Abstracts from the 36th Annual Meeting of the Society of General Internal Medicine

ABSTRACTS OF SUBMISSIONS ACCEPTED FOR PRESENTATION

SCIENTIFIC ABSTRACTS

"MY CLIENTS FALL THROUGH EVERY CRACK IN THE SYSTEM": ASSESSING THE NEED FOR GERIATRICS HEALTH TRAINING AMONG LEGAL PROFESSIONALS Tacara N. Soones[1]; Cyrus Ahalt[2]; Sarah Garrigues[2]; David Faigman[3]; Brie Williams[2]. [1]University of California- San Francisco, San Francisco, CA; [2]University of California-San Francisco, San Francisco, CA; [3]UCSF/UC Hasting Consortium on Law, Science & Health Policy, San Francisco, CA. (Tracking ID #1607152)

BACKGROUND: Older adults (age 55+) represent the fastest growing age group in jail. While attorneys, judges, and other legal professionals are not generally considered healthcare team members, they provide front-line identification and response to age-related health conditions affecting legal outcomes. For example, cognitive impairment can affect the ability to access adequate legal representation, participate in one's defense, or follow court orders; and physical impairment can jeopardize safety in jail. However, legal professionals' knowledge of age-related health issues is unknown.
METHODS: This was a cross-sectional, qualitative study of legal professionals in San Francisco County's criminal justice system. Questionnaires included open and close-ended questions to assess demographics, attitudes towards older adults (validated Geriatrics Attitudes Scale) and self-reported knowledge of geriatrics topics relevant to legal services, including cognitive and sensory impairment, legal competency, and knowledge of community resources. Questionnaires also elicited recommendations for closing geriatrics knowledge gaps. We analyzed questionnaires using standard grounded theory principles and conducted in-depth interviews with 9 participants to ensure that questionnaires were interpreted accurately.
RESULTS: Seventy-two of 83 legal professionals participated (87 % participation), including judges (6 %), District Attorneys (25 %), Public Defenders (58 %), and Pretrial Diversion case managers (11 %). Most legal professionals (73 %) worked with older adults on at least a monthly basis and 100 % had positive attitudes towards aging (Geriatrics Attitudes Scale >3). Self-reported geriatrics knowledge gaps were greatest in 3 areas: (1) General aging-related health- 14 % rated themselves as knowledgeable about age-related health issues, 74 % had never received training in aging; (2) Cognitive impairment-55 % did not feel knowledgeable at explaining how delirium, dementia and depression might affect behavior or the ability to follow instructions, and (3) Safety assessment-61 % felt unprepared to identify older adults at high safety risk and 62 % could not describe types of surrogate decision-makers, including public guardians or appointed power of attorneys. Five recommendations to close these knowledge gaps emerged: (1) educate legal professionals about aging-related health; (2) develop checklists to identify older adults at risk of health decline or poor safety; (3) train to assess older adults for cognitive and sensory impairments before legal proceedings; (4) create communication mechanisms between legal professionals, clinicians, and social services providers about client needs during and after detainment; and (5) encourage multidisciplinary research to improve health outcomes in older adults.
CONCLUSIONS: This study identifies critical gaps in the geriatrics knowledge of legal professionals in the criminal justice system and proposes recommendations to address these knowledge gaps, minimize adverse health outcomes, and improve legal outcomes for older adults.

"WHO'S ON FIRST?" IN THE CHAOS OF SHARED DECISION MAKING: A STUDY OF DOCTOR, PATIENT, AND OBJECTIVE RATINGS OF SHARED DECISION MAKING USING DIRECTLY OBSERVED ENCOUNTERS Patrick G. O'Malley[1,2]; Dorothy Becher[1]; Gretchen Rickards[2,1]; Janice L. Hanson[3,1]; Jeffrey L. Jackson[4,1]. [1]Uniformed Services University, Bethesda, MD; [2]Walter Reed National Military Medical Center, Bethesda, MD; [3]University of Colorado School of Medicine, Aurora, CO; [4]Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #1639946)

BACKGROUND: Shared decision making involves complex patient-physician interaction, yet patient encounters tend to be chaotic, without coherent direction or dyad symmetry. We sought to explore how patients and doctors perceive the degree of shared decision making in the same chronic care encounters, and how well their perceptions correspond with objective assessments of the interaction.
METHODS: Prospective, observational study of audiotaped encounters, with surveys of patients and physicians before and after the encounter. We enrolled a consecutive sample of 120 participants aged 40–80 y.o. with ≥3 additional chronic medical conditions (excluding dementia), and scheduled for a routine appointment with their primary provider. Immediately after the visit, patients and doctors were independently surveyed to assess the decision making style of the encounter along a 20-point spectrum ranging from "doctor-dominant" (0–6) to "shared" (7–13) to "patient-dominant" (14–20) decision making. The scale included behavioral descriptors in order to anchor one's choice. Three raters (PO, DB, GR) dual-rated transcriptions independently on the level of decision making complexity (low, medium, high), and the degree of shared decision making (20-item scale), blinded to the patient and doctor ratings; disagreements were reconciled through consensus. Agreement between patient, doctor, and objective ratings were measured using the intraclass correlation coefficient (ICC).
RESULTS: Of the 105 patients who completed the visit, complete data was available on 98. The demographics were as follows: 53 % F, 56 % AA, mean age: 66 yo, 88 % were on 5 or more medications, only 8 % had poor health literacy, and 30 % had a very good or excellent functional status. The physician profile (N=11) was: 55 % F, 28 % AA, mean age: 48 yo, and mean time since graduation: 19 yrs. The level of decision making in the encounters was low in 61 %, and mod/high in 39 %. Categorical ratings of encounters (by collapsing scores into 3 groups), stratified by perspective (doctor, patient, objective), is presented in the table (below). Immediately after the visit, there was no agreement between patients and physicians on the degree of shared decision making during the visit (ICC=0.06, P=0.37). By objective measurement, 88 of the 98 encounters were dominated by the physician (ie, scores from 0 to 9), and only 27 of those could be categorized as relatively "shared" (ie, scores of 7–9). When compared to objective ratings, physicians' ratings of shared decision making correlated more strongly (ICC=0.55, P<0.001) than patients' ratings (ICC=0.39, P=0.01).
CONCLUSIONS: Immediately after participating in the same chronic care encounter of mostly low to moderate decision complexity, both patients and physicians overestimated the degree of shared decision making, and neither agreed on the degree of shared decision making of the same encounter. Interventions to improve shared decision making will need to address 1. Physician lack of awareness of their tendency to dominate encounters, and 2. both parties' ability to engage in true shared decision making.

Shared Decision Making Spectrum

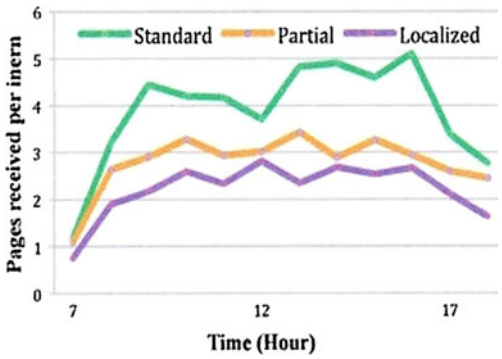
Perspective	Doctor Shared	Patient
Doctor	34 %	47 % 19 %
Patient	22 %	69 % 9 %
Objective	81 %	15 % 4 %

Ratings of the Same Encounter (N=98)

(RE)TURNING THE PAGES OF RESIDENCY: THE IMPACT OF LOCALIZING RESIDENT PHYSICIANS TO HOSPITAL UNITS ON PAGING FREQUENCY Laura Fanucchi[1]; Lia S. Logio[2]. [1]University of Kentucky College of Medicine, Lexington, KY; [2]Weill Cornell Medical College, New York, NY. (Tracking ID #1634924)

BACKGROUND: Pagers are ubiquitous, yet fundamentally flawed, as they do not prioritize, lead to communication errors, and interrupt patient care and educational activities. Given duty hour restrictions, there is concern that residents experience increased workload due to having fewer hours to do the same amount of work. Geographic localization of physicians to patient care units is thought to improve communication and agreement on goals of care, and also to reduce workload by decreasing paging and other inefficiencies attributable to traveling throughout the hospital. We investigated whether interns on geographically localized teams received fewer pages than interns on teams that were not localized.
METHODS: We conducted a retrospective analysis of the number of pages received by interns on 5 general medicine teams from Oct. 17–Nov. 13, 2011 at New York Presbyterian Hospital/Weill Cornell. Two teams were in a Geographically Localized Model (GLM), two in a Partial Localization Model (PLM), and one Standard Model (SM) team admitted patients irrespective of their assigned bed location. ANOVA and standard multivariate linear regression techniques were used to analyze the relationship between the number of pages received per intern and the type of team.
RESULTS: Over 28 days, 10 interns on 5 teams received 6652 pages. Eighty-five percent of patients in the GLM were on the designated unit, compared to 45 % in the PLM, and 37 % in the SM. The number of pages received per intern per hour, adjusted for team census and number of admissions, was 2.18 in the GLM, 2.77 in the PLM, and 3.87 in the SM. All of these differences were statistically significant in the linear regression analysis (p<0.0001). Figure 1 shows the pattern of paging for the three types of teams.
CONCLUSIONS: Geographic localization of resident teams to patient care units is associated with significantly fewer pages received by interns during the day. Previous research suggests that geographic localization decreases perceived paging frequency. We show a statistically significant relationship with a dose–response effect. We also demonstrate that interns whose patients are scattered throughout the hospital may experience five pages per hour, or an interruption by pager every 12 min. Geographically localized patient care models may improve resident workload in part by mitigating paging. Decreased resident workload has potential to improve both clinical and educational outcomes. A working environment that facilitates in-person communication decreases not only pager interruptions, but the latent communication errors inherent in unidirectional alpha-numeric paging, which may improve patient safety.

Figure 1. Average number of pages per intern per hour for each care model.



24 MONTH METABOLIC BENEFITS OF A COMMUNITY-BASED TRANSLATION OF THE DIABETES PREVENTION PROGRAM Carolyn F. Pedley[1]; Doug Case[1]; Mara Z. Vitolins[1]; Jeffrey A. Katula[1]; Caroline S. Blackwell[1]; Scott Isom[1]; David C. Goff[2]. [1]Wake Forest University, Winston-Salem, NC; [2]Colorado School of Pulbic Health, Denver, CO. (Tracking ID #1642380)

BACKGROUND: The practice of general internal medicine involves treating a high percentage of individuals with hypertension, increased waist circumference, glucose intolerance, hypertriglyceridemia and decreased HDL cholesterol. These individuals with metabolic syndrome are at an increased risk of developing cardiovascular disease and diabetes. Although several large-scale clinical trials have demonstrated that weight loss achieved through diet and physical activity can reduce the incidence of diabetes, translating lifestyle weight loss programs to general practice has been difficult. Numerous studies have attempted to translate the Diabetes Prevention Program (DPP) to community-based and primary care settings and have documented modest success. However, no translational studies to date have documented the impact of diabetes prevention interventions on aspects of the metabolic syndrome. The Healthy Living Partnership to Prevent Diabetes study (HELP PD; NIDDK) tested the impact of a community-based translation of the DPP on fasting blood glucose in participants at high risk for diabetes. The impact of HELP PD on fasting

blood glucose and waist circumference have been published previously. The purpose of the present study is to examine the HELP PD intervention on features of the metabolic syndrome.
METHODS: The study randomly assigned 301 overweight volunteers with fasting blood glucose 95–125 mg/dl and BMI 25–40 kg/m2 to two treatment groups: enhanced usual care (EUC vs DPP LWL (Lifestyle, Weight Loss) intervention. Ages ranged from 34 to 81 years with a median of 58 years; 57 % were female, 26 % minority and 73 % obese. The LWL intervention was administered through a local diabetes education program and participants met in 14 groups of 8–12 delivered by community health workers (CHW) in community locations. CHWs were volunteers with well-controlled diabetes.
RESULTS: Duriing 24 months of follow-up there were significant between group differences in metabolic parameters: fasting blood glucose, waist circumference, HDL and DBP differed significantly between the LWL and EUC groups, all in favor of the LWL. SBP and triglycerides were lower in the LWL group but the differences were not statistically significant. Fasting blood glucose decreased by 2.2 mg/dl in the LWL group and increased by that amount in the EUC group for a difference of 4.4 mg/dl at 24 months (p=.001). Waist circumference decreased by 3.4 cm in the LWL group and remained relatively unchanged in the EUC group (0.2 cm decrease) for 3.2 cm difference at 24 weeks (p<.001). HDL increased by 0.4 mg/dl in the LWL group while decreasing by 2.7 mg/dl in the EUC group (p=.004). Diastolic blood pressure decreased by 1.6 mmHg in the LWL group and increased by 0.5 mmHg in the EUC group (p=.024) while systolic blood pressure decreased by 2.3 mmHg in the LWL group and 1.0 mmHg in the EUC group (p=.437). Triglycerides decreased by 23.4 mg/dl in the LWL group compared to the 10.8 mg/dl in the EUC group (p=.083).
CONCLUSIONS: This study demonstrates that community-based partnerships can successfully deliver effective, affordable behavioral lifestyle weight loss programs in general medical patients who have several metabolic risks for diabetes and heart disease with resultant metabolic benefits. Utilizing community-based volunteers in community settings to deliver diabetes prevention programs has the potential to reduce health disparities in accessing such care.

"AM I CUT OUT FOR THIS?" UNDERSTANDING THE EXPERIENCE OF DOUBT AMONG FIRST YEAR MEDICAL STUDENTS Rhianon Liu; Jorie Colbert-Getz; Robert Shochet. Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #1628595)

BACKGROUND: Research on medical student wellbeing shows high rates of distress, yet doubt as a distinct phenomenon remains poorly understood. The purpose of our study was to examine how first year medical students experience and respond to doubt, and how doubt relates to other aspects of student distress.
METHODS: We conducted a mixed methods study involving a survey and focus groups examining the phenomenon of doubt among first year medical students at the Johns Hopkins University School of Medicine (JHUSOM). Students were asked to answer 14 questions about doubt embedded in an online advising program survey in June, 2012. Doubt survey items were developed and revised based on literature review, and included four questions from a validated wellbeing index. Results were analyzed by grouping students into categories of high, moderate, low, or no doubt. For each doubt item, logistic regression was used to compare the proportion of students who "agreed" among moderate/high doubters vs low/no doubters. For wellbeing questions, total doubt scores and total wellbeing scores were correlated with Spearman's rho. In addition, four 90-min focus groups were conducted with a convenience sample of students in June–July, 2012. Focus group questions were written by the authors, then pilot-tested and revised prior to use. Digital recordings were transcribed, independently coded, and iteratively reviewed by the authors to identify major themes.
RESULTS: 114/119 (96 %) students completed the survey. 20 % had high doubt, 29 % moderate doubt, 22 % low doubt, and 29 % no doubt. Compared to those with low/no doubt, students with moderate/high doubt were 5 to 13 times as likely to question their personal purpose, to question who they were, to struggle with coping with doubt, and to perceive the JHUSOM climate as discouraging them from expressing doubt, There was moderate correlation between total doubt and wellbeing scores (spearman's rho=0.36). 34 students participated in the focus groups. Three major themes were identified: types of doubt, ways of coping with doubt, and impact of doubt. Types of doubt were related to two main questions: -Do I want to become a doctor? Subtheme example: the opportunity cost of pursuing medicine -Am I capable of becoming a doctor? Subtheme example: concerns about one's ability to succeed and maintain work-life balance Ways of coping with doubt included: -Relying on supportive relationships -Maintaining perspective through a focus on long-term goals The impact of doubt included positive and negative aspects: -Positive examples: motivation and resilience in the face of uncertainty -Negative examples: burnout, stress, and poor academic performance
CONCLUSIONS: Doubt is prevalent among first-year medical students, affecting students' sense of confidence, identity, and purpose, and has both positive and negative consequences. Students also experience other forms of distress, which may be related to doubt. Doubt among medical students merits awareness and further study, as it may be an important mediator of students' emerging sense of identity and personal wellbeing.

A BEFORE/AFTER TRIAL OF A DECISION AID ON MAMMOGRAPHY SCREENING FOR WOMEN AGED 75 AND OLDER Mara A. Schonberg; Mary Beth Hamel; Roger B. Davis; Edward R. Marcantonio. Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #1636857)

BACKGROUND: Guidelines state there is insufficient evidence to recommend mammography screening for women aged >75 years. Instead, they encourage clinicians to discuss the potential benefits and risks of screening and engage older women in shared decision-making. We aimed to design and evaluate a decision aid (DA) for women >75 years to inform their decision-making around mammography screening.
METHODS: We designed the DA based on international standards and included data from medical literature review. An expert panel reviewed iterative versions of the DA and it was then reviewed for acceptability by 15 patients and 5 of their primary care physicians (PCPs). The 10-page DA (written at a 6th grade reading level) includes information on breast cancer risk, life expectancy, competing mortality risks, likely outcomes if screened or not screened over 5 years, and a values clarification exercise. We evaluated the DA in a before/after trial at a large academic primary care practice in Boston. Eligible women were >75 years, spoke and read English fluently, had not had a mammogram in the past 9 months but were screened in the past 3 years, did not have a history of invasive or non-invasive breast cancer or dementia, and were scheduled for a routine visit with their PCP within 8 weeks. Participants came early to their PCP appointment to complete a "before" survey and to read the DA. After the visit, they completed an "after" survey. The surveys included 10 knowledge questions, the 16-item decisional conflict scale (DCS, 0–100, lower scores = less conflict), and a question that assessed screening intentions. Participants were followed by medical record for up to 1 year to examine whether there was a note documenting a discussion of the pros/cons of screening and to abstract receipt of mammography. We used the signed rank test and McNemar's test to compare before/after responses. We also asked PCPs to complete a survey about using the DA in their practice.
RESULTS: Forty-nine before/after trial participants (from 26 PCPs) had median age of 79 years; 70 % were Non-Hispanic white; 63 % had attended some college; and 24 % had <7 year life expectancy. Comparison of "after" to "before" survey results found: 1) participants answered on average 1 more question correct (interquartile range 0–2) on the 10 item index from 6 to 7 questions correct, p<0.001; 2) decisional conflict declined by 4.8 points (range −10.2 to +4.7 points, mean DCS scores before = 20.1, p=0.03); and 3) fewer participants intended to be screened (59 % compared to 82 % before, p=0.01). In the following 6 months, 61 % of participants had a PCP note documenting a discussion of the pros/cons of screening compared to 10 % in the previous 5 years, p<0.001. While 86 % had been screened within 2 years before participating only 61 % were

screened within 1 year after, $p<0.001$ (a similar decline was found among women with <7 year life expectancy). Overall, 94 % reported that they would recommend the DA, 94 % found it helpful, and 78 % found the amount of information just right. PCPs (17/26) reported that using the DA would result in their patients making more informed (74 %) and value laden (79 %) decisions.

CONCLUSIONS: We developed a DA for women aged >75 years contemplating mammography screening. Our before/after trial demonstrates that this DA allows women to make more informed, preference-sensitive decisions around mammography screening. Next, we plan to test the effectiveness of the DA in a large randomized control trial.

A CENSUS OF STATE-BASED CONSUMER HEALTH CARE PRICE WEBSITES Jeffrey T. Kullgren[1]; Katia A. Duey[2]; Rachel M. Werner[3]. [1]Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; [2]University of Pennsylvania, Philadelphia, PA; [3]Philadelphia VA Medical Center and University of Pennsylvania, Philadelphia, PA. (Tracking ID #1642367)

BACKGROUND: As Americans' out-of-pocket health care costs continue to rise, many health plans, consumer groups, and state governments are reporting health care price information directly to patients. Though there is broad recognition that this information must be relevant, accurate, and usable to improve the value of patients' out-of-pocket spending, it is currently unknown what information is actually being reported to patients. The objective of this study was to describe the types of information that are currently being reported on state consumer health care price websites and identify opportunities to improve the usefulness of this information for patients.

METHODS: We conducted a systematic internet search to identify patient-oriented, state-based health care price websites that were operational in early 2012. We chose to focus on state-based websites since states are a focal point for health care price transparency initiatives and often publicly report the health care price information they collect under legislative or regulatory authority. For each website we identified, we classified the type of organization that reported the information, the kinds of health care services for which prices were reported, the type of price information that was reported (e.g., out-of-pocket cost, allowable charge, or billed charge), the patient-level factors that were incorporated in the estimate, and the presence of quality information alongside the reported price information. We then calculated frequencies for each of these characteristics.

RESULTS: We identified 62 state health care price transparency websites, most of which were provided by either a state government agency (46.8 %) or state hospital association (38.7 %). Most websites reported information on prices of inpatient care for medical conditions (72.6 %) or surgeries (71.0 %); prices for outpatient services such as diagnostic or screening procedures (37.1 %), radiology studies (22.6 %), prescription drugs (14.5 %), or laboratory tests (9.7 %) were reported less often. The reported prices usually reflected only billed charges (80.6 %). For outpatient services that commonly include both facility and professional fees (e.g., diagnostic procedures or radiology studies), the majority of price estimates (66.0 %) included just facility fees. Only a small minority of prices were tailored to individual circumstances that commonly affect what a patient is truly expected to pay out-of-pocket for a service, such as their insurance status (9.7 %) or specific health plan (8.1 %). For services where price and quality information together could help patients assess value across providers (e.g., outpatient clinician services or outpatient surgeries), quality information was infrequently portrayed alongside prices (13.2 %).

CONCLUSIONS: Most states now have websites that report health care prices directly to patients. However, the information being reported on these state health care price websites is unlikely to be useful for most patients, and often fails to reflect the true prices they would actually face for services. Improvements in the relevance, accuracy, and usability of publicly reported health care prices could help this information reach its full potential to improve the value of out-of-pocket health care spending for patients.

A HIGH RISK OF HOSPITALIZATION FOLLOWING RELEASE FROM CORRECTIONAL FACILITIES AMONG MEDICARE BENEFICIARIES Emily A. Wang[1]; Yongfei Wang[2]; Harlan M. Krumholz[1,2]. [1]Yale School of Medicine, New Haven, CT; [2]Yale-New Haven Hospital Center of Outcomes Research and Evaluation, New Haven, CT. (Tracking ID #1642216)

BACKGROUND: Healthcare is constitutionally guaranteed in correctional facilities, but not upon release, which could increase the risk of acute events. We studied the risk for hospitalizations among former inmates soon after their release from correctional facilities.

METHODS: We conducted a retrospective cohort study using data from Medicare administrative claims for all fee-for-service beneficiaries who were released from a correctional facility from 2002 to 2010. Using McNemar's test and condition logistic regression, we compared hospitalization rates after release among former inmates 7, 30, and 90 days after release to beneficiaries matched based on age, sex, race, Medicare status, and residential zip code. We also compared hospitalizations with the specified diagnosis codes between the two groups and examined whether being released from a correctional facility was associated with different risks for hospitalizations for ambulatory care-sensitive conditions compared with the matched control. We used Kaplan Meier survival analyses to compare time to the first hospitalization and death between the two matched groups after release. Data were censored at the time of death or the end of the observation period.

RESULTS: Of 110,419 released inmates, 1559 individuals (1.4 %) were hospitalized within 7 days after release; 4285 individuals (3.9 %) within 30 days; and 9196 (8.3 %) within 90 days. The odds of hospitalization was higher for released inmates compared with matched controls (within 7 days, odds ratio (OR) 2.5, 95 % confidence interval [CI] 2.3, 2.8; 30 days, OR 2.1, 95 % CI, 2.0, 2.2; and 90 days, OR 1.8, 95 % CI 1.7, 1.9). Compared with matched controls, former inmates were more likely to be hospitalized for ambulatory care-sensitive conditions (within 7 days, OR 1.7, 95 % CI 1.4, 2.1; 30-days, OR 1.6, 95 % CI 1.5, 1.8; and 90-days, OR 1.6, 95 % CI 1.5, 1.7). Mental health conditions were the most common reason for hospitalizations among former inmates 30 days post release (22.1 %). Diseases of the circulatory system (14.0 %), injury and poison (12.7 %), and disease of the respiratory system (10.5 %) were also common reasons for hospitalization among released inmates. In event-free analyses, former inmates were more likely to be hospitalized compared with the control group within a year following release.

CONCLUSIONS: About one in 70 former inmates are hospitalized for an acute condition within 7 days of release, and one in 12 by 90 days, a rate much higher than the general population. Transitions between correctional facilities and the community are a high-risk period; correctional and community healthcare systems should collaborate to reduce morbidity for this vulnerable population.

A META-ANALYSIS OF THE RAPID ANTIGEN STREPTOCOCCUS TEST Emily Stewart; Brian Davis; Lee Clemans-Taylor; Robert M. Centor; Carlos Estrada. The University of Alabama at Birmingham, Birmingham, AL. (Tracking ID #1624984)

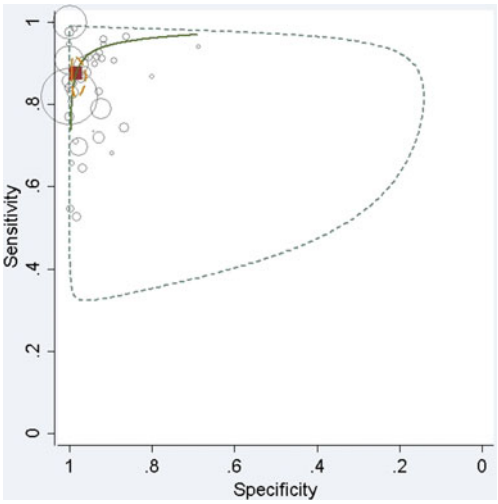
BACKGROUND: Current guidelines to diagnose and treat group A streptococcal (GAS) pharyngitis do not take into account the uncertainty of rapid testing. We examined the accuracy of the rapid antigen streptococcus test (RAST) to diagnose GAS pharyngitis.

METHODS: Systematic review and meta-analysis. MEDLINE search and reference lists, 2000–2012. We included clinical studies using RAST and a reference standard. We assessed quality with Quality Assessment of Diagnostic Accuracy Studies (QUADAS) criteria. We obtained hierarchical summary receiver operating characteristic (HSROC) curve and obtained adjusted estimates of test characteristics.

RESULTS: We included 41 of 728 studies; the overall prevalence was 28 % (13,588/48,377 patients; range 4–67 %). The setting was solely in the emergency department (27 %) or outpatient clinic (56 %); 22 % were solely in children; and 14 % were retrospective. Of 14 QUADAS criteria, eight

were fulfilled by over 90 % of studies, five by 60–80 %, and one by 22 %. The Deek's funnel plot was asymmetric ($p<0.001$) suggesting the presence of publication bias. Studies were heterogeneous as illustrated by a wide 95 % prediction region in the HSROC curve (Figure, dashed line) and high inconsistency estimates for sensitivity (I2=94.4 %) and specificity (I2=98.2 %). The adjusted pooled sensitivity was 88.2 % (95 % confidence interval [CI], 83.9 to 91.4 %; range 52.6 % to 99.9 %). The pooled specificity was 98.5 % (95 % CI, 96.7 to 99.3 %; range 68.8 % to 100 %). Inconsistency between studies remained high for sensitivity and specificity in sub-group analyses for location of test performance (point-of-care, laboratory), pediatric population, setting (outpatient, emergency department), study design (prospective, retrospective), study methodological quality (verification bias, non-differential bias, non-incorporation bias), and funding (commercial or not)(all I2>80 %).

CONCLUSIONS: The RAST is moderately sensitive and highly specific to diagnose group A streptococcal pharyngitis. However, significant heterogeneity and publication bias were observed among studies. Guidelines should incorporate uncertainty in estimates for rapid tests for the diagnosis of GAS pharyngitis.



A MIXED-METHODS RANDOMIZED CONTROLLED TRIAL OF EMPLOYER MATCHING OF DEPOSIT CONTRACTS TO PROMOTE WEIGHT LOSS Jeffrey T. Kullgren[1]; Andrea B. Troxel[2]; George Loewenstein[3]; Laurie Norton[2]; Dana Gatto[2]; Yuanyuan Tao[2]; Jingsan Zhu[2]; Heather Schofield[4]; Judy A. Shea[2]; David A. Asch[5]; Thomas Pellathy[6]; Jay Driggers[7]; Kevin G. Volpp[5]. [1]Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; [2]University of Pennsylvania, Philadelphia, PA; [3]Carnegie Mellon University, Pittsburgh, PA; [4]Harvard University, Cambridge, MA; [5]Philadelphia VA Medical Center and University of Pennsylvania, Philadelphia, PA; [6]McKinsey & Company, Pittsburgh, PA; [7]Horizon Healthcare Innovations, Newark, NJ. (Tracking ID #1642494)

BACKGROUND: Deposit contracts are behavioral economic devices that ask people to put money at risk that they forfeit if they do not meet a goal. While deposit contracts can effectively promote weight loss, a major challenge to wider impact of these programs is getting more people to participate. The goals of this study were to test whether matching of deposits can increase participation in deposit contracts, characterize the corresponding amount of weight loss, and identify factors associated with non-participation in these programs.

METHODS: We recruited 132 employees of Horizon BCBS of NJ who wanted to lose weight and had a BMI between 30 and 50. Participants were given a weight loss goal of 1 lb per week for 24 weeks and randomized to a monthly weigh-in control group or monthly opportunities to deposit $1 to $3 per day with daily feedback. Deposits were either not matched, matched 1:1, or matched 2:1 and provided back to participants at the end of the month for every day in that month that participant was at or below the goal weight for that day. After the 24-week intervention period, we conducted semi-structured interviews with intervention arm participants to identify factors that influenced their participation in deposit contracts. The primary outcome was weight loss at 24 weeks. Secondary outcomes included deposit contract participation; changes in eating behaviors, physical activity, and wellness program participation at 24 weeks; and weight loss 12 weeks after the interventions ended.

RESULTS: After 24 weeks, control arm participants gained an average of 1.0 lb (SD 7.6), compared to mean weight losses of 4.3 lbs (SD 8.9; P=.03) in the no match arm, 5.3 lbs (SD 10.1; P=.005) in the 1:1 match arm, and 2.3 lbs (SD 9.8; P=.29) in the 2:1 match arm. Overall, 29.3 % of participants in a deposit contract arm made at least one deposit, and there were no significant differences in participation rates across the 3 deposit contract arms. There were also no significant differences in changes in eating behaviors, physical activity, and participation in wellness programs after 24 weeks. In semi-structured interviews, the main factors that limited participation in deposit contracts were a lack of confidence in meeting weight loss goals and fear of losing money. 12 weeks after the interventions ended, control arm participants gained an average of 2.1 lbs from baseline (SD 7.9), compared to mean weight losses of 5.1 lbs (SD 11.1; P=.008) in the no match arm, 3.6 lbs (SD 9.6; P=.02) in the 1:1 match arm, and 2.8 lbs (SD 10.1; P=.12) in the 2:1 match arm.

CONCLUSIONS: Relatively few study participants assigned to deposit contract conditions took up opportunities to enter into deposit contracts designed to promote weight loss, and employer matching of deposits did not increase participation. Approaches to promote confidence in losing weight or seed deposit contract accounts might be alternative ways to increase participation in these programs. Greater weight loss in deposit contract arms at 24 and 36 weeks may have been mediated by the automated daily feedback these participants received, and this approach could be another promising tool to promote behavior change in workplace settings.

A NATIONAL ASSESSMENT ON PATIENT SAFETY EDUCATION IN UNDERGRADUATE MEDICAL EDUCATION: A SURVEY OF CLERKSHIP DIRECTORS IN INTERNAL MEDICINE C. Charles Jain[1]; Meenakshy K. Aiyer[1]; Jean C. Aldag[1]; Eric Alper[2]; Steven Durning[4]; Elizabeth A. Murphy[2]; Dario M. Torre[3]. [1]University of Illinois College of Medicine at Peoria, Peoria, IL; [2]University of Massachusetts, Worcester, MA; [3]Drexel University, Philadelphia, PA; [4]Uniformed Services University of the Health Sciences, Bethesda, MD. (Tracking ID #1638436)

BACKGROUND: Patient safety is an important aspect of quality patient care. For this reason, accreditation bodies emphasize educating learners on patient safety in both undergraduate and graduate medical education curricula. This study looks at the current status of patient safety curricula from the perspectives of internal medicine clerkship directors. In addition, this study compares the current status to what was found in a similar study from 20061.

METHODS: The patient safety survey was a part of the Clerkship Directors in Internal Medicine (CDIM) 2012 annual survey. Questions were identified based on literature review, then modified and edited by the CDIM research committee. 37 patient safety related questions were organized into sections including general information, curriculum content and delivery, learner assessment, and barriers to providing the curriculum. All analysis was done using SPSS with group difference tested with Chi-squares for nominal variables. IRB approval was obtained.

RESULTS: Of the 121 clerkship directors surveyed 99 (82 %) responded. Of those responding 45.6 % (n=41) describe having patient safety curriculum at some point during the 4 years of medical school curriculum. Patient safety curriculum was commonly taught in the third year (30.3 %) of medical school followed by the pre-clinical years (yr1=19.2 %, yr2=28.3 %). The top three content areas included in the curriculum were infection control (54.1 %), handoffs and sign outs (47.4 %), and medication safety (39.5 %). Small groups (42.4 %) followed by lectures (31.3 %), direct observation (30.3 %) and Morbidity and Mortality reports (28.3 %)

were used as educational strategies. Even though strategies such as patient safety project, simulations and OSCE were used for assessment of the curricula, only 20 % of the respondents reported satisfaction with student safety competency assessment during their IM clerkship. Lack of a mandate from their school's dean's office (38 %), lack of physician champions (43.7 %), lack of trained faculty (65.3 %), and lack of time (78.1 %) were cited as barriers to implementation. Schools with female clerkship directors were significantly more likely to have a patient safety curriculum compared to schools with male clerkship directors (p=0.01).
CONCLUSIONS: Less than half of medical school curricula report having patient safety curricula. Even though clerkship directors recognize the importance of teaching patient safety curriculum, barriers exist to implementing the curricula. National guidelines on patient safety curriculum are currently not enough and more needs to be done to bring about the desired changes. 1. A NOVEL WEBSITE TO PREPARE DIVERSE OLDER ADULTS FOR DECISION MAKING AND ADVANCE CARE PLANNING: A PILOT STUDY Rebecca L. Sudore[2,1]; Sara J. Knight[2,5]; Anita L. Stewart[4]; Ryan D. McMahan[2,1]; Mariko Feuz[2,1]; Yinghui Miao[2,1]; Deborah E. Barnes[3]. [1]UCSF, San Francisco, CA; [2]San Francisco VA Medical Center, San Francisco, CA; [3]UCSF, San Francisco, CA; [4]UCSF, San Francisco, CA; [5]Veterans Health Administration, Washington, DC. (Tracking ID #1638672)

BACKGROUND: Advance care planning (ACP) has typically focused on advance directives and preferences for treatments, such as CPR. We have reconceptualized ACP as a multi-step process focused on preparing patients with skills needed for communication and in-the-moment decision making. To operationalize this paradigm, we created a new ACP website called PREPARE that is interactive, written at 5th-grade reading level, and shows people through videos and a step-by-step process how to communicate what is most important in life and how to make informed medical decisions. To assess the efficacy of PREPARE, we created and assessed the validity of a new survey that detects behavior change in ACP and then conducted a separate pre-to-post efficacy study.
METHODS: Study #1 (Survey Validation) validates the ACP Engagement Survey, which includes Process Measures of behavior change (knowledge, self-efficacy, and readiness, 5-point Likert) and Action Measures (e.g., "Did you do X?" yes/no) of multiple ACP behaviors such as choosing a surrogate, asking someone to be a surrogate, and speaking to surrogates and doctors about one's wishes. We administered surveys at baseline and one-week later to 50 diverse, older adults from San Francisco hospitals. Internal consistency of the Process Measures was assessed using Cronbach's alpha (only for continuous variables) and test-retest reliability for both Process and Action Measures was examined using intraclass correlations. Study #2 (PREPARE Efficacy): Using a separate cohort (n=43) from low-income, San Francisco senior centers, we assessed change in ACP Engagement Survey responses (Process and Action Measures) and change in percentage of participants in the lowest, "precontemplation", behavior stage of change to higher stages (contemplation, preparation, action, maintenance) at baseline and one-week after viewing PREPARE. We also assessed PREPARE's ease-of-use on a 10-point scale, 10 being the easiest. To assess comparisons, we used paired t-tests and McNemar's tests.
RESULTS: Study #1 (Survey Validation): Mean age was 69.3 (SD 10.5) and 42 % were non-White. The internal consistency of the Process Measures was 0.94. Intraclass correlations were 0.70 for the Process Measures and 0.86 for the Action Measures. Study #2 (PREPARE Efficacy): Mean age was 68.4 (SD 6.6) and 65 % were non-White, and 33 % had limited health literacy. Behavioral change Process Measure average Likert scores increased from 3.1 (SD 0.9) to 3.7 (SD 0.7), p<.001. Action Measures did not change significantly in 1 week. However, precontemplation significantly decreased for most ACP actions including asking someone to be a surrogate 39.5 % vs. 23.3 %, p<.04; talking to the doctor about the surrogate, 62.8 % vs. 30.2 %, P,.001; talking with the surrogate and doctor about medical wishes, 46 % vs. 28 %, p=.02 and 61 % vs. 35 %, P=.003, respectively. PREPARE was rated 9 out of 10 (SD 1.9) for ease-of-use.
CONCLUSIONS: A new patient-centered ACP website prepares people for ACP communication and medical decision making and is easy-to-use among older adults from diverse backgrounds. The new ACP Engagement Survey that measures both ACP behavior change and ACP actions demonstrated good reliability and validity. And, the PREPARE website significantly improves individuals' behavior change and engagement in ACP. The website is available at www.prepareforyourcare.org and a clinical trial is underway.

A PEER-LED INTERVENTION IMPROVES STROKE SURVIVORS' BLOOD PRESSURE CONTROL Carol Horowitz[1]; Kezhen Fei[1]; Ian M. Kronish[2,1]; Stanley Tuhrim[1]; Rennie Negron[1]. [1]Mount Sinai School of Medicine, New York, NY; [2]NY Presbyterian, New York, NY. (Tracking ID #1641866)

BACKGROUND: Hypertension is a major risk factor for stroke recurrence but it is poorly controlled among stroke survivors, particularly from minority groups. The Prevent Recurrence of All Inner-city Strokes through Education (PRAISE) trial tests whether a community-based, peer-led stroke education intervention improves stroke risk factors, primarily blood pressure control.
METHODS: Using community-based participatory research, clinicians, educators and stroke survivors developed a six-session peer-led workshop to help stroke survivors understand their illness, and identify and manage their recurrent risks, particularly hypertension. We recruited 600 individuals with a history of stroke or TIA within the past 5 years who were randomized to the intervention or a wait-list control group. At baseline, 6 and 12 months, we measured participants' blood pressures, sociodemographics, beliefs and behaviors.
RESULTS: Participants have a mean of 63 years, the majority are female (60 %), Black or Latino (81 %) and live in poverty (56 %). At baseline, 31 % in both groups had uncontrolled blood pressure (<140/90 mmHg). At 6 months, the intervention group demonstrated better blood pressure control when compared to the control group, 76 % vs. 65 % (p=0.01). The intervention group also had a significant blood pressure reduction of 3.6/2.0 mmHg (p=0.005/p=0.04) compared to the control group (+0.5/−0.5 mmHg).
CONCLUSIONS: A peer-led educational program developed through a community-academic partnership was successful in improving blood pressure control at 6 months. While 12-month data will confirm the longevity of this impact, PRAISE is simple, culturally appropriate and inexpensive, and may represent an important and sustainable secondary stroke prevention strategy.

A PILOT STUDY OF A COMPUTER-BASED RELATIONAL AGENT TO SCREEN FOR SUBSTANCE-USE PROBLEMS IN PRIMARY CARE Steven R. Simon[1,5]; Kyle Checchi[1,2]; Sarah S. McNair[1,2]; Amy Rubin[3,4]; Thomas Marcello[1,5]; Timothy Bickmore[6]. [1]VA Boston, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Boston University, Boston, MA; [4]VA Boston Healthcare System, Boston, MA; [5]Brigham and Women's Hospital, Boston, MA; [6]Northeastern University, Boston, MA. (Tracking ID #1638383)

BACKGROUND: Because of time constraints in delivering office-based primary care, interventions are needed to offload some tasks from primary care clinicians. Relational Agents - computer characters that simulate face-to-face conversation using voice, hand gesture, gaze cues and other nonverbal behavior, and that use simulated social behaviors to establish trust and therapeutic alliance - can provide education and counseling. Patients may find this type of computerized system suitable for "discussing" sensitive topics, although empirical data are lacking. We therefore conducted a pilot study - the first in the Veterans Health

Administration (VA) - to test the feasibility of using this technology to screen for substance use problems in primary care.
METHODS: We recruited 24 male Veterans from VA Boston. Each participant completed the National Institute on Drug Abuse-Modified Alcohol, Smoking and Substance Involvement Screening Test (NM-ASSIST), administered once by a research assistant and once by the Relational Agent, with the order randomly counter-balanced. Following both screenings, the research assistant conducted a semi-structured interview that solicited the Veteran's perspectives of the Relational Agent for screening, strengths and weaknesses of the Relational Agent compared with live interaction, suggestions for improving the Relational Agent, and potential applications in primary care. We conducted a content analysis of transcribed interview notes, employing standard qualitative research techniques to identify dominant themes.
RESULTS: Among the 24 participants, 19 (79 %) expressed positive impressions of answering the NM-ASSIST with a Relational Agent, while 3 (13 %) were neutral and 2 (8 %) were negative. A total of 14 (58 %) reported being comfortable completing the NM-ASSIST with the Relational Agent. Only 6 participants (25 %) indicated that they preferred the Relational Agent over a live interviewer, while 11 (46 %) preferred the live interviewer and 7 (29 %) were indifferent. Live interviewer was generally preferred because of greater depth of interaction, ability to clarify questions and responses or unease with technology. In contrast, participants who favored the Relational Agent appreciated its ease and efficiency of use, privacy and lack of judgmentalism, and clear answer choices. Among 18 Veterans expressing an opinion, similar percentages favored the use of Relational Agents to ask questions about benign (diet and exercise [16/18, 89 %], family history [15/18, 83 %]), and sensitive (sexual history [15/18, 83 %]) topics. Participants offered constructive feedback on the Relational Agent's behavior, particularly her eye movements; speech, being unnatural and computerized; and relatively unsophisticated graphics. Veterans generally favored the Relational Agent's appearance (attractive woman dressed casually but modestly) and did not express a preference for other characteristics. Veterans frequently voiced concerns about how the Relational Agent would maintain confidentiality of their responses.
CONCLUSIONS: Although participants preferred a live interview to interaction with a computerized Relational Agent, a majority of Veterans were comfortable with the Relational Agent and would be willing to engage with it for counseling and screening for sensitive topics such as substance use and sexual history. Future randomized trials will test the effectiveness of Relational Agents in both screening and brief intervention for substance use problems.

A RANDOMIZED CONTROLLED TRIAL OF AN EVIDENCE-BASED TOOLBOX AND GUIDE TO INCREASE PRIMARY CARE CLINICIANS' RATES OF COLORECTAL CANCER SCREENING IN DIPLOMATES OF THE ABIM Lorna A. Lynn[2]; Carmen E. Guerra1; Kathryn M. Ross[2]; Eric Holmboe[2]; Kaitlin Woo[1]; Daniel F. Heitjan[1]; Debbie Kirkland[3]; Durado Brooks[3]. [1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]American Board of Internal Medicine, Phiadelphia, PA; [3]American Cancer Society, Atlanta, GA. (Tracking ID #1642572)

BACKGROUND: Colorectal cancer screening (CRCS) is effective, cost-effective and consistently recommended by clinical guidelines, yet only 64.5 % of Americans aged 50–75 years have been screened. Recommendation from a physician is the most influential factor in determining whether a patient is screened for CRC. This study was undertaken to determine whether the Evidence-Based Toolbox and Guide to Increase Primary Care Clinicians' Rates of CRCS, developed by the Centers for Disease Control and American Cancer Society, could help diplomates of the American Board of Internal Medicine (ABIM) recertifying for the Internal Medicine boards increase their practice rates of CRCS. The main study aim was to compare practice rates of CRCS in the the control (PIM only) and study (PIM + toolbox) arms.
METHODS: In this randomized controlled trial diplomates who are primary care providers for patients over age 50 and who were enrolled in ABIM's Maintenance of Certification program were invited to participate. Participants had to enroll in the Cancer Screening Practice Improvement Module (PIM), which requires physician-directed measurement of their performance and design of a quality improvement plan. Diplomates were randomized to the PIM or the PIM + toolbox arm. The toolbox consists of four essential sections and evidence-based tools: Your Recommendation, An Office-based Policy, a Reminder System and an Effective Communication System. Analysis was based on the intention-to-treat principle. An external auditor determined the validity of self-reported CRCS rates in a random sample of 20 % of the participants.
RESULTS: A total of 2288 recruitment emails were sent to ABIM diplomates who met the inclusion/exclusion criteria of whom 160 diplomates expressed interest in participation and 144 enrolled in the study. Of these, 79 diplomates completed the study. The CRCS rates declined in 17 of the 79, but improved in the remaining 62. We conducted an analysis of covariance, a GEE and mixed logistic regression models. All final CRCS were adjusted for the baseline performance and all results showed a non-significant treatment effect. In the final mixed logistic regression model adjusted for the baseline performance rate and treatment group of the physician and shown in Table 1, we determined the strength of various physician characteristics in predicting the probability of a successful screening that was performed post-treatment. Medical school country was the only predictor of improved screening rates post-treatment.
CONCLUSIONS: These results demonstrated that while most diplomates improved their CRCS rates from baseline during the study, the improvement was not significantly different in the control arm (PIM only) compared to the study arm (PIM plus toolbox). Medical school country was the only predictor of success rate, with those physicians who attended medical school abroad having an odds ratio of 4.32 (95 % CI: 1.75–10.65) of performing a successful screening than those physicians who attended medical school in the U.S.
Odds ratio estimates and 95 % confidence intervals
Effect Odds Ratio Estimate 95 % CI
Baseline Performance Rate 1,010 (1.00, 1.03)
Treatment vs. Control Arm 1.680 (0.88, 3.19)
Solo vs. Group Practice 1.463 (0.57, 3.76)
Female vs. Male 1.263 (0.65, 2.44)
Foreign vs. U.S. Medical School 4.318 (1.75, 10.65)
Age 0.950 (0.90, 1.01)
Years until MOC Expiration 0.990 (0.77, 1.28)

A RANDOMIZED TRIAL OF TWO APPROACHES TO TRAINING VETERANS AFFAIRS (VA) MEDICAL HOME HEALTHCARE PROVIDERS ON MOTIVATIONAL INTERVIEWING FOR TOBACCO CESSATION Steven Fu[1,2]; Craig Roth[2]; Catherine Battaglia[4]; David Nelson[1]; Melissa Farmer[5]; Tam Do[1]; Michael Goldstein[6]; Rahul Kavathekar[2]; Rachel Widome[1]; Hildi Hagedorne[1]; Alan Zillich[3]. [1]Minneapolis VA Health Care System, Minneapolis, MN; [2]Minneapolis VA Health Care System, Minneapolis, MN; [3]Roudebush VA Medical Center, Indianapolis, IN; [4]VA Eastern Colorado Health Care System, Denver, CO; [5]VA Greater Los Angeles Health Care System, Los Angeles, CA; [6]VHA National Center for Health Promotion and Disease Prevention, Durham, NC. (Tracking ID #1638026)

BACKGROUND: Tobacco cessation counseling from a clinician doubles a patient's odds of quitting. Motivational interviewing (MI) is an effective communication skill in tobacco cessation counseling, but strategies to train providers on MI are needed. This study evaluated a high-intensity versus moderate-intensity MI training program to improve delivery of tobacco cessation care.
METHODS: VA Patient Aligned Care Team (PACT) members at 2 VA facilities were randomized to moderate- or high-intensity MI training. Both training models included the following 3 components: 1) 3-day intensive MI training for site-based MI clinical champions and a site-based MI expert consultant, 2) Half day on-site training workshop for PACT members, and 3) self-study materials. The high-intensity model added 6 booster sessions coached by champions. Three booster sessions used telephone interactions with simulated patients and occurred at 4, 8, and 12 weeks after the initial training. Three additional booster sessions (at 2, 6, and 10 weeks) used small group coaching facilitated by the champions. Each 1-h booster

session focused on specific MI skills. To evaluate the 2 training models, a structured clinical evaluation (OSCE) was conducted with providers in each group before and 12 weeks after the onsite training. The OSCEs assessed provider competence with and acquisition of MI and tobacco cessation skills through interaction with a simulated patient. A trained, blinded rater assessed the provision of MI skills by listening to the audio-recorded OSCEs. The primary outcome was the Motivational Interviewing Treatment Integrity (MITI) scale scores, a validated assessment of MI skills. Hierarchical models compared the average changes in MITI scale scores from the pre-training OSCE to the 12 week post-training OSCE for the moderate intensity and the high intensity groups. The models incorporated random effects for study site and participant and fixed effects for simulated patient and pre-training OSCE MITI scores.

