardized way to communicate unmet PC patient care needs directly to the ICU attending during patient care rounds, rather than immediately involving the PC team. Future projects need to provide careful attention to the project design to assure that it fosters direct communication among the ICU team, and reduces misunderstanding about the outcome of a positive screen. While the screening tool appears to have been useful in increasing awareness of PC in the ICU, it is clear that further investigation is necessary to implement effective and sustainable strategies to address unmet ICU PC needs.

PATIENT ATTRIBUTION TO CARE PROVIDERS IN A PRIMARY CARE NETWORK: COMPARING RETROSPECTIVE AND PROSPECTIVE ALGORITHMS Steven J. Atlas[1]; Gregory Estey[2]; Jeffrey M. Ashburner[1]; Priya Rao[2]; Wei He[1]; Henry Chueh[2]. [1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA. (Tracking ID #1633399)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Population management systems, using advanced information technology to redesign care delivery, must identify and attribute patients to specific primary care physicians (PCPs) and practices. We previously developed and validated a retrospective algorithm to attribute patients seen witin a large primary care network to a specific PCP (PCP-linked). If a patient could not be linked to a PCP with high accuracy, the patient was linked to the practice where he/she received care (practice-linked). Though useful for quality assessment and reporting, real-time attribution is needed for population-based interventions. A prospective linkage algorithm was developed with the goal of performing more sensitive, near real-time patient attribution.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To compare retrospective and prospective patient attribution algorithms and examine differences in quality outcome measures. We hypothesized that differences in patient attribution using retrospective and prospective algorithms would be associated with differences in quality of care measures.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Both retrospective and prospective linkage algorithms use patient visit data to confirm linkage to PCPs and practices with patient age categories used to define the frequency of PCP visits. The prospective algorithm includes an age dependent "linkage expiration date" and excludes patient address and PCP practice style (used in the retrospective algorithm). We compared patient attribution and outcomes from each algorithm as of December 31, 2011.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Percentage of patients linked to a PCP, practice or neither using each algorithm. Comparison of preventive cancer screening and chronic disease (diabetes mellitus [DM] and coronary artery disease [CAD]) performance measures among patients: 1) PCP-linked in both algorithms, 2) practice-linked in both algorithms, and 3) PCP-linked in the prospective algorithm but practice-linked in the retrospective algorithm.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): There were 190,167 patients in either cohort (185,424 prospective and 153,747 retrospective). Compared to retrospective cohort patients, prospective cohort patients were more likely to be PCP-linked (63 % vs. 53 %) or not linked (19 % vs. 6 %), and less likely to be practice-linked (15 % vs. 22 %) or missing (3 % vs. 19 %). Comparing cancer screening rates, PCP-linked patients in both cohorts had higher screening rates than practice-linked patients in both cohorts (breast: 85.5 % vs. 69.8 %, cervical: 86.4 % vs. 74.4 %, colorectal: 79.4 % vs. 61.4 %). Patients PCP-linked in the prospective cohort but practice-linked in the retrospective cohort had intermediate screening rates (breast: 72.7 %, cervical: 84.6 %, colorectal: 67.7 %). For patients with diabetes or CAD, those PCP-linked in the prospective cohort but practice-linked in the retrospective cohort had the lowest rates compared to PCP- and practice-linked in both cohorts (Hemoglobin A1c <9 %: 48.4 % vs. 82.4 % and 66.2 %, DM low density lipoprotein [LDL] <100 mg/dl: 26.7 % vs. 59.2 % and 46.0 %, CAD LDL <100 mg/dl: 38.8 % vs. 70.4 % and 52.6 %).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This prospective patient attribution algorithm identified more individuals than a retrospective algorithm and was more likely to link patients to a specific PCP. Differences between these algorithms affected performance outcome measures. These results highlight the importance of patient attribution in population management activities.

PRE-VISIT PLANNING: A FOUNDATION FOR OUTPATIENT-CENTERED CARE Jaishree Hariharan; Melissa McNeil; Thomas Painter; Pamela Dittoe; Gary Fischer. University of Pittsburgh Medical center, Pittsburgh, PA. (Tracking ID #1641766)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The usual process of ordering chronic-disease monitoring labs and preventative health tests during the office visit uses valuable face-to-face time for low-value tasks and does not allow for decision-making during the visit

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Maximize the doctor-patient interaction by ensuring that chronic- disease monitoring labs, screening tests and self-

monitoring tasks are ordered prior and available at the appointment. 2. Improve quality of care and patient outcomes for diabetes, hypertension and prevention screening

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): University of Pittsburgh Physicians—General Internal Medicine (UPP-GIM), is an academic practice of 79 faculty and resident physicians, and cares for 18,400 adults, 35 % with hypertension and 11 % with diabetes. UPP-GIM uses an electronic health record (Epic) with built-in health maintenance prompts to track services for prevention and chronic- disease monitoring, and a secure patient portal (HealthTrak). The practice leadership recognized a need to contact patients with chronic diseases prior to their scheduled office visits ('pre-visit planning') to complete necessary laboratory tests,certain preventative services and by tracking self-monitoring tasks (glucose or blood pressure) in preperation for their appointment. A team comprising of physicians, the clinic manager, nurses, pharmacist, and information technology (IT) experts met regularly to develop a protocol for pre-visit planning. We focused on patients with diabetes or hypertension or requiring preventative services (i.e. mammograms). Targeted lab tests included for diabetes (i.e. A1c, LDL) and for medication monitoring (i.e. potassium for diuretics) The protocol involves two outreach coordinators (RNs) identifying patients who meet criteria and are due for targeted services 3 weeks in advance of their appointment by running daily reports in the electronic health record (EHR). The coordinators review each chart, identify and order necessary services, and attempt to call the patients. Patients who subscribe to HealthTrak receive secure electronic messages. All patients receive letters containing printed orders along with blood pressure and glucose logs, as appropriate, with instructions to record these values in preparation for the visit.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Process measures include method of contacting patients, time taken to complete a day's appointments and type of tasks performed. Outcome measures include percentage of patients completing tests before appointment, physician and patient satisfaction, compliance with mammogram screening, diabetic eye exam and improvement in A1c and lipids and BP control.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Preliminary results on process measures for the first 3 weeks are highlighted. Our practice averaged 118 visits a day between 11 faculty and five residents. 34 % of patients (595/1,774) met criteria for pre-visit planning. 75 % of targeted patients were reached (45 % by telephone, 30 % by secure email). Each nurse averaged 10 h to complete tasks for 1 day's appointments, including 1.2 orders per patient and BP logbooks for 17 %. Only 2 % declined pre-visit planning. Outcome measures will be evaluated.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Pre-visit planning transforms the clinic visit from reactive to pro-active care. It is feasible with care coordinators and protocol driven care, but is time- consuming. However we believe it is a valuable service for outpatient-centered care

PRIMARY CARE-BASED COMPLEX CARE MANAGEMENT: USING AN INTERDISCIPLINARY GERIATRIC APPROACH TO IMPROVE CARE FOR FREQUENTLY ADMITTED PATIENTS IN A SAFETY NET PRIMARY CARE CLINIC Elizabeth Davis[1]; Julia Janssen[1]; Anneliese Johnson[1]; Valy Fontil[1]; Louise Aronson[2]; Margaret A. Handley[1]; Fern Ebeling[3]; Lisa Tang[3]; Lindsay Evans[3]; Reena Gupta[1]; Claire Horton[1]. [1]San Francisco General Hospital, University of California San Francisco, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA; [3]San Francisco General Hospital, San Francisco, CA. (Tracking ID #1642923)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In the General Medicine Clinic (GMC) at San Francisco General Hospital, 2.7 % of patients account for 35 % of hospitalizations, reflecting both the poor health of these patients and the high cost of their care.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The GMC Complex Care Management Program is an interdisciplinary team embedded in GMC that aims to 1) reduce hospitalization, 2) reduce cost of care, and 3) improve patient satisfaction and functional status among the highest utilizing patients in GMC.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This primary care-based program uses lessons learned from geriatric care management as well as homeless and psychiatric case management to improve care for frequently admitted patients in a safety net primary care clinic. The team identifies patients using utilization data, provider referral, health plan referral, and referral from hospital-based programs. The team performs comprehensive assessments and creates patient centered care plans. The health coach proactively coaches patients toward care plan goals while the nurse focuses on complex clinical issues, resolving rising problems before they become critical. Patients have direct phone access to the team. When patients are admitted, the team sees them in the hospital, performs post-discharge coaching, and confirms follow up appointments. As patients stabilize, they move to less intensive levels of care, allowing capacity to bring new patients into the program. The nurse and health coach have frequent contact with primary care providers and round weekly with the program physician, social worker, and coordinator. A patient advisory board provides input on program design and services.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The team uses a weekly data dashboard to drive progress toward improvement goals. The evaluation uses the RE-AIM framework (Glasgow, 1999): 1) Reach: whether patients in the program are high risk. 2) Efficacy: utilization, functional quality of life, provider and patient experience, and cost. 3) Adoption: percentage of primary care providers and patients who participate. 4) Implementation: enrollment, home visits, clinic visits, phone calls, consults with providers, and completion of post-discharge care. 5) Maintenance: outcomes after graduation.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): 47 patients are enrolled in the program, 6 have been discharged, 37 declined to participate, and 40 are waitlisted. The patients are high risk: Most have 2–4 major chronic diseases, 50 % have histories of substance use and 37.5 % have a mental illness. Their average Charlson Comorbidity Index score indicates a relative risk of death of 4.4. 66 % are 59 or younger, and 12 % are over 70. Preliminary data shows a reduction in hospital days by 35 % (24.8/yr ->16.0/yr) and ED visits by 55 % as compared to the year prior to enrollment. In an average week, the team completes one home visit, 4 clinic visits, 15 consults with other providers, coordination of 2 discharges, and 50 phone visits.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): An interdisciplinary complex care management team can significantly reduce hospitalization for high-risk patients in a safety net clinic. Using a weekly data dashboard focuses the team on achieving program goals. Patients are very complex and at times require frequent contact to achieve utilization reductions, which limits the capacity of the team to enroll new patients.

PROVIDING TIMELY, LOW-COST, ACCESS TO SPECIALTY CARE IN A FEE-FOR-SERVICE SETTING: IMPLEMENTATION OF AN ECONSULT SYSTEM Nathaniel Gleason; Jennifer J. Monacelli; Chanda Ho; Michael Wang; Don Collado; Ralph Gonzales. UC San Francisco, San Francisco, CA. (Tracking ID #1635329)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Electronic consultations (eConsults) allow primary care physicians (PCPs) efficient access to specialist input on clinical questions that do not require

an in-person evaluation, and integrated delivery systems have shown that eConsults can improve access to specialty care; however, implementation of eConsults in a traditional fee-for-service setting has structural and financial barriers.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To develop common expectations, and a financial model, for an eConsult program with robust input from PCP and specialist stakeholders. 2. To integrate the workflow into the shared Electronic Health Record (EHR). 3. To evaluate the utility, acceptability and impact of the eConsult program.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The program was designed and implemented at an academic medical center with support from the Medicaid Delivery System Redesign and Innovation Program (DSRIP). Participating specialties included Cardiology, Endocrinology, Gastroenterology, Hepatology, Pulmonary Medicine, Sleep Medicine, Rheumatology, and Nephrology. The expected turnaround time for eConsults is 72 h. Both the PCP and specialist are compensated the equivalent of 0.5 wRVU for each eConsult completed. Specialist e-consultants can elect to decline the eConsult due to case complexity, and convert the referral to an office visit.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The observation period was June-November 2012. The 8 weeks prior to eConsult launch served as the baseline period, and the subsequent 13 weeks as the study period. EHR data was used to determine referral rates, and email surveys to examine acceptability. The primary outcome was defined as the total number of referrals to participating specialists per 100 primary care visits per week. Our a priori hypothesis was that the introduction of eConsults would decrease the standard office-based referral rates without increasing the overall referral rate (eConsult + office-based). Differences in average referral rates between baseline and study periods were compared with a paired *t*-test.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): During the study period, 79 different PCPs submitted 176 eConsults to 8 specialties. 14 % were converted by specialists to in-office visits. The 151 completed eConsults represented 8 % of primary care referral volume to participating specialties. 77 % were completed within 72 h. The average weekly referral rate for standard office-based visits was 12.1 (SD=1.63) during the baseline period, compared with 9.7 (SD=0.79) during the study period ($P<0.001$). Survey response rates were 61 % for PCPs and 78 % for specialists. Among PCPs, 83 % "strongly agreed" that the eConsult response influenced their care plan. Among specialists, 65 % "strongly agreed" that the eConsult question was clear, and 61 % "strongly agreed" that the question was of "optimal complexity". The distribution of time spent in responding to each eConsult was 56 % (<10 min), 36 % (10–20 min) and 8 % (>20 min).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This fee-for-service eConsult program has high acceptability and utility among primary care and medicine subspecialty providers, and appears to reduce office-based referral rates. Since total wRVU-based payments for eConsults (1.0 wRVU) are less than 50 % of typical office-based wRVU (2.4–3.2) for new patient visits, this program has the potential to reduce specialty-related health care costs.

STAR (SAFE TRANSITIONS ACROSS CARE): A FOCUS ON AN INTERDISCIPLINARY DISCHARGE PROCESS Nancy M. Denizard-Thompson; Kirsten Feiereisel; James L. Wofford. Wake Forest School of Medicine, Winston-Salem, NC. (Tracking ID #1637026)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Given the complexity of the discharge process and the needs of our patients, there are numerous potential sources of error, oversight or miscommunication that can lead to undesired outcomes during transitions of care.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Improve coordination of care with a focus on patient safety 2) Decrease variability in discharge process across teams through a standardized process 3) Engage clinical pharmacists in discharge planning to decrease medication error

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The discharge process is the final opportunity to address our patient's needs and to prepare for a safe transition out of the hospital. On busy teaching services at an academic medical center, there may be different approaches to discharge and varied knowledge of safe transition of care. Our program engages an interdisciplinary team to actively coordinate discharge planning using a standardized discharge tool. Central to the process are the attending leadership, clinical pharmacist engagement, and team communication. A one page discharge planning tool was developed to highlight key pitfalls of discharge including items such as follow-up, home needs and discharge medications. The team, led by the attending, completes the tool prior to a patient's discharge with the Care Coordinator and team pharmacist. The pharmacist plays an integral role in reviewing medications and addressing access to medications. The tool has the dual functionality of educating learners experientially on the critical aspects of the discharge process while ensuring engagement of the attending and pharmacist in discharge instruction, a task historically managed by less experienced team members. The program was implemented on one teaching service with one of four attendings rotating every 2 weeks. A retrospective analysis was completed reviewing impact on discharge medication errors.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Success is measured by evidence of increased tool usage, decreased discharge medication errors and favorable provider assessment as a clinical practice and educational tool.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): During 4 months of data collection, the percentage of completed tools steadily increased from 48 % to 89 % of discharged patients. Retrospective analysis evaluated 158 discharges that occurred prior to implementation of the tool. Findings demonstrated that when no standardized discharge process was used that medication errors occurred in one out of three discharges. With utilization of the discharge tool and the pharmacist as part of the discharge process, medication errors at discharge were dramatically reduced from 34.7 % to 13 % ($z=4.12$, $p<0.0001$). Of those errors that occurred, 100 % occurred when the discharge protocol was not followed completely. All four attendings noted the tool to be easy to use, time efficient, educational for learners and facilitated a hands-on approach to discharge management.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1) A standardized discharge tool and interdisciplinary approach to discharge planning incorporating a clinical pharmacist facilitates reduced discharge medication error, enhances team communication regarding discharge planning and promotes safe transitions of care. 2) Educators valued this intervention as a means of teaching learners about important components of discharge planning while actively engaging members of the team. 3) The team demonstrated steady growth in usage of the tool with persistent attending leadership and enthusiasm.

THE EVOLVING ROLE OF GRASS ROOTS EMERGENCY MEDICAL RESPONSE IN THE OCCUPY WALL STREET ERA: HURRICANE SANDY AND THE PEOPLE'S MEDICAL RELIEF, NEW YORK CITY 2012 Amit Patel; Noriyuki Murakami; Magni Hamso. Montefiore Medical Center, Bronx, NY. (Tracking ID #1646423)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Is there a role for horizontal democracy in disaster relief?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Coordinating an emergency medical response in

the immediate aftermath of Hurricane Sandy using horizontal democracy and Occupy Wall Street (OWS) philosophy. Establishing a long-term medical and social relief network to fill the gap in primary care for affected residents. Coordinating healthcare advocacy aimed at equitable resource distribution for disaster victims using OWS direct actions to interface with city, state and federal administrations.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Hurricane Sandy made landfall on October 26, 2012, affecting 24 states, causing 131 fatalities, and costing $63 billion dollars in damages to property, infrastructure and services. In New York, the Rockaways, Coney Island and Staten Island were among the most affected areas. Low income residents especially faced displacement, prolonged loss of heat and power and inadequate access to basic supplies and health care. Using the online InterOccupy hub, OWS created a network for disaster relief by coordinating teams to canvass every resident in heavily affected areas. Volunteer physicians joined street medics to do house calls, phone triage and direct EMS to people requiring emergency care. Community organizations donated supplies and provided space for storage, soup kitchens and medical clinics. Periodic systems evaluations took place with all key volunteers, and the People's Medical Relief (PMR) evolved into a complex system of medical service provision, pharmaceutical dispensing, medical information management, and advocacy. Currently, PMR is streamlining legal counsel for flood insurance relief, creating permanent clinics to address inadequate access to care, developing a wellness space for mental health, and re-programming electronic medical records for clinics still suffering after the storm.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Current data is limited to that collected just 1 week after the disaster. Successful interventions were promoted via general assembly meetings, allowing for immediate evaluation of efficacy and sustainability. Interventions deemed inefficient were terminated or redesigned by general consensus.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Over 60,000 residents were canvassed for needs including access to food, water, blankets, medications, and medical attention. Over 800 residents were evaluated and serviced at medical clinics and 200 homebound people were given medical care. Over 200 people were vaccinated. A weekly working group was formed with city officials to help relay the needs of the affected communities.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Grassroots interventions coordinated via horizontal democracy are an effective way to respond to the shifting needs of communities, particularly in disaster settings. Volunteer-run horizontal movements have the flexibility to allow simultaneous means-testing and immediate reconfiguration of services, allowing relief efforts to evolve in real-time. While federal agencies require time and finances to mobilize and federalize their medical corps from across the nation, movements such as the PMR access locally available medical professionals who are state licensed and eager to volunteer. They are further equipped to advocate for the communities they serve and are positioned to ensure that resources are distributed equitably to the areas that need them the most.

THE MEDICATION METRONOME: A HEALTH IT SYSTEM TO IMPROVE MEDICATION MANAGEMENT AND LABORATORY MONITORING FOR CHRONIC DISEASES Jeffrey M. Ashburner[1]; Richard W. Grant[1]; Michael Jernigan[2]; Leila H. Borowsky[1]; Steven J. Atlas[1]. [1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA. (Tracking ID #1636660)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Lack of timely medication intensification and inadequate medication safety monitoring are two prevalent and potentially modifiable barriers to effective and safe chronic care.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To test a model of chronic disease medication management in which medication initiation or dose adjustment orders are explicitly and immediately linked to future planned laboratory monitoring. We hypothesize that establishing a visit-independent, health information technology (HIT) supported cycle of laboratory monitoring and iterative medication dose adjustment will result in more effective chronic disease care.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We designed and implemented the Medication Metronome system in two primary care practices to facilitate laboratory monitoring and medication dose adjustment. Consenting providers were randomly assigned to intervention or control groups for the 1-year trial. Providers allocated to the intervention have an additional feature in their electronic medication prescription interface that enables them to schedule future laboratory tests when ordering new prescriptions or adjusting doses to treat type 2 diabetes, hypertension, or hyperlipidemia. Laboratory testing for efficacy and/or safety monitoring can be automatically ordered within the electronic medication order module. This process initiates automated patient reminders that includes a mailed letter and lab slip 1 week before the test is due and (if necessary) a second letter and lab slip 1 week after the test due date if no result is found. Notification of persistently overdue lab results (>3 weeks after due date) is added to a physician "Watchlist" of test results within the electronic health record (EHR). Control physicians have access to the same EHR but without the added Medication Metronome interface.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Primary outcomes include the percentage of follow-up time that a patient is at or below risk factor goal (HbA1c$\leq$7.0 % among type 2 diabetics prescribed hypoglycemic agents; LDL-cholesterol$\leq$130 mg/dl for patients with hyperlipidemia s without cardiovascular risk and$\leq$100 mg/dl for patients with cardiovascular risk). Additionally, safety monitoring outcomes include the percentage of laboratory tests (e.g. liver function tests after initiating statins) completed within a four-week period after corresponding medication prescription.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): The Medication Metronome system was implemented for intervention physicians beginning May 25, 2012. As of December 25, 2012, all 22 intervention physicians have used the system to initiate laboratory follow-up for 795 medication starts or adjustments. Among these patients, 131 safety laboratory tests and 664 efficacy laboratory tests were ordered. All patients received a mailed letter and a printed lab slip. Additionally, 142 patients received a second letter and lab slip after lab due date passed without documented completion within our network. 89 notifications were sent to physicians' Watchlist 3 weeks after an overdue, uncompleted lab test order.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A HIT infrastructure can be adapted to support non-visit based medication management for efficacy and safety monitoring. Outcomes assessing efficacy and safety of medication ordering will be performed after 1 year to determine whether this HIT system improved care compared to a usual care control group.

THE VA'S SPECIALTY CARE TRANSFORMATIONAL INITIATIVES TO IMPROVE ACCESS AND DELIVERY OF SPECIALTY CARE Michael Ho[1]; David Aron[4]; Anne E. Sales[2]; David Au[5]; Christian Helfrich[5]; Katherine Fagan[1]; Anne Lambert-Kerzner[1]; Julie Lowery[2]; Catherine Battaglia[1]; Leonard Pogach[3]; Glenn D. Graham[3]; Vaness Ellington[3]; Susan Kirsh[4]. [1]Eastern Colorado Health Care System, Denver, CO; [2]VA Ann Arbor Health Care System, Ann Arbor, MI; [3]Washington DC VA Medical Center, Washington, DC; [4]Louis Stokes Cleveland VA Medical Center, Cleveland, OH; [5]VA Puget Sound Health Care System, Seattle, WA. (Tracking ID #1640348)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In the VA, Veterans can experience difficult access, fragmented care, long wait times, and significant travel distances for specialty medical care.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): In May 2011, the VA Office of Specialty Care Transformation (OSCT) launched four initiatives to improve access and delivery of specialty care to Veterans.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): These initiatives include: 1) Innovations in Consult Management (E-Consults), 2) Specialty Care Access Network-Extension for Community Healthcare Outcomes (SCAN-ECHO), 3) Specialty Care Mini-Residency Program (SC-MRP), and 4) Specialty Care Neighborhood Team (SCNT). In E-consults, primary care providers (PCPs) can ask questions regarding a Veterans' care to specialists and receive recommendations through the electronic medical record within 48 h. In SCAN-ECHO, there are regular videoconferencing sessions between primary and specialty care providers. During these sessions, there is a didactic lecture about a clinical topic and patient case presentations, including discussions of diagnostic or therapeutic treatment options between providers. The SC-MRP initiative trains physicians, NPs, and PAs to perform procedures (e.g., knee injections) and principles of disease management within the scope of primary care settings. The goal of SCNT is to deliver coordinated medical, surgical and/or psychosocial care based on a Veteran's condition. A care coordinator facilitates communication among specialists, PCPs, and patients; and a patient navigator helps Veterans with their care.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): As part of the implementation process, OSCT also funded an evaluation center, whose goals are to provide data to OSCT to inform any changes needed to current and future implementation sites. The center is using a mixed-methods approach. Data sources include cross-sectional, in-depth interviews and surveys of administrators, PCPs, specialists, and patients; and administrative data from central VA data sources. Following data collection, meta-inferences are made based on a merging data approach to ask how the qualitative interview themes helped us understand the quantitative survey data findings, and vice versa.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): The evaluation is ongoing. By end of November 2012, E-Consults have been implemented at 115 hospitals for 51 specialties. There have been 242,054 E-consults generated for 188,299 Veterans. For SCAN ECHO, 11 sites have implemented the program for 15 specialties with 737 sessions conducted. There are 3 SC-MRP sites initiated in 2011 with 2 sites focused on musculoskeletal care and 1 site on dermatology. For SCNT, 25 sites have begun the initiative focused on 19 specialties/conditions. New sites and specialties are being added on a yearly basis.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): OSCT and the evaluation center have adopted a participatory action research framework where the needs of OSCT drive the evaluation and findings from the evaluation center inform OSCT of how to implement and adapt the initiatives with the goal of enhancing these initiatives and making them sustainable.

USE OF CLINICAL DECISION SUPPORT TOOLS TO IMPROVE PRIMARY CARE CHRONIC KIDNEY DISEASE MANAGEMENT
Cara Litvin[1]; Steven M. Ornstein[2]. [1]Medical University of South Carolina, Charleston, SC; [2]Medical University of South Carolina, Charleston, SC. (Tracking ID #1642050)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can electronic health record (EHR)-based clinical decision support (CDS) tools be used to improve management of chronic kidney disease (CKD) in primary care practices?
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) To develop and assess CDS tools that can be used to enhance care of patients with CKD 2) To implement these tools in participating practices using a multi-method intervention to facilitate adoption
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This 2 year demonstration study which began on September 1, 2012 is being conducted in PPRNet, a national primary care practice-based research network whose members share a common EHR. Twelve primary care practices in 12 states, representing 25 physicians, 9 physician's assistants, and 6 nurse practitioners are participating. CKD CDS tools developed by the research team include a risk assessment tool that may be embedded within progress notes, EHR health maintenance protocols, an EHR flow chart and a patient registry generated from EHR data. To facilitate implementation, practices are receiving quarterly CKD performance reports and hosting annual half-day practice site visits for academic detailing, performance review and CDS training.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): A set of 12 primary care CKD quality measures for primary care related to screening at-risk patients, monitoring, blood pressure management, lipid and hemoglobin assessment and avoidance of nephrotoxic drugs has been developed for this project using a consensus process among PPRNet providers. The primary emphasis of the analyses will be on changes over time in performance on each of these measures over the 2 year intervention. Quarterly semi-structured interviews with key practice personnel are being conducted to determine which CDS attributes are perceived to promote adherence to these measures. Barriers to using the CDS tools and "best practices" of successful adopters are being assessed.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Baseline data analyses reveal that CKD affects 6.7 % of the 38982 active patients in these practices. Notable among practices is the low frequency of screening for proteinuria in patients with CKD (practice median 23.9 %, range 10.7 % to 54.8 %) or in patients with risk factors for CKD (practice median 21.9 %, range 11.4 % to 50.6 %). To date, reported use of the CDS tools varies widely by practice and by provider. Reported barriers include incorporating CDS use into existing workflow, varying use of EHR tools among providers at the same practice, and lack of awareness of CDS functions by some providers. Facilitators include ease of use of the tools and practices' prioritization of improving CKD management.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): There is no "one size fits all" approach to CDS implementation in primary care practice. For successful adoption, CDS tools must be adapted to meet the needs of each practice.

USING SYSTEMS ENGINEERING TO IMPROVE HOUSESTAFF SCHEDULING AND CLINIC UTILIZATION
Shihfan Yeh[1]; Luci Leykum[1]; Jane O'Rorke[1]; Jonathan F. Bard[2]. [1]STVHCS/UTHSCSA, San Antonio, TX; 2UT Austin, Austin, TX. (Tracking ID #1635021)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Scheduling the block and clinic schedules for Internal Medicine residents is a logistical challenge: many hours are required; errors can be easily made, particularly when schedules are changed; and scheduling in a way that optimizes day-to-day clinic access is almost impossible on a practical level.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Our goal was to use systems engineering principles to optimize resident schedules in a way that allows for the greatest availability in continuity clinics and improves patient access to primary care physicians.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We sought to apply principles from systems engineering to the problem of

resident scheduling. Our Internal Medicine residency program has 87 residents, 77 of whom are categorical with primary care clinics. We considered this a scheduling problem related to control or disruption management. We first identified the "hard constraints" in the scheduling process, which includes days off, required rotations, and clinic availability during each rotation. These constraints could not be violated. We also identified the "soft constraints" that would optimally be followed, such as maximizing the trainee to supervising physician ratio in clinic. We wrote a scheduling program in C++ that included these constraints, assigning a weight to each that reflected its importance. This program was run in Windows 7 on a PC laptop with an i5 processor and 4GB of memory.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We compared the output of the program with the schedule done by hand monthly over a 7-month period with regard to number and type of constraint violations, allowing us to refine the program and the approach to the constraints. We also compared performance of the by-hand and programmed schedules with regard to number of clinic sessions, number of underutilized sessions, and ability to schedule two weekly sessions on the same day rather than different days.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): The total number of clinic sessions assigned by the programmed schedule increased by 2.3 % a month, or 22.6 clinic sessions/month. This translates into the ability to accommodate approximately 130 additional appointments each month, improving patient access. The number of underutilized clinic sessions decreased by 12.9 %/month. Finally, for residents who had 2 clinics/week, the percent of time that they were assigned these clinics on the same day increased by 8.9 %/month. The final program allowed no hard constraint violations. The by-hand schedule allowed a total of 12 constraints during this period (0 to 4/month). These constraint violations led to a suboptimal ratio of housestaff to attendings in the clinic during these sessions.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our approach to scheduling using an optimized program process is superior to a schedule done by hand. Interfacing our program with the commercial product we use to make the schedule available on the internet was initially a challenge. Our solution is cutting and pasting the program output into this product. We also had to create the program in a way that allows an interface that can be used by the Chief Residents. Updating the program as changes are made over time to our rotations and schedules will be a long-term consideration, but should not be difficult since the base program and user interface has been created. Because many of the rules for resident scheduling are mandated at the ACGME level, our program should be generally applicable to other IM residencies.

USING TEAM-BASED CARE TO IMPROVE MONITORING AND QUALITY OF CARE IN DIABETES Jason Higdon[1]; Jillian Gaumond[2]; Jennifer Zreloff[1]. [1]Emory University School of Medicine, Atlanta, GA; [2]Emory Healthcare, Atlanta, GA. (Tracking ID #1642366)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): As the focus of healthcare shifts towards providing high quality care for chronic medical conditions, we must develop novel ways to provide better care, meet quality metrics, and manage ever-increasing demands in primary care.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): In a university-based and NCQA recognized Patient-Centered Medical Home (PCMH), we sought to improve the percentage of patients with diabetes who have met all three quality goals (hemoglobin A1c <7 %, blood pressure <130/80, and LDL <100) and are compliant with comorbidity monitoring.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our PCMH pilot practice consists mostly of patients on an employer-sponsored health plan. We have developed standardized, protocol-driven diabetes care as outlined below: 1. Implementation of standardized medication initiation and titration protocols for both oral medication and insulin. 2. Empowering and educating team members to provide the highest level of care they are able to. RN's use an insulin titration protocol during post-visit telephone calls and a portal messaging system to help patients adjust their insulin in between office visits. Medical assistants, LPN's, and RN's have achieved competency in diabetic foot exams and perform them as part of the office visit. All team members have received training in helping patients set health-focused self-management goals. We have an in-house nutritionist who is available, particularly to those patients who are having difficulty meeting their goals. 3. Using a "diabetes report card" we track our performance at a clinic level for hemoglobin A1c, blood pressure, LDL, foot exam, eye exam, and urine protein. We can also drill down to the patient level to see who needs outreach for monitoring or more intensive care to bring them to goal. We have regularly scheduled disease registry meetings, a team-driven reminder system, and standing orders in place for our team to reach out to these patients to ensure they get the care they need.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We compared the percentage of patients who have met monitoring goals for hemoglobin A1c, foot exam, urine protein, and eye exam as well as those who have met their quality goals with hemoglobin A1c, blood pressure, and LDL.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): We compared the results from patients in our clinic to a traditional primary care clinic in the same healthcare system/geographic location and to another clinic whose patients are on a separate employer-sponsored plan but that does not function as a medical home. 16 % of PCMH patients met all three quality goals compared to 12 % in the traditional practice and 3 % in the other employer-sponsored clinic. 86 % of PCMH patients had their A1c checked within the last 6 months compared to 72 % in the traditional clinic and 55 % in the other employer-sponsored clinic. 71 % of our patents had a documented foot exam within the last 12 months compared to 18 % and 42 %, respectively. 56 % of our patients had a documented eye exam in the last 12 months compared to 36 % and 5 %, respectively. 74 % of our patients had a document urine protein within the last 12 months compared to 5 % and 43 %.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. Using standardized, protocol-driven care provides the foundation for team-based care 2. Empowering and educating team members to provide care beyond their typical roles leads to improved monitoring and quality of care 3. Access to accurate data is crucial in implementing population based-care for chronic medical conditions

USING TEXT MESSAGING TO PROVIDE SELF-MANAGEMENT SUPPORT AND CARE COORDINATION FOR INDIVIDUALS WITH CHRONIC DISEASE Shantanu Nundy[1]; Jonathan J. Dick[2]; Patrick Hogan[1]; Anna P. Goddu[1]; Arnell Bussie[3]; Marshall Chin[1]; Monica E. Peek[1]. [1]University of Chicago, Chicago, IL; [2]Columbia University College of Physicians and Surgeons, New York, NY; [3]University of Chicago Health Plan, Chicago, IL. (Tracking ID #1638381)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Self-management support is an essential component of the Chronic Care Model yet is often unavailable in primary care settings or limited by staff availability and reimbursement.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The objectives of the program are to improve self-management and support team-based care through the use of cell phone technology and remote case managers. Using diabetes as a model chronic disease for our initial pilot, we also aim to improve glycemic control.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): CareSmarts is a mobile phone-enabled care management program

developed for individuals with chronic illness. It is fully funded by the University of Chicago Health Plan (UCHP) and currently offered to individuals with type 1 or type 2 diabetes who receive primary care at the University of Chicago Medical Center (UCMC). The program was designed to address key barriers to care management including patient engagement, limited clinician availability, and integration with primary care. CareSmarts is theory-driven and leverages social support, self-efficacy, and health beliefs to promote behavior change. Eligible patients are enrolled over the phone by nurse-case managers at UCHP. Through CareSmarts, patients receive automated text messages on their personal mobile phones consisting of educational messages and reminders. They text back self-assessments that enable nurse-case managers to provide between-visit support. For example, if a patient texts that she is currently out of her medications, an alert is triggered that prompts the nurse-case manager to contact the patient. Nurse-case managers then communicate with the primary care team via email to coordinate next steps.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The primary outcome measure is pre-post changes in glycemic control (HbA1c). Secondary outcome measures include self-care measures and healthcare utilization and costs. Finally, we collect bimonthly feedback from health plan administrators and clinic staff on program implementation.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Ninety-one percent of physicians agreed to have their patients contacted for enrollment. Approximately one in five eligible patients agreed to participate and since May 2011 retention is over 95 %. Between enrollment and 3 months, improvements were observed in medication adherence (Morisky scale, $p=0.00$) and self-reported exercise ($p=0.04$) and foot care ($p=0.01$). Weekly timesheets suggest that 1 full-time-equivalent (FTE) can manage 350–400 patients. Nurse-case managers at UCHP value the opportunity to be involved with patient outreach while fulfilling their administrative responsibilities. Primary care physicians welcome having additional support for patient education and case management, which integrates into primary care yet does not require them to learn a new technology or modify clinic workflows.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Mobile technology, as a widely used communication platform, can be effectively used to provide self-management support and enhance team-based care. Mobile phone-based programs should strengthen traditional patient-provider communication and be integrated with primary care. Our practice innovation is designed for typical outpatient practices but incorporates remote monitoring from trained health professionals (e.g., MA or LPN). The growing trend towards care coordination, primary care medical homes, and accountable care organizations may enable widespread diffusion of this model.

INNOVATIONS IN MEDICAL EDUCATION (IME) A CLER LOOK AT MORBIDITY AND MORTALITY CONFERENCES Laura Fanucchi[1]; Lia S. Logio[2]; Eugenia Siegler[2]. [1]University of Kentucky College of Medicine, Lexington, KY; [2]New York-Presbyterian Hospital/Weill Cornell Medical College, New York, NY. (Tracking ID #1636556)

NEEDS AND OBJECTIVES: Needs: 1. Educate residents about patient safety concepts, human factors, system complexity, and communication. 2. Provide an open, non-judgmental forum to discuss patient care episodes that did not go as intended. 3. Increase resident interaction and communication with nursing, pharmacy, hospital administration, and departmental leadership Objectives: 1. Promote a systems-based, interdisciplinary culture of patient safety 2. Participate in a modified root-cause analysis. 3. Identify contributing factors to adverse events and near misses. 4. Consider action items as potential remedies for identified problems.

SETTING AND PARTICIPANTS: ● Monthly ● Part of core educational conference series for internal medicine residents ● Facilitators include departmental and residency program leadership as well as representatives from the hospital Division of Quality and Patient Safety. ● Interdisciplinary representation: Nursing, Pharmacy, Administration, other clinical departments

DESCRIPTION: Although most residency training programs incorporate a morbidity and mortality conference (M&MC) to analyze adverse events and medical errors and to promote quality assurance, there is no standard format. Given the growing focus on patient safety in residency education, during the 2011–2012 academic year, the university based internal medicine residency program at New York-Presbyterian Hospital/Weill Cornell Medical College, re-defined the M&MC as an interdisciplinary Patient Safety Conference (PSC). Once every 4 weeks, residents gather together with nursing, pharmacy, hospital administration, and departmental leadership to discuss in an open forum patient care episodes that did not go as intended. The communication errors, gaps in care, and systems issues are enumerated with clear explanations of the underlying concepts including human factors, system complexity, communication and hierarchy. The second half of the conference allows the inter-professional collective to consider action items as potential remedies to the problems identified. This approach is particularly relevant as it meets the Accreditation Council of Graduate Medical Education (ACGME) Clinical Learning Environment Review (CLER) Program patient safety focus area.

EVALUATION: In the first year of this conference, real change has occurred. Residents volunteer to help champion the best ideas from the conference and bring them to action. Examples of these changes include a marked reduction in unnecessary, disruptive pages to residents related to pharmacy orders by pharmacy participation in interdisciplinary rounds, the grassroots modification of the handoff tools in the electronic record, and the development of a structured transfer note for patients moving from the intensive care unit to the floors. Additional outcomes of this effort include increased engagement of house staff in incident reporting and a new recognition of gaps in care as well as solutions to those gaps that have replaced cynicism among the trainees.

DISCUSSION/REFLECTION/LESSONS LEARNED: Departmental M&MCs in are already an established component of most residency programs, and can be modified to an interdisciplinary PSC. Such modification meets the CLER objectives for patient safety in that it can provide an opportunity for residents to report errors, unsafe conditions, and near misses, and to participate in inter-professional teams to promote and enhance safe care. The model is simple and effective and has added value to both educational and patient care goals.