RESULTS: Thirty-five PACT members were enrolled in the study and 18 members were randomly assigned to the high intensity group. Compared to the moderate intensity group, the high intensity group scored significantly higher for 5 of the 10 MITI scales (Table 1). For 3 of the other 5 MITI scales, a non-significant improvement was seen in the high intensity versus the moderate intensity group.

CONCLUSIONS: A training model using several booster sessions incorporating telephone interactions with simulated patients, in addition to MI champions, expert consultant, ½day training and study materials,was effective for sustaining and enhancing providers' MI skills in the delivery of tobacco cessation care.

Table 1

MITI Scales	Training Group	Pre-MITI Score (SD)	Post-MITI Score (SD)	Model Estimated Change (SE)	p-value
Global Spirit	High Intensity	2.89 (0.61)	3.20 (0.77)	0.31 (0.20)	
	Moderate Intensity	2.67 (0.81)	2.50 (0.72)	−0.26 (0.21)	
	Difference			0.57 (0.20)	0.0091
Percent Open Questions	High Intensity	0.32 (0.21)	0.48 (0.23)	0.17 (0.04)	
	Moderate Intensity	0.27 (0.18)	0.32 (0.24)	0.03 (0.05)	
	Difference			0.14 (0.06)	0.0336
Percent MI Adherence	High Intensity	0.50 (0.37)	0.90 (0.19)	0.31 (0.11)	
	Moderate Intensity	0.62 (0.38)	0.57 (0.39)	−0.00 (0.12)	
	Difference			0.32 (0.10)	0.0047

	Difference			0.81 (0.28)	0.0083

A STRATEGY TO ENGAGE COMMUNITY BASED ORGANIZATIONS IN BUILDING RESEARCH CAPACITY Crispin N. Goytia[1]; Barbara Brenner[2]; Peggy M. Shepard[3]; Lea Rivera-Todaro[1]; Carol Horowitz[1]. [1]Mount Sinai School of Medicine, New York, NY; [2]Mount Sinai School of Medicine, New York, NY; [3]WE ACT for Environmental Justice, New York, NY. (Tracking ID #1642376)

BACKGROUND: Building and sustaining community-academic research partnerships is a challenge for both academic institutions and for community based organizations (CBOs). Each partner comes to the relationship with differing expertise and gaps in knowledge. Many Clinical and Translational Science Award (CTSA) sites are working to build CBO capacity to engage in research, but information about needs and goals of CBO's in this regard is lacking. Therefore, our CTSA's community and academic partners aimed to conduct a community research needs assessment.

METHODS: Based on literature review, informal interviews with research-interested CBOs locally and nationally, and with community-engaged research groups from other CTSAs, we developed a needs assessment survey. Key domains of this survey included experience and interest in research collaboration, skill development and program evaluation. The team identified a preliminary list of 80 eligible CBOs through network analysis and a list from the Foundation Center's Directory of New York City organizations that received grants in 2009–2010 in health services or research. We trained Community Health Workers (CHWs) to recruit a senior leader from each site and the CHW's encouraged them via mail, email and telephone over a 90-day period to complete the survey.

RESULTS: Fully 76 % (61) CBOs completed the needs assessment. Most (69 %) reported involvement with research or evaluation in the last 2 years, 42 % were currently involved in research or program evaluation and 33 % had some funding for research. Fully 75 % had collaborated with academic institutions in the past. Most were interested in collaborating or working as partners on research, with a mean score of 6 on a scale of 1 = not interested, to 8 = the most interested. The average experience with collaboration in research was unimpressive: "good" on a scale of "poor, fair, good, very good, excellent". The four areas of greatest interest were program evaluation, developing a needs assessment, statistical analysis and survey development. There was less interest in how to establish a research collaboration with academics. Respondents preferred a hybrid format of online and in- person workshops to other options to either format on its own.

CONCLUSIONS: A formal needs assessment of the research training and education needs of CBO's in New York City revealed that, despite underwhelming experiences with collaboration, most had significant interest in future collaboration and learning about research. CBO leaders were particularly interested in learning about how to conduct research and evaluation, and less interested in learning how to partner with academics to collaborate on research. Community representatives from the CTSA will use these findings to: develop a research capacity building course. Other partnerships should consider building or making use of such assessments to transform the capacity of community organizations to be active research partners and leaders.

A SUCCESSFUL COMMUNITY PARTNERSHIP MODEL FOR RECRUITING PUBLIC HOUSING RESIDENTS INTO RESEARCH Tracy A. Battaglia[1]; Jo-Anna L. Rorie[2]; Sarah W. Primeau[1]; Sarah E. Caron[1]; Sarah G. Bhosrekar[2]; Bing L. Chen[1]; Sharon Bak[1]; Gerry Thomas[3]; Rachel Goodman[5]; Eugenia Smith[4]; Deborah J. Bowen[2]. [1]Boston University School of Medicine, Boston, MA; [2]Boston University School of Public Health, Boston, MA; [3]The Boston Public Health Commission, Boston, MA; [4]The Community Committee for Health Promotion, Boston, MA; [5]The Boston Housing Authority, Boston, MA. (Tracking ID #1612855)

BACKGROUND: The Boston University Partners in Health and Housing Prevention Research Center (PHH-PRC), a partnership between the School of Public Health, Community Committee for Health Promotion, Boston Housing Authority and Boston Public Health Commission, aims to improve the health of Boston's Public Housing residents through research. This study aims to demonstrate the Center's ability to recruit and retain a representative sample of residents in the community setting to participate in a research study.

METHODS: An ongoing community engagement activity of the PHH-PRC is the conduct of monthly, on-site educational health screenings conducted in collaboration with housing development residents and research center staff. We conducted a descriptive analysis of enrollment outcomes from these community-based health screenings held across 6 housing developments from April 2011 through June 2012. The outcome of interest was enrollment into Project HHEART (Heart Health Equality Among ResidenTs), a patient navigation intervention study designed to improve clinical and community program participation among housing development residents at risk for cardiovascular disease. All those attending the health screenings completed a survey, underwent an evaluation for cardiovascular risk factors and received written educational materials. Those eligible for enrollment into Project HHEART were ≥18 years of age, spoke English or Spanish, resided in the respective housing development and screened positive for ≥1 risk factor (overweight/obese, hypertension, hypercholesterolemia, diabetes, tobacco use). We compared socio-demographic and risk factor characteristics of those eligible vs. ineligible for Project HHEART enrollment. Among those eligible, we compared characteristics of those who enrolled vs. declined.

RESULTS: 610 residents participated in screenings April 2011–June 2012. Most were female (74 %), non-White (30 % Black, 44 % Hispanic, 15 % other), had public (84 %) or no health insurance (10 %), reported a clinical visit with a primary care provider in the past 3 months (62 %) and screened positive for >1 risk factor (92 %). About half spoke a language other than

English (50 %), were foreign-born (49 %), and had less than high school education (45 %). Overall, 451 (74 %) of participants were eligible for enrollment. Reasons for ineligibility included: not living on site (n=106), no positive screens for risk factors (n=32) and significant language barriers (did not speak English or Spanish) (n=21). Compared to those ineligible for Project HHEART, eligible participants were more likely to be older (mean age 50 v. 49 years, p<0.01), Hispanic (48 % v. 33 %, p<0.01), and have public or no health insurance (93 % v. 86 %, p=0.05). Of the 451 eligible participants, 326 (72 %) agreed to participate and were enrolled into Project HHEART. Compared to those who declined to participate, enrolled subjects were slightly younger (mean age 50 v. 53, p<0.01), but did not differ in any other socio-demographic or health risk factor status. Of those enrolled (n=326), 80 % completed 3-month follow-up surveys.
CONCLUSIONS: Socio-demographic differences in eligibility reflect the study design. Among those eligible, we enrolled and retained a representative sample of public housing residents and engaged them into prevention research. This program serves as one viable model to engage a diverse population in research.

A TECHNOLOGY-BASED APPROACH TO IDENTIFYING UNDIAGNOSED HYPERTENSION Christopher Masi[1]; Michael Rakotz[1,2]; Ruth Ross[1]; Ari Robicsek[1]; Chad Konchak[1]; Bernard Ewigman[2]. [1]NorthShore University HealthSystem, Evanston, IL; [2]NorthShore University HealthSystem, Evanston, IL. (Tracking ID #1633262)

BACKGROUND: Affecting 30 % of all U.S. adults 18 years and older, hypertension is the leading modifiable risk factor for coronary artery disease, stroke, and congestive heart failure. According to the 2008 National Health and Nutrition Examination Survey, approximately 19 % of U.S. adults with hypertension are unaware of their diagnosis. Our goal was to identify primary care patients with suspected but undiagnosed hypertension and then clarify their status using an automated office blood pressure (AOBP) device.
METHODS: We queried the electronic health records (EHR's) of patients who receive care at one of twenty-three health system-affiliated primary care clinics to identify adults aged 18 to 79 years who had at least one primary care office visit within 12 months of the query, had elevated blood pressure readings as identified by at least one of five hypertension screening algorithms, and did not have a diagnosis of hypertension recorded in the EHR. Individuals who met these criteria were considered at-risk for undiagnosed hypertension and were invited to complete a clinic-based AOBP measurement using a BpTRU device which averages five readings over a five-minute period. Since each patient had one or more previously documented elevated blood pressure readings, we classified patients based upon their AOBP mean: hypertension if BP≥140/90 mmHg; prehypertension if BP≥120/80 mmHg and <140/90 mmHg; and white coat hypertension if BP<120/80 mmHg. The positive predictive value (PPV) of the hypertension screening algorithms was calculated by dividing the number of individuals with an AOBP mean in the prehypertension or hypertension ranges (true positives) by the number of individuals identified by at least one of the hypertension screening algorithms (all positives).
RESULTS: Of the 139,666 adults who receive care at one of the participating clinics, 1,586 met our inclusion criteria. After confirming the appropriateness of study participation with each patient's primary care physician, attempts were made to recruit 1,432 patients. 475 of these patients agreed to participate in the study and undergo a clinic-based AOBP measurement. Among participants, the median age was 54.4 years, the mean BP recorded in the EHR was 136/82 mmHg, and the mean BMI was 29.6 kg/m2. Fifty-two percent of participants were male. Participants identified themselves as Caucasian (70.9 %), African American (6.1 %), Hispanic/Latino (3.4 %), Asian (2.7 %), or other (16.8 %). Comparing the 475 participants to the 957 non-participants revealed the participants were older (54.4 vs. 50.0 years, p<0.001) but were similar in all other respects, including distribution of ethnicities, and prevalence of co-morbidities, including diabetes, congestive heart failure, and COPD. Based upon AOBP means among participants, 183 (39 %) had hypertension, 196 (41 %) had prehypertension, and 96 (20 %) had white coat hypertension. The positive predictive value for detecting prehypertension or hypertension using our technology-based approach was 80 %.
CONCLUSIONS: Essential elements of our approach included an EHR, computer-based screening algorithms, and an established AOBP protocol. Results from this study confirm the notion that technology-based strategies have significant potential to detect undiagnosed chronic disease - a critical first step toward enhancing chronic disease management.

A VALID MEASURE OF HEALTH-RELATED TRUST FOR USE IN DIVERSE POPULATIONS Rebecca J. Schwei[1]; Paul Rathouz[2]; Seung W. Choi[3]; Elizabeth A. Jacobs[1]. [1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]University of Wisconsin School of Medicine and Public Health, Madison, WI; [3]McGraw-Hill Education, Monteray, CA. (Tracking ID #1640804)

BACKGROUND: Varying levels of distrust in health care among racial/ethnic groups are hypothesized to contribute to health disparities in the US. However, few measures of trust and distrust have been developed and validated for use across racial/ethnic groups to allow adequate exploration of this hypothesis. The objective of the study was to develop a measure of health-related trust in the 3 major racial/ethnic groups in the US: African Americans, Hispanic-Mexicans, and non-Hispanic whites.
METHODS: We developed candidate items through extensive qualitative work, cognitive testing, piloting, and rigorous translation into Spanish. We administered the 81 candidate items to a convenience sample of African American (n=142), Hispanic-Mexican (n=143), and non-Hispanic white (n=155) individuals at Chicago-area supermarkets. Participants responded using a 5-item Likert response scale: never true, a little true, half the time true, mostly true, always true. We conducted exploratory and confirmatory factor analyses using Mplus. We also asked "In the past 5 years, have you had a negative health care experience you considered to be bad or negative?" (Y/N).
RESULTS: The final instrument contained 36 items and 7 factors: Discrimination (3 items), Equity (6 items), Hidden Agenda (4 items), Insurance (3 items), Negative Physician Perceptions (5 items), Positive Physician Perceptions (12 items) and System Welcoming (3 items). A higher trust score indicated increased trust. The instrument (α=.94) and individual factors performed well overall and in each racial/ethnic group (α=.61 to .94) The 7-factor CFA model provided reasonable fit statistics (CFI=.964, TLI=.961, RMSEA=.055) and evidence for construct validity. Across all racial/ethnic groups individuals reporting a negative health care experience had lower levels of institutional trust.
CONCLUSIONS: Our measure of health-related trust performed well across racial/ethnic groups while including constructs that may vary considerably across groups (e.g., Discrimination). There was increased trust in groups without a reported previous negative health care experience. We found trust in health care to be multi-faceted, incorporating perceptions about physicians, health care systems, and insurance. This measure has the potential to advance the field studying how health-related trust contributes to health disparities in the US.

A CASE METHOD EDUCATION ON MANAGEMENT OF DISCHARGE PLANNING FOR HEALTHCARE PROFESSIONALS Yukio Tsugihashi[1,2]; Noriko Kawai[2]; Hitoshi Ishii[2]. [1]Tenri Hospital, Tenri, Japan; [2]Tenri Hospital, Tenri, Japan. (Tracking ID #1627411)

BACKGROUND: In collaborative healthcare systems, reducing length of stay has been a priority for general hospitals. There is concern that the reduction may provide low-quality transitional care for the patients and the families. In order to secure the quality for the patients and the families, hospital workers should effectively acquire a management skill for discharge planning. A case method is a teaching method that is widely used in business schools. Students can enhance their leadership and management skills through discussion about a teaching case. The case is a document that objectively illustrates business cases to be solved and includes information for classroom discussion. Both business and discharge planning, there are no simple solutions. We hypothesized that the case method could be adjusted into education in discharge planning. Therefore, we developed a novel educational program for the discharge planning using

a case method education. The purpose of this study was to (1) develop educational strategies and (2) assess the learning outcomes of this program.
METHODS: This study was conducted from April 2012 to July 2012 at one general hospital in Japan (Tenri Hospital, Tenri City, Nara, Japan). Cornerstones of the program are provided in Table 1. The Participants were provided with a case method education consisting of following three steps: 1) Preparing their opinions for teaching cases before the classes. 2) Discussing with other participants in small groups and a classroom, 3) A short lecture summarizing key points in the cases. A medical doctor and a registered nurse specialized in care transition prepared four cases based on actual care transition in Tenri Hospital. In order to evaluate learning outcomes of the program, we performed questionnaire surveys after each lecture, including descriptive analyses about participants' satisfaction and qualitative content analysis focused on their self-awareness through the program.
RESULTS: This study enrolled 57 healthcare providers working in Tenri Hospital and affiliated care institutions. With regard to the occupation, 31(54 %) were registered nurses, 7 (12 %) were medical social workers, and 19 (38 %) were other occupations including physical therapists, long-term care support specialists, medical doctors, pharmacists, certified care workers, medical college teachers and medical secretary. Over 90 % of the participants were satisfied with the program. The participants' self-awareness was identified to the following three categories: acquiring core competencies for discharge planning, problem extraction through active interaction among the participants, and precious opportunities for inter-professional communications in the related institutions.
CONCLUSIONS: A case method by the discussion-based education using actual cases successfully contributed to enhance the participants' awareness for management of discharge planning in addition to obtaining the core competency. Furthermore, the program itself could promote inter-professional communications among the hospital workers.
Table 1. Cornerstones of a case method education on management of discharge planning
Teaching method A case method education with 3 h session per a month (Small group discussion: 60 min, Classroom discussion: 60 min, Short lecture: 30 min)
Duration/Frequency 4 months/One Saturday afternoon per month
Titles of teaching cases Case 1. An elderly woman emergently admitted to a hospital with acute pyelonephritis
Case 2. An elderly patient with advanced dementia and bilateral leg gangrenes
Case 3. A patients who can't eat by mouth because of severe neurological disease
Case 4. Tohoku earthquake. Effort of medical support teams from Nara prefecture
Learning outcomes Satisfaction level (descriptive analysis)/Self-awareness (qualitative analysis)

A MULTI-INSTITUTION RETROSPECTIVE STUDY ON CAUSATIVE DISEASES AND DIAGNOSTIC METHODS FOR FEVERS OF UNKNOWN ORIGIN IN JAPAN: A PROJECT OF THE JAPANESE SOCIETY OF GENERAL HOSPITAL MEDICINE

Toshio Naito[1]; Fujiko Mitsumoto[2]; Hiroyuki Morita[3]; Masafumi Mizooka[4]; Shiro Oono[5]; Akira Ukimura[6]; Keito Torikai[7]; Kenji Kanazawa[8]; Masashi Yamanouchi[1]; Susumu Tazuma[4]; Jun Hayashi[2]. [1]Juntendo University School of Medicine, Tokyo, Japan; [2]Kyushu University Hospital, Fukuoka, Japan; [3]Gifu University Graduate School of Medicine, Gifu, Japan; [4]Hiroshima University Hospital, Hiroshima, Japan; [5]Nara Medical University, Nara, Japan; [6]Osaka Medical College, Osaka, Japan; [7]St. Marianna University School of Medicine, Tokyo, Japan; [8]Kobe Universtiy Hospital, Kobe, Japan. (Tracking ID #1634255)

BACKGROUND: Fevers of unknown origin (FUO) are caused by a wide range of diseases, and they occur in a variety of regions and age groups. In Japan, research on the topic has been limited to single facilities/regions, and no national surveys have been conducted. Analysis is important, as causes may differ with race, region and era. Further, few studies have evaluated the usefulness of diagnostic exams, and FUO is diagnosed according to guidelines specific to each facility. In particular, there has been very little research on the efficacy of recently developed diagnostic methods, such as blood procalcitonin analysis and positron emission tomography (PET). Here, we conducted a national survey at facilities belonging to the Japanese Society of General Hospital Medicine, to clarify what exams are useful and what diseases deserve attention in the differential diagnosis and treatment of FUO.
METHODS: Seventeen facilities were surveyed nationwide from January to December 2011. The subjects were patients who were 18 years or older and diagnosed with "classical FUO (a fever with an axillary temperature of 38 °C or higher and measured 2 times or more in a period of 3 weeks or longer, and where the cause was unclear after 3 outpatient visits or a 3-day hospital stay)." Subject data were recorded in a common case report form and tallied using FAX.
RESULTS: A total of 121 FUO cases were recorded, with a median age of 59 years (19–94 years). The causative disease was infection in 28 cases (23.1 %), noninfectious inflammatory disease in 37 cases (30.6 %), malignant tumor in 13 cases (10.7 %), something else in 15 cases (12.4 %), and unknown in 28 cases (23.1 %). "Something else" included causes such as drug-induced fevers. The median number of days from fever onset to first examination was 28 days. A case of familial Mediterranean fever took the longest days to be diagnosed. Blood cultures were performed at 86.8 %, blood procalcitonin values measured at 43.8 %, and PET performed at 29.8 %.
CONCLUSIONS: With the increased use of computed tomography, FUO due to deep abscesses or solid tumors have declined markedly. The causative disease with the largest proportion was polymyalgia rheumatica (9 cases), reflecting the aging of the society. The relatively small number of cases due to an unknown cause was possibly attributable to the bias of the retrospective study. HIV/AIDS caused 4 FUO cases, showing that this has become an important cause of FUO in Japan. This study clarified diseases that deserve attention when differentiating FUO. We have a plan to analyze the usefulness of exams and create guidelines for diagnosing FUO.

A NATIONAL STUDY OF INTERNISTS' POINT OF CARE LEARNING

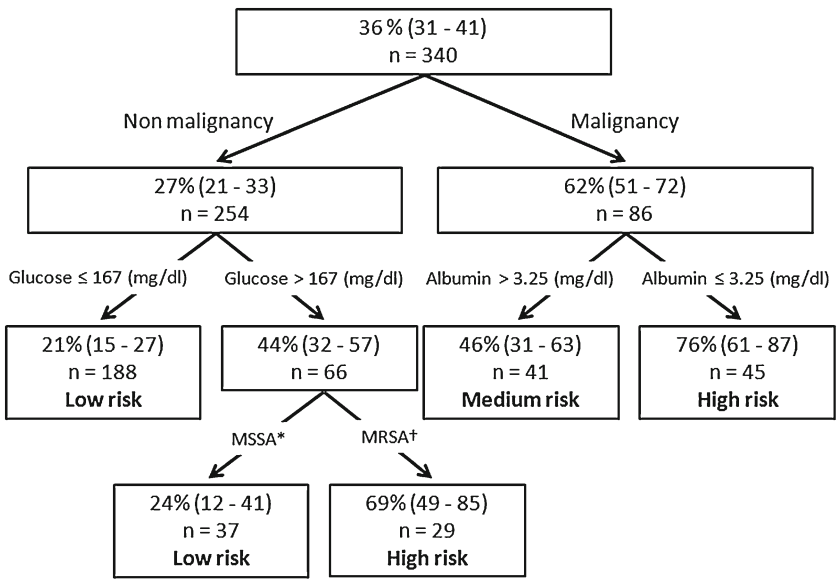
Michael Green[1]; Siddharta Reddy[2]; Eric Holmboe[2]. [1]Yale School of Medicine, New Haven, CT; [2]American Board of Internal Medicine, Philadelphia, PA. (Tracking ID #1639990)

BACKGROUND: Physicians frequently encounter clinical questions at the point of care (POC), which represent opportunities for learning, immediate application of new knowledge, and longer term performance improvement. An understanding of these POC learning episodes would inform continuing medical education programs, electronic information resources, evidence-based practice training, and reflective practice. Previous studies of POC learning have been confined to small numbers of physicians in limited geographic areas.
METHODS: We studied internists enrolled in the ABIM Maintenance of Certification (MOC) program who registered for and entered at least one question in the ABIM Point-of-Care Clinical Question Module between November 2010 and December 2012. To complete this web-based module, internists documented the characteristics, information seeking, learning, practice impact, and barriers of at least 20 point of care clinical questions. We compiled descriptive statistics for the module data.
RESULTS: Four-hundred-seventy-two internists entered at least one clinical question (224 completed the module, 188 are currently working on it, and 60 cancelled). Among those who completed the module, 197 (88 %) spent more than 30 h per week in patient care activities, 66 (28 %) were generalists, and 108 (48 %) worked in academic settings. The internists documented 5187 POC learning episodes over periods ranging from 1 to 19 months. The episodes most commonly were stimulated by direct patient care in the ambulatory setting, with or without a trainee (57 %); involved cardiovascular disease (21 %) or gastroenterology (14 %) content; represented foreground questions (58 %); and concerned therapy (55 %) or diagnosis (14 %) questions. The internists spent a median of 30 min looking up medical information, most often some time after the clinical encounter (61 %); using a median of 2 resources; and most commonly consulting UpToDate® (25 %) and articles retrieved via PubMed (17 %). The internists planned to change their practice based on 40 % of the point of care learning episodes. Among the remainder, they

reported that the information supported their current practice (47 %), they required more information before making a change (9 %), or the practice change was not feasible (3 %). Internists encountered barriers during 11 % of the learning episodes, including limited access to information resources (17 %), uncertainty about the sufficiency of the information initially obtained (13 %), difficulty searching information resources (11 %), and difficulty appraising the validity or usefulness of the information (8 %).
CONCLUSIONS: Using a novel web-based portfolio for MOC, internists' report POC learning episodes that most commonly occur in the ambulatory setting, involve cardiovascular disease or gastroenterology content, and concern questions of therapy and diagnosis. They consult an average of two information resources per episode, most commonly UpToDate and PubMed. Forty percent of POC learning episodes result in a planned practice change.

A PREDICTION RULE FOR MORTALITY FOR INPATIENTS WITH STAPHYLOCOCCUS AUREUS BACTEREMIA: A CLASSIFICATION AND REGRESSION TREE (CART) ANALYSIS Daiki Kobayashi[1,2]; Kyoko Yokota[4]; Osamu Takahashi[2,3]; Hiroko Arioka[2]; Tsuguya Fukui[2]; Christina C. Wee[1]. [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]St Luke's International Hospital, Tokyo, Japan; [3]St Luke's Life Science Institute, Tokyo, Japan; [4]Kagawa University, Takamatsu, Japan. (Tracking ID #1641328)

BACKGROUND: Staphylococcus aureus bacteremia (SAB) is one of the most common types of bacteremia in both community and healthcare settings. Previous studies suggest that the mortality associated with SAB is significant rangeing from 20 to 40 %. Although mortality is high, the risk factors for mortality among patients with SAB have not been sufficiently evaluated.
METHODS: This was a retrospective cohort study of all adult patients with SAB at a large community hospital in Tokyo, Japan, from April 1, 2004 to March 31, 2011. All patients with fever and afebrile patients who were suspected of having a bacterial infection had 2 sets of blood cultures sent at the time of admission. SAB was determined based on at least one positive blood culture. The primary outcome was death within 90 days. Baseline data and clinically relevant factors were collected from the electronic chart. All candidate predictors were included in a Classification and Regression Trees (CART) analysis to create a prediction rule to identify risk factors of mortality among patients with SAB. A receiver operating characteristic (ROC) curve was drawn, and the area under the curve (AUC) was obtained.
RESULTS: 340 patients had SAB during the study period. Of these, 121 (36 %) patients died within 90 days. Among 41 potential variables examined, the CART analysis revealed that underlying malignancy, serum blood glucose level, methicillin resistance, and low serum albumin were predictors of mortality. Our results suggest that patients can be categorized in 3 risk groups: low (< 30 % mortality), medium (40–60 %), and high (> 60 %) (see fig). For patients without underlying malignancy, the next best predictor was serum blood glucose level, where patients with a blood glucose level >167 mg/dl had higher risk of mortality (see fig). Methicillin resistance predicted mortality risk only among patients who had a glucose level higher than 167 mg/dl. For patients with malignancy, serum albumin was the most important predictor; patients with <3.25 mg/dl albumin were placed in the high risk group. The AUC was 0.76 (95 %CI: 0.70–0.81).
CONCLUSIONS: We propose a prediction model for mortality of patients with SAB consisting of 4 predictors: underlying malignancy, low serum albumin, high glucose, and methicillin resistance. This model, if validated in other populations, may facilitate appropriate preventative management for patients with SAB who are at high risk of mortality.
Decision tree for 90 Day Mortality (95 % Confidence Interval) Among Patients with Staphylococcus aureus Bacteremia. Results are derived from CART Analysis. Low risk = <30 % mortality, medium risk = 40–50 %, high risk = > 60 % MSSA* refers to Methicillin-sensitive Staphylococcus aureus, MRSA† refers to Methicillin-resistant Staphylococcus aureus



A RANDOMIZED CONTROLLED TRIAL OF A COMMUNITY HEALTH WORKER POST-HOSPITAL CARE TRANSITIONS INTERVENTION FOR LOW SOCIOECONOMIC STATUS PATIENTS Shreya Kangovi[1,6]; David Grande[2,3]; Nandita Mitra[4]; Jeffrey Sellman[1]; Mary L. White[6]; Sharon McCollum[6]; Richard Shannon[2]; Judith A. Long[5,2]. [1]Philadelphia Veterans Affairs Medical Center, Philadelphia, PA; [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA; [4]University of Pennsylvania, Philadelphia, PA; [5]Philadelphia Veterans Affairs Medical Center, Philadelphia, PA; [6]Spectrum Health Services, Inc., Philadelphia, PA. (Tracking ID #1631341)

BACKGROUND: The post-hospital transition is a focus of national policy attention. Low socioeconomic status (SES) patients are more likely to report poor quality of discharge planning, lack of social support during recovery and inability to access outpatient follow-up after hospitalization. Low-SES patients have an elevated risk of all-cause readmission and post-hospital death. Existing post-hospital transition interventions often employ clinical personnel and neglect socioeconomic factors that are important to low-SES patients. To address these issues, we performed a randomized controlled trial comparing a community health worker (CHWs) intervention (IMPaCT-Individualized Management towards Patient-Centered Targets) to usual discharge care.

METHODS: Participants were recruited from two academically affiliated hospitals in Philadelphia, PA. Eligible patients were:1)admitted to the General Medicine service; 2)uninsured or insured by Medicaid; 3)18–64 years old and 4)residents of low-income ZIP codes. Eligible patients were randomized to receive usual discharge care or IMPaCT. Patients randomized to IMPaCT received structured CHW social support, advocacy and health system navigation from the time of hospitalization until post-hospital primary care follow-up. CHWs were recruited through a network of community-based organizations, underwent a month-long training and were paid $15 per hour. The primary outcome of the trial was the proportion of patients who completed primary care follow-up within 2 weeks of hospital discharge. Secondary outcomes, which each ranged from 0 to 100, were: self-rated health (SF-12), quality of discharge communication (Consumer Hospital Consumer Assessment of Healthcare Providers and Systems-HCAHPS- discharge communication items), patient activation (Patient Activation Measure score) and readmission rate at 14,30,60 and 90 days. Patient-reported outcomes were measured by a blinded assessor 2 weeks after index discharge. We compared outcomes between control and intervention groups using an intention to treat analysis.
RESULTS: 442 patients were enrolled from May 15th, 2011 to December 1st, 2012. 86.6 % of participants completed the trial. The intervention group had a higher proportion of patients who engaged in post-hospital primary care than the control group (59.4 % vs. 48.4 %, p=0.03). Patients in the intervention group had higher self-rated health mental component summary scores (49.2 vs. 46.3, p=0.02), were more likely to report high-quality discharge communication (91.3 % vs. 78.3 %, p=0.002) and had higher levels of patient activation (64.0 vs. 60.3, p=0.04). At 14 days readmission rates were not different between groups (9.9 % vs. 7.2 %, p= 0.60). 30, 60 and 90-day readmission rates are pending.
CONCLUSIONS: A brief transitions intervention performed by CHWs can improve a variety of post-hospital outcomes for low-SES patients. 14-day rates of readmission are low and not different between groups. CHWs, who are inexpensive and rapidly trained, are well-suited to provide post-hospital support to a high-risk, underserved population.

Secondary Patient-Reported Outcomes*

	Control (n=221)	Intervention (n=221)	P Value
Self-rated health			
Mental Component Summary	46.3±12.9	49.2±12.4	0.02
Physical Component Summary	38.2±11.8	38.4±11.1	0.89
HCAHPS high-quality discharge communication	78.3 %	91.3 %	0.002
Patient Activation Measure	60.3±15.9	64.0±17.4	0.04
14-d Readmission	7.2 %	9.9 %	0.60

*Values are expressed as percentage or mean ± SD

A RANDOMIZED CONTROLLED TRIAL OF PRIMARY CARE BASED PHARMACIST-PHYSICIAN COLLABORATIVE MEDICATION THERAPY MANAGEMENT FOR HYPERTENSION Jan D. Hirsch[1]; Neil Steers[2]; David S. Adler[1]; Grace M. Kuo[1,4]; Candis M. Morello[1]; Megan Lang[6]; Renu F. Singh[1]; Yelena Wood[3]; Robert M. Kaplan[5]; Carol Mangione[2]. [1]University of California San Diego, La Jolla, CA; [2]University of California Los Angeles, Los Angeles, CA; [3]University of California San Diego, San Diego, CA; [4]University of California San Diego, La Jolla, CA; [5]University of California Los Angeles, Los Angeles, CA; [6]University of California San Diego, San Diego, CA. (Tracking ID #1634599)

BACKGROUND: Managing patients with chronic diseases to achieve therapeutic goals such as blood pressure (BP) control is challenging for busy primary care physicians. Collaborative care models that fully integrate pharmacists within the primary care team may help address this problem by giving patients better access to highly trained provider teams. We conducted a randomized controlled trial (RCT) evaluating BP control for hypertensive patients collaboratively managed by a pharmacist-primary care physician team versus those who were solely managed by their primary care physician (PCP).
METHODS: Patients with BP>140/90 mmHg or BP>130/80 mmHg with a diagnosis of diabetes mellitus were randomized to treatment by a pharmacist under a collaborative pharmacist-physician medication therapy management (MTM) protocol versus usual care in an academic General Internal Medicine practice. Patients were scheduled for pharmacist appointments independent of physician visits. Pharmacist actions included drug therapy monitoring, physical assessment, laboratory test review and order, medication adjustments (dosage change, initiation, discontinuation), and patient education. The primary outcome was mean change in systolic blood pressure (SBP) at 6 and 9 months after initial visit. Secondary outcomes were percent achieving BP goal, mean change in diastolic blood pressure (DBP), LDL and HDL cholesterol.
RESULTS: At baseline the MTM group (n=76) was similar to the Usual Care group (n=91) for all eight measured clinical markers; however MTM patients were slightly younger 65.4 (13.0) vs. 69.6 (11.4) years, had lower Charlson Comorbidity Index 3.1 (1.9) vs. 4.1 (2.6), and had more men (53.3 % vs. 31.9 %). Mean change in SBP in the MTM group was significantly greater at 6 months −7.1 (19.4) vs. +1.6 (21.0) mm Hg, (p=0.008) but the difference was no longer statistically significant at 9 months −5.2 (16.9) vs. −1.7 (17.7) mmHg, (p=0.22). The mean change in SBP from initial visit to 9 months for patients who had returned to their PCP after 6 months was +1.9 (13.8) compared to −7.8 (17.3) for those who continued to see the MTM pharmacist through the 9-month visit (p=0.03). Compared to Usual Care patients, a greater percentage of MTM patients were at goal at 6 months (81 % vs. 44 %, p< 0.001) and 9 months (70 % vs. 52 %, p=0.02). No significant difference in change in LDL or HDL was detected at 6 or 9 months between groups.
CONCLUSIONS: A pharmacist-physician collaborative medication therapy management service was more effective in lowering blood pressure than usual care at 6 months and at 9 months for patients who continued to see the pharmacist. Given the shortages of PCPs and the aging population, incorporating pharmacists in the primary care team can be a successful strategy for managing medication therapy, improving patient outcomes and extending primary care capacity.

A RANDOMIZED TRIAL OF A COMMUNITY HEALTH WORKER LED INTERVENTION USING HPV SELF-SAMPLING TO INCREASE CERVICAL CANCER SCREENING AMONG MINORITY WOMEN: PRELIMINARY FINDINGS Olveen Carrasquillo; Brendaly Rodriguez; Erin N. Kobetz-Kerman. University of Miami, Miami, FL. (Tracking ID #1642511)

BACKGROUND: Cervical cancer disproportionately affects minority and immigrant women. Among this population, there are multiple barriers to Pap smear screening including knowledge, limited access to care and cultural norms. In 2012, the USPSTF noted that self sampling for the human papilloma virus (HPV) holds great promise as a screening strategy among hard to reach populations. We present preliminary findings from our ongoing randomized trial testing this approach in three minority communities in Miami.
METHODS: The South Florida Center for Reduction of Cancer Disparities is a comprehensive NCI initiative aimed at reducing cervical cancer disparities in South Florida through community based participatory research. Using community health workers (CHWs) our community partners are recruiting 600 minority women ages 30–65 who had not had a Pap smear in the last three years into the study. Following a baseline intake, women are randomized into one of three arms. Group one receives culturally tailored cervical cancer education materials. Groups 2 and 3 receive a 1 hour CHW home health education session. CHWs subsequently refer and navigate women in group 2 to Pap smear screening at community based facilities that perform free or low cost testing. Women in group 3 have the option of Pap smear or doing HPV self sampling after a brief CHW instruction session. A research assistant blinded to study allocation performs a 6 month follow-up visit to assess screening status. A formal interim analysis was not part of the study design. However, we are able to present preliminary baseline data as well as follow-up status in Groups 2 and 3 based on CHWs logs. We do not include any hypothesis testing.
RESULTS: To date, using various community outreach strategies, CHWs have assessed 2,601 women for study inclusion. Of these 515 are study eligible; most ineligibles are due to being screened already or age exclusion. Less than 5 % of eligible women have declined to participate. Among the 280 women we have already randomized, 51 % are Hispanic, 39 % Haitian, and 11 % African American. Over half are uninsured. Among the 70 women randomized to group 2 and having already received the educational session, 48 % have obtained a subsequent Pap smear.

Among the 64 women randomized to Group 3 who have received the education, 95 % have been screened. Of these 69 % preferred to have the HPV self-sampling at time of CHW session over being referred for a Pap smear. In Little Haiti, 10 of 21 (48 %) HPV samples have been positive for high risk HPV versus 18 % in the other two communities.

CONCLUSIONS: Using the CBPR framework, in a 14 month period we have been able to recruit and randomize almost half of our planned 600 "hard to reach" study population with almost no women refusing to participate. Our rates of Pap smear completion among women in group 2 compares very favorably with data from other similar CHW led programs. Our preliminary data also makes an extremely strong case for HPV self-sampling as a strategy for cervical cancer screening among unscreened minority women.

A RANDOMIZED TRIAL OF A WEB-BASED VERSUS COUNSELOR-BASED INTERVENTION TO REDUCE CHD RISK Stacey L. Sheridan; Thomas C. Keyserling; Lindy B. Draeger. University of North Carolina at Chapel Hill, Chapel Hill, NC. (Tracking ID #1642611)

BACKGROUND: Coronary heart disease (CHD) is the leading cause of death in the United States and effective interventions are available to reduce CHD risk. However, the best way to implement risk reduction strategies is yet to be determined.

METHODS: We developed two versions of a combined lifestyle and medication intervention (counselor intevention (CI) and web intervention (WI)) to reduce CHD risk and compared their effects in a randomized trial conducted at five socioeconomically diverse clinics in a practice-based research network. Both interventions were tailored to participants' baseline risk factors and treatment preferences and included similar content: a web-based decision aid, 4 monthly contacts during an intensive intervention phase (4 months) and 3 brief contacts at 2 month intervals during a maintenance phase (8 months). The primary outcome was within group change in 10 year predicted risk by Framingham score at 4 month follow-up. Secondary outcomes included between group difference in predicted CHD risk and within group changes in CHD risk factors, lifestyle behaviors, and medication adherence. Cost-effectiveness from a societal perspective was also assessed.

RESULTS: We randomized 389 participants with no known CHD and 10-year Framingham CHD risk > or =10 % to either the CI (n=195) or the WI (n=194). Mean age was 63. 49 % were female, 25 % were African-American and 75 % white. Mean 10-year predicted CHD risk was 16.9 %. 14 % read at less than a 7–8th grade reading level. 88 % had health insurance. At 4 month follow-up, the CI reduced CHD risk by 2.2 percentage points (p<.0001) and the WI by 1.4 percentage points (p<0.001; adjusted mean difference between groups: 0.8 percentage points, p 0.04). These changes resulted from small changes in systolic blood pressure (CI: −2.85 mmHg; WI −1.1 mmHg), total cholesterol (CI: −8.4 mg/dL; WI −3.8 mg/dL), HDL cholesterol (CI: +1.4 mg/dL; WI: +1.8 mg/dL), smoking cessation (CI: −3 %; WI −2 %) and aspirin use (CI: +10 %; WI: +11 %). Small statistically significant changes were also noted in self-reported fruit and vegetable intake (CI: +0.4 servings/day; WI: +0.2 servings/day), walking (CI: +54 min/week; WI: +30 min/week), and adherence (% with high adherence in CI: +14 %; WI: +18 %). The incremental cost-effectiveness ratio for a 1 percentage point reduction in CHD risk was $129 for the WI compared with usual care, and $159 for the CI compared with the WI.

CONCLUSIONS: Both counselor and web interventions reduced CHD risk compared to baseline. The counselor intervention was somewhat more effective than the web intervention, but the web intervention was incrementally more cost-effective.

A RANDOMIZED, CONTROLLED TRIAL OF ALTERNATIVE FORMS OF FEEDBACK ON GLYCEMIC CONTROL IN PATIENTS WITH POORLY CONTROLLED DIABETES Anjali Gopalan[1,3]; Emin Tahirovic[2]; Haley Moss[2]; Andrea B. Troxel[2]; Jingsan Zhu[2]; Kevin G. Volpp[1,2]. [1]Philadelphia VA Medical Center, Philadelphia, PA; [2]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [3]Robert Wood Johnson Clinical Scholars Program, Philadelphia, PA. (Tracking ID #1633742)

BACKGROUND: Prior work has indicated that understanding of the hemoglobin A1c (A1c) among diabetic patients is low. A 2008 study in the British Medical Journal by Parkes et al. showed the potential effectiveness of translating poorly understood medical values into more universally understood forms. This study expressed FEV1 in terms of "lung age" to active tobacco users. Patients given their "lung age" in place of their FEV1 value had significantly higher rates of smoking cessation at study completion. This approach may hold promise for improving feedback for diabetic patients on glycemic control.

METHODS: We randomly assigned 177 poorly controlled diabetics seen at University of Pennsylvania outpatient practices to receive a "diabetes report card" with individualized information about glycemic control in one of three study arms: (1) letter grades ranging from A-F (grade arm); (2) faces whose emotion reflected current glycemic control (face arm) or (3) actual A1c value (control arm) (Figure 1). The primary study outcome was change in A1c values between baseline and 6 months. Secondary outcomes were changes in participant perceptions of their current diabetes control, disease severity, and future risk of associated complications.

RESULTS: The average A1c for enrolled participants was 9.9±1.7 % and did not differ significantly between study arms. The pre-intervention survey confirmed high levels of misunderstanding of current glycemic control, with the majority (63 %) of participants describing their control as 'moderate' or 'good'/'excellent' in spite of an average A1c of 9.8 % and 10.2 %, respectively. We noted no significant differences in change in A1c at 6 months between the control arm and the experimental arms. Using multiple imputation to handle missing A1c values, the change in A1c for the grade, face, and control arms was −0.55±0.3 %, −0.89±0.3 %, and −0.74±0.37 %, respectively (p=0.67 for grade vs. control, p=0.76 for face vs. control). We found no significant differences between study arms for the changes in perceptions of current diabetes control, severity, and future complication risk.

CONCLUSIONS: Letter grades and faces did not differentially affect A1c at 6 months or participant perceptions of current control in this population of poorly controlled diabetics. This may reflect the particular alternatives tested in this study, without invalidation of the concepts that improving communication and patient understanding of disease management targets could significantly improve diabetes outcomes.

A SYSTEMATIC REVIEW OF INTERVENTIONS TO IMPROVE PALLIATIVE CARE REFERRAL Irene Kirolos[1]; Leonardo Tamariz[1]; Barbara A. Wood[2]; Ana M. Palacio1. [1]University of Miami-Miller School of Medicine, Miami, FL; [2]University of Miami-Miller School of Medicine, Miami, FL. (Tracking ID #1642043)

BACKGROUND: Palliative care is underutilized among patients at the end of their lives despite evidence that it improves patient satisfaction and that it reduces costs. The purpose of this study is to synthesize the evidence regarding interventions to increase palliative care usage.
METHODS: We performed a MEDLINE database search (1979 to November 2012) supplemented by manual searches of bibliographies of key relevant articles. We selected all studies in which an intervention was used in palliative care or hospice. Study design, quality criteria, population, interventions and outcomes for each study were extracted. The main outcome evaluated was increase in hospice/palliative care referral.
RESULTS: Our search strategy yielded 412 studies, of which only five met our eligibility criteria (table). Three studies included nursing home populations and only one study reported on heart failure patients. Three studies had a cohort design, one had a pre-post design and only one study had a randomized design. The specific intervention differed in each study. The cohort studies that implemented a palliative care program that ranged from a facilitator to a comprehensive program had a median increase in referrals of 14 %. The randomized study that included a triage system to identify patients' needs and preferences increased referral by 19 %. Similar trends were seen in the pre-post design.
CONCLUSIONS: Interventions of different levels of complexity can improve the use of palliative and hospice services among subjects with high mortality risk, particularly nursing home patients. More data is needed on the impact of interventions targeting high risk groups in other clinical environments.

Study design	Number of studies	Population	Intervention	% Referral to palliative care in intervention group	% Referral to palliative care in control group
Cohort	3	At risk of death	Palliative care program	47(31–56)	33(7–37)
Pre-post	1	Nursing home	Educational	7	4
Randomized	1	Nursing home	Triage system	20	1

A WEB-BASED LIFESTYLE INTERVENTION TO DECREASE POSTPARTUM WEIGHT RETENTION IN WOMEN WITH RECENT GESTATIONAL DIABETES MELLITUS: THE BALANCE AFTER BABY PILOT RCT Jacinda M. Nicklas[1,2]; Chloe A. Zera[3]; Bernard A. Rosner[4,5]; Sue E. Levkoff[6,7]; Ellen W. Seely[2]. [1]University of Colorado School of Medicine, Aurora, CO; [2]Brigham and Women's Hospital, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA; [5]Harvard School of Public Health, Boston, MA; [6]Brigham and Women's Hospital, Boston, MA; [7]University of South Carolina, Columbia, SC. (Tracking ID #1631193)

BACKGROUND: Women with a history of gestational diabetes mellitus (GDM) have a 7-fold increased risk for developing type 2 diabetes (T2DM). A post-hoc analysis of women with self-reported history of GDM in the Diabetes Prevention Program (DPP) demonstrated that an intensive face-to-face lifestyle intervention focused on weight loss significantly decreased the incidence of T2DM by 53 % over 3 years. However, face-to-face weight loss interventions in postpartum women in general have demonstrated poor adherence and efficacy. We sought to develop and test a postpartum lifestyle intervention based on the DPP and modified for women with recent GDM.
METHODS: After conducting focus groups and informant interviews with women with prior GDM, we developed a web-based program named Balance after Baby. Key modifications from the DPP included web-delivery to allow 24-h access, lifestyle coaching by phone/email, and content tailored for the postpartum period. Women with GDM in their most recent pregnancy were recruited during pregnancy or early postpartum and randomized into the Balance after Baby program or enhanced control arm (glucose tolerance tests) 4–12 weeks postpartum. Pre-pregnancy weight was self-reported at recruitment; gestational weight gain and insulin use were extracted from medical records. We administered demographic questionnaires and measured height, weight, and response to a 2 h 75 g oral glucose tolerance test, at 6 weeks, 6 months, and 12 months postpartum. We compared mean weight changes using an intent-to-treat model by t-tests and by estimating a mixed-effects regression model using a random intercept and an unstructured covariance matrix. We conducted structured exit interviews with women completing the program.
RESULTS: 75 women with recent GDM were randomized (mean age 33.4 ±5.4 years; BMI 31.4 (±5.6) kg/m2; 57 % White, 29 % African-American, 15 % Asian, with 20 % Hispanic; 34 % low-income). There were no significant differences between groups at baseline for age, race, education, income, weight, BMI, pre-pregnancy weight, gestational weight gain, insulin use in pregnancy, breastfeeding, or glucose tolerance. Clinically determined weights were collected 12 months postpartum for 95 % of eligible participants. Women assigned to the Balance after Baby arm lost a mean 5.0 (±13.5) lbs compared to women in the control arm who gained 1.3 lbs (±9.8) (p=.0223) between 6 weeks and 12 months postpartum. Women in the Balance after Baby arm were at their pre-pregnancy weight (mean −0.2±15.4 lbs) at 12 months postpartum vs. the control arm (+7.9±15.3 lbs) (p=0.025). In a longitudinal mixed model controlling for pre-pregnancy weight, assignment to the Balance after Baby arm resulted in greater loss at 6 (mean 8.5 lbs, SE 2.7, p=0.002) and 12 months (mean 7.0 lbs, SE 2.9, p=0.0175) compared to women in the control arm. While there were no significant group differences in glucose tolerance at 12 months, 3 women in the control group developed T2DM compared to none in the intervention group. Women randomized to the Balance after Baby program expressed a high degree of satisfaction with the program.
CONCLUSIONS: The web-based Balance after Baby program is feasible, acceptable, and resulted in greater postpartum weight loss in women with recent GDM. If confirmed and found cost-effective in a longer study, the Balance after Baby program could be used at the population level to increase postpartum weight loss and potentially delay or prevent development of T2DM in women with recent GDM.