A CURRICULUM TO IMPROVE AND TEACH PRIMARY CARE TEAM FUNCTION Carole M. Warde[1]; Marjorie Pearson[2]. [1]Greater Los Angeles VA Health System, North Hills, CA; [2]RAND, Santa Monica, CA. (Tracking ID #1623552)

NEEDS AND OBJECTIVES: Coordination of front-line primary care teams has led to improved quality and efficiency of care. Over 900 VA clinics are transforming to a team-based primary care model called PACT (Patient-Aligned Care Teams). VA primary care health professionals have been regrouped into "teamlets" and are now expected to function as multidisciplinary teams. We aimed to develop an interactive program to assist PACT teamlets with trainees to learn, practice and coach effective team function in their practice settings. Our specific objectives were to: 1. Identify a conceptual model to guide the development and evaluation of this educational intervention 2. Develop a pilot interprofessional educational curriculum and associated teaching and evaluation tools 3. Deliver the pilot curriculum to 2 VA teamlets 4. Evaluate and revise the pilot curriculum and teaching and evaluation tools

SETTING AND PARTICIPANTS: Two coaches pilot-tested the developed program with two volunteer PACT teamlets from different VA facilities

DESCRIPTION: Our conceptual model of team function includes three domains: team work—team relationships; task work—quality improvement activities; and team processes—venues of team work (team meetings). We used this model to design the first iteration of our curriculum, coaching, and evaluation tools. Each pilot included 4 site visits, followed by 4

conference calls with teamlet leaders, and a final site visit. Our formative evaluation included quantitative and qualitative methods to monitor the effectiveness of the innovation and to adapt and revise the curriculum and instruments. The final iteration emphasized specific behaviors in each of the three aspects of team function: 9 for team relationship performance, 7 for effective team meetings, and 6 for quality improvement performance.
EVALUATION: Teamlets demonstrated learning needs in all three areas of team function. The curriculum was generally well-received, especially the relationship-centered coaching practices, onsite sessions, and teamlet leader coaching. There was modest evidence of improvement in the specific behaviors of teamlet relationships, QI processes, and meeting processes. One teamlet mastered team meeting processes early on, tackled barriers to relationships and improvement activities, and made significant improvements in all three areas of team function. Additionally, we found that teamlet leaders needed and wanted more coaching in leadership practices and that more administrative involvement was necessary.
DISCUSSION/REFLECTION/LESSONS LEARNED: There are three major lessons from TEX. 1) The triple-focused model of team function was useful for curriculum development and participant learning. Early mastery of team meeting processes facilitated learning in the other two areas and simultaneous learning of team relationship and QI behaviors were complimentary. 2) We learned that coaching is necessary for the teamlets, teamlet leaders and the administrative leaders directing and supporting the teamlets in the three aspects of team function. Coaching of teamlet leaders should target leadership practices knowledge and skills. Administrative leaders could improve teamlet function by setting goals and determining incentives to improve teamlet engagement and accountability. 3) Finally, situating health professions trainees within PACT teamlets is a "win-win" situation for both trainees and their teamlets in terms of learning and facilitation of quality improvement processes.

A HOME VISIT CURRICULUM TO FOSTER INTERPROFESSIONAL LEARNING AND IMPROVE CARE COORDINATION FOR HIGH-RISK PATIENTS IN TRAINEE PRIMARY CARE CONTINUITY CLINICS Melissa Bachhuber[1,2]; Shalini Patel[1,2]; Bridget O'Brien[1,2]. [1]UCSF, San Francisco, CA; [2]San Francisco VA Medical Center, San Francisco, CA. (Tracking ID #1636783)

NEEDS AND OBJECTIVES: Home visits are an important component of healthcare delivery to high-risk patients, yet most trainees receive little hands-on training in home care medicine skills. To address this need we developed an interprofessional home visit curriculum using a combination of formal instruction, experiential learning and reflective practice. Specific objectives included:—Engage learners from medical and nursing backgrounds to collaborate and participate in a shared home visit experience.—Demonstrate the importance and challenges of care coordination and interdisciplinary communication through home visits.—Encourage trainees to reflect on patient safety issues and impact on outpatient clinical practice that arise during home visits.
SETTING AND PARTICIPANTS: At the San Francisco VA Primary Care Clinics, two resident trainees are paired with an NP student practice partner. Residents and NP student partners often see one another's high-risk patients in clinic. Our home visit curriculum extended this collaboration by having practice partners conduct joint home visits.
DESCRIPTION: The interprofessional home visit curriculum included an introductory home visit session focused on skills such as functional assessment and home safety evaluations. After this formal instruction, each trainee selected one panel patient using general guidelines on an ideal high-risk patient for the home visit. Preceptors consulted with trainees to ensure appropriate patients were selected. Resident and NP student pairs, along with a supervising preceptor from medicine or nursing, visited the two patients during a half-day session. This allowed each trainee to lead one home visit on their own panel patient and to observe one home visit led by their practice partner. Trainees developed multidisciplinary care plans for their patients identified during the home visit. A group debrief session following the home visits provided an opportunity for trainees to reflect upon and discuss care coordination and patient safety issues.
EVALUATION: Twenty-one trainees and 9 faculty preceptors participated in the home visit curriculum. Trainees evaluated the home visit curricular sessions favorably. The mean rating for overall quality was 4.0 out of 5 (n=11); likelihood of changing clinical practice as a result of the session was 4.5 out of 5 (n=10). Analysis of trainees' written reflections (n=15) on lessons learned during the visits highlighted three themes: improved insight into patients' functional status, medication errors, and home safety assessment. A sample trainee reflection was "[What surprised me] was the method by which the patient took medications- how chaotic it was".
DISCUSSION/REFLECTION/LESSONS LEARNED:—Many trainees participate in home visit observations as medical or nursing students. However, leading a home visit on a selected panel patient can promote later stage trainees to learn concepts such as patient safety, coordination of care and interprofessional communication.—Coordinating trainee, preceptor, and patient schedules was a significant logistical challenge, so providing plenty of lead time is critical.—Faculty development on home visits was important to the success of the curriculum. Enlisting clinic preceptors for home visits bolsters the longitudinal relationship between preceptors and trainees.—Participating in home visits with trainees from other professions and with practice partners promotes team building.

A NOVEL OSCE CURRICULUM FOR TEACHING THE MUSCULOSKELETAL EXAM TO INTERNAL MEDICINE RESIDENTS Trishul Siddharthan; Sarita Soares; Stephen Holt. Yale University, New Haven, CT. (Tracking ID #1643985)

NEEDS AND OBJECTIVES: Musculoskeletal complaints are among the most common presenting symptoms to a primary care provider. Despite the high burden of musculoskeletal disorders, physicians are often underprepared to manage such disorders due to inadequate training during medical school and residency. We present here a novel experiential curriculum to teach internal medicine residents the evaluation and management of joint specific disorders using a multi-station objective structured clinical exam model (OSCE). The objectives were to improve trainee knowledge of and confidence in the musculoskeletal exam for a range of conditions common to primary care practice.
SETTING AND PARTICIPANTS: Twenty-one of forty-six residents from Yale's Primary Care Internal Medicine Program rotated over a period of 6 months through the musculoskeletal curriculum during their ambulatory blocks. Participants included all 3 years of residency training. Eleven Yale Medical Student volunteers who had received 45 min of training served as standardized patients. Two chief residents and nine clinical faculty served as evaluators and instructors at each OSCE station.
DESCRIPTION: Three musculoskeletal teaching workshops (Neck Pain, Back Pain and Knee Pain) were created. Each workshop was preceded by a 1 h lecture which reviewed relevant anatomy, history, exam findings, work up and treatment. The workshops themselves consisted of three to four case-based OSCE's through which residents rotated over a 90 min period. Residents were evaluated on exam technique, assessment and treatment plan and received feedback from faculty instructors and medical student standardized patients.
EVALUATION: Outcomes assessed in this study include: formative assessment of the individual residents by faculty instructors; perceived educational value of the curriculum as assessed by anonymous surveys of participating faculty, residents, and students; and efficacy of the educational intervention as assessed by a formal post-workshop OSCE exam and a confidence and knowledge based questionnaire. As half the residency program had yet to participate in their ambulatory block OSCE, we are able to compare participants of the curriculum to internal controls using a retrospective cohort analysis.
DISCUSSION/REFLECTION/LESSONS LEARNED: Whereas previous studies have utilized OSCE's to evaluate resident medical knowledge, this curriculum aims to utilize the OSCE itself as a standardized teaching tool. Preliminary data suggests improved disease specific knowledge, as well as improved confidence and competence in the musculoskeletal exam among participating trainees. Furthermore, both resident and student participants reported high levels of satisfaction with the curriculum.

Importantly, our curriculum involves learners across several levels of medical training including medical students, residents, and faculty, thus meeting both undergraduate, graduate, and continuing medical education needs. The voluntary and enthusiastic participation of medical students in our study suggests a cost-effective and pragmatic model for combining medical student and resident physical exam education as well as a tool to generate interest in primary care medicine among medical students. We have shown that it is possible to implement an effective OSCE-based musculoskeletal exam curriculum in a medium sized training program. Further evaluation is needed to determine whether this intervention leads to sustained improvements in musculoskeletal exam confidence and competence in the outpatient setting.

A NOVEL TRANSITIONS OF CARE CURRICULUM FOR PGY-1 RESIDENTS IN INTERNAL MEDICINE Justin P. Lafreniere[1]; Evelyn Gathecha[3]; Nowreen Haq[3]; Nancy L. Schoenborn[2]; Fatima Sheikh[2]; Colleen Christmas[2,1]. [1]Johns Hopkins Bayview, Baltimore, MD; [2]Johns Hopkins Bayview, Baltimore, MD; [3]Johns Hopkins Bayview, Baltimore, MD. (Tracking ID #1623437)

NEEDS AND OBJECTIVES: Twenty percent of Medicare patients are readmitted within a month of discharge, costing $26 billion annually. Most have multiple chronic conditions, require complex systems to safely coordinate their care, and experience negative outcomes when such systems are not in place. Physicians are ill-trained in how to provide these services. Many have called for evidence-based curricula emphasizing interprofessional and experiential learning to address this urgent, currently unmet need. We designed a curriculum focusing on the skills, attitudes and behaviors necessary to promote safe transitions. After completing the curriculum, learners:—Demonstrate an understanding and appreciation of the importance of 1) primary care physician involvement; 2) medication reconciliation; 3) goals of care; 4) functional assessment; and 5) transitional care, during care transitions.—Demonstrate high quality 1) medication reconciliation; 2) discussion of goals of care; and 3) functional assessment, during care transitions.—Identify barriers associated with poor care transitions and propose quality improvement projects to address these barriers.
SETTING AND PARTICIPANTS: This 2 week rotation for PGY-1 Internal Medicine residents employs interprofessional experiential learning in inpatient, outpatient and subacute care settings.
DESCRIPTION: There are four educational activities. 1) Teaching Modules provide didactics on medication reconciliation, goals of care, functional assessment and transitional care in a multimedia format. Learners use this knowledge and practice these skills during Transition Audits. 2) Transition Audits ask learners to use a tool to evaluate care transitions executed by their colleagues in outpatient and inpatient settings, focusing on the topics emphasized in the modules. Learners fill in gaps uncovered by the audit by completing the necessary assessments. 3) Transitional Care Site Visits give learners guided observational experiences in rehabilitation centers, assisted living facilities, nursing facilities and home care. 4) The Transition Conference is a capstone experience during which learners host a collaborative conference attended by multidisciplinary members of the health care team. Learners present a patient-based care transition experience, facilitate group reflection on related system- and individual-level issues, and propose quality improvement initiatives.
EVALUATION: We developed mini-CEX instruments to provide formative evaluation of learner skills at functional assessment, medication reconciliation, and discussing goals of care. A reflective writing exercise provides summative evaluation of learner attitudes related to care transitions. These are analyzed for themes related to our stated curricular objectives and are also used to evaluate learner reflective capacity. The results of the Transition Audits combined with a chart review provide a summative evaluation of learner behaviors. Since we implemented this curriculum in September 2012, there are only preliminary evaluation data available at this time.
DISCUSSION/REFLECTION/LESSONS LEARNED: This curriculum is highly innovative and fills the gaps that are present in resident education nationwide. It was developed as part of a course in curriculum development using a well-established approach to designing evidence-based curricula; nevertheless, we have found its implementation to be invigorating and challenging. We hope to share with our audience not only our preliminary evaluation data but also our personal perspectives related to program implementation.

A PILOT PRIMARY CARE RESIDENCY TRACK: EDUCATION AND LEADERSHIP IN PATIENT-ALIGNED CARE TEAMS (ELPACT) Olivia A. Arreola-Owen[1]; Carole M. Warde[2]; Arthur G. Gomez[2]. [1]Cedars-Sinai Internal Medicine Residency, Los Angeles, CA; [2]Greater Los Angeles VA Health System, Los Angeles, CA. (Tracking ID #1637787)

NEEDS AND OBJECTIVES: To recruit and prepare future general internists to practice in a patient centered medical home (PCMH) model, the balance of inpatient to outpatient residency training must change. We propose situating residents within patient-centered care teams will increase the appeal of primary care as a career choice while improving residents' abilities to care for patients with chronic diseases. In July 2012, we began a pilot primary care track for two PGY2 Cedars-VA Internal Medicine Residents where they: 1) Practice team-based, longitudinal care for a panel of complex medical patients 2) Develop and implement quality improvement processes targeting patient outcomes and care efficacy 3) Learn to be primary care mentors and role models from dedicated and satisfied generalist faculty 4) Learn, apply, and teach PCMH-relevant knowledge, attitudes and skills in chronic care management, quality improvement, teamwork, and team leadership
SETTING AND PARTICIPANTS: The Greater Los Angeles VA Healthcare System is implementing the PCMH model called PACT (Patient Aligned Care Teams). Patients are cared for by teamlets consisting of a general internist, nurse practitioner (NP), registered nurse care manager, licensed vocational nurse, pharmacist, and medical service assistant. Our new primary care track, entitled ELPACT (education and leadership in PACT) incorporates 2 internal medicine (IM) residents, 2 NP students and a pharmacy student into academic PACT teamlets, where the trainees participate as team members. We are reporting on the clinical experiences of the IM residents.
DESCRIPTION: Our training pilot includes two alternating 3-month block rotations during the PGY2 year. These blocks consist of 12 weeks of a 10-half day weekly schedule that includes: four PACT clinics; one PACT educational session; and 5 outpatient subspecialty clinics most relevant to primary care (e.g. endocrinology, nephrology, rheumatology, women's health, mental health). Each resident is responsible for an assigned patient panel and ongoing QI with longitudinal coaching and mentoring by the team's general internist faculty. The weekly educational conferences are learner-centered, interactive, and are attended by the whole team, including current patients. Topics include patient-centered care, team member relationship behaviors, the chronic care model emphasizing self-management support, quality improvement process development and implementation, care coordination, and leadership practices.
EVALUATION: We are currently planning to evaluate the new track in 4 domains: 1) Reaction: residents' feedback on the quality and usefulness of the curriculum, mentoring, and clinical experiences; 2) Knowledge: residents' scores on the residency in-service exam which will be compared to a random sample of their peers; 3) Behaviors: faculty evaluation of patient-centered communication skills using a mini-CEX format, a QI process performance, team member evaluation of teamwork, communication and participation in team meetings; 4) Outcomes: residents' performance on 6 quality of care measures as measured for all VA primary care physicians as well as quality improvement processes developed and implemented.
DISCUSSION/REFLECTION/LESSONS LEARNED: Thus far, resident perception of the primary care track has been positive with high ratings for consistent longitudinal care of complex patients, increased mentorship, and patient-centered communication. Team cohesiveness, care coordination, and quality improvement activities have benefited from incorporation of the residents into PACTs.

A SMARTPHONE APPLICATION FOR TEACHING BAYESIAN INTERPRETATION OF RANDOMIZED CLINICAL TRIALS Robert L. Goodman. Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1615323)

NEEDS AND OBJECTIVES: Clinicians are familiar with the use of Bayes' theorem for the interpretation of diagnostic test results (sensitivity and specificity and all that). However, clinicians are less familiar with the use of these same methods in the interpretation of clinical trial results. Here, we (mistakenly) believe that we can estimate "posterior probability" (that the "null hypothesis is true," for example) without taking into account "prior probability." As a result, we misinterpret trial results, most notably p-values and 95 % confidence intervals. The goal of the "Bayesian Clinical Trialist" app is to teach Bayesian interpretation of clinical trials to clinicians, trainees, and students, as well as to help them actually perform simple Bayesian analyses of clinical trial results themselves, with the hope of achieving better understanding of RCT results, and, ultimately, better patient care. Objectives of the app:—Users are able to calculate 95 % "credible intervals" using results of randomized trials and the users' own "prior probabilities."—Users are able to demonstrate the effect that different "priors" have on their posterior probabilities, just as in diagnostic testing.—Users are able to correctly interpret classical, frequentist 95 % confidence intervals and p-values.
SETTING AND PARTICIPANTS: The application is currently used in small group didactic sessions with internal medicine housestaff. It is also used in "journal club" settings and "at the bedside." The app is intended for those who will be applying the medical literature—that is, clinicians, trainees, and students.
DESCRIPTION: The app is used as part of a session on Bayesian interpretation of clinical trials. The session consists of a review of conditional probability and Bayes' theorem; its application to diagnostic test interpretation; an introduction to its application to clinical trial interpretation. The app is then used to interpret results of randomized trials. For example, a trial of pentoxifylline in subjects with alcoholic hepatitis (Gastroenterology 2000;119:1,637–164) showed a dramatic absolute risk reduction of 21.6 % (95 % CI, 3 %–40 %). If the user enters a prior estimate of "0" (i.e., no effect), and an imprecise "confidence region" of 20 % to–20 %, the 95 % "credible interval" is–2 to 25 %, a result no longer conventionally "statistically significant." The user can then change his/her prior and see how changes in the prior affect posterior estimates.
EVALUATION: Evaluation of the use of the app is planned. This will consist of pre- and post- evaluation of learners' ability to calculate posterior estimates using users' own priors; ability of users to recognize the impact of prior probability on posterior estimates; and ability to correctly interpret "classical" measures such as p-values and 95 % confidence intervals.
DISCUSSION/REFLECTION/LESSONS LEARNED: Using the app, learners can see exactly how their priors affect their posterior estimates, and how, in some cases (where there is a lot of data, for example), the prior will have little or no impact on the posterior probability, while in other cases (where there is little data, e.g.), the prior can have large effects on posterior estimates. As expected, users have difficulty estimating "prior probabilities," and some find the subjectivity objectionable. Parallels are made, however, with diagnostic test interpretation, and the unavoidable subjectivity inherent therein as well.
ONLINE RESOURCE URL (OPTIONAL): The app (Bayesian Clinical Trialist) can be downloaded for free from the Apple App store onto iPhone or iPad.

A MULTIDISCIPLINARY TRANSITIONS IN CARE WORKSHOP FOR MEDICAL STUDENTS Lauren Block; Melissa Morgan-Gouveia; Danelle Cayea. Johns Hopkins University, Baltimore, MD. (Tracking ID #1629621)

NEEDS AND OBJECTIVES: Transitions in care represent a vulnerable time for patients. While medical students are often involved in negotiating safe transitions for patients, identified knowledge gaps in the discharge process speak to the need for more formal and coordinated education in this area. We implemented an interactive workshop for medical students highlighting key skills in effective discharges and available resources appropriate for their developmental stage.
SETTING AND PARTICIPANTS: We developed a three-hour curriculum for second and third-year medical students at the midway point of their internal medicine clerkship.
DESCRIPTION: Students participated in five interactive small-group sessions focusing on case-based learning of key skills in safe transitions. These sessions were taught by pharmacists, nurses, case managers, and internists. Key skills emphasized included medication reconciliation, identifying barriers to discharge, patient education and discharge instructions, effective discharge summaries, communication with outside providers, and collaborating with a multidisciplinary team. Techniques used to encourage student involvement in the sessions included role playing, brainstorming, critiquing written text, and discussion. A large-group reflective exercise before and after the case-based sessions was used to contextualize learning within students' experiences during their clinical clerkships, and focused on ways to improve problematic transitions in care for their patients using a multidisciplinary approach.
EVALUATION: Program evaluation included qualitative, quantitative, and experiential feedback, and was IRB approved. All participating students completed a mini-CEX in which they reviewed discharge instructions with a patient under the observation of a nurse or a physician. The reflective exercise applied skills students learned to a discharge witnessed on the wards and generated qualitative data. Finally, students were asked to complete a pre- and post-workshop survey focused on frequency and independence in performing ten discharge tasks and collaboration in discharge-related activities. Responses were scored on a scale of 0–4, with 4 representing better scores. Pre- and post-curriculum data were analyzed using paired t-tests. During the first three sessions, a total of 72 students participated in this workshop. All completed their mini-CEX and contributed qualitative data. Survey response rate was 68 % (N= 49). Post-workshop, students reported significant increases in independence in medication reconciliation (mean score 3.2 vs. 2.7, p=0.01), educating patients at discharge (3.3 vs. 2.8, p=0.02), reviewing discharge instructions (3.3 vs 2.8, p<0.01), communicating with the outpatient provider (3.1 vs. 2.6, p<0.01), and collaborating with the team in discharge activities (3.4 vs. 3.0, p<0.01). A significant increase in understanding of the role of nurses, case managers, and pharmacists in discharge planning and communication with these individuals was observed following workshop participation.
DISCUSSION/REFLECTION/LESSONS LEARNED: A brief, interactive, case-based workshop integrated into the medical students' clinical clerkship and taught by an interdisciplinary team was effective in promoting independence in discharge-related tasks as well as collaboration with allied health professionals.

AN INTERCLERKSHIP INTENSIVE ON ADDICTION AMONG CLERKSHIP-YEAR MEDICAL STUDENTS Babak Tofighi[1]; Joshua D. Lee[2]; Demian Szyld[3]; Jennifer McNeely[4]; John Rotrosen[5]; Paul Kim[6]; Melanie Jay[7]. [1]New York University School of Medicine, New York, NY; [2]New York University School of Medicine, New York, NY; [3]New York University School of Medicine, New York, NY; [4]New York University School of Medicine, New York, NY; [5]New York University School of Medicine, New York, NY; [6]New York University School of Medicine, New York, NY; [7]New York University School of Medicine, New York, NY. (Tracking ID #1628418)

NEEDS AND OBJECTIVES: Despite the high prevalence of substance use disorders, medical students (MS) often lack adequate training in dealing with addiction and its comorbidities. New York University School of Medicine's (NYU SOM) curriculum reform committee developed a four-week Addiction Interclerkship Intensive (ICI). The ICI aimed to integrate basic and clinical addiction science, develop clinical reasoning and practical skills, and expose MS to an interdisciplinary body of medical faculty. Objectives were improved knowledge of addiction neurobiology,

treatment principles, and health systems, and improved self-efficacy and skills as addiction treatment providers through practice-based learning.
SETTING AND PARTICIPANTS: NYU SOM MS in their 9th month of clinical clerkships
DESCRIPTION: The NYU SOM Office of Medical Education led an interdisciplinary panel of faculty and MS clerkship directors to provide 29 h of ICI training. Nationally, MS are exposed to less than 15 h of SU training. Teaching modalities included plenary lectures, small group workshops, objective structured clinical exams (OSCE), ultrasound (US) guided vascular access workshop, clinical simulators, and at-home web-based modules. Session topics included: an addiction basic science overview, workshops in epidemiology, screening, treatment, and tobacco control, an interactive session with Alcoholics Anonymous (AA) participants, a prescription opioid pain and addiction OSCE, and simulations of pathologies (upper gastrointestinal bleed (GIB), pneumonia, respiratory distress) associated with addiction. Online surveys were completed after each component using a 4-point Likert scale and queried open-ended suggestions for improvement.
EVALUATION: 34 faculty, 13 staff, and 17 actors conducted the ICI involving 162 MS across 4 days. Assigned survey response rates were 100 %. Using a 4-point Likert scale, MS agreed or strongly agreed they were more knowledgeable of: screening, diagnosing, counseling, and treating SU patients (80 %); the behavioral effects of substance misuse (72 %); the risks/benefits of chronic opioid pain management (77 %); self-efficacy of referring patients to AA (86 %); developing a differential and plan for upper GIB, pneumonia, and respiratory distress (63 %, 65 %, and 62 %); and were more skilled at US guided vascular access (68 %). MS ratings (1–4) of ICI components ranked their favorability from high to low: clinical simulations (mean score, 3.5), US guided vascular access (3.49), OSCE case (3.0), addiction treatment workshop (2.9), SU epidemiology (2.9), opioid addiction (2.9), overview lecture of addiction (2.8), tobacco control (2.8), and basic science review of SU (2.7). Thematic analysis of open-ended responses suggested: MS participation in ICI planning, clinical case presentations, and immediate OSCE feedback.
DISCUSSION/REFLECTION/LESSONS LEARNED: This curriculum was innovative for its interdisciplinary approach in integrating several interactive teaching modalities. Strengths of the ICI included skills-based OSCE and simulations, small group workshops, and interdisciplinary faculty. Evaluation of this 4-day ICI MS intervention appeared to demonstrate the acceptability of an addiction curriculum in undergraduate medical education. Basic science and addiction research lectures were rated less favorably. Our outcomes highlight prior addiction education research findings suggesting the integration of experiential learning in order to better develop students' skills for assessment and intervention.

AN INNOVATIVE EDUCATIONAL PROGRAM FOR PRIMARY CARE SOCIAL SERVICE PHYSICIANS IN RURAL CHIAPAS, MEXICO Andrew J. Van Wieren[1,2]; Patrick F. Elliott[1,2]; Patrick M. Newman[1,2]; Lindsay B. Palazuelos[2]; Jafet Arrieta[2]; Hugo E. Flores[2]; Andrew L. Ellner[1,3]; Daniel Palazuelos[1,2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Partners in Health, Jaltenango, Mexico; [3]Harvard Medical School, Boston, MA. (Tracking ID #1631523)

NEEDS AND OBJECTIVES: Graduating Mexican medical students are required to complete a year of primary care social service (pasantia) before obtaining their full medical license. Theoretically, distributing social service physicians (pasantes) throughout Mexico would provide a safety net for the underserved. However, pasantes are typically unpracticed and unsupervised, distracted by pending residency entrance exams, and often never arrive to the rural areas where they are needed most. Compañeros en Salud (CES), a sister organization of Partners in Health, has worked in Chiapas, Mexico for over 20 years, and has found the provision of high quality primary care limited by a shortage of well-trained physicians. Identifying known shortcomings of the pasantia, several U.S. medical residents and CES staff have created and implemented an innovative educational program that aims to: 1) mentor pasantes to more effectively deliver primary care; 2) expose pasantes to central concepts of global health and social medicine; and 3) foster career development of pasantes.
SETTING AND PARTICIPANTS: Since February 2012, CES has placed 6 pasantes in previously unstaffed rural clinics in Chiapas. Several U.S medical residents from Brigham and Women's Hospital (BWH) and other programs have contributed to curriculum development and delivery. Attending physicians from both BWH and the Mexican CES team have supervised the educational program.
DESCRIPTION: Our program mentors pasantes to more effectively deliver primary care through: 1) accompaniment in clinic by U.S. medical residents and CES staff; 2) teaching evidence-based treatment algorithms for common primary care problems; and 3) reviewing challenging clinical cases. We host monthly 2–3 day global health seminars in an effort to help pasantes design and implement quality improvement projects within their communities, and to frame their work within the larger historical and political context of Chiapas. Finally, we foster career development by providing pasantes with test preparation materials and future job opportunities with CES.
EVALUATION: We have IRB approval for an ongoing research study to qualitatively evaluate pasantes' experience with the educational curriculum and seek their input on how to improve it. In the future, we hope to quantitatively assess how the curriculum influences process measures such as pasantes' adherence to treatment algorithms and clinical outcomes like control of chronic diseases.
DISCUSSION/REFLECTION/LESSONS LEARNED: The pasantia system is intended to serve as a safety net for the poor. However, the lack of formal mentoring offered to pasantes often results in dissatisfied physicians and patients. To our knowledge, we have developed the first educational program to support pasantes as they transition from medical students to independent primary care providers. A major challenge was that our initial model relied largely on 3 BWH resident volunteers to mentor a growing number of pasantes. Thus, we have created a formal elective in global primary care education open to residents from other programs to meet additional need. To make the model sustainable, we have begun to retain graduating pasantes as CES employees to train future pasantes. Given the ubiquity of the pasantia model in Latin America, our educational curriculum could be exported to impact both pasantes and their patients in countless other settings.

ATTENDING TO OUR FIRST OBLIGATION: THE DO NO HARM PROJECT Brandon Combs; Tanner Caverly. University of Colorado, Denver, CO. (Tracking ID #1621208)

NEEDS AND OBJECTIVES: Harms from overtesting, overdiagnosis, overtreatment, and preference misdiagnosis are a serious threat to the health of our patients and the long-term solvency of our health care system. Harms of overuse have not traditionally been taught to medical trainees and there are few incentives to pay attention to overuse. We have introduced the Do No Harm Project as a means to raise awareness and emphasize scholarship among housestaff and faculty highlighting the importance of doing "as much as possible for the patient and as little as possible to the patient."
SETTING AND PARTICIPANTS: All internal medicine housestaff and faculty at the University of Colorado.
DESCRIPTION: Interns and residents are asked to submit reflective clinical vignettes that demonstrate harms from overtesting, overdiagnosis, overtreatment, or preference misdiagnosis as well as the benefits of shared decision making. Participating housestaff are offered a writing day to complete their work. Vignettes are written in collaboration with any attending in any specialty. Vignettes are submitted for voting among a panel of physicians to determine quarterly and annual winners to whom cash prizes will be awarded. Vignettes are judged on two criteria: 1) clarity and 2) relevance to the concepts of avoiding overdiagnosis/overtreatment and enhancing shared decision making. All cases are published to our website and housestaff are encouraged to submit cases to local and national conferences as well as to peer reviewed journals for publication.
EVALUATION: We will measure the effect of the project longitudinally with a survey that assesses attitudinal change among housestaff around concepts of overdiagnosis and shared decision making. We will dissemi-

nate the Do No Harm Project at regional and national meetings to promote extension of this project to other institutions.
DISCUSSION/REFLECTION/LESSONS LEARNED: Housestaff and faculty have been eager to participate in the Do No Harm Project. Since we began 5 months ago in August 2012, housestaff have submitted 15 vignettes. Cases have highlighted harms from incidental findings and low-value diagnostic testing, as well as the benefits of incorporating patient preference to avoid unnecessary procedures. Two abstracts outlining this program have already been presented at local conferences in Colorado. Other academic institutions have been interested in collaboration and we are in the process of extending the Do No Harm project outside the University of Colorado. Vignettes provide a potent way to humanize the harms that can result from overdiagnosis or failing to consider patient preferences in the course of routine medical practice. The Do No Harm Project attempts to counteract deeply held cultural beliefs that more care is better through clinical vignettes reminding us of our first obligation—to do no harm.
ONLINE RESOURCE URL (OPTIONAL): www.medschool.ucdenver.edu/gim/donoharmproject

BRINGING EFFECTIVE CHRONIC PAIN EDUCATION TO LIFE FOR RESIDENT PHYSICIANS Michael Picchioni. Baystate Medical Center/Tufts University School of Medicine, Springfield, MA. (Tracking ID #1644279)

NEEDS AND OBJECTIVES: Chronic Pain management remains a major challenge for primary care internists and is routinely reported by trainees as an area they are not comfortable with. In addition this part of practice is a source of frustration for all providers; perhaps resident physician the most. Though a minority within each resident's practice, these patients often take up a disproportionate share of time and attention from the resident and the clinic. This can be very distracting from the care of other patients and other learning objectives. A variety of educational strategies have been implemented to help physicians in training learn to deal with or in spite of these challenges. Unfortunately, they frequently fail to meet the learner's needs. Some institutions have sequestered these patients among attending physicians which may help the patients and the practice, but certainly does not educate the trainees. The objectives of this program were to (1) provide the support needed to prevent burnout and negative attitudes toward patients with chronic pain and (2) prepare residents to manage chronic pain patients by actively involving them in a Best Practice model of care.
SETTING AND PARTICIPANTS: The setting is an urban clinic affiliated with a large independent academic medical center where the predominant providers are resident physicians.
DESCRIPTION: For nearly 10 years this clinic has had a comprehensive policy for managing patients requiring long-term opioid analgesics (LTO) that was developed and periodically refined by a multidisciplinary team. All new providers are oriented to the policy through a workshop when they first join the group and each patient is case managed by a nurse. Residents serving as PCP for patients with chronic pain have this policy reinforced during routine care by their team nurse, advanced practitioner and supervising attending physician. In addition, for the past 3 years, all patients receiving LTO are seen approximately once per year for a "Controlled Substance Review" visit that is highly structured to ensure the clinic's policy is being followed and for supplemental advice from a physician experienced in chronic pain management. Residents rotate through this clinic several times during PGY-2.
EVALUATION: All 5 of the Team Nurses describe this structure as invaluable in managing this cohort of patients Faculty preceptors commonly report that having this clinic reduces the frustration they feel as not being able to fully address the needs of chronic pain patients while trying to manage other co-morbidities. Similarly, PCP's find the support of this clinic helpful in providing comfort with their decisions to either continue or cease LTO therapy with their patients for whom the indications are unclear. Most importantly, the residents who participate in this clinic almost universally describe a sharp new sense of understanding of a rational approach to patients with chronic pain.
DISCUSSION/REFLECTION/LESSONS LEARNED: The "Controlled Substance Review" clinic appears to have provided the missing link between education and practice in chronic pain management. It simultaneously provides the additional structure needed to help our policy be successful and provides the learning experience needed by residents to solidify their understanding of safe and effective management of chronic pain.

BROWN MEDICAL SCHOOL PRECLINICAL ELECTIVE ON HEALTHCARE OF UNDERSERVED POPULATIONS Lucinda B. Leung[1]; James E. Simmons[2]; Joseph S. Rabatin[2,3]. [1]UCLA Medical Center, Los Angeles, CA; [2]Alpert Brown Medical School, Providence, RI; [3]Memorial Hospital of Rhode Island, Pawtucket, RI. (Tracking ID #1626066)

NEEDS AND OBJECTIVES: Brown medical students have a strong interest in medical service, yet receive little formal education on care of underserved populations; this may impact their preparedness for residency. A multi-institutional survey of US residents revealed that actual and perceived knowledge about underserved patients is low. Internal medicine residency training devotes less time to addressing unique cultural and healthcare needs of non-English speaking patients, compared to other vulnerable populations (e.g., substance abuse). Data from UCLA/Drew medical school, which stress minority/multicultural health and offer clinical rotations in underserved settings, suggest that such medical education programs may influence students to practice in underserved areas. Thus, Brown's preclinical elective course aimed to: (1) provide students with knowledge, skills and support to care for the underserved, (2) enable the opportunity to practice clinical skills in underserved settings, and (3) create future leaders in primary care and care of the underserved.
SETTING AND PARTICIPANTS: In 2010–2011, Brown opened a new elective to any preclinical medical student. A total of 19 students successfully completed the class, with 4 s-year and 15 first-year students.
DESCRIPTION: The course consisted of student-led seminars with guidance from a faculty advisor, focusing on medical care of vulnerable populations. Examples of seminars include: "Healthcare for Underserved Populations in Rhode Island," "Paying for Healthcare for the Underserved in New England" and "Making Fun of Patients: Cynicism, Humor, and Physician Response to Underserved Populations." Second, the class mandated clinical experience as a student provider at one of three free clinics: Brown Student Community Clinic, Rhode Island Free Clinic and Clinica Esperanza. Third, a culminating project experience required students to identify a healthcare problem and brainstorm feasible solutions.
EVALUATION: An anonymous written survey following the course included six 5-point Likert scale questions and three open-ended questions. Satisfaction was strongly positive, with the majority (93 %) of participants in agreement with "Recommend class to future students" (n=15). Other categories similarly received positive reviews ("Class was informative" 93 %; "Clear, well-organized" 80 %; "Stimulating and interesting" 93 %; "Sufficient opportunity to ask questions" 100 %; "Final project employed critical thinking and brainstorming that will be helpful in the future"100 %). Notable responses to "My favorite part of this class…" were "deconstructing specific problems (relevant to underserved communities)," "the volunteer experiences" and "the final project … to synthesize many of the ideas and information presented throughout the course." When asked how to improve the course, notable responses included "the final paper really helped me focus and get excited about topics" and "entrepreneurial guidance/logistical advice about what it takes to make our ideas a reality." Under additional comments, one student wrote "I'm really glad this class was given. I hope to see it really expand and help future students!"
DISCUSSION/REFLECTION/LESSONS LEARNED: Based on course evaluations and continued course participation this year, a preclinical elective dedicated to healthcare of the underserved is both promising and feasible. More research is needed to determine if course participants attained improvements in knowledge and skills and if participants will serve as leaders in medical care of the underserved.

CAMBRIDGE INTEGRATED CLERKSHIP SYSTEMS ROUNDS: MEDICAL STUDENT-DRIVEN QUALITY IMPROVEMENT AND PATIENT ADVOCACY Arjun Suri[1]; Alejandra Ellison-Barnes[1]; David R. Ziehr[1]; Benjamin Jastrzembski[1]; Juliana E. Morris[1]; Ariel Wagner[1]; Andres Patino[1]; Divya Mallampati[1]; David Bor[2,1]; David Hirsh[2,1]; Elizabeth Gaufberg[2,1]. [1]Harvard Medical School, Boston, MA; [2]Cambridge Health Alliance, Cambridge, MA. (Tracking ID #1642468)

NEEDS AND OBJECTIVES: The rigorous third year of medical school seldom encourages students to analyze social and systemic factors that compromise or enhance patient care. To advance this imperative, students at the Cambridge Integrated Clerkship (CIC) designed the CIC Systems Rounds as a reflective and educational initiative. The objectives are to engage students in a collaborative experience that fosters creativity in quality improvement, enable students to address gaps endemic to the health care system, and empower students to serve as advocates.
SETTING AND PARTICIPANTS: The CIC at Harvard Medical School comprises a cohort of 12 third-year medical students who engage in a longitudinal integrated curriculum and contribute to the care of a panel of medically and socially diverse patients at the Cambridge Health Alliance, a safety net institution. Whether observing poorly coordinated care or recognizing innovative practices, students experience with patients the strengths, frailties, and injustices found within the local and national healthcare and social support systems. As patients teach students, students gain an awareness of—and the ability to contribute to—potential improvements to the health care system.
DESCRIPTION: The process of this student-driven initiative begins when students collect cases from clinical experiences that demonstrate recurrent, surprising, or inspiring events in the health care system. During monthly Systems Rounds, students informally present stories on topics including medication reconciliation, health literacy, and immigration documentation status. The group then deconstructs each case, emphasizing major themes, sharing similar experiences, and proposing how providers, systems, or other actors might have helped or hindered the patient's care. After meeting, participants document cases in a standardized format that incorporates both quantitative and qualitative data.
EVALUATION: The outcomes of CIC Systems Rounds reflect the impact upon both patients and students. In terms of patient care, students organize quarterly meetings with faculty, administrators, and community groups as well as an annual CIC Systems Grand Rounds to share cases, discuss solutions, and contribute to quality improvement efforts. Compiling and coding cases allows students to reflect on the breadth and depth of their experiences in the third year. The group is also developing scholarly work for a broader audience and collaborating with other medical schools across the country.
DISCUSSION/REFLECTION/LESSONS LEARNED: The CIC grants students a unique view of patients' journeys through the medical system. The Systems Rounds further allows them a forum to analyze the systems successes and failures they witness daily in their medical training. These physicians-in-training are thus better positioned to become change agents and advocates early in their medical careers. With individual patient experiences at its core, CIC Systems Rounds inspires students to examine health holistically, think creatively about interventions to improve patient outcomes, and deliver compassionate, patient-centered care. Finally, the simplicity and flexibility of the program enables medical residents, community groups, patients, and other providers to replicate the process and broaden the movement for quality improvement. Engaging these diverse perspectives can be a tool to encourage active participation and collaboration. Cambridge Integrated Clerkship Systems Rounds demonstrates how educational transformation furthers the transformation of our health care system.