ACADEMIC DETAILING TO TEACH AGING AND GERIATRICS Cathryn Caton; Ashley Duckett; Theresa Cuoco; Pamela Pride; Patty J. Iverson; William P. Moran. Medical University of South Carolina, Charleston, SC. (Tracking ID #1643098)

BACKGROUND: Detailing has been employed by the pharmaceutical sales industry to increase physician knowledge about new medications. Work hour rules have challenged residency training programs to develop and utilize efficient and effective teaching methods. We chose to employ academic detailing as a teaching intervention in our residents' clinic and on the general medicine inpatient wards to improve clinical knowledge and skills in geriatric care.
METHODS: Aging Q3 - Quality Education, Quality Care and Quality of Life- is a longitudinal curriculum focusing on improving geriatric knowledge in the residency program at the Medical University of South Carolina. Sixteen geriatric topics were chosen based on the Assessing Care of Vulnerable Elder (ACOVE) paradigm and each topic was delivered over 3 months. For each ACOVE, faculty workgroups of 6 members identified key educational messages and skill instruction to teach residents over a three-month intervention period. Each workgroup created one page academic detailing sheets with specific knowledge and skills to be reviewed. Residents were detailed at the time of encounters with geriatric patients with key messages of the current ACOVE by faculty using the provided detailing sheets. By design, the one-on-one detailing process took about 5 min, thereby ensuring that residents were not significantly delayed on rounds or in their clinics.
RESULTS: Over three years noon conference attendance for Aging Q3 topics ranged from 20 % to 51 %, while the percentage of residents detailed by faculty ranged from 61 % to 93 %. ACOVEs with the highest rates of resident detailing had statistically significant increases in medical knowledge, as measured by pre-test/post-test. For ACOVEs with the highest resident detailing rates, general medicine faculty participation in the detailing process ranged from 60 % to 86 %. In some instances, despite good detailing rates and improvement in self-efficacy, there was not a statistically significant improvement in medical knowledge.
CONCLUSIONS: We found that academic detailing is an efficient way of reaching a high percentage of residents and increasing knowledge in aging and geriatrics. Topics with a narrow focus are best taught in this format.

ACCESS TO SUBSPECIALTY CARE FOR PATIENTS WITH MOBILITY IMPAIRMENT Tara Lagu[1,2]; Nicholas S. Hannon[1]; MIchael B. Rothberg[8]; Annalee S. Wells[9]; K. Laurie Green[3,4]; McAllister O. Windom[5]; Katherine R. Dempsey[1]; Penelope S. Pekow[1,6]; Jill S. Avrunin[1]; Aaron Chen[7]; Peter K. Lindenauer[1,2]. 1Baystate Medical Center, Springfield, MA; [2]Tufts University School of Medicine, Boston, MA; [3]Baystate Medical Center, Springfield, MA; [4]Baystate Medical Center, Springfield, MA; [5]Duke University School of Medicine, Durham, NC; [6]University of Massachusetts-Amherst, Amherst, MA; [7]University of New England College of Osteopathic Medicine, Biddeford, ME; [8]Cleveland Clinic, Cleveland, OH; [9]Dorchester House, Dorchester, MA. (Tracking ID #1615945)

BACKGROUND: The Americans with Disabilities Act (ADA) states that all medical practitioners are required to provide "full and equal access to their health care services and facilities," yet adults who use wheelchairs have difficulty accessing physicians and receive less preventive care than their able-bodied counterparts. We aimed to describe access to medical and surgical subspecialists for patients with mobility impairment.
METHODS: Using a standardized script, we called subspecialty (endocrinology, gynecology, orthopedic surgery, rheumatology, urology, ophthalmology, otolaryngology, psychiatry) practices in four metropolitan areas in the United States and attempted to make an appointment for a fictional patient who used a wheelchair and was unable to transfer from chair to exam table. If a practice reported that they were able to make an appointment for the patient, the investigator would then probe to clarify that both the building and office were accessible and to determine the method by which the practice planned to transfer the patient from the wheelchair to the exam table. If the practice was unable to accommodate the patient, the investigator responded with the question, "Can you please explain why you are unable to accommodate this patient?" We calculated summary statistics and conducted a qualitative analysis of the responses.
RESULTS: Of 256 practices, 56 (22 %) reported they could not accommodate our fictional patient. Only nine of these reported that the building was inaccessible. The remaining 47 reported that they were unable to transfer a patient from a wheelchair to an exam table. Reasons for the inability to transfer the patient included a lack of staff who could perform the transfer (37 practices), a concern about liability (five practices), or that the "patient was too heavy" (five practices). Inaccessibility varied by subspecialty: only 6 % of psychiatry practices were inaccessible, while gynecology was the subspecialty with the highest rate (44 %) of inaccessible practices. The other subspecialties had proportions of inaccessible practices ranging from 13 to 28 %. Of 200 accessible practices, 67 (33 %) reported they had equipment that could adjust to the patient while sitting in the wheelchair (e.g., otolaryngology, ophthalmology) or, in the case of psychiatry, that they did not need to move the patient for an exam. 103 practices (51 %) reported they planned to "manually transfer" the patient from her wheelchair to a non-accessible high table without the use of a lift. Only 22 practices (11 %) reported the use of accessible tables or use of a lift for transfer.
CONCLUSIONS: More than 20 years after the passage of the ADA, many subspecialty practices were unable to accommodate a patient with mobility impairment. This was rarely due to building inaccessibility. More frequently, practices were inaccessible because they were unable to transfer the patient to perform an exam. A minority of accessible of practices possessed equipment that would facilitate the safe transfer (from chair to table) of our fictional patient. Instead, a majority of accessible practices reported transfer methods that have been deemed to be unsafe by disability experts. These results provide one possible explanation for the health care disparities observed in this population and identify the need for better awareness among physicians about the requirements of the ADA and the standards of care for patients with mobility impairment.

ACCULTURATION AND RISK FACTORS FOR HYPERTENSION AMONG A HETEROGENEOUS POPULATION OF BLACK MEN Candace Tannis; Jessica M. Forsyth; Joseph Ravenell. NYU School of Medicine, New York, NY. (Tracking ID #1638147)

BACKGROUND: Black men are at increased risk for developing hypertension and consequent morbidity compared to other racial/ethnic groups. The composition of the Black population in the United States is diversifying rapidly, with many implications for the prevention and management of hypertension. This study seeks to examine the role of acculturation on engagement in therapeutic lifestyle changes (TLCs; healthy diet, physical activity, smoking and alcohol consumption, and medication adherence) to lower blood pressure (BP).
METHODS: Participants were recruited during health screening events for a larger clinical trial at barbershops and churches. All adult men who self-identified as Black were eligible. Acculturation, the main predictor variable, was measured using a single item regarding place of birth and a 10-item questionnaire adapted from two measures: the Cultural Lifestyle Inventory (CLSI); and the Measures of Acculturation Strategies for People of African Descent (MASPAD). Items taken from the CLSI and MASPAD were measured on 5-point and 6-point Likert scales respectively with items summed to create scale scores. Outcome variables included 1) diet, measured using the National Cancer Institute fat screener and a 2-item modified Food Frequency Questionnaire measuring daily fruit and vegetable consumption; 2) physical activity, measured with the shortened International Physical Activity Questionnaire; 3) medication adherence, measured with the 4-item Morisky scale; and 4) smoking and alcohol consumption, measured using items adapted from the Behavioral Risk Factor Surveillance Survey. BP was measured using an automated BP cuff, and co-morbidity was measured using the Charlson Co-morbidity Index. We utilized ANCOVA to test group differences in outcome variables between foreign-born and US-born at baseline, and linear regression to examine relationships between acculturation and outcome variables at baseline. All analyses controlled for age, income, employment status and education level.
RESULTS: 171 men completed the survey. 26 % were foreign-born. The mean age of participants was 53.6 years (SD=10.24) and the median annual income was $11,400. Twenty-seven percent of men in the study reported having less than a high school education, and 75 % of the men were currently unemployed. Foreign-born participants had lower percentage of fat in their diets (p=0.003). There were no differences between foreign-born and US-born men in mean BP, presence of co-morbidity, and lifestyle behaviors other than fat consumption. However, among partici-

pants who reported taking BP medication, foreign-born blacks had poorer adherence (p=0.028). Medication non-adherence was also associated with the "traditionalist" MASPAD dimension (p=0.015, R2adj .333), as well as positively with the individual item corresponding to ethnic pride (p=0.021) and negatively with maintenance of cultural practices (p=.035). There was no relationship between acculturation and the TLCs other than medication adherence or measured BP.

CONCLUSIONS: This study provides evidence that nativity and acculturation among Black men may play a role in engagement in certain TLCs to lower BP. More research is needed to determine how best to tailor TLC interventions to control hypertension for the rapidly diversifying population of Black men, the highest risk group in the United States.

ACCURACY OF RACE/ETHNICITY AND LANGUAGE PREFERENCE IN AN ELECTRONIC HEALTH RECORD Sara V. Carlini[1]; Elissa Klinger[1]; Irina Gonzalez[1]; Jeffrey A. Linder1; Elyse R. Park[2]; Emily Kontos[3]; Nancy A. Rigotti[2]; Jennifer Haas[1,3]. [1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Harvard School of Public Health, Boston, MA. (Tracking ID #1634097)

BACKGROUND: Eliminating health care disparities requires accurate data on race/ethnicity and language preference. Health care organizations that receive federal funds are required to record information about patient race/ethnicity and language preference, yet little is known about the accuracy of these electronic health record (EHR) data.

METHODS: We compared the accuracy of race/ethnicity and language preference data recorded in an EHR, compared to self-reported race/ethnicity and language preference (English, Spanish) from an Interactive Voice Recognition (IVR) survey as part of a randomized controlled trial of a telephone-based tobacco treatment program. Using IVR, we called 6,771 low-income (by zip code) white, black, or Latino smokers who were listed in the EHR as English or Spanish-speaking and had made a primary care visit in the preceding 60 days; 2,189 (32 %) answered the phone and selected a language preference, and 434 (6 %) enrolled and provided information about race/ethnicity.

RESULTS: Median age was 51 years; 53 % self-reported race/ethnicity as white, 26 % as African-American, and 21 % as Hispanic; and 10 % reported that they were Spanish-speaking. Overall agreement between EHR-recorded and self-reported race/ethnicity information was excellent (Kappa 0.84; p<0.001). However, the sensitivity and positive predictive value (PPV) for EHR-recorded race/ethnicity compared to self-report varied by race/ethnicity: 82 % and 97 % for Hispanics, 78 % and 95 % for African-Americans, and 100 % and 87 % for whites, suggesting that for both Hispanics and African-Americans, some individuals are misclassified in the EHR as white. For language preference, EHR-documentation and self-report showed good overall agreement (Kappa 0.74, p<0.001), but the PPV for an EHR-documented language preference of Spanish was only 68 % with a sensitivity of 86 %. While only 1.2 % of EHR-documented English speakers elected to hear the IVR call in Spanish, 31.9 % of EHR-documented Spanish speakers elected to hear the call in English.

CONCLUSIONS: We demonstrate strong agreement between EHR-recorded and self-reported race/ethnicity and language preference. However, there were inaccuracies that indicate the need to investigate how EHR data are obtained and perhaps systems to improve EHR documentation. The results also demonstrate the importance of offering services that respond to multilingual patients, who may have differing preferences based on the specific content and method of contact.

ACCURATE DISEASE ATTRIBUTION IS A HURDLE FOR DEVELOPMENT OF A PAY FOR PERFORMANCE REIMBURSEMENT MODEL Jennifer Zreloff; Jillian Gaumond; Jason Higdon. Emory University, Atlanta, GA. (Tracking ID #1642285)

BACKGROUND: With medical reimbursement shifting away from fee for service and toward quality incentives, it is important to understand the accuracy of data being used by insurance companies and clinics for quality incentive payouts.

METHODS: In the setting of a university-based and NCQA recognized Patient-Centered Medical Home with a single payer, we sought to reconcile quality reports generated by our payer versus by our clinic's data warehouse. Lists of patients were generated with diabetes, CHF, and COPD. Our private payer generated its list based on their methods that utilize billing data.. Lists generated by the PCMH were generated by diagnoses on the "problem list" in the EMR and diagnosis billing data specific to that clinic. The two lists were compared and evaluated by chart review when they were discordant. Chart review included all data available such as labs, echo, radiology, specialty clinic notes, and PCP notes. Patients were then divided into groups of inclusion error by insurance, inclusion error by PCP, exclusion error by insurance, and exclusion error by PCP

RESULTS: Percentage of times that the Private Payer and the PCMH agreed varied by disease state. Based on the total number of patients included in a disease group by either the insurance company or the PCMH, 61.2 % of the patients on the diabetes list, 32.1 % of those on the CHF list, and 21.2 % of those on the COPD list, were agreed upon by both the insurance company and the clinic. There were both errors of omission and inclusion by the insurance company. Errors of inclusion (those attributed to have the disease that did not actually have it) occurred for diabetes in 16.9 % of the total attributed patients, 32.1 % for CHF, and 78.8 % for COPD. Errors of exclusion (those that had the disease but were not listed by the insurance company) occurred for 21.9 % of diabetics, 35.7 % of patients with heart failure, and 0 % with COPD. A small percentage of errors of exclusion occurred with the PCMH. There were no errors of inclusion by the PCMH. Looking at only the data generated by the insurance company, 21.7 % of insurance-attributed diabetic patients were incorrect, and 26.3 % of the patients on the final, verified diabetic list were missing. For CHF, 50 % of insurance-attributed patients were incorrect, and 52.6 % of patients on the verified CHF list were missing. COPD had the worst data accuracy with 78.8 % of insurance-attributed patients being incorrect, and with no missing patients.

CONCLUSIONS: When entering the world of pay for performance, it is important to recognize the inherent inaccuracies of data based primarily on claims data. This clinic had the added luxury of a separate attribution process which allowed both sides to agree on the total pool of patients. For most clinic sites the quality data would be expected to have more errors due to discrepancies of attribution to PCP. For these reasons, it is important for clinics to have opportunities to collect their own quality data specific to disease attribution, and have a reconciliation process with payers participating in pay for performance initiatives.

ACETAMINOPHEN RECEIPT AMONG HIV-INFECTED PATIENTS WITH ADVANCED HEPATIC FIBROSIS E. J. Edelman[1]; Kirsha S. Gordon[2]; Vincent Lo Re[3]; Melissa Skanderson[4]; David A. Fiellin[1]; Amy C. Justice[2,1]. [1]Yale University, New Haven, CT; [2]VA Connecticut Healthcare System, West Haven, CT; [3]University of Pennsylvania, Philadelphia, PA; 4VA Pittsburgh Healthcare System, Pittsburgh, PA. (Tracking ID #1642388)

BACKGROUND: HIV-infected (HIV+) patients may be at particular risk for acetaminophen-induced hepatotoxicity given their underlying risk of liver disease, high prevalence of hepatitis C virus (HCV) coinfection, differences in acetaminophen metabolism, and exposure to antiretroviral therapy. However, acetaminophen overuse (greater than 2 g per day) in the context of liver injury has been incompletely examined among HIV+ patients. Among a cohort of HIV+ patients, our aims were to: 1) describe the patterns of acetaminophen receipt; 2) assess the cross-sectional association between acetaminophen receipt and advanced hepatic fibrosis; and 3) determine whether factors associated with acetaminophen overuse varied by HCV status.

METHODS: We performed a cross-sectional analysis of the Veterans Aging Cohort Study-Virtual Cohort. We excluded patients who had a cancer diagnosis other than non-epithelial skin cancers; no inpatient or outpatient visit in FY2006; or missing laboratory or pharmacy data.

Outpatient acetaminophen receipt among HIV+ patients in the cohort was categorized as: 1) no acetaminophen use, 2) appropriate use (<2 g/day); or 3) overuse (> 2 g/day). The primary independent variable was advanced hepatic fibrosis, defined as a FIB-4 > 3.25. The FIB-4 score is a validated non-invasive index that identifies advanced fibrosis/cirrhosis using age, alanine aminotransferase, aspartate aminotransferase, and platelet count. We evaluated acetaminophen daily dosage stratified by FIB-4 status. We then performed multivariable ordered polytomous logistic regression to determine adjusted odds ratios (AOR) for acetaminophen daily dosage, classified as a three level outcome variable. The final model included patients characteristics that were clinically relevant or significant at the $p<$ 0.05 level. Results were stratified by HCV status.

RESULTS: Our sample included 14,885 HIV+ patients, 4,592 (31 %) of whom received at least one acetaminophen prescription and 1,885 (41 %) of whom were HIV/HCV-coinfected. Among those receiving acetaminophen, 1,442 (31 %) patients were identified with acetaminophen overuse, with no differences observed between HIV-monoinfected and HIV/HCV-coinfected patients (846 [31 %] vs. 596 [32 %], p=0.59). Among HIV-monoinfected patients, the average daily acetaminophen dose was not significantly different between those with a FIB-4 < 3.25 and those with a FIB-4 > 3.25 (1.50 vs. 1.20 g/day, p=0.08); results were similar for HIV/HCV-coinfected patients (p=0.14). After adjusting for age, gender, race/ethnicity, HCV status, alcohol use disorders, and pain-related diagnoses, FIB-4 was associated with a decreased odds of acetaminophen overuse (AOR [95 % CI] = 0.80 [0.65, 1.00]). After stratifying by HCV status, HIV+ patients with advanced hepatic fibrosis were equally likely to receive acetaminophen. Further, HIV-monoinfected patients with an alcohol use disorder were more likely to have acetaminophen overuse (AOR [95 % CI] = 1.56 [1.21, 2.02]).

CONCLUSIONS: Acetaminophen overuse was common in this sample of HIV+ patients. Strategies to minimize acetaminophen exposure in HIV+ patients are warranted.

ACHIEVING COMMUNICATION BETWEEN PRIMARY CARE AND MENTAL HEALTH: WHY IS IT SO DIFFICULT, EVEN IN THE VA? A QUALITY IMPROVEMENT APPROACH Evelyn Chang[1]; Kenneth B. Wells[5,4]; Alexander S. Young[3,2]; Susan E. Stockdale[3]; Jacqueline Fickel[3]; Megan Johnson[2,3]; Kevin Jou[2]; Lisa V. Rubenstein[3,4]. [1]VA- Greater Los Angeles, Los Angeles, CA; [2]VA- Greater Los Angeles, North Hills, CA; [3]VA- Greater Los Angeles, North Hills, CA; [4]RAND, Santa Monica, CA; 5UCLA, Los Angeles, CA. (Tracking ID #1624000)

BACKGROUND: Research shows that bi-directional communication between mental health (MH) and primary care (PC) clinicians is critical for improving patient outcomes, yet achieving this in health care organizations is challenging. In the Veterans Administration (VA), the high prevalence of co-occurring physical and mental illnesses can make PC-MH collaboration essential for providing effective care. Despite extensive national VA efforts to integrate PC and MH, however, local settings continue to experience barriers to effective communication and collaboration.

METHODS: We proposed a project to the local VA site's quality improvement (QI) council directed at improving communication between PC and MH providers. We used QI diagnostic tools to understand barriers to PC/MH communication and to initiate a change strategy in a multi-specialty academic community-based outpatient clinic serving 16,000 veterans in Los Angeles. The clinic has two PC teams with five to six teamlets each using the patient-centered medical home model. We recruited 11 on-site PC and MH clinical providers, administrators, and researchers for our workgroup, which held 4 monthly meetings. The workgroup constructed fishbone diagrams of causes of poor communication and mapped communication flow among providers for emergent and non-urgent situations for the VA site. We performed chart reviews on patients with established PC and MH providers to assess documentation of communication. We conducted a rapid literature review of interventions for improving PC/MH communication and identified potentially feasible evidence-based interventions to address the problems we found.

RESULTS: PC providers were frustrated by inconsistent access to psychiatrists for emergent and routine situations. MH providers did not respect PC management of uncomplicated depression. Key communication barriers included geographic distance, cultural differences, and lack of standardized communication processes. A key facilitator was personal relationships across disciplines. Chart review confirmed considerable between-provider variation in documenting MH and medical problems and in communication strategies. Literature review, combined with the workgroup's assessments, identified joint care planning and joint case conferences as two feasible interventions. While these interventions were developed, the site began to collocate MH specialists to PC.

CONCLUSIONS: QI tools suggested that there were procedural, cultural, and structural factors affecting communication and respect. Clarifying these factors helped to initiate an ongoing change strategy. A locally tailored QI process focusing on communication helped initiate change strategies that had not originated from policy or health information systems.

ADEQUACY AND CORRECTION OF MEDICAL RECORD DOCUMENTATION IN PATIENTS WITH A PRIOR ADMISSION FOR ACE-INHIBITOR ANGIOEDEMA IN AN URBAN ACADEMIC MEDICAL CENTER: A PATIENT SAFETY INTERVENTION Andrew M. Davis[1]; Eric R. Yoo[3]; Cheryl Nocon[2]; Jacquelynne P. Corey[2]. [1]University of Chicago, Chicago, IL; [2]University of Chicago, Chicago, IL; [3]University of Illinois College of Medicine, Chicago, IL. (Tracking ID #1626449)

BACKGROUND: Angiotensin-converting enzyme inhibitor (ACEI) induced angioedema affecting the upper airway is a potentially life-threatening condition, occurring in 0.1 to 2.2 % of recipients, with a higher incidence in African-American patients. Over 40 million patients in the U.S. currently take a medication in this class. Recurrent ACEI-induced angioedema is readily preventable, but requires proper allergy documentation in the medical record after the first event. Our institution's transition from Oacis to an Epic Electronic Medical Record (EMR) in 2008 improved clinician training and engagement with the EMR. This transition provided an opportunity to assess allergy documentation following episodes of ACEI-induced angioedema requiring inpatient admission, and to correct deficits in EMR allergy documentation in our urban academic medical center.

METHODS: We reviewed charts of patients with inpatient encounter codes for "angioneurotic edema, NOS" (ICD 995.1), hereditary angioedema (277.6), anaphylactic shock (995.0), anaphylactic shock due to food reaction (995.6), or anaphylactic shock due to serum (995.4). Cases with clear corroboration of ACEI-induced angioedema in the clinical notes were split by admit dates: 2000–2007 (n=372 total, 82 ACEI related) and 2008–2011 (n=139 total, 37 ACEI related). We also reviewed a random sample of 30 ED cases (2008–2011) with ACEI-related angioedema not requiring admission. The current Epic allergy and problem lists were examined for each case; elements abstracted included documentation of the ACEI allergy, the severity of reaction, and presence of the name of the specific causative agent. As a patient safety intervention, incomplete allergy documentation in the EMR was corrected.

RESULTS: Overall 95 % of the admitted patients were African American and 66 % were female; the median age was 64. The severity of angioedema in admitted patients was quite high, with 43 % requiring intubation in 2000–2007, and 59 % during the 2008–2011 period. Before current EMR implementation in 2008, 60 (73.2 %) of charts for admitted patients were completely missing ACEI-allergy documentation and 17 (20.7 %) had incomplete allergy lists. After transition to the current EMR, inpatient charts (2008–2011) markedly improved in ACEI allergy documentation ($p<.001$), though 5 (13.5 %) of the 2008–20011 admitted patients were completely missing data, and 29 (78.4 %) had incomplete allergy lists, lacking the specific agent or reaction severity. Patients treated and released from the ED were more likely to have absent documentation (23.3 %). In several instances, the ACEI remained on patient medication list, but review of recent notes found that ACEI had actually been discontinued, and that the medication list was in error.

CONCLUSIONS: ACEI-allergy documentation markedly improved following transition to a newer EMR; however, an unacceptably high number of patients with an admission for ACEI angioedema continued to have no documentation of this reaction on their current allergy list, and missing agent or severity data remained common. Urban medical centers should regularly review ACEI allergy angioedema events, and establish a redundant patient safety process to confirm event documentation in the EMR allergy list.

ADHERENCE TO PRESCRIPTION OPIOID MONITORING GUIDELINES AMONG RESIDENTS AND ATTENDING PHYSICIANS IN THE PRIMARY CARE SETTING Laila Khalid; Jane M. Liebschutz; Christopher W. Shanahan; Shernaz Dossabhoy; Yoona R. Kim; Karen E. Lasser. Boston Medical Center, Boston, MA. (Tracking ID #1636318)

BACKGROUND: Prescription opioid misuse is a significant public health problem, with primary care providers being the principal prescribers of opioids for chronic non-cancer pain. While one study showed that residents provide higher quality primary care than attendings, opioid prescribing practices have not been compared between resident and attending physicians. We compared adherence to opioid prescribing guidelines as well as evidence for potential patient misuse of prescribed opioid medications between resident and attending physician.
METHODS: We conducted a retrospective cross-sectional study at a primary care practice of a large Northeastern safety-net hospital using data abstracted from the electronic medical record through the institution's clinical data warehouse. Patients included were 18–89 years old, who had at least one visit to primary care and were prescribed long-term opioid treatment (3 or more opioid prescriptions written at least 21 days apart within 6 months) for chronic non-cancer pain from 8/31/11 to 9/1/12. The primary outcome was adherence to any one of two key American Pain Society Guidelines; 1) documentation of at least one opioid agreement (contract) ever, and 2) any urine drug testing in the past year; and evidence of potential prescription misuse with 1, 2 or more than 2 early refills. Early refill was a prescription written 7–25 days after the previous prescription of the same drug. Patients were classified as a resident patient if they received 2, or more prescriptions from a resident physician. Statistical analysis was performed using chi-square tests.
RESULTS: 96 residents prescribed opioid prescriptions to 136 patients, while 49 attendings prescribed to 609 patients. The results are summarized below.
CONCLUSIONS: Despite the low numbers of contract documentation in resident and attending patients, the majority of the patients did receive urine drug testing. It is not clear whether the documentation of a contract indicates guideline adherence. Evidence for potential misuse of prescription opioids, indicated by two or more early refills, was significantly higher in resident patients relative to attending patients. Features of a resident-based practice that may be associated with prescription opioid misuse need to be explored.

Variable	Resident Patients n=136 (%)	Attending Patients n=609 (%)	p-value
Documentation of contract ever	46 (33.8)	136 (22.3)	0.005
Urine drug screen in past year	93 (68.4)	445 (73.1)	0.27
Early refill(s) in past year			
0	35 (25.7)	299 (49.1)	<0.0001
1	42 (30.9)	157 (25.8)	0.22
≥2	59 (43.4)	153 (25.12)	<0.0001

ADMISSION TO TEACHING HOSPITALS AND WEEKDAY DISCHARGES ARE ASSOCIATED WITH BETTER OUTCOMES IN HEART FAILURE PATIENTS Anita G. Au; Raj S. Padwal; Erik Youngson; Sumit R. Majumdar; Finlay A. McAlister. University of Alberta, Edmonton, AB, Canada. (Tracking ID #1635314)

BACKGROUND: It is unclear whether hospital teaching status or the day of discharge influences post-discharge outcomes for patients hospitalized with heart failure (HF).
METHODS: We linked four population-based databases in Alberta, Canada to identify adults hospitalized for HF who were discharged alive between 1999 and 2009. We conducted a retrospective cohort study comparing outcomes between patients discharged from teaching versus non-teaching hospitals and on weekends versus weekdays. The primary outcome was the composite of death or non-elective readmission 30-days post-discharge.
RESULTS: Over 10 years, 12,216 HF patients were discharged from teaching hospitals and 12,157 from non-teaching hospitals; 21,001 (86 %) discharges occurred on weekdays. Although they had greater comorbidity and used more health care resources in the year prior to HF hospitalization, patients discharged from teaching hospitals exhibited significantly lower rates of 30-day death or readmission than those discharged from non-teaching hospitals (17.4 % vs. 22.1 %, aHR 0.83, 95 % CI 0.77–0.89). Patients discharged on weekdays were older and had greater comorbidity, yet exhibited significantly lower rates of death or readmission at 30-days than those discharged on weekends (19.5 % vs. 21.1 %, adjusted hazard ratio [aHR] 0.87, 95 % CI 0.80–0.94). Compared to weekend discharge from a non-teaching hospital (reference), the 30-day risk of death or readmission was lower for weekday discharge from a non-teaching hospital (aHR: 0.85, 95 %CI 0.77–0.94), weekend discharge from a teaching hospital (aHR: 0.79, 95 %CI 0.69–0.92), and weekday discharge from a teaching hospital (aHR: 0.71, 95 %CI 0.63–0.79, with p<0.001 for trend).
CONCLUSIONS: Patients discharged from non-teaching hospitals or on weekends exhibited poorer risk-adjusted outcomes than those discharged from teaching hospitals or on weekdays. The structures and processes which may have yielded better outcomes for those admitted to teaching hospitals and those discharged on weekdays should be studied and possibly emulated in order to optimize heart failure related outcomes.

ADVERSE OUTCOMES OF POLYSEDATIVE USE IN VETERANS WITH PTSD Brian C. Lund[1,2]; Stephen L. Hillis[1]; Elizabeth A. Chrischilles[2]. [1]Center for Comprehensive Access & Delivery Research and Evaluation, Iowa City, IA; [2]University of Iowa College of Public Health, Iowa City, IA. (Tracking ID #1628276)

BACKGROUND: While department of Veterans Affairs (VA) clinical practice guidelines recommend against their use, benzodiazepines are prescribed to 30–40 % of veterans with posttraumatic stress disorder (PTSD). Nationally, opioid abuse has been labeled as epidemic, and inpatient chemical dependency admissions involving the combination of opioids and benzodiazepines have risen more than 500 % in the last decade. Therefore, our objective was to determine whether benzodiazepines, opioids, and other sedatives - particularly in combination - are associated with adverse events in veterans with PTSD.
METHODS: National VA administrative data were used to identify veterans with PTSD. Among these patients, new benzodiazepine starters during FY04-09 (N=66,406) were matched to nonusers (N=128,062) using high dimensional propensity scores. Adverse events were based on prior work involving sedative use in veterans and included emergency visits and hospitalizations for wounds/injuries, drug-related accidents/overdoses, and self-inflicted injuries identified by ICD-9 coding. One year adverse event risk was determined using a stratified Cox proportional hazards model. Exposure to opioids and other sedatives was modeled with time-dependent covariates. Prazosin use was included as a control exposure because it is prescribed in PTSD for the treatment of nightmares and other sleep disturbances but does not have significant sedating properties.

RESULTS: Adverse events occurred within 1 year in 2,926 (1.5 %) patients. Hazard ratios (95 % C.I.) for adverse events were: benzodiazepines, 1.8 (1.6–2.0); opioids, 1.4 (1.2–1.7); atypical antipsychotics, 1.9 (1.7–2.1); and hypnotics, 1.4 (1.1–1.8). In addition, the benzodiazepine-opioid interaction was significant ($p<.001$), indicating a multiplicative effect where the hazard ratio for this combination was 3.8 compared to nonusers of both. Among dual users of benzodiazepines and opioids, 78 % were prescribed by different providers. Prazosin exposure and other interaction terms were not significantly associated with adverse events.
CONCLUSIONS: Polysedative use in veterans with PTSD leads to incremental risk for serious adverse events. The combination of benzodiazepines and opioids is particularly troublesome given the synergistic interaction and the tendency toward being prescribed by different providers. The clinical complexity of caring for veterans with PTSD creates an environment that, without careful coordination of care, can lead to high-risk polysedative use.

AFTER THE FACT: EDUCATING WOMEN INCARCERATED IN JAIL ON THE USE OF MEDICAL THERAPIES TO PREVENT HIV ACQUISITION FOLLOWING A RISKY EXPOSURE Neha Gupta[3]; Heidi Schmidt[3]; Timothy Buisker[2]; Mi-Suk Kang Dufour[2]; Janet Myers[2]; Jacqueline P. Tulsky[1]. [1]University of California San Francisco, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA; 3University of California San Francisco, San Francisco, CA. (Tracking ID #1634988)

BACKGROUND: Women incarcerated in jail face increased risk of HIV infection because they over represent members of communities at risk. Antiretroviral therapy following an HIV exposure–non-occupational post-exposure prophylaxis (nPEP)–has been endorsed by federal guidelines as an effective HIV prevention strategy since 1997. However, there is little information regarding nPEP awareness or its use among women leaving jail. This study assessed baseline awareness and knowledge regarding nPEP among women incarcerated in a local jail and evaluated the effectiveness of a brief educational intervention in increasing nPEP awareness and knowledge.
METHODS: A 15-min lesson was developed to teach principles of nPEP to detained women at the San Francisco jail. Participants were recruited from September 2012 to January 2013, and the intervention was delivered in small groups. Prior to the intervention, participants completed a survey (T1), reflecting demographics, HIV risk factors and nPEP awareness, knowledge and attitudes. The nPEP section was repeated immediately after the program (T2) and at one week (T3). Knowledge scores were calculated and assessed in 2 domains: risky behaviors and nPEP logistics (initiation timeframe, duration of use, side effects). Baseline knowledge scores and awareness were compared to answers at T2 and T3 using paired t-tests. Linear regression analysis was used to identify predictors of baseline awareness, baseline knowledge and improvement in knowledge scores.
RESULTS: Of 62 women enrolled, 53 completed T1, 48 completed both T1 and T2, and 34 completed both T2 and T3. 43 % identified themselves as black or African American, 21 % as white, 13 % as Hispanic, and 23 % as other. The mean age was 34 years, and mean total time incarcerated was 5.8 years. 32 % of the women had less than a high school education. 83 % of women were tested for HIV in the past year. 82 % reported sex-related HIV exposures in the past year, yet only 38 % perceived themselves at risk. Similarly, 28 % reported drug-related HIV exposures, while only 10 % perceived themselves as at risk. Baseline awareness of nPEP's existence was 55 %. Increased education was associated with improved risk knowledge and overall knowledge (β=0.252, p=0.015 and β=0.291, p=0.011). Additionally, while knowledge scores increased in both domains after the intervention (see Table 1), the increase in nPEP logistics knowledge was greater than the increase in behavioral knowledge ($p<0.001$). The percent of participants who would "definitely seek out nPEP after a risky exposure" was high at baseline (77 %), and remained high at T2 and T3 (83 % and 95 %, respectively), despite possible side effects and the need to take medications for 4 weeks.
CONCLUSIONS: Despite the high rates of recent HIV testing and engagement in high-risk behaviors, awareness of individuals' own risk and the existence of nPEP as an HIV prevention strategy was low among women in this study. A 15-min educational intervention is an effective means of delivering HIV prevention information to women in jail, but may be more useful for teaching basic information about taking nPEP than changing knowledge about risk behaviors.

AGING, CHRONIC HEALTH CONDITIONS, AND SEXUAL FUNCTION IN WOMEN Ayesha A. Appa[1]; Jennifer Creasman1; Jeanette S. Brown[1]; David Thom[1]; Stephen K. Van Den Eeden[2]; Leslee L. Subak[1]; Alison J. Huang[1]. [1]University of California, San Francisco, San Francisco, CA; [2]Kaiser Permanente Division of Research, Oakland, CA. (Tracking ID #1633496)

BACKGROUND: Sexual function in women is thought to decline with age, yet some women report preserved sexual function in older age. Changes in health, such as the development of chronic health conditions, may play an important role in determining whether sexual desire, activity, or satisfaction decrease in women in middle and older age.
METHODS: Sexual function was evaluated prospectively in a multiethnic, population-based cohort of 2,270 women aged 45 to 80 years randomly selected from age and race/ethnicity strata from an integrated healthcare delivery system in California. Using structured-item, self-administered questionnaires, women described their level of sexual desire, frequency of sexual activity, and overall sexual satisfaction at baseline and after 5 years. Additional questionnaires assessed participants' detailed medical histories, medication use, and health-related behaviors, including diagnosed chronic conditions such as cancer and cardiometabolic, colorectal, neuropsychiatric, respiratory, and urogynecological disorders. Repeated measures multivariable models were developed to assess the relationship of age and chronic conditions to self-reported sexual desire, activity, and satisfaction, adjusting for race/ethnicity and relationship status.
RESULTS: Of the 2,270 participants (1007 White, 443 Black, 419 Latina, and 401 Asian), 54 % reported low sexual desire, 50 % reported less than monthly sexual activity, and 46 % reported low sexual satisfaction at baseline. Over 5 years of follow-up (N=1,395), 34 %, 26 %, and 38 % of women reported decrease in sexual desire, frequency of sexual activity, and sexual satisfaction, respectively. In repeated measures analyses using data from all study visits and controlling for age, race/ethnicity, and relationship status, greater number of chronic conditions was independently associated with low sexual desire (OR 1.14 [1.09–1.19] per condition), less than monthly sexual activity (OR 1.14 [1.09–1.19] per condition), and low overall sexual satisfaction (OR 1.13 [1.08–1.18] per condition). Women with neuropsychiatric conditions in particular (stroke, dementia, Parkinson's disease, depression) were more likely to report low sexual desire (OR 1.55 [1.31–1.83]), less than monthly sexual activity (OR1.41 [1.18–1.68]), and low sexual satisfaction (OR 1.44 [1.21–1.71]), independent of other types of chronic conditions. Age persisted as a significant predictor of low desire, lower frequency of sexual activity, and low overall sexual satisfaction even after adjustment for number and types of chronic conditions ($P<0.001$ for all).
CONCLUSIONS: Decline in sexual desire, activity, and satisfaction appear common but not inevitable as women age. Sexual function may decrease as women acquire chronic conditions, although differences in the number and type of conditions do not fully explain differences in sexual function with aging. Clinicians caring for female patients across the aging spectrum should consider the specific impact of chronic conditions, particularly neuropsychiatric conditions, on women's interest in and ability to enjoy sexual activity.

AMBULATORY RESIDENT PRACTICE REDESIGN: THE CREATION OF PRACTICE TEAMS WITHIN A 6+2 MODEL Christina Harris; Lauren Acinapura; Johanna Martinez; Judy Tung; Cathy Jalali. Weill Cornell Medical College, New York, NY. (Tracking ID #1642447)

BACKGROUND: Calls for Internal Medicine residency redesign have emphasized the strengthening of ambulatory education with the IM Residency Review Committee specifically mandating that programs "develop models and schedules for ambulatory training that minimize conflicting inpatient and outpatient responsibilities". In response, in 2011 we restructured our residency program away from traditional block time with weekly half day continuity clinics to a model where inpatient and outpatient time were independent of each other in a 6+2 model (6 weeks inpatient followed by 2 weeks of ambulatory practice) and created resident teams ("pods") of four residents each.
METHODS: We implemented a 6+2 scheduling template at the start of the 2011–2012 academic year for all 130 residents across 3 continuity practices. In order to ensure adequate coverage of patient care matters during the 6 weeks away from practice, we created pods of four residents who hand off to each other every 2 weeks. The resident on ambulatory block functions as the "pod leader" and is responsible for ensuring that all direct and indirect patent care needs of the pod are met. Resident surveys were administered prior to the block restructuring and 1 year after implementation. Residents were asked to rate their satisfaction in four main areas including clinical and learning environment, personal experience and satisfaction with ambulatory preceptors using a 5-point rating scale. In addition, individual resident visit volume and patient continuity data were obtained for the main resident practice.
RESULTS: The survey data, analyzed using Wilcoxon Signed Rank Test, revealed that the scheduling template and creation of resident teams significantly improved resident satisfaction with their overall clinical environment (3.33 vs 4.13; $p<.005$) and learning environment (3.55 vs 4.16; $p=.002$), as well as personal reward (3.68 vs 4.11;$p=.041$) from their ambulatory practice. Residents reported improved satisfaction with their ability to focus while on the wards (2.68 vs 4.33; $p<.005$) and as well while on outpatient rotation (3.65 vs 4.51; $p<.005$). The repetitive nature of the schedule resulted in residents feeling significantly more connected to each other (3.81 vs 4.43, $p=.003$), however, without a similar increase in satisfaction in the exposure to their assigned continuity preceptor (4.13 vs 4.21; $p=.732$). With the creation of coverage pods, there was in improvement in resident satisfaction in how patient calls were answered (3.21 vs 3.82; $p=.006$), as well as with how patients results were managed (3.54 vs 4.08; $p=.009$) for the resident practice. The patient volume lost by the elimination of weekly afternoon continuity clinics was offset almost exactly with the increase in ambulatory block from 8 to 12 weeks per year (15,822 vs 15,972 resident visits/year). Despite an increase in satisfaction with the sense of patient ownership (4.17 vs 4.47; $p=.029$) individual resident-patient continuity remained unchanged (47 % vs 46 %). No change in resident reported spectrum of type patient care issues was seen.
CONCLUSIONS: Utilizing a 4 resident pod team approach, our residency program was able to effectively decouple the inpatient and outpatient residency experience in a way that improved the residents' perceived ambulatory experience without negatively impacting patient volume or continuity of care. Future efforts to improve resident-patient continuity both within their individual panel and within the pod are underway.

AN EHR-BASED INTERVENTION TO PROACTIVELY IDENTIFY AND MITIGATE DELAYS IN CANCER DIAGNOSIS: A RANDOMIZED CLINICAL TRIAL Daniel R. Murphy[2,1]; Louis Wu[2,1]; Archana Laxmisan[2,1]; Eric J. Thomas[3]; Samuel N. Forjuoh[4]; Hardeep Singh[2,1]. [1]Baylor College of Medicine, Houston, TX; [2]Michael E. DeBakey VA Medical Center, Houston, TX; [3]University of Texas Houston Medical School and the UT-Memorial Hermann Center for Healthcare Quality & Safety, Houston, TX; [4]Scott & White Healthcare, Texas A&M Health Science Center, Houston, TX. (Tracking ID #1642092)

BACKGROUND: Delays in cancer diagnosis can results in poor patient outcomes and increased malpractice litigation. Many of these delays are related to "missed" follow-up of non-life threatening abnormal clinical findings such as positive cancer screens (i.e. red flags). Methods to identify patients at risk for delayed diagnosis due to missed follow-up are in their infancy and have not been evaluated thus far.
METHODS: We conducted a randomized clinical trial to test the effectiveness of an intervention using EHR-based triggers (i.e., specific set of data signals that prompt record review) to improve follow-up of red flags related to colorectal, breast, and prostate cancer. The two-part intervention included: (1) using an electronic trigger to identify high-risk patients with missed red flags suggestive of the cancer, and (2) communication of information about high-risk patients to primary care providers (PCPs). Study settings included a large urban VA facility and a large private health system. PCPs were the unit of randomization and were randomly assigned to intervention or controls using a randomized block design. Triggers identified patient records with red flags that had no EHR evidence of follow-up action. Red flags included a positive fecal occult blood test (FOBT), labs consistent with iron deficiency anemia, new diagnosis of hematochezia, imaging study with a lung mass, and an elevated prostate specific antigen. Triggers were prospectively applied every 2 weeks to EHR data of all patients assigned to an intervention provider. Each triggered chart was manually reviewed initially to determine whether follow-up was truly delayed per a priori definitions (e.g. no colonoscopy within 60 days of positive FOBT). If so, the respective provider was contacted by secure email. One week later, if no action was taken, the provider was called. The primary outcome was a documented follow-up action in response to the red flag, which was determined through blinded final reviews performed 7 months after the date of red flag. A chi-squared analysis was performed to test if the intervention improved follow-up.
RESULTS: A total of 72 PCPs participated in the study, and 36 were randomly assigned to each group. Seven PCPs left their facility during the study period. The intervention was applied to all patients seen at the study sites for 15 months from April 20, 2011 to July 19, 2012 and identified a total of 1257 high-risk patients. After initial review, 376 (29.9 %, 210 intervention and 166 control) records were excluded because they did not meet study criteria (e.g., patient declined follow-up or pursued outside care), leaving 881 patients with confirmed delays. Patients assigned to an intervention provider were more likely to receive subsequent follow-up (RR:1.22; 95 % CI:1.002,1.485; $p=0.047$).
CONCLUSIONS: A proactive EHR-based intervention to identify patients at risk for delays in cancer diagnosis has potential to improve their follow-up. Similar EHR-based interventions could be applied to other conditions where delays in diagnosis and/or follow-up are a problem.

AN ITERATIVE, COMMUNITY FEEDBACK-DRIVEN APPROACH TO HOUSEHOLD SURVEY DESIGN Lujia Zhang[1]; Dennishia Banner[2]; Rachelle Bross[5]; Nell Forge[4]; Felica U. Jones[2]; Loretta Jones[2,4]; Katherine L. Kahn[1]; Roberto Vargas[1]; Keyonna M. King[1]; Aziza L. Wright[2,4]; Sigrid K. Madrigal[2]; D'Ann M. Morris[3]; Keith C. Norris[4]; Orwilda L. Pitts[4]; Ibrahima Sankare[1]; Arleen Brown[1]. [1]UCLA, Los Angeles, CA; [2]Healthy African American Families, Los Angeles, CA; [3]Los Angeles Urban League, Los Angeles, CA; [4]Charles Drew University, Los Angeles, CA; [5]Los Angeles Biomed, Los Angeles, CA. (Tracking ID #1641961)

BACKGROUND: While household surveys are common in epidemiologic research, few studies have employed community partnered participatory research (CPPR) in the research design phase. The Healthy Community Neighborhood Initiative (HCNI) is a collaborative effort between the Los Angeles Urban League, and Healthy African American Families (HAAF), Charles Drew University, and University of California in Los Angeles (UCLA) to improve health and health care in a South Los Angeles community disproportionately affected by preventable chronic conditions. Community-academic input informed survey development and study design to build capacity for community engaged research to reduce health disparities.
METHODS: HCNI members identified key topics for the interview and examination and then iteratively ranked items, refined and piloted elements

of the survey and clinical examination; obtained community input on the informed consent form, the survey, and the clinical and laboratory data collection protocols; and piloted household surveys. After each household visit, observer and participant recommendations were incorporated into the protocol for the next visit.

RESULTS: Over six household visits ($n=11$), changes to the data collection instruments and protocols enhanced participant understanding of the informed consent form (ICF) and survey questions, reduced time spent "in-home" by 30 min, and streamlined the protocol to facilitate fewer surveyors in the household.

CONCLUSIONS: An iterative, community-academic feedback-driven revision process resulted in substantive changes to the ICFs, surveys, and data collection protocols that reflected the unique characteristics of the community and its residents. By emphasizing community engagement early in the study design phase, we established bidirectional knowledge exchange between researchers and the community.

AN UNDER-APPRECIATED ETHICAL PROBLEM: DELAYS IN DEATH CERTIFICATE COMPLETION Philip C. Carullo[1]; Daniel Sulmasy[2]. [1]University of Chicago, Chicago, IL; [2]University of Chicago, Chicago, IL. (Tracking ID #1627627)

BACKGROUND: Death certificates are legal documents that permit families to finalize a multitude of end-of-life tasks. Physicians play a key role in generating these documents, in partnership with hospital staff, funeral directors, and state health departments. While delays and errors in the completion of a death certificates increase waiting times for families and, anecdotally, have been reported to cause great anguish, there have been no systematic studies of delays in death certificate completion by physicians, especially the impact of such delays on families. The purpose of this study was to gain broad insight into the phenomenon of delayed death certificate completion by physicians, especially the impact of such delays on families.

METHODS: The authors selected 12 academic medical centers dispersed throughout the US and interviewed 30 participants, including hospital staff dedicated to death certificate paperwork, and local funeral parlor and medical examiner office personnel to understand the phenomenon and the impact of delays in death certificate completion by physicians. They used a phenomenological, qualitative approach; 2 independent coders analyzed the interview data and jointly resolved coding disagreements; no more interviews were conducted once thematic saturation was reached.

RESULTS: Delays of several days were reported to be as common as 10–20 % of all deaths by some informants. Delays were noted to be associated with adverse emotional, bureaucratic, and even financial consequences for families, to result in delayed funeral arrangements, and to cause consternation for responsible hospital staff, funeral parlor personnel, and medical examiners' offices. Quotes such as the following from a hospital "expiration clerk" help illustrate the problem: "I have had one doctor say I'll fill it out when I get to it. He said he believes that the death certificate is a bureaucratic and political thing and that he didn't like the idea of being told what to do."

CONCLUSIONS: While generalizability is limited in a qualitative study, this investigation provides evidence for a long neglected problem in medical ethics, namely, that physicians are often remiss in their death certificate responsibilities and some do not understand this procedure as a final act of care for their patients and their grieving families. Educational and policy improvements could help rectify this situation.