CREATION OF A WEB-BASED MOBILE APP TO TEACH AND FACILITATE SYSTEMS NAVIGATION IN A STUDENT-RUN FREE CLINIC Ammar Siddiqui; Yasmin S. Meah; Chloe Ciccariello; Alexa Gips; Mark Kurzrok; Noa Simchoni; Thomas McBride; David C. Thomas. Ichan School of Medicine at Mount Sinai, New York, NY. (Tracking ID #1642709)

NEEDS AND OBJECTIVES: 1) Educate students about patient barriers to accessing needed services through an experiential learning process; 2) Design a program in which students develop systems-level solutions to problems of healthcare access; 3) Create a web-based mobile app which educates clinical providers about specialty appointment requirements and costs at the point of care.
SETTING AND PARTICIPANTS: The East Harlem Health Outreach Partnership (EHHOP) is Mount Sinai's student-run primary care clinic (SRC) for uninsured adults. The population carries a high-burden of diseases that frequently require specialty care. Obtaining referrals for uninsured patients is cumbersome; specialties have variable procedures and costs, and long wait-times. In 2012, EHHOP trained preclinical medical students as Referrals Managers (RMs) to develop systems-level interventions to access specialty services. Providers at EHHOP involved in the referrals process consist of Teaching Seniors (MS4s), Senior Clinicians (MS3s), and the Access to Care Team (MS2s).
DESCRIPTION: RMs collaborated with clinical administrators to determine average wait-times, appointment hours, prerequisite medical tests, costs of referrals, and documentation needed at appointments. To gather information on real-time barriers, RMs accompanied patients to all specialty appointments. RMs used this field-data to develop specialty-specific protocols and create a mobile-phone application that providers can access on-site when making referrals. The mobile application allows providers to educate patients on referral procedures and may drive providers to make more educated decisions about whether a specialty service is necessary or feasible.
EVALUATION: Evaluation of this intervention is on-going and will include the following: 1. Qualitative feedback from RMs and clinicians on the utility of the mobile application in facilitating the referrals process and educating students on barriers to care; 2. Quantitative surveys on the educational impact of this project on the RMs' ability to navigate healthcare systems; 3. Quantitative data on the percentage of completed referrals and average time from referral to specialty appointment. Preliminary data suggests that systems interventions implemented since the development of this app have significantly improved referral completion rates and reduced wait-times.
DISCUSSION/REFLECTION/LESSONS LEARNED: The mobile-phone application allows clinical students to factor in access-to-care issues when referring patients for specialty care. Through the process of creating and updating the mobile phone application, preclinical students in this program apply system-level solutions to address barriers to access and learn to navigate healthcare systems, particularly for vulnerable patients. The challenges to sustaining this program are encouraging clinicians to use the application at the point-of-care, keeping the application accurate and up-to-date and quality control of the program particularly as EHHOP, like other SRCs, experiences yearly transitions of student leadership. An additional challenge has been to preemptively determine costs of medical procedures, which hospital administrators were reluctant to share.
ONLINE RESOURCE URL (OPTIONAL): http://ehhop0.appspot.com

DEVELOPMENT AND EVALUATION OF AN INTERPROFESSIONAL COLLABORATIVE CASE CONFERENCE SERIES Meg Pearson; Bridget O'Brien; Rebecca L. Shunk. UCSF, San Francisco, CA. (Tracking ID #1620786)

NEEDS AND OBJECTIVES: Interprofessional collaboration (IPC) is widely recognized as an important part of quality primary care, but many primary care clinics provide inadequate opportunities for trainees to develop the knowledge, skills, and attitudes needed for IPC. To address this gap, we created a yearlong series of monthly collaborative case conferences (CCC) beginning August 2012 in which trainees from a variety of health professions facilitate and participate in an interprofessional discussion about medically and psychosocially complex patients from their primary care panels with the goal of developing an improved plan of care for the patient. The two overarching educational objectives of CCC are to: 1) enhance our primary care educational curriculum by adding interactive, multidisciplinary trainee-led conferences that supplement team-based

clinical practice and didactic teaching conferences. 2) foster a culture of interprofessional collaboration within our program.

SETTING AND PARTICIPANTS: Our project is housed in the San Francisco VA Center of Excellence in Primary Care Education (COE-PCE), which trains nurse practitioner students and internal medicine residents to work as part of a Patient Aligned Care Team with a designated RN, LVN, and clerk as well as associated health professionals and trainees (clinical psychology fellows, clinical pharmacy residents, social work interns, and dietetic interns)—all of whom participate in CCC.

DESCRIPTION: Each CCC is an hourlong case-based conference. Trainees work closely with a faculty mentor to prepare, which includes selecting an appropriate patient, creating a case write-up and discussion questions, inviting discussants involved in the patient's care or with relevant expertise, selecting two pertinent articles from the literature, creating a facilitation plan to encourage participation and collaboration among all participants, and disseminating the learning materials. The trainee writes a post-conference care plan detailing 2 or more innovations for the patient's care that arose during CCC and completes a 3-month update on the status of the proposed interventions.

EVALUATION: Our evaluation of CCC includes interprofessional trainee, staff, and faculty participants' satisfaction with the organization, facilitation, educational value, and collaborative nature of the conference and their self-assessment of knowledge, skills and attitudes related to IPC. Our evaluation of participants' achievement of learning objectives combines observed behaviors during the conferences, documents generated in preparation for and subsequent to the conferences, and formative assessments by peers and faculty mentors. Conference evaluations forms and check-ins with faculty mentors create opportunities for trainees to engage in self-reflection.

DISCUSSION/REFLECTION/LESSONS LEARNED: In response to trainee feedback, we ask consultants to prepare a concise presentation (5 min max), specifically addressing the following question: "What key points should primary care providers know about this topic and when should they refer?" These mini-lectures allow our trainees to come away with clinical pearls without detracting from the collaborative, conversational nature of the conference. Some cases are sensitive in nature, involve bad outcomes, and trigger emotional responses. We learned that it is best to disseminate a draft of the case template to discussants at least a week prior to the conference to allow for written revisions if necessary, as well as for in-depth phone and email conversations prior to the conference.

DEVELOPMENT AND EXECUTION OF AN INTERNAL MEDICINE SUBSPECIALTY FELLOW TEACHING COMPETITION Dustin T. Smith[1,2]; Wendy S. Armstrong[1]; Ryan M. Ford[1]; Karen L. Law[1]; Kimberly D. Manning[1]. [1]Emory University School of Medicine, Atlanta, GA; [2]Atlanta Veterans Affairs Medical Center, Decatur, GA. (Tracking ID #1628940)

NEEDS AND OBJECTIVES: Excellence in teaching exists amongst trainees at academic medical institutions and may be an underrecognized teaching resource. Many fellowship programs have adopted curricula to enhance trainees' teaching skills, but effective ways to promote the teaching skills of fellows have yet to be fully defined. We created a teaching competition using internal medicine subspecialty fellows identified as excellent teachers in order to augment the opportunity for learning and highlight the teaching skills of trainees in our Department.

SETTING AND PARTICIPANTS: Active fellowship trainees in our Department who were identified as excellent teachers were selected to participate in a teaching competition in front of a live audience in the School of Medicine.

DESCRIPTION: Fellowship program directors in the Department of Medicine at our institution were asked to recommend one fellow to represent their program in a teaching competition. Programs were given suggestions for how to identify a fellow with excellent teaching skills but ultimately programs had the final decision for whom to select to represent their program. The only criterion for participation was that the fellow had to be an active trainee. No limitations were placed with regards to postgraduate year, ACGME versus non-ACGME status, chief fellow status, or type of fellowship track. Eight fellows were selected and consented to participate. The Department provided instruction and orientation to participants via a session on effective teaching skills prior to the competition. Fellows had intellectual freedom to develop a presentation on a medical topic of their choice but the primary focus of this activity was on creative and effective teaching techniques. The competition was held for one night during the Spring of 2012. Faculty, house staff, and medical students from the School of Medicine were invited to attend. The presentation order was randomly assigned. Six judges were recruited to observe the presentations in front of a live audience. Judges were selected by a committee based on a record of teaching excellence and included 2 senior faculty members and 1 junior faculty member from our department, 1 chief medical resident, 1 senior medical student, and 1 faculty member from another department.

EVALUATION: Judges scored the presentations on design (subcategories included purpose, organization, attention, retention, and audio-visual) and delivery (subcategories included pitch, pace, clarity, posture, and energy). Points were deducted for those speakers who exceeded the time limit of 8 min. Following all presentations, final scores were tabulated and the fellow with the highest average score was designated winner and awarded a monetary prize and teaching award plaque to be displayed by that particular trainee's fellowship program.

DISCUSSION/REFLECTION/LESSONS LEARNED: The development and execution of a fellow teaching competition at our institution celebrated learning for a variety of learners, encouraged collegiality amongst different divisions within our Department, spotlighted fellows who were excellent teachers, allowed for role modeling of teaching skills, and demonstrated how to effectively optimize a teachable moment in a short amount of time. Future evolutions will quantify the benefits of faculty, house staff, and students attending and further refining this competition based on subsequent feedback. Exceptional presentations will be circulated within the Department, demonstrating teachable moments and scaling effective teaching techniques to a larger audience.

DEVELOPMENT AND EVALUATION OF A NOVEL ONLINE ETHICS CURRICULUM FOR GLOBAL HEALTH TRAINING Matthew DeCamp[1,2]; Joce Rodriguez[3]; Michele Barry[3]; Jeremy Sugarman[1,2]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Stanford University, Stanford, CA. (Tracking ID #1629378)

NEEDS AND OBJECTIVES: Medical students, residents and faculty increasingly participate in global health training and service programs abroad. These programs raise ethical issues—for example, regarding cultural differences, sustainability and supervision—that if unaddressed might hinder program success or harm trainees or host communities. To prepare trainees for these issues, we developed a novel ethics curriculum to increase trainees' knowledge of these ethical issues; provide skills for navigating them; and increase trainees' confidence.

SETTING AND PARTICIPANTS: An interdisciplinary team with expertise in global health training programs and ethics developed an online curriculum and pre/post-test evaluation strategy. Content validity and pilot testing were provided by external experts and participants in the Stanford Center for Innovation in Global Health (CIGH) scholars program, which includes global health training and a six-week experience abroad.

DESCRIPTION: With funding from the Doris Duke Charitable Foundation, we built upon ethics and best practice guidelines by soliciting actual ethics cases from leaders in global health and colleagues. We developed ten cases covering common and important ethical issues, altering details to protect privacy and confidentiality and to meet educational objectives. Example scenarios include navigating cultural norms, minimizing safety risks to trainees, ensuring appropriate benefits for the host community, and managing situations where trainees might act beyond their skill level. Employing adult learning strategies, cases are problem-based; provide real-time corrective feedback; allow self-guided navigation; include multimedia content; and require <10 min

to complete. To enhance accessibility, the curriculum is free, requires no login, and is optimized for low bandwidth.

EVALUATION: We evaluated the curriculum using (1) web data; (2) open user demographic data; and (3) pre- and post-tests tailored to content. One pre/post-test group, the July 2012 cohort of Stanford CIGH scholars, is reported here. Knowledge assessment included five multiple choice questions and free text description of ethical issues. Confidence and perceived skills were assessed using 5-point Likert scales. Since normality and equal intervals could not be assumed, we used non-directional Wilcoxon signed-rank tests of statistical significance at $p<0.05$ (STATA r.12). Following IRB approval, 38 eligible CIGH scholars were recruited to complete a pre-test, the curriculum, and a post-test within a month prior to their experience abroad. Nineteen residents (50 %) completed both pre- and post-tests (8 internal medicine, 7 in pediatrics, 4 other). Fifteen (79 %) had been abroad before; of these only 4 (27 %) reported prior ethics training specific to short-term global health programs. Following the curriculum, the mean knowledge exam score increased from 52 % to 64 % ($p<0.01$); the average number of ethical issues described increased from 4.1 to 4.6 ($p<0.05$ one directional test). There were significant increases in respondents' confidence (3.1 to 3.4; $p=0.02$) and available strategies for managing ethical issues (3.4 to 3.9; $p=0.01$).

DISCUSSION/REFLECTION/LESSONS LEARNED: Our curriculum meets a critical need and effectively increases trainees' knowledge, confidence and strategies for managing ethical issues in short-term global health training. While the case-based, online format is uniquely tailored to this objective, more comprehensive curricula are needed to improve further trainees' attitudes, skills and behaviors.

ONLINE RESOURCE URL (OPTIONAL): http://ethicsandglobalhealth.org

DEVELOPMENT AND IMPLEMENTATION OF AN INTERPROFESSIONAL STANDARDIZED PATIENT ASSESSMENT

Sandra K. Oza[1]; Aimee Sznewajs[1]; Maria A. Wamsley[1]; Christy K. Boscardin[1]; Win May[2]; Andrew Nevins[3]; Malathi Srinivasan[4]; Ann Homan[1]; Bernie Miller[1]; Mark Lovett[1]; Karen E. Hauer[1]. [1]University of California, San Francisco, School of Medicine, San Francisco, CA; [2]Keck School of Medicine, University of Southern California, Los Angeles, CA; [3]Stanford University School of Medicine, Palo Alto, CA; [4]University of California, Davis School of Medicine, Sacramento, CA. (Tracking ID #1642592)

NEEDS AND OBJECTIVES: The World Health Organization identifies interprofessional collaborative practice as a means to improve the quality of patient care in increasingly complex care systems, and interprofessional education (IPE) as essential preparation for health professions trainees entering practice. Interprofessional learning assessments can determine "work-readiness" and simultaneously highlight the importance of interprofessional practice to trainees. To achieve these objectives, we developed and implemented an interprofessional standardized patient (SP) assessment for medical students.

SETTING AND PARTICIPANTS: The assessment was administered to eligible students at four California medical schools during the 2012 California Clinical Performance Examination, a clinical skills assessment conducted at the completion of the core clerkships.

DESCRIPTION: Four authors (SKO, AS, MW, KEH) representing both medicine and nursing developed an interprofessional SP case for the 2012 California Clinical Performance Examination. The case portrays a 55 year-old hospitalized woman who develops acute chest pain, a common clinical problem that is a learning objective of the Clerkship Directors in Internal Medicine. The student is tasked with collaborating with a standardized nurse (SN) to gather information and initiate a diagnostic and management plan. To adhere to principles of IPE, we employed an interprofessional team at all stages of case development and actor training. Each encounter lasts 15 min, after which SPs assess students using a 29-item SP checklist comprising the expected history taking, physical exam, information sharing, and communication skills (based on the SEGUE Framework). We developed an 11-item SN assessment checklist targeting the Core Competencies for Interprofessional Collaborative Practice, which assesses the student's collaboration in the domains of information gathering and communication skills. The case was implemented at four medical schools between April-August 2012. The Institutional Review Boards at the participating schools approved a study of the case. Complete data is available from two schools ("A" and "B").

EVALUATION: Of 333 eligible students, 307 consented to participate in the study (146 of 163 students from A). Of a possible 100 %, mean overall performance on the SP checklist was 73.56 % (standard deviation (SD) 9.63) at A and 74.41 % (SD 9.31) at B. Mean SP communication scores were 87.88 % (SD 14.25) at A and 87.41 % (SD 9.81) at B. Mean overall performance on the SN checklist was 80.07 % (SD 13.72) at A and 81.71 % (SD 13.25) at B. Mean SN communication scores were 90.18 % (SD 13.23) at A and 95.78 % (SD 12.44) at B.

DISCUSSION/REFLECTION/LESSONS LEARNED: We developed and implemented a case and training procedure using both a SP and a standardized health professional for assessment of medical students' clinical skills and interprofessional collaboration. Participation from an interprofessional team upheld the principles of IPE, and ensured accurate portrayals of healthcare professionals by actors. Our data show that students were successful in this high-stakes assessment, particularly with respect to communication with both the SP and SN. We demonstrate that a SP exercise can be adapted to assess interprofessional collaborative practice, and believe this is a useful method to guide curriculum design and assessment. Future work should compare these findings to assessments of trainees' interprofessional competency in authentic clinical settings to enhance future SP and interprofessional assessments.

DEVELOPMENT OF HOSPITAL MEDICINE EDUCATORS: DESIGN AND IMPLEMENTATION OF A PHYSICAL DIAGNOSIS COURSE FOR PHYSICIAN ASSISTANT STUDENTS

Dustin T. Smith[1,2]; Joanna M. Bonsall[1]; Marquitha S. Mayfield[3]; Margaret DeMoss[1]; Jennifer N. Larson[1,2]; Dana Sayre-Stanhope[3]; Daniel D. Dressler[1]. [1]Emory University School of Medicine, Atlanta, GA; [2]Atlanta Veterans Affairs Medical Center, Decatur, GA; [3]Emory University School of Medicine, Atlanta, GA. (Tracking ID #1628921)

NEEDS AND OBJECTIVES: Advanced practice clinicians such as physician assistants (PAs) represent a growing proportion of providers who care for hospitalized patients. While many PA training programs rely on community outpatient clinicians to train early-level PA students in physical diagnosis, Hospital Medicine (HM) faculty and Internal Medicine (IM) residents with an interest in teaching can potentially provide a more consistent learning experience in physical examination for 1st year PA students. In 2011, the PA Student Physical Diagnosis Preceptorship (PASPDP) course was designed in collaboration with leadership in the School of Medicine's PA Program and the Division of Hospital Medicine to 1) augment history and physical examination skills of pre-clinical PA students and 2) provide a valuable teaching and academic pursuit vehicle for a growing academic HM faculty group as well as IM residents interested in developing teaching skills.

SETTING AND PARTICIPANTS: We designed a physical diagnosis course for 1st year PA students at our institution. The PA program transitioned their student physical diagnosis training from experiences in outpatient clinician offices to training by HM faculty plus IM residents—all managed and coordinated by our Division of Hospital Medicine and the PA program.

DESCRIPTION: From January to September 2012, 56 PA students spent one afternoon bimonthly at one of our six hospitals where our faculty and residents practice. During each session, Hospitalist or resident preceptors introduced students to hospitalized patients with diagnoses related to the organ system the students were studying in concurrently-running didactic modules. The students interviewed and examined the patients and formulated a focused presentation to their preceptors, who provided feedback. Preceptors then returned to the bedside with students to observe them performing portions of the physical exam, provide feedback on technique, demonstrate clinical findings and engender learner competency.

EVALUATION: Both students and preceptors received formal course evaluation. Future directions will focus on quantifying the faculty, resident, and student benefits and further refining the course based on feedback. A program and course evaluation is currently underway and will utilize surveys, focus groups, and structured interviews with students and preceptors.
DISCUSSION/REFLECTION/LESSONS LEARNED: The PASPDP course successfully trained 56 first-year PA students. Student feedback was overwhelmingly positive, with many commenting on instructor enthusiasm, personal attention and in-depth teaching. HM faculty and IM residents who served as preceptors perceived the course as a valuable way to teach early level learners and actively engage in an academic pursuit that offers professional fulfillment. The IM residency program lauded residents who voluntarily participated, and some have applied their efforts to achieve graduation with Distinction in Teaching. Leadership from the PA Program, the Division of Hospital Medicine and the IM residency program identified the course as a strong and successful collaboration in education, and plan for a robust 2nd year of the course.

DEVELOPMENT OF A LEADERSHIP OBSERVATION AND FEEDBACK TOOL (LOFT) Sandra K. Oza[1]; Edna Miao[2]; Read Pierce[4]; Anda Kuo[3]; Sandrijn van Schaik[3]. [1]University of California, San Francisco School of Medicine, San Francisco, CA; [2]University of California, San Francisco School of Medicine, San Francisco, CA; [3]University of California, San Francisco School of Medicine, San Francisco, CA; [4]University of Colorado School of Medicine, Denver, CO. (Tracking ID #1642790)

NEEDS AND OBJECTIVES: Competency in team leadership is a required outcome of residency training, but assessment tools for leadership skills outside of high-acuity settings are lacking. The Leadership Practice Inventory (LPI) is a validated leadership assessment tool used widely in a variety of non-clinical settings. We aimed to identify appropriate terminology and important skills associated with clinical team leadership based on the LPI construct, in order to create a behaviorally anchored tool for use during observation of and feedback on resident physician clinical leadership skills.
SETTING AND PARTICIPANTS: The initial phase of the study was conducted among PGY-2 and PGY-3 residents leading multidisciplinary inpatient pediatrics and internal medicine teams at a single academic medical center. The second phase of the study utilized an invited panel of 15 national and international experts in healthcare leadership.
DESCRIPTION: We modified the LPI based on in-depth review of the clinical teamwork and leadership literature to create an on-line instrument with open-ended questions about residents' leadership skills. We asked PGY-2 and PGY-3 residents leading multidisciplinary inpatient pediatric and internal medicine teams at UCSF to identify 5 team members to provide feedback using our instrument. We utilized an iterative qualitative analysis process to code this feedback and identify major themes. We then extracted leadership behaviors from these themes, and asked an expert panel in healthcare leadership to rate the importance of behaviors using modified Delphi methodology. In a second round, the experts assigned the training level at which each behavior can be expected of physicians in training.
EVALUATION: During the first phase, a total of 75 team members provided feedback. Qualitative analysis resulted in ten major domains of clinical leadership, and 30 associated behaviors. The ten domains are: 1) shows appreciation to motivate the team, 2) balances autonomy and supervision, 3) is accessible and involved, 4) ensures collaboration with team members for shared decision making, 5) assists with workload management, 6) provides supportive feedback, 7) manages challenges productively, 8) promotes a learning environment, 9) models professional behavior, and 10) establishes expectations and goals. Importance ratings given to each of the 30 behaviors by the expert panel during the first of two Delphi rounds were analyzed using Content Validity Index (CVI, a measure of agreement or consensus). CVI estimates were all 0.80 or greater, indicating high agreement on the importance of behaviors. The panelists also recommended the addition of seven new clinical leadership behaviors. In the second Delphi round, experts identified the training level at which each behavior could be expected of a trainee. Using this data, we developed a behaviorally anchored, developmentally oriented tool, which we plan to pilot among residents leading multidisciplinary teams.
DISCUSSION/REFLECTION/LESSONS LEARNED: Our study identified important clinical leadership behaviors and fostered the development of a behaviorally anchored instrument, the Leadership Observation and Feedback Tool (LOFT). Piloting this tool in real-world clinical settings will provide additional data with which to determine the construct validity and reliability of the instrument. Ultimately, we hope that the LOFT instrument will fill an unmet need of graduate medical educators by serving as a validated tool for assessing clinical leadership skills.

DEVELOPMENT OF A SYSTEMATIC REVIEW TRAINING PROGRAM FOR ATTENDING PHYSICIANS TO MENTOR INTERNAL MEDICINE RESIDENTS Tanu S. Pandey; Brian P. Lucas. John H Stroger Jr. Hospital of Cook County, Chicago, IL. (Tracking ID #1642279)

NEEDS AND OBJECTIVES: ACGME requires that Internal Medicine residency programs assign sufficient educational resources to facilitate resident participation in scholarly activity. Yet there are few programs with structured mentorship programs for research. Other obstacles seem prohibitive including lack of mentorship, limited funding and feasibility constraints with unexpected delays, slow institutional review boards, and lack of statistical expertise. We created a house staff research mentorship program to foster resident research through a formal faculty development course. Neither this course nor the research projects developed from it require funding, IRB review, or participant recruitment.
SETTING AND PARTICIPANTS: Junior faculty physicians from the Department of Medicine were chosen to undergo a five-week training session of 1-h lectures on how to conduct systematic reviews and meta-analyses by an institutional expert. Webcasts of these training sessions were developed for review to ameliorate scheduling conflicts. Mentors were then matched with 2 to 3 residents, with an effort to align the career interests of the mentee.
DESCRIPTION: In September 2012, 12 core faculty members were invited to attend training sessions to learn how to conduct systematic reviews and meta-analyses. 46 residents signed up for this program and 30 were matched with mentors after an interview and elimination process. 11 topics were listed, encompassing a wide variety of specialties in Medicine. Research questions were generated by the physician faculty. There were responsible for teaching the elected residents how to design and conduct a systematic review, extract data, perform statistical analyses using freely available software, and assessing quality control of work done by the residents. The expectation was to submit a manuscript for publication before the end of the academic year. The institutional expert was available to address concerns and gaps in learning during regular meetings. Authorship order was to be arranged based on the quality and amount of effort, timeliness of tasks, overall contribution, and in the case of ties, random chance.
EVALUATION: The program is currently in its fourth month since inception and progressing as expected. All projects are expected to culminate in a manuscript by the end of the academic year. An official research director will be appointed to administer the program in future and we hope that funding will be granted by the Department to support future training and publication to open access journals.
DISCUSSION/REFLECTION/LESSONS LEARNED: Residents have generally indicated that the mentorship has promoted their critical thinking and analytical skills. Others aspire to conduct an independent project in the future as well as mentor other residents through the process. Publications will enhance their fellowship applications and stimulate interest in research. A successful mentorship program will also encourage departmental support and funding. This program is feasible, easily implemented, and worthwhile to residents, junior faculty, and their institutions.

DEVELOPMENT OF A MULTIDISCIPLINARY CURRICULUM IN ACCORDANCEWITH NATIONAL COMMITTEE FOR QUALITY ASSURANCE (NCQA) GUIDELINES FOR THE PATIENT-CENTERED MEDICAL HOME (PCMH) Stacie Schmidt; Shelly-Ann Fluker; Jada C. Bussey-Jones; Danielle Jones; Kristina L. Lundberg; Stacy Higgins. Emory University, Atlanta, GA. (Tracking ID #1628435)

NEEDS AND OBJECTIVES: Teach internal medicine residents the PCMH-principles of (1) managing patient populations, (2) coordinating patient care, and (3) working within multidisciplinary teams

SETTING AND PARTICIPANTS: The Grady Primary Care Center (PCC) is an academic safety-net, hospital-based clinic accommodating ~70,000 visits annually. The patient population is largely uninsured with low literacy and other cultural challenges to caring for their chronic diseases. To overcome this, we piloted a curriculum whereby Emory internal medicine residents work collaboratively with other team members to deliver multidisciplinary patient-centered care in accordance with NCQA guidelines for a PCMH.

DESCRIPTION: During their ambulatory months, residents have a half-day of protected time weekly for PCMH activities. During the first half of the year, PGY-1 residents "shadow" their team nurses, pharmacists, and social workers in the outpatient setting, in an effort to learn the roles of other members within their healthcare team. During the second half of the year, interns participate in patient-population management, whereby they run electronic reports on panels of patients with uncontrolled disease (e.g., diabetes) and conduct follow-up encounters to target those individuals. PGY-2 s work with other team members (e.g. pharmacists) to discuss a panel of patients with socioeconomic, cultural, and systemic obstacles to controlling specific chronic diseases. Residents are given protected time to invite patients back for prolonged sessions to discuss these issues. Pharmacists are present in the clinic room with the resident during the encounter so that identified issues can be addressed; this promotes direct communication and coordination with the patient, pharmacist, and resident as a team. PGY-3s expand upon the population management skills by running a report on continuity patients with a particular uncontrolled disease (e.g. diabetes) and inviting them back for group education sessions. Residents have protected time to plan the sessions and lead the group education simultaneously with team nurses. While individual components of our program were adapted from other published reports, no study to our knowledge has incorporated all of the aforementioned strategies into a sustainable curriculum run longitudinally over the postgraduate years. Further, the tactics employed in our curriculum enabled us to achieve the rare level 3 NCQA accreditation for a PCMH, and may allow other residency programs with similar demographics and resources to attain the same.

EVALUATION: Residents complete a written post-course survey addressing the curriculum using a 10-point scale as well as open-ended questions eliciting suggestions for improvement. Residents also document PCMH patient encounters in the electronic medical records, which serves to prove our adherence to NCQA guidelines.

DISCUSSION/REFLECTION/LESSONS LEARNED: We found it difficult to perform scheduling due to the volume of residents (e.g. two pharmacists, but up to six residents available to work with them at a time). At times, residents repeated components of the curriculum (e.g. patient population management) because of this overscheduling problem. Further, we would like to implement PCMH principles year-round (not just on ambulatory months) and are currently building protected time into the clinic schedule for team meetings to occur quarterly. Finally, our current evaluation system focuses mainly on resident feedback; we plan to evaluate patient satisfaction and outcomes going forward.

DIRECT OBSERVATION OF RESIDENTS: A NOVEL FACULTY FINANCIAL INCENTIVE PROGRAM Lauren Acinapura; Nicole Sirotin; Johanna Martinez; Pamela Apolaya; Christina Harris. Weill Cornell Medical Center/New York Presbyerian, New York, NY. (Tracking ID #1642554)

NEEDS AND OBJECTIVES: The advent of milestone "core-competency based" evaluations put forth by ACGME has caused effective resident evaluation to be based largely on criteria ascertained through direct observation. In 2011, the Weill Cornell Internal Medicine Associates (WCIMA) began utilizing milestone evaluations for ambulatory rotations and realized that increased direct observation was essential to meaningfully complete the milestone evaluations, but was limited by multiple faculty-reported barriers, including time constraints, conflicting priorities, and lack of a simple framework to use to observe residents quickly and provide meaningful feedback. To address this need we created the Direct Observation Faculty Group Incentive Program, a novel effort to increase faculty direct observation of residents by linking direct observation to a group faculty financial incentive with the ultimate goal of improving patient care, and resident evaluation.

SETTING AND PARTICIPANTS: WCIMA, the academic General Internal Medicine practice of Weill Cornell Medical Center, serves as the primary site for general medicine ambulatory education for the Internal Medicine Residency Training Program, consisting of 129 residents. In August, 2012, four WCIMA faculty members underwent direct observation training at the ABIM. In October, 2012, we conducted the first part of a series of faculty development sessions for WCIMA faculty on direct observation techniques.

DESCRIPTION: The faculty group incentive program requires every faculty preceptor to directly observe a portion of one resident-patient encounter during at least 75 % of their precepting sessions. They must record their observations on a mini-CEX form, adopted from the ABIM, give the resident verbal feedback and submit the form to the resident's evaluation file. All mini-CEX forms are entered into a central electronic database to share summative data with each resident's assigned preceptor, and to monitor faculty progress towards the group incentive. The increase in billing codes for each resident observed (from 99213GE to 99214GC or higher) contributes to the funds for the faculty group incentive. If the group meets the 75 % goal, the allocated funds will be distributed based on the number of precepting sessions each faculty member does. A post intervention evaluation to measure the impact of this program is planned.

EVALUATION: To date 16 faculty members have been trained in direct observation techniques and the incentive program was fully implemented in January 2013. Pre-intervention surveys were conducted among the 16 faculty members that completed the training session. This seasoned group of preceptors, with an average 18 years of precepting experience, all reported that in the first 6 months of the academic year they directly observed their resident "40 % or less of precepting sessions". Preliminary feedback from preceptors and residents who underwent direct observation has been positive from both parties.

DISCUSSION/REFLECTION/LESSONS LEARNED: We present a novel program that links ACGME and ABIM goals of increased direct observation of resident physicians with a group faculty financial incentive. Our goal is to improve patient care, resident education and feedback while increasing the revenue of our practice. Increased direct observation and mini-CEX data will improve continuity preceptor's ability to evaluate milestones progress. Future directions include evaluating patient related quality measures and both the resident and faculty experience of increased direct observation.

EDUCATING RESIDENTS ON HEALTH AND HEALTH CARE DISPARITIES THROUGH AN INTERACTIVE WEB-BASED MODULE USING CLINICAL CASES Jessie K. Kimbrough-Sugick[1]; Letitia Wright[2]; Stephen Sisson[2]. [1]University of Michigan, Ann Arbor, MI; [2]Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #1642776)

NEEDS AND OBJECTIVES: Racial and ethnic disparities in health are well documented and will magnify as the diversity of the US population continues to grow. Residency programs care for a significant amount of racial and ethnic minorities, yet national studies have shown residents' perceived preparedness to be deficient in various areas of cross-cultural care (e.g. caring for patients who have mistrust of the health system). Other national studies have shown that residents recognize that health disparities are prevalent but they lack adequate training and role-modeling on

addressing disparities. To help meet these needs in medical education, we created an interactive web-based module using clinical cases to educate internal medicine residents on health and health care disparities and the role that they can assume to help eliminate disparities. Our primary objective is to educate and promote a commitment to eliminating disparities in health.
SETTING AND PARTICIPANTS: The curriculum will be disseminated through the Johns Hopkins Internet Learning Center to internal medicine residency programs across the US.
DESCRIPTION: Our web-based module was designed to be interactive and educate resident learners about the root causes and impact of health and health care disparities. The content of the curriculum uses a patient-based approach. The module uses a diverse group of patients in a variety of clinical settings. Clinical cases include highlighting the role of the social determinants of health for a Latina woman who has had a recent stroke. Another case, explores the role of cultural and language barriers for an elderly Middle Eastern immigrant man with newly diagnosed type 2 diabetes mellitus. Our module also discusses the roles that residents can assume as health care professionals to help eliminate disparities in health. The accompanied assessment questions cover a range of topics in cross-cultural care, including caring for patients with language barriers, limited health literacy, disabilities, and chronic diseases with stigma such as HIV.
EVALUATION: Pre and post test questions will be used to evaluate the effectiveness of the curriculum and analyzed with descriptive statistics.
DISCUSSION/REFLECTION/LESSONS LEARNED: As the US population continues to grow in diversity, the need for physicians trained in cross-cultural care continues to expand. Residents' self-perceived preparedness to care for diverse populations is deficient. Our curriculum attempts to meet the needs of educating residents on cross-cultural care with a focus on health and health care disparities, in addition to promoting a commitment to eliminating disparities in health for all patients.

EFFECTIVENESS OF A QUALITY IMPROVEMENT MODULE WITHIN AN INTERNAL MEDICINE (IM) HONOR'S ELECTIVE FOR MEDICAL STUDENTS Kimberly M. Tartaglia; Curt Walker. Wexner Medical Center at the Ohio State University, Columbus, OH. (Tracking ID #1633079)

NEEDS AND OBJECTIVES: Numerous studies exist that assess resident curricula on quality improvement (QI), but rigorous evaluation of QI curricula in undergraduate medical education is lacking.
SETTING AND PARTICIPANTS: We developed a QI curriculum that was embedded in a 9-month Honor's elective offered to high-performing, fourth year medical students interested in Internal Medicine.
DESCRIPTION: During the QI module, students completed a reflection on writings by Atul Gawande and completed web-based QI modules offered by the Institute for Healthcare Improvement. Knowledge was reinforced through two 60-min discussions entitled "Patient Safety" and "Improving Performance." Students then participated in a QI project that focused on creation of a team, summary of best practices, and identification of well-defined aims and measures.
EVALUATION: The impact of the curriculum was assessed using both a self-assessment and Quality Improvement Knowledge Assessment Tool (QIKAT), a validated tool that examines student comfort on QI skills in 12 domains and assesses knowledge through 3 scenarios (each scored 0–5). Students who received the curriculum were administered the QIKAT at the end of the module. Fourth year students who matched in IM but were not in the Honor's elective served as controls. Data were collected for two academic years and included 14 intervention and 11 control students. At baseline, there was no difference between groups in prior exposure to QI principles. Results of independent samples *T*-test analyses suggested that students in the intervention group were significantly more comfortable with their skills in quality improvement in 8 of the 12 domains ($p<0.05$). Additionally, intervention students scored significantly higher in each of the three case scenarios (knowledge assessment) when compared to controls (Case 1, MI=4.2, MC=2.0; Case 2, MI=3.9, MC=2.0; Case 3, MI=4.1, MC=2.0; $p<0.05$). Although multiple regression analyses suggests that students who self-report greater comfort with QI principles scored higher on each of the three case scenarios, participation in the QI curriculum remained the primary driver of success on the QIKAT assessment tool (Case 1, $\beta=.73$, $p<.01$; Case 2, $\beta=.57$, $p<.05$; Case 3, $\beta=.68$, $p<.01$).
DISCUSSION/REFLECTION/LESSONS LEARNED: A 9-month curriculum in quality improvement can effectively increase student comfort and knowledge on QI principles. An experiential component that builds on independent preparation is the hallmark of the curriculum. With a faculty champion, this curriculum is highly portable to other settings.

EVALUATION OF A PATIENT SAFETY AND TRANSITIONS OF CARE CURRICULUM FOR THIRD YEAR MEDICAL STUDENTS Sara M. Bradley[1,2]; Dennis Chang[2]; Reena Karani[3,1]. [1]Mount Sinai School of Medicine, New York, NY; [2]Mount Sinai School of Medicine, New York, NY; [3]Mount Sinai School of Medicine, New York, NY. (Tracking ID #1610939)

NEEDS AND OBJECTIVES: The Joint Commission, American Geriatrics Society, Accreditation Council on Graduate Medical Education (ACGME), and the Liaison Committee on Medical Education (LCME) have all recognized patient safety and transitions of care as key components of high quality patient care and noted that there is a critical unmet need for medical education in these areas. In response, we developed a clinically relevant curriculum on patient safety and transitions of care for third year medical students during the Integrated Internal Medicine-Geriatrics Clerkship. The curriculum includes a post-discharge visit to a patient the student took care of in the hospital following interactive didactic sessions on the core principles of these important topics and an opportunity to debrief and reflect following the patient visit. The objectives of this study are to assess the feasibility of implementing a post-discharge visit in an urban tertiary care setting and to evaluate the effectiveness of the curriculum on students' knowledge, skills, and attitudes.
SETTING AND PARTICIPANTS: Third year medical students at an urban medical school on the Internal Medicine-Geriatrics clerkship
DESCRIPTION: The curriculum includes interactive didactic sessions covering an introduction to patient safety and discharge planning and transitions of care. Students then go in pairs on post-discharge visits to patients they took care of in the hospital and complete a template of questions with the patient. The curriculum also includes reflective writing and a debriefing session after the post-discharge visit. Participants complete pre and post intervention assessments of knowledge, skills, and attitudes, and an evaluation of their satisfaction with the curriculum.
EVALUATION: After 6 months, all 71 students completing the Internal-Medicine-Geriatrics clerkship received the didactic sessions. All students completed a post-discharge visit as well. Thirty-nine students visited their own patient while the remainder visited their partner's patient. The average time to complete the post-discharge visit was approximately 1.5 h. On average, students rated the didactic sessions as good to very good (mean score 3.82 on 1 to 5 scale). Students agreed to strongly agreed that they gained skills they plan to apply to future patient care experiences and that the program added to their learning about discharge planning and transitions of care beyond other experiences in the clerkship. Analysis of pre and post assessments did not show significant changes in attitudes or confidence. The percent of knowledge questions correct did increase from 61 % to 68.8 % ($p=0.00549$). In the reflective questions, when asked if they would change how they communicated with patients at discharge in the future, students most often cited the importance of ensuring clear patient education about the reason for hospitalization and treatment plan. Barriers to being able to visit patients included distance to patient's home, inability to contact patient, death, readmission, and that the patient changed their mind.
DISCUSSION / REFLECTION / LESSONS LEARNED: Third year medical students were satisfied with a patient safety and transitions of care curriculum and felt it added to their learning beyond other experiences in the clerkship. Lessons learned include having students identify more than one patient to visit after discharge in case the original patient is unavailable and liberalizing patient criteria for the visit including allowing visits to more distant sites.

EVALUATION OF A POCKET-SIZED ULTRASOUND DEVICE AS AN AID TO THE PHYSICAL EXAMINATION Jason Ojeda[1,3]; James Colbert[1,3]; Graham T. McMahon[1,3]; Carol Benson[2,3]; Peter Doubilet[2,3]; Justina Wu[1,3]; Joel T. Katz[1,3]; Maria Yialamas[1,3]. [1]Brigham and Women's Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA. (Tracking ID #1642158)

NEEDS AND OBJECTIVES: Studies have shown that internal medicine residents do not routinely possess necessary expertise in the physical exam. Recently, pocket-sized ultrasound devices have become available that can be used as point-of-care tools by practicing clinicians. We hypothesized that such devices could be utilized by resident physicians as tools to improve their physical diagnostic skills. As such, we set out to determine the diagnostic accuracy of residents using a pocket-sized ultrasound device compared with residents using physical exam techniques for the following physical findings: pleural effusion, paralyzed hemidiaphragm, splenomegaly, aortic stenosis, aortic regurgitation, mitral regurgitation, tricuspid regurgitation, elevated right atrial pressure, hypertrophic cardiomyopathy, dilated left ventricle, mitral valve prolapse, abdominal aortic aneurysm. We also set out to determine the diagnostic accuracy of internal medicine residents using the standard physical exam as compared to a master clinician, evaluate the perceived utility of the physical exam versus ultrasound for various findings among medical residents, and determine the perceived ability of residents to integrate ultrasound examination into their daily patient care routines.
SETTING AND PARTICIPANTS: We studied 40 internal medicine residents across all years of training at an academic medical center. Ten patient subjects with previously identified physical findings were recruited from attending clinics across the same academic medical center.
DESCRIPTION: Forty residents were randomized into the intervention group by blindly selecting names out of a bag based on the residents' ability to attend one of two training sessions. Two groups of 10 residents attended 1 of 2 identical 3 h training sessions on the use of pocket-sized ultrasound for cardiac, lung, and abdominal findings that included both a didactic and hands-on component. After completing the training, residents had 4 weeks to practice with the devices on the wards and in their continuity clinic. The control group did not receive any ultrasound training or access to ultrasound devices.
EVALUATION: After 4 weeks all 40 residents underwent an assessment of their physical diagnosis skills by performing physical exams on 10 patient subjects with various physical exam findings and noting their findings on assessment form. Each of the patient subjects was also examined by a master clinician and had an ultrasound performed by professional faculty. The residents in the ultrasound group also performed a focused ultrasound exam on each patient as well and again documented their findings. All residents also completed a qualitative survey on the day of assessment examining their perceived confidence in their physical exam as well as their attitudes regarding the utility of ultrasound.
DISCUSSION / REFLECTION / LESSONS LEARNED: The data has been collected and is in the process of being analyzed and will be ready for presentation and discussion at the SGIM meeting.

EVOLUTION OF AN INTERNET-BASED QUALITY-FOCUSED MEDICAL EDUCATION PROCESS IN AN AMBULATORY CARE ORGANIZATION Maura J. McGuire[1,2]; Thomas Bogetti[1]; Steven J. Kravet[3,2]. [1]Johns Hopkins Community Physicians, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Johns Hopkins Community Physicians, Baltimore, MD. (Tracking ID #1639066)

NEEDS AND OBJECTIVES: As organizations implement team-based workflows to achieve quality, safety, and compliance goals, assuring primary care providers (PCP) understand and participate is important. In our experience, PCPs need training in quality systems and teamwork (QST) beyond what they might otherwise absorb in traditional CME and staff meetings. We implemented a mandatory QST curriculum, delivered by a distance learning program (DLP), combined with a participation incentive to (1) assure PCPs completed QST (2) provide real-time access to subject matter experts (3) promote high quality care, as a complement to support staff training in these areas.
SETTING AND PARTICIPANTS: Our group is an academically affiliated, multispecialty group practice with more than 35 practices and 220 PCPs caring for 220,000 patients. We have 8 patient centered medical homes (PCMH), attest to meaningful use of our electronic medical record, and use protocol orders to enhance delivery of preventive care.
DESCRIPTION: The QST curriculum and participation incentive were implemented in 2007 to provide additional education after an electronic medical record (EMR) implementation. It provided PCPs with 1 education-related relative value unit (E-RVU), per hour, worth approximately $27. Each PCP was required to complete 4 h of EMR training each year. We added non-EMR QST content in 2009, and allowed PCPs to earn up to 8 E-RVU/year. Annual learning needs assessments and management input inform the QST curriculum. DLPs provide accessible interactive and recorded learning, and CME credit has been available for most programs since 2010.
EVALUATION: From 2007 to 2009, training was provided by both in-person and distance-learning programs. After investment in enhanced web-conferencing system (Adobe Connect@), DLP programming expanded from 10 to 49 programs between 2009 and 2011. PCP evaluations of DLPs (2010 vs. 2011) showed high satisfaction with knowledge gains (89 % vs. 97 %) and program quality (93 % vs. 99 %); with 437 CME vs. 631 CME hours earned. Recorded content is available. Sample QST topics in 2011 included: Meaningful Use of the EMR; Team-based Care, Performance Improvement in Hypertension, and Safety Attitudes in our Practices. In 2011, the program cost $60,000, including $43,000 to cover an average of 6.4 E-RVU earned by each PCP.
DISCUSSION / REFLECTION / LESSONS LEARNED: Healthcare organizations may struggle with the quality and operations-related education of busy PCPs, despite their role as leaders of healthcare delivery teams. Our program allowed us to confirm completion of QST material and assure PCPs knew we valued their time. The program has also been used to provide a variety of clinical and quality content with expert interaction to PCPs. While we have not linked this process directly with outcomes, evaluations indicate increasing use and high satisfaction, and we believe it has assisted our group with top box performance in HEDIS and other metrics.

EXPANDING HEALTH POLICY EDUCATION: INTEGRATING A SKILLS-BASED CURRICULUM FOR THE NEXT GENERATION OF PRACTITIONERS Krisda Chaiyachati[1,2]; Theodore Long[1,2]; Trishul Siddharthan[1,2]; Ali M. Khan[1,2]; Rebecca Brienza[1,2]. [1]VA Connecticut Healthcare system, West Haven, CT; [2]Yale University School of Medicine, New Haven, CT. (Tracking ID #1637033)

NEEDS AND OBJECTIVES: As legislative action increasingly shapes health care delivery, health policy has become a critical component of all levels of health professional training. A paucity of formal curricula, however, limits the impact of that education. What curricula do exist emphasize the acquisition of facts, rather than the complementary skills necessary to develop effective change agents. Rapid change in the US health care system demands that health professional trainees be able to apply policy concepts to improve institutions of care, whether large or small. To that end, we developed a novel curriculum, integrating core policy concepts with advocacy and leadership skills needed to effect change utilizing the following objectives: 1. Understand current, core healthcare issues and their historical underpinnings 2. Develop effective leadership and organizational skills for effective team functions 3. Practice strategies for engaging with civic organizations and media outlets

SETTING AND PARTICIPANTS: Internal medicine residents and nurse practitioner fellows (n=20) participating in the VA Connecticut Healthcare System (VACHS) Center of Excellence in Primary Care Education (COEPCE) in West Haven, Connecticut.
DESCRIPTION: Serving as a foundation for our leadership and practice objectives, the knowledge-based curriculum provides an introduction to domestic health policy, health economics, healthcare delivery systems, health law, and quality improvement. Leadership is taught through interactive workshops on organizational and team-based strategies, complemented by plenary sessions with invited speakers from state legislature, local media, and local civic leaders. We subsequently focused on key skills for advocacy—public speaking, debate strategy, and opinion-based writing—through workshops designed to apply knowledge into practice, like creating opinion-editorial (Op-Ed) and letter-to-editor (LTE) pieces for publication and hosting forums for formal engagement with local government officials.
EVALUATION: Currently, in the second year, the model has become an integral part of our curriculum within the VACHS COEPCE. Current and ongoing evaluation strategies for trainees include three domains: attitude change via Likert scales; acquired knowledge via questionnaires and performance evaluation in workshops; and skill application through tangible products generated in experiential workshops. We are encouraged by Likert scales and questionnaires that indicate improved trainee confidence in health policy knowledge and the tangible products of trainee work. To date, our trainees have published Op-Ed and LTE pieces in the Washington Post, Yale Daily News, Connecticut Post, and Academic Medicine.
DISCUSSION / REFLECTION / LESSONS LEARNED: We believe that our curriculum integrating core health policy knowledge with advocacy skills represents a novel approach to health professional education, fostering a spectrum of effective health advocates, ranging from team leaders in routine clinical settings to future change agents in the national healthcare arena. Moving forward, we aim to improve our ability to evaluate and teach skill competency, adapt the curriculum to trends in the American healthcare agenda, and modify our curriculum so that all trainees, in spite of the variety of career ambitions, feel equally empowered to apply health policy knowledge for advocacy.

FACILITATING THE DIRECT OBSERVATION OF STUDENT PERFORMANCE WITH MOBILE TECHNOLOGY Gary S. Ferenchick; David Solomon. Michigan State University, East Lansing, MI. (Tracking ID #1640265)

NEEDS AND OBJECTIVES: Direct observation of a medical trainees' performance in authentic clinical settings remains challenging. The rationale for direct observation is to ascertain and document the acquisition of the clinical skills needed to care for patients. One of the few feasible ways to efficiently distribute criterion-based assessment tools in clinical settings is with technology; including internet enabled mobile devices such as smartphones. The objectives of this study were to assess the feasibility and acceptability of a clinical assessment tool called the CEX app, and to measure its inter-rater reliability and validity.
SETTING AND PARTICIPANTS: Between July 2010 and October 2012, 367 third year medical students at Michigan State University's College of Human Medicine completed 5 to 10 formative CEXs during their internal medicine clerkship. Observers (attendings and residents) used the CEX app to guide and document their observations, record their time observing and giving feedback to the students, and their overall satisfaction. Inter-rater reliability and validity were assessed with 17 observers who viewed 6 videotaped student-patient encounters, and by measuring the correlation between student CEX scores and their scores on subsequent standardized-patient OSCE exams.
DESCRIPTION: We developed a web-based content management system which enables users with average computing skills to author customizable assessment tools for delivery to any internet enabled device. These customized tools function like "Apps", but they work on most internet enabled mobile devices. We developed, implemented and assessed a specific clinical assessment tool (i.e. the CEX app) and measured its utility in displaying problem-specific checklists corresponding to training problems created by the Clerkship Directors in Internal Medicine (CDIM), and evaluated its utility in the assessment of students in authentic clinical settings.
EVALUATION: 3567 CEXs were completed by 506 different observers (125 attendings and 381 residents). The average number of completed CEXs per student was 9.8 (±1.8), and the average number of CEXs completed per rater was 6.9 (±15.9 SD). Of the 18 CDIM training problems, students were assessed on 8 problems > 5 % of the time (abdominal pain, altered mental status, chest pain, CHF, COPD, dyspnea, diabetes and headache). Of the 3567 CEXs, 27.6 % assessed communication skills, 21.1 % history taking and 48.8 % physical exam skills. On average students performed 82.5 % of the items correctly. Faculty reported that 45.2 % of the CEXs took them <10 min, and for 69 % of the CEXs, feedback lasted <10 min. Faculty reported a high satisfaction (91.7 %) with the CEX. Inter-rater reliability was measured at 0.69 among the observers viewing the videotapes, and their ratings discriminated between competent and non-competent performances. Student CEX grades, however, did not correlate with their end of third year OSCE scores.
DISCUSSION / REFLECTION / LESSONS LEARNED: The implementation of this CEX app, which displays on most contemporary mobile devices, was found to be feasible and its use reliably captured students' clinical performance data with a high rate of user satisfaction. Our embedded checklists had adequate inter-rater reliability and concurrent validity. The grades measured on this app, however, were not predictive of subsequent student performance.
ONLINE RESOURCE URL (OPTIONAL): The CEX app can be accessed with any internet connection (including desktop computers) at: www.justintimemedicine.com/mobile; log in with the username cexapp@msu.edu and the password test

FROM DETROIT TO YOUR CITY - A PUBLIC HEALTH SOLUTION; A MEDICAL EDUCATION PILOT PROGRAM'S SUCCESS AND ITS POTENTIALLY GROUNDBREAKING NATIONAL IMPACT **COURTNEY M. MOORE, M.D. CANDIDATE 2014*; DIANE L. LEVINE, M.D.* WAYNE STATE UNIVERSITY SCHOOL OF MEDICINE*** Courtney M. Moore; Diane L. Levine. Wayne State University School of Medicine, Detroit, MI. (Tracking ID #1635001)

NEEDS AND OBJECTIVES: 60 % of Michiganders suffer increased morbidity and disability from chronic ailments including hypertension and cardiovascular disease. Escalating health care costs, mounting numbers of the uninsured, difficulty in accessing care and an insufficient supply of practitioners hinder diagnosis and treatment. As medical students in Detroit we recognized a unique opportunity to address these issues while enriching our educational experience by conducting a need-based, mobile, and cost-effective public health initiative longitudinally during our medical training. We elucidated a public health need, considered obstacles which limit healthcare access and developed an efficacious and sustainable solution while infusing our community with much needed medical trainees. This mutually advantageous arrangement enhanced our education through exposure to public healthcare program development, statistical analysis, and the publication process.
SETTING AND PARTICIPANTS: Our organization adopted a multidisciplinary approach to address the global health needs of our population through collaboration with colleagues from a variety of health fields. Access to medicine is an obstacle in Detroit therefore our organization was designed with mobility in mind. To increase accessibility we hosted our health fairs at locations which catered most conveniently to our patient population; churches, recreational areas, public transportation hubs, and street-side in high foot traffic areas.
DESCRIPTION: Cardiovascular health (the foci of our program) is a multidimensional ailment which can be improved by healthy lifestyle education, counseling and management which we delivered as an inclusive four station health fair. We conducted blood pressure screenings as an inexpensive, easily obtained objective measurement of one aspect of

cardiovascular health. Exercise, nutrition and stress management screening, education and counseling were provided through comprehension level appropriate discussion and literacy level adjusted reading materials and illustrations. Physician referrals were made to those who did not already have an existing primary care physician. Contact information for our organization and institutions which offered low-cost or free healthcare services (including radiologic, laboratory, physical therapy, prescriptions and transportation) were also provided.
EVALUATION: More than 1,500 patients attended our health events in two years. Subjective data via surveys and discussion groups and objective data including patient demographics (blood pressure readings, previous hypertension diagnosis, and time spent receiving counseling) was collected. Data analysis revealed that 70 % of our patients were amenable to the cardiovascular health counseling demonstrating that our program was efficacious and also illustrated areas which required further investigation including time spent counseling, age specific counseling techniques and follow-up methods.
DISCUSSION / REFLECTION / LESSONS LEARNED: Our innovative, pilot health initiative efficaciously addressed public health needs in Detroit. The 1,500 patients who attended our health fairs accessed health screenings, education, counseling and resources they might not have otherwise received while students garnered educational enhancements which will serve as invaluable career assets. The positive public health improvements which could result if a portion of the 19,000+ U.S. medical students, schools, and their communities replicated a similar, mutually beneficial four year academic course would be immense.

GHACS: THE GLOBAL HEALTH/CLINICAL SKILLS FACULTY DEVELOPMENT FELLOWSHIP AT MONTEFIORE Shwetha Iyer; James Grigg; Erin J. Goss; Linnea Capps; Darlene LeFrancois; Gerald Paccione. Montefiore Medical Center, Bronx, NY. (Tracking ID #1642645)

NEEDS AND OBJECTIVES: Resident interest in Global Health (GH) is at an all-time high as evidenced by increased global health curricula in resident training programs. Ethics and the ACGME require that residents abroad be supervised by U.S. board certified physicians. But finding suitable faculty is hard, financing time abroad expensive, and stable funding is scarce. To address these challenges, Montefiore established in July 2012, a unique faculty development fellowship in Global Health and Clinical Skills (GHACS) for Internists and evaluation of its impact is currently underway.
SETTING AND PARTICIPANTS: Montefiore is the main teaching hospital of the Albert Einstein College of Medicine in NY. Its principle GH site is in Kisoro, Uganda, where for 8 years we've collaborated with Kisoro District Hospital (KDH) and the NGO, Doctors for Global Health in supporting hospital services, community projects, and education for staff and Village Health Workers. Kisoro is a farming district in SW Uganda whose population makes <$2/day. KDH has 150-beds staffed by only 1–3 Ugandan doctors. Montefiore helps staff the IM wards: 18 Montefiore PGY IIIs and 12–16 Einstein students work in the hospital and surrounding community over the year. GHACS faculty-fellows supervise the wards and co-lead community projects. GHACS fellows are junior faculty internists with prior experience in the developing world, commitment to social justice through health, and interest in careers as clinician-educators.
DESCRIPTION: GHACS is a 2-year faculty-fellowship with 4 fellows, 2 per year, who divide their time between New York 8 months/year, and Kisoro 3 months/year in two six-week blocks. In both locations, fellows engage in patient care, teaching, and research in 2 arenas: health services delivery through community projects in Kisoro, and clinical education. In NY, GHACS spans 12 sessions/week (5 clinical/precepting; 7 teaching/research). The increased number of sessions in NY support >90 % of the clinical income, making the fellowship sustainable at a salary between fellow and attending, while allowing for time abroad. Partners share a panel of patients and cross-cover residents who are in Uganda. In Kisoro, fellows hold daily attending rounds with residents, consult on difficult cases with Ugandan faculty, and work on community projects. Fellows are mentored by senior clinicians in NY and Uganda to develop clinical skills, curricula in clinical reasoning, and small-group exercises. Novel activities sponsored in the residency program include weekly Kisoro cases; journal clubs in Clinical Skills, Medical Education and Global Health; Physical Diagnosis Rounds; Clinical Reasoning Seminars, and a 1 month GH Course (earning NYS Certification).
EVALUATION: GHACS activities have received excellent evaluations by residents and GHACS fellows feel positively about their experience thus far. Written evaluations are underway and include feedback on resident and fellow journal clubs and formal teaching seminars.
DISCUSSION / REFLECTION / LESSONS LEARNED: GHACS is a novel program in generalist education that grows from the synergy of two experiences in clinical mentoring: supervising residents and students in a resource-poor setting in Africa where clinical skills are essential; and using those skills to strengthen bedside acumen in housestaff at home. It allows globally-minded primary care clinician-educators to practice both internationally and in the US, while developing and teaching low-tech clinical skills valuable everywhere.

GOTMEDS? DESIGNING AND PILOTING AN INTERACTIVE MODULE FOR TRAINEES ON REDUCING DRUG COSTS Vineet Arora[1]; Rupali Kumar[1]; Jeanne M. Farnan[1]; Andrew Levy[1]; Neel Shah[2]. [1]University of Chicago Medical Center, Chicago, IL; [2]Massachusetts General Hospital, Boston, MA. (Tracking ID #1641454)

NEEDS AND OBJECTIVES: Patients are facing a rise in the out-of-pocket cost of drugs. Multiple studies show physicians are unaware of how much prescription drugs cost to patients. Patients and physicians agree that more discussion of patients' out-of-pocket drug costs is necessary. While patients have expressed a desire to have their physicians educate them on the cost and quality of their treatment options, physicians are unlikely to do so. One reason is because of the lack of standard education on drug cost reduction strategies exists in medical training. Our aim was to create an interactive educational module that makes strategies and resources for lowering patients' prescription drug costs readily accessible and easily applicable for medical trainees.
SETTING AND PARTICIPANTS: The module was piloted with the Pritzker School of Medicine Quality and Safety Track (QST), consisting of four medical students and two attendings. Feedback on potential improvements to the module was elicited from the stakeholders and pilot participants and was subsequently incorporated into the module.
DESCRIPTION: Based on expert opinion from a pharmacoepidemiologist and pharmacist, literature review, and input from trainees, an educational module was designed, comprised of a PowerPoint presentation, Pocket Reference Cards, and a Video Vignette. The participants completed pre- and post-tests to evaluate their preparedness and confidence regarding drug cost reduction strategies and counseling. Participants ranked each item 1–5 (Strongly Disagree-Strongly Agree). Paired t-tests comparing mean response on Pre- and Post-Test were performed for each item, as well as Wilcoxon signed-rank tests.
EVALUATION: The resulting curriculum used the mnemonic "GOTMeDS?" which encompassed the strategies trainees should use to reduce patient out of pocket costs: (G) Generics; (O) Ordering in bulk; (T) Therapeutic alternatives; (Me) Medication review; (D) iscount programs; (S) Splitting pills. The interactive module includes a case that highlights the costs for a patient on multiple medications (ASA, statin, beta blocker, ARB, Plavix, and non-generic antidepressant) and asks trainees to use the GOTMeDS strategy along with online resources (LowestMed App & Consumer Reports Best Buy Drugs) to potentially save the patient over 50 % of the cost. Paired t-tests revealed a significant increase in mean score for the following three Pre-/Post-test items: (1) "I know where to look to find the most cost-effective drugs in a particular drug class," (2.00 vs. 3.50, $p<0.01$) (2) "I know where to look online for medication cost-saving resources," (2.33 vs. 3.83, $p<0.01$) and (3) "I know which mobile applications are useful for medication cost-saving resources" (2.17 vs. 3.83, $p<0.05$). The module was piloted with all 88 first year medical students. 100 % reported confidence in screening patients for difficulty to pay for medications after the session. 100 % found it useful & 98 % helpful

for free clinics they work in. Comments were very positive: "These [are] skills easily implemented to make a very significant impact. A.k.a. SUPER high yield!"
DISCUSSION / REFLECTION / LESSONS LEARNED: An interactive educational module may improve medical trainee knowledge and confidence regarding ability to communicate with about drug costs. Future work will test the module on a larger scale and assess changes in practice using a standardized patient exercise to evaluate trainees behaviors in practice.
ONLINE RESOURCE URL (OPTIONAL): http://www.costsofcare.org/education/teaching-value-project

GLOBAL HEALTH AT HOME: DEVELOPMENT OF THE VULNERABLE AND IMMIGRANT POPULATIONS (VIP) PROGRAM FOR MEDICAL RESIDENTS Nicole Sirotin[1]; Anthony Pho[1]; Carla Boutin-Foster[1,2]. [1]Weill Cornell Medical College, New York, NY; [2]Weill Cornell Medical College, New York, NY. (Tracking ID #1642122)

NEEDS AND OBJECTIVES: The ACGME recommends that residency programs provide residents with core knowledge and skills that will enable them to respond with sensitivity when interacting with patients. Traditionally, these curricula focus on the vulnerability and health disparities of racial and ethnic minorities, a valid but incomplete view of vulnerable groups. The urban and rural poor, newly insured and uninsured, multiethnic, lesbian, gay, bisexual and transgender (LGBT) populations, and people with disabilities, many of whom are foreign born, represent emerging groups that may not be addressed in traditional resident curricula. The benefits of creative and competency based curricula are well established. First, training focused on health disparities and cultural competency improves both doctor and patient satisfaction. Secondly, medical trainees increasingly desire global health education, although most physicians trained in the United States will practice here. Health equity themes that are traditionally taught in global health curricula utilize teaching frameworks that can be applied to emerging local populations. Thirdly, trainees who have received advanced training in health disparities are more likely to practice in underserved areas.
SETTING AND PARTICIPANTS: We present the Vulnerable and Immigrant Populations (VIP) program at the Weill Cornell Medical College/New York Presbyterian Internal Medicine Residency Program as an illustrative case that creatively incorporates themes of global and local health disparities.
DESCRIPTION: The components of VIP were developed based on a thorough review of the literature and consultation with domain experts. The final curriculum consists of a six-part series focusing on 1) Health Disparities, 2) Food Insecurity, 3) Immigrant Health, 4) LGBT health, 5) People with Disabilities and 6) Mistrust/Bias. This PGY-2 curriculum is taught using small group discussions, case presentations, critical review of the literature and role-play. The series starts by introducing a conceptual framework for how disparities affect the health of individuals and concludes with a reflective look at the impact of unconscious bias on the provider patient relationship. Unique aspects of the VIP program include discussing the role of hospitals in deportations, the health effects of asylum seekers and the care of US and foreign born transgendered people.
EVALUATION: To date 17 residents completed VIP, representing half of the PGY-2 class. Of the surveys completed, 86 % rated the sessions as good or excellent and 76 % agreed these sessions would change their clinical practice. Qualitative feedback included, "very relevant to public health service but something we hear very little about," "very valuable to discuss multifactorial impact on health."
DISCUSSION / REFLECTION / LESSONS LEARNED: The Vulnerable and Immigrant Populations (VIP) curriculum trains culturally competent physicians who recognize global health themes in vulnerable populations at home. VIP focuses on population health through three ACGME core competencies: patent care, interpersonal and communication skills and professionalism. The goal of VIP is to enhance interest, knowledge and skills in caring for vulnerable populations, build understanding in common themes of global and local population health and inspire long-term involvement in the care of vulnerable populations. Future directions include formal evaluation of the effectiveness of the VIP curriculum on improving knowledge and attitudes and expansion into more clinical experiences with vulnerable populations.

HEALTH POLICY AND ADVOCACY FOR THE BUSY CLINICIAN 101: CAN WE MAKE AN IMPACT? Maggie K. Benson; Vikram Krishnasamy; Peggy Hasley. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1628426)

NEEDS AND OBJECTIVES: Physicians work in a complex health system where providing care for patients requires understanding of pathophysiology and therapeutics, as well as knowledge of the health care system and skills for implementing change. We designed a two-week elective for internal medicine residents to address the following goals: 1. To understand the basic structure and function of and influences on the American healthcare system. 2. To practice techniques for advocacy that can be used by clinicians in promoting the health of their patients.
SETTING AND PARTICIPANTS: We enrolled seven second and third year residents, including 2 men and 5 women. Participants had a variety of career aspirations, including general and subspecialty medicine. The elective took place at an academic medical center and in offices of state legislators in Harrisburg, Pennsylvania.
DESCRIPTION: Participants completed selected readings and participated in interactive discussion sessions organized around subtopics in health policy during week one. Learners were also asked to match the current state legislative agenda with a preventable adverse outcome experienced by one of their patients. They researched and presented their topics to each other, and prepared a one-page "Leave Behind," summarizing the main advocacy points. The topics selected by residents included Medicaid expansion, controlled substance monitoring, and reproductive rights. In the second week, participants traveled to the state capitol to meet with health care advocacy groups, legislators and policymakers. Participants presented the "Leave Behind" on their chosen topic and discussed their patients' stories to advocate for change. The final day of the elective included a reflective wrap up session.
EVALUATION: In quantitative evaluation, we evaluated the knowledge of the participants before and after the elective, and compared their knowledge to a group of PGY and gender matched control residents. The mean number of questions answered correctly was 4.6/7 in the control group and 4.8/7 in the participant group before the elective. After the elective, the participants scored 5.7/7. We did not perform statistical analysis secondary to the small sample size. We asked participants to compare their attitudes pre and post course. Questions were asked on a 5 point scale with 1 being "not likely at all" and 5 being "very likely." For example, participants were asked their likelihood of "teaching about topics of health policy and advocacy with learners on your medicine team." For this question, scores increased from 2.4/5 to 4.6/5. Similar changes were seen in other attitude and behavior questions.
DISCUSSION / REFLECTION / LESSONS LEARNED: A few central themes emerged during qualitative analysis. Participants realized that health policy has a tremendous impact on how practitioners care for patients and underestimated the impact their patients' stories would have on policymakers. Participants expressed disbelief at the lack of physician involvement in the health policymaking, and pledged to be more involved in the future. At the end of the elective, participants stated they will "become a more outspoken advocate for my patients," "vote for people who stand for what I now know," and "be aware of both national and domestic politics." It is our impression that our elective had a lasting impact on the residents who participated, both in their knowledge of health systems and policy, and in their skills, attitudes and behaviors in becoming advocates for change in the health care system.

IF YOU BUILD IT…REDESIGNING PRIMARY CARE TRAINING AROUND ACTIVELY TRANSFORMING CONTINUITY CLINICS Richard Pels[1,2]; Rachel Stark[1,2]; Priyank Jain[1,2]; Barbara Ogur[1,2]; David Bor[1,2]. [1]Cambridge Health Alliance, Cambridge, MA; [2]Harvard Medical School, Boston, MA. (Tracking ID #1640361)

NEEDS AND OBJECTIVES: Diagnosis and therapy in internal medicine have shifted profoundly to the ambulatory setting. But the lack of satisfying primary care continuity experiences, the need to prioritize acute inpatient responsibilities, the minimal engagement in practice management and the dearth of positive role models discourage trainees from pursing careers in primary care. We seek to transform resident professional development through the redesign of medicine residency training at our institution. We seek to do this concurrent with enhancing systems performance via patient-centered practice transformation at resident continuity clinic practice sites.
SETTING AND PARTICIPANTS: The Cambridge Health Alliance Internal Medicine Residency Program is a university-affiliated, community hospital primary program in an urban, highly diverse and largely underserved setting. All three continuity clinic sites and all twenty-four residents are participating in the innovation.
DESCRIPTION: In July 2012, the residency implemented a "2+4" immersion schedule. Residents spend 2 weeks in ambulatory training alternating with 4 weeks of other experiences, throughout the 3 years of residency, resulting in 25 % greater time on ambulatory rotations and 30 % more clinic sessions. Resident continuity clinics are transforming into Patient-Centered Medical Homes. Residents are assigned to care teams with two other residents, a preceptor, nurse, and medical assistant, and work with this team throughout residency. During ambulatory rotations, residents have four clinic sessions and one administrative session each week. They participate in population and complex case management, and systems improvement.
EVALUATION: Early feedback from residents and preceptors has been very positive. Residents report they are better able to focus on their clinic patients and to provide meaningful longitudinal care. Residents meet regularly with their care teams and review panel quality metrics and complex cases. Two of the three resident clinic sites are co-locating providers (including residents) alongside nurses and medical assistants. And residents are engaged in site-based practice improvement teams. Year-long experiential curriculums in community health and health advocacy, and longitudinal experiences for first-year residents with specialists in mental health, addictions, and geriatrics have been successfully launched. A robust plan for quantitative and qualitative program evaluation is underway. Data from the first 6 months will be available for reporting at the time of the SGIM meeting.
DISCUSSION / REFLECTION / LESSONS LEARNED: Residency redesign with concurrent practice transformation provides a facilitating framework for innovative, longitudinal care experiences with patients, and for educational immersion in outpatient medicine. When residents are fully integrated with care teams and have predictable clinic schedules, without the distraction of concurrent acute care responsibilities, they can develop meaningful relationships as members of care teams and practice improvement teams, and participate in practice transformation. We believe the emphasis on continuous relationships with patients, staff and clinic sites will enhance residents' humanistic professional identity. Outcomes may help to inform similar efforts in other residency programs.
ONLINE RESOURCE URL (OPTIONAL): http://www.challiance.org/Academics/Ambulatoryblockrotations.aspx

IMPLEMENTATION OF HOSPITAL BASED CLINICAL PERFORMANCE METRICS TEACHING SESSIONS FOR MEDICINE RESIDENTS ON DUKE GENERAL MEDICINE David Gallagher; Noppon P. Setji; Jonathan Bae. Duke University, Durham, NC. (Tracking ID #1637066)

NEEDS AND OBJECTIVES: Medicine residents have limited exposure to some of the common topics in quality improvement and clinical performance. One identified need in medicine resident education was promoting knowledge of how inpatient clinical performance is measured. We designed teaching sessions for medicine residents to improve understanding of how clinical performance is measured and acted upon in hospitals and health systems and specifically at Duke. The goals for these presentations were: a. To define for residents common clinical performance measurements and review quality improvement strategies that could impact the measurement b. To align the presentations with Duke University Health System clinical care priorities c. To present the information in a small amount of time and an efficient manner so as not to interfere with resident report or clinical work
SETTING AND PARTICIPANTS: Third year (Senior) medicine residents on Duke University Hospital inpatient general medicine rotations.
DESCRIPTION: Duke hospital medicine partnered with the Duke internal medicine residency program to design a series of weekly short educational sessions focused on clinical performance metrics. A fixed group of hospital medicine faculty developed the curricula and educational materials to present to the residents and engage them in discussion. These topics included: work culture, hospital throughput and discharge efficiencies, patient satisfaction, readmissions, and infection control. These educational sessions were integrated into existing resident case conferences on a rotating basis. The performance metric data was shown via powerpoint presentation and followed by a hospitalist-led discussion. The effectiveness of the teaching sessions was evaluated with an anonymous cross-sectional survey of the Duke third year senior residents who had participated in the weekly educational sessions from July 2011–June 2012. This included evaluations of how the learner's knowledge increased because of the presented material (Likert Scale of 1–5) as well their satisfaction with the educational value of the material itself. The survey was reviewed by Duke IRB and declared exempt.
EVALUATION: From July 2011–June 2012, 51 residents participated in the clinical performance review sessions. Surveys were sent to all learners of which 28 (55 %) responded. Overall the residents rated the presentations as highly influential on increasing their knowledge of the topics. The highest scored presentation was on work culture (Likert score 4.15/5) and the lowest scoring presentation was hospital throughput and discharge efficiencies (Likert scale 3.73/5). Residents indicated that we met our 3 educational goals (89–96 % answering "yes"). Ninety percent of residents indicated these sessions were of educational value to them. Many residents commented on the positive learning experience; "Interesting, valuable, and time efficient. I enjoyed exposure to systems based issues that are not frequently addressed at other parts of the curriculum. Presenters were enthusiastic and interested in teaching".
DISCUSSION / REFLECTION / LESSONS LEARNED: Because of the high level of satisfaction with these educational sessions we have expanded the course in scope and topics. Residents gave very useful specific feedback for future topics included glycemic control, coding and billing, and unintended consequences of performance metrics. These sessions have served as a tool to educate residents in quality improvement and as a valuable means to engage residents in local performance improvement efforts.

IMPLEMENTATION OF A NOVEL CURRICULUM IN SOCIAL MEDICINE AND HEALTH ADVOCACY IN INTERNAL MEDICINE RESIDENCY TRAINING Danny McCormick[1,2]; Rachel Stark[1,2]; Priyank Jain[1,2]; David Bor[1,2]; Richard Pels[1,2]. [1]Cambridge Health Alliance, Cambridge, MA; [2]Harvard Medical School, Boston, MA. (Tracking ID #1641708)

NEEDS AND OBJECTIVES: Physicians often identify social, political and health care system level forces that produce inequalities in access to and quality of care for socially disadvantaged patients; they can be highly effective advocates in shaping health policy, health care delivery and the health of the public. Yet most physicians are inadequately trained to take advantage of their unique position to engage in advocacy to improve health care systems. To address this training gap, we created an experiential required curriculum in social medicine and health advocacy for primary care residents.
SETTING AND PARTICIPANTS: Each year, one third of the intern, second and third year resident groups (n=8) in the internal medicine residency training program participate together in a year-long didactic and project-based curriculum at the Cambridge Health Alliance, a public integrated health care system in Cambridge, Massachusetts.
DESCRIPTION: Participation in the social medicine and health advocacy curriculum is now a program requirement, modeled after a highly successful

one-month elective offered for the past decade. It is delivered in 27 half day group sessions over the course of a year; twenty different faculty members participate. The sessions are equally divided between didactic and project-based learning. Didactic sessions are conducted as interactive lectures and workshops. They cover topics such as health policy and financing, social determinants of health, health challenges of specific vulnerable populations (such as the poor, uninsured, immigrants, homeless persons, racial and ethnic minorities, prisoners and people in resource-poor settings globally), theoretical foundations of physician advocacy and principals of organizing for social change. Two groups of four residents participate in a project-based learning experience in which they identify a clinical or health care system barrier to equitable health/medical care, conduct a literature review on these barriers, formulate a solution to the problem identified and conduct an advocacy campaign to realize the proposed solution. Projects selected by the 2012–2013 cohort focus on access to outpatient suboxone treatment for opiate addiction and on residency training in the use of suboxone nationally.

EVALUATION: We measure the educational impact of the year-long curriculum, with a 15-item survey designed to assess changes in residents' self-reported knowledge and skills on aspects of social medicine and research-based advocacy. We also assess changes in the likelihood of residents' intention to incorporate advocacy in to their medical careers. The survey is administered prior to and following completion of the curriculum and mean changes in ratings for each item will be calculated.

DISCUSSION / REFLECTION / LESSONS LEARNED: Increasingly, society recognizes physicians' professional duty to advocate on behalf of patients, communities and the broader society. The American Medical Association (AMA) has stated that physicians must "advocate for the social, economic, educational, and political changes that ameliorate suffering and contribute to human well-being". Working collaboratively with, and in large part motivated by the expressed educational needs of residents in our program, we designed and implemented this novel curriculum. Preliminary data suggest residents' feel that the course helps then reconnect with the idealism that drew them to careers in medicine and value this.