AN ANALYSIS OF PATIENT AND PHYSICIAN PERSPECTIVES OUTPATIENT ADVERSE DRUG EVENTS: "I KNEW SOMETHING WAS WRONG SO I HAD TO GO" Urmimala Sarkar; Sarah Gertler; Zlatan Coralic; John Stein; Andrea Lopez. University of California, San Francisco, San Francisco, CA. (Tracking ID #1641555)

BACKGROUND: Adverse drug events (ADEs) which occur when patients or caregivers administer medications are a significant cause of emergency department (ED) visits. Although root cause analysis is required by the Joint Commission for in-hospital adverse events, this approach is seldom applied to understand ADEs that happen in outpatient settings. We conducted root cause analysis for outpatient adverse drug events that led to ED visits.

METHODS: Trained pharmacists identified ADEs and then enrolled adult patients 18 years of age and older (or their primary caregivers), who presented to an urban academic medical center's ED with symptoms or diagnoses consistent with ADEs. We conducted semi-structured interviews of the patients and physicians and reviewed ED records. The interview questions were about patient, provider, or health system factors affecting the administration of medications- all with respect to adverse drug events and the injury prevention framework. Interviews were audio-taped, transcribed verbatim, and subsequently de-identified. All transcripts were coded by two investigators (SG, AL), with differences finalized via discussion.

RESULTS: A total of 25 patients were consented and enrolled over 18 months while pharmacist coverage was available. Of these, a total of 17 patients or caregivers, and 11 physicians were interviewed, representing a total of 18 ED visits, 13 for chronically and 5 for acutely prescribed drugs. Our analysis identified the following themes within the injury prevention framework: Agent (drug) factors including high risk drugs, with narrow therapeutic indices. Host (patient) factors: patient capacity or understanding of how to use medications, awareness of side effects, mistrust of the medical system, and clinical acuity including patients with multiple comorbidities on multiple drugs, and difficult risk-benefit assessment. Environment (social and physical factors): lack of social support for medication management or basic needs, and health systems issues including access to care, access to specialists, and lack of continuity.

CONCLUSIONS: Our analysis identified several common root causes of outpatient ADE's, particularly high-risk drugs being used chronically in medically and socially complicated patients, with clear difficulties in daily self-management. We identified limitations in continuity, access to care, and communication between providers.

Themes with Clinical Scenarios and Representative Quotes

Theme Clinical scenario Representative quote

Patient factor: Patient capacity or understanding of how to use drugs A patient with diabetes presented with hypoglycemia after giving himself his insulin prior to eating breakfast. Patient expressed persistent confusion regarding proper insulin administration \"I still don't know what causes it (low blood sugar) or how it comes on. They showed me about eating, I should eat first, then my shot. Before, it was my shot, then eat. I don't know which is right?\"

Social factor: Lack of social support for drug management or basic needs A patient with diabetes, on insulin, who presented with hypoglycemia, identified poor oral intake when he runs out of money at the end of the month. A patient with diabetes, on insulin, who presented with hypoglycemia, identified poor oral intake when he runs out of money at the end of the month. \"So sometimes at the end of the month I don't have a lot to eat and then I got out and I eat inexpensive food…at the time I was eating a lot of candy.\"

Healthcare System factor: Access to care (appointments, prescriptions, and pharmacist education) A patient with diabetes and vision impairment had insurance difficulties which caused a delay in receiving her insulin pen prescription. A stressful housing situation prevented her from getting to an appointment to learn how to use it, and she became hypoglycemic when attempting to use them on her own. \"We had some trouble with her insurance to get her insulin supplies. And when we were finally able to do that, she was supposed to come into clinic so she could be taught how to use them but she didn't do that. So she missed a couple of appointments, and she finally got the insulin supplies but, instead of coming to clinic, she decided to try to use them on her own.\"

Limitations in continuity A patient with chronic migraines had an insurance change and had been unable to get a referral to a new neurologist Therefore when she got a migraine, she took a friend's medicine, which may have interacted with her SSRI causing an ADE. \"I'm planning to see my primary care doctor so she can refer me to a neurologist because the one I saw before was from another insurance. So the last time I saw a neurologist was 2010.\"

Access to care A patient with diabetes and vision impairment had insurance difficulties which caused a delay in receiving her insulin pen prescription. A stressful housing situation prevented her from getting to an appointment to learn how to use it, and she became hypoglycemic when attempting to use them on her own. \"We had some trouble with her insurance to get her insulin supplies. And when we were finally able to do that, she was supposed to come into clinic so she could be taught how to use them but she didn't do that. So she missed a couple of appointments, and she finally got the insulin supplies but, instead of coming to clinic, she decided to try to use them on her own.\"
Communication between providers A complicated patient with memory loss, and a recent hospitalization had a seizure, likely related to buproprion. Diagnosis was made more difficult by patient's memory loss, and incomplete records from her hospitalization. \"According to her social working and doctor down at (outside hospital) it's imperative that she have this doctor, but they don't seem to feel that it's imperative that her medical records get up here. She's been up here for 2 weeks and they still have not gotten her medical records up here.\"

ANTIBIOTIC PRESCRIBING FOR ADULTS WITH ACUTE BRONCHITIS IN THE UNITED STATES, 1997–2010 Michael L. Barnett; Jeffrey A. Linder. Brigham and Women's Hospital, Boston, MA. (Tracking ID #1638813)

BACKGROUND: Guidelines state and performance measures assert that antibiotics are not indicated for acute bronchitis. Efforts to decrease antibiotic prescribing for acute bronchitis have been underway for over 15 years. We used nationally representative surveys to examine the rates and types of antibiotics prescribed for acute bronchitis in outpatient primary care practices and emergency departments (EDs) from 1997 to 2010 in the US.
METHODS: We performed a cross-sectional analysis of the National Ambulatory Medical Care Survey and National Hospital Ambulatory Medical Care Survey of visits by adults aged 19–64 years old with a diagnosis of acute bronchitis (ICD-9 codes: 466.x or 490.x) to office-based primary care physicians and emergency departments (EDs) between 1997 and 2010 in 2-year periods (n=9,266). We excluded visits by patients with concomitant diagnoses of chronic lung disease, cancer, antibiotic-appropriate conditions, or immunosuppression. We examined the overall antibiotic prescribing rate as well as the prescribing rate for extended spectrum macrolides. We calculated weighted numbers of visits, prescribing rates, and their standard errors taking account of the multistage probability design of the surveys. We tested prescribing trends over time using survey-weighted logistic regression.
RESULTS: Between 1997 and 2010, there were 97 million (95 % confidence interval [CI], 87 to 106 million) visits to outpatient offices and EDs for acute bronchitis. Visits for acute bronchitis decreased from 18.5 million (95 % CI 14.3–22.6) in 1997–1998 to 9.8 million (95 % CI 6.7–12.9) in 2009–2010 (p<0.001). Patients made 76 % of visits for bronchitis to office-based primary care offices and 24 % of visits to EDs. Patients with acute bronchitis had a mean age of 39, were 61 % female, 77 % white, and 48 % with private insurance. Physicians prescribed antibiotics at 74 % (95 % CI, 71 to 76) of visits. During this time period the overall national antibiotic prescribing rate did not change (p=0.47) though the prescription rate in EDs increased from 66 % to 71 % (p<0.001). Adjusting for patient demographic factors, EDs prescribed antibiotics significantly less often than office-based physicians (OR 0.92; 95 % CI, 0.88–0.97). The most commonly prescribed antibiotics were extended spectrum macrolides (35 % of visits; 95 % CI, 33 to 38), fluoroquinolones (10 % of visits; 95 % CI, 8 to 12), and aminopenicillins (9 % of visits; 95 % CI, 7 to 10). Macrolide prescribing rates increased from 34 % to 42 % of all bronchitis visits from 1997 to 98 to 2010–11 (p=0.04).
CONCLUSIONS: Despite guidelines and performance measures stating that antibiotics are not indicated for acute bronchitis, physicians prescribed antibiotics at 74 % of visits for acute bronchitis from 1997 to 2010. Physicians frequently prescribed broad-spectrum, expensive antibiotics for acute bronchitis. The number of acute bronchitis visits halved between 1997 and 2010, which may signal patients making fewer visits or physicians selecting alternative diagnoses.

ANTIBIOTIC PRESCRIBING FOR ADULTS WITH SORE THROAT IN THE UNITED STATES, 1997–2010 Michael L. Barnett; Jeffrey A. Linder. Brigham and Women's Hospital, Boston, MA. (Tracking ID #1638786)

BACKGROUND: Among adults with sore throat, the prevalence of group A streptococci (GAS) - the only common cause of sore throat for which antibiotics are indicated - is about 10 %. Penicillin, to which GAS is universally susceptible, remains the antibiotic-of-choice.
METHODS: We performed a cross-sectional analysis of the nationally representative National Ambulatory Medical Care Survey and National Hospital Ambulatory Medical Care Survey examining visits by adults with a chief complaint of sore throat to office-based primary care physicians and emergency departments (EDs) between 1997 and 2010 in 2-year periods (n =8,191). We examined the overall antibiotic prescribing rate and the prescribing rate for penicillin, erythromycin, azithromycin, amoxicillin, and non-recommended antibiotics. In addition, we examined antibiotic prescribing for the three most common primary diagnoses: acute pharyngitis, non-specific upper respiratory infection, and streptococcal sore throat. We calculated weighted annual numbers of visits, prescribing rates, and their standard errors taking account of the multistage probability design of the surveys.
RESULTS: Between 1997 and 2010, there were 94 million (95 % confidence interval [CI], 86 to 102 million) visits by adults with a chief complaint of sore throat in the United States. Patients made 82 % of sore throat visits to office-based primary care physicians and 18 % to EDs. Patients had a mean age of 35 years old, 65 % were women, 84 % were white, and 65 % had private insurance. Physicians prescribed antibiotics at 60 % (95 % CI, 57 to 63) of visits. From 1997 to 1998 to 2009–2010, the overall antibiotic prescribing rate did not change (p=0.31). In the same time period, there was no change in the rate of antibiotic prescribing (both p>0.35) by office-based physicians (61 %; 95 % CI, 58 to 64) or EDs (55 %; 95 % CI, 53 to 57). Penicillin prescribing averaged 9 % during the study period and did not change significantly: 13 % in 1997–1998 and 7 % in 2009–2010 (p=0.27). Erythromycin prescribing was consistently below the threshold of reliability set by the CDC. Azithromycin prescribing increased from less than 5 % in 1997–1998 to 15 % of visits in 2009–2010 (p<0.001). There was no change in the prescribing rate for amoxicillin (17 %, p=0.32) or non-recommended antibiotics (15 %, p=0.37). For visits with a primary diagnosis of acute pharyngitis, antibiotic prescribing rates decreased from 78 % of visits in 1997–1998 to 58 % of visits in 2009–2010 (p=0.002). There was no change in the antibiotic prescribing rate for visits with the primary diagnoses of non-specific upper respiratory infection (43 %; p=0.32) or streptococcal sore throat (89 %; p=0.66)
CONCLUSIONS: Physicians prescribed antibiotics to 60 % of adults with sore throat between 1997 and 2010. Physicians continue to prescribe broad-spectrum, expensive, or non-recommended antibiotics at the majority of sore throat visits. Prescribing for penicillin, the antibiotic-of-choice, was stable and infrequent at 9 %.

ANTIRETROVIRAL THERAPY USE AND ADHERENCE AMONG PLWHAS WHO HAVE PANIC DISORDER Tanyka S. Sam[1]; Heidi Hutton[2]; Jeanne C. Keruly[1]; Richard D. Moore[1,3]; Geetanjali Chander1,3. 1The Johns Hopkins University School of Medicine, Baltimore, MD; [2]The Johns Hopkins University School of Medicine, Baltimore, MD; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Tracking ID #1642198)

BACKGROUND: Mental disorders are twice as common in persons living with HIV/AIDS (PLWHA) than the general population and are associated with decreased adherence to antiretroviral therapy (ART). However, there are few studies exploring the relationship between individual mental disorders and HIV adherence outside of depression. Among these disorders

is anxiety, of which approximately 16 % of PLWHAs are estimated to be afflicted. Within the spectrum of anxiety disorders, panic disorder is five times more common in PLWHA than the general population. The objective of this study is to investigate the association between panic disorder, ART use, and adherence in an urban HIV outpatient setting.

METHODS: In an observational cohort study of HIV-infected persons in care in Baltimore, MD, we prospectively assessed alcohol use, illicit drug use, panic, depressive symptoms, ART use, and medication adherence at 6 month intervals using audio computer assisted interviews (ACASI). Our outcomes of interest were ART use, defined as the use of ART at the time of the interview, and self-reported ART adherence using a visual analog scale, with <90 % defined as non-adherent. Current panic disorder was assessed using the 4 panic items from the Patient Health Questionnaire (PHQ). Individuals were classified as having panic if they responded positively to all items. Depressive symptoms were characterized via the PHQ with a score greater than 8 being classified as positive. Alcohol use was classified as hazardous, moderate or none, per NIAAA guidelines and illicit drug use was defined as current, past, or never use. We used generalized estimating equations to analyze the association between the independent variables and outcomes. Analyses were adjusted for age, sex, race, drug use, alcohol use, and depressive symptoms.

RESULTS: Between June 2010 and September 2012, 1533 individuals participated in 3292 ACASI interviews. 63.1 % were male and 83.7 % were African-American with a mean age of 40.6 years. 15.5 % of participants were current drug users and 5.9 % of individuals engaged in hazardous drinking. Depressive symptoms were endorsed by 9.5 % of participants. The overall prevalence of current panic disorder was 5.9 % with 91.5 % of individuals on ART at the time of the visit and 75.9 % of participants with greater than 90 % adherence. Panic disorder was negatively associated with ART use (AOR 0.64; 95 % CI 0.41 to 1.01) but was not associated with decreased adherence (AOR: 0.79; 95 % CI 0.53 to 1.16) when adjusted for depressive symptoms, alcohol, and illicit drug use.

CONCLUSIONS: Panic disorder was associated with decreased ART use independent of depressive symptoms, alcohol, or illicit drug use. Panic disorder was not associated with adherence. Future work should continue to delve into the determinants of ART usage in people with panic disorder as well as the relationship between ART usage and adherence with psychiatric intervention. Given the potential for disrupted medical treatment that may contribute to disease progression, early clinical detection and management, including social and psychological support and the development of coping strategies and stress management techniques, are of tantamount importance to patient success in the management of HIV.

ARE CLINICIANS OVERESTIMATING THE HEALTH LITERACY OF THEIR PATIENTS? Marianne Camargo; Alex Federman; Carol Horowitz. Mount Sinai Hospital, New York, NY. (Tracking ID #1632907)

BACKGROUND: Low health literacy (HL) is prevalent in the United States (US), especially among people of lower socioeconomic status, racial minorities, and the elderly. Previous studies have found that low HL is associated with worse health outcomes, and some have suggested that clinicians are unable to identify low HL patients. The objective of our study is to investigate clinicians' ability to detect low HL patients, and factors associated with HL overestimation.

METHODS: We administered the Short Test of Functional Health Literacy in Adults (S-TOFHLA) to heart failure patients at an urban academic medical center. In a complimentary survey, the clinician who most frequently cared for each patient (internist, cardiologist, geriatrician or nurse practitioner) was asked to estimate the patient's HL level based on the S-TOFHLA scale (low, marginal or proficient). For analysis, we used bivariate and multivariate methods to evaluate factors associated with overestimation of patients' HL level.

RESULTS: We collected data from 193 patients and 85 clinicians. Patients were mainly Black and Latino (72 %), and of lower socioeconomic status (40 % did not finish high school, and 60 % earned less than $15 K/year). Clinicians were mainly White (80 %), US trained (90 %), and in internal medicine (55 %). Nearly half (47 %) of patients had low HL. Of these, 73 % had a clinician overestimate their HL by at least one full category. Patients with low HL were more likely to be older ($p<0.001$), less educated ($p<0.001$), poorer ($p<0.001$), and non-White ($p=0.014$). In an adjusted analysis, clinicians trained in the US were less likely to overestimate their patients' literacy level (odds ratio [OR]: 0.255, 95 % CI 0.066–0.988). Other clinician factors (age, race, gender, specialty) did not correlate with overestimation of HL. Older and less educated patients were more likely to have their HL overestimated by their clinicians (OR: 1.037, CI: 1.008–1.068, and OR: 3.793, CI: 1.490–9.655 respectively).

CONCLUSIONS: Our study found that clinicians often overestimate their own patients' HL, especially among vulnerable populations. A high index of suspicion for low HL is warranted, and further work should explore interventions aimed at improving clinician HL assessment.

ARE PHYSICIAN-REPORTED BARRIERS TO SPECIALIST REFERRAL AN IMPORTANT PREDICTOR OF CAREER SATISFACTION AMONG PHYSICIANS CARING FOR CANCER PATIENTS? Daniel Kwon[1]; Diana Tisnado[2]; John Adams[3]; Afshin Rastegar[3]; Carrie Klabunde[7]; Mark C. Hornbrook[4]; Nancy L. Keating[5,6]; Katherine L. Kahn[3,2]. [1]David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]UCLA, Los Angeles, CA; [3]RAND, Santa Monica, CA; [4]Kaiser Permanente Center for Health Research, Los Angeles, CA; [5]Brigham and Women's Hospital, Boston, CA; [6]Harvard Medical School, Boston, CA; [7]National Cancer Institute, Bethesda, MD. (Tracking ID #1641815)

BACKGROUND: Referrals to specialists are important in ensuring that patients with complex conditions receive the technical expertise required, but little is known about barriers to referrals for newly diagnosed cancer patients. We assessed the prevalence of, and physician and practice characteristics associated with, physician-reported barriers to cancer patient's referrals for more specialized care. We also assessed the impact of referral barriers on physician career satisfaction in light of increasing rates of physician burn-out.

METHODS: We used data from 4,372 surgeons, medical oncologists, radiation oncologists and non-cancer specialists responding to the multi-regional Cancer Care Outcomes Research and Surveillance Consortium (CanCORS) Physician Survey (response rate 61 %). We first assessed the prevalence of five physician-reported barriers to referring cancer patients: 1) restricted provider networks; 2) pre-authorization requirements; 3) patient lack of ability to pay; 4) lack of surgical sub-specialists; and 5) excessive patient travel time, using a 5-point Likert scale from never (1) to always (5); we then calculated a barrier score by averaging the 5 items. We used multivariable linear regression to analyze physician and practice site predictors of the barrier score. Finally, for modeling the association between barriers and physician report of career satisfaction, we used a propensity score approach to adjust for potential selection effects in physician and practice setting characteristics associated with physician reports of barriers.

RESULTS: One in five physicians reported always or usually encountering any barrier to cancer patient referrals to specialists. The mean referral barrier score was 2.0 (SD 0.50, range 1.0–5.0). Multivariable regression showed physician age <40 years, oncologist specialty type (vs. PCP), foreign medical school graduate, and small practice size predicted more frequent reports of referral barriers (all $p<0.01$). Physicians in practices with high proportions of managed care patients, multi-specialty physician-owned offices, and government-owned practices were less likely to report referral barriers (all $p<0.01$). Almost half of physicians (45 %) reported very high career satisfaction. Logistic regression models weighted for the propensity of physician-reported barriers showed a significant association between a higher barrier score and a lower report of career satisfaction (odds ratio 0.711, 95 % CI 0.65–0.78). A one SD increase in the average barrier score was associated with a 36 % reduction (.50 SD × .71 OR= 0.36) in very high career satisfaction.

CONCLUSIONS: A fifth of physicians reported always or usually encountering barriers to referring cancer patients for more specialized care. Barriers to referrals varied across physician and practice setting characteristics and were significantly associated with lower physician-reported career satisfaction. Physicians caring for cancer patients in practices with established strategies to facilitate referrals across disciplines (e.g., HMO,

multi-specialty practices) reported fewer barriers to referring to cancer specialists than did physicians in smaller, less integrated practice settings. Practices that implement strategies to improve timely referrals for cancer patients may also improve physician career satisfaction.

ARE BIOMARKERS USEFUL TO IDENTIFY HEAVY DRINKING AMONG PEOPLE WITH ALCOHOL DEPENDENCE? Nicolas Bertholet[1]; Michael Winter[5]; Debbie M. Cheng[2,4]; Jeffrey H. Samet[2,6]; Richard Saitz[2,3]. [1]Alcohol Treatment Center, Lausanne, Switzerland; [2]Section of General Internal Medicine, Boston University and Boston Medical Center, Boston, MA; [3]Department of Epidemiology, Boston University School of Public Health, Boston, MA; [4]Department of Biostatistics, Boston University School of Public Health, Boston, MA; [5]Data Coordinating Center, Boston University School of Public Health, Boston, MA; 6Department of Community Health Sciences, Boston University School of Public Health, Boston, MA. (Tracking ID #1635024)

BACKGROUND: Managing patients with alcohol dependence includes assessment for heavy drinking, often done by asking patients. Biomarkers have been recommended to detect heavy drinking but evidence of their accuracy is limited. We assessed the operating characteristics of disialo-Carbohydrate-Deficient Transferrin (%dCDT), gamma-glutamyltransferase (GGT), %dCDT and GGT together, and breath alcohol for identifying heavy drinking among people with dependence.
METHODS: We used cross-sectional data from 402 adults with alcohol dependence and current heavy drinking. Subjects were referred to primary care and assessed with biomarkers 6 months after enrollment. For %dCDT a cutoff point of ≥1.7 % defined a positive test; a positive GGT was ≥66 U/L; the combination test was defined as positive if either individual test was positive; a positive breath alcohol test was >0. We assessed biomarker performance for detecting three heavy alcohol use levels over the past 30 days as determined using the Timeline Follow-back calendar method reference standard in confidential research interviews : 1) any heavy drinking (≥4 drinks in a day or >7 drinks/week for women, ≥5 drinks in a day or >14 drinks/week for men), 2) recurrent heavy drinking (≥5 drinks in a day on at least 5 days) and 3) persistent heavy drinking (≥5 drinks in a day on at least 7 consecutive days).
RESULTS: By self-report reference standard, the prevalence of any heavy drinking, recurrent, and persistent heavy drinking was 54 %, 34 %, and 17 % respectively. The Table displays the performance of each studied test (%dCDT, GGT, both, breath alcohol) for each of the three self-reported heavy alcohol use levels over the past 30 days.
CONCLUSIONS: %dCDT alone yielded the best likelihood ratio positive for each alcohol use level, however it was not adequately sensitive to detect any, recurrent, or persistent heavy drinking. A non-invasive breath alcohol test was comparable to GGT but neither of these two was sufficiently sensitive (both tests missed 70–80 % of the cases). Although biomarkers may provide useful information, determination of their role and incremental value over self-report in clinical settings is needed.
Table: Performance of biomarkers to detect three heavy alcohol use levels
Target condition and test Sensitivity Specificity Likelihood Ratio + Likelihood Ratio-
Any heavy drinking
%dCDT 40.7 95.7 9.47 0.62
GGT 20.0 86.1 1.44 0.93
%dCDT+ or GGT + 52.6 82.3 2.97 0.58
Breath alcohol 19.9 96.6 5.85 0.83
Recurrent heavy drinking
%dCDT 52.5 90.3 5.41 0.53
GGT 19.3 83.9 1.20 0.96
%dCDT + or GGT + 60.0 75.2 2.42 0.53
Breath alcohol 26.0 94.4 4.64 0.78
Persistent heavy drinking
%dCDT 66.1 84.2 4.18 0.40
GGT 29.3 85.1 1.97 0.83
%dCDT + or GGT + 74.6 70.9 2.56 0.36
Breath alcohol 30.7 91.4 3.57 0.76

ARE PHYSICIAN AND NURSE PRACTITIONER TRAINEES BUILDING AN INTERPROFESSIONAL MICRO-CULTURE? A QUALITATIVE ANALYSIS OF PROFESSIONAL AND GROUP IDENTITY DEVELOPMENT AT THE VETERANS HEALTH ADMINISTRATION CONNECTICUT HEALTHCARE SYSTEM CENTER OF EXCELLENCE IN PRIMARY CARE EDUCATION (COEPCE) Emily M. Meyer[1,3]; Rebecca Brienza[1,2]. [1]VA Connecticut Healthcare System, West Haven, CT; [2]Yale University, New Haven, CT; [3]Yale University, New Haven, CT. (Tracking ID #1623929)

BACKGROUND: The United States Department of Veterans Affairs Connecticut Healthcare System (VACHS) is home to one of five Centers of Excellence in Primary Care Education (CoEPCE). Our CoEPCE employs an innovative approach to post-graduate health professional education by training resident physicians and nurse practitioner (NP) fellows to function effectively in teams and provide exceptional patient-centered team-based care. Based on four core domains of shared decision making, sustained relationships, performance improvement and interprofessional collaboration, the CoEPCE is one of the first national efforts to embrace an interprofessional training approach that directly addresses divergence in nursing and medical care models.
METHODS: Qualitative methods were used to assess how our first cohort of VACHS trainees developed personally and professionally over time. Three sets of semi-structured interviews were conducted at discrete data collection time points to assess individual and group growth (n=20). Interviews were transcribed and uploaded into Atlas.ti 9.0. Implementing theoretically-grounded qualitative methods, we assessed how CoEPCE NP fellows and residents' professional and team identities developed over an academic year of training. The data underwent three phases of reduction, which resulted in several distinct themes and sub-themes.
RESULTS: Findings indicate that NP Fellows and Residents entered the CoEPCE with a strong sense of self; however an understanding of how they complement other professionals in an educational and clinical environment was less apparent. Over time, both groups demonstrated increased understanding of others' roles and were able to reflect on how differences/similarities informed interprofessional patient-centered care: "I just think it's great to have the opportunity [to debate] issues and figure out how different people are coming at [patients] and have differences and work them through and really challenge your own assumptions about how you practice." Trainees' thoughts on how the CoEPCE team evolved from an "artificial group" to one with shared meaning and goals were of particular interest. An intern remarked at midyear, "I feel very comfortable managing patients and I feel comfortable working on a team. I feel comfortable working with a diverse set of practitioners, whether they be NPs or even PAs and… understanding where they're coming from and being able to arrive at a mutually acceptable conclusion for patients." His colleague commented at year-end, "what I really value about this group is that everybody's open to it. Everybody seems quite open and we were just like at it and all going at it as equals… there was… no hierarchy."
CONCLUSIONS: This study investigated group formation and meaning-making in order to capture the experiences of a non-traditional, team-based approach to post-graduate primary care training. We found evidence supporting a shift in how trainees perceive their professional roles and connections to other clinical colleagues. This mutual understanding appears to contribute to a novel 'micro-culture' of post-graduate health professional training in that CoEPCE teams not only share patients, but through this model develop understanding and trusting practice partnerships. The insights and experiences of this inaugural group of interprofessional trainees can be used to inform research, along with program and curricula development as the VACHS program grows.

ASSESSING QUALITY OF CARE TO ADOLESCENTS USING STANDARDIZED PATIENTS IN REAL CLINIC SETTINGS Kathleen Hanley[1]; Angela Burgess[1]; Shoshanna Handel[3]; Elet Howe[3]; Richard Zapata[3]; Colleen Gillespie[1]; Jean-Marie Bruzzese[2]; David Stevens[3]; Sondra Zabar1. [1]NYU School of Medicine, New York, NY; [2]NYU Child Study Center, New York, NY; [3]NYC Health and Hospitals Corporation, New York, NY. (Tracking ID #1640548)

BACKGROUND: Clinicians' effectiveness eliciting and counseling on high-risk behaviors, such as unsafe sexual practices, and patient-centeredness of the clinician and the setting are essential to providing high quality care for adolescents. Improving the quality of care requires efficient, valid measurements. We created a novel program enlisting adolescent standardized patients (SPs) to evaluate pediatricians' competencies in real-life settings.
METHODS: Twenty-five pediatricians volunteered to see one standardized patient during primary care clinic. The physicians knew when they would see the SP but were unaware the SP case would focus on risk reduction counseling. Twelve young men were trained to portray a 16-year-old new patient with high-risk sexual behavior whose explicit agenda was obtaining a pre-employment physical. SPs were trained to reveal risk behavior only if pediatricians took specific steps to put them at ease, including clarifying confidentiality protections and demonstrating non-judgmental behavior. SPs were trained to assess providers' communication skills (data gathering, relationship building, counseling; 13 items; Cronbach's alpha for internal consistency = .88); risk assessment (16 items; alpha = .87); risk counseling (16 items; alpha = .87); treatment plan (3 items; alpha = .81); and patient-centeredness (3 items; alpha = .71) using a behaviorally-anchored checklist, and to provide verbal feedback on providers' specific communication skills (behaviors that helped SPs feel comfortable discussing risk and sexual history).
RESULTS: Providers at seven public hospital primary care clinics (mean 3.8 physicians/clinic, range 1–7) participated. They performed well in listening without interrupting, using understandable words, and discussing condom use (84 %, 88 %, 92 % well done respectively). SPs system-wide reported a need for more detailed information about confidentiality (44 % well done), a more collaborative approach to developing a plan (32 % well done), more detailed information about reducing risk (36 % well done), and more screening for specific sexual risks (e.g. 8 % screened for sex while high/drunk, 12 % screened for intimate partner violence, 28 % screened for male sex partners). SP satisfaction with pediatrician communication skills was mixed (24 % excellent, 32 % good, 36 % okay, 8 % poor). Strengths and weaknesses of individual pediatricians varied widely, suggesting a need for targeted feedback and coaching in individual physicians. Scores in communication, screening, and counseling did not vary significantly between the seven clinical sites. Participating pediatricians reported the experience to be useful in a post-program survey (46 % very useful; 31 % somewhat useful). All 25 agreed that the experience would help improve the care they provide. The SPs agreed (1/3 somewhat, 2/3 strongly) they would take greater responsibility for their health after participating in the program. Average cost for each visit (SP compensation and transportation) was $50.35.
CONCLUSIONS: This adolescent SP model effectively identified health system and individualized areas for improving pediatrician communication with adolescents about health risk, despite the physicians' awareness that the visit was an evaluated simulation. These findings support the case for wider-spread implementation. Previous evidence suggests that participation enhances health outcomes among SPs themselves; further investigation will explore whether this effect will be observed among adolescent SPs.

ASSESSING STUDENT NEEDS FOR LEADERSHIP SKILLS TRAINING IN MEDICAL SCHOOL April S. Fitzgerald; Redonda G. Miller; David M. Levine; Mary Catherine Beach; Bimal Ashar. Johns Hopkins University, Baltimore, MD. (Tracking ID #1640800)

BACKGROUND: Studies in the medical literature validate the importance of effective teams and leaders on clinical outcomes including patient safety, satisfaction, and hospitalization rates. The ACGME incorporates teamwork as a common program requirement and encourages residency programs to develop leadership and followership ability beyond on-the-job training. However, the medical literature is lacking information on a needs assessment or effective curriculum to teach these skills to physicians and trainees. The goal of our study is to perform a medical student needs assessment and pilot a leadership skills curriculum.
METHODS: Students in the Johns Hopkins School of Medicine voluntarily participated in a leadership skills questionnaire upon matriculation to medical school and. Students rated their level of comfort on a 5-point scale from 0 (not at all comfortable) to 4 (extremely comfortable) with leadership skills focused in the areas of teamwork, negotiations, feedback, and networking. Students were then offered leadership skills training as an elective during the fall of their first year, which included four 1-h sessions, each devoted to one of the four leadership skills.
RESULTS: Overall, 419/480 students from the classes of 2013–2016 completed the leadership questionnaire upon matriculation (87 %). Most student respondents were male (53 %) with a mean age of 23.1 years (range 21–38). Most students reported that leadership was very (47 %) or extremely (40 %) important to the practice of medicine. Less than half (47 %) of matriculating students reported having any form of leadership training prior to arriving at medical school. Students were more comfortable working alone than working in teams (mean 3.54 vs. 2.97, $p<0.001$); and when working on a team they were more comfortable leading than following (mean 2.9 vs. 2.6, $p<0.001$). Students were more comfortable negotiating on behalf of another than for themselves (mean 2.5 vs. 2.3, $p<0.001$), and more comfortable accepting criticism than providing negative feedback (2.4 vs. 1.8, $p<0.001$). Students with previous leadership training were significantly more comfortable than those without training in working on a team (mean 3.18 vs. 2.79, $p<0.001$), leading a team (mean 3.16 vs. 2.69, $p<0.001$), negotiating for another (mean 2.74 vs. 2.39, $p<0.001$), giving negative feedback (mean 1.99 vs. 1.62, $p<0.001$), and networking with other professionals (mean 2.37 vs. 1.86, $p<0.001$). Students in the leadership skills elective ($n=37$) rated the course as an outstanding (74 %) or excellent (21 %) learning experience.
CONCLUSIONS: Matriculating students rate leadership as important to the practice of medicine, yet the majority arrive without prior leadership training and are more comfortable working alone than in teams. Students without training are less likely to feel comfortable with basic leadership skills, and an elective curriculum on the leadership skills of teamwork, negotiations, giving peer feedback, and networking was well received. Continuation of the curriculum and further study is necessary to see if leadership skills training subsequently impacts student attitudes and performance.

ASSOCIATION BETWEEN A HOSPITAL'S QUALITY PERFORMANCE FOR IN-HOSPITAL CARDIAC ARREST AND COMMON MEDICAL CONDITIONS Lena M. Chen[1,5]; Brahmajee K. Nallamothu[1,5]; Harlan M. Krumholz[2]; John A. Spertus[3,4]; Fengming Tang4; Paul S. Chan[3,4]. [1]University of Michigan, Ann Arbor, MI; [2]Yale University, New Haven, CT; [3]University of Missouri-Kansas City, Kansas City, MO; [4]Saint Luke's Mid-America Heart and Vascular Institute, Kansas City, MO; 5VA Ann Arbor Healthcare System, Ann Arbor, MI. (Tracking ID #1635203)

BACKGROUND: Public reporting on hospital quality has been widely adopted for a few medical conditions. Broadening the scope of these efforts to include cardiac arrest is now being considered. Given growing evidence that hospital organization and culture can have hospital-wide effects on quality of care, it is unknown if a measure of inpatient survival after cardiac arrest would be redundant.
METHODS: Using data between 2007 and 2010 from a large, national in-hospital cardiac arrest registry, we calculated risk-standardized in-hospital survival rates for cardiac arrest at each hospital. We then obtained risk-standardized 30-day mortality rates for acute myocardial infarction (AMI), heart failure (HF), and pneumonia from Hospital Compare for the same time period. The relationship between a hospital's performance on cardiac arrest and these other medical conditions was assessed using weighted Pearson correlation coefficients.
RESULTS: Among 26,270 patients with in-hospital cardiac arrest at 130 hospitals, survival rates varied across hospitals, with a median risk-standardized hospital survival rate of 22.1 % and an inter-quartile range (IQR) of 19.7 % to 24.2 %. Similarly, there was site-level variation in hospital outcomes for common medical conditions, with median risk-standardized

30-day mortality rates at hospitals of 15.4 % (IQR: 14.4 % to 16.6 %) for AMI, 11.3 % (IQR: 10.3 % to 12.3 %) for HF, and 11.9 % (IQR: 10.7 % to 13.0 %) for pneumonia. There were no significant correlations between a hospital's outcomes for its cardiac arrest patients and its patients admitted for AMI (correlation of −0.12; P=0.16), HF (correlation of −0.05; P=0.57), or pneumonia (correlation of −0.15, P=0.10).
CONCLUSIONS: Hospitals that performed better on publicly reported outcomes for three common medical conditions did not necessarily have better cardiac arrest survival rates. Public reporting on cardiac arrest outcomes could provide new information about hospital quality. _____ Note: The authors are submitting this study for the American Heart Association's Get With the Guidelines®-Resuscitation (formerly the National Registry of Cardiopulmonary Resuscitation) Investigators.

ASSOCIATION BETWEEN MULTIMORBIDITY AND THE QUALITY OF PRIMARY CARE IN A COUNTRY WITH UNIVERSAL HEALTHCARE COVERAGE Sven Streit[1]; Stefan Weiler[2]; Tinh-Hai Collet[3,4]; Douglas Bauer[5]; Lukas Zimmerli[6]; Peter Frey[1]; Jacques Cornuz[3]; Jean-Michel T. Gaspoz[7]; Edouard Battegay[6]; Eve A. Kerr[8]; Drahomir Aujesky[2]; Nicolas Rodondi[2]. [1]University of Bern, Bern, Switzerland; [2]University Hospital Bern, Bern, Switzerland; [3]University Hospital Lausanne, Lausanne, Switzerland; [4]University Hospital Lausanne, Lausanne, Switzerland; [5]University of California, San Francisco, CA; [6]University Hospital of Zurich, Zurich, Switzerland; [7]University Hospitals of Geneva and Faculty of Medicine, Geneva, Switzerland; [8]University of Michigan, Ann Arbor, MI. (Tracking ID #1625309)

BACKGROUND: Clinical trials often exclude patients with comorbidities, but caring for patients with multimorbidity is very common for general internists. Data on the impact of multimorbidity on quality of care are conflicting. In Switzerland, a country with universal health coverage, little is known about the prevalence of multimorbidity and its impact. We aimed to analyze the association of multimorbidity and quality of preventive care.
METHODS: In a random sample of 1002 patients attending four Swiss university primary care settings, we abstracted medical charts over 2 years to build a retrospective cohort. The inclusion criteria were patients aged between 50 and 80 years followed for at least 1 year. As published definitions of multimorbidity are inconsistent, we derived a new set of comorbidities based on previous studies and added comorbidities used for the Charlson index and psychiatric diseases (e.g. schizophrenia) as an important comorbidity, finally leading to 17 conditions as comorbidities. To evaluate the quality of preventive care and care for cardiovascular risk factors, we searched medical charts for indicators from RAND's Quality Assessment Tool. We calculated the percentage of provided care as recommended care divided by patients who were eligible for each indicator. We calculated two aggregate scores of quality of preventive care and care for cardiovascular risk factors. Data were adjusted for possible confounders.
RESULTS: The mean age was 63.5 years, 44 % were women. Participants had a mean of 2.6 (SD 1.9) comorbidities, while only 7.6 % had no comorbidities. The mean Charlson index was 1.8 points (SD 1.9). Overall, participants received 69 % of recommended preventive care and 84 % received recommended care for cardiovascular risk factors. Quality of care remained stable with increasing number of comorbidities both for prevention and for cardiovascular risk factors. Results were similar in analyses limited to Charlson index and after adjusting for age, gender, civil status, legal status, work, center and number of visits. Among subgroups of diseases (cardiovascular disease, psychiatric disorders, chronic pulmonary disease, cancer or depression), we found similar quality of care.
CONCLUSIONS: In university primary care settings in Switzerland, multimorbidity was very common and less than 10 % of participants had no comorbidities. Quality of care for preventive care as well as for cardiovascular risk factors was independent of increasing number of comorbidities. These findings confirm the high prevalence of patients with multimorbidity in primary care and demonstrate that a high level of preventive care is possible despite multimorbidity.

ASSOCIATION BETWEEN RESIDENT LABORATORY TEST UTILIZATION, UNCERTAINTY & THE BIOPSYCHOSOCIAL MODEL OF PATIENT CARE Jessica R. Singer[1,2]; Deborah Jones[1,2]; Nancy Chang[1,2]; Rafael A. Lantigua[1,2]; Steven Shea[1,3]. [1]Columbia University College of Physicians and Surgeons, New York, NY; [2]NewYork Presbyterian Hospital, New York, NY; [3]Mailman School of Public Health, Columbia University, New York, NY. (Tracking ID #1626640)

BACKGROUND: There is significant variation in physician laboratory test utilization, with potential negative consequences for patients, provider organizations and the health care system from over- and under-utilization. Prior studies have found that some variation is explained by patient factors, physician demographic factors, or physician characteristics including clinical competencies and personality; however, much of the variation remains unexplained. Additionally, previous research has focused largely on attending physician and inpatient utilization. Our interest was in factors accounting for utilization that are potentially modifiable during residency, specifically how residents deal with uncertainty in primary care settings and their comfort with the biopsychosocial model. We aimed to assess the relationship between resident physician outpatient laboratory test utilization and reaction to uncertainty in the clinical encounter and to investigate whether this relationship was modified by belief in the biopsychosocial model of care.
METHODS: We conducted a cross-sectional study of internal medicine residents at an urban academic medical center. Residents were asked to complete a self administered web-based survey. Uncertainty was measured using an 8-item version of the Physician Reaction to Uncertainty Scale (PRUS) which measures anxiety due to uncertainty and concern over bad outcomes. To measure beliefs about the biopsychosocial model we used the 32-item Physician Belief Scale (PBS). Additional survey items included post graduate year (PGY) and gender. The outcome of laboratory test utilization was operationalized as the number outpatient of laboratory tests ordered by each resident during the academic year 6/15/11–6/14/12 divided by the total number of patient visits to that provider in that same academic year. Analyses were conducted using correlation, ANOVA and multivariable linear regression.
RESULTS: The survey response rate was 53 % (n=62). Respondents were 59 % male and about equally distributed between each post-graduate year (PGY1 31 %, PGY2 37 %, PGY3 32 %). The PRUS was normally distributed with mean 27.2±6.1 and cronbach alpha 0.86. The PBS was normally distributed with mean 73.6±15.0 and cronbach alpha 0.90. The mean laboratory test utilization was 2.5±0.9 tests ordered per patient visit. Interns ordered more laboratory tests per patient compared with PGY2 residents (3.0±1 vs. 2.3±0.8 p=0.04); gender was not associated with laboratory utilization (p=0.60). Resident discomfort with uncertainty was associated with increased laboratory utilization (r=0.3 p=0.03). After adjusting for PGY, discomfort with uncertainty remained associated with laboratory utilization (p=0.02). Together, PGY and reaction to uncertainty explained approximately 13 % of the variability in laboratory utilization. The association between physician reaction to uncertainty and laboratory utilization was not modified by belief in the biopsychosocial model (p interaction = 0.55).
CONCLUSIONS: Residents who were more comfortable with uncertainty in the clinical encounter ordered fewer laboratory tests. This association between uncertainty and laboratory utilization did not depend on degree of agreement with the biopsychosocial model of care. Further research should continue to assess the unexplained variation in utilization and design medical education interventions to support resident decision analysis and uncertainty in primary care settings with the goal of promoting safe and effective test utilization.

ASSOCIATION BETWEEN THE PATIENT-CENTERED MEDICAL HOME AND QUALITY OF CARE Lisa M. Kern[1,2]; Alison M. Edwards[1,2]; Rina V. Dhopeshwarkar[1,2]; Rainu Kaushal[1,2]. [1]Weill Cornell Medical College, New York, NY; [2]Health Information Technology Evaluation Collaborative, New York, NY. (Tracking ID #1639909)

BACKGROUND: The Patient-Centered Medical Home (PCMH) model of primary care is being implemented widely, although its effects on quality

are not yet clear. The PCMH model typically involves electronic health records (EHRs) but goes beyond that to include changes in the responsibilities of physicians and staff, including for care coordination. Our objectives were to compare the quality of care provided by physicians in PCMHs to the quality of care provided by: 1) physicians using paper medical records, and 2) physicians using EHRs without a PCMH model.
METHODS: We conducted a prospective cohort study from 2008 to 2010 in the Hudson Valley, a multi-payer, multi-provider, 7-county region in New York State. We included 388 primary care physicians (109 physicians in the PCMH group, 194 in the paper group and 85 in the EHR group), and 110,314 patients. The physicians in the PCMH group implemented the PCMH model in the Hudson Valley in 2009 and all achieved Level III Patient-Centered Medical Home, as defined by the 2008 standards of the National Committee for Quality Assurance. We used claims data to assess 10 quality measures from the Healthcare Effectiveness Data and Information Set (HEDIS). We used restricted maximum likelihood estimates to determine differences in quality, adjusting for 9 physician characteristics.
RESULTS: In 2010, PCMH physicians performed significantly better than physicians using paper records on 5 of the 10 quality measures: hemoglobin A1c testing, LDL testing, and nephropathy screening for patients with diabetes; breast cancer screening and colorectal cancer screening ($p<0.01$ for each comparison). The absolute effect size was 5–15 percentage points per measure. PCMH physicians similarly outperformed physicians using EHRs alone. Study group was not associated with a change in the rate of quality improvement over time.
CONCLUSIONS: Although this study does not prove that the PCMH model caused higher quality, it suggests that early adopters of the PCMH model are practicing differently from and better than physicians using either paper or EHRs alone. For patients and payers, the implication is that higher quality is more likely to be found in the PCMH practices.

ASSOCIATION BETWEEN WEIGHT LOSS AND THE PATIENT-PROVIDER RELATIONSHIP IN THE POWER WEIGHT LOSS TRIAL Wendy L. Bennett[1]; Yi-ting Chang[1]; Kimberly Gudzune[1]; Nae-Yuh Wang[1]; Arlene Dalcin[1]; Sara N. Bleich[2]; Lawrence J. Appel[1]; Jeanne M. Clark[1]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Tracking ID #1643416)

BACKGROUND: Despite recommendations for primary care providers (PCPs) to counsel obese patients on weight management, few studies have examined the influence of the PCP on patients' weight loss. Our objective was to understand the association between the patient-PCP relationship and weight loss in a practice-based weight loss trial.
METHODS: We performed a cross-sectional analysis using data from the Hopkins POWER Trial, a 24 month practice-based randomized controlled behavioral weight loss 3 armed trial comparing the effectiveness of an in-person or telephone-based intervention to a control group in obese adults who had an additional cardiovascular disease risk factor. All participants completed an end of study questionnaire with 8 questions about their relationship with their PCP, based on the Consumer Assessment of Healthcare Providers and Systems (CAHPS) survey and we calculated a summary score. Participants in the intervention arms additionally completed a survey assessing the helpfulness of their PCP in the trial (scale: 0 = not helpful to 4 = extremely helpful). Our main outcome was the mean percent weight loss from baseline to 24 months. We used a likelihood-based approach to general linear mixed models with an autocorrelation covariance structure among repeated-measures, adjusting for participant race, gender, age and clinical site, stratified by the 2 intervention arms combined and the control arm.
RESULTS: Of the 415 participants enrolled in the POWER trial, 347 (239 in the combined 2 intervention arms) completed these surveys and were included in this analysis. Overall, mean age was 54.8 years, mean baseline weight and BMI were 103.3 kg and 36.3 kg/m2, respectively, and mean 24 month percent weight loss was 3.9 %. 11 % reported changing PCPs during the study. All participants in the sample reported high quality patient-PCP relationships, with mean scores ranging from 3.3 to 3.8 (out of a maximum of 4) on all 8 relationship questions, and 29.1 for the summary score (range 14–32). There was no significant association between mean percent weight loss in the trial and the 8 patient-PCP relationship questions or summary score in control or intervention arms. Participants in the 2 intervention arms who rated their PCPs' involvement as "extremely helpful" compared to "not helpful" had 4.5 % ($p=0.02$) more weight loss at 24 months.
CONCLUSIONS: Participants reported high quality patient-PCP relationships and their relationships were not associated with 24 month weight change. Rating their PCPs as extremely helpful in the intervention was associated with significantly greater weight loss. We need further research to identify PCP and practice characteristics associated with higher patient satisfaction with the PCP role and greater weight loss. Understanding the PCP's role in weight management, including the quality of the patient-PCP relationship and patient's satisfaction with the PCP's involvement, will inform broader implementation of practice-based weight loss programs.