IMPLEMENTING A LEADERSHIP AND HEALTH SYSTEMS INNOVATION ELECTIVE FOR FIRST AND SECOND YEAR MEDICAL STUDENTS Janine Knudsen[1]; Barsam Kasravi[3]; Bradley Turner[3]; Molly Coye[2]. [1]Harvard Medical School, Boston, MA; [2]UCLA Health System, Los Angeles, CA; [3]UCLA David Geffen School of Medicine, Los Angeles, CA. (Tracking ID #1642901)

NEEDS AND OBJECTIVES: Today's health care environment is changing dramatically and there is a growing need for physician leaders with skills, insight, and vision to help develop more effective, efficient health care systems. However, most medical schools lack a clear leadership pipeline or curriculum that prepares their graduates for these new opportunities. Additionally, few medical school curricula provide students with first-hand exposure to health system operations and innovations occurring within their local institutions. The elective "Leadership in Health Systems Innovation" is a new course at the UCLA David Geffen School of Medicine that aims to address this education gap through interactive sessions and conversations with health care leaders. The course is focused on three main areas: 1. Introduction to major challenges and innovations in the US health care system 2. Development of leadership and operational skills 3. Facilitation of student involvement in innovative local health care projects

SETTING AND PARTICIPANTS: 17 first and second year medical students at the UCLA David Geffen School of Medicine participated in a seven-week long elective course involving weekly 2-hour sessions. Each session was divided into a 1 h discussion with a guest speaker and a 1 h activity to build leadership skills or health system knowledge.

DESCRIPTION: Through its interactive weekly sessions, the elective introduces medical students to key leaders and projects within UCLA and the Los Angeles area and engages students in leadership and health system skill-building activities. An emphasis is placed on self-reflection and identification of leadership styles and attributes. Sessions are supplemented with readings on health policy, business strategy, quality improvement, and leadership. Course speakers to date have included the CEO and COO of the UCLA Health System, the Director of the Los Angeles County Department of Health Services, and UCLA's Chief Quality Officer for the Departments of Medicine and Neurosurgery. Speakers are asked to describe their work, reflect on their leadership path and attributes, and comment on major changes occurring within their institution. Discussions are then directed by the student audience. Skill-building sessions include health policy lectures and debates, personality assessments, introductions to quality improvement tools, and reflections on the speakers. A final assignment encourages students to identify and develop a relationship with a mentor and create long-term goals for personal development throughout medical school.

EVALUATION: Medical students are assessed based on their final assignment submission. The course will be evaluated by surveying students to assess satisfaction with the course, development of a leadership and/or health system skillset, and suggestions for course improvements.

DISCUSSION / REFLECTION / LESSONS LEARNED: The "Leadership in Health Systems Innovation" elective was successfully implemented in Fall 2012 and will continue in Spring 2013. The course succeeded in creating a growing community of medical students interested in health systems, exposing them to key health system leadership, and laying the groundwork for leadership skill development. The diverse interest of student participants, including policy, research, and business topics, were identified at the start of the course and used to guide course content. This built-in flexibility to address student interests ensured that speakers, activities, and readings were engaging and supported professional growth during and after the course.

IMPROVING RESIDENT COUNSELING COMPETENCE: A 5A'S SKILLS-BASED OBESITY CURRICULUM Shwetha Iyer[1]; Hillary Kunins[2,1]; Angela Jeffers[1]; Melanie Jay[3]; Sheira Schlair[1]. [1]Montefiore Medical Center, Bronx, NY; [2]Department of Health, New York, NY; [3]NYU School of Medicine, New York, NY. (Tracking ID #1643058)

NEEDS AND OBJECTIVES: Obesity is a significant problem that primary care physicians should be equipped to address. The 5A's counseling framework has been shown to be effective at addressing obesity in primary care. We therefore adapted and conducted a pilot evaluation of a previously developed 5A's obesity counseling curriculum that was novel in its approach to integrating motivational interviewing into the 5A's framework. We evaluated change in residents' self-assessed 5A's obesity counseling.

SETTING AND PARTICIPANTS: Our target audience was 28 interns and residents in the Primary Care/Social Internal Medicine Residency Program at Montefiore Medical Center (Bronx, New York).

DESCRIPTION: Residents were trained in the 5A's to: Assess obesity risk, Advise a weight-control program, Agree on mutual goals, Assist in establishing appropriate intervention, and Arrange for follow-up. The curriculum was delivered 4 times over a 6-month period to residents during ambulatory medicine blocks. The 3-hour curriculum included a 2-hour interactive session on the epidemiology of obesity, 5A's obesity counseling framework and practical tools. It was novel in highlighting motivational interviewing microskills practice in teaching how to "Agree" and "Assist" in obesity management, an area seldom emphasized in residency behavioral medicine training.

EVALUATION: One week prior to curriculum participation, residents (n= 28) completed a previously validated survey with 16 items (4-point Likert scale with 1=not able to perform to 4=able to perform well) measuring self-assessed 5A's obesity counseling competence. A post-intervention survey was conducted 2 months later. The 16 items on the survey were grouped into the five 5A's domains. Likert scores were dichotomized to 1= not able to perform and 2=able to perform and analyses compared mean scores of questions in each domain before and after curriculum participation using the Wilcoxin signed-ranks test. Twenty residents reported their counseling competence in: 1) Assessing (i.e. identifying co-morbidities, stage of change, obtaining a diet history and BMI, psychosocial screening); 2) Advising (i.e. discussing the effect of obesity on present and future health, discussing treatment options); 3) Agreeing on common goals; 4) Assisting (i.e. providing brief counseling interventions and using motiva-

tional interviewing to change behavior); 5) Arranging further help (i.e. recognizing and referring patients with eating disorders, making referrals). After the curriculum, there was a significant increase in mean scores in ability to Assess (pre test mean=1.55, post test mean=1.83; z=.001), Advise (pre test mean=1.38, post test mean=1.85; z=.001) and Agree (pre test mean=1.44, post test mean=1.73; z=0.010). There were no significant differences in the Assist (pre test mean=1.58, post test mean=1.77; z=0.083) and Arrange (pre test mean=1.35, post test mean=1.52; z=0.213).
DISCUSSION / REFLECTION / LESSONS LEARNED: We implemented a novel curriculum for residents to master 5A's obesity counseling strategies, which incorporated obesity counseling skills practice specifically in motivational interviewing. Analyses showed improvement in the domains of Assessing, Advising and Agreeing with the patient. Further evaluation with additional learners and direct observation of counseling skills is needed to fully elucidate the impact of the curriculum in promoting effective use of the 5A's for obesity counseling.

IMPROVING RESIDENT DOCUMENTATION, CODING AND BILLING WITH A PRACTICAL TUTORIAL Moyna H. Ng. Lenox Hill Hospital, New York, NY. (Tracking ID #1624275)

NEEDS AND OBJECTIVES: While Internal Medicine residents undergo rigorous clinical training, they rarely participate in any structured learning in inpatient medical coding, billing and adequate supporting documentation. There is cursory exposure in the ambulatory care setting. Residents perceive medical billing and coding as extremely complex. Since these skills are essential once they become practicing physicians, an innovative tutorial was developed and incorporated into the Medical Consultation rotation targeted at the PGY-3 trainees.
SETTING AND PARTICIPANTS: During a 2 week rotation on Medical Consultation, a PGY-3 resident works with an academic hospitalist and they are charged with coding and billing each inpatient encounter on mock billing cards.
DESCRIPTION: The tutorial is divided into four phases. Phase One - the resident codes and bills each patient visit without any aide. Phase Two - the resident is given a reading packet consisting of two articles on coding and billing, a hospitalist progress note template, a hospital pocket pamphlet on coding and billing and a one page reference guide published by CMS. Phase Three -the resident meets with the academic hospitalist to review each mock billing card and the corresponding documentation for appropriate coding and level of service billing. Phase Four - a billing report card is generated at the end of the rotation.
EVALUATION: A pre- and post-rotation survey based on a Likert scale assessing the resident's knowledge, confidence and ability to teach documentation, coding and billing is given at the beginning and end of the rotation, respectively. At the end of the rotation, billing report cards are generated that show the percentage of levels of service billed for initial encounters (99221–99223) and subsequent visits (99231–99233); percentage of underbilling and overbilling and appropriately coded notes.
DISCUSSION / REFLECTION / LESSONS LEARNED: Results to date reveal a statistically significant trend towards improvement in knowledge, confidence and ability to teach the fundamentals of medical coding and billing with proper documentation. Residents are highly satisfied with this short and effective tutorial. It is noted that residents became more cognizant of the need for supportive documentation. Review of their consultations and subsequent progress notes revealed more attention to detail and improved documentation. Residents have commented that this tutorial also helped to sharpen their critical thinking skills as they documented their thought process. This tutorial also incorporates the Systems Based Practice competency to teach residents to work effectively in various health care delivery settings.

INCREASING RESIDENT EDUCATION AND CONFIDENCE IN PRESSURE ULCER STAGING Keri Holmes-Maybank; Patty J. Iverson; Justin Marsden; Jingwen Zhang; Patrick D. Mauldin; William P. Moran. Medical University of South Carolina, Charleston, SC. (Tracking ID #1642097)

NEEDS AND OBJECTIVES: Pressure ulcers have a major impact on patients including decreased quality of life, decreased functionality, increased infection, and increased pain. 10–18 % of acute care patients have pressure ulcers either at presentation or develop pressure ulcers over the course of hospitalization. An 80 % increase in pressure ulcer-related hospitalizations was seen from 1993 to 2006 nationally. Pressure ulcer-related hospitalizations result in an approximately 8 day increase in average length of stay (LOS 13–14 days). As a result in the increase of pressure ulcers, both state and federal agencies may penalize hospitals for pressure ulcers which occur during hospitalization, but not those present on admission. With the serious healthcare and financial implications, it is imperative for residents to identify and stage pressure ulcers.
SETTING AND PARTICIPANTS: We performed a three month focused effort on pressure ulcer education for 99 internal medicine residents years 1–3. The emphasis was on residents working in the inpatient setting.
DESCRIPTION: A multi-strategy approach of a one hour lecture and one-on-one academic detailing session about pressure ulcer staging based on the National Pressure Ulcer Advisory Panel criteria was performed. Educational posters were placed in resident work areas and laminated cards with staging information were given to the residents after detailing. Seventeen residents were at the lecture and ninety-three were detailed. Eighty-eight residents took a pre-test and ninety-three residents took a post-test via survey monkey to assess their confidence with staging and staging knowledge. The pre- and post-tests had identical questions. One question assessed self-efficacy of resident staging using a five point Likert scale (range 1=not confident to 5=very confident). Three additional questions included photos and descriptions of a deep tissue injury, stage II pressure ulcer, and an unstageable pressure ulcer for the residents to assess.
EVALUATION: The pre and post-test results of 85 residents were matched and compared. The resident comfort level was assessed via Wilcoxon signed rank test with a significant increase in confidence after education (pre-test 6(1), 24(2), 38(3), 13(4), 4(5), post-test 1(1), 8(2), 25(3), 41(4), 10(5), $P<0.0001$). A significant improvement in knowledge of deep tissue injury (DTI) and unstageable pressure ulcers was revealed via McNemar's test (DTI pre-test 25, post-test 55; unstageable pre-test 40, post-test 66, $P<0.0001$). A non-significant improvement was seen in the question regarding identifying a stage II pressure ulcer (pre-test 48, post-test 55, $P=0.3105$).
DISCUSSION / REFLECTION / LESSONS LEARNED: Our multi-strategy approach to pressure ulcer education by a 1 hour lecture and one-on-one detailing led to a significant increase in resident knowledge and confidence of pressure ulcer staging.

INTEGRATING A CURRICULUM ON COST-CONSCIOUS CARE INTO UNDERGRADUATE MEDICAL EDUCATION Kimberly M. Tartaglia; Nicholas Kman; Holly Cronau; Cynthia Ledford. Wexner Medical Center at the Ohio State University, Columbus, OH. (Tracking ID #1640836)

NEEDS AND OBJECTIVES: Although physicians direct as much as 87 % of all health care spending, studies demonstrate that physicians have poor knowledge regarding the costs of medical care. According to the 2011 Association of American Medical Colleges (AAMC) Graduate Questionnaire, 64 % of medical students nationally felt they received inadequate instruction on health economics.
SETTING AND PARTICIPANTS: Medical students enrolled in their clinical clerkships participated in a cost-conscious care curriculum integrated across clerkships.
DESCRIPTION: The purpose of our project was to develop an interdisciplinary curriculum that provides medical students foundational knowledge in health economics and cost-effectiveness principles. Learning opportunities have been integrated into the inpatient internal medicine, family medicine, emergency medicine, and subinternship experiences. For the inpatient internal medicine clerkship, students complete a brief e-learning module that outlines the principles of cost-effectiveness and provides guidance on how these principles can be applied in the inpatient setting. Students then complete a reflective exercise describing a scenario in which a patient experienced lack of

attention to cost-conscious care, and students are asked to identify solutions and barriers to reducing inefficiencies. During the subinternship experience, students participate in an interactive case-conference that blends clinical reasoning with principles of cost-conscious care. The case uses real hospital charges to highlight how inefficiencies, lack of communication, and wasteful care can impact cost. Additional topics provided in other clerkships include healthcare financing, the impact of the patient-centered medical home on cost, and the impact of the uninsured population on the cost of healthcare.
EVALUATION: Thematic analysis on the reflective exercise during the inpatient internal medicine clerkship is underway. Student perceptions of the interactive case conference were assessed using a five question survey. To date, 51 students (96 %) completed the survey. The results showed 100 % of students who completed the survey felt the material was presented at an appropriate level. All students felt that the case conference was an effective way to teach about the financial cost of diagnostic testing. Eighty-eight percent felt the case-conference would change their future practice patterns. Comments were universally very positive.
DISCUSSION / REFLECTION / LESSONS LEARNED: Our initial survey results confirm that students value discussions on cost-conscious care as applied to patients. Our next steps are to develop a knowledge application tool that can be used to evaluate students and assess the curriculum as a whole. Additionally, the American College of Physicians (ACP) in collaboration with the Alliance for Academic Internal Medicine (AAIM) created a High-Value Cost Conscious Care Curriculum that provides medical schools and residency programs excellent foundational content for teaching this necessary curricular addition.

INTENSIVE MENTAL HEALTH TRAINING FOR MEDICAL RESIDENTS Robert C. Smith. Michigan State University, East Lansing, MI. (Tracking ID #1624581)

NEEDS AND OBJECTIVES: Two-thirds of all mental health patients are under the sole care of untrained primary care physicians. Even larger numbers of less severely distressed patients routinely have their psychosocial and emotional needs overlooked, and patients with organic diseases like diabetes do worse in the presence of unchecked mental illness. To generate discussion and to inform our work, we present an intensive mental health curriculum for medical residents that we are developing under a 5-year HRSA grant. We have demonstrated positive patient outcomes in RCTs for the models being taught. Our overarching objective: graduating residents will be as skilled with mental and psychosocial problems as they are with medical problems.
SETTING AND PARTICIPANTS: The curriculum is integrated with the standard medical residency curriculum for 39 residents who care for a socioeconomically diverse patient population. They are taught primarily by 17 GIM faculty in a university-based program's medical clinic and its affiliated underserved clinic and community hospital.
DESCRIPTION: Curriculum Objectives. Following training, residents will demonstrate mastery of: 1) an evidence-based patient-centered interviewing model; 2) advanced patient-centered interactions, such as efficiency and working with special populations; 3) an evidence-based model of shared decision-making; 4) an evidence-based mental health treatment model for the management of common primary care mental health conditions like depression, medically unexplained symptoms, drug/alcohol misuse/abuse, non-adherence, stress, working with families, practical psychopharmacology, community resources, and referral to mental health professionals; 5) personal awareness; 6) working in a multi-disciplinary team to improve patient safety. Procedure. We use 100 h a year of mostly experiential training to teach the objectives. In PGY-1, objectives 1–3 above are the focus, occurring in lectures throughout the year as well as a concentrated, full-time one-month rotation. In PGY-2/3, objectives 4–6 are the focus, training for diagnosis and management of mental health problems in the same out- and in-patient settings where residents' other training occurs. Primary care faculty trained to the fellowship level train the residents with back-up from mental health professionals.
EVALUATION: Using a quasi-experimental design that compares trained residents to untrained controls in a similar residency in Grand Rapids, MI, we will evaluate learning by residents at the start of PGY-1 and the end of PGY-3 in these ways: a) blinded ratings of digitally recorded simulated patient interviews to assess patient-centered interviewing, shared-decision making, and mental health care, b) knowledge of the objectives; and c) attitudes of self-efficacy for the objectives. We also will conduct extensive formative evaluation.
DISCUSSION / REFLECTION / LESSONS LEARNED: We present this curriculum to initiate discussion of how to better prepare our graduates, especially when there are not sufficient numbers of mental health professionals to play more than a consultative role. We are not proposing to turn physicians into psychiatrists but to train them to handle most high prevalence psychosocial and mental health problems, training them also in referral to mental health professionals for more severe problems. Ample evidence indicates that patients would prefer seeing primary care doctors for their mental health and other psychosocial problems.

INTERPROFESSIONAL PANEL MANAGEMENT: TEACHING RESIDENTS DATA-DRIVEN LONGITUDINAL AND CONTINUOUS CARE Catherine P. Kaminetzky[1,2]; Jacqueline R. Keedy[2,1]; Ginger A. Evans[1,2]; Anne P. Poppe[3,1]; Joyce E. Wipf[1,2]. [1]VA Puget Sound Health Care System, Seattle, WA; [2]University of Washington, Seattle, WA; [3]University of Washington, Seattle, WA. (Tracking ID #1635790)

NEEDS AND OBJECTIVES: The Institute of Medicine and others have issued urgent calls to improve the quality of health care; however, few physicians have been trained to use clinic patient panel data in decision making with the health care team. Panel management is defined as providing high quality continuous care of the entire panel of patients, which requires periodic tracking of panel data on clinical and preventive measures, not only during clinic visits. ACGME requires that medicine residents receive their continuity panel performance data related to chronic disease and preventive health, faculty guidance in developing data-based action plans that are evaluated bi-annually, and work in interprofessional (IP) teams to enhance patient care and safety. We developed an innovative panel management curriculum to teach medicine residents how to review and utilize data related to indicators of quality of care, including measures of chronic disease, prevention and access. We describe one workshop focused on emergency room (ER) utilization as an exemplar of our Panel Management curriculum.
SETTING AND PARTICIPANTS: In an academic primary care continuity clinic, faculty physicians and pharmacists teach an IP group of trainees that includes medicine residents, nurse practitioner students and pharmacy residents.
DESCRIPTION: Funded as a VA Center of Excellence in Primary Care Education, we implemented a series of workshops as a longitudinal panel management curriculum with the following learning objectives: 1) promote preventive health and chronic disease care for all patients in the resident's panel; 2) use data to take individual- and population-focused action; and 3) work collaboratively and effectively with health care team members from other professions. During the ER utilization session, trainees are provided with a list of their own continuity patients, which rank orders the high ER-utilizers over the past 2 years. Then the IP group brainstorms potential factors that may contribute to ER visits and creates a chart biopsy tool. Next, each trainee is given time to independently review the charts of their top ER utilizers using this newly developed tool. Then, the group reconvenes, trainees present their patients' cases and group discussion ensues with the following emphasis: 1) explore management strategies and untapped system resources to improve individual care, 2) track factors found to result in ER visits and plot all results in a frequency graph, 3) generate ideas for population-focused improvement projects to promote appropriate ER utilization.
EVALUATION: The Panel Management curriculum is assessed for trainee perception of curriculum content (importance and relevance), level of trainee confidence in performing Panel Management activities, subsequent frequency of using Panel Management techniques covered in workshops, and tracking of patient data on ER utilization and chronic disease measures (e.g. diabetes and hypertension) for longitudinal outcome.
DISCUSSION / REFLECTION / LESSONS LEARNED: This panel management curriculum provides trainees with the skills and tools to

evaluate their own performance data and formulate an action plan with their clinic team. Early feedback from participants is positive for: 1) greater understanding of ER utilization and contributing factors and 2) perceived value of between-visit-care and IP collaboration. Not only does this panel management meet ACGME requirements, but it prepares trainees for lifelong performance improvement.

INVOLVING ATTENDING FACULTY IN RESIDENT QUALITY IMPROVEMENT CURRICULUM TO ACHIEVE ABIM MAINTENANCE OF CERTIFICATION CREDIT Julie L. Oyler; Lisa M. Vinci; Vineet Arora. University of Chicago, Chicago, IL. (Tracking ID #1641411)

NEEDS AND OBJECTIVES: Attending faculty require American Board of Internal Medicine (ABIM) Practice Improvement Module (PIM) Points to achieve Maintenance of Certification (MOC). This can be challenging for academic faculty with varied administrative, teaching, and clinical responsibilities. Our aim was to include attending faculty in a preexisting resident quality improvement curriculum designed around the ABIM PIMs and provide an opportunity for faculty to meet the self evaluation of practice performance requirements of the MOC program.
SETTING AND PARTICIPANTS: Faculty interested in gaining MOC credit were enrolled in a year long course with internal medicine residents. Up to three faculty joined groups of 8–12 residents in four weekly 75 min lectures over the course of the first month.
DESCRIPTION: Three courses were held each year. Faculty supervised residents' collection of chart review and patient survey data using the Cancer Screening PIM. Faculty also facilitated the completion of the system survey. Faculty and resident reviewed the preliminary data at the end of the month and brainstormed ideas for improvement in the residents' continuity clinic. Residents then spent the rest of the year using the Donabedian model for improvement to develop sustainable quality improvement (QI) projects in their continuity clinic. Faculty enrolled in the ABIM MOC course came to a final presentation during which resident presented the results of their QI project. Faculty gave feedback to the residents using the Quality Improvement Project Assessment tool (QIPAT) developed at Mayo. Residents then entered the final data into the ABIM PIM. Faculty received 20 MOC points in self-evaluation of practice performance from the ABIM at the end of the course.
EVALUATION: From July 2009 to December 2012, 24 faculty enrolled in the quality improvement course to receive ABIM MOC credit. Twenty-four Faculties have completed the year long curriculum. Faculty were surveyed about their comfort with QI methodology using the Quality Improvement Knowledge Assessment Tool (QIKAT) before and after their participation the ABIM MOC course. Of the 22 (90 %) responders, there was a low level of comfort with basic QI methodology. Comfort with "implementing a structured plan to test change was low at the beginning of the course (30 %) but improved significantly to 80 % after the course. Similarly, comfort with implementing a PDSA cycle" was low before the course (20 %) but improved to 80 % of the faculty being moderately or extremely confident in these areas of QI methodology after the course. Faculty noted in qualitative analysis that they were interested in taking the QI skills they learned by observing the residents and using them in their own practice. For instance, "I may apply this knowledge to future attempts to improve care delivery in my patient population, like meeting blood pressure goals in renal transplant recipients." and "I will use this to teach QI to Hematology Oncology fellows." 60 % (9/15) of faculty who completed the course over 1 year ago renewed their ABIM certification.
DISCUSSION / REFLECTION / LESSONS LEARNED: Involving faculty in a preexisting resident quality improvement curriculum can both help faculty become more comfortable with QI methods and help them receive maintenance of certification credit.

LEADERSHIP CURRICULUM HELPS PRIMARY CARE RESIDENTS LEARN METHODS TO DECREASE HEALTH DISPARITIES Katy Hicks; Kristin Burnett Fernandez. Alameda County Medical Center, Oakland, CA. (Tracking ID #1625509)

NEEDS AND OBJECTIVES: For 26 years, the Alameda County Medical Center (ACMC) Primary Care Training Program (PCTP) has trained diverse primary care physicians with the goal of improving access to high quality care for underserved populations. Our program aims to improve primary care residents' preparedness to practice in low income underserved communities, and by doing so, improve health outcomes, reduce health disparities, and increase the number of medical graduates choosing to become primary care providers. With assistance from a federally funded grant, we have created and launched a leadership curriculum for our PCTP. This curriculum is part of our innovative 5 year primary care training project, Project LINC. Project LINC prepares primary care residents to lead efforts in reducing health disparities by teaching change agent and advocacy skills and by linking behavioral and addiction medicine to chronic disease management and healthy aging.
SETTING AND PARTICIPANTS: Highland Hospital, a public hospital serving a diverse population in Oakland, CA. Nineteen primary care residents within the internal medicine residency program received the Leadership Training Curriculum during the 2011–2012 academic years.
DESCRIPTION: Teaching methods included small group participatory discussions, assigned readings with discussion, personality testing with discussion, pilot leadership activities with mentorship by leadership faculty. Topics included collaboration skills, learning to work in a group, and being a change agent
EVALUATION: 53 % of PGY1-3 residents completed online evaluations via the online site Survey Monkey. A retrospective pre-test design was used wherein residents were asked to rate their beliefs, knowledge and attitudes before and after the program at the same time. A 5-point Likert scale was used with 1=Strongly Disagree, 3=Agree and 5=Strongly Agree. Following completion of the Leadership Curriculum, residents felt they were: -Better able to describe potential causes of racial and ethnic disparities -Better able to describe individual actions that may reduce health disparities -More likely to believe that developing health advocacy skills are an important part of becoming a physician -More likely to know when to consider social barriers to health care for their patients -More confident in their abilities to influence others to act toward a mutual goal -Better able to identify ways to improve the health of their communities -Better able to describe how physicians can effectively partner with community organizations
DISCUSSION / REFLECTION / LESSONS LEARNED: Preliminary results demonstrate that residents' awareness of barriers facing the underserved was increased, as was their ability and desire to work toward overcoming these barriers. Leadership training should be considered an important curricular element for training primary care providers who plan to work with the underserved. Primary care leadership training has been demonstrated to be successful in creating physician advocates for the underserved in Title VII residency programs.

LEANING TOWARDS PATIENT-CENTERED TEACHING ROUNDS Himani Divatia; Joseph Deutsch. Christiana Care Health System, Newark, DE. (Tracking ID #1638570)

NEEDS AND OBJECTIVES: The current process for managing patients on an inpatient teaching service at Christiana Care Health System ("CCHS") contributes to redundancy in patient care. At baseline, we found that medical interns were spending approximately 30 min with each patient each morning on tasks and communication that were ultimately duplicated by others. Additionally, no patients had an initial plan of care documented by the completion of teaching rounds around noon. There was also limited standardization of work flow between teaching services, and restrictions on resident duty hours, without a concurrent reduction in patient care responsibilities, were limiting opportunities for medical education. With this background in mind, our goal was to develop a way to manage teaching patients which would eliminate waste, improve efficiency, improve resident education and ultimately improve patient care. Our overall goal was to have 100 % of CCHP teaching patients to have an initial plan of care communicated to the patient and the healthcare team by 11:30am.

SETTING AND PARTICIPANTS: Our team was comprised of Christiana Care Hospitalist Partners ("CCHP") teaching attendings, Internal Medicine (IM) residency program director, IM residents and the nurse manager of 5D. The intervention was implemented on a CCHP Inpatient Teaching Team, with a focus on the 5D unit. Our intervention consisted of redesigning teaching rounds in order to create a more lean and efficient rounding process.
DESCRIPTION: Specific initiatives included establishment of a progress note template in order to facilitate efficient note writing, specific role designation of each team member, and definition of a new work flow pattern that emphasized team rounding instead of each team member working in isolation. Implementation of these initiatives was intended to decrease the time spent by each team member doing similar tasks, increase the time the entire teaching team spent with each patient, increase time for resident education, enhance communication, and complete all patient care tasks and documentation as part of a one piece flow.
EVALUATION: Post-intervention, 94 % of CCHP teaching team patients had their plan of care communicated to them and documented in the chart by 11:30am, which facilitated earlier access to current information by other health care providers. Time spent per patient by each intern before rounds was reduced from 30 min to 10 min. Additionally, valuable time spent with each patient was increased by 8 min in this new rounding methodology, while still reducing overall rounding time by an average of 12 min. This resulted in increased opportunities for resident education.
DISCUSSION / REFLECTION / LESSONS LEARNED: Rounding as a team at the bedside resulted in a structure which facilitated concurrent communication amongst team members and the patient and family. Reduction of "pre-rounding" time improved team efficiency, while template notes and defined role assignments standardized documentation and the rounding process. Our intervention can be adopted by additional teaching teams but would require focusing on faculty and resident development through presentations as well as simulation sessions. Future directions include standardizing the rounds process among the different CCHP teaching teams, improving the computer/iPad access in rooms, and integrating this process with the Multidisciplinary Rounds process.

MASTERY LEARNING OF ORAL CASE PRESENTATION SKILLS
Heather L. Heiman; Toshiko Uchida; Gary J. Martin. Northwestern University Feinberg School of Medicine, Chicago, IL. (Tracking ID #1642491)

NEEDS AND OBJECTIVES: The oral case presentation is a challenging yet essential skill for medical students. We have previously shown improvement in the oral case presentation skills of second year students through a curriculum of online learning and deliberate practice. Deliberate practice is a component of the mastery learning model. In mastery learning, students deliberately practice a task until they demonstrate a fixed standard of competency. All learners achieve competency, but the practice time required varies. Mastery learning is shown to improve trainees' skills in advanced cardiac life support, central venous catheter insertion, and cardiac auscultation. While these are primarily psychomotor tasks, we sought to extend mastery learning to the oral presentation, a more cognitive skill. We aimed to set competency standards for a set of six cases, to determine whether all students could achieve those standards, and to understand how much practice would be required for all students to achieve competence.
SETTING AND PARTICIPANTS: Ten clinicians from medicine and pediatrics participated in a 4-hour workshop to establish minimum passing scores for each case. Following a curriculum of online learning and deliberate practice, all 170 students in the second year class at Northwestern University Feinberg School of Medicine were required to take a summative clinical skills assessment including an oral presentation case. All students had to achieve a passing score on that case or to remediate it through more practice and re-assessment. One-hundred nine students (64 %) provided consent for their data to be included.
DESCRIPTION: Students constructed oral presentations based on cases that were presented as video interviews accompanied by written physical exams. Presentations were scored by trained fourth-year medical students using dichotomous checklists of 22–26 items. We used the Angoff and Hofstee standard setting procedures to establish passing scores for each of six cases. Angoff and Hofstee outcomes were averaged to determine a minimum passing score, which ranged from 66 % to 70 % of items correct.
EVALUATION: Of the 109 students who consented for data inclusion, 13 (12 %) did not achieve the passing standard during their clinical skills assessment. These students prepared one new practice case and met with a fourth year medical student who listened to their presentation and provided specific feedback. At least 1 day later, the remediating students presented a different test case. All 13 students achieved the passing standard on their second test case.
DISCUSSION / REFLECTION / LESSONS LEARNED: We successfully applied a mastery learning model to the oral case presentation. A panel of clinician educators set reasonable minimum passing scores. Most students (88 %) passed their case after the standard curriculum of online learning plus deliberate practice. Twelve percent of students required one more practice case and could then demonstrate competence. Our main limitation of was the use of a single case to test students. This limitation resulted from time constraints and the need for trained fourth-year raters. We plan to continue this curriculum for future classes, and we hope to determine how it affects student performance with real patient cases during the third year.

MEASURING AND EVALUATING SYSTEMS THINKING
Mamta K. Singh[1]; Mary Dolansky[2]; Shirley Moore[2]; Aleece Caron[3]; Patrick Palmeri[4]. [1]Louis Stokes Cleveland VA Medical Center, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH; [3]Case Western Reserve University, Cleveland, OH; [4]Summa Health System, Akron, OH. (Tracking ID #1640983)

NEEDS AND OBJECTIVES: Systems Thinking is an approach to problem solving that views 'problems' as parts of an overall system, rather than a specific part and requires cyclical rather than linear cause-effect thinking. This is a critical skill needed for professional development. The Accrediation for Graduate Medical Education recognizes this with its establishment of Systems Based Practice as one of its core 6 competencies with systems thinking at the heart of this competency. However, the measurement and evaluation of Systems Based Practice skills is vague especially the ability to evaluate the extent to which educational interventions that teach systems thinking are effective is not widely known. Using the conceptural framework of Miller's Pyramid of Assessment, the basic tenet of "Knows" needs to be fulfilled in Systems Thinking and therefore a valid and reliable measure of systems thinking is needed.
SETTING AND PARTICIPANTS: To assess discriminant validity of the Systems Thinking Scale, three dose levels of systems thinking education were provided to different sets of students and changes in systems thinking were compared among the groups. The first group consisted of graduate level healthcare students (N=12) taking a 12-week improvement course that emphasizes systems thinking during experiential quality improvement projects (high dose). The second group consisted of graduate medical students (N=78) who were exposed to a 4- hour error case that addressed systems thinking using root case analysis (low dose). The third group consisted of graduate entry nursing students (N=32) in a nursing pharmacology course who did not receive systems thinking training
DESCRIPTION: The Systems Thinking Scale (STS) consists of 20 items that use a 4-point likert-type response scale. The STS was administered in a pretest-posttest format and validity was assessed by comparing change differences among the three groups.
EVALUATION: Psychometric analyses of the STS included assessment of internal reliability (α=.83; n=342) and test-retest reliability (r=.74; n=26) To assess discriminant validity, three dose levels of systems thinking education were provided to different sets of students and changes in systems thinking were compared among the groups. The STS was administered in a pretest-posttest format and validity was assessed by comparing change differences among the three groups. There were no differences in STS mean scores at pretest. At post test, the high dose-

education group scored significantly higher on the STS than both the low and no dose groups (p=.05 and .01, respectively).
DISCUSSION / REFLECTION / LESSONS LEARNED: A reliable and valid measure of systems thinking increases our ability to assess the effect of our educational efforts to enhance systems thinking of our healthcare professional graduates.

MEDICAL STUDENTS AND PHYSICIANS REFERRED FOR REMEDIATION: DESCRIPTIVE STATISTICS AND OUTCOMES
Jeannette Guerrasio; Eva M. Aagaard. University of Colorado, Aurora, CO. (Tracking ID #1618679)

NEEDS AND OBJECTIVES: Regardless of the level of training and specialty, approximately 7–28 % of medical trainees will require remediation in the form of an individualized teaching or learning plan to achieve competence in the necessary skills to become a physician. 17 % of attendings are also able to identify peers that are in need of remediation. Yet, only a few small studies on remediation exist in the literature. This innovation was designed to determine trends and predictors of poor academic outcomes among struggling medical students and physicians
SETTING AND PARTICIPANTS: From academic years beginning 2006–2011, the remediation program at the University of Colorado accepted self-referrals, medical students referred by their clerkship director, residents and fellows referred by their program director, students who received negative comments on their evaluations, all learners in and danger of failing a course or who had failed a course (n=151).
DESCRIPTION: Once referred, the learner's areas of deficiency were identified, a remediation plan implemented, and their performance subsequently assessed. The following metrics were analyzed using chi square, Fisher's Exact Test, analysis of variance and logistic regression: gender, level of learner, deficits, faculty time needed to remediate the learner, reassessment methods used and learner outcomes, including program completion and probation.
EVALUATION: Referred medical students were more likely to have mental well-being problems (p=0.025) and physicians (residents and in practice) were more likely to be referred for clinical reasoning deficits and poor professionalism. Males were more likely to struggle with communication skills (p=0.014) and mental well being (p=061). Clinical reasoning, and mental well being struggles each required significantly most faculty time to remediate (p<0.001;p=0.03) Among students, difficulty with interpersonal skills showed trends towards not matching into a residency program. Poor professional was the only predictors of probationary status (p=0.001). Being placed on probation were more like to have a negative outcome, including restricted practice, be transferred to another program, to withdraw or be terminated (p<0.0001). Faculty time reduced the odds of probation by 3.1 % per hour and negative outcomes by 2.6 % per hour (p= 0.001, OR 0.969; p=0.002, OR 0.974)
DISCUSSION / REFLECTION / LESSONS LEARNED: Deficits among learners referred for remediation vary based on the level of learner. The type of deficit can be used to predict the amount of time needed for remediation, not matching into a residency program, probationary status and negative academic and career outcomes. Faculty time dedicated to remediation has been shown to decrease probation and negative academic and career outcomes. Overall, the remediation process had highly successful outcomes for its participants.

MENTAL HEALTH EDUCATION FOR MEDICINE TRAINEES THROUGH A PRIMARY CARE INTERPROFESSIONAL CASE CONFERENCE: PROMOTING COLLABORATIVE LEARNING AND ADDRESSING CHALLENGES Shalini Patel[2,1]; Christina Kim[2]; Erick Hung[1]. [1]UCSF, San Francisco, CA; [2]VA San Francisco, San Francisco, CA. (Tracking ID #1642458)

NEEDS AND OBJECTIVES: Internal medicine residents often train in the same outpatient clinics as mental health trainees and students from other professions (nursing, pharmacy, and social work). This innovative model for an ambulatory case conference brings interprofessional trainees together to promote collaborative learning and care models. Objectives: - Describe the advantages and challenges of teaching in an interprofessional educational setting. - Discuss how to engage trainees at various developmental levels and in other medical disciplines and health professions. - Understand how to model and teach interprofessional case presentation, inquiry, and collaboration to care for high-risk patients. - Identify opportunities for medicine residents to collaborate and learn with trainees from other professions such as mental health at various institutions.
SETTING AND PARTICIPANTS: The learning environment at the Downtown San Francisco VA community based outpatient clinic includes psychiatry and internal medicine residents, NP and medical students, psychology fellows, and pharmacy trainees. The clinic serves a significant proportion of high-risk homeless patients with chronic medical and psychiatric disease whose care depends on collaborative interprofessional work.
DESCRIPTION: The weekly case conference model emphasizes several principles, including: (1) assessing the trainee's needs; (2) interprofessional learning and engagement; (3) a learner-driven approach; (4) modeling consultation and inquiry with different professions. The model uses a format in which a trainee is encouraged to present a case that he/she finds interesting, challenging or frustrating that would benefit from interprofessional input. The interprofessional group of trainees then generates questions for further inquiry and the facilitator assigns trainees to research answers for each of the questions. At the next session, the group reviews the case and questions and trainees present their findings succinctly (5–10 min). Educators involved in the case conference facilitate the discussion and provide context when needed.
EVALUATION: Fifteen trainees who participated in the case conferences for 6 or 12 months completed evaluations of the conference and surveys regarding attitudes towards interprofessional care. Trainees agreed that they saw greater value in discussing patients in an interprofessional group as a result of the conferences (mean score 5.4 on a Likert scale of 1 to 6). Additionally, trainees felt they had a better understanding of other professions' roles (mean score 5.2). Trainees' written reflections underscored the value of interprofessional team based care. An example includes: "[I value] interactions with such a diverse group about complicated issues. I utilize other providers better, they utilize me better"
DISCUSSION / REFLECTION / LESSONS LEARNED: (1) A learner driven conference about patient care issues that trainees feel challenged with can increase participant engagement in interdisciplinary conferences. (2) Encouraging trainees to use multiple sources for queries (i.e. evidence-based literature or discussion with colleagues) can help all levels and backgrounds of trainees feel comfortable in participating. (3) Facilitators need to resist from answering questions immediately or dominating discussion to allow cross disciplinary teaching among trainees. (4) It is critical that facilitators ensure that learning topics are clear and well balanced among disciplines.

MIXED-METHODS EVALUATION OF THE MGH GLOBAL PRIMARY CARE CURRICULUM Patrick T. Lee[1,2]; Elizabeth Cunningham[1]; David Munson[1]; Joseph Joyner[1]; Sarah Wakeman[1]; Renuka Tipirneni[1]; Ashley Dunkle[1]; Debora Paterniti[3]; Valerie E. Stone[1]. [1]Massachusetts General Hospital, Boston, MA; [2]Cambridge Health Alliance, Cambridge, MA; [3]University of California, Davis, Davis, CA. (Tracking ID #1631145)

NEEDS AND OBJECTIVES: Global learning and local innovation are particularly relevant for US health reform and the care of vulnerable populations. Future GIM leaders require training that prepares them to compare, select, implement, and continuously improve innovations at the care team, practice setting, and community levels. Current educational models and ACGME competencies strongly emphasize domestic health system issues, overlooking useful global lessons that are directly relevant to these domestic challenges. We evaluated the impact of a novel comparative health systems curriculum on trainees' preparedness to engage in health system strengthening for vulnerable populations.

SETTING AND PARTICIPANTS: 13 Massachusetts General Hospital (MGH) internal medicine interns (8 primary care, 5 categorical) participated in the IRB-approved study.
DESCRIPTION: The MGH Global Primary Care (GPC) Curriculum customizes a four-week, call-free ambulatory month with 70 h of instruction focused on comparative lessons in improving care for vulnerable populations. The curriculum, which is tailored to the learning preferences of MGH interns, provides an entry point in integrated global health and primary care training for all MGH primary care, global primary care, and self-selected categorical internal medicine interns. Interns are introduced to potential faculty mentors at an early point in their training. Interactive case studies of best practices in health care policy and delivery from the US, Mexico, Bangladesh, Uganda, and Liberia are paired with local health care delivery experiences in Boston. Seven learning objectives are linked to ACGME core competencies in medical knowledge, practice-based learning and improvement, professionalism, and systems-based practice.
EVALUATION: We performed a mixed-methods evaluation of the GPC Curriculum. Preparedness was assessed in 4 domains: knowledge, self-reported preparedness, practice intentions, and complexity of thinking. Twenty-four knowledge questions, Three multi-part Likert questions, and a semi-structured interview were administered before and after the curriculum. Knowledge and Likert scores were compared quantitatively. Interviews were analyzed iteratively for persistent themes in the qualitative data. Mean knowledge scores increased from 59 % before to 80 % after the curriculum ($p<0.0001$). Likert scores (1=strongly agree; 5=strongly disagree) for self-reported preparedness improved significantly for all 7 learning objectives, with mean scores improving from 2.93 before to 1.84 after the curriculum ($p<0.0001$). Specific lessons learned included: new insights regarding the role of physicians, the nature and composition of teams, and the integration of public health and clinical medicine; the usefulness of comparative analysis to inform US health care delivery; and a rise in optimism "to make a difference on the system as a whole," which was linked to a shift in focus from problems to solutions. There was no observable impact on future practice intentions.
DISCUSSION / REFLECTION / LESSONS LEARNED: The GPC Curriculum improved MGH interns' preparedness to engage in health systems strengthening for vulnerable populations. Further studies are needed to validate the longer-term impact of the GPC Curriculum and the efficacy of comparative health systems training in other settings. Teaching the next generation of GIM leaders a set of comparative health systems competencies may serve to accelerate diffusion of innovation in US health care.
ONLINE RESOURCE URL (OPTIONAL): https://hub.partners.org/globalprimarycare/Programs/Curriculum

NOVEL INTEGRATION OF SYSTEMS-BASED PRACTICE INTO INTERNAL MEDICINE RESIDENCY PROGRAMS: THE INTERACTIVE COST-AWARENESS RESIDENT EXERCISE (I-CARE) Robert L. Fogerty[1,4]; Jason Heavner[3]; John P. Moriarity[1]; Andre N. Sofair[1]; Grace Y. Jenq[2]. [1]Yale School of Medicine, New Haven, CT; [2]Yale School of Medicine, New Haven, CT; [3]Yale School of Medicine, New Haven, CT; [4]Yale-New Haven Hospital, New Haven, CT. (Tracking ID #1638279)

NEEDS AND OBJECTIVES: The Accreditation Council for Graduate Medical Education (ACGME) and American Board of Internal Medicine (ABIM) have identified cost-awareness as an important component to residency training. However, cost-awareness is generally not emphasized in traditional residency curricula. Novel methods are needed to provide cost-awareness in a time efficient manner.
SETTING AND PARTICIPANTS: Internal Medicine interns, residents, Faculty and Yale School of Medicine third year students at three Yale-affiliated teaching hospitals in Connecticut.
DESCRIPTION: The Interactive Cost-Awareness Report (I-CARE) follows a traditional, Morning Report style teaching session run by a Chief Resident, where the diagnostic workup of a patient is discussed in a 1 hour didactic session. I-CARE takes place over a 4 day period every fourth week. One hour each day is provided for each level of training: medical students, interns and sub-interns, residents, and lastly, attending physicians. Those planned to participate in a later session are prohibited observing the trainee sessions, however all trainees are present to observe the attending physician session. Following the initial case presentation, trainees can inquire of the Chief Resident for further information in an effort to make a diagnosis. Additional history and/or physical exam maneuvers not included in the initial presentation (such as travel history, dermatographism, straight leg raise) have no associated cost and are free to the group of trainees should they be specifically requested. Laboratory tests, diagnostic imaging, and diagnostic procedures can also be requested, and the actual patient charge from our institution for that item is recorded by the Chief Resident in real time. These charges are blinded to the participants at the time of the exercise. The actual charges for each group's diagnostic workup are recorded and shared in a friendly competition across training levels and training sites.
EVALUATION: Anonymous, voluntary survey of all participants and comparison of expenditures by training level.
DISCUSSION / REFLECTION / LESSONS LEARNED: Interns, residents and attending physicians were asked to complete the survey. Thirty-seven surveys were returned (39 % response rate). Response was overwhelmingly positive, with 31 respondents (84 %) identifying the SBP case as 'an overall improvement' to Morning Report. Using a 10 point Likert Scale, survey respondents rated the educational quality of the I-CARE case 8.57 and the educational quality of the prior morning report format 6.81 ($p<0.001$). Narrative responses from survey respondents were also positive. (Fig. 1) Sampling of the first five cases revealed 100 % accuracy of diagnosis by the attending physician group, 60 % accuracy by residents and interns and 50 % accuracy by medical students. Furthermore, dichotomous *t*-test was performed (Excel 2010, Redmond, WA) to determine difference in expenditures. The attending physician group spent less on average than non-attending participants ($1027.45 vs $4264.00, $p=0.02$). This difference persisted with medical students excluded from the analysis ($1027.45 vs $3962.80, $p=0.03$). The I-CARE provides for immediate inclusion of cost-awareness and enhances Systems-based Practice education in an Internal Medicine Residency Program with minimal additional resources by using a pre-existing educational conference. The I-CARE is easy and quick to implement, and the preliminary results show a popular cost-awareness educational experience.

OUTCOMES OF A NEW WEB-BASED PTSD TRAINING FOR PRIMARY CARE PROVIDERS Karen H. Seal[1,2]; Kristin Samuelson[1,3]; Nicole McCamish1; Christopher J. Koenig[1]; Daniel Bertenthal[1]; Gary Tarasovsky[1]; Gerard Choucroun[1]. [1]San Francisco VAMC, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA; [3]Alliant International University, San Francisco, CA. (Tracking ID #1633151)

NEEDS AND OBJECTIVES: Patients with posttraumatic stress disorder (PTSD) diagnoses most often present to primary care providers (PCPs) first. Many patients, particularly Iraq and Afghanistan veterans, resist specialty mental health treatment, primarily due to stigma. Most PCPs have not been trained to assess for and initiate management of PTSD. Web-based instructional programs are increasingly used to facilitate continuing medical education. The main aim of this study was to develop, disseminate, and evaluate the effectiveness of a web-based PTSD training for PCPs.
SETTING AND PARTICIPANTS: Between 10/25/2011 and 12/06/2012, PCPs were recruited and enrolled in the study, primarily in response to UCSF CME e-mail announcements. Consenting study participants completed online assessments at baseline, end-of-training, and after at least 30 days to receive 2 units of CME credit.
DESCRIPTION: A general internist and a PTSD psychologist developed evidence-based educational content for a 70-minute web-based PTSD training program for PCPs, accredited by the University of California, San Francisco (UCSF) Office of Continuing Medical Education (CME). The training focused on the management of combat-related trauma, but also generalized to other types of trauma. The training consisted of 4 modules: (1) Assessment and Diagnosis of PTSD; (2) Comorbid Conditions and

Differential Diagnoses; (3) Pharmacological Interventions, and (4) Psychotherapeutic Interventions for PTSD. Clinical vignettes of PCPs interacting with patients brought to life concepts introduced in the modules.
EVALUATION: To date, 80 PCPs have completed the baseline and end-of-training assessment, and 66 have completed the 30-day follow-up assessment. Descriptive quantitative statistics were used to describe changes in participants' PTSD-related knowledge, self-efficacy, and self-reported practice behavior. Qualitative data was summarized for quality improvement. PCPs reported practicing a mean of 14 years; 65 % endorsed caring for veterans or military personnel. There was a significant increase in PTSD-related knowledge from baseline to post-training, and from baseline to follow-up after 30 days (both p's<0.001). After completing the training, PCPs reported significantly increased comfort with 11 of 12 PTSD-related skills (i.e., evaluating comorbid conditions, prescribing medication for nightmares, explaining evidence-based psychotherapeutic options etc....); 97 % found the training to be moderately to very educational, whereas 16 % found it burdensome; 92 % anticipated applying training content in their practices, and after 30 days, 47 % reported having actually done so. Qualitatively, compared with scheduled web-casts, many PCPs preferred the asynchronous web-based modules because they could complete them at any time, at their own pace, and in any setting. PCPs responded favorably to video-recorded clinical vignettes, but requested more interactive exercises before and after each module to reinforce content.
DISCUSSION / REFLECTION / LESSONS LEARNED: This is the first evaluation of an online PTSD training program for PCPs, many of whom care for large numbers of patients with trauma, but have had limited training in this area. PCPs responded very favorably to the training and many were able to apply concepts in their daily practice. Future implementation considerations involve condensing the training and adapting it for smartphone use for even greater convenience and usability, with clinical outcomes confirmed by chart review.
ONLINE RESOURCE URL (OPTIONAL): https://ihrc.ucsf.edu/Collector/Survey.ashx?Name=ELearning_SGIM

OUTPATIENT DOCUMENTATION IN THE ELECTRONIC HEALTH RECORD: CURRENT RESIDENT PRACTICES, OPPORTUNITIES AND TOOLS FOR CURRICULAR INNOVATION Jaishree Hariharan; Sarah A. Tilstra; Thomas Radomski; Jodie Bryk; Peggy Hasley. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1642054)

NEEDS AND OBJECTIVES: Clinical documentation is essential for tracking disease over time, supporting clinical decision-making, and is vital for appropriate billing. The electronic health record (EHR) has simplified communication among providers and improved clinical decision support. Nevertheless, it has created complexity in documentation for medical trainees to master. Very little is known about documentation practices of trainees, and how to best teach this complex system. Our objectives are: 1. Describe documentation practices of residents for outpatient clinical encounters 2. Identify weaknesses in EHR documentation utilizing chart review and resident survey 3. Develop standardized EHR documentation templates for common visit types to improve efficiency and quality of documentation
SETTING AND PARTICIPANTS: The University of Pittsburgh medical center is an urban academic center with 120 internal medicine residents. The pilot site is the Division of General Internal Medicine faculty and resident practice, where fifty- two categorical residents have their weekly continuity clinic and see 3–7 patients per half-day session. The practice has a fully integrated EHR (Epicare).
DESCRIPTION: A chart audit tool to describe current practices in resident documentation and use of the EHR was created by a team consisting of three faculty preceptors and two residents. The tool contained a scoring system addressing the appropriateness of essential components of the visit. "Appropriateness" is based on component needs for quality documentation and billing level as determined by the team. These components included (1) the written note, (2) the presence of pertinent patient instructions, and (3) updated sections in the EHR, which includes tabs for problem list,history section, health maintenance and medication list. Approval was obtained from our institutional QI board prior to chart review. Thirty charts from 30 unique residents, (10 from each PGY level) were audited by the team, targeting a variety of clinical encounters (new patient, follow-up, annual visit, pre-operative evaluation). A resident survey is planned to assess perceived weaknesses in documentation efficiency and quality and barriers to EHR use. Based on these results, we plan to develop standardized templates for common clinic encounters using best practice information.
EVALUATION: Results show that the most common visit types were "follow-up visits" (53 %) followed by "annual physicals" (23 %). Eighty percent of residents used templates for visit documentation. Appropriateness of visit note documentation was greater than 80 % for chief complaint, history of present illness, medications, physical exam, and assessment and plan. Only 37 % of resident charts had updated problem lists, 23 % of medication lists were not updated or incorrect, and 50 % of health maintenance tabs were updated. Patient instruction section use was infrequent at 27 %, and 33 % failed to meet billing standards.
DISCUSSION / REFLECTION / LESSONS LEARNED: Our initial audit suggests that medical care is more completely documented in the visit note, but not updated within the EHR and appropriate billing needs to improve. Curricular innovation and training is required to utilize the full potential of the EHR. Our resident survey will be vital in determining the necessary components to improve quality and efficiency of EHR documentation.

OUTPATIENT INTENSIVE ORIENTATION PROGRAM Ryan Nall; Anita Vanka; Kelly Ford; Howard Libman. BIDMC, Boston, MA. (Tracking ID #1642599)

NEEDS AND OBJECTIVES: At Beth Israel Deaconess Medical Center, interns have three two-week ambulatory block rotations. While continuity clinic is scheduled weekly throughout the year, some interns may not have their first ambulatory block until 2 months into the year and, based on resident surveys and feedback from preceptors, are slow to gain familiarity with outpatient practice. Through the use of an intensive ambulatory orientation program (IOP), interns will improve their efficiency and familiarity with the ambulatory setting earlier in the year.
SETTING AND PARTICIPANTS: Outpatient general medicine practice. Internal medicine interns/general medicine faculty.
DESCRIPTION: An IOP in the ambulatory setting was scheduled for all interns during the first 2 weeks of the academic year. The class was divided in half; one group began on the inpatient service, and the other group began in the ambulatory setting. The groups switched after 1 week. Specific IOP learning objectives are described below. ● Identify clinical support staff and their role in patient care ● Demonstrate comfort in the ambulatory setting ● Demonstrate the effective use of the online medical record ● Demonstrate means of effective documentation and patient communication ● Identify effective ways to keep track of follow up items ● Identify how to get the most out of the preceptor-preceptee relationship ● Describe several strategies to manage difficult patients
EVALUATION: Interns (n=43/49, 88 %) and faculty (n=21/80, 27 %) completed anonymous surveys. Intern Survey Results ● 86 % of interns agreed or strongly agreed with the statement, "I feel that I now have a reasonable understanding of how my outpatient practice site works." ● 88.4 % of interns agreed or strongly agreed with the statement, "I am comfortable documenting a clinical encounter." ● 92.9 % of interns agree or strongly agree with the statement, "I am comfortable ordering a test and following it up." Faculty Survey Results ● 76.2 % agreed or strongly agreed with the statement, "I believe that the 1 week intensive outpatient orientation for interns has allowed them to function comfortably in clinic." No faculty disagreed with this statement. ● 90.5 % agreed or strongly agreed that interns were functioning better in clinic at this stage of the year than they had in previous years. ● 90.5 % agreed or strongly agreed that they would recommend continuing the outpatient IOP for interns in future years.
DISCUSSION / REFLECTION / LESSONS LEARNED: Upon completion of the IOP, the majority of interns felt that they understood how their practice site worked, the role of staff, how to order and follow up tests, and how to document clinical encounters. The IOP improved faculty impressions of intern function in clinic, and over 90 % of faculty who completed the survey felt that the program

should continue in future years. While we have no prior data for comparison, the intern survey results would suggest that IOP learning objectives were met. In addition, faculty believed that the IOP improved intern function in clinic compared to previous years.

PATIENT SAFETY MORNING REPORT: USING AN OLD CONFERENCE TO TEACH NEW TRICKS Christopher J. Smith[1]; Allison Ramey[1]; Elizabeth Lyden[2]; Julie Fedderson[1]. [1]University of Nebraska Medical Center, Omaha, NE; [2]University of Nebraska Medical Center, Omaha, NE. (Tracking ID #1636625)

NEEDS AND OBJECTIVES: Root-cause analysis (RCA) is a method for investigating and correcting systems defects. While it is expected that residents learn how to recognize and analyze system errors, it can be logistically challenging to teach given competing duty obligations. Although residents are on the front-lines of patient care, they rarely take part in institutional patient safety initiatives. To address these challenges, we developed an interactive case conference ("Patient Safety Morning Report") in which learners explored themes of patient safety via a modified-RCA.
SETTING AND PARTICIPANTS: Patient Safety Morning Report took place at a university-based Internal Medicine residency program. Participants were senior residents, interns, and medical students rotating on the inpatient wards service.
DESCRIPTION: Patient Safety Morning Report was developed and moderated by a chief resident and faculty with expertise in patient safety. It was held over three 45 min sessions, during the normal morning report time. After a didactic primer on RCA, a clinical vignette demonstrating an adverse patient outcome was presented. An event flow-diagram was displayed and the group analyzed the case to identify contributing factors. Systems-focused questions were generated and researched independently by participants prior to the next session. During the second session, participants reported their findings which were integrated into a fish-bone diagram. During the third session, participants created causal statements and solutions to address the root-causes of error.
EVALUATION: Participants' attitudes and knowledge relating to patient safety and RCA were tested pre- and post-intervention. Thirty-five learners attended at least one of the three conferences, and twenty-two (10 students and 12 residents) took both pre- and post-tests (63 %). There was significant improvement in the median Likert score for three of ten attitude-based questions related to blame, the RCA process, and identification of systems-level problems. There was significant improvement in three of nine knowledge-based topics, including contributing factors, causal statements, and hierarchy of actions. There was borderline significant improvement (p= 0.0522) in understanding of fishbone diagrams. The median number of correct answers to knowledge based questions increased from six to eight (p=<0.001). Scores were similar for residents and students.
DISCUSSION / REFLECTION / LESSONS LEARNED: Patient Safety Morning Report is an effective strategy for teaching RCA and principles of patient safety. Pilot data indicate that participants find the conference enjoyable, relevant, and sustainable. The current study shows the intervention also improves attitudes and knowledge related to patient safety. By integrating the intervention into the pre-existing morning report schedule, learners did not sacrifice time from other duties. The intervention also served to diversify the morning report experience, while teaching and assessing several important educational outcomes (i.e. Milestones) across multiple Accreditation Council for Graduate Medical Education competency domains. Future areas of interest include making the conference inter-professional. Ultimately, learner-generated solutions will be conveyed to hospital administration, serving as a means by which residents can impact institutional patient safety.

PILOT OF A DIRECT OBSERVATION PROGRAM OF FACULTY TEACHING CLINICAL SKILLS Rupel Dedhia; Melanie Gordon; Andem Ekpenyong. Rush University Med Center, Chicago, IL. (Tracking ID #1642546)

NEEDS AND OBJECTIVES: Clinical educators charged with the responsibility of educating medical students and residents often receive minimal feedback on their teaching behaviors. At Rush Medical College (RMC), a direct observation project was implemented to evaluate the teaching behaviors of faculty during our clinical skills course and provide them with detailed feedback. The objectives of the project were as follows: 1) Outline an approach to evaluate faculty teaching clinical skills in a small group setting 2) Implement feedback from the project to improve the course.
SETTING AND PARTICIPANTS: The Medical Interviewing and Physical Examination Course for first and second year medical students. In each year, there are six small group workshops, each consisting of approximately twenty students and one faculty member.
DESCRIPTION: During the 2011–2012 academic year, six faculty members were observed teaching a clinical skills teaching workshop. Direct observation was performed by three peer observers (current and former course directors of the physical diagnosis course). Faculty began the two-hour session by discussing a clinical case (focused on one organ system) followed by demonstration and practice of the corresponding physical examination. The workshop was videotaped and peer observers were present for the entire session. The Stanford Faculty Development Program-26 tool (SFDP-26) was used. Although this tool was validated for medical students evaluating their teachers, we opted to also use it for peer observation and faculty self-assessment. At the completion of each session, students and faculty were asked to complete the SFDP-26 tool. Feedback was provided to the faculty in one-on-one sessions using his or her video clips and an action plan was developed. Participation in the project was purely voluntary. All participants consented to the study and approval was obtained from the institutional review board.
EVALUATION: The data collected (student, peer, and self-assessments) using the SFDP-26 tool is currently being analyzed to compare teaching behaviors both before and after the feedback session. Faculty were also surveyed about their experience during this project.
DISCUSSION / REFLECTION / LESSONS LEARNED: While the initial goal of the project was to provide specific feedback to our faculty about their teaching, this project also offered faculty the opportunity to reflect on their teaching and discuss concrete ways to improve the course. During the one-on-one feedback sessions, both effective and less effective teaching behaviors were highlighted using the video clips and data from the student evaluations to create specific action plans. Faculty made recommendations to the course directors, which led to upgrading the resources for the course (e.g. increasing laboratory space for students to practice the exam and providing every classroom with a smart board for displaying abnormal physical examination findings). We were also able to evaluate the ability of faculty to deliver the goals and objectives of the course. We have used insights gained from the project to enhance faculty orientation and redesign some of the small group workshops to better engage the students. Overall, this project allowed us to utilize several modalities to provide detailed feedback to our faculty about their teaching and make significant improvements to the course.

PODCAST PEARLS: THE IMPACT OF A BRIEF WEEKLY 21ST CENTURY EDUCATIONAL TOOL Melissa Dattalo; Ryan E. Childers; Colleen Christmas. Johns Hopkins Bayview Medical Center, Baltimore, MD. (Tracking ID #1642545)

NEEDS AND OBJECTIVES: Morning report is an age-old venue for teaching in residency training. New challenges to resident work hours have challenged these old teaching paradigms. We sought to capture the essential teaching points from the Johns Hopkins Bayview Internal Medicine residency program's daily morning reports and synthesize them into an educational tool for our housestaff. We created the "Podcast Pearl," an audio file consisting of teaching pearls from each morning report, and sent it electronically to residents and faculty at the end of each week. We aimed to assess the impact this weekly audio recording had on resident and faculty education, satisfaction, and connectedness to the residency program.

SETTING AND PARTICIPANTS: We distributed the "Podcast Pearl" audio file to 57 residents and 49 faculty members at Johns Hopkins Bayview Medical Center.
DESCRIPTION: To create the Podcast Pearl, one of the Assistant Chiefs of Service (chief residents) helped the resident presenter identify the salient teaching points from the morning report, and then conducted a brief 1–2 min interview with the resident using a digital recording device. These recordings were edited using freely available software (iTunes, Wavosaur), converted into 6–8 min MP3 recordings, and sent via secure intranet to residents and teaching faculty weekly. After 4 months of use, the residents and teaching faculty were surveyed to examine utilization patterns, educational impact, satisfaction, and degree of connectedness to the residency program.
EVALUATION: 30 out of 57 residents (53 %) and 18 out of 49 (37 %) of teaching faculty responded to the survey. 26.6 % of residents reported they attended morning report more than 70 % of the time. 70 % of residents reported using the Podcast Pearl, with 23 % using at least half of the recordings. 60 % of residents who listened to the Podcast Pearl used a computer, 35 % used a smartphone, and 10 % used a tablet. 100 % of residents who used 1 or more Podcast Pearls and who were not able to attend morning report (due to ICU rotations, vacation, etc.) reported that they learned something new. 46 % reported they learned something new "often" or "always". 100 % of teaching faculty who responded to the survey reported using 1 or more of the Podcast Pearls, with 56 % reporting using at least half of the recordings, and 17 % reporting using all available recordings. Faculty were more likely than residents (94 % vs. 60 %) to use a computer to listen to the Podcast Pearl. 56 % of faculty reported that the Podcast Pearl improved their learning. 94 % of faculty reported that listening to the Podcast Pearl made them feel more connected to housestaff. 78 % of faculty strongly agreed that educators should integrate technology into residency curricula.
DISCUSSION / REFLECTION / LESSONS LEARNED: A brief, weekly recording of teaching pearls from daily morning reports within an internal medicine residency program was a popular educational tool among both residents and teaching faculty. Residents tended to be more likely to use smartphones and tablets to listen to the educational recording, whereas faculty were more likely to use computers. The Podcast Pearl was an effective educational supplement for residents unable to attend morning report. This recording made nearly all faculty feel more connected to the residency program. Though further study of objective educational outcomes is needed, a brief weekly recording of teaching pearls in the form of a "podcast" is a satisfying educational supplement for residents and faculty.

PUBLIC NARRATIVE AS A TOOL TO PROMOTE TEAM-BASED CARE Rachael E. Bedard[1,2]; Rachel Stark[1,2]; Elizabeth Gaufberg[1,2]. [1]Cambridge Health Alliance, Cambridge, MA; [2]Harvard Medical School, Cambridge, MA. (Tracking ID #1643075)

NEEDS AND OBJECTIVES: Healthcare organizations across the country are undergoing significant changes to become Accountable Care Organizations and Patient-Centered Medical Homes. A key transformation is the transition to a team-based model of care that requires a new approach to leadership. How to best integrate internal medicine residents into this team-based structure remains a challenge. Our project provides a tool to help practicing clinical teams work together effectively by sharing the strategy of Public Narrative. Objectives: -To teach participants the leadership art of Public Narrative -To teach elements of effective story-telling and invite participants to practice the art of story-telling with their clinical team members -To assess the impact that training in Public Narrative has on team identity and efficacy
SETTING AND PARTICIPANTS: The Cambridge Health Alliance (CHA) is an integrated public healthcare system comprised of three hospital campuses and an extensive primary care network. Public Narrative workshops are held with practicing clinical teams (comprised of primary care physicians, resident providers, nurse practitioners, nurses, medical assistants, front desk staff) at CHA's three teaching ambulatory practice sites. Participating teams include at least two internal medicine residents.
DESCRIPTION: Public Narrative, developed by Marshall Ganz at the Kennedy School of Government, is the art of translating values into action. Individuals engage in public narrative to interpret themselves to one another, to forge a sense of shared community, and to inspire their community to action. The process involves learning to tell a "story of self", a "story of us", and a "story of now". We believe Public Narrative is a tool that can be leveraged for change in healthcare settings at multiple organizational levels. Participating care teams attend a 3-hour workshop during which they are introduced to the concept of public narrative and review its theory and practice. They then craft and share 'stories of self' in small groups by being prompted by the question "why do you do the work you do?". In developing their stories, participants find opportunity to explore and articulate core values. In hearing others' stories told, participants find that they share motivations for their work and are energized by the emergence of common themes. A large group discussion builds on these commonalities as a foundation for crafting a "story of us". Participants are then encouraged to think about their "story of now", the challenges they face as a community that demand urgent action.
EVALUATION: Following the workshop, participants are surveyed about their experience. Three months later, the same team is asked again to reflect on their experience, the impact that it has had on their sense of "teamness", on team communication and on their team's ability to navigate challenges. Data collection for our first workshop is underway and will be available at the time of the SGIM meeting.
DISCUSSION / REFLECTION / LESSONS LEARNED: The workshop provides a rare opportunity for individuals who have worked side-by-side for years to connect in new and meaningful ways. Feedback has been consistently positive thus far. Public narrative is a useful strategy to engage individuals to begin to work across disciplines in teams in the ambulatory setting. Participating residents emerge from the workshop better prepared to become effective leaders in their current institution's transformations and in the team-based approach to care that will be the norm when they graduate.

REMEDY AT UCSF: A SUSTAINABLE STUDENT-RUN INITIATIVE Lily B. Muldoon[1]; Jessica Gould[1]; Jacob Mirsky[1]; Sharad Jain[1]; Hemal K. Kanzaria[2]. [1]UCSF School of Medicine, San Francsico, CA; [2]UCLA, Los Angeles, CA. (Tracking ID #1627410)

NEEDS AND OBJECTIVES: The US healthcare system annually discards over $200 million worth of medical equipment from operating rooms and spends additional millions in disposal costs. This translates to 33 lb of waste per patient per day. Many health professional students do not recognize the magnitude of this waste, or the extent of worldwide healthcare discrepancies. Remedy at UCSF (R@UCSF), an interdisciplinary service-learning program, reduces medical waste and health disparities through socially responsible supply redistribution. Medical supplies are recycled and delivered based on identified need to international and local projects that support under-resourced regions.
SETTING AND PARTICIPANTS: Founded by University of California San Francisco (UCSF) medical students in 2004, R@UCSF partners student volunteers from each of the UCSF health professional schools with nurses, medical assistants, midwives, operating room technicians and physicians working in under-resourced communities.
DESCRIPTION: R@UCSF provides a sustainable experiential curriculum for students to link essential medical supplies with underserved communities by recovering unused surplus at UCSF. Working with both hospital staff and resource-poor clinics, students first identify supplies that are often discarded due to federal regulations or procedural excess but remain in demand by recipient clinics. Students then hold educational sessions for staff to put unused medical supplies in 17 collection bins strategically placed throughout the hospital. Through the UCSF Interprofessional Health Education Program, R@UCSF recruits nursing, medicine, dentistry, and pharmacy students. New students partner with current members to collect, transport, and sort medical supplies. Students then coordinate supply redistribution with UCSF staff traveling to in-need clinics. The hands-on experience exposes new students to the magnitude of medical waste and

demonstrates which supplies recipient communities deem most useful. Students distribute supplies during summer volunteer projects and international fourth year rotations.

EVALUATION: Quantitative and qualitative evaluation to inform program improvement is on-going. Over 50 students from across disciplines have engaged in the program. R@UCSF surveys students to determine how the program has impacted travel-abroad experiences, formation of career plans, and potential for scalability outside of UCSF. For example, students have recently integrated the R@UCSF model at Kaiser Oakland Hospital; the long-term goal is to replicate this throughout the Kaiser system. The volume and type of collected supplies and donations to receiving communities are recorded. R@UCSF has donated over 26,000 lb of supplies in the past 4 years. From 2010 to 2012, the organization directly supplied health projects in over 20 countries.

DISCUSSION / REFLECTION / LESSONS LEARNED: Recognizing the need for interdisciplinary team building in health education, R@UCSF bridges each of the professional schools in a service-learning curriculum that recovers and redistributes medical equipment. Student participation is high, reflecting the desire of students to work in teams to engage in systems-based practice to help address real-world problems. Student enthusiasm, administrative support, storage space, and socially responsible donation are essential for success. The R@UCSF model can be implemented at other medical centers with the ability and responsibly to recover unused medical supplies and reduce waste and inequity worldwide.

RESIDENT ATTITUDES AS LEARNERS AND TEACHERS IN MEDICAL SIMULATION: A SURVEY STUDY FROM THE MASSACHUSETTS GENERAL HOSPITAL DEPARTMENT OF MEDICINE Lee Park; Ian Barbash; Ada Stefanescu; Katie Famous; Paul F. Currier. MGH, Boston, MA. (Tracking ID #1641375)

NEEDS AND OBJECTIVES: Mannequin-based simulation has been widely accepted across multiple specialties, but its routine use in internal medicine training has been limited. Our internal medicine residency has developed a mandatory simulation-based education curriculum for interns, facilitated by second and third year residents. Simulation has not yet been employed in an evaluative fashion in our program. This survey study was designed to assess resident attitudes toward medical simulation, characterize the experience of residents as facilitators and teachers during simulation, and to understand resident attitudes toward the possibility of simulation as an evaluative tool.

SETTING AND PARTICIPANTS: The simulation curriculum was composed of 8 ward emergency cases distributed over 4 one-hour sessions, and was administered to interns in four-week blocks. A total of 65 interns participated in the curriculum. A total of 38 s and third year residents facilitated the sessions and debriefings. The simulation sessions took place in the hospital's simulation laboratory.

DESCRIPTION: During each one-hour session, groups of 2–3 interns participated in two simulation cases, with ~15 min of active simulation and ~15 min of debriefing. The cases included congestive heart failure, COPD, gastrointestinal bleeding, alcohol withdrawal, hypertensive emergency, atrial fibrillation, myocardial infarction, and pericardial tamponade.

EVALUATION: An online survey tool was used (REDCap) to create and distribute an anonymous survey to all interns and residents who participated in the simulation sessions. The survey was distributed to the interns at the end of their simulation experience (at the end a 4 week block) and to the second/third year residents at the end of the entire simulation curriculum. Response rates were 69 % (45/65) for interns, and 95 % (36/38) for residents. Among the residents, 58 % (21/36) were PGY-2, and 42 % (15/36) PGY-3. Among the interns 95.6 % felt that simulation was a safe environment, and that they were better prepared to take care of patients after participating in simulation. The majority (73 %) of interns wanted to participate in simulation on a monthly basis during residency. More interns than residents thought that participation in simulation should be required (93 % vs. 69 %, $p=0.007$). Among the residents, 91.7 % thought that participating in the sessions improved their teaching skills, and 53 % felt that teaching via simulation should be a required experience during residency. Interns and residents agreed that the cases accurately represented actual clinical encounters (both 89 %). More interns believed that graduation from residency should require demonstrated competency in management of basic internal medicine cases (50 % vs. 78 %, $p=0.01$). Both interns and residents were concerned that evaluation during simulation would undermine the safe environment, and that it would not be a valid assessment of their clinical competency.

DISCUSSION / REFLECTION / LESSONS LEARNED: Internal medicine interns and residents enjoyed simulation and felt that participation should be required for all trainees. Interns felt that simulation helps them with clinical management, and residents felt that it improved their teaching skills. While both interns and residents felt that the simulation cases accurately represented actual clinical encounters, they had concerns about the use of evaluation during simulation. These concerns would need to be addressed if simulation is employed as an evaluative tool.

RESIDENT ENGAGEMENT IN QUALITY IMPROVEMENT THROUGH THE PATIENT-CENTERED MEDICAL HOME Thomas B. Morland[1]; Kathie Huang[1]; Alithea Gabrellas[1]; Nicholas Leon[2,1]; Judy A. Shea[1]. [1]University of Pennsylvania, Philadelphia, PA; [2]Jefferson School of Pharmacy, Philadelphia, PA. (Tracking ID #1639039)

NEEDS AND OBJECTIVES: The Patient-Centered Medical Home (PCMH), Ambulatory Intensive Care Unit (A-ICU), and Accountable Care Organization (ACO) are expanding the role of primary care. It is unclear to what degree internal medicine programs are preparing residents to function within these emerging healthcare structures. The objective of this study is to document residents' baseline knowledge, attitudes, skills and behaviors related to emerging healthcare structures and to demonstrate the feasibility of a curriculum to improve resident performance.

SETTING AND PARTICIPANTS: Junior residents in the primary care-internal medicine program at the University of Pennsylvania were recruited to participate. A total of six residents constituting an entire class of the program enrolled.

DESCRIPTION: Residents were administered a survey assessing their knowledge and attitudes related to the PCMH and ACO. Participants attended a lecture covering key concepts of the PCMH, ACO, and A-ICU. To assess residents' skills and behaviors, residents worked to improve three quality improvement metrics drawn from elements of the PCMH certification process. To address the PCMH standard of providing self-care support to patients, residents were asked to enroll patients in a resident-run A-ICU. Patients had to be consented prior to enrollment. In the A-ICU, care plans were created to achieve both patient and provider goals. The plan was to be followed through by a team of 2 resident doctors and a pharmacist with supervision from an attending physician.

EVALUATION: Six residents completed the baseline survey. Although all residents had heard of the PCMH, none could reliably distinguish the PCMH from the ACO. Residents reported low-to-moderate preparedness to lead a modern primary care practice. The baseline quality metrics included rates of colonoscopy and enrollment of patients in the electronic portal. Response times to results in the electronic inbox were also tracked. At baseline the colonoscopy rate for the residents' panel was 62 %, and 23 % of patients were enrolled in the electronic portal. No resident on an outpatient rotation had more than 1 result in the electronic inbox which remained unviewed after 48 h. Residents received individual quarterly feedback reports on the key metrics. They were also expected to participate in quarterly update meetings with the program director and other residents. During these meetings, they were asked to present an update on one of their A-ICU patients or discuss their work on a key quality metric.

DISCUSSION / REFLECTION / LESSONS LEARNED: Baseline survey results indicate that residents lack knowledge regarding the details of emerging healthcare structures and have low confidence in their preparedness to lead a modern primary care practice. We test the feasibility of implementing a formal curriculum to teach residents the knowledge,

attitudes and behaviors they will need to be leaders of a future healthcare system based in an expanded role for primary care. Increasing exposure of trainees to the PCMH and other emerging primary care structures will be necessary to improve the pipeline for primary care and to nurture leaders for a reformed healthcare system.

SAFE MED RECONCILIATION (SATISFY PATIENTS USING A MEDICAL RESIDENT EDUCATIONAL INTERVENTION TO IMPROVE OUTCOMES) Jessica Logan[1,2]; Cherinne Arundel[2]; Rebecca Swenson[2]; Hanna Mariani1. [1]George Washington University, Washington, DC; [2]Washington DC VA Medical Center, Washington, DC. (Tracking ID #1640995)

NEEDS AND OBJECTIVES: The ACGME has mandated teaching quality improvement concepts to medical trainees. Our aim is to improve the accuracy of medical reconciliation by doing a real-time, experiential learning curriculum on medication reconciliation and quality improvement. The learning objectives of our intervention are: -Recognize the relevance of proper medication reconciliation -Demonstrate accurate discharge medication reconciliation -Recognize trainees' role in System-Based and Practice-Based Learning and Improvement -Apply quality improvement principles to the medication reconciliation process

SETTING AND PARTICIPANTS: This project is a two part learning session held bimonthly during morning report. Morning report is attended by residents, interns, and medical students from three university based programs (George Washington University, Georgetown University, and Uniformed Health Services).