ASSOCIATION OF HOSPITAL VOLUME WITH RISK-STANDARDIZED READMISSION RATES Leora I. Horwitz; Zhenqiu Lin; Jeph Herrin; Chohreh Partovian; Jacqueline N. Grady; Julia Montague; Lisa G. Suter; Joseph S. Ross; Susannah Bernheim; Harlan M. Krumholz; Elizabeth E. Drye. Yale School of Medicine, New Haven, CT. (Tracking ID #1639577)

BACKGROUND: A large literature has demonstrated a positive association of hospital or operator volume with patient outcomes. Large volume centers produce fewer complications and deaths following surgical procedures, and fewer deaths from major medical conditions. Whether there is a similar relationship for readmissions is uncertain.
METHODS: We identified all hospitalized patients over 65 with Medicare fee for service who were discharged alive, not against medical advice, and not transferred out in 2010. We excluded patients admitted for medical treatment of cancer or primary psychiatric disease. We used the National Quality Forum-endorsed hospital-wide readmission measure to calculate overall risk-standardized readmission rates (RSRRs) for all hospitals, adjusting for age, principal diagnosis and comorbidity. We also calculated specialty cohort-specific standardized readmission ratios (SRRs) for five mutually exclusive cohorts within each hospital: surgery/gynecology, cardiorespiratory, cardiovascular, neurology and medicine. An SRR of 1 indicates the hospital is at expected readmission rate; SRR>1 indicates having greater than expected readmission rate. We divided hospitals into strata based on yearly volume of index admissions and compared RSRRs or SRRs for each strata, omitting hospitals with fewer than 25 cases.
RESULTS: We studied 7,678,216 discharges from 4,821 hospitals. Overall, higher volume hospitals had higher RSRRs. The mean RSRR for hospitals in the lowest quartile of index admissions ($N=1,073$, median 127 admissions) was 16.12, compared to 16.34 for those in the highest decile ($N=482$, median 5,782 admissions). A total of 39.0 % of hospitals in the lowest quartile of admissions had SRR>1, compared to 50.6 % of hospitals in the highest decile. Within specialty cohorts, this association held for cardiorespiratory, neurology and medicine patients. However, the surgery/gynecology cohort showed no association and the cardiovascular cohort an inverse relationship. The largest difference between volume strata in specialty cohorts was in the cardiorespiratory cohort (mean SRR 0.99 for hospitals in the lowest half [$N=1,185$] vs 1.02 for top decile [$N=200$]). In the cardiorespiratory cohort, 39.5 % of hospitals in lowest half of admissions had SRR>1, compared to 57.1 % of hospitals in highest decile of annual volume. By contrast, in the cardiovascular cohort, the mean SRR for hospitals in the lowest half of admissions but with at least 25 cases ($N=943$) was 1.00 compared to 0.98 for those in top decile ($N=456$). In this cohort, 51.5 % of hospitals in bottom half of volume had SRR>1 compared to 43.4 % of those in top decile.
CONCLUSIONS: In contrast to findings for other outcomes, higher hospital volume is associated with slightly worse overall risk-adjusted readmission rates. This relationship is modest and not consistent across all specialty cohorts. The care processes that lead to high quality transitional care may be more difficult to achieve in high volume institutions.

ASSOCIATION OF POSTTRAUMATIC STRESS DISORDER AND INCIDENT CEREBROVASCULAR DISEASE IN A VETERANS ADMINISTRATION POPULATION Beth Cohen[1,2]; Thomas Neylan[1,2]; Daniel Bertenthal[1]; Kristine Yaffe[1,2]. [1]San Francisco VA Medical Center, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA. (Tracking ID #1633684)

BACKGROUND: Several studies have demonstrated that patients with posttraumatic stress disorder (PTSD) are more likely to develop and die from ischemic cardiovascular disease. Animal models suggest PTSD may have a similar effect on cerebral arteries, leading to increased risk of stroke, but this has not been well-studied in humans. Understanding the association of PTSD and cerebrovascular disease, a costly, debilitating disorder, is particularly important for healthcare systems such as the Department of Veterans Affairs (VA) that care for a large population of aging patients with PTSD. Therefore, we evaluated the association of PTSD and incident cerebrovascular disease in a large, national VA sample.
METHODS: We used national Veterans Affairs electronic medical records to examine the association of PTSD and incident cerebrovascular disease diagnoses, restricting our analyses to patients aged 45 and over. We used data from 10/1/1996–9/30/2000 to identify 185,911 patients with a diagnosis of PTSD and 371,231 patients without a diagnosis of PTSD who were free of cerebrovascular disease diagnoses during this baseline period. We then used Cox proportional hazards models to evaluate the association of PTSD and incident cerebrovascular disease diagnoses during a follow-up period from 10/1/2000–3/31/2011. We used a previously validated ICD-9 coding algorithm to identify cerebrovascular disease from inpatient and outpatient records. We found a significant interaction with gender, and therefore examined men and women separately. We constructed hierarchical regression models serially adjusting for age, traditional cardiovascular risk factors (hypertension, tobacco use, diabetes, dyslipidemia, and obesity), and depression.
RESULTS: The mean age of the overall study population was 61 years (62 for men and 59 for women). 43,393 (7.8 %) patients received a cerebrovascular disease diagnosis during follow-up. In unadjusted analyses, cerebrovascular disease was significantly more common among patients with PTSD (for men: 9.5 % in those with PTSD versus 7.4 % in those without PTSD, $p<.001$; for women: 7.2 % in those with PTSD versus 2.2 % in those without PTSD, $p<.001$). The association of PTSD and incident cerebrovascular disease remained significant after adjusting for traditional cardiovascular disease risk factors and depression (see Table). The magnitude of all associations was stronger in women than in men.
CONCLUSIONS: PTSD is prospectively associated with increased incident cerebrovascular disease diagnoses in VA patients, particularly in women, independent of traditional cardiovascular risk factors and depression. Future epidemiologic and neuroimaging studies should further explore this association as well as the gender differences. Though additional research is needed, our results highlight the potential adverse physical health consequences of PTSD.

Association of PTSD with incident cerebrovascular disease diagnoses

	Men HR (95 % CI)	Women HR (95 % CI)
Adjusted for age	1.32 (1.30–1.35)	3.10 (2.74–3.50)
+Traditional cardiac risk factors	1.31 (1.29–1.34)	1.96 (1.72–2.24)
+ Depression	1.30 (1.25–1.33)	2.04 (1.59–2.64)

ASSOCIATIONS BETWEEN PROCESSES OF CARE AND MORTALITY IN A NATIONAL COHORT OF ELDERLY PATIENTS HOSPITALIZED FOR PNEUMONIA Jonathan S. Lee[1]; Wato Nsa[2]; Leslie R. Hausmann[1,3]; Amal N. Trivedi[4]; Dale W. Bratzler[5]; Dana Auden[2]; Kate Goodrich[6]; Fiona M. Larbi[6]; Michael J. Fine[1,3]. [1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Oklahoma City, OK; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA; [4]Alpert Medical School of Brown University, Providence, RI; [5]Oklahoma University Health Sciences Center, Oklahoma City, OK; 6Centers for Medicare and Medicaid Services, Baltimore, MD. (Tracking ID #1638617)

BACKGROUND: While often used as proxies for healthcare quality, it is not clear whether processes of care are associated with improved survival for patients with community-acquired pneumonia (CAP). Our aim was to assess independent associations between publicly reported processes of care and short-term mortality for elderly patients hospitalized for CAP.
METHODS: We studied elderly patients (age ≥ 65) hospitalized for CAP in U.S hospitals participating in the CMS Inpatient Quality Reporting program from 2006 to 2010, who met eligibility criteria for the CMS inpatient pneumonia process measures. We linked patient-level performance rates for these 7 publicly reported process measures (i.e., timely and appropriate antibiotics, blood cultures in the ED and for ICU patients, smoking cessation counseling, and pneumococcal and influenza vaccination) to 30-day all-cause mortality using Medicare administrative data. We used multivariable logistic regression to assess independent associations between all individual and an all-or-none composite measure of processes of care and mortality for each study year, controlling for baseline patient and hospital characteristics.
RESULTS: From 2006 to 2010, 1,818,979 elderly patients with CAP were admitted to 4,740 unique hospitals (range 326,956 to 399,243 patients per year). Overall mortality was 10.4 %, ranging from 9.2 to 11.4 % per year. Absolute mortality was significantly lower for each study year for patients who received (versus did not receive) appropriate antibiotics (difference −3.7 to −5.9 % per year), blood cultures in the ED (difference −0.7 to −1.2 % per year), smoking cessation counseling (difference −2.3 to −3.2 % per year), pneumococcal vaccination (difference −0.9 to −1.6 % per year), and influenza vaccination (difference −1.4 to −2.0 % per year) [$p<0.05$ for each measure, each year]. As shown in the Table, adjusted odds ratios demonstrated similarly significant reductions in mortality each year for these processes of care with the exception of blood cultures in the ED, which was only associated with reduced mortality in 4 study years. While absolute unadjusted mortality was 1 to 3.1 % higher for patients who received all processes for which they were eligible, adjusted odds ratios demonstrated decreased mortality for this all-or-none composite measure.
CONCLUSIONS: Appropriate antibiotic therapy and 3 preventive measures (smoking cessation counseling, and pneumococcal and influenza vaccination) were consistently associated with improved short-term survival in this large national cohort of elderly patients hospitalized for pneumonia. While these findings support the ongoing use of these process measures in public reporting and pay-for-performance programs, they also suggest removal of measures such as timely antibiotic initiation that are not consistently associated with improved patient survival.

Table. Multivariable associations between processes of care and mortality

Process measure	Study Year 2006 AOR (95 % CI)	2007 AOR (95 % CI)	2008 AOR (95 % CI)	2009 AOR (95 % CI)	2010 AOR (95 % CI)

ASSOCIATIONS OF MATERIAL HARDSHIP WITH GESTATIONAL WEIGHT GAIN AND POST-PARTUM WEIGHT RETENTION Audrey M. Provenzano[1]; Sheryl M. Rifas-Shiman[2]; Sharon J. Herring[3]; Janet Rich-Edwards[4]; Matthew W. Gillman[2]; Emily Oken[2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; [3]Temple University School of Medicine, Philadelphia, PA; [4]Harvard School of Public Health, Boston, MA. (Tracking ID #1627766)

BACKGROUND: Inadequate gestational weight gain (GWG) is associated with lower fetal weight gain, whereas excessive GWG is associated with macrosomia, birth complications, and post-partum weight retention (PPWR). Only 30–40 % of pregnant women gain within Institute of Medicine (IOM) guidelines. Women entering pregnancy with elevated BMI are more likely to have inadequate or excessive GWG and PPWR. Although researchers have identified some social factors related to these indicators of weight status, the influence of recent and especially remote material hardship is not clear.
METHODS: We studied 1714 women enrolled in the Project Viva birth cohort who received prenatal care between 1999 and 2002 at a multispecialty practice in eastern Massachusetts. Main outcome measures were GWG (inadequate, adequate, or excessive) and substantial PPWR (≥ 5 kg difference between self-reported weight at 1 year post-partum and pre-pregnancy weight). The main exposure was maternal report in early pregnancy of having experienced material hardship, i.e., receiving public assistance, welfare, or lack of basic necessities such as food, rent, or medical care in 3 time periods: childhood: before age 18; adulthood: between age 18 and the current pregnancy; or during pregnancy. We used multivariable logistic models, adjusted for age, race/ethnicity, and parity, to examine the extent to which hardship exposure during each of the 3 time periods was associated with pre-pregnancy BMI, GWG, and SPPWR.
RESULTS: Among 1714 women, mean age was 32.4 years (SD 4.7). Mean pre-pregnancy BMI was 24.6 kg/m2 (SD 5.2), and 13.9 % of women were obese (BMI≥30 kg/m2). 72.6 % were white, 11.3 % Black, 6.1 % Hispanic, 5.9 % Asian, 3.5 % other race/ethnicity; 51.6 % were parous. 139 (8.1 %) reported material hardship in childhood, 61 (3.6 %) in adulthood, and 22 (1.3 %) in pregnancy. Rates of excessive (49.8 %) and inadequate (14.5 %) GWG and of SPPWR (15.7 %) were similar to other studies. Pre-pregnancy obesity was more common among women who experienced hardship in adulthood (odds ratio [OR] 2.54, 95 % confidence interval [CI]: 1.33, 4.83), but not during childhood (OR 1.33, 95 % CI: 0.81, 2.18). Women with childhood hardship were more likely to have excessive (vs. adequate) GWG (OR 1.70, CI: 1.12, 2.60) and SPPWR (OR 1.58, CI: 0.93, 2.67) but not inadequate GWG. In contrast, women with hardship exposure in adulthood were more likely to have inadequate GWG (OR 2.04, CI: 1.05, 3.97) but not excessive GWG (OR 0.78, CI: 0.42, 1.46) or SPPWR (OR 1.69, CI: 0.74, 3.90). Results were similar for hardship exposure during pregnancy for inadequate GWG (OR 3.15, CI: 0.99, 9.98), excessive GWG (OR 1.34: 0.44, 4.1), and SPPWR (OR 1.23, CI: 0.34, 4.43). Examination of hardship exposure limited to one period of life yielded similar results.
CONCLUSIONS: The timing of hardship exposure may differently influence weight status before, during, and after pregnancy. Material hardship in adulthood predicted obesity and inadequate GWG, whereas childhood hardship exposure, even if limited to early life, may increase risk for excessive GWG and SPPWR.

ASTHMA BELIEFS AND SELF-MANAGEMENT BEHAVIORS AMONG OLDER ASTHMATICS Alex Federman[1]; Michael S. Wolf[2]; Anastasia Sofianou[1]; Melissa Martynenko[1]; Ethan Halm[3]; Howard Leventhal[4]; Juan P. Wisnivesky[1]. [1]Mount Sinai School of Medicine, New York, NY; [2]Northwestern University, Chicago, IL; [3]UT Southwestern Medical Center, Dallas, TX; [4]Rutgers, The State University of New Jersey, New Brunswick, NJ. (Tracking ID #1636505)

BACKGROUND: Older adults with asthma experience high rates of poor asthma outcomes and the reasons they fare poorly remain vague. Misconceptions about asthma are common among older adults and associated with low adherence to controller medications. In this analysis, we examined the association of asthma health beliefs with other key asthma self-management behaviors (SMB) such as self-monitoring, inhaler technique (metered dose inhaler [MDI], and trigger avoidance in a cohort of older asthmatics.
METHODS: Asthmatics ages ≥60 years were recruited from hospital and community practices in New York, NY and Chicago, IL (n=420). Validated instruments derived from the Common Sense Model of Self Regulation were used to assess asthma beliefs. We examined three beliefs that are commonly held by older adults and have been associated with poor asthma outcomes: no symptoms means no asthma (asthma is an episodic disease); physician (MD) can cure my asthma (unrealistic curability expectations); and will not always have asthma (illness is transitory). Multiple SMB were assessed in three categories: self-monitoring (has an action plan, peak flow meter [PFM] use, has a regular doctor for asthma care), inhaler technique (metered dose inhaler [MDI] and dry powder inhaler [DPI]), trigger avoidance (use of allergy covers, sheets washed in hot water, others clean the home, windows kept closed in spring and summer months, smoking not allowed in the home, avoid animals with fur, and does not live with pets). The association of beliefs with SMB was tested with univariate statistics with 2-tailed p-values.
RESULTS: Self-management was generally poor: 63 % had poor MDI technique, 73 % had poor DPI technique; 77 % had no self-monitoring plan, and 39 % had no regular physician for asthma care. Trigger avoidance varied: 91 % did not allow smoking in the home, and 72 % did not live with pets; however only 43 % avoided animals with fur and 36 % used allergy covers on their beds. Patients with the no symptoms no asthma belief (n=234, 53 %) and those who believe they will not always have asthma (n=128, 29 %) were less likely to correctly use a DPI (47 % vs. 67 %, p=0.04, and 43 % vs. 58 %, p=0.04, respectively). For those with the MD can cure asthma belief (n=89, 20 %), there were no significant differences in DPI performance (p>0.05), and there were no significant differences for MDI use by any belief category. Patients with the no symptoms no asthma and the MD can cure asthma beliefs were less likely to have a regular physician for asthma care (54 % vs. 71 %, p=0.0004, and 52 % vs. 64 %, p=0.03, respectively). In contrast, patients with the no symptoms no asthma and MD can cure asthma beliefs were significantly more likely to live without pets (p<0.05). There were no significant associations between the remaining asthma trigger avoidance behaviors and asthma beliefs.
CONCLUSIONS: Common misconceptions about asthma among older asthmatics were associated with reduced likelihood of having a regular asthma care provider and with poor DPI technique, but were otherwise inconsistently associated with other asthma self-management behaviors. Regular asthma care and DPI technique, in addition to asthma controller medication adherence, may be appropriate teaching points in educational interventions aimed at addressing asthma misconceptions.

ASTHMA SEVERITY AND CONTROL AND COGNITIVE IMPAIRMENT IN A COHORT OF ELDERLY PATIENTS Maile Ray[1]; Juan Wisnivesky[1]; Anastasia Sofianou[1]; Melissa Martynenko[1]; Michael S. Wolf[2]; Alex Federman[1]. [1]Mount Sinai School of Medicine, New York, NY; [2]Feinberg School of Medicine, Northwestern University, Chicago, IL. (Tracking ID #1640842)

BACKGROUND: The prevalence of cognitive impairment increases with age and may impact self-management of patients with chronic disease such as asthma. We assessed the association of asthma severity with three measures of cognitive function in a cohort of older asthmatics.
METHODS: Asthmatics ages 60 and older were recruited from inner-city primary care practices in New York City and Chicago. Patients with a documented or self-reported history of dementia, other chronic respiratory illnesses, or ≧ 10 pack-years were excluded from the study. We measured asthma control using percent predicted FEV1 and the Asthma Control Questionnaire (ACQ), a five-item questionnaire, modified from the original seven-item version, that assesses specific control symptoms, timing of symptoms, and activity limitation using a seven-point scale for each item. Cognitive function was assessed with three measures: (1) the Mini-Mental State Examination (MMSE; general cognitive function), (2) the Wechsler Memory Scale IV Delayed Recall Story A (delayed memory), and (3) the Trail Making Test A (executive function). Logistic and linear regression analyses were performed to test the association of asthma control with general cognitive function (MMSE ≦ 27), delayed recall, and executive function, respectively, adjusting for education, English-speaking ability, race, age, and sex.

RESULTS: The sample consisted of 441 patients, 84 % of whom were female; mean age was 68 years. Fifty-nine percent of patients had impaired cognition based on the MMSE. In adjusted analyses, worse asthma control (higher ACQ score) was associated with worse Trail A scores (β=0.0455, p=0.009) and higher odds of an abnormal MMSE score (OR=1.44, 95 % CI=1.14, 1.81, p=0.0004). There was no significant association with delayed recall (β=−0.26, p=0.11). Percent FEV1 was significantly associated with all three measures of cognitive function in univariate analysis, but were no longer significant after confounder adjustment: MMSE, OR=0.99, 95 % CI=0.98, 1.01, p=0.35; delayed recall, β=0.01, p=0.29; (ln) Trail A, β=−0.001, p=0.33.
CONCLUSIONS: Poorer asthma control is associated with worse general cognitive function and executive functioning in older adults with asthma. Clinicians of older patients with asthma should consider screening for cognitive impairments, especially among those with poorer asthma control.

AT EASE AND DIS-EASE: PATIENT REQUESTS FOR REASSURANCE
Carter Neugarten1; Somnath Saha[3,4]; Deborah Roter[2,1]; Philip T. Korthuis[4]; Jonathan A. Cohn[6]; Victoria L. Sharp[5]; Richard D. Moore[1]; Mary Catherine Beach[1,2]. [1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Portland VA Medical Center, Portland, OR; [4]Oregon Health & Science University, Portland, OR; [5]St. Lukes Roosevelt, New York, NY; [6]Wayne State University, Detroit, MI. (Tracking ID #1640977)

BACKGROUND: Reassurance is an important mechanism by which physicians can reduce anxiety among patients, but little is known about the circumstances under which patients explicitly request reassurance. Our study examined how and when patients make requests for reassurance from their physicians in routine outpatient encounters.
METHODS: We analyzed audio-recorded and transcribed encounters between 45 providers and 418 HIV-infected adult patients. We used the Roter Interaction Analysis System (RIAS) to identify all explicit patient requests for reassurance, defined as "questions of concern that convey the need or desire to be reassured or encouraged [considering] voice tone, intonation and emotional content." We qualitatively analyzed these requests within the visit context, and then used logistic regression models with generalized estimating equations to account for clustering of patients within providers while adjusting for study site to compare characteristics of patients who made vs. did not make a request for reassurance.
RESULTS: In 418 encounters, there were 53 encounters with at least one request and 72 total patient requests for reassurance. There were no differences between patients who did versus did not ask for reassurance in age, gender, race/ethnicity, education, health literacy or social support. However, patients who asked for reassurance reported more depressive symptoms than those who did not (OR 2.3 95 % CI 1.1–4.9 for middle vs. low and OR 2.2 95 % CI 1.1–4.6 for high vs. low depressive symptom tertile), and visits with a patient request for reassurance were longer than those without such a request (21.8 without vs. 28.6 min with a patient request, p<0.001). Our qualitative analysis generated eight categories describing the topic of patient requests: overall health, symptom/illness, physical exam, therapy, testing logistics, interpreting personal data, general information, and administrative. The most common type of request (n=19) was about the interpretation of one's own personal data such as vital signs and test results (e.g. P"I gained 5 lb"/D "Is that right?"/P "So that's…that's a good thing, right?"), followed by requests regarding therapy (n=12, "Is this a permanent thing though for me, forever? I mean if I'm taking the Fuzeon, is it gonna be forever?") and symptoms or illness (n=10, "Do you all think I might have cancer of my stomach?"). While there were only four requests regarding overall health, these carried a great deal of emotional weight (e.g. "Am I gonna ever have the days again where I just feel good?" and "I just want to know when I can…will I be all right?").
CONCLUSIONS: Our study demonstrates that while patients may wish for reassurance for a variety of reasons, they do not often request reassurance directly, even in the context of a chronic, life-threatening illness. Future studies could examine the value of physicians' providing reassurance when appropriate, even if not requested, particularly among patients with depressive symptoms.

ATHEROSCLEROTIC RENAL ARTERY STENOSIS (ARAS): WHO SHOULD BE SCREENED AND BY WHOM?
Ralph DeBiasi[1]; Srinath Adusumalli[1]; Robert Schainfeld[2]; Michael R. Jaff[2]. [1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA. (Tracking ID #1635349)

BACKGROUND: The prevalence of hypertension (HTN) due to atherosclerotic renal artery stenosis (ARAS) is unknown and screening for ARAS remains challenging. Clinical clues suggestive of ARAS among patients with uncontrolled HTN are often used as indicators for diagnostic testing and possible subsequent revascularization. The incidence of ARAS is higher in patients with peripheral (PAD) or coronary artery disease (CAD) but little is known about the predictive value of other clues suggesting ARAS. It is believed that subspecialists are more accurate in predicting ARAS than generalists; however, this has never been studied. We assessed the predictive power of accepted clinical clues to diagnose ARAS using renal artery duplex ultrasonography (RADUS). We also determined whether generalists or subspecialists had a higher diagnostic yield when screening for ARAS.
METHODS: We retrospectively identified 207 patients referred to a quaternary medical center's (Massachusetts General Hospital) accredited vascular diagnostic laboratory from 2011 to 2012 for RADUS testing for ARAS. We excluded patients with known ARAS, renal artery fibromuscular dysplasia, or prior renal revascularization. Thirty-two patients had ARAS while 175 patients did not. Using an internal informatics tool we reviewed records to determine age, gender, smoking status, blood pressure, serum creatinine, multivessel CAD, PAD, abdominal aortic aneurysm (AAA), diabetes mellitus, hyperlipidemia, and history of myocardial infarction or cerebrovascular accident. Additionally, we identified the specialty of the ordering provider. We performed statistical comparisons with the SAS platform (SAS Institute, Cary, NC) utilizing Chi-square, Fisher's exact and Wilcoxon signed-rank tests. A multivariate stepwise logistic regression model identified characteristics predictive of ARAS.
RESULTS: The only two predictors of ARAS were multivessel CAD (OR 2.8, p=0.01, 95 % CI 1.3–6.2) and female gender (OR 2.5, p=0.02, 95 % CI 1.1–5.6). Traditional clinical clues for ARAS screening including severe HTN (>160/90 mmHg), use of three or more anti-hypertensive medications (one being a diuretic), AAA, and PAD were not associated with ARAS. As compared to internists, subspecialists (including vascular specialists, cardiologists, and nephrologists) did not identify a greater percentage of patients with ARAS. Cardiologists were much more likely than internists or other subspecialists to screen patients with known multivessel CAD (p=.000003) but not those who were female (p=0.19).
CONCLUSIONS: Only multivessel CAD and female gender were predictive of ARAS in our cohort. Generalists demonstrated similar predictive accuracy as subspecialists when screening for ARAS even though cardiologists screened a much higher proportion of patients with multivessel CAD. These results suggest that more clinically useful clues to detect ARAS are needed.

ATTENDING USE OF THE ELECTRONIC HEALTH RECORD AND IMPLICATIONS FOR HOUSESTAFF SUPERVISION: PRELIMINARY RESULTS FROM A MIXED METHODS STUDY
Shannon K. Martin[1]; Kiara Tulla[2]; David Meltzer[1,2]; Vineet Arora[1,2]; Jeanne M. Farnan[1,2]. [1]University of Chicago, Chicago, IL; [2]University of Chicago, Chicago, IL. (Tracking ID #1638575)

BACKGROUND: With current health information technology, the electronic health record (EHR) is accessible to review clinical information from remote locations. Though patterns of remote EHR access by residents have been described, little information exists regarding usage by attending physicians. We hypothesized that the EHR may be a novel tool already in use for housestaff oversight. We aimed to assess how attending physicians are using the EHR remotely, and how they may use it to provide supervision to trainees.
METHODS: Attendings on the general medicine teaching service for 2–4 weeks at a single institution from January to November 2012 were

contacted for participation. Participants were consented and privately interviewed and surveyed regarding use of EHR. Descriptive statistics were obtained for preliminary analysis. Interview transcripts were reviewed in anticipation of qualitative analysis to follow.

RESULTS: Response rate was 83 % (59/71). 97 % of attendings used EHR from home. Over 70 % of attendings spent at least 60–90 min daily using EHR in total, and at least 30–60 min using it remotely. EHR was most commonly accessed remotely for signing notes (88 %), monitoring vital signs and test results (83 %), reviewing consultant notes (76 %), and reviewing past history (59 %). With respect to clinical oversight involving EHR, 93 % used EHR to confirm clinical information received by housestaff, and 54 % reported this frequently (i.e., at least 3 times per week). 89 % had discovered information upon personal review of EHR that housestaff had not relayed adequately, with 33 % noting this frequently. With respect to actions taken due to EHR oversight, 93 % reported changes in management as a result of these discoveries, with 20 % noting this frequently. Nearly all attendings reported management changes the following day due to viewing EHR from home (52 % frequently), and 54 % had management changes at the time of reviewing EHR from home via immediate communication to housestaff (13 % frequently). Preliminary qualitative analysis revealed several major themes regarding attending use of the EHR for housestaff supervision that were closely aligned with ACGME competencies and milestones. These themes included patient care (EHR use as a safety net check, verification of information received by trainees, use when there is need for urgent intervention), medical knowledge (trainee utilization of appropriate tests, prioritization of problems in assessment and plans), intrapersonal communication (documentation timeliness and accuracy) and professionalism (transparency, respect for resident autonomy, trust in team and assessment of skill level).

CONCLUSIONS: Attendings commonly access the EHR remotely, and report a high frequency of electronic oversight supervision activities, including confirmation of clinical data. Discovery of information not adequately relayed by housestaff often occurs, as do attending-driven changes in management as a result of these discoveries. It will be important to understand implications of this practice for housestaff autonomy and attending provision of supervision, and future qualitative work will more closely examine motivating factors behind attending EHR use. Furthermore, this attending practice of "electronic observation" may be an untapped resource for more useful and meaningful milestones-based evaluation of trainee patient care skills (PC-C1, C2, C3), medical knowledge (MK-B1, B2), intrapersonal communication (ICS-F1, F2) and professionalism (P-A1, F3).

ATTENDING AND INTERN EVALUATIONS OF RESIDENTS Cynthia Kay[1]; Michael Frank[1]; Jeffrey L. Jackson[1,2]. [1]Medical College of Wisconsin, Milwaukee, WI; [2]Zablocki VAMC, Milwaukee, WI. (Tracking ID #1625536)

BACKGROUND: Residents are evaluated in medicine residencies by attendings using questions developed by the ACGME. Many programs also evaluate residents using ratings by interns. We sought to answer several questions: 1) the factor structure of attending and intern evaluations, 2) the correlation between evaluations and ABIM certifying exam scores, 3) whether interns and attendings agreed on resident evaluations and value the same characteristics.

METHODS: We included internal medicine residents at the Medical College of Wisconsin between 2004 and 2012. Attending evaluations assessed residents on 6 ACGME domains (patient care, medical knowledge, interpersonal communication, professionalism, practice-based learning and improvement, systems based practice). Intern evaluations rated residents using 12 questions, many modified from ACGME attending questions. Both interns and attendings provided an "overall" rating of residents. In addition, we had ABIM certifying examination scores for most residents. Analyses included principal component factor and regression analysis, adjusted for clustering on resident.

RESULTS: There were 232 residents who had 6345 attending and 6817 intern evaluations. Both attending and intern evaluations were consistent (Cronbach's α=0.96 for both). The correlation between all questions were high for questions asked of attendings (r=0.69–0.86) and interns (r=0.56–0.86), but there was little correlation between intern and attending ratings (r=0.09–0.20), even when of the same construct (medical knowledge: r=0.11). Both intern and attending evaluations had a single factor solution. Aspects Interns valued included being supportive (β=0.22, 95 % CI: 0.14–0.31), explaining decisions (β=0.28, 95 % CI: 0.17–0.40), being organized (β=0.23, 95 % CI: 0.14–0.33), enthusiasm (β=0.23, 95 % CI: 0.14–0.33) and medical knowledge (β=0.18, 95 % CI: 0.17–0.29). Attendings valued all the ACGME domains, but resident knowledge (β=0.20, 95%CI: 0.17–0.22) and interviewing skills (β=0.23, 95 % CI: 0.19–0.25), were the two most important variables. Of all questions asked of interns and attendings, no intern questions and only one attending question (medical knowledge) was associated with performance on the ABIM examination (β=9.6, 95 % CI: 4.9–14.4), but attending ratings of resident medical knowledge only explained 2 % of the variance in ABIM scores.

CONCLUSIONS: Interns and attendings value different characteristics in residents and had low agreement, even on common questions such as resident medical knowledge. While the ACGME form evaluates residents on multiple domains, attending evaluations suggest they are only evaluating residents on a single construct. this suggests that attendings either don't understand or are not assessing residents on the multiple ACGME domains. Only medical knowledge ratings by attendings correlated with resident performance on the ABIM certifying examination, though it was a very poor predictor. This suggests that neither attending nor intern evaluations can help program directors predict residents at risk of failing their boards.

ATTITUDES AND BELIEFS TOWARDS EVIDENCE BASED MEDICINE IN HEALTH Marilyn M. Schapira[1]; Eric Oh[2]; Diana Imbert[1]; Elena Byhoff[1]. [1]University of Pennsylvania, Philadelphia, PA; [2]Swarthmore College, Swarthmore, PA. (Tracking ID #1639755)

BACKGROUND: Significant resources in the United States and other countries are being directed to comparative effectiveness research. Medical care decisions arising from evidence based medicine involve input from policy makers, clinicians, and patients. The degree to which the methods and results of scientific studies in health are of interest to patients is not known. The objectives of this study are to describe patient attitudes and beliefs towards evidence based medicine in health.

METHODS: A focus group study was conducted. Participants were recruited from a primary care population in the urban community of West Philadelphia. Purposeful sampling was used to recruit a population that was diverse in race and education. A focus group guide was developed to explore participant attitudes towards science and interest in and value placed on scientific evidence in health. Sessions were audio-recorded, transcribed verbatim, and entered into NVivo10 software for analysis. Transcripts were coded by two independent coders with agreement determined using the Kappa statistic and % agreement. A thematic analysis was undertaken and a theoretical framework developed to describe the relationships and insights gained in the study.

RESULTS: Four focus groups were conducted with a total of 31 participants. Study subjects were diverse in race (71 % African-American, 23 % White, and 3 % Asian), educational background (48 % with only a high school level education) and gender (61 % female). Age ranged from

30 to 68 years. Subjects described a wide range of attitudes towards science and knowledge about the scientific process. The perceived value of scientific studies in health varied according to the medical topic addressed by the study (screening, prevention, or treatment studies), personal relevance of the condition, the organization designing and funding the study, and source of information. Some participants expressed interest in details regarding methods and results of scientific studies while others wanted only general information. Four factors were found to inform attitudes towards scientific studies in health; 1) education and scientific literacy, 2) trust in the medical care system and medical research, 3) cultural and family values, and 4) medical conditions of self and significant others. A theoretical framework emerged in which attitudes regarding evidence based medicine were defined by the following factors; 1) perceived importance of knowledge regarding scientific studies in health, 2) interest in details regarding the methods and results of scientific studies, and 3) perceived value of information about scientific studies from trusted sources.

CONCLUSIONS: The study reports a wide range of attitudes and beliefs regarding scientific studies in health. Attitudes and beliefs were informed by individual factors including scientific literacy, education, culture and family values, and personal health experiences. A segment of the study population expressed a strong interest in detailed information regarding methods and findings of scientific studies in health. These findings have policy implications. Efforts are needed to effectively communicate comparative effectiveness research findings to patient populations who desire and value this information. Communication strategies may include identification of trusted sources and tailoring information to levels of scientific literacy.

AVOIDANCE AND RESILIENCE IN THE MEDICAL ENCOUNTER AMONG PERSONS WHO STUTTER Hector R. Perez[1]; Joanna L. Starrels[2]. [1]Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY. (Tracking ID #1638929)

BACKGROUND: Among persons who stutter, concealment behavior, including fear and avoidance of speaking, can hinder effective communication in various aspects of life. Effective communication between patients and their medical providers is essential to timely and accurate diagnoses, and optimal health outcomes. However, previous studies have not described the experiences of persons who stutter when communicating with their medical providers. We sought to understand how persons who stutter engage with their medical doctors by eliciting their experiences, beliefs, and attitudes about the medical encounter.

METHODS: For this exploratory study using focus groups and basic survey methods, we recruited a convenience sample of adults, 18 years or older, who attended a National Stuttering Association conference and self-identified as stutterers. All participants completed questionnaires about sociodemographic characteristics; self-reported health status; and perceptions of their stuttering along a ten-point Likert Scale, using the 13 item St. Louis Inventory of Life Perspectives and Stuttering (SLILPS), a tool used for measuring the effect of stuttering on one's life. Three focus groups of 4–7 participants were stratified by age to facilitate discussion that reflected shared medical experiences and overall effects of stuttering on health. Transcripts from the focus groups were coded and analyzed using a Grounded Theory approach.

RESULTS: Of the 16 participants, most were below 50 (n=11, 69 %) and employed (n=14, 88 %). Most rated their health status as excellent or very good (n=12, 75 %) and had one person they considered as their primary care doctor (n=12, 75 %). Most participants rated stuttering as a minor concern in their lives (mean score ≤4 on the SLILPS; n=12, 75 %). During focus groups, the majority of participants expressed that they did not have major difficulty communicating with their doctors. Grounded theory analysis revealed several themes, including the importance of continuity of care on strengthening the patient-doctor relationship, the challenges of discussing stuttering with medical doctors, and the impact of subtle avoidance behaviors on making appointments and discussing medical issues, especially amongst those with more severe SLILPS scores. A prominent theme among participants who reported little or no negative impact of their stuttering on their health was "resilience," which manifested as assertiveness in assuring they were properly heard by the medical provider. For example, one participant advised: "You should be strong enough to ask those pertinent questions…I think you have to speak up for yourself."

CONCLUSIONS: In this sample, communication difficulties shared by most participants were largely outside the medical office, but closer analysis revealed competing themes of avoidance and resilience during the medical encounter. Because this is the first study of stuttering in the medical encounter, a convenience sample was appropriate, but our sample of conference attendees who opted to participate might be more resilient than the general population of people who stutter. The true effects of avoidance and resilience during the medical encounter should be investigated further by testing these hypotheses in a more diverse population of persons who stutter.

BARRIERS AND FACILITATORS OF CONTRACEPTIVE COUNSELING BY GENERAL INTERNAL MEDICINE FACULTY AND INTERNAL MEDICINE RESIDENTS Rachael R. Dirksen[1]; Benjamin Shulman[3]; Stephanie B. Teal[4]; Amy G. Huebschmann[2]. [1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Univeristy of Colorado School of Medicine, Aurora, CO; [3]Colorado School of Public Health, Aurora, CO; [4]University of Colorado School of Medicine, Aurora, CO. (Tracking ID #1630844)

BACKGROUND: Almost half of US pregnancies are unplanned, resulting in many unintended births and over a million induced abortions each year. Contraceptive counseling (CC) is an effective tool to increase patients' use of contraception and thus decrease the rates of unplanned pregnancies and abortions. Internists are increasingly caring for reproductive age women and contraceptive counseling is a core competency of preventative care in this population, particularly when teratogenic medications are prescribed (e.g., HMG-coA reductase inhibitors and angiotensin-converting enzyme inhibitors). This study's objectives were: 1) evaluate the frequency of contraceptive counseling provided to reproductive age women during a prevention-focused visit by internal medicine faculty and resident providers, 2) identify factors affecting the frequency of CC.

METHODS: University of Colorado internal medicine residents and affiliated outpatient internist faculty working in seven separate metropolitan practice settings were invited to complete a 20 question online survey on demographics and CC-related factors. We asked providers to report the frequency of CC during an "annual physical" for women 15–45 years of age on a 4-point Likert scale with verbal anchors: "rarely ≤ 20 %", "sometimes 21–49 %", "often 50–79 %", "routinely ≥80 %". We also assessed possible facilitators of CC (e.g., high self-efficacy, women's health educational exposures, provider gender) and possible CC barriers (e.g., low frequency of sexual history, low perceived importance).

RESULTS: Our survey response rate was 61 % and responders were demographically similar to nonresponders. Although greater than 95 % of residents and faculty respondents agreed that CC is important, only 33 % of faculty and 19 % of residents reported that they provide CC routinely (≥80 % of the time) to reproductive age women during a prevention-focused visit. Providing CC routinely was strongly associated with taking a sexual history ≥ 50 % of the time (OR=11.6 (3.3 to 39.9)), high self-efficacy to provide CC (OR=6.5 (1.5 to 29.0)), and female provider gender (OR=4.3 (1.9 to 9.8)), all reported as unadjusted odds ratio (95 % CI). Over 80 % of residents and over 60 % of faculty reported they would provide CC more often if they had more knowledge of contraceptive methods. However, educational exposures such as women's health electives during residency were not significantly associated with perceived adequate knowledge regarding contraceptive methods.

CONCLUSIONS: Even considering a "best-case scenario" of prevention-focused visits with reproductive age women, a minority of faculty and resident providers reported routinely providing CC. Obtaining a sexual history and high provider self-efficacy were strongly associated with

providing CC and are likely predictors of provider CC behavior. We need to design and test interventions to increase contraceptive counseling among internists to reduce unplanned pregnancies. Such interventions should include elements to increase provider CC knowledge and self-efficacy, and should also target health care system intake processes and provider preferences to ensure that a sexual history is taken routinely.

BARRIERS AND FACILITATORS TO GOAL-SETTING IN OVERWEIGHT AND OBESE LATINA PRIMARY CARE PATIENTS: A QUALITATIVE STUDY Melanie Jay[1]; Damara N. Gutnick[1]; Lauren Gerchow[1]; Stella Savarimuthu[1]; Maria Barbara Tagliaferro[1]; Adina Kalet[1]; Allison Squires[2]. 1New York University School of Medicine, New York, NY; [2]New York University College of Nursing, New York, NY. (Tracking ID #1641270)

BACKGROUND: The obesity epidemic disproportionately affects Latina women. To address this disparity, primary care providers can employ goal-setting, a central component of the chronic care model and 5As counseling framework and a tool often used for health promotion in primary care. However, little is known about goal-setting for Latina patients around lifestyle changes, barriers to goal-setting, and the types of goals that are most likely to be achieved. The purpose of this qualitative study was to explore overweight and obese Latina patients' culturally specific barriers and facilitators to healthy eating and physical activity and their use and understanding of goal-setting to promote lifestyle behavior change.
METHODS: We recruited women from the Caribbean, Central America, and Mexico in the waiting room of an inner city, New York City public primary care clinic. Women were invited to participate in focus groups scheduled according to their region of origin and conducted in their preferred language. Semi-structured interviews were digitally recorded, transcribed verbatim, and translated into English. To minimize potential bias, the translation was first validated by a single native speaker. Axial coding was then completed by 2 independent investigators in English and by an independent native speaker in Spanish. The research team met regularly during an eight-week period to conduct member checks on the coding process, harmonize language use and correct translation errors, and identify themes. ATLAS t.i. was used to facilitate coding and thematic analysis.
RESULTS: Three Spanish-language groups (1 Caribbean, 1 Mexican/Central American, and 1 heterogeneous) and 1 English-language Caribbean group were conducted. Focus groups had an average of 6 participants (25 total). The mean age was 59 (SD=14); mean BMI was 30 (SD=4.6). The term "goal" resonated with participants who described several short-term and long-term lifestyle and aspirational goals. We identified 4 themes to describe unique barriers and facilitators to achieving lifestyle goals: Migration Experience, Family Dynamics, Social Support, and Interactions with Healthcare Providers. Limited education and English proficiency were common barriers to attaining goals. Time spent in the US also affected responses. While participants acknowledged that traditional foods were often unhealthy, they perceived that the food in the United States had chemicals and caused more weight gain than food from their country of origin. Healthier, "organic," food in the US was prohibitively expensive. Latina women also described multiple familial responsibilities and found it difficult to balance personal goals and family needs. They sought out and relied on support from friends, family, and the healthcare system to maintain motivation. They also valued and desired more advice from healthcare providers, but wanted more group-based, obesity-related activities.
CONCLUSIONS: This study supports the use of goal setting to facilitate treatment and prevention of obesity in Latina women while providing insights for healthcare providers utilizing goal setting in this population. Latina women use goal-setting in their daily lives but encounter unique barriers and facilitators to achieving lifestyle goals. The generalizability of the findings should be tested against other Latin American countries, SES groups, and primary care clinics in different geographic locations.

BARRIERS TO HIV SCREENING IN A COMMUNITY HEALTH CENTER David Feldstein[1]; James M. Sosman[1]; Marge Sutinen[1]; Mandy Kastner[3]; Pamela Wilson[2]. [1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]Sixteenth Street Community Health Center, Milwaukee, WI; [3]AIDS Resource Center of Wisconsin, Milwaukee, WI. (Tracking ID #1635067)

BACKGROUND: Patients not aware of their HIV positive status are more likely to transmit HIV and develop HIV related morbidities. Early detection is important to prevent transmission and morbidity. In 2006 the CDC recommended routine HIV screening in all patients ages 13–64 regardless of risk. However, routine screening has not been readily adopted and there is little data published about actual screening rates. Our goal was to determine HIV screening rates and barriers to screening in an urban, Midwestern Community Health Center.
METHODS: The Systems Engineering Initiative for Patient Safety (SEIPS) model was used as a framework for exploring barriers. The SEIPS model is comprised of five components that make up the clinic worksystem: technology and tools; environment; people; organization; tasks. These components lead to processes of care and ultimately outcomes. We used a mixed methods approach with quantitative surveys and semi-structured interviews. Current HIV screening rates were determined from electronic health record (EHR) data. Unique non-pregnant patients age 13–64 with visits during 2010 were included. Patients were considered screened if they had an HIV test recorded during 2010. Providers completed questionnaires of attitudes toward HIV testing, knowledge of CDC recommendations and barriers to HIV screening. Attitude questions used a 7 point Likert scale (1 = strongly disagree, 7 = strongly agree). Semi-structured interviews of providers and medical assistants (MAs) were completed by one of the authors. The interviews were recorded and themes were developed by a single author using content analysis.
RESULTS: 12,615 unique non-pregnant patients age 13–64 visited the clinic. 2488 (20 %) of the patients received an HIV test with 22 % of women and 16 % of men tested. Screening rates varied by age. Questionnaires were completed by 34 providers. Providers felt that routine HIV testing is important (mean 6.4, 7 = strongly agree) and that offering testing to their patients would improve the health of their community (mean 6.3). 68 % of providers were aware of the CDC guidelines and 97 % knew that patients age 13–64 should be tested regardless of risk. Common described barriers were patient reluctance or refusal (65 %), other priorities at time of visit (56 %), lack of time (35 %) and lack of training on offering HIV screening (29 %). Five providers and 12 MAs were interviewed. Common provider themes included: screening at all annual visits; never having a patient test positive; not screening during acute visits; not consistently using the EHR's preventative health reminders. Common themes from the MA interviews included: varying roles of MAs across departments; inconsistent use of EHR health reminders; positive attitudes toward routine screening of patients; comfort with asking patients about HIV screening.
CONCLUSIONS: In a Community Health Center with excellent attitudes toward HIV screening and where providers felt they were screening regularly actual screening rates were still relatively low. This demonstrates the importance of a mixed methods approach and a framework for determining barriers to HIV screening across the multiple area of the clinic worksystem. The next step is developing interventions to affect the various aspects of the worksystem and measure changes in HIV screening rates. Interventions like audit and feedback may be particularly useful to demonstrate to providers actual screening rates. These methods should be generalizable to other Community Health Centers.

BEGINNING WITH THE END IN MIND: A QUALITATIVE ANALYSIS OF PERSONAL RETIREMENT SPEECHES WRITTEN BY MEDICAL INTERNS Eunice Yu; Scott Wright. Johs Hopkins Bayview Medical Center, Baltimore, MD. (Tracking ID #1633549)

BACKGROUND: Beginning with the end in mind is a time honored strategy for achieving success and it is the second principle covered in

Covey's acclaimed book The 7 Habits of Highly Effective People. Medical training is fast paced and there may not be ample time for planning and goal setting. To facilitate reflection on their futures, we invited new interns to write and share comments that they hope might be used to introduce them at their retirement luncheon.

METHODS: Groups of 6–7 interns participated in a two-week curriculum during the first third of the internship year that focused on professional development. This optional exercise was introduced on day 1 of the rotation. The analogy of writing one's own eulogy was shared. On the final day of the rotation, an hour was set aside for interns to read what they had composed to the group. Qualitative methods were used to analyze the data. The written introductions were independently coded by two investigators. Content analysis identified several themes related to aspirations of these new doctors who were looking ahead.

RESULTS: Eighteen of 20 interns in our internal medicine residency program participated in the exercise (one missed the rotation due to illness, one declined to participate). Thirteen (65 %) of these new doctors are women. The average year of the retirement celebrations was 40 years in the future and the individuals making introductory comments about the retirees varied widely - spouses, children, mentees, and both physician and nurse staff colleagues. Thematic domains related to: (i) virtuous personal qualities such as integrity, dedication, and compassion; (ii) academic successes including advancing science, clinical excellence, and accomplishments as teacher or mentor, (iii) making the world a better place and giving back through actions like advocating for vulnerable populations and improving systems of care; and (iv) valuing relationships and realizing work-life balance. Every single intern expressed a deep sense of appreciation for having had a fulfilling career in the profession of medicine. This representative quote nicely captures the sentiments expressed by many: "Dr. X remains a role model for each of us, an astute physician, a meticulous researcher, an outstanding teacher and a wise mentor. He was a keen observer, and has always had the vision to think ahead, constantly improving the medical system through simple yet innovative ways… The cancer screening model established by Dr. X …has led to a substantial decline in cancer related mortality in these countries over the last few decades. Despite his numerous engagements as a Professor of Oncology and Global Health…he was a great friend, an inexhaustible resource of information and a raconteur par excellence…I join his admiring students and colleagues in thanking him…" In debriefing, interns were glad to have participated in this exercise and were inspired by learning about the ambitions of their colleagues.

CONCLUSIONS: Encouraging new doctors to imagine what they hope to accomplish at the beginning of their careers can be a powerful experience. Such an exercise has several potential benefits: 1) clarity about goals, 2) reinforced commitment to these goals, and 3) opportunity for teachers to make connections with other mentors who may be able facilitate the initial steps on the long path toward realization of their dreams.

BEHAVIORS OF PREGNANT WOMEN WHO ACHIEVE AND EXCEED RECOMMENDED GESTATIONAL WEIGHT GAIN Cynthia H. Chuang[1,2]; Jennifer Kraschnewski[1,2]; Michael Stengel[1]; Sandra Hwang[3]; Diana Velott[2]; Kristen Kjerulff[2]. [1]Penn State College of Medicine, Hershey, PA; [2]Penn State College of Medicine, Hershey, PA; [3]Cornell University, Ithaca, NY. (Tracking ID #1643104)

BACKGROUND: Excessive gestational weight gain (GWG) results in increased risk for pregnancy-related complications, postpartum weight retention, and long-term obesity. The majority of U.S. pregnant women gain more than the Institute of Medicine recommended GWG guidelines (25–35 lb, 15–20 lb, and 11–20 lb for pre-pregnancy normal weight, overweight, and obese women, respectively). Little is known about the specific behavioral habits of pregnant women who achieve vs. exceed GWG recommendations. Our objective was to identify habits of overweight and obese women who achieve and exceed current GWG recommendations.