DESCRIPTION: In the first session, the importance of medication safety is highlighted using a case in which a serious medication error occurred. A literature review and internal data on medication errors is presented. Trainees learn how to perform a proper discharge medication reconciliation, and an instructional pocket card is provided. In the second session, the principles of quality improvement are introduced in individualized team based small group discussions. The facilitators discuss principles of quality improvement, help the team develop an aim statement, and gather ideas on continual improvement and sustainability of the project. The teams assess their own medication reconciliation performance using a self evaluation rubric at the start and end of the educational intervention. Suggestions for improvement by the residents are incorporated for continuous project enhancement.

EVALUATION: The accuracy of discharge instructions pre- and post-intervention will be compared using a predetermined scoring system with chi-squared analysis. Pre-intervention data on the accuracy of medication reconciliation has been collected and scored. We are also soliciting continuous feedback from learners for continuous project improvement.

DISCUSSION / REFLECTION / LESSONS LEARNED: This educational intervention should result in more accurate patient medication lists at discharge and increased patient satisfaction. It is our hope that this will lead to a decrease in readmissions and morbidity/mortality due to medication errors. In addition, with the advent of the ACGME milestones, quality improvement has become an important educational topic. The milestones mandate that residents "engage in a quality improvement intervention," and this innovation will allow them to engage in such a project. We have encountered several challenges in the implementation stage including finding the right format to engage an ever changing group of learners with varied "switch" dates among academic institutions, engaging learners who have participated in the curriculum before, and involving all stakeholders in the medication reconciliation process.

SELF-ASSESSMENT OF PERFORMANCE: A NOVEL CURRICULUM FOR QUALITY IMPROVEMENT EDUCATION Kartik K. Patel; David A. Wininger. The Ohio State University, Columbus, OH. (Tracking ID #1639945)

NEEDS AND OBJECTIVES: The ACGME mandates the inclusion of practice-based learning and improvement education in GME training program curricula. Trainees must demonstrate the ability to "continuously improve patient care based on constant self-evaluation…" The Self Assessment of Performance (SAP) curriculum was designed to meet these requirements. The objective of this educational program is to enrich routine inpatient care with real-time assessment of quality performance and to develop skills in designing effective quality interventions.

SETTING AND PARTICIPANTS: Internal medicine residents rotating through General Medicine (GM) four-week inpatient blocks participate in the SAP curriculum. There are 10 participants each block. While all trainees (n=140) are eligible to participate, the curriculum is used by 4 of 5 GM services. By the end of the academic year, 95 unique residents will have participated.

DESCRIPTION: The four-week SAP curriculum starts by instructing trainees to build a registry of patients they encounter during the first 2 weeks of the block. Residents are expected to have at least 25 patients on their registry. At the start of week 3, each participant is assigned a quality metric and instructed to perform a chart review on their registry of patients. To complete their self-assessment, they calculate a SAP score: number of eligible patients compliant to the metric/total number of eligible patients. Five metrics have been developed for the curriculum: Same day discharge summary; verified code status order; appropriate DVT prophylaxis for low risk patients; pneumococcal vaccination for eligible patients; and discharge summary sent to next care provider. All metrics were designed to be applicable to GM patients, and be easily captured from chart review. The metrics assignment email includes background information, instructions for chart review with screen shots of the EMR, and a data reporting worksheet. The worksheet also contains three questions used for reflection: How would you improve your personal performance? How would you improve performance across the medical center? Do you agree or disagree that your metric represents quality care and why? In the 4th week, a faculty instructor precepts the final meeting where the SAP score results and ideas for improving are discussed as a group. The meeting is scheduled for 30 min to mitigate conflict with clinical time. All participants are required to submit a completed worksheet by the end of the block.

EVALUATION: Residents are provided feedback at the final meeting regarding the efficacy and feasibility of their proposed interventions, and the thoughtfulness of their metric critique. Average SAP scores ranged from 39.1 % (DVT prophylaxis) to 94.9 % (timely DC summary). The SAP curriculum was generally well accepted by housestaff. Over the first 6 blocks, 98 % of trainees completed the basic requirements. 88.9 % of participants agreed or strongly agreed that the exercise would affect their patient care in the future. 90.7 % and 92.6 % favorably rated (agreed or strongly agreed) the ease of creating the patient list and the ease of performing the chart review respectively.

DISCUSSION / REFLECTION / LESSONS LEARNED: A key feature of the SAP curriculum is the opportunity for residents to assess their individual performance in real-time using their own patients. Performance can be tracked over time as trainees rotate through each year. The SAP curriculum can be modified to include rotations outside of GM. A formal tool to quantitatively evaluate performance and give feedback is being developed.

SHARED MEDICAL APPOINTMENT CURRICULUM FOR INTERNAL MEDICINE RESIDENTS IN A SAFETY-NET HEALTH CENTER Katherine Lupton[1,2]; Michelle E. Hauser[1,2]; Barbara Ogur[1,2]. [1]Cambridge Health Alliance, Cambridge, MA; [2]Harvard Medical School, Boston, MA. (Tracking ID #1642170)

NEEDS AND OBJECTIVES: Changes in the primary care landscape—incorporation of new technologies into healthcare, transformation to team-based medical care, and new payment structures—increasingly require physicians to be facile with models of care delivery beyond the traditional 1:1 office visit. Shared medical appointments (SMA), also called group visits, are a well-described innovative format for providing care for chronic disease, and many primary care doctors are incorporating them into their practice. The skills necessary for success in the group setting, however, are often not part of residency training and must be learned independently or in venues outside the training environment.

SETTING AND PARTICIPANTS: The Cambridge Health Alliance internal medicine residency curriculum was recently redesigned to provide increased focus on skills needed in the ambulatory setting. Internal medicine residents now follow a 2+4 schedule, spending 2 weeks on ambulatory—including 4 weekly continuity sessions—alternating with 4 weeks of traditional inpatient and elective rotations. The Windsor Street Health Center, a safety-net community health center serving a large underserved and immigrant population in Cambridge, MA, is a new continuity site for residents. Many providers at Windsor Street are experienced with SMAs, having successfully conducted SMAs for low-income and non-English speaking patients on topics ranging from diabetes to men's health to buprenorphine therapy for opioid addiction. Each continuity resident at Windsor Street will participate in the SMA curriculum.
DESCRIPTION: We have developed and are currently piloting a curriculum to teach SMA skills to internal medicine residents. Beginning in the PGY2 year, residents will attend didactics and complete core readings outlining SMA principles. They will then spend several months observing SMAs conducted by experienced faculty while they work individually or in groups to design a SMA group focus that fits their clinical interests. Residents will recruit a core group of patients to their SMA groups, and by the end of the PGY2 year will begin to conduct SMAs that will continue for the remainder of their residency. Residents will be observed by and receive feedback from experienced faculty, and there will be reflection sessions to discuss the experience of conducting SMAs and get help with any issues that arise.
EVALUATION: Residents will complete a questionnaire before beginning the SMA curriculum examining their knowledge of and attitudes toward SMAs, familiarity with how SMAs are planned and conducted, issues best addressed in the group setting, and their confidence in skills necessary to conduct SMAs. They will take the same questionnaire after completing the didactic and observation portions of the curriculum, and again after gaining experience conducting SMAs. Objective patient measures such as hemoglobin A1c, weight or smoking status will be examined pre- and post-SMA participation where appropriate.
DISCUSSION / REFLECTION / LESSONS LEARNED: An initial pilot by one resident has proven successful with patients and was assessed as educationally valuable by the resident. Questions that have arisen to date include how to carve out time to plan and conduct SMAs in addition to residents' regular clinic duties, how to ensure appropriate supervision and feedback on residents' SMA implementation, and how to incorporate patient experiences and feedback into resident evaluations.

SIGN-OUT: A BRIEF EDUCATIONAL INTERVENTION AND ANALYSIS Kevin D. Hauck; Lauren Shapiro. Montefiore Medical Center, Bronx, NY. (Tracking ID #1641791)

NEEDS AND OBJECTIVES: Failure to give complete sign-outs during clinical handoffs is a potential source of patient harm. Duty hour restrictions have increased the number of handoffs that occur between primary and covering residents, and highlight the need for high quality sign-outs. This study examined the effect of an hour-long educational intervention on sign-out quality. The intervention was adapted from a previously developed curriculum that preliminary testing showed to be well received and increase resident comfort with the sign-out process.
SETTING AND PARTICIPANTS: Participants were interns and residents on an inpatient medical service at Montefiore Medical Center. The intervention took place during an hour usually reserved for clinical education.
DESCRIPTION: This hour-long educational intervention consisted of a lecture supported by a slide presentation and behavior modeling. The lecture component emphasized the importance of a standardized sign-out format, and thorough, 360-degree communication between day and night residents. There was additional time provided for the participants to practice thorough sign-outs in pairs with a trained moderator. Finally, the intervention was summarized in an easy to remember mnemonic (SIGNOUT) that participants learned to incorporate into their sign-outs.
EVALUATION: Eight days of sign-outs between day and night residents on the internal medicine teaching service at Montefiore Medical Center were audiotaped and any written components collected. Four days of data were collected before the intervention, and four after. To assess sign-out quality, investigators adapted a previously evaluated 6-component coding scheme which included a patient's clinical condition, code status, recent or scheduled events, anticipatory guidance, tasks to be completed, the presence of a plan and rationale for any task assigned and a global assessment of the sign-out's quality. A total of 534 sign-outs were evaluated; 16 sign-outs had missing data and could not be coded. Four hundred forty-nine sign-outs contained both written and verbal elements; 29 were written only. The overall quality and completeness of the sign-out did not significantly change after the intervention. The clinical condition, code status, recent/scheduled events and global assessment were significantly more likely to be included in the sign-out before the intervention.
DISCUSSION / REFLECTION / LESSONS LEARNED: This one-hour educational intervention did not improve the quality of the sign-outs. The sign-outs were collected during the same month with the same primary interns, with 4 days in the first 2 weeks and then 4 days in the last 2 weeks. Thus fatigue among residents in the post intervention 4 day period of the study may have accounted for some of the decrease in quality. Performing high-quality sign-outs requires several different skills including superior communication and organization. A single hour session may not be long enough to impart these skills and improving sign-out quality may require a longer, more intense intervention. While previous research has shown that a one-hour intervention increased comfort with sign-outs, our study suggests that it does not increase quality. Future research should focus on developing more potent educational interventions.

TEACHING ADVOCACY: A MODEL FOR CLINICAL SKILLS DEVELOPMENT AND HUMAN RIGHTS-BASED SERVICE LEARNING Luis Villegas[1]; Taryn Clark[1]; Margaret Fabiszak[1]; Terri G. Edersheim[3]; Joanne Ahola[1]; Nicole Sirotin[2]. [1]Weill Cornell Medical College, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Weill Cornell Medical College, New York, NY. (Tracking ID #1642204)

NEEDS AND OBJECTIVES: Over 400,000 foreign-born torture survivors live in the United States; approximately 20 % of them reside in the New York metropolitan area. Over the previous year, New York City has experienced a significant increase in the number of asylum applications filed, indicating a potential rise in the number of torture survivors. Approximately 10–15 % of foreign-born patients who present to urban primary care centers and emergency departments are survivors of torture; however, few are recognized as such by healthcare professionals. Article 10 of the UN Convention Against Torture states that education on torture should be included in all medical training. The American College of Physicians and the US government have ratified this declaration, but few medical schools include any formal training or education on torture as part of their curriculum.
SETTING AND PARTICIPANTS: The Weill Cornell Center for Human Rights (WCCHR) was established in 2010 to educate medical students on the health sequelae of physical and psychological torture, while performing medical evaluations of torture survivors seeking asylum.
DESCRIPTION: WCCHR is the first medical asylum evaluation clinic in the United States to be founded, directed, and run by medical students. WCCHR partners with Physicians for Human Rights to perform medical, psychological and gynecologic evaluations for torture survivors who seek asylum. Through WCCHR, first and second year students have their first contact with patients, learn basic history-taking as well as focused physical exam skills, including gynecologic exams and learning how to characterize scars. The students also engage in diagnosing psychological conditions, such as Post Traumatic Stress Disorder and Major Depression, in these patients. The students learn vital advocacy skills, such as writing medical affidavits, used in the legal process of gaining asylum.
EVALUATION: WCCHR has trained 116 medical students, including 84 from Weill Cornell Medical College (WCMC) and 32 from Columbia University. The center holds two trainings per year, and students, as well as

faculty from other institutions (including UPenn, UCLA, and NYU) have participated. WCCHR has completed 95 evaluations for 84 clients from 35 different countries. As of December 2012, 67 WCMC students have attended at least one asylum evaluation, 29 have attended at least two, and 13 have attended three or more. A questionnaire administered to 32 medical students trained in 2012 revealed 88 % were likely to do another evaluation, 97 % would recommend WCCHR to a colleague, and 53 % planned to conduct asylum evaluations after graduation.

DISCUSSION / REFLECTION / LESSONS LEARNED: WCCHR is a novel, interdisciplinary model for teaching both clinical skills and human rights training to medical students in the pre-clinical years. This model will serve to create a workforce of physicians who are trained in these important skills and contribute to this work throughout their lifetime, regardless of specialty. In addition, the students learn valuable clinical skills in a safe, service-oriented environment. WCCHR is a truly interdisciplinary program; students learn medical, psychological and gynecological clinical skills while collaborating with physicians, community-based organizations and attorneys in advocacy work.

ONLINE RESOURCE URL (OPTIONAL): http://wcchr.com

TEACHING ELECTRONIC PATIENT-DOCTOR COMMUNICATION USING A PATIENT WEB PORTAL Bradley H. Crotty; Arash Mostaghimi; Bruce E. Landon. Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #1642385)

NEEDS AND OBJECTIVES: Patients frequently use secure web portals to access their medical record and communicate with their doctors. Few institutions, however, train residents on best practices for electronic communication or provide opportunities for electronic communication with patients. We aimed to create an electronic communication curriculum for residents using PatientSite, a web-based patient portal, and to explore resident attitudes toward online communication over an academic year.

SETTING AND PARTICIPANTS: This intervention was created and implemented at Beth Israel Deaconess Medical Center, Boston, MA. Residents who practiced at the hospital based primary care site (n=125/159) were enrolled in the PatientSite portal. All medical residents were eligible to participate in the didactic components. Patients must enroll in the portal through an eligible provider, and can then access their medical information, order med refills, and send messages to their clinician.

DESCRIPTION: We designed the curriculum based upon a review of the literature of patient portal experiences and best practices. All residents participated in a lecture and a small group discussion; those at the hospital based primary care site also had experiential learning through PatientSite. The major domains covered were: Patients, The Patient Experience, The Provider Experience, and Systems-Based Practice. The lecture covered an overview of portal functionality and usage, while the small group discussion focused more on developing skills to respond to patient concerns and use the communication tool effectively. Equity in access and health literacy were addressed in both sessions. The practice did not make any attempt to notify patients that they were eligible to enroll in the portal and individual residents varied in promoting the site to their patients. Faculty preceptors were automatically copied on all messages sent to residents as a redundancy feature.

EVALUATION: Residents were surveyed at the beginning and end of the intervention regarding perceived benefits and burdens of using a web portal for patient communication. In the pre-intervention survey, the majority of residents felt that the portal would increase work for providers but would benefit patients. The survey also revealed that 53 % of residents had already used email to communicate with their patients. Almost 75 % of surveyed residents were concerned about medical liability. Post-intervention surveys demonstrated statistically significant changes in areas of provider workflow (Agree +20 % p=0.04), patient care delivered (Agree +38 % p<0.01) and patient empowerment (Agree +18 % p=0.02) among those residents who used the portal. Usage statistics were recorded from the patient portal. Residents enrolled 424 patients, 26 % of whom emailed their resident at least once. Six residents (14.6 %) reported that they had missed or delayed responding to a patient's message, and four (9.8 %) reported that they had received an inappropriately urgent message.

DISCUSSION / REFLECTION / LESSONS LEARNED: Implementing a patient web portal and secure messaging in a residency clinic is feasible, and may improve the work and educational experience of trainees, better preparing them for real-world practice. Residents remained concerned about medical liability from inappropriately urgent messages, and about 1/10 residents reported receiving such a message. Clinic supervision policies appear warranted. Our next step will be testing an assessment tool for faculty to use when reviewing resident-patient exchanges to facilitate feedback.

TEACHING ESSENTIAL SKILLS: TRAINING MEDICAL STUDENTS IN QUALITY IMPROVEMENT, PROCEDURES, AND TRANSITIONS OF CARE Saumil Chudgar; William C. McManigle; Aubrey Jolly Graham; Jonathan Bae; Noppon P. Setji; Cara L. O'Brien. Duke University School of Medicine, Durham, NC. (Tracking ID #1641002)

NEEDS AND OBJECTIVES: Medical school educators are charged with providing students the tools needed to succeed as physicians. After 4 years, trainees begin residency with a knowledge base shaped by individual experiences and with an awareness of both strengths and potential gaps in preparation. At the our institution, four areas—overnight patient care ("cross-cover"), consultative General Internal Medicine, hands-on experience performing procedures, and an understanding of quality improvement in medicine—are areas in which additional training can be provided in an effective, efficient manner. The overall objective is to determine whether introducing a selective in Hospital Medicine and Quality Improvement provides students a way to grow their understanding of these crucial topics.

SETTING AND PARTICIPANTS: A new clinical selective was approved for second-year medical students at the Duke University School of Medicine. Students are required to have successfully completed the eight-week core Internal Medicine rotation prior to registration. Five students have participated to date.

DESCRIPTION: The selective exposes students to overnight cross-coverage care and emergencies, common bedside procedures (thoracentesis, paracentesis and lumbar puncture), training in consultative General Medicine, practice with patient care transitions, and an introduction to quality improvement in healthcare. Students completed optional pre-rotation and post-rotation confidence and knowledge assessments. Self-reported confidence was reported using a five-point Likert-type scale. Students were directly observed and given feedback on transitions of care by practicing physicians. Data were analyzed using the paired t-test. IRB exemption was obtained.

EVALUATION: Post-rotation confidence improved in management of cross-cover emergencies including chest pain, dyspnea, hyperglycemia, altered mental status, and responding to alert laboratories (p<0.05). Similar improvement in confidence was seen in common General Medicine consultation diagnoses, encompassing cardiac risk assessment, hypertension, anemia, acute kidney injury, and delirium (p<0.05). Students' ability to explain risks of and describe the techniques to perform a thoracentesis and paracentesis improved as well (p<0.05), though this was not true for lumbar puncture (p>0.05). Confidence in delivering clear, concise verbal handoffs of care (p<0.05) also improved. Significant improvement was seen in developing a quality improvement project, writing an aim statement, and using a PDSA cycle to document a test of change (p< 0.05). All students scored 100 % on the post-rotation knowledge assessment of quality improvement principles.

DISCUSSION / REFLECTION / LESSONS LEARNED: These data frame evidence of an effective, novel medical school curriculum. Early results indicate a promising combination of improved clinical knowledge, improved procedural skills, and improved confidence in areas such as quality improvement and transitions of care that have increasing recognition of importance in the medical school curriculum. Medical student training requires an increased and earlier emphasis on clinical skills and understanding of quality improvement to improve patient safety and care. By beginning this training earlier in medical school and in a directed manner, it provides a framework for a more competent and confident healthcare provider.

TEACHING MEDICAL STUDENTS TO REFLECT "DEEPER" Amy C. Hayton; Raymond Wong; Ilho Kang; Lawrence Loo. Loma Linda University, Loma Linda, CA. (Tracking ID #1628510)

NEEDS AND OBJECTIVES: While many studies have examined the importance of reflective writing in medical education, there is a paucity of research evidence for any particular intervention to improve the quality or "depth" of reflection among medical students. To facilitate the development of critical reflection, a new curriculum enhancement was introduced during the third year of medical school. Prior to the intervention the students were given a written reflection assignment with no explanation of critical reflection. The objectives of this curriculum were to impart the importance of reflection, define critical reflection, identify the components of critical reflection, and produce a written critical reflection paper.
SETTING AND PARTICIPANTS: Participants included all medical students rotating through their required junior Internal Medicine (IM) ten-week clerkship at the Loma Linda University School of Medicine.
DESCRIPTION: A ninety-minute interactive teaching session on critical reflection was introduced at the start of each rotation. Key components included: ●A 4 minute video from the popular TV show Scrubs, highlighting a young doctor's reflection experience of a patient facing death. ●A large group discussion of the key concepts and core components of critical reflection. ●A small group interactive exercise where students compared and contrasted three essays portraying different levels of reflection. Each small group reported their findings to the larger group. ● A faculty presenter shared a personal reflection critical to her own professional development. During the course of each ten-week rotation, students were asked to write two reflection papers about a clinical experience.
EVALUATION: A previously validated tool, the REFLECT rubric, was used to grade the written reflection papers as either nonreflective (=1), thoughtful action (=2), reflection (=3), or critical reflection (=4). Students were credited with completion of the assignment after submitting their papers. The REFLECT rubric grades were not used to evaluate the students but rather as a means to evaluate the curriculum intervention. Sixty-seven reflection papers after the intervention were compared to sixty reflection papers written prior to the intervention. To minimize bias and blind the four faculty graders, names and dates were removed from each typed reflection paper. Differences in grading were discussed and consensus was reached. The primary analysis showed that the number of students writing "critical reflection" papers increased after the educational intervention, from 15 % (9/60) to 42 % (28/67) $p=0.0012$. The kappa statistic used to measure inter-rater reliability was found to be "slight to moderate" at 0.37.
DISCUSSION / REFLECTION / LESSONS LEARNED: In the initial analysis, our ninety-minute educational intervention successfully improved the depth of reflection by increasing the number of students who wrote "critical reflection" papers as measured by the REFLECT rubric. Strengths include the number of faculty evaluators and their blinding that minimized bias in grading. The low inter-rater reliability highlighted a significant limitation of the REFLECT rubric which may limit the applicability of our results to other institutions. We believe this curriculum enhancement could readily be adapted to a clerkship seeking to enhance student reflection and ultimately promote educational activities that foster lifelong learning.

TEACHING PATIENT-CENTERED USE OF THE ELECTRONIC MEDICAL RECORD Wei Wei Lee; Lollita Alcocer. University of Chicago, Chicago, IL. (Tracking ID #1642502)

NEEDS AND OBJECTIVES: When electronic medical records (EMRs) are used during clinic visits, they can be viewed as an obtrusive "third party" in the doctor-patient interaction. Over the past decade, EMR use in clinic visits have become the norm. Preliminary studies demonstrate that EMR use in exam rooms can prevent physicians from focusing on patients and may be detrimental to the doctor-patient relationship. Currently, there is no curriculum at the University of Chicago that teaches students how to optimize EMR use to build relationships with patients. Our objectives are to: 1) Identify best practices in patient-centered EMR communication and teach these skills and behaviors to medical students through an interactive lecture. 2) Develop an OSCE to allow students to practice patient-centered use of EMR skills. 3) Evaluate the impact of the lecture and OSCE on students' knowledge and skills.
SETTING AND PARTICIPANTS: We will deliver an interactive lecture on patient-centered use of the EMR to all second year students ($n=88$) as part of their required Clinical Skills Course. They will also be required to participate in an OSCE to practice these skills.
DESCRIPTION: We developed an interactive lecture on how to conduct patient-centered interviews while engaging patients with the EMR. Our lecture outlines the problem, reviews the literature and identifies best practices. We screen a teaching video depicting a poorly conducted patient interview to stimulate discussion. Students reflect on the video and fill out a checklist on barriers related to communication, behaviors and patient-doctor relationship. We then introduce a toolkit with our "Best Practices" and "Ten-tips" for patient-centered EMR use. Each student is given a pocket card summarizing the main teaching points, behaviors and skills. At the conclusion of our lecture, we role-play a clinic visit to demonstrate an improved patient-doctor-EMR interaction using the tools and tips we introduced. After the lecture, the students participate in an OSCE to evaluate their patient-centered use of the EMR skills. We developed a Clinical Evaluation Exercise (CEX) tool for preceptors and observing students to use in rating the student's performance. Standardized patients also fill out an evaluation form to rate their satisfaction with the student's communication skills, with a focus on EMR integration.
EVALUATION: 1) We will distribute a pre and post-test at the lecture to evaluate impact on student knowledge and attitudes. 2) The OSCE allows us to evaluate students' skills in patient-centered EMR use. The CEX tool allows observing students and faculty to rate the student's performance. 3) The standardized patient's evaluation will also be used to assess the student's skills. 4) To assess the impact of our curriculum, we will use third year students who did not get the lecture on patient-centered EMR use as historical controls by having them participate in the same OSCE. We will compare their scores on the CEX tool and standardized patient evaluations with those of the second year students who did received the lecture.
DISCUSSION / REFLECTION / LESSONS LEARNED: Our project on patient-centered EMR use is innovative and timely and addresses an existing gap in medical education. This curriculum can be adapted for residents and practicing physicians in the future and has the potential to improve the integration of technology in a patient-centered manner. We believe that teaching students these skills early on will help to improve their relationships with patients in their clinical practice.

TEACHING TRANSITIONS OF CARE THROUGH ANALYZING READMISSIONS Kara Bischoff; Aparna Goel; Jayson Morgan; Michelle Mourad; Sumant Ranji. UCSF, San Francisco, CA. (Tracking ID #1634621)

NEEDS AND OBJECTIVES: Nearly one in five Medicare patients are readmitted within 30 days of discharge from the hospital. Preventing readmission has become a central priority nationwide and many medical centers have developed multifaceted programs aimed at improving transitions of care and reducing readmissions. However, residents have not been fully utilized in these efforts and literature suggests improvements are needed in how we educate and employ residents in efforts to decrease readmissions. By engaging residents in analyzing their patients' readmissions, we aim to develop residents' practice-based learning and systems-based practice regarding transitions of care.
SETTING AND PARTICIPANTS: All PGY-2 medicine residents rotating on an inpatient wards month at University of California at San Francisco Medical Center, a 600-bed tertiary care hospital.
DESCRIPTION: Residents receive formal education about safe discharge practices for preventing avoidable readmissions during regularly scheduled noon conference didactics. Thirty days after completing a wards month, residents receive a list of patients discharged under their care who were subsequently readmitted to the hospital within 30 days. Using a structured tool, residents collect follow-up information on at least four of their

patients. In addition to reviewing the electronic medical record, residents are also expected to contact patients and their families, outpatient providers, and the readmitting team. Residents are responsible for recording patient outcomes, identifying systems issues and reflecting on how this review will impact their clinical practice. Residents share their results with their team members at either a team dinner or electronically on a shared "Portfolio" website. Residents receive informal feedback from the outpatient and inpatient providers who they contacted, and faculty mentors are responsible for providing comments for the resident on the "Portfolio" site.

EVALUATION: Residents' work is reviewed by their wards attendings and a four-member evaluation subcommittee. Residents receive feedback on their ability to execute safe transitions of care, as well as their process of analyzing readmissions and forming plans for improvement. They are scored on five relevant milestones and are awarded an overall level of entrustment based on their ability to safety execute transitions of care from the inpatient to outpatient setting.

DISCUSSION / REFLECTION / LESSONS LEARNED: In order to assess the value of this educational exercise, residents are asked to complete post-surveys. Preliminary results from the first 11 participants show that all residents believe that following up on their patients after discharge will lead to improvements in their care, most (73 %) are motivated to pursue a system change based on what they learned and nearly all (91 %) believe that this should be a required exercise for all residents. Through qualitative analysis of residents' work, the most commonly identified themes contributing to readmission are medication issues, the importance of timely outpatient follow-up and the need for advance care planning. Our results suggest that this is a valuable exercise that fills a current educational gap and can inform systems changes to improve care transitions.

TEAM-BASED EDUCATION FOR IMPROVING PANEL MANAGEMENT IN A PATIENT CENTERED MEDICAL HOME Anne Dembitzer[1,2]; Colleen Gillespie[2]; Lucas Dreamer1; Ashley E. Jensen[2,1]; Rachel Blitzer[2,1]; Katelyn Bennett[2,1]; Mark D. Schwartz[2,1]; Scott Sherman[1,2]. [1]NY Harbor VA, New York, NY; [2]New York University, New York, NY. (Tracking ID #1641516)

NEEDS AND OBJECTIVES: To maximize the benefits of the medical home (PCMH) model, staff needs to be well-trained in interdisciplinary teamwork, panel management, and staff-led quality improvement projects. Currently, few programs are in place to foster development of such capacities through team-based learning. To address these educational gaps, we created, implemented, and evaluated a tailored curriculum within VA's Patient Aligned Care Teams (PACT).

SETTING AND PARTICIPANTS: The educational intervention was part of the PROVE study (Program for Research on the Outcomes of VA Education) which sought to assess the impact of panel management on chronic disease outcomes through the addition of a non-clinical panel management assistant (PMA) to randomly selected PACT teams. Of the 12 teams allocated a PMA, six were randomly selected to participate in five, Twenty-minute education sessions over the nine-month intervention. Each PACT team met bi-weekly and included 1–5 Primary Care Providers (PCPs), a nurse (RN), a Licensed Practical Nurse, and a clerk.

DESCRIPTION: The curriculum was developed based on relevant literature and VA guidelines for PACT implementation. The case-based sessions were held during PACT team meetings. Sessions were facilitated by a MD and/or PhD education specialist and divided into 3 modules: working in multidisciplinary teams, practicing panel management, and leveraging the clinical microsystem. A case of a hypertensive patient with suboptimal medication adherence was presented in the first module and the team discussed role responsibilities and communication. The second module utilized panel data, a list of PCP's uncontrolled hypertensive patients were presented to enhance understanding of panel management. Teams discussed data quality, interpretation, and gaps and then prioritized a set of interventions. The third module addressed team motivation and barriers to population-based care within the microsystem. Discussions resulted in proposals for microsystem change including group visits and improved tracking of missed RN blood pressure appointments.

EVALUATION: Following the intervention, we surveyed the 44 PCPs and 17 RNs to assess the impact of the educational sessions (response rate 76 %). Survey items were rated on a 5-point Likert scale, and reported as the proportion that agreed or strongly agreed. Teams assigned to the intervention, participated in 1.5–2 h of education. Most participants felt that the education sessions promoted constructive discussion (63 %), creative problem solving (56 %) and brainstorming of panel management strategies (56 %). Half reported that the sessions offered time not otherwise available for panel management. About a third felt the sessions improved their understanding of team roles (38 %).

DISCUSSION / REFLECTION / LESSONS LEARNED: This brief curriculum appeared to enhance the ability of PACT teams to communicate and collaborate effectively, implement panel management and brainstorm microsystem ideas as a team. Surveys revealed sustained role confusion, barriers to PM implementation, and uncertainty about working as a team, highlighting areas for further educational intervention and quality improvement within PCMH models. By making use of existing meeting times and using team panel data at two busy outpatient clinics, this intervention demonstrates that it is possible to implement such a training program in a real world setting.

THE BEHAVIORAL MEDICINE TOOLBOX: EQUIPPING RESIDENTS WITH THE TOOLS NECESSARY TO NAVIGATE THE SOFTER SIDE OF MEDICINE Katherine J. Kueny; Rachel Bonnema; Emily Leasure. University of Nebraska Medical Center, Omaha, NE. (Tracking ID #1640449)

NEEDS AND OBJECTIVES: Though behavioral medicine is a specialty valued by many, educators might struggle to incorporate behavioral medicine topics into their curriculum, due to lack of time, resources, or other factors. Figuring out what behavioral medicine education should consist of, who is responsible for teaching the curriculum and finding the time to teach it, are a few of the many barriers that programs face. These are all barriers that we considered prior to implementing our new curriculum. Objectives: 1) To improve the residents' ability to conduct a patient-centered interview and use motivational interviewing techniques. 2) To improve residents' knowledge when assessing and treating psychosocial issues. 3) To enhance residents' confidence assessing and treating psychosocial concerns. 4) To provide a forum for residents to discuss concerns related to treating difficult patients. 5) To enhance the residents' ability to self-evaluate their patient care skills and provide constructive feedback to peers.

SETTING AND PARTICIPANTS: We initially developed one curriculum for 1st, 2nd, and 3rd year residents. The noon conference series is taught in a classroom setting. The behavioral medicine seminar is conducted in a seminar setting. Videotape reviews take place at our resident-run continuity clinic, which is a NCQA Level III certified patient centered medical home.

DESCRIPTION: This curriculum was designed to fill a gap in our residency program by equipping residents with a behavioral medicine "toolbox" to help them remember tools they can access when challenging patient encounters arise. Our curriculum was implemented in 3 phases. We first hired a behavioral medicine director and licensed mental health provider to provide residents with informal education in the clinic and on-site consultation with their patients. The second and third phases were the implementation of our formal curriculum. We chose to have a behavioral medicine expert, along with an MD, teach the curriculum to provide both perspectives. The second phase was the development of a behavioral medicine noon conference series that rotates through a variety of behavioral medicine topics. The conferences are hands on, utilizing role plays, videos, and interaction with the residents. During each noon conference, we provide new "tools" to add to the overall "behavioral medicine toolbox". The third phase of the curriculum was the implementation of a 4 week seminar that 3–4 residents would participate in once a week. The seminar includes didactic teaching, videotape reviews, and informal discussions guided by the particular needs of the residents.

EVALUATION: We utilized a pre- and post-test method to evaluate the seminar. We chose a knowledge questionnaire that was already validated, along with an efficacy questionnaire to assess the residents own confidence level with managing psychosocial concerns. We also have a general evaluation to evaluate the resident's overall experience of the seminar.
DISCUSSION / REFLECTION / LESSONS LEARNED: Lessons Learned: 1) A separate curriculum is needed for 3rd year residents. 2) We need to develop our own assessments to more adequatley assess our specific curriculum. 3) Having residents start videotaping prior to the seminar will allow us to hit the ground running. 4) Residents are often uncomfortable with viewing their encounters at first. We will tape a role play to view at the first seminar to ease their discomfort. 5) Seminars seem most conducive to 3–4 residents, and are not as effective with only 1–2.

THE COURTEOUS CONSULT: A POCKET CARD AND TRAINING TO IMPROVE HOUSE STAFF CONSULTS Lauren Peccoralo; Anna Podolsky; David T. Stern. Mount Sinai School of Medicine, New York, NY. (Tracking ID #1636401)

NEEDS AND OBJECTIVES: Communication and courtesy are important components of consultations, but little is known about the quality of physician trainee consults and no published interventions have improved these interactions. The goal of this study was to assess residents' views on the impact of consults on patient care and assess the impact of a pocket card on the quality of trainee consults.
SETTING AND PARTICIPANTS: Survey participants included all levels of physician trainees in all specialties at Mount Sinai School of Medicine in New York, New York (approximately 1000 eligible trainees). Training session participants included incoming first year residents (approximately 350 eligible trainees).
DESCRIPTION: From March to May 2011, we conducted an online pre-intervention survey (based on focus groups) about consultation interactions. Based on survey results, previous literature and guidelines, we developed a pocket "Consult" card and a training session for calling consults (the intervention). The forty-minute long training session included a 20 min didactic component 2 five-minute videos and ten-minute role-play scenario. The session was given to 300 incoming first year residents as part of hospital-wide orientation in June 2011. We evaluated the training session and card from October to December 2011 using online post-intervention surveys. Results were analyzed using descriptive and nonparametric tests.
EVALUATION: Three hundred ninety nine trainees (40 % response) responded to the pre-intervention survey. When asked to rate the impact of the consultation interaction on the following patient outcomes, participants reported a large impact on: timeliness of treatments (62 % of participants), timeliness of tests performed (57 %), appropriateness of diagnosis (56 %), discharge planning (49 %), and timing of discharge (43 %). Three hundred trainees (30 % response rate) responded to the post-intervention survey. After the training, trainees felt that the caller more often showed appreciation to the consult team (Mean [M]; 3.28(pre) vs. 3.50(post), $p=0.016$) and came to the bedside for evaluation (M; 2.4 vs. 2.7, $p=0.013$). In addition, 60 interns that attended the session responded to the survey (20 % response rate). These trainees felt more comfortable calling consults after the training session (M; 3.0 vs. 3 .45, $p<0.001$) and using the consult card (M; 3.25 vs. 3.4, $p<0.001$).
DISCUSSION / REFLECTION / LESSONS LEARNED: Trainees believe that consult interactions impact patient care and outcomes. Evidence suggests that our consult training intervention improved trainee comfort calling consults and may improve consult interactions especially regarding courtesy and in person interaction.

THE INTERNATIONAL SCHOLARS PROGRAM (ISP): BALANCING RESEARCH AND CLINICAL CARE. OUR TEN YEAR EXPERIENCE Peter D. Bulova; Adeel Butt; Shanta M. Zimmer. UPMC, Pittsburgh, PA. (Tracking ID #1635189)

NEEDS AND OBJECTIVES: To recruit an elite and internationally diverse group of medical graduates who have a clear ambition to pursue careers in academic medicine. To foster and enhance clinical, educational, and research relationships with medical schools throughout the world. To train future clinician-investigators to serve as key contacts and bridges for international collaboration in medical clinical research and medical education. To develop future leaders in research and academic medicine
SETTING AND PARTICIPANTS: Over the past 10 years we have recruited 4–6 International Medical Graduates per year who demonstrate promise in research careers or as academicians. We have now trained 34 residents in the program. Applicants are selected for excellence in clinical care as well as evidence of an interest in a career involving research. The residents are a part of a track within our categorical residency program, and at the end of the three-year training program, the ISP graduates are eligible to sit for the American Board of Internal Medicine (ABIM) Certification Examination. Clinical training in the ISP is similar to training in the categorical training program and conforms to all requirements of the Residency Review Committee and the ABIM. In addition, time is protected for ISP scholars to receive formal classroom or hands-on training in various aspects of clinical or basic science research.
DESCRIPTION: Residents participate fully in our traditional 3 year residency. In addition, they have 2 months of a clinical research methods curriculum. The classes are as follows: Clinical research methods. Statistical approaches in clinical research Computer methods in clinical research Measurement in clinical research. Ethics in clinical research Residents have a clinical mentor, an assigned general research mentor, and a research mentor chosen by the ISP scholar in their field of study. All participate in a monthly seminar series to discuss issues in research.
EVALUATION: All 34 Residents entered the program with an interest in Academics. They are from over 20 different medical schools in Austria, Brazil, China, Greece, India, Iran, Lebanon, Pakistan, and Peru. Thirty-two of the 34 graduates obtained fellowships at peer institutions, while all 34 continued in academics. All have successfully completed residency with a 100 % board pass rate. The number of publications per resident by the international scholars far exceeds that of categorical residents. For example, in 2011–2012 the international scholar residents averaged 2 publications in peer reviewed journals per resident (32 by 16 residents), compared with an average of 0.5 per categorical resident. The International Scholars as well as our Clinician Scientists have served as models for integrating research and scholarly projects into our clinical program.
DISCUSSION / REFLECTION / LESSONS LEARNED: The ISP has added diversity to our residency training program and enhanced the research mission without compromising the clinical mission of excellence in patient care. The residents found the integration within the general categorical program to be its most important component. Recruitment of talented scholars from around the world to a specific curriculum has created a successful model of academic training for international medical graduates seeking research careers in subspecialties of internal medicine.
ONLINE RESOURCE URL (OPTIONAL): http://www.residency.dom.pitt.edu/Program_Overview/tracks/isp.html

THE RESIDENT AS PRECEPTOR: INCORPORATING SUPERVISION OF MEDICAL STUDENTS IN THE AMBULATORY SETTING INTO A RESIDENCY CURRICULUM Sudha Dubey[1]; Robert Hirten[2]; Sheira Schlair[2]. [1]Beth Israel Medical Center, New York, NY; [2]Montefiore Medical Center of Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1638660)

NEEDS AND OBJECTIVES: Supervising students in the inpatient hospital setting has long been an important component of internal medicine residency training and reinforces residents' medical knowledge and teaching skills. However similar interaction between students and residents in the ambulatory setting is rare in academic training programs as is formal evaluation of resident teaching skills. Several studies have shown that junior attendings exhibit low confidence and competence in teaching skills, suggesting residency is an appropriate time for intervention. Our aim was to teach residents effective precepting skills in the ambulatory setting by providing a resident-as-preceptor curriculum followed by supervised medical student precepting sessions.