METHODS: In 2011, we conducted semi-structured interviews with 29 women following the birth of their first child. Participants were overweight or obese prior to pregnancy. Using principles of positive deviance—an inductive approach of identifying the effective practices of people who have succeeded at a task that many people fail—we describe the diet, physical activity, and self-monitoring habits of women who achieve and exceed GWG recommendations.

RESULTS: Of the 29 women interviewed, 14 women were overweight and 15 were obese before pregnancy. Eighteen (62 %) exceeded the GWG recommendations. Women achieving appropriate GWG reported deliberate planning to avoid gaining too much weight with only modest increases in caloric intake (if at all) and careful meal and snack planning ("I put more time and effort in my eating choices, it was definitely a conscious decision.") Women with excessive GWG described liberalized eating ("I had the mindset that I was eating for two, so I could eat double. I allowed myself to eat way more than I ever would had I not been pregnant, thinking I will show quicker, I can eat whatever I want.") Nearly all women with excessive GWG reported exercising less during pregnancy (or remaining sedentary), while women with appropriate GWG largely increased or maintained pre-pregnancy physical activity levels. About half of the sample reported self-monitoring weight gain during pregnancy, but women achieving recommended GWG tied their weight monitoring with GWG goals consistent with recommended guidelines.

CONCLUSIONS: Women who were overweight or obese prior to pregnancy and achieved appropriate GWG reported deliberately planned diet and physical activity habits, in addition to appropriate GWG goals during pregnancy. Women exceeding recommended GWG described "eating-for-two," were sedentary, and either had no goals for GWG or intended to gain more than recommended.

BLIND SPOT: ASSESSING AND CORRECTING VISION AMONG HOSPITALIZED PATIENTS-AN UNDER-RECOGNIZED RISK FACTOR FOR SENIORS Valerie G. Press[1]; Madeleine I. Shapiro[2]; Alisha S. Ranadive[2]; Kristin L. Constantine[1]; Ainoa M. Mayo[1]; Gavin W. Hougham[1]; Seenu M. Hariprasad[3]; David Meltzer[1]; Vineet Arora[1]. [1]University of Chicago Medical Center, Chicago, IL; [2]University of Chicago, Chicago, IL; [3]University of Chicago, Chicago, IL. (Tracking ID #1639455)

BACKGROUND: Hospitalized seniors are especially vulnerable to the many well-known hazards of hospitalizations, including delirium and falls; impaired vision increases the risk for these hazards. However, the prevalence of poor vision among hospitalized patients, particularly for older inpatients, has not been characterized. Therefore, our objective was to quantify the prevalence of poor vision among hospitalized patients and to test an innovative, low cost bedside approach to improve vision among hospitalized inpatients.

METHODS: General medicine inpatients were enrolled from an ongoing study of resource allocation and quality of care at two academic medical centers beginning in June 2011. Eligible patients were asked if they wear corrective lenses and were instructed to use them if available prior to vision screening (Snellen Eye Chart). Sufficient vision was defined 20/50 or better in at least one eye. Beginning June 2012, eligible participants at one institution with insufficient vision (i.e. did not have bilateral eye disease, not already wearing lenses) were fitted with readers titrated from +2 to +3.25 and retested to determine the proportion of participants whose vision could be corrected at bedside.

RESULTS: Vision screening was completed in 1139 participants, of whom 79 % were African-American and 56 % were female. The mean age was 56 years. One third of participants had insufficient vision (33 %, 372/1139). More than 1/3 of the cases of insufficient vision were due to participants not having their glasses in the hospital (38 %; 141/372); the rest were due to inadequate baseline corrective lenses (31 %, 114/372) or not having been prescribed corrective lenses (29 %, 106/372). As of June 2012, 118 participants were screened for eligibility for testing with readers (insufficient vision, not wearing corrective lenses, absence of bilateral eye disease). Compared to participants with sufficient vision, participants with insufficient vision were more likely to be 65 or older ($p=0.02$), to have cataracts ($p=0.01$), to have last seen an eye doctor two or more years ago

(p=0.01), and to feel they needed to see an eye doctor soon (p=0.02). Forty-five participants in this cohort had insufficient vision; of these 28 remained eligible and 26 participants consented. Overall, 75 % (21/28) of eligible participants' vision was corrected to 20/40 or better in at least one eye using a non-prescription readers. Using the lowest calibration readers (+2), 14 (54 %) participants corrected, and an additional 7 participants corrected using the next-highest calibration (+2.25). Nearly 1/3 of participants in this cohort were ≥65 (7/26); older participants were as likely as younger participants to correct their vision with readers.
CONCLUSIONS: Impaired vision appears to be an under-recognized risk factor for hospitalized patients, particularly older patients. Our results to date indicate, however, that an simple, in-hospital screen and low cost innovative intervention may be useful to improve hospital care. Further, by recognizing a missed opportunity to assess and potentially correct vision care needs, this approach may this approach may improve health and wellbeing of patients both in the hospital and after they return to their community.

BOSNIAN, IRAQI, AND SOMALI REFUGEE WOMEN SPEAK: A COMPARATIVE STUDY OF REFUGEE HEALTH BELIEFS ON PREVENTIVE HEALTH AND BREAST CANCER SCREENING Sanja Percac-Lima[1,3]; Barbara Bond[2]; Altaf Saadi[3]. [1]Massachussetts General Hospital, Chelsea, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA. (Tracking ID #1638329)

BACKGROUND: Despite evidence that reductions in breast and cervical cancer morbidity and mortality can be achieved through early detection and treatment, patients continue to present with advanced cancer without prior screening. This is particularly true for thousands of recent immigrants and refugees to the United States. The migration experience may have varied impacts on health practices and attitudes of refugees, while the impact of prior trauma and current resettlement makes these among the most vulnerable members in our society. To understand documented disparities in use of preventive cancer care, we studied refugee women receiving care in an urban community health center which delivers state funded health assessments for refugees. The objective of the study was to assess their perspectives on preventive care and perceived barriers to breast cancer screening.
METHODS: The three groups selected for study (Somali, Iraqi and Serbo-Croatian/Bosnian) belong to refugee communities whose emigration to the United States came as a result of extremely violent conditions of war in their countries of origin. Women included in the study were a convenience sample of 57 women, 30–74 years of age, self-identified as speaking Serbo-Croatian (Bosnian), Somali, or Arabic, receiving primary care at the health center. In-depth, semi-structured, one-on-one interviews were conducted by native language speakers. Interviews were transcribed, translated and coded according to best practices for content and thematic analysis in development of grounded theory. We compared the responses of the three refugee groups of women studied, as part of a larger study of their participation in health screening patient navigation programs.
RESULTS: Of 57 women included in the study 20 spoke Arabic, 17 Somali and 20 Serbo-Croatian. Interviews were conducted from 2010 to 2011. Similarities included (1) personal and psychosocial barriers to care such as fear of pain, fear of diagnosis, work or childcare commitments, and culturally mediated beliefs that define illness as symptomatic; (2) facilitative factors to care such as appreciation of community-based outreach efforts, appointment reminders and personal contact and education from health care providers; (3) comparisons of medical infrastructures between their home countries and the United States, the former which were deemed to have fewer resources; and (4) an overall positive attitude toward medicine and the healthcare profession. On the other hand, the refugee women had differing health beliefs and experiences pertaining to (1) medical exposure to doctors in their home countries and the centrality of war in their experience of health systems; (2) their understanding of preventive health; (3) the use of herbal and traditional medicines; and (4) knowledge of mammography. Notably, there was a trend toward heightened awareness of preventive health practices with increased time in the US.
CONCLUSIONS: Knowledge of both similarities and differences in health beliefs, health information and behavior are crucial to enable design and delivery of individualized, culturally appropriate health care services to these varied refugee populations.

BREAST CANCER PATIENTS' BELIEFS AND ADHERENCE TO HORMONAL THERAPY Jenny J. Lin; Jennifer Chuang; Liliana Serrano; Nina A. Bickell; Juan P. Wisnivesky. Mount Sinai, New York, NY. (Tracking ID #1642405)

BACKGROUND: In women with estrogen receptor-positive (ER+) breast cancer, hormonal therapy (HT) has been shown to reduce breast cancer recurrence and mortality rates. However, studies have demonstrated that early discontinuation and non-adherence to HT are common. Negative beliefs about medications and bothersome side effects may increase medication non-adherence, whereas positive patient-physician interactions may improve adherence. Using the framework of the Self-regulation Model, we conducted a survey of women with ER+ breast cancer who were recommended to take HT, to assess if medication beliefs were associated with patient reports about side effects and medication adherence.
METHODS: Women with ER+ breast cancer currently on HT were invited to participate in a survey after an outpatient visit with either their medical oncologist or breast surgeon. Questions assessed women's reasons for taking HT, side effects, and patient-physician communication. Medication adherence was assessed with the 4-item Morisky medication adherence scale; non-adherence was defined as a positive answer to >2 questions. Beliefs about HT were assessed using the Beliefs about Medicines Questionnaire (BMQ), which consists of two 5-item scales that assess patients' beliefs about the necessity of taking medication and their concerns about possible adverse effects of medication. Medication beliefs, adherence, side effects, and discussion about side effects with medical providers were compared using t tests or Fisher's exact test.
RESULTS: 33 women have completed the survey thus far. The mean age of respondents was 59 years (34–82 years) and the mean duration of taking HT were 23 months, respectively. Twenty-four women (73 %) reported having side effects from HT, although only two-thirds of these 24 women reported they had discussed side effects with their medical provider. Nineteen (58 %) were classified as non-adherent by self-report via the Morisky medication adherence scale. Women who had greater concerns about HT (higher scores on the BMQ-concerns scale) were more likely to report side effects (p=0.01). Presence of side effects and discussing side effects with medical providers did not differ by age, race/ethnicity, education level or reason for taking HT, but women who had been on HT longer were less likely to discuss side effects with their medical providers (p=0.03). However, medication non-adherence was not associated with report of side effects, discussion with medical providers or medication beliefs (p>0.05 for all comparisons).
CONCLUSIONS: Non-adherence with HT is prevalent but does not appear to be associated with presence of side effects, beliefs about medication or discussion of side effects with medical providers. Further research is needed to explore other reasons for HT non-adherence in breast cancer patients.

BREAST CANCER SCREENING BEFORE AND AFTER THE 2009 USPSTF GUIDELINE CHANGES James F. Wharam[1]; Fang Zhang[1]; Bruce E. Landon[2]; Claire Canning[1]; Steve Soumerai[1]; Dennis Ross-Degnan[1]. 1Harvard Medical School, Boston, MA; [2]Harvard Medical School, Boston, MA. (Tracking ID #1640358)

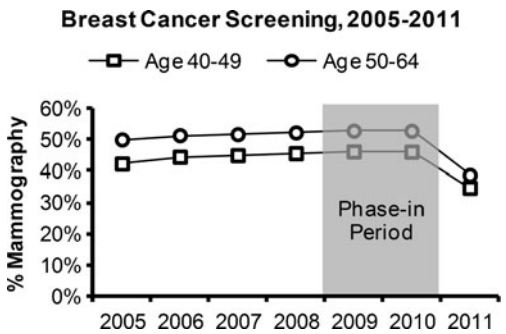
BACKGROUND: Major controversy surrounds the issue of appropriate breast cancer screening intervals for women over 40. Some authorities believe that overuse of mammography creates unacceptably high rates of false positive detection, anxiety, and morbidity. Prior to 2010, the United States Preventive Services Task Force (USPSTF) recommended screening

every 1–2 years for women 40 and older. New USPSTF guidelines published in December 2009 recommended no screening in women 40–49 and screening every 2 years among women 50–75. The impact of these recommendations in unknown

METHODS: We examined annual mammography rates from 2005 to 11 among women age 40–64. Our data source was administrative and claims data from a large US health plan with a total sample of 56 million members. We included women continuously enrolled for at least 11 months and our outcome was receipt of a yearly mammogram. For women whose enrollment spanned calendar years, we used their person time in a given calendar year to generate the denominator. We used a time-series display to examine annual breast cancer screening rates from 2005 to 11. We assigned 2005–9 as the baseline period and 2010–2011 as the policy change period. We used stepwise autoregressive forecasting to calculate the baseline trend and determine the expected rates in 2010–2011. We stratified results by age 40–49 and 50–64 and compared the 2011 predicted results to the observed values.

RESULTS: Subjects were from all 50 states and the mean annual denominator was 1.2 million women during 2005–11. In 2005, women from the West, Midwest, Northeast, and South represented 13.7, 28.9, 9.9, and 47.5 % of the sample, respectively; 78.2 % were white and 5.8 % were black. Women age 40–49 and 50–64 experienced upward trends in mammography rates from 2005 to 9 but a flattened trend and relative decline in 2010–2011 (Figure). Observed rates in 2011 for women age 40–49 and 50–64 were 48.5 % and 53.0 %, respectively, while projected rates were 51.6 % and 56.8 %. Women age 40–49 and 50–64 had 2011 screening rates 6.2 % and 6.8 % below expected, respectively.

CONCLUSIONS: Mammography rates climbed from 2005 to 2009 but flattened during 2010–2011 after publication of new UPSTF guidelines in late 2009. This resulted in 6–7 % relative reductions in breast cancer screening by 2011 among women age 40–49 and 50–64. Advocates of the USPSTF guidelines would consider the reductions in women age 40–49 appropriate or even too small, but longer-term studies should assess impacts on quality of life, mortality, and costs. Among women age 50–64, subsequent analyses should determine if the reductions we observed in 2010–2011 decrease recommended biennial screening rates.



BREASTCARE: A PRIMARY CARE CLINIC-BASED RCT TO INCREASE BREAST CANCER KNOWLEDGE AND DISCUSSION OF RISK AND LIFESTYLE BEHAVIORS Celia P. Kaplan1; Jennifer Livaudais-Toman[1]; Steven Gregorich[1]; Jeffrey A. Tice[1]; Karla Kerlikowske[1,2]; Rena Pasick[1]; Alice H. Chen[1,3]; Eliseo J. Perez-Stable[1]; Leah Karliner[1]. 1University of California San Francisco, San Francisco, CA; [2]Veterans Affairs Medical Center, San Francisco, CA; [3]San Francisco General Hospital, San Francisco, CA. (Tracking ID #1629493)

BACKGROUND: Despite the availability of breast cancer risk assessment tools and interventions for risk reduction, these tools are not well integrated into clinical practice. As a result, many women do not engage in a discussion of their breast cancer risk with their physician, which may lead to underuse of effective risk reduction interventions.

METHODS: We conducted a randomized controlled trial comparing usual care to a tablet-PC based breast cancer risk assessment and education intervention (BreastCARE) delivered in a primary care setting. We enrolled women aged 40–74 years with no personal breast cancer history prior to their scheduled primary care visits at two clinics (one academic medical center, one safety-net) between June 2011 and August 2012, and randomized them to Intervention or Usual Care (UC) arms, stratified by race/ethnicity. The Intervention group completed the BreastCARE intervention at the clinic just prior to their visit and women and physicians received tailored risk reports. The UC group completed a telephone-based risk assessment after their visit. We categorized women as high or average risk based on family history using the Referral Screening Tool (RST) or breast cancer risk factors using the Gail/Breast Cancer Surveillance Consortium (BCSC) models. We contacted all women for a follow-up telephone survey 1 week after risk assessment. We used generalized estimating equations to account for clustering by physician, and to estimate differences at follow-up between Intervention and UC groups in above average knowledge of breast cancer risk factors (cut-point based on mean knowledge score in sample), and discussion of breast cancer risk and lifestyle behaviors with physician.

RESULTS: A total of 1,278 women completed risk assessments and signed consent forms (596 Intervention and 665 UC) and 1,235 (97 %) completed follow-up interviews (580 Intervention and 655 UC). The mean sample age was 56 years (SD=9) with 35 % non-Latina White, 23 % Latina, 22 % African American, 18 % Asian/Pacific Islander and 2 % Native American/other. Demographic characteristics and breast cancer risk distributions were well-balanced between Intervention and UC groups. Nine percent of women qualified for high-risk referral based on RST score and 16 % qualified based on Gail/BCSC models. Compared to women receiving UC, those in the Intervention group reported greater knowledge of breast cancer risk factors (69 % vs. 55 %), and more discussion of breast cancer risk (41 % vs. 14 %), exercise (75 % vs. 61 %) and weight (67 % vs. 57 %). Discussion of risk was greatest among women at highest risk for breast cancer who received the intervention (51 % Intervention vs. 18 % UC). Multivariable analysis results are presented in Table 1.

CONCLUSIONS: Our primary care based intervention increased discussion of breast cancer risk and lifestyle behaviors with physicians and improved women's knowledge of breast cancer risk factors. Our findings support integration of health-related information technology in a clinic setting to enhance individualized risk assessment and promote patient-physician discussion, particularly for women at highest risk for breast cancer.

Table 1. Multivariable Analysis at Follow-up*

	Above average knowledge of breast cancer risk factors	Discussed breast cancer risk with physician	Discussed regular exercise with physician	Discussed weight with physician

BUILDING COST-CONSCIOUSNESS THROUGH COST TRANSPARENCY: IS THIS THE RIGHT APPROACH? THE CLINICIAN PERSPECTIVE L. E. Goldman[1]; Jenna Kruger[1]; Alice H. Chen[1]; Alex Rybkin[2]; Kiren Leeds[1]; Dominick Frosch[3,4]. 1University of California, San Francisco, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA; [3]University of California, Los Angeles, Los Angeles, CA; [4]Palo Alto Medical Foundation Research Institute, Palo Alto, CA. (Tracking ID #1642532)

BACKGROUND: The demand for radiologic imaging studies has increased dramatically, contributing to rising health care costs and exposing patients to radiation. Medicare and Medicaid reimbursement policies are moving towards global payments and capitation, increasing pressure on health systems relying on these payers to increase clinicians' cost-consciousness. One strategy to increase clinician cost-consciousness is greater cost transparency when clinicians order imaging studies. We sought to evaluate (1) clinician attitudes and practices toward considering cost information when ordering diagnostic imaging studies in an urban outpatient safety-net setting; and (2) clinician reactions to a planned intervention posting Medicare reimbursement information for imaging studies at the point of clinician electronic order entry.

METHODS: We conducted a qualitative study consisting of 9 focus groups among a diverse group of salaried clinicians representing 12 safety-net clinics using a common electronic order entry system (6 focus groups with primary care clinicians and 3 with subspecialty physicians in nephrology, pulmonary, and neurology, total *N*=44 clinicians). Focus group guides focused on clinician attitudes about how costs to patients and to society affect their practice, potential harms and benefits of posting Medicare reimbursement information at clinician electronic order entry for imaging studies (ultrasound, cat scan, and magnetic resonance imaging), and suggestions to improve the intervention. Focus groups were audio-recorded and transcribed. Two researchers (JK, LG) systematically coded the transcripts, and discussed differences to reach consensus using an inductive thematic analysis framework to identify emergent themes.
RESULTS: Clinician responses to incorporating cost in clinical decision-making varied widely. Some clinicians reported regular discussions with patients about costs (to patients and to society) while others were highly concerned about cost influencing individual patient care decisions. In general, clinicians believed that they only ordered clinically impactful tests due to resource constraints in the safety-net and lack of personal financial incentives to order imaging, yet most noted that the lack of patient co-pays in their practice limited their consideration of costs in clinical decisions. Several clinicians expressed ethical concerns with posting reimbursement information at the site of electronic order entry; they worried that it could lead to inappropriate rationing of care, and if viewed by patients, could exacerbate patient perceptions of receiving "second class" care. Many clinicians emphasized the limitations of an intervention focused on the costs of imaging tests without a global understanding of other health system costs. Clinicians recommended that cost-consciousness be promoted through system-wide education and peer-practice feedback rather than a point of service intervention, particularly in safety-net settings.
CONCLUSIONS: Initiatives to increase cost-consciousness in health care should incorporate an educational component relevant to the target audience and should monitor for potential unanticipated adverse consequences for patient care, particularly in safety-net settings where patients may be more vulnerable. System-wide education and peer-practice feedback may be more appropriate tools to building cost-consciousness among clinicians in the safety-net than cost transparency at the site of order entry.

BUILDING THE FOUNDATION FOR A PATIENT-CENTERED MEDICAL HOME IN A LARGE VA ACADEMIC MEDICAL CENTER Jane Forman[1]; Molly Harrod[1]; Claire H. Robinson[1]; Jessica Ott[1]; Ann Annis-Emeott[1,3]; Darcy Saffar[1]; Leo Greenstone[1,2]. 1VA Ann Arbor Healthcare System, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]University of Michigan, Ann Arbor, MI. (Tracking ID #1642228)

BACKGROUND: The Department of Veterans Affairs (VA) has launched an initiative to transform primary care using the patient-centered medical home (PCMH) model, which features the following principles: care is patient-driven, team-based, continuous, comprehensive, coordinated, efficient and effective, with frequent communication among the health care team and with patients. It requires redesign of the system of care delivery (formation of small interdisciplinary teams called teamlets that work closely together to deliver care to a prescribed patient panel), as well as practice redesign involving changes in roles and work processes. The current literature on PCMH implementation has focused largely on relatively small private practices, and has not examined implementation in larger, more complex settings. A high proportion of VA primary care is delivered in medical centers, most of which are academically affiliated. These clinics have part-time physicians and residents providing the majority of patient care, and large staffs and patient populations. We conducted an in-depth qualitative study of early PCMH implementation in a large VA academic medical center to identify the barriers and facilitators to transforming primary care in this complex setting.
METHODS: We conducted 33 semi-structured interviews with leadership, providers, and staff, and observations of nurse staff meetings, during the first year of PACT implementation (February to December 2011), in one VA academic medical center. Interviews were audio-recorded and transcribed; staff meeting field notes were handwritten. We coded data using selected constructs from the Consolidated Framework for Implementation Research, which consists of common constructs from the implementation science literature, and developed findings through constant comparison to inductively identify themes within, and interactions between, constructs.
RESULTS: We identified several contextual factors that presented barriers to implementing the PCMH model in a large VA academic medical center. These included: 1) Part-time providers and residents had multiple roles outside the clinic, which delayed communication with nurses and clerks about clinical issues and changes in work processes. 2) The complexity of garnering and reconfiguring space in a large institution delayed co-location of teamlets, further impeding communication essential to meeting PCMH goals such as interdisciplinary discussion of patient needs and improving access to care. 3) Doubling the number of clinic staff to fully staff teamlets, combined with having multiple part-time providers on each teamlet, made teamlet formation logistically complex. Further, the need to train and integrate new staff into the clinic at a time of rapid change made it more challenging for staff to establish relationships with multiple providers.
CONCLUSIONS: Large academic medical centers may face special challenges in implementing the medical home model. The presence of part-time providers and residents and large size make their existing care model less compatible with the PCMH model than settings in which PCMH was initially conceived and implemented. Delays in building a foundation for teamwork make it difficult to redesign practices to attain key PCMH goals. Our framework to identify barriers and facilitators to PACT implementation in large academic medical centers should be tested and expanded, and strategies developed based on this knowledge to foster successful implementation in these settings.

BURDEN OF MENTAL ILLNESS AMONG VA PRIMARY CARE PATIENTS Ranak Trivedi[1,2]; Dan Kivlahan[5]; John McCarthy[3,4]; Edward P. Post[3,4]; Andrew J. Saxon[1,2]; Andrew Pomerantz[5,6]; Haili Sun1; John D. Piette[3,4]; Stephan D. Fihn[7,2]; Karin M. Nelson[1,2]. 1VA Puget Sound Health Care System, Seattle, WA; [2]University of Washington, Seattle, WA; [3]VA Ann Arbor Health Care System, Ann Arbor, MI; [4]University of Michigan, Ann Arbor, MI; [5]VA Office of Mental Health Services, White River, VT; [6]Dartmouth College, Hanover, NH; [7]VA Office of Analytics and Business Intelligence, Seattle, WA. (Tracking ID #1634680)

BACKGROUND: Although data regarding prevalence are limited, primary care is often the first opportunity to treat patients with for common mental illnesses. The patient centered medical home provides an opportunity to integrate psychiatric care within primary care settings. VA is the largest integrated health care system to widely implement this model. Known as the Patient Aligned Care Team (PACT), the VA patient centered medical home provides an opportunity to estimate the prevalence of common mental illnesses and associations with patient outcomes.
METHODS: We examined the VA's corporate data warehouse to identify all Veterans who made at least one face-to-face to a primary care provider during the year prior to PACT implementation. We determined the prevalence and co-occurrence of 5 common psychiatric conditions: depression, post-traumatic stress disorder (PTSD), substance use disorders (SUD), anxiety, and serious mental illness (SMI; consisting of bipolar disorder and schizophrenia). We considered a Veteran to have a diagnosis of depression, PTSD, anxiety, or SMI if he or she had ≥2 outpatient or ≥1 inpatient diagnosis of the relevant ICD9 codes. A patient was deemed to have SUD if there was ≥1 inpatient or outpatient diagnosis based on ICD9 codes. Multivariate regression models were used to assess associations between presence of psychiatric conditions hospitalization or death during the subsequent year.
RESULTS: Of 4,273,729 Veterans included, 58 % were White, 94 % were male, and 59 % were married. The prevalence of the 5 mental conditions was: depression (12 %), PTSD (8 %), SUD (5 %), anxiety (4 %), and SMI (4 %). 29 % were diagnosed with 1 of these 5 mental illnesses. 14 % had 2 mental illnesses and 3.65 % had 3 illnesses. The most common co-occurring mental illnesses were depression and PTSD (4 %). Among Veterans with depression, 31 % also had PTSD and 17 % had SUD. Among Veterans with SMI, 28 % also had depression, 23 % had SUD and 21 % had PTSD. Chronic medical problems were also common among Veterans with mental illness is high including diabetes (25 %), hypertension (>50 %) and ischemic heart disease (17 %). Hospitalizations within

1 year ranged from 14 % for patients with PTSD to 24 % for those with SUD. One-year mortality ranged from approximately 2 % (PTSD) to 3.5 % (SUD). After adjustment for age, co-morbidity, and primary care utilization, the presence of SUD (OR=2.0; 95%CI=1.9, 2.1) and depression (OR=1.3; 95%CI=1.3, 1.3) were independently associated with admission. Similarly, the presence of SUD or depression were associated with higher odds of death within 1 year (OR=1.7, 95%CI= 1.6, 1.8 and OR=1.2; 95%CI=1.15, 1.22 respectively).
CONCLUSIONS: Mental health conditions are common among Veterans receiving primary care and frequently co-occur. Presence of these conditions was associated with a higher risk for hospitalization and mortality.

BURNOUT IN CLINICIAN-EDUCATORS AND THE IMPORTANCE OF LIFELONG LEARNING: FINDINGS FROM A MEDICAL EDUCATION FACULTY DEVELOPMENT PROGRAM Anne Dembitzer[1,2]; Binhuan Wang[1]; Audrey Grask[1]; Colleen Gillespie[1]; Kathleen Hanley[1]; Sondra Zabar[1]; Colleen Gillespie[1]; Mark D. Schwartz[1,2]. [1]NYU School of Medicine, New York, NY; [2]NY Harbor VA, New York, NY. (Tracking ID #1641509)

BACKGROUND: Clinician-educators (CE) are the primary teachers of medical students and residents, yet most have not had formal training in education. Physician burnout is common and is associated with job turnover, poor morale, and reduced efficiency, and may lead to poorer patient care. We sought to determine how participation in a longitudinal faculty development program (FDP), designed to improve mentoring and teaching skills, is associated with better job-related outcomes for CE, including burnout, commitment to learning, career fit, and job satisfaction.
METHODS: We recruited faculty who teach weekly in an 18-month clinical skills course for medical students. These CE are experienced teachers with extensive outpatient teaching and clinical responsibilities. CE participated in a year-long FDP that met for 1 h each month and focused on medical education skills, academic advancement, and care of vulnerable populations. The format included small group discussions, participation in two three-station Objective Structured Teaching Exercises (OSTE), and individual and group videotape review sessions of small group teaching and OSTE encounters. Participants completed pre- and post-program questionnaires assessing burnout (Maslach), career fit, job satisfaction, teaching confidence, and commitment to lifelong learning (Jefferson Scale of Physician Lifelong Learning). The Maslach burnout inventory assessed three types of burnout - Emotional Exhaustion, Depersonalization, and Personal Accomplishment - in CE's roles as clinicians and as educators. We determined the change in these variables from baseline to post-FDP participation.
RESULTS: Of the 18 CE who completed the program, 13 were internists and 5 were pediatricians. At baseline, 56 % reported emotional exhaustion (EE) burnout as clinicians vs. 6 % as educators, and 22 % experienced depersonalization (DP) burnout as clinicians vs. 0 % as educators. 39 % had personal accomplishment (PA) burnout as clinicians and as educators, 77 % said they were either somewhat or very confident in all teaching domains, 82 % indicated they had good career fit, and 78 % reported they were somewhat or very satisfied with their job. After participating in the FDP, three CE who had reported EE burnout as clinicians were no longer burned out; two CE who had reported DP burnout as clinicians were no longer burned out; and two CE who had reported PA burnout as clinicians were no longer burned out. While commitment to lifelong learning did not change from baseline, CE who no longer met the threshold for DP burnout demonstrated a significant ($p<.05$) increase in lifelong learning scores compared with all other CE. Similarly, while career fit and job satisfaction did not improve for the entire group, CE who reported increased career fit from baseline were more likely to report improved job satisfaction ($p=.01$).
CONCLUSIONS: These experienced clinician-educators in urban, underserved settings had high rates of burnout as clinicians despite reporting high teaching confidence, good career fit, and high job satisfaction. After a year-long FDP, they experienced modest reduction in burnout. Reduction in depersonalization burnout was associated with increased lifelong learning skills. Future FDPs for CE should consider training in lifelong learning skills as this might mitigate burnout.

CHARACTERIZING THE POST-DISCHARGE FOLLOW-UP VISIT Ethel Wu; Cindy Lai; Margaret Fang. University of California, San Francisco, San Francisco, CA. (Tracking ID #1642794)

BACKGROUND: There is increasing emphasis on timely outpatient follow-up visits after hospital discharge. However, there is little consensus regarding what should take place in the follow-up visit. In this study, we described the content documented in post-discharge follow-up visits.
METHODS: We reviewed the medical records of all adult patients discharged to home from the general internal medicine service in June 2012 at a 600-bed academic medical center. Subjects were included if they had at least one outpatient visit with a medical center-affiliated primary care physician (PCP) or specialist within 60 days of discharge. We evaluated the subsequent outpatient note to determine visit content. We measured 5 parameters based on checklists proposed by the California HealthCare Foundation and by other facilities: 1) medication reconciliation or discussion, 2) whether the reason for hospitalization was discussed, 3) follow-up on pending or recommended tests (if recommended by the discharge summary), 4) assessment of functional status, and 5) discussion of advanced directives. T-tests were used to compare the mean parameters documented.
RESULTS: Of the 271 discharges to home during the 1 month period, we analyzed 150 (55 %) follow-up visits of 142 patients (6 individuals had multiple hospitalizations with follow-up in this time period); 9 % of patients had recurrent hospitalizations, ED visits, or died before a follow-up visit, and 36 % had no subsequent visit at the medical center. Of the 142 subjects, the mean age was 61.5±18.7 years, 78 (55 %) were female, and 64 (45 %) were white. Over half, 85 (60 %), had a PCP in the medical center, and the remaining, a specialist. In 97 % of cases, discharge summaries were available and completed prior to the outpatient visit. In 150 follow-up visits, 108 (72 %) visits occurred within 2 weeks of discharge, and 72 (48 %) were performed by specialists. The content of the visit varied (Table). There was no difference in the mean number of content parameters met when visits with PCPs vs. specialists were compared (2.9 vs. 2.8, $p=0.40$), nor was it different when follow-up occurred within 2 weeks compared to more than 2 weeks from discharge (3.0 vs. 2.7, $p=0.21$). There were no significant differences by patient age, gender, or race/ethnicity.
CONCLUSIONS: In the post-discharge follow-up visit, medications and the reason for hospitalization were almost universally addressed; beyond that, visit content varied. Standardization of the post-discharge visit may help the transition between hospital and home.

Table: Content Parameters Met During Follow-up Visits

	Number of Visits
Specific Parameters Met:	
Medications	141 (94%)
Reason for Hospitalization	144 (96%)
Pending Tests	61 (68%)*
Functional Status	56 (37%)
Advanced Directives	34 (23%)
Number of Parameters Met:	
0-1	7 (5%)
2	44 (29%)
3	60 (40%)
4-5	39 (26%)

*out of 90 discharges with pending or recommended tests.

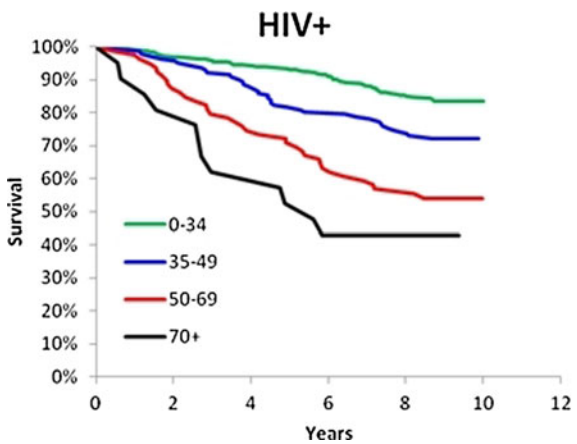
COPD AND COGNITIVE IMPAIRMENT: ASSOCIATIONS WITH INHALER TECHNIQUE Katherine Krauskopf; Alex Federman; Anastasia Sofianou; Melissa Martynenko; Minal Kale; Maile Ray; Juan P. Wisnivesky. Mount Sinai School of Medicine, New York, NY. (Tracking ID #1641346)

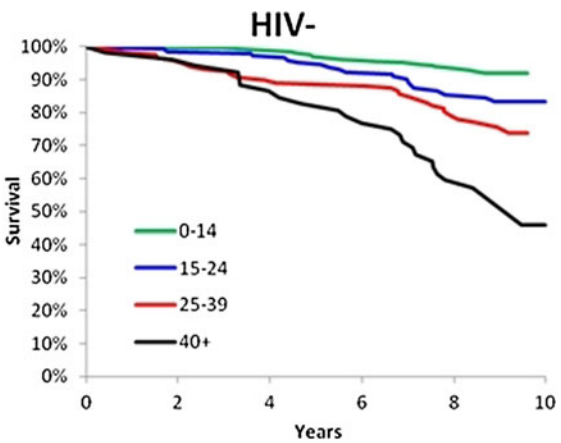
BACKGROUND: Chronic Obstructive Pulmonary Disease (COPD) outcomes are determined, in part, by complex self-management behaviors (SMB), including proper administration of inhaled medications. Cognitive deficits are common among patients with COPD due to chronic hypoxemia. However, little is known about how cognitive impairment affects COPD SMB. We examined the association between cognitive impairment and proficiency with COPD inhaler use.

METHODS: Prospective cohort of patients ≥55 years with COPD, recruited from diverse outpatient practices in New York City and Chicago. Patients with known dementia were excluded. All participants had a physician-derived COPD diagnosis. Cognitive impairment was evaluated with the Mini-Mental Status Exam (MMSE, age- and education-adjusted score <25 indicated impaired cognitive function). Proficiency in metered dose inhaler (MDI) and dry powder inhaler (DPI) use was assessed by observed use of MDI and/or DPI devices using validated checklists. Performing less than 75 % of 8 standard steps correctly was considered poor inhaler technique. The chi-square test and multivariate regression analysis were used to determine associations between cognitive impairment and inhaler technique.
RESULTS: Overall, 166 participants were included (mean age 69±8 years, 61 % female, 44 % Black, 12 % Hispanic); 33 % met criteria for cognitive impairment. MDI technique was performed proficiently by 73 % of participants without cognitive impairment compared to 60 % of those with cognitive impairment (p=0.1). The proportion of participants without cognitive impairment who demonstrated proficient DPI technique was 52 % compared to 33 % in those with cognitive impairment p<0.03). Adjusted analysis demonstrated similar findings showing that participants with cognitive impairment were more likely to have poor DPI technique (odds ratio [OR]: 2.28, 95 % confidence interval [CI] 1.01–5.15), but not poor MDI technique (OR: 1.53, 95 % CI: 0.68–3.46).
CONCLUSIONS: Patients with COPD have high rates of cognitive impairment, which may compromise performance of crucial SMB. Results from this study of urban adults with moderate-severe COPD show that those patients with cognitive impairment were more likely to have poor DPI technique, a commonly prescribed medication device for this illness. Further studies should explore associations between specific domains of cognitive impairment and inhaler technique, as they may identify modifiable targets for interventions to improve COPD outcomes.

CAN THE VETERANS AGING COHORT STUDY INDEX IMPROVE CLINICAL JUDGMENT FOR BOTH HIV INFECTED AND UNINFECTED VETERANS? Amy C. Justice[1,2]; Janet P. Tate[1,2]; Sheldon T. Brown[3,4]; Cynthia Gibert[5,6]; Maria Rodriguez-Barradas[7,8]; David Rimland[9,10]; Kathleen M. Akgün[1,2]; Kendall Bryant[11]. [1]Yale University, West Haven, CT; [2]VA Connecticut Healthcare System, West Haven, CT; [3]James J. Peters VA Medical Center, New York, NY; [4]Mt. Sinai School of Medicine, New York, NY; [5]George Washington University School of Medicine, Washington, DC; [6]Washington DC Veterans Affairs Medical Center, Washington, DC; [7]Baylor College of Medicine, Houston, TX; [8]Michael E. DeBakey Veterans Affairs Medical Center, Houston, TX; [9]Emory School of Medicine, Atlanta, GA; [10]Atlanta Veterans Affairs Medical Center, Atlanta, GA; [11]National Institute on Alcohol Abuse and Alcoholism, Bethesda, MD. (Tracking ID #1640592)

BACKGROUND: The Veterans Aging Cohort Study (VACS) Index, composed of age and 8 routine biomarkers (CD4 count, HIV-1 RNA, hemoglobin, AST, ALT, platelets, creatinine, and HCV serostatus), predicts mortality, hospitalization, and MICU admission among those with HIV infection. With the assumption of a CD4 count >500 cells/mm3 and undetectable HIV-1 RNA, with the assumption of a normal CD4 count and undetectable HIV-1 RNA, it predicts mortality among veterans without HIV with equal accuracy. Since these biomarker values are routinely available to the provider, we asked whether use of the index improves accuracy of risk assessment (clinical judgment) for patients with and without HIV infection (HIV−/+).
METHODS: VACS 8 is an indepth, observational cohort of >7,500 HIV+ demographically matched to HIV- Veterans at 8 sites within the National Veterans Affairs Healthcare System that includes patient and provider surveys and full access to electronic medical records. During a clinic visit from 2002 to 2003, at which providers had access to these biomarkers, we asked them to assess sickness level: "How sick is this patient?" with options of "not sick, somewhat sick, moderately sick, very sick, and on the edge of death"; and prognosis: "What is the probability that the patient will live 10 years?" Accuracy of provider assessments was compared with VACS Index using proportional hazards models to calculate C statistics. We plotted Kaplan Meier curves stratified by sickness level and index score stratified by HIV status. We also calculated risk reclassification using net reclassification improvement (NRI).
RESULTS: Among 1582 HIV+ and 1282 demographically similar HIV- veterans for whom providers completed surveys, there were 424 and 243 deaths during a median of 9 years of follow-up. Provider assessment of sickness level and probability of mortality were correlated (HIV+/−: 0.54, 0.51), but only fairly predictive of mortality (C statistics ranging from 0.63 to 0.66). VACS Index alone was a better predictor of mortality and was equally accurate among HIV+ (C=0.71, 95 % CI 0.69–0.74) and HIV- (C= 0.71, 95 % CI 0.68–0.74). When combined with clinical judgment, accuracy improved (for sickness level C stat: HIV+ =: 0.73, 95 % CI 0.70–0.75; HIV- = 0.73, 95 % CI 0.70–0.76 results were similar for overall prognosis) Findings for "somewhat sick" group–the largest grouping illustrated below. Addition of the VACS Index to either form of clinical judgment resulted in reclassification of >50 % of HIV+ and HIV- subjects with NRI >7 % in all groups.
CONCLUSIONS: Among HIV +/−, clinical judgment of mortality risk can be equally and substantially improved by the VACS Index. Potential applications include informing choice of follow up interval, hospital admission, case management, preventive screening, and end of life decision making—all of which rely upon accurate risk assement.





CAN WE IDENTIFY SUBJECTS AT RISK OF INAPPROPRIATE ANTIPLATELET ADHERENCE AFTER CORONARY STENT PLACEMENT? Leonardo Tamariz; Ana M. Palacio; Hua Li; Olveen Carrasquillo. University of Miami, Miami, FL. (Tracking ID #1642174)

BACKGROUND: Racial minorities who have received coronary stents have lower medication adherence to antiplatelet agents. Certain interventions such as motivational interviewing (MI) could be offered to improve adherence if we could identify those at risk. We report

predictors of adherence to clopidogrel or prasugrel among participants of a randomized control trial who had recently received a coronary stent.

METHODS: We conducted a secondary analysis of a randomized trial of Black and Hispanic patients enrolled in a health benefits plan who had recently received a coronary stent. Study patients were randomly assigned to either a telephone based MI intervention or an educational video. Predictor variables were collected at baseline using a survey and claims data and included demographics, cormorbidities using the Charlson score, depression using the PHQ-9, patient-physician communication, health literacy, income and education. The outcome variable was collected using administrative data and included the medication possession ratio (MPR) of clopidogrel or prasugrel categorized into appropriate/inappropriate based on a previously validated measure that defines appropriate adherence as an MPR>=0.80. Other outcomes were self-reported adherence (Morisky score) and self reported forgetfulness and carelessness when taking antiplatelet medications. We used logistic regression to model predictors of an MPR>=0.80 as well as self reported forgetfulness taking medications.

RESULTS: We recruited 452 minorities with a new coronary stent (44 % Hispanics and 56 % Black). The patients had a mean age of 69.5±8.8, 58 % were males, 78 % had an income inferior to 30 K per year and only 22 % had achieved high school education or higher. At the end of the study period, 12 months post index stent placement, we had claims data available on 422 subjects, 213 had received the MI intervention and 209 had received the DVD. Table 1 reports selected predictors of adequate adherence. A PHQ score of 10 or higher (moderate to severe depression), comorbidity score and randomized group were significant predictors of appropriate medication possession ratio. Depression, health literacy and black race were predictors of self-reported adherence to antiplatelet medications.

CONCLUSIONS: The identification of certain personal characteristics and the screening for depression and health literacy at the time of stent placement can help us identify subjects at risk of inappropriate adherence to antiplatelet medications.

Predictors of appropriate adherence
Predictor OR (95 % CI) p-value
Female gender 1.09(0.68–1.74) 0.71
Age 1.01(0.98–1.03) 0.37
Physician listens 1.47(0.52–4.15) 0.46
Physicians spends enough time 0.86(0.34–2.16) 0.75
Patient beliefs about antiplatelets 1.82(0.71–4.69) 0.20
Confidence in filling out forms 0.95(0.8–1.3) 0.83
Income 1.01(0.57–1.76) 0.31
Higher education 1.1(0.67–1.82) 0.68
PHQ9 score 0.93(0.88–0.99) 0.03
Charlson score 0.87(0.77–0.98) 0.02
Black race 1.06(0.67–1.67) 0.79
Motivational interviewing 1.92(1.1–1.3) <0.01

CANCER TYPE PREDICTS OUTCOMES OF WARFARIN THERAPY

Daniel B. Ambrus; Joel Reisman; Adam Rose. Bedford Veterans' Association, Boston, MA. (Tracking ID #1637579)

BACKGROUND: Patients receiving warfarin who are newly diagnosed with cancer experience poorer anticoagulation control, as summarized by percent time in therapeutic range (TTR), and higher rates of bleeding. Relatively little is known about whether specific types of cancer carry greater risks in this regard.

METHODS: We began with 122,159 patients who received warfarin from the Veterans Health Administration (VA) from October 2006–September 2008. ICD-9 codes were used to define cancer diagnoses. We excluded 20,405 patients who had a cancer diagnosis prior to the study period which limited the study population to patients who either recorded a new cancer during the study or never had cancer. The study was further limited to patients with fee-for-service Medicare (to ensure complete data capture) and to patients who received warfarin therapy both before and after the cancer diagnosis (or the midpoint of the analysis window for those who did not have cancer). New cancers were divided into 29 types, excluding benign neoplasms, carcinoma-in-situ and non-melanoma skin cancers. We compared TTR between the six-month period before and after the cancer diagnosis for cancer patients, and between the analogous time periods for controls. Cox models were used to examine the impact on TTR from each subtype of cancer, and the hazard for major hemorrhage, with adjustments for age and TTR in the bleeding analysis. Major bleeding was defined as bleeding into a critical anatomic site or a bleeding event leading to hospitalization, requiring transfusion, or resulting in death.

RESULTS: After exclusions, there were 27,734 patients without cancer and 2,670 patients with a new diagnosis of cancer. The most common types of cancer were prostate (n=626), lung (n=325), bladder (n=297), colorectal (n=247), and leukemia/lymphoma (n=227). Most types of cancer were associated with decreased TTR during the 6 months following diagnosis (mean for all cancers: −6.6 %) relative to control patients (−0.9 %, p<0.001). The greatest effect was seen for patients with esophageal cancer (−21 %), but patients with cancers of lung (−13 %), melanoma (−12 %), bladder (−10 %) and colorectal (−10 %) also experienced reductions in TTR (all p values<0.001). The most common type of cancer, prostate cancer, was associated with a 0.5 % increase in TTR, which was not significantly different from controls (p=0.32). Similarly, some types of cancer were associated with considerably increased hazard for major hemorrhage compared to patients without cancer. The greatest hazard was seen with colorectal cancer (HR=4.08 compared to no cancer), followed by bladder cancer (HR=3.06) and lung cancer (HR=2.83, all p values<0.001). Effect sizes were smaller, and results were not statistically significant, for leukemia/lymphoma (HR=1.68, p=0.15) and prostate cancer (HR=1.45, p=0.14).

CONCLUSIONS: The impact of a new cancer diagnosis on anticoagulation control among patients who were already receiving warfarin is highly variable depending on the type of cancer that is diagnosed. Among commonly-diagnosed cancer types, the hazard for major hemorrhage is highest with colorectal cancer, bladder cancer and lung cancer. Prostate cancer did not seem to adversely impact either anticoagulation control or bleeding hazard.

CASE MANAGEMENT PERFORMANCE IN A MEDICAL HOME AND ASSOCIATIONS WITH PATIENT SATISFACTION AND HEALTHCARE UTILIZATION

Lindsay E. Jubelt[1,3]; Jove Graham[4]; Daniel D. Maeng[5]; Joshua Metlay[2,1]; Andrew Epstein[2]. [1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [3]Philadelphia VA Medical Center, Philadelphia, PA; [4]Geisinger Center for Health Research, Danville, PA; [5]Geisinger Health System, Danville, PA. (Tracking ID #1634384)

BACKGROUND: In traditional medical care models, stronger physician-patient relationships have a positive impact on patient satisfaction with care and subsequent medical outcomes. Despite the heightened role of nurse case managers in many patient-centered medical home models, little is known about the relationship between case management and patient satisfaction or future health behaviors. The first aim of our study was to measure the association between patient perceptions of case manager performance and satisfaction with overall care. The second aim was to determine the association between patient perceptions of case manager performance and subsequent health care utilization.

METHODS: We conducted a retrospective cohort study of 2,147 patients in the Geisinger Health Plan (GHP) who received primary care at a clinic site in the Geisinger Health System and who were exposed to clinic-embedded nurse case managers. We obtained data on patient satisfaction and case manager performance from a patient satisfaction survey based on the CG-CAHPS survey. The survey was administered at approximately six-month intervals starting in 2009 to different cohorts of eligible patients. Claims data from 2006 to 2011 were obtained from the GHP and linked to all survey respondents. From the claims database, we obtained demographic data and MEDai (Medical Artificial Intelligence, Inc., Orlando, FL)

risk adjustment scores. These scores were calculated on a 1–5 scale using MEDai software to perform validity checks and assign a sophisticated severity level to each patient. The patient satisfaction survey included six questions on primary care provider (PCP) performance, four questions on case manager performance, and two questions on satisfaction with care, all using 4-point Likert scales. We generated three new variables based on the average ratings for questions within each of these three domains and used multivariable regression to identify significant predictors of overall satisfaction, including case manager and PCP ratings.

RESULTS: We analyzed six phases of survey data. The mean age of the sample was 74.3 years (sd=10.8 years). 52 % of subjects were female and 93.6 % were of white race. The average MEDai risk score was 3.3 (sd=1.2). Average case manager ratings (mean=3.7, sd=0.4), PCP ratings (mean=3.9, sd=0.3), and overall satisfaction ratings (mean=3.8, sd=0.4) did not differ significantly by age, sex, race, MEDai risk score, or survey phase. In adjusted analysis of predictors of overall satisfaction ratings, a one point increase in case manager rating resulted in a 0.27 point increase in satisfaction rating ($p<0.005$), and at one point increase in PCP rating resulted in a 0.54 increase in satisfaction rating ($p<0.005$).

CONCLUSIONS: Patient perceptions of their case manager are significantly associated with overall satisfaction with care, even after controlling for patient perceptions of their primary care doctor. Given the known effect of primary care doctors on health care utilization, the independent and significant case management finding raises the possibility that case management may also impact patient health outcomes and health behaviors. The next steps in our analyses will focus on examining the associations between patient perceptions of case management and health care utilization patterns.

CAUSES OF READMISSIONS AND THEIR AVOIDABILITY FOR THE MOST COMMON COMORBIDITIES Jacques Donze[1,2]; Stuart R. Lipsitz[1,2]; Jeffrey L. Schnipper[1,2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA. (Tracking ID #1637167)

BACKGROUND: Readmissions to the hospital are costly and sometimes avoidable. A better understanding of the reasons for readmission among different patient populations (e.g., those with different chronic conditions) may lead to more targeted and successful interventions. We aim to describe the proportion and pattern of 30-day readmissions and potentially avoidable readmissions (PAR) in medical patients, according to the most common comorbidities.

METHODS: We included all consecutive discharges from any medical service of an academic tertiary medical center in Boston between July 1, 2009 and June 30, 2010. Potentially avoidable 30-day readmissions to the index hospital or two other hospitals within its network were then identified using a validated computerized algorithm based on administrative data (SQLape®). Most common comorbidities were identified using ICD-9 codes of the index admission. Main cause of readmission was based on patient Diagnosis Related Groups (DRGs). For this analysis, we present the 5 most frequent causes of PAR overall and for each comorbidity separately. We also compared the proportion of readmissions deemed potentially avoidable for patients discharged with and without each comorbidity using logistic regression. Proportions and their 95 % confidence intervals were adjusted for length of stay, mode of admission (elective or not), number of admissions in the previous 12 months, number of procedures during the index admission, hemoglobin and sodium level at discharge of index admission, and number of other comorbidities.

RESULTS: Among 10,731 discharges, 2,398 (22.3 %) were followed by a 30-day readmission, of which 879 (8.5 %) were identified as PAR. The top 5 causes of 30-day PAR were infection, neoplasm, heart failure, gastrointestinal disorder and liver disorder (Table 1). For most chronic conditions except neoplasm (diabetes, heart failure, ischemic heart disease, atrial fibrillation and chronic kidney disease), the first two causes of PAR were heart failure (12.2 to 25.5 %) and infection (8.02 to 11.5 %). Only patients discharged with a diagnosis of diabetes or chronic kidney disease had a significantly higher proportion of readmissions deemed potentially avoidable than those without those comorbidities: 39.4 vs 34.8 %, p-value 0.03 for diabetes vs no diabetes; 44.2 vs 33.7 %, p-value 0.005 for chronic kidney disease vs no chronic kidney disease.

CONCLUSIONS: Interestingly, this study shows that patients with diabetes or chronic kidney disease have a higher proportion of potentially avoidable readmission than patients without each of these comorbidities. The main causes of PAR for most of the common comorbidities are heart failure and infection. Together, these findings may help hospitals target interventions to populations most likely to benefit from them.

Most frequent causes of potentially avoidable readmission for common comorbidities

Comorbidity 1st cause 2nd cause 3rd cause 4th cause 5th cause

Diabetes mellitus (n=2,639) Heart failure (12.2 %) Infection (9.4 %) Neoplasm (6.1 %) IHD (4.5 %) Liver disorder (4.5 %)

Heart failure (n=2,308) Heart failure (25.5 %) Infection (8.02 %) IHD (7.6 %) Renal failure (3.3 %) Arrhythmia (2.8 %)

Ischemic heart disease (n=2,823) (IHD) Heart failure (13.3 %) Infection (11.4 %) IHD (9.5 %) Arrhythmia (5.2 %) Renal failure (3.3 %)

Atrial Fibrillation (n=1,832) Heart failure (17.3 %) Infection (11.5 %) Stroke (8.6 %) Arrhythmia (7.9 %) GI disorder (3.6 %)

COPD (n=1,078) Infection (15.9 %) Heart failure (15.9 %) Neoplasm (9.1 %) COPD (5.7 %) VTE (3.4 %)

Neoplasm (n=4,129) Neoplasm (16.1 %) Infection (12.9 %) Metabolic disorder (5.0 %) GI disorder (3.9 %) Renal failure (2.6 %)

Chronic Kidney Disease (n=1,776) Heart failure (19.9 %) Infection (7.9 %) Renal failure (7.3 %) IHD (5.8 %) Liver disorder (2.6 %)

All (n=10,731) Infection (11.7 %) Neoplasm (8.4 %) Heart failure (6.9 %) GI disorder (4.6 %) Liver disorder (3.9 %)

COPD = chronic obstructive pulmonary disease; GI = gastrointestinal; IHD = ischemic heart disease; VTE = venous thrombo-embolism event.

CHALLENGES TO CONTROLLING HYPERTENSION IN MINORITY MEN OF LOW SOCIOECONOMIC STATUS Stewart B. Reed[1]; Jose J. Escarce[1]; Suzanne B. Shu[1,2]; Craig R. Fox[1,2]; Noah J. Goldstein[1,2]; Ronald G. Victor[3]; Estivali Villa[1]; Rocio Castaneda[1]; Chi-Hong Tseng[1]; Martin F. Shapiro[1]. [1]UCLA David Geffen School of Medicine, Los Angeles, CA; [2]UCLA Anderson School of Management, Los Angeles, CA; [3]Cedars-Sinai Medical Center, Los Angeles, CA. (Tracking ID #1641817)

BACKGROUND: Hypertension remains untreated or inadequately treated in the majority of affected people. It disproportionately affects African-Americans, and Latinos are at greater risk than Whites of having uncontrolled hypertension. We studied persons with uncontrolled hypertension in two clinics caring for indigent persons in South Los Angeles and evaluated the differences between men and women in their levels of blood pressure at baseline and 6 months after initiation of an intervention to improve blood pressure control.

METHODS: We identified subjects with uncontrolled hypertension (at levels consistent with conducting interventions to achieve meaningful improvement, defined in the study as 149 mmHg systolic or greater and/or 94 mmHg diastolic or greater). Those eligible and consenting were randomized into two groups. The control arm received educational materials on blood pressure as well as home blood pressure monitors along with training in their use. The enhanced intervention arm received the control interventions, but also received contingent payments (based on improvement in blood pressure) as well as an intervention to identify and reinforce reasons for staying healthy. Both groups came in for monthly blood pressure checks. The study is still in progress, so results on the impact of the enhanced intervention are not yet available. We report here on the impact of gender on change in blood pressure for the 125 subjects who have completed 6 months of follow-up to date.

RESULTS: Of the 125 total subjects, 59 were assigned to the enhanced intervention arm and 66 to the control arm. The study population included 71.2 % Latinos and 25.6 % African-Americans; 59.8 % were born outside of the United States; 88.8 % had mean family incomes less than $30,000; 58.2 % had not completed high school. The mean age was 54.0 years;

49.6 % of subjects were female. At baseline, mean systolic blood pressure was higher in women (164.1 mmHg in women versus 161.0 mmHg in men, $p=0.050$), and mean diastolic blood pressure was higher in men (86.0 mmHg in women versus 94.4 mmHg in men, $p=0.001$). After 6 months, mean change in systolic blood pressure was −22.1 mmHg in women and −14.0 mmHg in men ($p=0.007$). Mean change in diastolic blood pressure was −10.7 mmHg in women and −7.3 mmHg in men ($p=0.069$). In separate multivariable analyses for systolic and diastolic blood pressures at 6 months, controlling for baseline blood pressure values, experimental arm assignment, race/ethnicity, age, income, country of birth, and gender, blood pressure at 6 months was lower in women than in men: adjusted systolic blood pressure was 7.95 mmHg lower in women than in men ($p=0.025$); adjusted diastolic blood pressure was 6.00 mmHg lower in women than in men ($p=0.007$).

CONCLUSIONS: In this South Los Angeles community clinic-based minority patient population, men were less responsive to interventions to improve blood pressure control than were women. This suggests that more intensive interventions or combinations of interventions may be necessary to control hypertension in men relative to women in similar patient populations.

CHALLENGING THE ASSUMPTION THAT TEAMWORK ALWAYS PROMOTES SAFETY: A STUDY OF TEAMWORK IN AN EMERGENCY DEPARTMENT Deborah Hutchinson; Katherine M. McKinney. VA Medical Center, Lexington, KY. (Tracking ID #1641878)

BACKGROUND: Healthcare facilities rely on surveys such as the AHRQ's Patient Safety Culture Survey or the Safety Attitudes Questionnaire (Sexton et al.) to assess staff's perception of facility culture. These instruments focus on a variety of dimensions, including questions about teamwork within and between units. While surveys do provide useful information, qualitative methods often augment what is known regarding social phenomena such as teamwork. Using anthropological research methods, we explored how healthcare providers negotiate working together and overcoming barriers to teamwork in a high stress, high acuity environment.

METHODS: This study was conducted over a six-month period in a 15-bed Veteran's Administration Emergency Department with average of 20,000 patient visits per year. We utilized ethnographic participant-observation of the daily routines of Emergency Department staff [$N=46$] via shadowing physicians, nurses, and ancillary staff members during their daily activities and engaging in informal, non-structured interviews about their work-related experiences. These observations were supplemented with audio-recorded, semi-structured, open-ended interviews conducted with 22 staff members. Ethnographic field notes generated during observation and transcripts from interviews were analyzed for themes and patterns utilizing Atlas.ti qualitative data management software. Sampling for this study was purposive and opportunistic with the aim of reaching informational saturation.

RESULTS: The following patterns/themes related to teamwork emerged from data analysis: 1) The importance of communication for successful teamwork: both physicians and nurses were emphasized verbal communication, but unexpectedly physicians mentioned nonverbal communication issues as a barrier more frequently than nurses. 2) "Us vs Them:" Staff frequently engaged in dichotomous identification when referencing teamwork issues. Among these references, was the common assertion that physician and nurses worked better as a team on the night shift. And 3) Use of humor to diffuse tense situations. Both interviews and observations revealed generally good teamwork among staff. However, observational findings uncovered situations that challenge the premise that teamwork is always positive in creating a culture of safety.

CONCLUSIONS: This study reveals the limitations of safety culture surveys by challenging the assumption that teamwork always contributes positively to patient care and that the better the teamwork, the safer the care. Further assessment of teamwork approaches utilized within both emergency department and other clinical units may provide new insights into how to provide safe and effective clinical care.

CHANGES IN MORTALITY AFTER MASSACHUSETTS' HEALTH CARE REFORM Benjamin D. Sommers[1,2]; Sharon K. Long[3]; Katherine Baicker[1]. [1]Harvard School of Public Health, Brookline, MA; [2]Brigham & Women's Hospital, Boston, MA; [3]Urban Institute, Washington, DC. (Tracking ID #1637574)

BACKGROUND: Massachusetts' health reform of 2006 has been called the model for national health reform under the Affordable Care Act. The law attained near-universal insurance coverage in the state, as well as well-documented gains in access to care. The policy's impact on population health is less clear, as prior work has relied on self-reported health measures. Our objective was to determine whether Massachusetts' health reform was associated with any change in all-cause mortality and in mortality amenable to health care.

METHODS: We used a quasi-experimental differences-in-differences design, comparing the change in mortality rates for Massachusetts from 2001 to 2005 (pre-reform) to 2007–2009 (post-reform) versus a propensity-score matched group of U.S. counties similar to Massachusetts in the pre-reform period. Analyses used multivariate regression to further control for population demographics, local economic factors, and county/state of residence. The primary outcome was annual all-cause mortality, obtained at the state- and county-level, in sex-age-race specific cells ($n=32,121$ for state-level analyses, $n=323,538$ for county-level analyses). Secondary analysis examined deaths from causes more likely amenable to health care, using a definition adapted from previous research. The primary study sample contained non-elderly adults (ages 20–64) in Massachusetts and in the control group. Subgroup analyses examined outcomes based on age, race/ethnicity, and local area pre-reform insurance coverage rates and median income. Data were from the CDC's Compressed Mortality File.

RESULTS: Massachusetts' health reform was associated with declines in all-cause mortality of 13.0 per 100,000 (relative decline 4.6 %; $p=0.003$) and deaths amenable to health care of 10.2 per 100,000 (relative decline 5.5 %; $p<0.001$), compared to matched controls in states without expansions. The greatest changes occurred for adults in areas with lower incomes and lower insurance coverage rates pre-reform, and among those ages 35–64. We found mixed evidence on whether the reform narrowed racial disparities in mortality. Our results imply that for every 600 adults who gained insurance under the state's health reform law, one death was prevented per year.

CONCLUSIONS: Massachusetts' 2006 health care reform was associated with significant declines in all-cause mortality compared with matched controls in states without a reform. Those declines were concentrated in causes of death amenable to timely health care and in populations most likely to benefit from expanded access, including residents of areas with lower pre-reform insurance coverage and demographic groups with higher baseline mortality. Our results offer encouraging evidence that the Affordable Care Act - modeled after the Massachusetts law and slated to extend health insurance to over 30 million Americans beginning in 2014 - may not only affect coverage and access, but also objective health measures such as mortality.

CHANGES IN SODIUM DURING HOSPITALIZATION IS ASSOCIATED WITH INCREASED IN-HOSPITAL MORTALITY IN HYPO- AND NORMONATREMIC PATIENTS Valeria C. Pazo; David W. Bates; Gordon D. Schiff. Brigham and Women's Hospital, Boston, MA. (Tracking ID #1637412)

BACKGROUND: Hyponatremia is the most prevalent electrolyte abnormality in hospitalized patients and is associated with increased inpatient mortality. Further, sodium levels at the low end of the normal range or slightly below it are also associated with increased mortality. Because few data about the impact of change in sodium are available, we sought to evaluate whether sodium change in hypo- and normonatremic patients is associated with in-hospital mortality.

METHODS: We assembled a retrospective cohort of adult patients admitted between July 1, 2007 and September 30, 2007. Pregnant women as well as surgical and dialysis patients were excluded. Only first

admissions were considered and data on the following variables were gathered: age, gender, race, admit/discharge dates, Deyo-Charlson Score, comorbidities, in-hospital mortality and [Na+] on admission and at discharge to calculate the Delta [Na+]. [Na+] values were adjusted to concomitant glucose levels. Delta [Na+] was considered the exposure regardless of the circumstance under which the sodium changed. The association between Delta [Na+] and in-hospital mortality was evaluated by fitting logistic regression models, stratified by normo- ([Na+] levels of 135–145 mEq/L) and hyponatremic ([Na+] ≤134 mEq/L) status upon admission. A stepwise forward approach (inclusion and exclusion thresholds $p=0.2$ and $p=0.1$, respectively) was utilized for model building. Final models included age, gender, admission [Na+], Charlson score, and length of stay (LOS). Variance inflation factor was used to assess possible collinearity between admission [Na+] and Delta [Na+].

RESULTS: The study period included 8,966 hospitalizations. Of these, 3078 (34 %) had [Na+] measurements on admission and discharge. Overall, there were 2697 (88 %) normonatremic, 353 (11 %) hyponatremic and 28 (1 %) hypernatremic patients. Mean admission [Na+] in hyponatremics was 131.2 mEq/L (SD=3.4). Compared to normonatremics, they had a higher comorbidity score (mean: 1.8 vs 1.5; $p<0.001$), longer LOS (mean 4.6 vs. 4.0; $p=0.01$) and a mean change in delta [Na+] of 3.7 vs −0.3 mEq/L ($p<0.001$). They had higher crude in-hospital mortality (6.8 % [95 % CI 4.6–9.7]) vs 2.0 % [95 % CI 1.5–2.6]). Delta [Na+] was independently associated with increased in-hospital mortality in both hypo- (OR 1.16; 95 % CI 1.05–1.2; $p=0.001$) and normonatremics (OR 1.17; 95 % CI 1.10–1.24; $p<0.001$). There was a trend towards significance for admission [Na+] and in-hospital mortality in both hypo- (OR 0.91; 95 % CI 0.81–1.01; $p=0.09$) and normonatremics (OR 1.12; 95 % CI 0.99–1.28; $p=0.08$). No significant collinearity between admission [Na+] and Delta [Na+] was observed. The graphic relationship between in-hospital mortality and Delta [Na+] demonstrated a U-shape, with the lowest mortality found in those with relatively stable Delta [Na+].

CONCLUSIONS: Sodium change is associated with increased in-hospital mortality both in hypo- and normonatremic patients, even after adjusting for baseline sodium and comorbidities. These data suggest that Delta [Na+] provide additional predictive power in terms of in-patient mortality in hypo- and normonatremic patients in addition to that obtained by admission sodium. Furthermore, the causal implication of these associations should be explored in future studies.

CHARACTERISTICS OF OLDER ADULTS WHO USE THE EMERGENCY ROOM PRIOR TO JAIL DETAINMENT Anna H. Chodos[1]; Cyrus Ahalt[1]; Irena Stijacic Cenzer[1]; Brie Williams[1]; Joe Goldenson[2]. [1]UCSF, San Francisco, CA; [2]San Francisco Department of Public Health, San Francisco, CA. (Tracking ID #1626484)

BACKGROUND: In jails, older adults are the most rapidly growing population and have the worst health. Nearly all inmates are released within 6 months and jail is increasingly a place to link older adults to needed healthcare and social services. However, little is known about their healthcare needs or utilization, and characteristics associated with expensive emergency room (ER) use are unknown. We describe older jail inmates' ER use prior to detainment, characteristics associated with ER use, and plans for post-release healthcare.

METHODS: Cross sectional study of 244 inmates age 55 or older (82 % participation) who spent ≥1 night in the San Francisco Jail. Questionnaires included validated items about demographics, health, persistent distressing symptoms, past and future healthcare use. ER use was defined as answering yes to: "In the 3 months before jail, did you ever visit an emergency room?" Characteristics associated with ER use were examined using chi-square tests.

RESULTS: Overall, 118 participants (48 %) visited an ER within 3 months of jail detainment. Participants were more likely to report ER use if they also reported recent homelessness or marginal housing (50 % vs. 46 %), or lacking money for medicine (60 % vs. 41 %) or food (54 % vs. 40 %). Those with "poor" or "fair" health (56 % vs. 40 %), screened positive for depression (59 % vs. 40 %), or reported a heart condition (66 % vs. 43 %) were also more likely to report ER use, as were participants with persistent distressing symptoms including pain (58 % vs. 38 %), lack of energy (69 % vs. 43 %), or shortness of breath (65 % vs. 45 %). All associations were significant with $p<0.05$. Chronic conditions not associated with ER use included COPD, HIV, diabetes, hypertension, mental health, substance use, and abnormal MOCA cognitive screen (all $p>0.1$). Many (53 %) who used ER before jail planned to seek care primarily in ERs upon release.

CONCLUSIONS: Nearly half of older jail inmates reported using an ER within 3 months of arrest. Most factors associated with increased ER use related to lack of social support (homelessness, poor access to medications, food insecurity) and persistent distressing symptoms. This suggests that jails may be a critical healthcare site for addressing symptoms and social service needs for older adults to reduce ER use in this population.

CHARTING THE DIVERSITY OF INTERNAL MEDICINE: RESULTS OF A NATIONWIDE PRACTICE ANALYSIS Steven A. Haist[1,2]; Gerard Dillon[1]; Janet Mee[1]; Mark Raymond[1]. [1]National Board Medical Examiners, Philadelphia, PA; [2]Drexel University, Philadelphia, PA. (Tracking ID #1643022)

BACKGROUND: NBME conducted a national survey to identify the practice characteristics of physicians entering unsupervised practice. The survey provided the opportunity to determine how practice profiles of newly licensed internists compare to other specialists.

METHODS: Questionnaires were mailed in May 2011 to a national sample of 8000 recently licensed physicians (unrestricted license 4 years or less). The survey included questions related to training and practice setting, followed by a list of 58 tests and procedures. Respondents indicated if they ordered, performed, and/or interpreted each of the 58 procedures. The survey excluded routine activities all physicians perform (e.g., physical exam), while focusing on nonroutine activities intended to sample the boundaries of general, undifferentiated medical practice. Logistic regression was used to compare internists to other specialists on their specific responsibility (order, perform, interpret) for each the 58 procedures.

RESULTS: 2448 usable surveys were returned (response rate 31 %), including surveys from 499 internists. Two-thirds of recently licensed physicians were still residents or fellows, while one-third had completed training and entered independent practice. Internists were comparable to other specialists in the percentage who moonlight, although they devoted slightly more hours to moonlighting. Internists spent less time in outpatient settings and emergency departments than other specialists, and more time in inpatient settings. Internists were far more likely to order the various tests/procedures. The largest odds ratio was for "order cardiovascular stress test" which was endorsed by 77 % of internists and only 33 % of other specialists. In contrast, internists were less likely to actually perform some procedures, being less likely to perform 25 of them and more likely to perform 17. The procedure with the largest difference favoring internists was pulsus paradoxus measurement (48 % vs. 10 %), while the largest difference favoring other specialists was repair obstetric laceration (1 % vs. 17 %). Meanwhile, internists were more likely to interpret the results of procedures (e.g., interpret paracentesis, 58 % vs. 21 %). The exception was for interpreting the various medical imaging procedures, which internists were less likely to interpret. The broader practice profile for internists was more pronounced when residents/fellows were compared to physicians who had completed training and entered independent practice. For example, 43 % of independent practice internists performed central line placement compared to 32 % of other specialists. However, in the resident/fellow group the corresponding percentages were 81 % and 43 %.

CONCLUSIONS: The fact that internists engage in a broader range of clinical activities has implications for residency training, initial licensure, and maintenance of certification (MOC). First, the broad practice patterns argue for a wide range of content on USMLE. The NBME is currently investigating the extent to which procedural skills can be addressed at entry into unsupervised practice. The fact that newly licensed internists see a large proportion of inpatients argues for a similar balance during their residency training. The extent to which the practice profiles of internists remain broad, or tend to narrow as internist become more seasoned, should be the study of future research as it will have implications for the focus of assessments intended to ensure MOC.

CHRONIC OPIOID THERAPY IN HOSPITALIZED PATIENTS: COMMON BUT NOT IMMUTABLE Hilary Mosher[1,2]; Lan Jiang[2]; Mary Vaughan Sarrazin[2]. [1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Iowa City VA Healthcare System, Iowa City, Iowa City, IA. (Tracking ID #1629933)

BACKGROUND: Chronic opioid therapy has grown more prevalent over the last two decades, as have concerns about effectiveness and adverse events. While a robust literature is emerging regarding outpatient management of pain conditions and chronic opioid therapy, there is little to guide management during hospitalization of patients on chronic opioid therapy. Some practitioners are concerned that this paucity of evidence may contribute to ineffective acute management or inappropriate dose escalation at hospital discharge. This study aims to define the prevalence of chronic opioid therapy among patients admitted to hospital, as well as describe the effect of hospitalization on the trajectory of chronic opioid therapy.
METHODS: This secondary analysis of Veterans Administration inpatient hospitalizations from 2004 to 2011 included all patients with an index admission, defined as a medical or surgical hospitalization occurring following a minimum 30-day hospitalization-free period. In the case of patients with multiple index admissions, one index hospitalization was chosen at random. Opioid-use status was determined using outpatient prescription records. Patients were classified into one of three categories: 1) no opioid use, defined as no outpatient opioid prescriptions in 6 months prior to hospitalization; 2) chronic opioid use, defined as 90 or more days supply of opioids prescribed within the 6 months preceding index hospitalization and 3) occasional opioid use, defined as patients who received any opioid prescription during the 6 months prior, but did not meet definition of chronic use. Opioid-use status in the 6 months post-discharge was defined similarly. Frequencies pre- and post-discharge and change in opioid-use status following hospitalization were calculated.
RESULTS: A total of 1,341,073 patient hospitalizations were included. In the 6 months prior to admission 847,664 (63.2 %) of patients had no opioid use, 232,211 (17.3 %) had chronic opioid use, and 261,198 (19.5 %) had occasional opioid use. In the 6 months following hospital discharge, 803,969 (60.0 %) had no opioid use, 232,040 (17.3 %) had chronic opioid use, and 305,064 (22.7 %) had occasional opioid use. Although the total percentages were fairly stable, a substantial number of patients transitioned between opioid use categories before and after index hospitalization (Table).
CONCLUSIONS: In this large sample of hospitalized Veterans, nearly 1 of 5 patients was on chronic opioid therapy at the time of admission, emphasizing the scope of the challenge posed by pain management for inpatients on prior chronic opioid therapy. Hospitalization appears to be a factor in both initiation and cessation of chronic opioid therapy for some patients, suggesting the hospital stay plays an under-recognized role in chronic pain management. Future work will examine opioid use by indication, compare dose intensity of opioid therapy pre- and post-hospitalization, and better characterize patients who transition between opioid-use categories.
No opioid therapy on admission N (%) *N*=847,664 Chronic opioid therapy on admission N (%) *N*=232,211 Occasional opioid therapy on admission N (%) *N*=261,198
No opioid therapy post discharge N (%) 644,834 (76.1) 37,226 (16.0) 121,909 (46.7)
Chronic opioid therapy post discharge N (%) 35,409 (4.2) 152,681 (65.8) 43,950 (16.8)
Occasional opioid therapy post discharge N (%) 167,421 (19.7) 42,304 (18.2) 95,339 (36.5)

CLINICAL DECISION-MAKING AFTER PORTABLE CHEST X-RAYS WITH 'RETROCARDIAC INFILTRATE' IN ADULT INPATIENTS Samuel E. Cohen; Calie Santana. Montefiore Medical Center, New York, NY. (Tracking ID #1642680)

BACKGROUND: As opposed to a PA/Lateral chest x-ray, the portable chest x-ray is a view from a single direction. Consequently, the retrocardiac area, seen in one dimension, is particularly difficult to evaluate. It is unclear what types of clinical decisions are made based on the limited interpretation of retrocardiac findings. Our objective was to assess how patients with portable x-rays read as equivocal or positive for 'retrocardiac infiltrate' are affected in their hospital course compared to patients with 'atelectasis', a non-specific finding.
METHODS: Our large urban academic medical center in New York performs more than 20,000 portable chest x-rays yearly. We selected adults admitted in 2011 to the inpatient medicine/surgery service who had a portable chest x-ray during their admission. We randomnly selected 100 patients whose results had the word 'retrocardiac' using our clinical information system. For comparison, we randomly selected 100 patients with x-rays that were negative for any infiltrate but positive for atelectasis. Patients were excluded if they had an ICU admission during their hospital course, if the retrocardiac/atelectatic findings were explicitly compared to similar findings reported in past imaging, or if the x-ray report included additional findings that were pathologic. We extracted clinical characteristics (inpatient service, presence of fever, elevated white count, and respiratory symptoms) and aspects of hospital course (subsequent PA/Lateral chest x-ray, CT Thorax, and antibiotic use) from our information system and via chart abstraction. The main outcomes were administration of pneumonia-related antibiotics or subsequent PA/Lateral chest x-ray or CT Thorax within 2 days of the portable x-ray. We compared differences in outcomes between our patient groups using chi-square tests.
RESULTS: Among patients with retrocardiac infiltrates, 51 % received pneumonia-related antibiotics compared to 28 % of patients with the finding of 'atelectasis' ($p<0.01$). In terms of follow-up imaging, 37 % of patients with retrocardiac infiltrates underwent follow-up PA/Lateral chest x-ray while this occurred in 10 % of patients with 'atelectasis' ($p<0.01$). Follow-up CT Thorax was performed in 11 % of patients with retrocardiac infiltrates compared with 8 % of patients with findings of 'atelectasis,' which was not significantly different.
CONCLUSIONS: There is an association between the finding of retrocardiac infiltrates on portable chest x-ray and both increased use of antibiotics and increased rates of follow-up imaging with PA/Lateral chest x-rays but not CT. Although we excluded patients in the ICU, where physicians might react more aggressively to a non-specific finding, it remains to be determined if this association is strictly due to clinical characteristics. It is also unknown if the increased treatment and testing among this group of patients is warranted or if it is excessive. Still, our findings are evidence of the current use of a limited imaging modality (portable x-rays) in clinical decision-making.

CLINICIANS AND NUMBERS: USABILITY AND VALIDITY OF A MEASURE OF CRITICAL RISK INTERPRETATION (CRIT) Tanner Caverly[1]; Allan V. Prochazka[1]; Brian P. Lucas[2]; Shane Mueller[1]; Ingrid A. Binswanger[1]; Jean Kutner[1]; Brandon Combs[1]; Daniel Matlock[1]. [1]University of Colorado Denver, Denver, CO; 2Stroger Hospital of Cook County, Chicago, IL. (Tracking ID #1631294)

BACKGROUND: Misinterpretation of benefits and harms can bias testing and treatment decisions and communication with patients. A valid measure of clinician risk interpretation is needed to assess the effect that risk interpretation has on clinical performance. We sought to determine the acceptability and validity of a measure of critical risk interpretation among different groups of clinicians.
METHODS: The critical risk interpretation test (CRIT) was developed by the authors to measure a clinician's ability to: 1. modify interpretation based on meaningful differences in the type of outcome or timeframe of a risk, 2. maintain a stable interpretation when a risk is framed in different ways and 3. correctly interpret how testing modifies risk (Table 1). Questions were developed and revised based on literature review and expert feedback. Each item was made up of 2 or more separated survey questions with items scored as correct based on the ideal responses presented in Table 1. Items with missing answers were counted as incorrect and each of the 10 items counted for 1 point. Scores on the 10 items were then transformed onto a 100 point scale. We recruited 380 clinicians at educational conferences to take a self-administered paper test: 115 nurse practitioners (NPs), 131 third year medical students, and 134 residents in

internal medicine at 2 institutions. Using a web-based survey, we administered the same test to 17 national experts (7 physicians and 10 non-physician researchers) in critically evaluating health news. We aimed to explore the test's usability, content validity, convergent validity, and predictive validity and used linear regression to test trends of test scores across groups.

RESULTS: Item usability was excellent (< 3 % non-response for each item). Item difficulty was broad (proportion of respondents who answered items correctly was 7 % to 56 %). The mean score was 42 on a 100 point scale (standard deviation 13; range 11–82). Experts had favorable views of the CRIT's clarity and content validity (Table 2). Supporting convergent validity, scores on our test correlated with other tests of related abilities - Berlin Numeracy Test (r=0.28, p<0.001); Cognitive Reflection Test (r=0.18, p=0.004). Mean test scores varied as expected among groups with differences in prior evidence-based medicine training (35 for NPs, 43 for medical students, 45 for residents, and 59 for physician experts; p<0.0001).

CONCLUSIONS: Our test of critical risk interpretation is usable, discriminates among clinicians, and demonstrates content, convergent, and predictive validity.

Table 1. Critical Risk Interpretation Test Items.

Items, Grouped by Concept
Modify interpretation based on meaningful differences
Rate a risk over the next 10 years more important than the same risk over a lifetime.***
For a screening test, understand that mortality reduction is a better end-point than disease detection rates or improved 5-year survival rates.**
Rate the risk of dying from a disease more important than the risk of getting the disease.***
Understand that a patient-oriented end-point is a better than a surrogate end-point.**
Understand that all-cause mortality is a better end-point than disease-specific mortality.**
Understand that a patient-oriented end-point is better than a composite containing surrogate end-points.**
Maintain a stable interpretation when the same risk is framed in different ways
Rate an absolute number the same as a proportion when they are equivalent.***
Rate an absolute risk reduction, a number needed to treat, and a relative risk reduction the same when they are equivalent.**
Correctly interpret how testing modifies a risk
Understand that changing a test-cutoff affects both false-positives and false negatives.*
Understand how the prevalence affects the predictive value of a test.*

*Multiple-choice questions with 4 options. **10-point response scale from 1 ("no proof") to 10 ("good proof"). ***10-point response scale from 1 ("not important") to 10 ("very important").

CLINICIANS RARELY MAKE CHANGES IN TREATMENT FOLLOWING MONITORING DENSITOMETRY IN WOMEN ON THERAPY FOR LOW BONE MINERAL DENSITY Michelle Rappaport; Brandon Combs; Tanner Caverly; Trina C. Mizrahi; Daniel Matlock. University of Colorado School of Medicine, Denver, CO. (Tracking ID #1594564)

BACKGROUND: Approximately 98 % of patients on bisphosphonates experience an increase in bone mineral density (BMD) suggesting that routine monitoring with repeat densitometry may not be necessary. Furthermore, guidelines for monitoring low BMD therapy vary widely, ranging from recommending yearly monitoring to no monitoring at all. This study explored clinician rationale for ordering monitoring dual-energy X-ray absorptiometry (DXA) scans and the management changes that follow in an average risk population on treatment for low BMD.

METHODS: We identified 1782 unique patients with more than 1 DXA between January 1, 2003 and August 1, 2011 who had been to one of 5 primary care clinics at the University of Colorado Hospital within the past 18 months. Men (n=120) and patients on medications or with conditions known to cause secondary osteoporosis (n=580) were excluded. Of 1082 patients remaining, 552 had exposure to treatment defined as: bisphosphonates, teriparatide, raloxifene, denosumab, calcitonin, hormone replacement therapy, or ergocalciferol 50,000 IU. We reviewed charts on a random sample of 92 women, collecting data on clinician rationale for ordering monitoring DXA and the management changes that followed. We defined monitoring DXA as any subsequent DXA after initiating treatment for low BMD with bisphosphonates or teriparatide. Management changes due to DXA were defined as: a) change in drug class in setting of decrease in BMD; b) stopping drug in the setting of stable or increased BMD; or c) stopping drug in a patient with osteopenia whose FRAX® score would not merit treatment. We considered changes as being due to factors other than monitoring DXA if: a) change occurred due to drug side-effects or payment issues; b) medication change in the setting of a stable or increased BMD; c) or drug holiday in the setting of decreased BMD.

RESULTS: Average age of our population was 68.4 years and mean calculated 10-year probability of hip or combined major osteoporotic fracture (by FRAX®) was 3.46 % and 13.31 % respectively. Ninety-one (99 %) patients were treated with bisphosphonates. Our population received 196 monitoring DXA scans during the study period and clinicians ordered scans out of a sense that they were "due" 90 % of the time. Most scans (n=165, 84 %) resulted in no change in management. Fifteen (8 %) scans resulted in changes not due to DXA. There were 16 changes due to DXA (8 %), and of those, 5 (3 %) were starting a drug or changing drug class and 11 (6 %) were drug stoppages. Thirty-six scans showed a significant decrease in BMD and most (n=26, 72 %) led to no change in therapy. Of the 10 changes that occurred when BMD decreased, half were not due to DXA.

CONCLUSIONS: Our data indicate that clinicians frequently order monitoring DXA scans out of a sense they are "due" and rarely make changes in treatment based on the results. When treatment changes occur, approximately half are not due to DXA and thus could have been made without additional testing. Even when DXA showed significant decline in BMD, changes were uncommon. We conclude that monitoring DXA scans could be done less often. This study highlights the need for additional research to assess the value of monitoring DXA scans before this practice can be justified.

COLORECTAL CANCER SCREENING IN A VULNERABLE POPULATION: CAN PROVIDERS PREDICT WHO IS LIKELY TO COMPLETE FECAL OCCULT BLOOD TESTING? Matthew Chin[1]; Dana Romalis[1,2]; Sara Doorley[1,2]; Angela Bymaster[1,2]; Halley Tsai[1]; Ahmad Kamal[1,3]; Cheryl Ho[1,2]. [1]Santa Clara Valley Medical Center, San Jose, CA; [2]Santa Clara Valley Medical Center, San Jose, CA; [3]Santa Clara Valley Medical Center, San Jose, CA. (Tracking ID #1621779)

BACKGROUND: Colorectal cancer (CRC) screening is a cornerstone of preventative medicine and an important component of primary care. Studies have shown that the rates of CRC screening are lower in the uninsured and marginalized patient populations. Fecal occult blood testing (FOBT) is part of one strategy for CRC screening, but requires that a patient be counseled annually on the proper collection of three consecutive stool samples after the visit. Given the unique barriers to care in the homeless population, screening is often overlooked in favor of more acute concerns. The purpose of this study is to identify if providers are able to predict which patients are most likely to complete FOBT, to determine if alternative screening modalities may be more practical in this population.

METHODS: Providers at a multidisciplinary safety-net healthcare system servicing an ethnically diverse homeless population were included in the study. Over a 6-month period, all patients eligible for FOBT were offered screening. After each encounter, providers were asked to rate, on a Likert scale of 1–5, how likely it was that they felt patients would complete screening. Demographic data, including age, sex, ethnicity (by patient self-report), and number of psychiatric conditions (by billing data), was collected. Actual rates of test completion were determined at the end of the study period

RESULTS: 110 patients (71 male, 39 female, mean age 55 years), were offered screening. 35 (32 %) patients successfully completed the screening. 37 (34 %) patients were judged to have a low likelihood of compliance (score of 1 or 2), of which 4 (11 %) completed the screening. 44 (40 %) patients were judged to have a high likelihood of compliance (score of 4 or 5), of which 18 (41 %) completed the screening. 85 % of patients had at least 1 psychiatric diagnosis. 46 patients, with an average likelihood score of 3.3, had 1 or fewer psychiatric diagnoses, of which 15 (33 %) completed the screening. 45 patients, with an average likelihood score of 2.5, had at least 3 psychiatric diagnoses, of which 10 (22 %) completed the screening.
CONCLUSIONS: Overall rates of FOBT compliance in our study were low, but appeared to be twice as high as that reported in other studies which examined similar populations. Patients with a low likelihood score were less likely to complete screening than those with a high likelihood score. Psychiatric disease, which is common in this population, is also a predictor of poor patient compliance. One of the barriers to quality care in a vulnerable population is the irregular schedule of patient visits, perhaps making annual FOBT a less practical strategy for CRC screening. Over the past decade there has been a nationwide trend away from the strategy of annual FOBT in tandem with sigmoidoscopy every 5 years in favor of colonoscopy, which, in an average risk population, is required once every ten years, independent of annual FOBT, and has the potential to be both diagnostic and therapeutic. In a safety net healthcare system with limited resources, FOBT is used as a tool to determine which patients are most likely to benefit from endoscopic CRC screening. Further studies may be useful to determine if provider predictability of patient compliance could be a valid measure to determine which patients would be most likely to take advantage of more involved CRC screening strategies.

COMMUNITIES IMPACT DIABETES CENTER'S VISION HEALTH TOOLKIT: UTILIZING LAY HEALTH SOCIAL SERVICE PROVIDERS AS MESSENGERS OF VISION HEALTH INFORMATION Michelle A. Ramos[1]; Ashley Fox[1]; Brett Ives[2]; Carol Horowitz[1,3]. [1]Mount Sinai School of Medicine, New York, NY; [2]Mount Sinai School of Medicine, New York, NY; [3]Mount Sinai School of Medicine, New York, NY. (Tracking ID #1640432)

BACKGROUND: Racial and ethnic disparities in vision impairment are prevalent as are low rates for recommended eye screenings, such as annual dilated eye exams for people with diabetes (40–65 %). A community-academic partnership aimed to improve vision screening in a low-income, minority neighborhood by developing a multi-component vision health toolkit for social service providers to promote comprehensive vision exams among their consumers.
METHODS: The team developed and tested a bilingual toolkit that included posters, brochures, table tents and magnifier cards. Thirty-seven local social service agencies (i.e., senior centers, food pantries), faith-based organizations and health centers were recruited to adopt the toolkit and have at least one staff member or volunteer serve as a Vision Health Champion for that site. We surveyed a subset of consumers at 15 intervention and 3 control sites before and 6 months after disseminating the toolkits to assess receipt of comprehensive eye exams, vision knowledge and comorbidities, and surveyed Vision Health Champions to assess implementation and provider knowledge at these same times.
RESULTS: The 156 consumers surveyed were largely female (68 %), Black (55 %) and had high diabetes (23 %) and hypertension (33 %) rates. At baseline, 72 % reported an eye exam in the past year and vision knowledge was fairly high (91 % correctly answered 3 or more out of 7 vision knowledge items). There was no baseline difference between intervention and control sites self-reported eye exam rates in the past year. Six month follow-up surveys were completed with 62 % of consumers. People at intervention sites were more likely to report a comprehensive eye exam in the past 6 months (45 % vs. 24 %, $p=0.06$). Those with diabetes at intervention sites were also more likely to have had an eye exam in the past 6 months than those with diabetes at control sites (66 % vs. 33 %, $p<0.01$). With respect to 44 of 61 Vision Health Champions surveyed at follow-up (72 % response rate), 80 % stated that the toolkit was easy to implement, 32 % integrated it into pre-existing programming and 90 % planned to continue using it.
CONCLUSIONS: Even in a small pilot project, we demonstrated a significant increase in comprehensive eye examinations at intervention sites compared with control sites and among the targeted group - individuals with diabetes. We further demonstrated the feasibility of implementing a sustainable community-based intervention in a low-income setting at locations where people frequently congregate and interact with a range of social service providers. Novel, scalable approaches such as the use of Vision Health Champions in social service settings are a viable means of preventing and controlling diabetes complications, including vision loss.

COMMUNITY PARTNERED PARTICIPATORY RESEARCH (CPPR) AS AN EFFECTIVE METHOD FOR DEVELOPING NEW PARADIGMS FOR THE RECRUITMENT AND RETENTION OF UNDERREPRESENTED POPULATIONS IN MEDICAL RESEARCH Ibrahima Sankare[1]; Rachelle Bross[2]; Arleen Brown[1]; Keyonna M. King[1]; Loretta Jones[3]; D'Ann Morris[4]; Keith C. Norris[5]; Felica U. Jones[3]; Aziza L. Wright[3,5]; Sigrid K. Madrigal[3]; Dennishia Banner[3]; Roberto Vargas[1]; Nell Forge[5]; Lujia Zhang[1]; Katherine L. Kahn[1]. [1]UCLA, Los Angeles, CA; [2]Los Angeles Biomedical Research Institute, LOS ANGELES, CA; [3]Healthy African American Families, LOS ANGELES, CA; [4]Los Angeles Urban League, LOS ANGELES, CA; [5]Charles Drew University, LOS ANGELES, CA. (Tracking ID #1640988)

BACKGROUND: Low levels of recruitment, retention and participation of minority populations in medical research studies hinder efforts to address and reduce ethnic and racial disparities in health care and health status. As part of the Healthy Community Neighborhood Initiative (HCNI) community-partnered study that aims to improve health and health care in a community in South Los Angeles, we (1) identified barriers to participation of minority populations in research, and (2) identified effective recruitment and retention strategies for use with predominantly African American and Latino residents in South Los Angeles.
METHODS: Using the PubMed database, we conducted a literature review and found 20 articles specifically related to the recruitment and retention of federally underrepresented minorities (African Americans/blacks, Latinos/Hispanics). We evaluated each article based on: (1) the use of a CPPR process to design the recruitment and retention strategies, (2) the effectiveness of reported strategies in yielding positive outcomes in a predominantly Latino and African American populated area, and (3) the effectiveness of these strategies in generating trust among these demographics that have historically mistrusted health-related studies due to negative historical precedents. The findings of the selected articles were summarized in an oral presentation to community and academic partners. To reflect the diversity of the HCNI partners in the selection of recommended strategies, 13 HCNI community and academic partners subsequently ranked each of the identified strategies. The HCNI partners then applied the highest ranked strategies to recruitment efforts in South Los Angeles and queried enrolled study participants about what motivated their study participation.
RESULTS: We identified 10 recruitment and 17 retention strategies that had been proven to increase participation of underrepresented populations in medical research by maximizing the quality of a research participant's experience through (1) meaningful interactions with study team members, (2) demonstration of appreciation for the participant's efforts and (3) the provision of feedback throughout and upon the completion of the research study. The three highest ranked recruitment strategies were: word of mouth, use of newsletters, and postings of fliers on bulletin boards. The highest ranked retention strategies were: compensation through gift cards, mailing of holiday cards, and provision of certificates of study completion. To date, the HCNI partners have contacted 90 potential participants and enrolled 79 participants using a combination of the cited strategies. Sixty percent of the enrolled

participants cited word of mouth as the strategy that most motivated their interest in study participation.
CONCLUSIONS: CPPR provides an extraordinary opportunity to identify relevant and effective mechanisms for recruiting underrepresented populations. After applying recruitment strategies supported by the literature and by a diverse set of community-academic partners, we learned from enrolled study participants that "word of mouth" involving personal interaction was the most effective recruitment strategy in this community. While initially, this recruitment strategy may cause selection bias as we disrupt the mistrust barrier, with time, the development of trust between community and academia is likely to facilitate building a highly engaged and unbiased population-based sample.

COMMUNITY CHARACTERISTICS ASSOCIATED WITH THE LOSS OF LOCAL RURAL HEALTH CLINICS AND CENTERS
Michelle Ko[1]; Janet R. Cummings[2]. [1]UCSF, San Francisco, CA; [2]Emory University, Atlanta, GA. (Tracking ID #1642708)

BACKGROUND: The Rural Health Clinics (RHCs) and Federally Qualified Health Centers (FQHCs) programs provide critical support for primary care services to underserved rural areas. In the past decade, both RHCs and FQHCs received considerable expansions in federal investment. Nevertheless, these providers face substantial challenges to survive, including limited outside funds, difficulties in staff recruitment, isolation from larger health systems, and lack of community support. We examined associations between community characteristics and loss of rural health centers from 2000 to 2007.
METHODS: We conducted a retrospective cohort study of 1354 U.S. rural counties from 2000 to 2007 using the Area Resource File 2008. Rural counties were defined as those not located in Metropolitan or Micropolitan Statistical Areas. Rural health center supply was measured as the total number of RHCs and FQHCs in the county. The primary outcome was whether the county experienced a net loss in the number of rural health centers from 2000 to 2007. We performed logistic regression models to estimate associations between the outcome and multiple community characteristics, including percent urbanized population, poverty rates, percentage of non-white minorities, elderly population and infant mortality rates. Models controlled for total population, physician supply, the number of hospitals, and the baseline number of clinics/centers. We estimated two models: (1) community characteristics at baseline in 2000, and (2) measures of change over time from 2000 to 2007. For significant characteristics, we calculated predicted probabilities of loss of centers for high (95th percentile) versus low (5th percentile) counties. In secondary analyses, we also tested associations between community characteristics and gains in the number of rural health centers. Models adjusted for within-state correlation using state-level clustered robust standard errors.
RESULTS: In 2000, 917 rural counties maintained at least one rural health center. As of 2007, 197 counties lost one or more centers. In multivariate analyses, the percentage of minority residents was positively associated with loss of rural health centers (OR: 1.018, $p<0.001$), whereas the poverty rate was negatively associated (OR: 0.948, $p=0.025$). The predicted probability of loss of rural health centers was 22.1 % for counties with a high minority population, vs. 8.6 % for low minority counties ($p<0.001$ for both). The effects of other community characteristics, including urbanization and elderly population, were not significant. Likewise, measures of change in community characteristics over time were also not significant. In the same period, 464 counties experienced a net increase in the number of rural health centers. Controlling for other community characteristics, minority percentage was associated with lower odds of addition of a new health center (OR: 0.982, $p<0.001$).
CONCLUSIONS: Rural minority populations may be at increased risk of loss of access to primary care safety net providers. In the absence of rural health centers, the potential for improved access to care, as a result of coverage expansions under the Affordable Care Act, may not be fully realized.