SETTING AND PARTICIPANTS: Senior internal medicine residents (n =11), fourth year medical students (n=11) and attending internal medicine physicians (n=6) at an ambulatory internal medicine teaching clinic at Montefiore Medical Center (Bronx, NY.)
DESCRIPTION: A resident committee at one ambulatory teaching clinic site performed an informal needs assessment that showed senior resident interest in developing ambulatory precepting skills. Clinic and residency administration buy-in was achieved for a pilot project of residents serving as preceptors in clinic sessions with fourth year medical students. A two-hour learner-centered, highly interactive curriculum focused on effective ambulatory teaching strategies, adult learning theory, and the one-minute preceptor model and RIME scheme was developed by two senior residents led by one faculty member. The residents were then assigned to precept medical students in the ambulatory medicine clinic for 1–2 sessions each supervised by an attending physician. A resident led the precepting encounter while an attending was instructed to silently observe the session and interject only if he/she disagreed with management.
EVALUATION: Resident preceptors, students and supervising attendings were surveyed to assess whether goals of precepting were met, as well as to assess learner satisfaction and overall precepting effectiveness. All questions were scored on a 1–4 Likert scale or open-ended qualitative format. Precepting goals included: 1. Eliciting the student's clinical reasoning and independently formed assessment and plan; 2. Teaching general principles that can be applied in future encounters; 3. Giving behaviorally specific positive feedback; 4. Correcting errors with specific feedback about how to improve; 5. Completing the encounter in a time-efficient manner. On preliminary review of the data, all groups felt that each of these goals were met. 55 % of residents and 33 % of attendings "strongly agreed" that the resident preceptors were able to elicit the student's reasoning, assessment, and plan, while the remaining 45 % and 67 % respectively indicated that they "agreed." Residents overall felt that they were comfortable in their role as preceptor (82 % indicated "agree" or "strongly agree") and that the experience had added educational value to their residency (73 % indicated "strongly agree" and the remaining 27 % indicated "agree.")
DISCUSSION / REFLECTION / LESSONS LEARNED: In an innovative resident-as-teacher initiative, senior medical residents found a brief learner-centered curriculum to be practical and precepting experience to be empowering. Learners and supervising attendings agreed that resident preceptors met teaching objectives effectively and residents found it to be a meaningful and educationally valuable component of their residency experience.

THE SIMULATED MEDICAL EDUCATION PROGRAM: NEW SENIOR BOOT CAMP Bridget B. Stiegler. Banner Good Samaritan Medical Center, Phoenix, AZ. (Tracking ID #1641009)

NEEDS AND OBJECTIVES: Restriction of resident work hours has prompted the need for supplementary forums wherein we educate and evaluate resident's ability to apply important internal medicine skills. In addition, there have been measurable changes in public expectation of how new doctors learn new skills. The shifting focus of patient advocacy groups towards quality improvement, the emergence of a more team-oriented approach to patient care, and the development of high fidelity medical technology have highlighted simulation education as a viable component of internal medicine residency training. In response to these changes the Banner Good Samaritan Academic Medical Service developed the Internal Medicine Simulation Boot Camp, a program utilizing high fidelity mannequins in patient hybrid simulation exercises. In September of 2012 the new senior residents participated in a series of four installations focusing on the fields of Pulmonology, Cardiology, Gastroenterology, and Neurology. Residents took a pre-quiz at the start, and a post-quiz at the completion of each boot camp. The simulation team looked at change in quiz scores from pre to post quiz after the intervention of intensive simulation training. Residents were also surveyed on multiple subjective outcomes, results of which were highly in favor of simulation training.
SETTING AND PARTICIPANTS: Internal Medicine and Medicine-Pediatrics residents in their second year of training were included in Boot Camp. These residents were excused from their regularly scheduled Tuesday morning academic lectures for the month of September. The Internal Medicine attendings, as well as consultants and fellows worked together to run boot camp in the Simulation Training Lab at Banner Good Samaritan Medical Center.
DESCRIPTION: Two weeks prior to camp residents received study materials related to the upcoming session. The day of boot camp, they were split into three teams, with six residents each. Teams then rotated through a total of six stations, comprised of simulated clinical cases, simulated procedures, and focused academic small groups. The residents took a quiz at the start of each boot camp and prior to leaving the simulation center. Subjective outcomes surveyed included preparedness for the experience, the value of the reading matierial provided, the relevance of the simulated cases and the likelihood that the boot camp experience would influence practice and clinical decision making.
EVALUATION: There was an average score increase of 33 % between the pre and post quiz results, from 54 % (pre) to 87 % (post). Paired t-test was significant for post versus pre test total at $p<0.001$ for all four boot camp sessions. 100 % of participants completed the survey, with 82 % of participants feeling their simulation training will enable them to make better clinical decisions. 95 % of participants felt extremely confident performing new skills on their patients after simulation training, and 100 % of those surveyed would recommend that other residency programs adopt high fidelity simulation training as part of internal medicine curriculum.
DISCUSSION / REFLECTION / LESSONS LEARNED: Our goal as physician educators is to build a comprehensive, efficient, clinically relevant educational experience for our residents. With the Senior Boot Camp, we are able to impart a large amount of practical information to a large number of learners in a systematic and reproducible fashion. The boot camp format shows statistically significant improvement in scores and subjectively positive evaluations for all involved.

THE UNIVERSITY OF QUEENSLAND/OCHSNER CLINICAL SCHOOL PARTNERSHIP: A MODEL OF TRANSNATIONAL MEDICAL EDUCATION AIMING TO CREATE PRIMARY CARE PHYSICIANS Gerald D. Denton; Richard Deichmann; Leonardo Seoane. Ochsner Health System, New Orleans, LA. (Tracking ID #1629687)

NEEDS AND OBJECTIVES: After many years of preparatory work, the Australian Medical Council (AMC) formally accredited a partnership between the University of Queensland (UQ) in Australia and the Ochsner Health System in New Orleans in 2010. One of the goals of the partnership is to emphasize primary care while training physicians capable of practicing in Australia, New Zealand, and the US.
SETTING AND PARTICIPANTS: The UQ/Ochsner Clinical School (UQ-OCS) partnership allows a cohort of US citizens to enroll in an Australian medical degree program in which they complete their first 2 years of medical school in Brisbane, Australia (Phase I), finish the final 2 years in New Orleans (Phase II) and graduate with a MB BS (MD equivalent) degree. Students are college graduates who meet minimal MCAT and undergraduate GPA criteria
DESCRIPTION: The curriculum of the UQ/OCS differs from traditional US medical school curricula with regards to primary care. Traditional US models have a heavily structured clerkship year that generally includes mandatory rotations in pediatrics, internal medicine, surgery, obstetrics/gynecology, psychiatry, family medicine, and/or neurology. Some of these clerkships include outpatient care, but most do not. The less structured fourth year includes some required rotations but is largely structured to meet each student's perceived needs. In contrast, the UQ/OCS curriculum has a strong focus on outpatient primary care starting early in the preclinical years. Phase I is a Problem-Based Learning program, where students principally work in small groups of 10 students and receive bedside teaching in small groups of 5 students. Additionally, students complete 8 weeks of clinical electives during phase 1 in Australian health settings including rural and primary health care. After moving to New Orleans for Phase II students complete an integrated third and fourth year, with ten eight-week rotations, including required rotations in general practice, primary care in rural or disadvantaged populations, inpatient

internal medicine, general surgery, psychiatry, pediatrics, obstetrics/gynecology, 2 rotations in specialty medicine or surgery and one elective.
EVALUATION: Traditional UQ students in Australia choose to do primary care/rural medicine at a relatively high rate. The first UQ/OCS cohort of students appear to be well qualified (Step 1 pass rate=89 %, step 2CS pass rate=89 %, step 2 CK pass rate=100 %, mean step 1 score of 213 and mean step 2 score of 243). Five of the nine graduating students have interviews with US primary care specialties—Family Medicine (1) and Internal Medicine (4).
DISCUSSION / REFLECTION / LESSONS LEARNED: The UQ-OCS Partnership is a unique entity designed to train US citizens in an international setting with a focus on outpatient primary care. The first graduates of the program are well-qualified and are interviewing for primary care specialties at a high rate. Ongoing data collection and analysis are required. While there are multiple influences on student specialty choice in the US, this model of education may direct more students towards primary care.

THE USE OF HEALTH SERVICES DATA TO INFORM CURRICULUM DEVELOPMENT Lynn Byars; Charles D. Magee; William F. Kelly; Michael Roy. Uniformed Services University of the Health Sciences, Bethesda, MD. (Tracking ID #1643129)

NEEDS AND OBJECTIVES: Curriculum content has largely been determined based on educators' opinion, intuition, and preferences, which vary with their own expertise, and are shaped by national accreditation bodies. Many US medical schools undertook curriculum reform to integrate basic and clinical sciences. Ideally, the process should be informed by the specific health needs of patient populations, which may be quite distinct by geographic region, setting or mission. The Association of American Medical Colleges asserts, "medicine must always be responsive to evolving societal needs, practice patterns, and scientific developments." Delays in recognizing and incorporating emerging health trends into curricula deprive trainees of the "preparedness for practice" they are promised. Health services data provides a means to inform curriculum developers of the specific health needs for their population by identifying trends in common and emerging health issues. This allows new curricula to respond to emerging diseases while confirming clinical topics with enduring educational value. The primary objective of this innovation is to utilize health services data, specifically admissions and outpatient encounters, to inform curriculum development of the most common and emerging diagnoses in our patient population.
SETTING AND PARTICIPANTS: This innovation uses health services data from our health system to assist curriculum design committees for both preclerkship and clinical settings.
DESCRIPTION: Admission and outpatient encounter ICD-9 diagnoses were analyzed to generate a population health profile. This data was stratified to look at the needs of the population as it applied to unique educational components of our medical school curriculum. Emerging disease patterns were identified for incorporation into our curriculum as we undertook redesigning our educational activities.
EVALUATION: Admission and top outpatient encounter ICD-9 diagnosis codes were accessed for all facilities in our medical system for calendar year 2011. Applied to the Internal Medicine population, the top non-obstetric admissions include chest pain, anxiety, pneumonia, and epilepsy/convulsion diagnoses. Although chest pain and pneumonia are well represented in our current curriculum, anxiety and epilepsy/convulsion diagnoses receive less representation. The top outpatient encounter diagnoses include diabetes mellitus, spine and appendicular diagnoses, anxiety and affective mental health, and upper respiratory infections. Diabetes and musculoskeletal disease seem intuitive and are well represented in our current curriculum. However, the emerging mental health profile identifies a need to review the existing neurobehavioral health curriculum.
DISCUSSION / REFLECTION / LESSONS LEARNED: Using health services data to inform curriculum development addresses the societal obligation to graduate students competent to provide care to a defined patient population. Tailoring curriculum to meet unique and emerging health needs present in our populations may improve both curriculum content and delivery. Data monitoring may decrease latency in curriculum development, and further align basic and clinical sciences. However, this data should inform, rather than direct curriculum development, as physicians must still be prepared to practice safely in any population. Access to health services data is not ubiquitous and many institutions may not have representative population level information available.

THE "PROFESSIONALISM MATRIX": A TOOL TO TEACH AND EVALUATE PROFESSIONALISM Van Geslani; Lawrence Loo; Sam Baz; Leah Tudtud-Hans. Loma Linda University School of Medicine, Loma Linda, CA. (Tracking ID #1639099)

NEEDS AND OBJECTIVES: While professionalism is a widely accepted core clinical competency, students residents, and faculty often disagree whether certain actions are unprofessional or not. What constitutes a breach of professional conduct often requires an understanding of the context of the situation and reasoning by those involved. We developed a tool, the "Professionalism Matrix," that was incorporated into a case based educational conference with the specific goals of describing the challenges in defining professionalism, recognizing professionalism as a competency, and using the Professionalism Matrix as a systematic approach to teach and evaluate professionalism.
SETTING AND PARTICIPANTS: We have applied the Professionalism Matrix in 3 interactive conferences to date—the first for house staff in our Internal Medicine (IM) residency, the second at our annual institutional chief residents conference that included all departmental specialties and finally in a University wide faculty development session that had representatives from the School of Medicine, Nursing and related Allied Health professionals.
DESCRIPTION: The Professionalism Matrix incorporates the Accreditation Council for Graduate Medical Education's (ACGME) definition of Professionalism along with the American Board of Internal Medicne's (ABIM) 10 related milestones, cross-referencing this with a systems-based practice definition that considers the context of the situation. The contextual framework includes 3 levels: the "Micro" level (or behavior that is influenced by the individuals' knowledge, skills, beliefs, and attitudes); the "Meso" level (or behavior that is influenced by the immediate organizational structure such as the School of Medicine, Department or residency program); and finally the "Macro" level (or behavior that is influenced by national organizations, policies or trends within the United States). Based on the authors' actual experiences, a series of clinical vignettes are presented with situations that pose opportunities for potentially unprofessional behavior. Participants are broken into small groups and each is given one clinical vignette to discuss the observable actions within the context of the Professionalism Matrix and the possible clinical reasoning of those involved. An audience response system polls the larger group as to what they believe the individual in the vignette should do versus what they actually do in the particular situation. Small groups then report their discussions using the Professionalism Matrix as a framework for how the context and reasoning of those involved might explain the potentially unprofessional behaviors reported in each vignette.
EVALUATION: Conference evaluations have been uniformly positive that the Professionalism Matrix facilitated a systems-based practice approach to the interpretation of potentially unprofessional conduct.
DISCUSSION / REFLECTION / LESSONS LEARNED: The small and large group discussions highlighted the importance of considering the micro, meso, and macro levels that may have influenced individuals reasoning and motivations for seemingly unprofessional actions. Whether these simulations actually translate into actual behavioral changes by participants still remains to be determined. This integration of the ACGME's definition of professionalism, the ABIM/ACGME related milestones, cross-referenced with a system-based framework to analyze issues contextually makes the Professionalism Matrix a novel educational tool that could readily be adopted by other institutions.

USING STANDARDIZED PATIENTS TO TEACH RESIDENTS SKILLS IN RISK COMMUNICATION AND SHARED DECISION MAKING WITH EVALUATION VIA THE OPTIONS INSTRUMENT
Kathleen Fairfield; Thomas P. Gearan; Kristen A. Sciacca. Maine Medical Center, Portland, ME. (Tracking ID #1636482)

NEEDS AND OBJECTIVES: The clinical skill of shared decision making (SDM) is important, yet many faculty members have limited SDM experience, particularly around risk communication. Our objective was to develop curricular materials, teach, and evaluate residents in the curricular milestone, "Engage patients/advocates in shared decision making for uncomplicated diagnostic and therapeutic scenarios".
SETTING AND PARTICIPANTS: PGY3 residents experienced newly developed SDM simulation cases using standardized patients (SP) over two academic years at a state-of-the-art Simulation Center allowing for faculty observation of multiple concurrent sessions from a control room.
DESCRIPTION: We developed two cases to illustrate SDM for counseling about colorectal screening choices (CRC) and mammography for women in their 40s, and trained SP for these cases. We also developed instructions to anchor residents in risks and benefits for each scenario, and icon arrays to use as risk communication tools. Each half-day session began with a brief faculty introduction to SDM, use of icon arrays, and review of screening guidelines. Each resident then completed one case, with immediate SP feedback. This was followed by a 30 min faculty debrief and didactic session focusing on the key steps and competencies in SDM. Each resident then completed the second case with immediate SP feedback. Every SP completed the Options Instrument after each scenario and reviewed it directly with the resident. The Options Instrument includes 12 items, each with a 5 point scale (a higher point value indicates the desired behavior was observed) to evaluate the degree of SDM.
EVALUATION: 16 PGY3 residents completed the SP event in May and August 2012. Faculty observers observed a wide range of skills in counseling about risk and benefit and other SDM skills. Resident feedback was positive, although August PGY3 residents were more enthusiastic than graduating PGY3 (May), and both groups found the CRC case more challenging. Residents requested access to icon arrays to use for risk communication in clinic. Options scores were higher for mammography (median 3.07, SD=0.64) than for CRC (median 1.86, SD=0.53), $p<0.001$. We did not observe statistically significant increases in scores within case when comparing the first to second encounter ($p=0.94$ for CRC, $p=0.24$ for mammography).
DISCUSSION / REFLECTION / LESSONS LEARNED: Using SP for SDM education is novel and allows for teaching and evaluating SDM. Immediate feedback by the SP and use of the Options tool were positive and allows for systematic evaluation. Other alternatives to didactics to extend resident knowledge and skills for SDM should be explored. Notably, this format requires trained faculty and SP, and is time intensive. An alternative would be to have residents role-play SDM using icon arrays and give feedback to each other. A substantial challenge will be determining whether residents use SDM techniques during actual clinical encounters.

WEIGHT MANAGEMENT: A PRIMARY CONCERN (INTEGRATION OF A PRIMARY CARE WEIGHT MANAGEMENT CURRICULUM INTO GRADUATE MEDICAL EDUCATION)
Leon I. Igel[1]; Louis Aronne[2]; Erica Phillips[3]. [1]New York Presbyterian-Weill Cornell Medical Center, New York, NY; [2]New York Presbyterian-Weill Cornell Medical Center, New York, NY; [3]New York Presbyterian-Weill Cornell Medical Center, New York, NY. (Tracking ID #1628073)

NEEDS AND OBJECTIVES: Despite the heightened focus on the obesity epidemic in America, formal weight management curricula are rarely integrated into graduate medical education for Internal Medicine residents. Several studies demonstrate that Internal Medicine residents have negative opinions about their skills for treating obese patients. They report feeling unprepared to perform obesity counseling and ill-equipped to use available pharmacological agents in the treatment of obesity. It is essential that residency training programs bolster knowledge of clinical weight management and address physicians' negative views toward the treatment of obesity.
SETTING AND PARTICIPANTS: A two-week-long outpatient weight management elective was piloted in the Internal Medicine residency program at NYP-Weill Cornell in 2012. 131 Internal Medicine residents, at all training levels, were eligible to participate. A maximum of 2 residents were permitted to enroll for each elective block during the academic year.
DESCRIPTION: A literature review was conducted to evaluate previously-developed, resident-level weight management curricula. Licensure testing domains for specialty certification in Obesity Medicine were also reviewed. Finally, a representative panel of experts in the field of Obesity Medicine was assembled and polled for additional guidance in creating and piloting a comprehensive curriculum for weight management. The summative curriculum emphasized nine obesity-related content areas: 1) endocrinology 2) cardiology/lipidology/hypertension 3) sleep disorders 4) osteoarthritis/joint disease 5) diet/nutrition 6) eating disorders 7) pharmacology for weight loss 8) bariatric surgery 9) direct clinical management of the obese patient in a newly formed weight management practice housed in the faculty-resident outpatient center. A syllabus was created with supplemental reading in each content area.
EVALUATION: In the development of the curriculum, an IRB-approved survey was conducted among 177 faculty, fellows and residents within the Department of Medicine. Of the 121(68 %) respondents, 94.8 % indicated that a weight management elective would be very useful for the residency program, with 88.6 % of all respondents stating that they had not received sufficient weight management education. While 93 % of all respondents indicated that they believe obesity to be an international epidemic, only 23.4 % reported having successfully helped patients lose weight, and 15 % of respondents felt that they could effectively prescribe pharmacological agents to assist obese patients with weight loss. A 46 item multiple choice test composed of MKSAP-style questions on the topic of obesity and its comorbidities was rendered at the beginning and end of the elective. To date, 6 residents have completed the elective. The mean pre-test score was 21.8, while the mean post-test score was 27.4 (out of 46). Of the patients referred to the weight management practice for treatment, a formal evaluation of patients' mean weight loss, weight loss maintenance, and improvement in co-morbid conditions (i.e. A1c reduction in diabetics) is in progress.
DISCUSSION / REFLECTION / LESSONS LEARNED: There is limited published information directly outlining the topic areas that should be addressed for resident-level weight management curricula. However, there is a great need for structured training given the prevalence of obesity in our culture. Ideally, the NYP-Weill Cornell weight management elective can serve as a model for the future implementation of weight management curricula in national residency education.

WRITING FOR CHANGE: TRAINING RESIDENTS IN ADVOCACY THROUGH PUBLIC MEDICAL COMMUNICATION
Louise Aronson[1]; Anda Kuo[1]; Sharad Jain[1]; Vanessa Grubbs[1]; Jennifer Siegel[2]; Alice H. Chen[1]. [1]UCSF, San Francisco, CA; [2]Boston University, Boston, MA. (Tracking ID #1640417)

NEEDS AND OBJECTIVES: Medical narratives are used in advocacy to educate, change opinions and influence policy. From letters to the editor or opinion columns in newspapers to essays in medical or policy journals, physician's stories inspire change and give a voice to society's most vulnerable. Although law and business schools teach persuasive communication, medicine has used narrative principally for self-reflection and humanism. The new field of Public Medical Communication broadens communications skills in medicine to include persuasive writing and engagement with the public and policymakers about health and health care. We developed, implemented and assessed a brief curriculum to train residents in advocacy-based Public Medical Communication.
SETTING AND PARTICIPANTS: Nineteen internal medicine ($n=15$) and pediatrics ($n=4$) residents at the University of California, San Francisco, participating in advocacy educational tracks at San Francisco General Hospital.

DESCRIPTION: Five faculty with narrative, policy, advocacy, and underserved medicine expertise collaborated to develop a 3-part workshop. Each 2-hour-long session included: close reading of newspaper, medical journal and health policy journal articles; discussion of narrative craft and how to select target audience, publication venues and advocacy levels; development of opening paragraphs or ledes (session 1) and writing workshop style works-in-progress sessions of the residents' draft articles (sessions 2–3). Faculty reviewed additional drafts as needed. Participants scored session quality, relevance and usefulness on a 0–5 scale and provided qualitative feedback. Faculty tracked resident publications.
EVALUATION: All 19 residents completed evaluations. Most had little writing experience. Combined session ratings for quality, relevance and usefulness were 4.95, 4.925 and 4.975, respectively, on a 5-point Likert scale. All residents drafted articles based on their clinical experience and tied to an advocacy issue. With additional revisions and faculty help, six residents published seven articles in the New York Times (2), Health Affairs Narrative Matters (2), Huffington Post (2) and Annals of Internal Medicine. Qualitative feedback included: "Thank you for pushing us—I thought that the writing was incredible painful and so valuable," "Glad we were encouraged to read aloud, great experience," and "I enjoyed the pre-reading and discussion of how to actually write a piece/lede."
DISCUSSION / REFLECTION / LESSONS LEARNED: Narrative writing is a relevant and useful advocacy tool for generalist residents. Despite initial discomfort with both writing and reading works-in-progress aloud, this advocacy-focused Public Medical Communication workshop was enthusiastically received by the learners. All trainees were able to develop the basics of publishable pieces within the framework of a few structured seminars, and a quarter completed articles accepted for publication in national media, medical and health policy journals. Although publication was possible from just a 6 hour curriculum, it required additional faculty time after the workshop. This is an innovative method to address core ACGME competencies and help residents translate their clinical experiences into meaningful public service and discourse.

"ARE YOU UPDATED?" USING A SIGNOUT AUDIT TOOL TO ADDRESS ACGME MILESTONES AND ENTRUSTABLE PROFESSIONAL ACTIVITIES IN PATIENT HANDOFFS Shannon K. Martin; Elizabeth A. Paesch; Jeanne M. Farnan; Julia Espel; John McConville; Vineet Arora. University of Chicago, Chicago, IL. (Tracking ID #1629822)

NEEDS AND OBJECTIVES: ACGME Milestones and Entrustable Professional Activities (EPAs) have emerged as benchmarks for housestaff professional development. Residents must demonstrate expertise in these patient care activities in order to progress in training, and thus programs will require tools for direct observation in order to evaluate these skills. These tools must evaluate milestone-specific performance in a manner that can provide both summative and formative feedback in a timely fashion. We report the use of one such tool, the UPDATED signout audit tool, to evaluate ACGME milestones related to handoffs.
SETTING AND PARTICIPANTS: This intervention occurred with interns in the internal medicine residency program at the University of Chicago, an academic medical center whose electronic health record features an electronic signout. This is a document generated from a template that partially automates some fields using information from the electronic chart (e.g. patient medications). Other information must be entered in free-text form (e.g., hospital course and tasks for overnight care).
DESCRIPTION: The UPDATED audit tool was used to evaluate electronic signouts done by internal medicine interns on non-critical care internal medicine services. This tool emphasizes several key areas reflected in ACGME milestones, including ensuring accurate documentation (ICS-F1, P-A1), appropriate synthesis and definition of clinical problems (PC-C1) and effective communication during transitions of care (ICS-C1). All 45 interns were assigned independent review of two electronic signouts from July-October by one of eight faculty auditors (4 chief residents and 4 hospitalists). Seven items specific signout attributes were scored, and an overall score of 0 to 9 was assigned. Audits scoring 0–3 were categorized as "Poor", 4–6 as "Fair", and 7–9 as "Good". Ratings among faculty members were compared for consensus.
EVALUATION: Of the 45 interns, 32 had complete audits, 6 partial audits, and 7 were unable to be audited during the initial period. Interns were identified for immediate feedback if they received two "Fair" scores or one "Poor" score. If signouts were unable to be fully audited or received at least one "Fair" score, interns were assigned additional review in subsequent months. Signouts were considered satisfactory if both audits were scored as "Good". Of the 32 completed audits, 16 % (n=5) of interns were identified for immediate feedback, and 41 % (n=19) for additional future review. The remaining interns (44 %) were satisfactory. Audits were incorporated into intern semi-annual performance reviews within the housestaff evaluation committee. Interns achieving a satisfactory audit were designated as "Competent", those awaiting further review as "Undergoing further evaluation of competence", and those flagged for immediate feedback as "Received immediate feedback and undergoing further evaluation of competence." The 13 interns not fully audited were designated as "Waiting to be evaluated." A second round of audits will be done from December-April.
DISCUSSION / REFLECTION / LESSONS LEARNED: The UDPATED Signout Audit Tool is a feasible and effective way to use direct observation to address resident achievement of competency in ACGME milestones related to handoffs. The tool is a useful way to incorporate milestones in evaluation of housestaff readiness to progress in training and is well-suited to be included as an assessment for the proposed EPA encompassing patient handoffs, Managing Transitions of Care.

"HOW DOES A STUDENT-RUN CLINIC IMPACT MEDICAL STUDENT ABILITY TO CARE FOR PATIENTS WITH CHRONIC ILLNESS?" Linda Wang[3]; Matthew A. Spinelli[3]; Nandini C. Palaniappa[3]; Yasmin S. Meah[1,2]; David C. Thomas[2]. [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY. (Tracking ID #1642314)

NEEDS AND OBJECTIVES: Traditional medical school curricula rarely allow the opportunity to follow patients longitudinally or care for patients with chronic illness. Given the largely inpatient setting of most clerkships, students receive limited exposure to chronic illness management and seldom engage in systems-based care in ambulatory or primary care practices. Student Run Clinics (SRCs) are a novel setting through which students may gain exposure to the care of patients with chronic illness. For 5 years the SRC of the Icahn School of Medicine at Mount Sinai, the East Harlem Health Outreach Partnership (EHHOP), has implemented a Chronic Care Program for senior medical students. The objectives of the program include positively impacting medical student experiences in 1) knowledge about managing patients with chronic illness, 2) ability to practice cost-conscious chronic care, 3) engagement in interdisciplinary teamwork, 4) exposure to primary care mentors, and 5) likelihood of engaging in a career in primary care.
SETTING AND PARTICIPANTS: All clinical encounters, with the exception of group and home visits, take place in EHHOP's Saturday morning clinics for uninsured patients. There are currently 30 third, fourth, and MD/PhD students enrolled, who are selected through an application process, as well as 50 patients with chronic conditions who benefit from dedicated provision of care.
DESCRIPTION: This track allows medical students to experience the role of primary care provider, under attending supervision, for patients with complex medical conditions. Through this track, students are pivotal in executing long-term care plans, engaging in systems-based navigation of care and interacting with interdisciplinary partners. To date, however, we lack data on the impact of such a program on improving knowledge about chronic illness, the ability to practice cost-conscious care, the depth of involvement in interdisciplinary care and the effect of such a program on career choice.
EVALUATION: Current and former medical students will be invited to participate in an anonymous online survey. Responses will be stratified into Chronic Care participants versus non-participants to compare Chronic Care track medical student experiences with the experiences of other medical students in the 5 domains listed above. We anticipate that current medical

student exposure to chronic illness management and systems-based care through traditional medical school curricula is minimal as compared to the training through the EHHOP Chronic Care Program. We hypothesize that chronic care curricula within EHHOP fills a void in primary care education, and positively impacts the likelihood that medical students will choose a career in primary care.
DISCUSSION / REFLECTION / LESSONS LEARNED: SRCs provide a valuable setting to increase exposure to systems-based practice and chronic illness management, and may have a significant role in leading students toward careers in primary care.

"MEET YOUR COLLEAGUES": ENHANCING THE APPEAL OF EDUCATION IN COLLABORATIVE CARE Traci A. Takahashi[1,2]; Douglas B. Berger[1,2]; Joyce E. Wipf[1,2]; Sarah E. Shannon[3]; Brenda K. Zierler[3]. [1]VA Puget Sound, Seattle, WA; [2]University of Washington, Seattle, WA; [3]University of Washington, Seattle, WA. (Tracking ID #1629931)

NEEDS AND OBJECTIVES: Interprofessional Education (IPE) is designed to produce team-players whose collaborative practice will avoid medical errors, reduce costs, and improve quality. IPE is particularly pressing for primary care providers (PCPs), who are increasingly working in team-based patient centered medical homes responsible for care coordination. However, teaching IPE to physicians is challenging because team-skills may be seen as non-essential and flattening of traditional hierarchies may be threatening. Responding to early trainee feedback suggesting limited tolerance for sessions explicitly teaching team skills, we developed a new blended curriculum called "Meet Your Colleagues" to teach clinical content in a way that also advanced core competencies for interprofessional practice as defined by the IPE Collaborative.
SETTING AND PARTICIPANTS: Our academic outpatient clinic is participating in a grant-funded program to innovate primary care training. Learners include internal medicine residents and Doctor of Nursing Practice (DNP) students, with associated health trainees participating in selected workshops.
DESCRIPTION: "Meet Your Colleagues" workshops are interactive, with members of other health professions teaching clinical skills relevant to primary care practice and briefly introducing their training, scope of practice, and typical work environments. Areas of possible miscommunication or discipline-specific differences in approach are explored when they arise. Selected examples of content include physical therapists demonstrating selection, fit, and safe use of mobility aids and trainees learning to walk with aids; pharmacists and pharmacy residents leading a game-show style quiz on adverse drug reactions and teaching proper use of respiratory inhalers; an optometry resident and blind rehab therapist demonstrating tools for low vision adaptation and helping trainees interact with a blinded person; and wound care nurses teaching lymphedema care, dressing selection and application. Future workshops include dentistry, podiatry, and spiritual health.
EVALUATION: In anonymous written evaluations completed after each session, trainees rated the usefulness of these workshops as good to excellent (4.7 on a 5 point scale) and reported increased confidence using the relevant skills. Descriptive comments showed that trainees learned key lessons for interprofessional practice, such as respecting the culture and role of other health professions and cross-discipline communication. In informal group evaluations, trainees requested more of these workshops and preferred them to sessions designed solely to teach interprofessional skills. Future evaluations will specifically assess impact on trainees' perceptions of participating professions and referral patterns, as anecdotally we observed increased pharmacy referrals after pharmacy workshops.
DISCUSSION / REFLECTION / LESSONS LEARNED: Content-focused workshops that introduce other health professionals and their skill sets can promote IPE competencies in ways that primary care trainees find appealing. Close collaboration between educators in primary care and other disciplines is essential in choosing topics and ensuring relevance for trainees. This model does not replace IPE focused solely on team and communication skills. However for residents and students eager to learn facts essential for primary care, positioning other health professionals as content experts may be a complementary approach to foster interprofessional respect and collaborative practice.

"SHOW ME THE FOLLOW-UP!": IMPLEMENTATION OF ASSESSMENT BASED ON AN ENTRUSTABLE PROFESSIONAL ACTIVITY FOR INTERNS IN CONTINUITY CLINIC Ryan Laponis; Karen E. Hauer; Maya H. Dulay; Reena Gupta; Tacara N. Soones; Jeff Kohlwes; Harry Hollander; Patricia S. O'Sullivan; Katherine Julian. University of California San Francisco, San Francisco, CA. (Tracking ID #1642540)

NEEDS AND OBJECTIVES: As a mechanism to assess the required American Board of Internal Medicine (ABIM) milestones in residency training, the Alliance for Academic Internal Medicine (AAIM) developed sixteen end-of-training Entrustable Professional Activities (EPAs). These EPAs are intentionally broad and the AAIM has encouraged the development of discrete, more specifically characterized EPAs that, in aggregate, inform the broader end-of-training EPAs. In the often chaotic and time-pressured learning environment of continuity clinic, a discrete EPA can focus learners and faculty on key competencies that learners need to acquire and upon which they will be assessed. To begin to meet the emerging need for milestone-based assessment, we developed and implemented an assessment of a discrete EPA for interns in the continuity clinic setting that maps to seven ABIM milestones, named Implementation of a Patient Follow-up Plan EPA.
SETTING AND PARTICIPANTS: Sixty-two internal medicine interns and thirty-six faculty members at six continuity clinic sites (3 Veterans Affairs clinics, 1 safety-net clinic and 2 academic clinics) in a single internal medicine residency program participated.
DESCRIPTION: Our discrete EPA is the Implementation of a Patient Follow-up Plan EPA. This EPA begins at a continuity visit when the intern communicates the attending-approved plan to a continuity clinic patient and ends when the intern follows-up with the patient at an appropriate interval. The assessment is performed by a single attending for each intern and consists of three elements: 1. Direct observation by an attending of visit closure via a 4-item behaviorally-anchored checklist; 2. Chart review of visit documentation via a 4-item checklist completed when the attending signs the intern's note; and 3. Assessment of follow-up via a 3-item checklist completed at an agreed-upon time between the intern and the attending depending on the clinical scenario (i.e.: active diuresis for heart failure may require follow up within days, whereas stable diabetes may require follow-up in 3 months). All checklist items allow for comments, but require that the attending identify whether the intern behavior was present or absent (ie: yes/no). The checklist items map to seven ABIM milestones. Each attending is assigned to at least one intern and must perform three discrete EPA assessments per intern over the course of the first 6 months of the year. After three assessments, the attending provides an overall level of entrustment for this discrete EPA.
EVALUATION: We plan to survey both interns and attendings regarding feasibility, meaningfulness of the EPA assessment, confidence in completing/assessing the EPA and reflections on receiving/granting entrustment.
DISCUSSION / REFLECTION / LESSONS LEARNED: Assessment of an EPA in the continuity clinic setting provides a meaningful structure to trainee assessment because it focuses on a particular patient care activity and, in this case, facilitates specific feedback on observable behaviors. Key obstacles to successful implementation have been identifying time for intern and faculty development on both the concept of EPAs and the three elements of this discrete EPA as well as identifying time for verbal feedback from attendings to interns. Next steps include generating an electronic platform that allows for efficient capture of EPA assessments, remediation strategies and developing additional discrete EPAs in continuity clinic for more advanced trainees.

THE EFFECT OF THE US GREAT RECESSION ON UTILIZATION OF OUTPATIENT AND EMERGENCY DEPARTMENT CARE FOR MENTAL HEALTH AND SUBSTANCE ABUSE PROBLEMS Karen E. Lasser[1], David Himmelstein[2], Steffie Woolhandler[2]; [1]Boston Medical Center, Boston, MA; [2]CUNY School of Public Health at Hunter College, New York, NY, United States (control ID# 1625557)

Background: The US Great Recession which began in December 2007 and was worst in 2009 led to significant job losses resulting in loss of health insurance as well as increased psychological distress. Few population-based data are available on changes in utilization of outpatient and emergency department care for mental health and substance abuse problems prior to and during the recession.

Methods: We analyzed data from the 2006 to 2010 National Hospital Ambulatory Medical Care Survey (NHAMCS) and National Ambulatory Medical Care Survey (NAMCS), nationally representative samples of ED-based, hospital clinic-based, and community office-based visits. We calculated visit volume according to the following categories of visit diagnoses: substance use diagnoses only, and mental health diagnoses only. Defining outpatient visits as hospital clinic and office-based visits, we calculated the number of outpatient visits in which buprenorphine was prescribed. We defined these visits as office based opioid treatment (OBOT) visits.

Results: Outpatient and ED visits for substance use problems rose from 2006 to 2009 (Table). OBOT visits accounted for 25 % of outpatient substance abuse visits in 2006, and rose to 36 % of such visits in 2010. There was no trend in number of mental health visits over the study period, or in number of mental health visits according to insurance type (data not shown).

Conclusions: The Great Recession had mixed effects on mental health visits, perhaps reflecting the counterbalancing effects of health insurance loss and increased psychosocial stress. Substance abuse visits rose continuously, to more than double their 2006 level. Increasing use of OBOT does not explain the observed increase in outpatient substance abuse visits. In the wake of the Great Recession, a strong social safety net is needed for individuals with substance abuse problems.

Visits, millions	2006	2007	2008	2009	2010
Substance abuse, total	2.9	3.9	3.9	4.4	5.9
Outpatient	1.6	2.8	2.7	3.1	4.5
OBOT	0.4	0.7	1.0	1.6	1.6
ED	1.3	1.1	1.2	1.4	1.4
Mental health, total	50.3	59.2	46.7	63.0	53.3
Outpatient	47.3	56.4	43.8	59.7	50.1
ED	3.0	2.8	2.9	3.3	3.2