COMMUNITY-PARTNERED CLUSTER-RANDOMIZED COMPARATIVE EFFECTIVENESS TRIAL OF COMMUNITY ENGAGEMENT AND PLANNING OR PROGRAM TECHNICAL ASSISTANCE TO ADDRESS DEPRESSION DISPARITIES
Michael Ong[10]; Kenneth B. Wells[1,2]; Loretta Jones[5,6]; Bowen Chung[1,7]; Elizabeth Dixon[8]; Lingqi Tang[2,4]; James Gilmore[9]; Cathy Sherbourne[1]; Victoria K. Ngo1; Susan E. Stockdale[2,12]; Esmeralda Ramos[2]; Thomas R. Belin[3,11]; Jeanne Miranda[2,4]. 1RAND Corporation, Santa Monica, CA; 2UCLA, Los Angeles, CA; 3UCLA, Los Angeles, CA; [4]UCLA, Los Angeles, CA; [5]Healthy African American Families II, Los Angeles, CA; [6]Charles R. Drew University of Medicine and Science, Los Angeles, CA; [7]Harbor-UCLA Medical Center, Torrance, CA; [8]QueensCare Health and Faith Partnership, Los Angeles, CA; [9]Behavioral Health Services, Gardena, CA; [10]UCLA, Los Angeles, CA; [11]UCLA, Los Angeles, CA; [12]Greater Los Angeles VA Health Care System, Los Angeles, CA. (Tracking ID #1640930)

BACKGROUND: Depression contributes to disability and there are ethnic and racial disparities in access to and outcomes of care. Quality improvement (QI) programs for depression in primary care improve outcomes relative to usual care, but little is known about whether implementing them across health and social service programs in under-resourced communities improves outcomes. This study compared the effectiveness of two approaches to implement depression QI, a community-based participatory approach promoting multi-sector collaboration (community engagement or CE) compared to a typical QI approach focused on individual programs(technical assistance or TA), at improving client health and quality of life outcomes.
METHODS: We conducted a group-level randomized comparative effectiveness trial in two under-resourced communities. We identified and enrolled 93 programs from health, social and other services sectors using a community partnered approach; matched programs were randomized to the CE or TA trial arms. Of the 4,440 clients screened from 93 programs, 1,322 were eligible by PHQ-8>= 10; 1,246 enrolled and 1,018 completed baseline or 6 month follow-up. Primary outcome measures were self-reported mental health quality of life and depressive symptoms. We conducted intent-to-treat analyses using logistic regression models for dichotomous measures and loglinear models for counts, adjusting for baseline status of the dependent variable and covariates (age, sex, >=3 chronic conditions, education, race/ethnicity, family poverty, past-year alcohol abuse or illicit drug use, past-year depressive disorder, and community). All analyses accounted for clustering of clients within programs, weighting to characteristics of the eligible sample, and item-level imputation for missing data and wave-level imputation for missing surveys.
RESULTS: Of 1,018 depressed clients, 57 % were female, 87 % were Latino and/or African American; 44 % had less than a high school education, 74 % had income below the poverty level, 20 % worked and 54 % were uninsured. The percentage having past-year depressive disorder was 62 %, while 39 % had substance abuse and 55 % had multiple chronic conditions. Over half had risk factors for homelessness. There were no significant differences by intervention status. Community engagement was significantly ($p<0.05$) more effective than program technical assistance at reducing poor mental health quality of life (odds ratio or OR: 0.74), improving physical activity (OR: 1.50), reducing risk factors for homelessness (OR: 0.61), reducing hospitalizations for behavioral health conditions (OR: 0.51) and medication visits among mental health specialty users (OR: 0.49), while increasing depression care visits in primary care/public health (OR: 2.63), faith-based (OR: 2.84), and park/community center (OR: 6.20) settings. Employment, antidepressant use, and total depression contacts were not significantly affected ($p>0.05$).
CONCLUSIONS: Community engagement to collaboratively address depression across multiple sectors was more effective than individual program technical assistance in improving mental health quality of life, physical activity and homelessness risk factors while shifting utilization away from hospitalizations and mental health specialty medication visits toward primary care and community-based sectors, offering a partnership model to address multiple outcome disparities for depressed clients in under-resourced communities.

COMMUNITY-PARTNERED EVALUATION OF DEPRESSION SERVICES FOR CLIENTS OF COMMUNITY-BASED AGENCIES IN UNDER-RESOURCED COMMUNITIES IN LOS ANGELES
Michael Ong[3]; Jeanne Miranda[1,2]; Loretta Jones[4,5]; Bowen Chung[6,7]; Elizabeth Dixon[8]; Lingqi Tang[1,2]; James Gilmore[9]; Cathy Sherbourne[6]; Victoria K. Ngo[6]; Susan E. Stockdale1,[10]; Esmeralda Ramos1; Thomas R. Belin[11,12]; Kenneth B. Wells[1,6]. [1]UCLA, Los Angeles, CA; [2]UCLA, Los Angeles, CA; [3]UCLA, Los Angeles, CA; [4]Healthy African American Families II, Los Angeles, CA; [5]Charles R. Drew University of Medicine and Science, Los Angeles, CA; [6]RAND Corporation, Santa Monica, CA; [7]Harbor-UCLA Medical Center, Torrance, CA; [8]QueensCare Health and Faith Partnership, Los Angeles, CA; [9]Behavioral Health Services, Gardena, CA; [10]VA Greater Los Angeles Healthcare System, Los Angeles, CA; [11]UCLA, Los Angeles, CA; 12UCLA, Los Angeles, CA. (Tracking ID #1636684)

BACKGROUND: As medical homes are developing under health reform, little is known regarding depression services need and use by diverse safety net populations in under-resourced communities. For chronic conditions like depression, primary care services may face new opportunities to partner with diverse community service providers, such as those in social service and substance abuse centers, to support a collaborative care model of treating depression. This study aimed to understand the distribution of need and current burden of services for depression in under-resourced, diverse urban communities.
METHODS: We analyzed data from client screening and follow-up surveys from the baseline phase of a community-based participatory research trial to improve depression services within two under-resourced, diverse communities. 93 programs, including 17 primary care/public health, 18 mental health, 20 substance abuse, 10 homeless services, and 28 social/other community services were identified through a community-partnered process and participated in the trial. 4,440 clients were screened from the 93 programs, 1,322 were potentially depressed by PHQ-8 and gave contact information; 1,246 enrolled and 981 completed surveys. We conducted univariate analyses to describe the sample and bivariate analyses to compare types of screening locations. Significance testing ($p < 0.05$) was conducted accounting for intra-class correlation within program using Chi-square tests for bivariate analyses. To control for potential response bias, attrition weights were constructed by fitting logistic regression models stratified by intervention condition to predict enrollment status and baseline completion from screener predictors. For item level missing data (<5 % for all variables except 10–15 % for income and mental health disorders assessed by the Mini-international neuropsychiatric interview), we used an extended hot-deck multiple imputation based on the predictive mean matching methods. We imputed 5 data sets, averaged results and adjusted standard errors for uncertainty due to imputation. We conducted 3 sensitivity analyses: 1) multiple imputation for missing surveys to the full eligible sample (1,322); 2) raw data; and 3) sex and age adjustment.
RESULTS: Overall, 69.2 % (SE: 2.5 %) of clients had a primary care/public health visit in the prior 6 months. Depression prevalence ranged from 51.9 % (SE: 3.7 %) in mental health programs to 36.2 % (SE: 2.5 %) in primary care/public health programs to 17.2 % (SE: 2.2 %) in social-community programs. 41.7 % (SE: 2.4 %) of clients had primary care/public health visits for mental health/depression. However, primary care/public health settings had only 7.7 % and mental health specialty care settings had only 26.6 % of the total volume of depression contacts. Clients received most of their depression services (65.8 %) outside of traditional healthcare settings, and in multiple program settings (2.0, SE=0.1). More clients preferred counseling (90.0 %, SE: 1.1 %) over medication (59.9 %, SE: 2.7 %) for depression treatment.
CONCLUSIONS: Need for depression care was high and a broad range of agencies provide depression-related care. Although most participants had contact with primary care, most depression services occurred outside of primary care settings and the majority preferred counseling over medication for depression treatment, emphasizing the need to coordinate and support the quality of community-based services across diverse community settings.

COMMUNITY-BASED VERSUS RANDOM DIGIT DIALING SAMPLES IN CHRONIC DISEASE PREVALENCE ESTIMATES AMONG OLDER BLACK MEN IN NEW YORK CITY
Helen Cole. New York University School of Medicine, New York, NY. (Tracking ID #1641743)

BACKGROUND: Accurate assessment of the prevalence of chronic diseases and health behaviors among underserved populations is essential for addressing disparities. Previous research suggests probabilistic sampling modalities such as random digit dialing (RDD) may yield different epidemiologic estimates than diverse venue-based sampling in minority populations. We aimed to compare these sampling approaches in older black men in New York City (NYC).
METHODS: A short survey was administered to Black men age 50 and over intercepted in community-based venues including barbershops, mosques, churches, soup kitchens, and social service agencies throughout New York City as part of eligibility screening for two large randomized-control trials. Survey data included self-reported hypertension, diabetes, high cholesterol and history of timely colorectal cancer (CRC) screening. We used descriptive statistics to calculate prevalence rates within our community-based sample, and compared them to estimates from the NYC Community Health Survey (CHS), a population-based RDD survey.
RESULTS: Among 4,888 survey respondents recruited from community-based sites, prevalence rates for self-reported hypertension, diabetes and high cholesterol were 58.6 %, 21.1 % and 31.3 % respectively. Prevalence rates for hypertension, diabetes and high cholesterol among black men over 50 in the CHS were 55.9 %, 26.5 % and 43.5 %. Compared to 75 % of black men >50 in the CHS, only 48.0 % of the community-based sample reported having ever having had a screening colonoscopy. Differences in prevalence estimates between the CHS and the community-based sample were statistically significant for diabetes, high cholesterol and history of CRC screening ($p<0.0001$). In the venue-based sample, over 9 % of the screened individuals did not have a working telephone. Almost one third of the venue-based sample had less than a high school education compared to only 20 % of the CHS sample. However, demographic variables did not explain the difference in self-reported prevalence estimates for diabetes, high cholesterol, or high blood pressure or in self-reported CRC screening history.
CONCLUSIONS: The prevalence of certain chronic diseases and health behaviors among older Black men recruited from community-based settings in NYC differed substantially from population-based estimates. This marked discordance is particularly important for CRC screening; since black men have the highest CRC mortality rates, potentially due to lack of timely screening. Research is needed to improve health assessment in black men who may not be captured by conventional population-based survey methods.

COMORBID DEPRESSION AND SUBSTANCE ABUSE IN SAFETY-NET CLIENTS OF HEALTH AND COMMUNITY-BASED AGENCIES IN LOS ANGELES: CLINICAL NEEDS AND SERVICE USE PATTERNS
Evelyn Chang[1]; Bowen Chung[3]; James Gilmore[4]; Lingqi Tang[3]; Anna Morgan[5]; Kenneth B. Wells[2,3]. 1VA- Greater Los Angeles, Los Angeles, CA; [2]RAND, Santa Monica, CA; [3]UCLA, Los Angeles, CA; [4]Behavioral Health Services, Inc., Los Angeles, CA; [5]Harbor- UCLA, Torrance, CA. (Tracking ID #1624043)

BACKGROUND: Depression and substance use disorders (SUD) are common among low-income, minority adults who may receive services from health and other community-based sectors. Depending on the sector visited, this population may receive screening, treatment or referral for depression or substance use but rarely integrated services. Little is known about the level of comorbidity across a range of service sectors supporting safety-net clients or use of services for depression in the context of substance abuse comorbidity for clients across diverse community-based settings. This study describes clinical characteristics and service utilization for low-income, primarily African-American and Latino, adults with depression with and without comorbid substance abuse in under-resourced communities.

METHODS: The study uses baseline data from Community Partners in Care (CPIC), a Community-Partnered Participatory Research initiative to improve depression services in two under-resourced communities in Los Angeles County: Hollywood-Metro and South Los Angeles. Clients were screened for depression (PHQ 8>=10) in primary care/public health (PC), mental health (MH), substance abuse (SA), and social services (SS), and other community-based settings such as churches and senior centers. Eligible depressed clients enrolled and completed a baseline survey (n=845). We conducted univariate and bivariate analyses to describe the sample and compare those with and without comorbid SA in clinical need and services utilization in the past 6 months.
RESULTS: Across sectors, 48.5 % (n=407) had co-morbid substance use disorder (SUD); most (n=323, 79.4 %) were receiving SUD treatment, but less than half (46.0 %) had health insurance. Most (73.8 %) had family incomes below poverty levels with no significant difference by presence of co-morbid SUD. Clients with co-morbid SUD were more likely than those without to be in transitional housing (21.3 % vs 3.8 %, p<0.001) and had a higher rates of arrests (39.9 % vs 7.3 %, p<0.001), 12-month depressive disorder (73.5 % vs 53.8 %, p<0.001), post-traumatic stress disorder (57.8 % vs 39.9 %, p<0.001), and mania/psychosis (60.8 % vs 27.7 %, p<0.001). A greater proportion of clients with both depressive symptoms and SUD went to the ER for any health problems (59.1 % vs 46.7 %, p<0.001) and were significantly more likely to be admitted for an alcohol, drug, or emotional problem than those without SUD (23.0 % vs 7.9 %, p<0.001). Clients with both depressive symptoms and SUD had more MH specialty visits (70.4 % vs 50.6 %, p<0.001) and fewer PC visits (65.6 % vs 74.9 %, p=0.006) than those without SUD. Those with comorbid SUD received depression services during 67.9 % of visits to outpatient MH clinics, 65.0 % of visits to PC, 73.4 % of visits to SA agencies, 56.6 % of visits to SS agencies, 44.6 % of visits to churches, and 19.0 % of visits to senior centers.
CONCLUSIONS: Half of low-income minority adult clients across health and community-based agencies with depressive symptoms were found to have co-morbid SUD. These individuals have significant psychosocial stressors, including lack of housing, insurance and arrests. Depressed clients with co-morbid SUD utilized emergency, MH, and SS agencies at higher rates than those without SUD and had higher admission rates. The high prevalence of comorbid substance abuse across diverse agencies supporting safety net clients suggests that a community-wide approach may be needed to stabilize health and social outcomes for this vulnerable population.

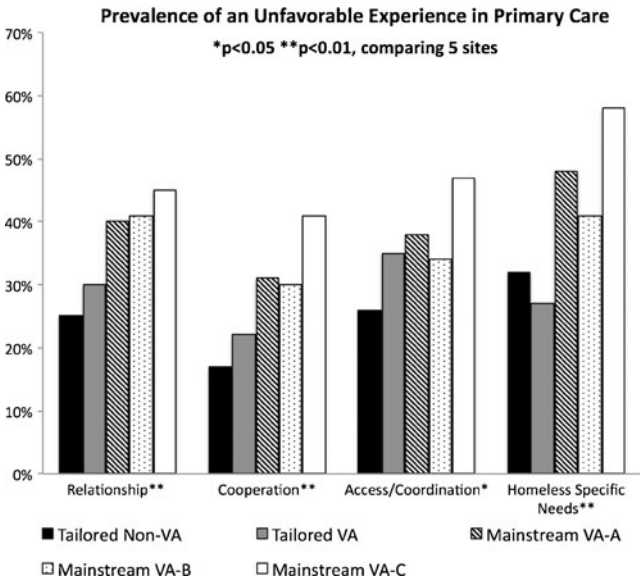
COMPARATIVE EFFECTIVENESS OF PHARMACOLOGIC AND MECHANICAL STRATEGIES FOR PREVENTION OF VTE AMONG SPECIAL POPULATIONS Sonal Singh[1,4]; Elliott R. Haut[2]; Daniel Brotman[1,3]; Ritu Sharma[4]; Yohalakshmi Chelladurai[4]; Kenneth M. Shermock[3]; Sosena Kebede[1,3]; Kent A. Stevens[2]; Luis J. Garcia[2]; Kalpana Prakasa[1,3]; Hasan M. Shihab[4]; Jodi B. Segal[1,4]. [1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]Johns Hopkins University, Baltimore, MD. (Tracking ID #1626687)

BACKGROUND: Venous thromboembolism is a prevalent and avoidable complication of hospitalization. Patients hospitalized with trauma, traumatic brain injury, burns, or liver disease; patients on antiplatelet therapy, obese or underweight patients, those having obesity surgery, or with acute or chronic renal failure have unequal risks for bleeding and thrombosis and may benefit differently from prophylactic medication. Our objective was to systematically review the comparative effectiveness and safety of pharmacological and mechanical methods of prophylaxis of VTE in these special populations
METHODS: We searched MEDLINE®, EMBASE®, SCOPUS, CINAHL®, www.clinicaltrials.gov, International Pharmaceutical Abstracts (IPA), and the Cochrane Library in July 2012. This was complemented by hand searches from the reference lists and unpublished studies provided by sponsors. We included randomized controlled trials on these special populations. Since these populations may be excluded from trials, we also included controlled observational studies of pharmacologic agents, and uncontrolled observational studies and case series of inferior vena cava filter use. Two reviewers evaluated studies for eligibility, serially abstracted data using standardized forms, and independently evaluated the risk of bias in the studies and strength of evidence for major outcomes and comparisons. We qualitatively synthesized the evidence and also pooled the relative risks from the controlled studies.
RESULTS: After a review of 30,902 unique citations, we included 102 studies of which just 8 were trials. Fifty eight studies reported on patients with trauma, thirteen studies reported on patients with traumatic brain injury, one study reported on patients with burns, two studies reported on patients with antiplatelet agents, twenty one studies reported on patients having bariatric surgery, two studies reported on obese patients and five studies reported on patients with renal failure. We found no studies that reported on patients with liver disease or those who were underweight. The majority of observational studies had a high risk of bias. The strength of evidence is low that IVC filter placement is associated with a lower incidence of PE and fatal PE in hospitalized patients with trauma compared to no IVC filter placement. The strength of evidence is low that enoxaparin reduces DVT and that UFH reduces mortality in patients with TBI when compared to patients without anticoagulation. Low grade evidence supports that IVC filters with usual care are associated with increased mortality and do not decrease the risk of PE in patients undergoing bariatric surgery compared to usual care alone. All other comparisons, for all of the key questions, had insufficient evidence to permit conclusions.
CONCLUSIONS: Our comparative effectiveness review demonstrates that there is a paucity of high quality evidence to inform treatment of these special populations. Future research using robust observational studies that control for confounding by indication and disease severity are needed as randomized controlled trials typically exclude or do not report on these populations

COMPARING HOMELESS PERSONS' CARE EXPERIENCES IN TAILORED VERSUS NON-TAILORED PRIMARY CARE SETTINGS Stefan Kertesz[1]; Theresa W. Kim[2]; Adam Gordon[3]; Alexander S. Young[5]; David E. Pollio[4]; Richard N. Jones[8]; Cheryl L. Holt[6]; Erika L. Austin[1]; David Roth[7]. [1]Birmingham VA Medical Center & U. Alabama Birmingham, Birmingham, AL; [2]Boston University, Boston, MA; [3]VA Pittsburgh Health System and U. Pittsburgh, Pittsburgh, PA; [4]U. Alabama, Tuscaloosa, AL; [5]VA Greater Los Angeles, Los Angeles, CA; [6]U. Maryland, Baltimore, MD; [7]Johns Hopkins University, Baltimore, MD; [8]Hebrew SeniorLife, Boston, MA. (Tracking ID #1638015)

BACKGROUND: Although the Affordable Care Act's expansion of coverage may increase access to primary care (PC) for vulnerable populations, like the homeless, a key challenge will be to promote innovative delivery models that can sustain their engagement in PC. Some agencies tailor PC services for homeless patients in ways that include outreach, care in shelters or streets, team-based care, co-location of providers, provider education, tangible items (i.e. clothing, food), or a consumer governance role. To date, there has been no study of whether these "tailored" service designs yield a better patient experience. Using a new survey we developed for this population, we compared homeless patients' perceptions of PC across settings that differed in the degree of PC service tailoring.
METHODS: We surveyed homeless-experienced patients at 3 mainstream PC settings in the Veterans Administration (VA) (n=312), a homeless-tailored VA clinic (n=94), and a highly tailored non-VA Health Care for the Homeless Program (n=195). Patient ratings were obtained with the 33-item Primary Care Quality-Homeless (PCQ-H) survey. Derived from interviews and the application of Item Response Theory, the PCQ-H survey results in 4 scales: 1) Patient-Clinician Relationship, 2) Cooperation among clinicians, 3) Accessibility/Coordination, and 4) Homeless-Specific Needs. A categorical "unfavorable experience" was defined by the number of "negative" responses in the top 33 % for each scale. A negative response is agreement with a negative item (e.g. "It is often difficult to get health care at this place") or disagreement with a positive item. In comparing sites, we

adjusted for patient health and demographic characteristics with linear and logistic regression.
RESULTS: Mean PCQ-H scores at the tailored non-VA site were higher than those from 3 Mainstream VA sites ($p<0.001$). Adjusting for patient characteristics, these differences remained significant for scales assessing Patient-Clinician Relationship ($p<0.001$) and Cooperation ($p=0.004$). In categorical analysis, an unfavorable experience was 1.5–2 times more common at Mainstream VA sites compared to the Tailored non-VA site (all $p<0.05$, Figure), remaining significant after adjusting for patient characteristics for the Relationship, Cooperation and Access/Coordination scales.
CONCLUSIONS: Tailored primary care service design is associated with a superior experience for homeless patients. Further research will need to identify which aspects of tailoring matter most, and are most readily adopted in new settings.



COMPARING SELF-PERCEIVED CROSS-CULTURAL SKILLFULNESS BETWEEN PHYSICIANS AND NURSES AT A SWISS UNIVERSITY HOSPITAL: DOES PROVIDER ROLE MAKE A DIFFERENCE? Alejandra Casillas[1,3]; Sophie Paroz[1]; Alexander Green[2]; Hans Wolff[3]; Patrick Bodenmann[1]. [1]Lausanne University Hospital, Lausanne, Switzerland; [2]Harvard Medical School, Boston, MA; [3]Geneva University Hospital, Genève, Switzerland. (Tracking ID #1618344)

BACKGROUND: As the diversity of the Swiss population evolves, measuring providers' cultural competency and understanding what contextual factors may influence this skillfulness is necessary. We compared perceived skillfulness and explanatory predictors between physicians and nurses at one of five university hospitals. Given a lack of study on the effect of provider role, this was doubly relevant from a Swiss perspective, where nurse practitioners are increasingly assuming clinical responsibilities for vulnerable patients.
METHODS: A 64-item cultural competency questionnaire, including translated/back-translated items from the validated survey, "Residency training in cross-cultural care," was mailed in November 2010 to residents, chief residents and nurses working in patient-care units at Lausanne's university hospital. Using Student's t-tests, we compared physicians' and nurses' mean composite scores for the nine self-perceived skillfulness items (4-point Likert-scale), and proportion of "3-good/4-very good" responses using Chi-square tests. We used linear regression to examine how provider role (physician vs. nurse) was associated with composite scores, adjusting for demographics (gender, non-French dominant language), workplace (time at institution, work-unit "sensitized" to cultural-care), items on reported cultural-competence training, and on cross-cultural care problem-awareness. We subsequently stratified analyses to physicians and nurses, alone. We present results significant at the $p=0.05$ level.
RESULTS: Of 885 mailed questionnaires, 371 individuals (41.2 %) returned the completed survey: 123 (33.6 %) physicians and 239 (66.4 %) nurses, reflecting the distribution of providers in the institution. Physicians were more likely to be male, have worked at the institution for less than 5 years, have more training experiences, and more problem-awareness regarding cross-cultural care. They had better mean composite scores for perceived skillfulness than nurses (2.7 vs. 2.5, $p=.0005$), and significantly higher proportion of "good/very good" responses for 4/9 items. After adjusting for explanatory variables, physicians remained more likely to have higher skillfulness ($\beta=0.13$, $p=.049$). Among all, two problem-awareness items were significantly correlated with higher skillfulness: inadequate cross-cultural training ($\beta=0.14$, $p=.012$) and lack of practical experience caring for diverse populations ($\beta=0.11$, $p=.040$). Among physicians alone, having a non-French dominant language ($\beta=0.34$, $p=.000$), and problem-awareness about inadequate cross-cultural training ($\beta=0.22$, $p=.003$), were positively correlated with skillfulness. Among nurses alone, having received training on the history/culture of a specific group ($\beta=0.25$, $p=.016$) was associated with skillfulness, as was problem-awareness about the lack of practical experience caring for diverse populations ($\beta=0.16$, $p=.037$).
CONCLUSIONS: Overall, perceived cross-cultural skillfulness among Lausanne providers was low. Physicians had higher skillfulness than nurses, even after adjustment. Having a non-native dominant language was associated with skillfulness among physicians, emphasizing diversity in the medical workforce as important for improving patient care. Among all providers, problem-awareness about cross-cultural care was positively associated with skillfulness. Thus, attuning providers' awareness to the surrounding problems in cross-cultural patient-care, can improve skillfulness- especially among nurses with rising responsibilities.

COMPARING THE TIME REQUIRED TO COMPLETE RISK ASSESSMENT MODELS FOR VENOUS THROMBOEMBOLISM Kassem Bourgi[1]; Matthew George[1]; Rami Abboud[1]; Sana Ali[1]; David Paje[1]; Scott Kaatz[2]. [1]Henry Ford Hospital, Detroit, MI; [2]Hurley Medical Center, Flint, MI. (Tracking ID #1635115)

BACKGROUND: Venous thromboembolism (VTE) is one of the most preventable causes of hospital acquired mortality. Recent guidelines by the American College of Chest Physicians suggest using risk assessment models to help determine which non-surgical hospitalized patients should receive pharmacologic VTE prophylaxis. However, some risk assessment models tend to be cumbersome and time consuming and may not be practical to implement, while others may be more pragmatic but are not as widely recognized. This study sought to assess and compare the time needed by admitting physicians to complete two different VTE risk models, individually and in combination with a bleeding risk model in non-surgical patients.
METHODS: Adult patients newly admitted for non-surgical conditions were assessed by one of four medical interns who were randomly assigned to complete either a VTE risk assessment tool (Padua or Maynard), a bleeding risk tool (IMPROVE), or a combination of a VTE risk tool and bleeding risk tool. The clinical data necessary to determine the risks were obtained in a manner that closely approximated what happens during routine admissions, which included brief reviews of the electronic medical record and direct patient interviews. Data elements required for risk assessment were clearly defined at the beginning of the study by adopting descriptions from the derivation and validation studies, and by corresponding with the primary authors when necessary. The amount of time to complete the risk assessment tools individually and in combination were compared using the two sample *t*-test.
RESULTS: In the assessment of VTE risk alone, 25 patients were evaluated using the Maynard tool with a mean time of 56.6 s (95 % CI: 46.2–67.1), and in another 25 patients the Padua score was completed in an average time of 237.3 s (95 % CI: 200.2–274.5), $p<0.001$. When the risks for both VTE and bleeding were both assessed in 25 patients using the combination of Maynard and IMPROVE tools, it took a mean time of 211.5 s (95 %: 178.0–245 .0); but when both Padua and IMPROVE scores

were calculated in another 25 patients, it took an average of 336.5 s (95 % CI: 293.9–379.2) to complete, $p<0.001$.

CONCLUSIONS: The Padua VTE risk assessment model requires significantly more time to complete compared to the simplified Maynard tool, and thus may not be practical to implement unless the collection of some of its elements can be automated through an electronic medical record system. The inclusion of bleeding risk assessment incurs additional time to the admission process.

Time Needed for Different Risk Assessment Scores

Time to Complete Risk Assessment (in seconds)

Risk Assessment Model	N	Mean	95 % Confidence Interval Around the Mean		p-value
Maynard (VTE)	25	56.6	46.2	67.1	<0.001
Padua (VTE)	25	27.3	200.2	274.5	
IMPROVE (Bleed)	25	186.1	165.7	206.6	
Maynard (VTE) + IMPROVE (Bleed)	25	211.5	178.0	245.0	<0.001
Padua (VTE) + IMPROVE (Bleed)	25	336.5	293.9	379.2	

COMPARISON AND ACCURACY OF LIFE EXPECTANCY PREDICTIONS BY PATIENTS, PHYSICIANS, AND PROGNOSTIC MODELS IN OLDER PATIENTS WITH TYPE 2 DIABETES Claire E. O'Hanlon[1]; Sang Mee Lee[2]; Priya John[1]; Marshall Chin[1]; Elbert S. Huang[1]. [1]University of Chicago, Chicago, IL; [2]University of Chicago, Chicago, IL. (Tracking ID #1638605)

BACKGROUND: Diabetes care guidelines have called for the individualization of care goals for older patients (e.g., A1C) based on life expectancy (LE). To carry out these recommendations, the estimation of LE is critical for setting appropriate diabetes care goals. We compared LE predictions in a cohort of older patients with type 2 diabetes with actual mortality. The prognostic estimates were made by the patient, the patient's physician, Vital Statistics life tables, and the Chicago Type 2 Geriatric Diabetes Simulation Model.

METHODS: The cohort of older (65+ years of age) type 2 diabetes patients were enrolled in a study of treatment preferences between 12/2000–1/2003. During this study, each patient and his/her physician provided a life expectancy prediction in separate surveys. The CDC Vital Statistic life tables were used to obtain life expectancy estimates based on age and sex of the patients. The Chicago Type 2 Geriatric Diabetes Simulation Model, a combination of diabetes complication and geriatric mortality prediction models, was used to calculate LE based on patient demographics, duration of diabetes, risk factor levels, functional status, and comorbid illnesses. We also considered the predictive performance of the average of physician and model estimates. Observed survival time was determined with data from the National Death Index through December 31, 2010. Each estimate of five-year mortality and LE was compared to observed survival. We compare the sensitivity, specificity, and c-statistic from logistic regression for prediction of 5-year mortality. Harrell's c-statistic and standard deviation for survival time were also calculated.

RESULTS: 447 patients had both patient and physician estimates. 63 % were female and 79 % were Black. The mean (standard deviation) age of the cohort was 73.4 (5.9) years and duration of diabetes was 13.2 (10.4) years. At 5 years, 108 (24 %) had died and 201 (45 %) had died by the end of the period of observation. For estimating 5 year mortality, the worst performing individual prognostic method according to the c-statistic was Vital Statistics (0.599), followed by patients (0.625). Both had very low sensitivities and high specificities. Physician estimates had one of the highest c-statistics (0.692) with a sensitivity of 0.528 and a specificity of 0.755 for predicting 5-year mortality. The simulation model had a similar c-statistic (0.683) but had a high sensitivity (0.907) and low specificity (0.307). The average of the physician and model estimates generated a higher c-statistic (0.733) than any individual prognostic method. The hierarchy of predictive performance according to Harrell's c-statistic was similar.

CONCLUSIONS: Physicians and a diabetes simulation model provided LE estimates that performed similarly well in this cohort, although physicians were more optimistic and the model more pessimistic than observed mortality. The average of these estimates had a higher c-statistic than any individual prognostic method. This result suggests that diabetes prediction models may complement and support the intuition of physicians as they make treatment decisions for older diabetes patients.

5-year mortality Survival time

Sensitivity	Specificity	c-statistic (logistic regression)	Harrell's c-statistic	St. dev. Harrell's c-statistic
Patient	0.444	0.791	0.625	0.611	0.020
Physician	0.528	0.755	0.692	0.650	0.019
Vital Statistics	0.009	0.985	0.599	0.594	0.020
Model	0.907	0.307	0.683	0.650	0.019
Average of Physician and Model Estimates	0.602	0.687	0.733	0.684	0.019

COMPARISON OF CHRONIC PAIN MANAGEMENT IN A LEVEL 3 PATIENT CENTERED MEDICAL HOME BETWEEN RESIDENT PHYSICIANS, FACULTY PHYSICIANS, AND A DEDICATED CHRONIC PAIN MANAGEMENT PROGRAM Kathryn Sweeney; Shana Ratner; Brooke B. McGuirt. UNC Chapel Hill, Chapel Hill, NC. (Tracking ID #1633982)

BACKGROUND: Safe and effective pain management involves careful considerations of controlling pain, improving function, choosing efficacious therapies, as well as attention to misuse, abuse, and diversion of controlled substances. The North Carolina State Medical Board gives detailed recommendations for evaluation and management of chronic pain. A subset of patients with chronic pain in our clinic are managed by a pharmacist-run chronic disease management program. Our aim was to review and compare adherence with these recommendations in our Internal Medicine practice among resident physicians, faculty physicians, and the embedded pain clinic.

METHODS: We reviewed charts for patients seen in the Internal Medicine Clinic (IMC) from 8/1/2011–8/1/2012 who had been given ≥3 prescriptions for Schedule II–III controlled substances for the management of chronic pain during that time period. After reviewing 299 charts, 150 met our inclusion criteria. Fifty charts each were reviewed from resident, faculty, and pain clinics. Each chart was assessed for patient demographics, opiate prescriptions, documentation of drug monitoring (urine toxicology screens and NC Controlled Substance Reporting System [NCCSRS] database queries), adjuvant pain therapies, depression screening, and patient education. Each patient was subsequently reviewed in the NCCSRS Database to determine the number of Schedule II–III controlled substance prescribers per patient in the past year. We used descriptive statistics to compare averages.

RESULTS: Fifty charts each (150 total) were reviewed from the following subsets of our practice: resident, faculty, and pain clinic. The average patient age was 56, with an older population in faculty clinic (average age 53 resident clinic, 60.5 faculty clinic, 55 pain clinic). Resident and pain clinic patients were more likely to be male (46 % resident, 34 % faculty, 40 % pain clinic). More pain clinic patients had a history of substance abuse (26 % resident, 10 % faculty, 40 % pain clinic). A urine toxicology screen had been obtained in 60 % of total patients in the past year, with large differences between settings of care (52 % resident, 28 % faculty, 100 % pain clinic). A pain contract had been documented in half of all patient charts with much higher adherence in pain clinic (32 % resident, 12 % faculty, 100 % pain clinic). Twenty-eight percent of patients had received prescriptions for opioid analgesics from 3 to 5 different prescribers (range of 0–16) during the year reviewed. Review of the NCCSRS Database was documented in very few patient charts (4.7 %). Seventy-nine percent of patients were screened for depression, and 37 % were given a decision aid about chronic pain treatment options.

CONCLUSIONS: In an era of ever-increasing demands on the primary care physician, the complex and time-consuming nature of safe chronic pain management continues to become more difficult. We found deficiencies in documentation and adherence to monitoring guidelines in the resident and faculty continuity clinics when compared to the embedded pain clinic. Practices should explore the creation of structured chronic pain management programs embedded within the primary care clinic, similar to a model of warfarin management in anti-coagulation clinics.

COMPARISON OF HIV TESTING WITH OTHER MARKERS OF CHRONIC DISEASE SCREENING Bradley C. Fetzer[1]; Florence Momplaisir[2]; Judith A. Long[1]. [1]University of Pennsylvania, Philadelphia, PA; [2]Temple University School of Medicine, Philadelphia, PA. (Tracking ID #1638481)

BACKGROUND: Routine opt-out HIV testing has been recommended by the CDC since 2006 with the aims of identifying infected persons early and decreasing transmission rates as well as missed opportunities for treatment. Low risk persons should be screened at least once in their lifetime, while higher risk individuals should be screened annually with opt-out testing strategies. Since these guidelines were released, overall rates of HIV testing in the U.S. have been increasing. Data suggests that these increases are largely attributable to community clinics and emergency departments, outside the traditional primary care setting, and that primary care providers face a number of barriers to routine opt-out testing. However, data regarding actual HIV testing practices of primary providers is lacking. Our aim was to compare how rates of HIV testing compare with other routine screening measures overall and in the primary care setting.
METHODS: We used data from the 2002–2010 Southeastern Pennsylvania (SEPA) Household survey to evaluate how HIV testing compared with other markers of chronic disease screening. The SEPA Household survey is the largest and most comprehensive health survey of the Philadelphia region; it is administered every two years to evaluate respondent's health status and health care experiences. Weighted survey data were used to compare the number of people who had ever been tested for HIV with those who had received age and sex appropriate screening for chronic disease including hypertension, cervical cancer, breast cancer, and colorectal cancer. Further, logistic regression was performed to determine the likelihood of ever having received an HIV test and chronic disease screening between respondents by primary source of care.
RESULTS: Between 2002 and 2010, 50,698 individuals 18 and over were surveyed, approximately 10,000 per survey year. Participants had a mean age of 40, were majority Caucasian (69.2 %) and female (53.3 %). The primary source of medical care was a private clinic for 79.1 % of respondents compared with 4.2 % reporting a community health clinic, 2.5 % emergency department (ED) care, and 14.2 % as none or 'other'. The percentage of respondents who had ever been tested for HIV (44.4 %) was noticeably lower when compared with other markers of blood pressure and cancer screening (62.2 % to 95.9 %). Compared with private clinics, respondents had a higher likelihood of ever having received an HIV test if their primary source of care was a community clinic (OR 1.94 95 %CI 1.51–2.51), the ED (OR 3.33 95 %CI 0.92–8.28), or listed as none or 'other' (OR 1.49 95 %CI 1.23–1.52). Conversely, the majority of blood pressure and cancer screening measures had a lower likelihood of being reported if the source of care was not a private clinic, however community clinics were not significantly different.
CONCLUSIONS: HIV testing rates fall well below the rates of other chronic disease screening in this cohort. Populations whose primary source of care lies in community health clinics, emergency rooms, or other non-private clinics are more likely to receive HIV testing compared with traditional private clinics. Physicians providing primary care in private clinics adhere well to screening guidelines for blood pressure and cancer screening, but may neglect appropriately screening their populations for HIV.

COMPARISON OF THE QUALITY OF PATIENT REFERRALS FROM PHYSICIANS, PHYSICIAN ASSISTANTS, AND NURSE PRACTITIONERS TO AN ACADEMIC GENERAL INTERNAL MEDICINE PRACTICE Thomas J. Beckman; Robert Lohr; Colin P. West; Margaret Beliveau; Paul Daniels; Mark Nyman; William Mundell; Nina M. Schwenk; Jayawant N. Mandrekar; James M. Naessens. Mayo Clinic, Rochester, MN. (Tracking ID #1633875)

BACKGROUND: Physician Assistants (PAs) and Nurse Practitioners (NPs) are increasingly utilized to improve healthcare access. There has been limited research on the abilities of PAs and NPs to care for complex medical patients and we are unaware of any studies examining the quality of patient referrals from PAs and NPs to academic medical centers. Our objectives were to compare referrals to the Mayo Clinic Rochester General Internal Medicine (GIM) regional practice from physicians, PAs and NPs regarding: 1) quality of patient management and referrals based on a validated measure, 2) patient complexity determined by the Charlson Index and 3) treatment costs during the first 30 days after the referral visit.
METHODS: We conducted a retrospective comparison study of all 160 patients of NPs and PAs, and a random sample of 160 patients of physicians, who were referred to the GIM regional practice from 2009 to 2011. Eight physicians, each with over 10 years practice experience and blinded to the identities of referral sources and patients, used a seven-item instrument with five-point scales (1 = strongly disagree; 5 = strongly agree) to assess the appropriate management and referral of patients. Internal consistency and interrater reliability were determined using Cronbach alpha and intraclass correlation coefficient (ICC) respectively. Factor analysis with an adjusted correlational matrix to account for non-independent data was used to ascertain the dimensionality of item scores. Differences between item scores for patients referred by physicians, versus PAs and NPs combined, were verified using multivariate ordinal logistical regression, adjusted for patient age, gender, referral distance and Charlson Index. Differences between groups for Charlson Indices and total costs were determined using ANOVA. The sample size of 160 patients per group provided 80 % power to detect a small-to-moderate Cohen's effect size of 0.32. Two-tailed statistical significance was set at alpha = 0.05.
RESULTS: Factor analysis revealed a one-dimensional measure of the quality of patient referrals by physicians, PAs and NPs. Interrater reliability (ICC) for all individual items (range 0.77 to 0.93) and overall (0.92), and internal consistency for all items combined (Cronbach alpha = 0.75), were very good. Physicians scored significantly higher (% agree/strongly agree) than PAs and NPs for each of the following instrument items: referral question clearly articulated (86.3 vs 76.0; p=.0007), clinical information provided (72.6 vs 54.1; p=.0033), documented understanding of the patient's pathophysiology (51.0 vs 30.3; p<.0001), appropriate evaluation performed locally (60.3 vs 39.0; p<.0001), appropriate management performed locally (53.5 vs 24.1; p<.0001), referral was unnecessary (30.1 vs 56.2; p<.0001), and confidence returning patient to referring provider (67.8 vs 41.4; p<.0001). There were no significant differences between groups regarding patient complexity or costs of outpatient treatment, hospitalization, laboratory testing or consultations.
CONCLUSIONS: This is the first study to demonstrate that the quality of referrals to an academic medical center, as determined by a panel of experienced and blinded internal medicine faculty members, is significantly higher for physicians as opposed to PAs and NPs with respect to several characteristics including clarity of the referral question, understanding of pathophysiology, and adequate pre-referral evaluation and documentation.

COMPASSION FATIGUE, PROFESSIONAL BURNOUT AND SELF-CARE AMONG MULTIDISCIPLINARY PROVIDERS WORKING IN OUTPATIENT PRIMARY CARE SETTINGS Christopher J. Koenig[1,2]; Shira Maguen[1,3]; Jose D. Monroy[1]; Karen H. Seal[1,3]. [1]San Francisco Veterans Affairs, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA. (Tracking ID #1637822)

BACKGROUND: Health care providers manage complex medical, psychological, and social health problems of their primary care patients. Regular exposure to patient trauma narratives associated with gang violence, experiences of war, or other violent social problems can lead to compassion fatigue and professional burnout. Self-care for providers is recognized as critical in the prevention of compassion fatigue and burnout that may affect both professional and personal well being. This study examines self-care strategies among multidisciplinary providers working in outpatient primary care settings who care for retuning Iraq and Afghanistan veterans.
METHODS: We conducted qualitative, semi-structured interviews with 31 multidisciplinary providers in Veterans' Affairs outpatient clinics serving

returning Iraq and Afghanistan veterans. One clinic fully integrated primary care, mental health, and social work providers for comprehensive multidisciplinary care, and another clinic co-located multidisciplinary providers for referral. We purposively sampled providers who saw at least two returning veterans within a six-month period. Interviews were transcribed verbatim and uploaded into Atlas.ti software for qualitative data management. All self-care segments were identified and analyzed using Grounded Practical Theory to develop a descriptive framework of self-care communication among multidisciplinary providers as part of a research interview.

RESULTS: Preliminary analyses show that sampled providers were aware that regular contact with veterans returning from Iraq and Afghanistan who experienced war trauma may lead to compassion fatigue and professional burnout. Provider groups shared some general strategies for managing negative psychological consequences associated with regular contact with returning veterans, including physical exercise, personal reflection, such as journaling, and discussion with professional colleagues. However, provider groups also differed according to the norms of their respective training cultures. For example, primary care providers (PCPs) were more likely to manage negative emotions through discussion outside of work with close personal relationships, such as a spouse, partner, or close friend. In contrast, mental health providers (MHPs) and social work providers (SWPs) were more likely to share negative feelings by debriefing with their professional colleagues during work hours. Further, MPHs and SWPs were aware that PCPs may not have adequate training to deal with strong negative emotions as a result of close professional contact with veterans who have firsthand experience of war trauma.

CONCLUSIONS: Debriefing with colleagues is a routine practice that both MPHs and SWPs learn as part of their professional training, however PCPs are not typically trained to debrief with colleagues during work hours. Training norms associated with different provider types may have an important impact on the day-to-day management of work-related psychological risk involving violent trauma. When faced with compassion fatigue and professional burnout, primary care training culture may emphasize independence, whereas other provider cultures may emphasize interdependence. Primary care providers may learn from other disciplines to improve self-care strategies that prevent compassion fatigue and professional burnout, which may lead to increased professional development, personal job satisfaction, retention, and, ultimately higher quality health care.

CONSIDERING RADIATION EXPOSURE TO PATIENTS WHEN ORDERING CAT SCANS: THE CLINICIAN PERSPECTIVE L. E. Goldman[1]; Jenna Kruger[1]; Alice H. Chen[1]; Alex Rybkin[2]; Kiren Leeds[1]; Dominick Frosch[3,4]. [1]University of California, San Francisco, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA; [3]University of California, Los Angeles, Los Angeles, CA; [4]Palo Alto Medical Foundation Research Institute, Palo Alto, CA. (Tracking ID #1642618)

BACKGROUND: The rise in cat-scan use over the past decade is associated with a substantial increase in medically-associated radiation exposure. To increase safe use of imaging, starting in 2012 California legislation required the inclusion of cat scan radiation dose metrics in radiology reports. We sought to examine (1) outpatient clinician attitudes regarding the consideration of radiation exposure when ordering cat scans; and (2) clinician reactions to a planned intervention posting radiation exposure information for cat scans at the point of clinician electronic order entry in an urban safety-net setting.

METHODS: We conducted a qualitative study consisting of 9 audio-taped focus groups of salaried clinicians working in an urban safety-net setting. To obtain diverse opinions, 6 focus groups were with primary care clinicians and 3 were with subspecialty physicians in nephrology, pulmonary, and neurology across 12 clinics (total N=44 clinicians). Focus group guides focused on clinician knowledge and attitudes about how radiation exposure from cat scans affect their ordering practices, barriers to considering radiation exposure in clinical decisions, potential harms and benefits of posting radiation exposure information at the site of order entry for cat scans, and suggestions for improvement of the intervention. Focus groups were audio-recorded and transcribed. Two researchers (JK, LG) systematically coded the transcripts, and discussed differences to reach consensus using an inductive thematic analysis framework to identify emergent themes.

RESULTS: Clinicians expressed a general awareness of the radiation risks with cat scans, although most felt uncomfortable with their knowledge of the clinical implications of radiation exposure from particular studies. Most primary care clinicians believed clinically relevant information such as the increased risk of malignancy from a given cat scan would be useful to inform decision-making and patient discussions, although reported that patients in their practices seldom raised concerns about radiation exposure. Clinicians felt that patient-level cumulative radiation exposure would be most useful, though not currently available. Clinicians also noted that long wait times for imaging studies with less radiation exposure (such as MRI or ultrasound) often acted as a barrier to minimize patient radiation exposure from cat scans and felt that to effectively limit radiation exposure would require a system-wide approach that included emergency room and hospital-based clinicians.

CONCLUSIONS: Posting radiation exposure information at the site of clinician electronic order entry may improve clinician knowledge and inform clinician discussions with patients regarding risks and benefits of various imaging studies. However, limitations in access to tests with lower radiation exposure and lack of a system-wide approach that includes emergency room, hospital, and outpatient clinicians may trump efforts to minimize unnecessary patient radiation exposure. Clinician decision-aids regarding cat scan use in safety-net settings should consider issues of wait times for various imaging studies and should incorporate clinician education regarding cumulative patient radiation exposure once this information is available.

CONTRACEPTIVE ADHERENCE AMONG WOMEN VETERANS: DIFFERENCES BY RACE/ETHNICITY AND CONTRACEPTIVE SUPPLY Sonya Borrero[1,2]; Xinhua Zhao[2]; Maria Mor[2]; E. Bimla Schwarz[1]; Chester Good[2,1]; Walid F. Gellad[2,1]. [1]University of Pittsburgh, Pittsburgh, PA; [2]VA Pittsburgh, Pittsburgh, PA. (Tracking ID #1637423)

BACKGROUND: Contraception, when used consistently and correctly, can prevent unintended pregnancy. As the number of women of reproductive age rises in the VA, contraceptive care is a growing priority, yet little is known about contraceptive use patterns among female patients. The objective of this study was to assess contraceptive adherence among women Veterans and examine the relationships between race/ethnicity and months of contraceptive supply dispensed with contraceptive adherence.

METHODS: We used national VA databases to examine contraceptive adherence over a 12-month period among women Veterans aged 18–45 who received primary care from VA and had hormonal contraceptive (pills, patch, injection, or vaginal ring) coverage during the first week of FY08. Women who were sterilized or used a long-acting, highly effective contraceptive method in FY 2008 were excluded from analysis. We examined several adherence indicators including gaps of ≥7 days between refills, total months of contraceptive coverage over the year, and whether the woman had contraceptive coverage during the last week of FY 2008. For those women who had contraceptive coverage during the last week of FY 2008, we distinguished between coverage with gaps from continuous coverage over the year (perfect adherence). Descriptive statistics and multivariable models were used to examine the associations between race/ethnicity and months of contraceptive supply dispensed with adherence.

RESULTS: Our cohort included 6,946 women on hormonal contraception: 47 % were white, 6 % Hispanic, 22 % black, and 25 % were other race or had missing race information. Most women (83 %) consistently received 3-month supplies at each fill over the year, 4 % consistently received 1-month supplies, and 13 % received varied months of supply over the course of the year. Over 64 % of women had at least one gap in coverage of ≥7 days. Only 22 % of women received a full 12 months of contraception without any gaps (perfect adherence). Compared to whites, Hispanics were

significantly more likely to experience gaps (64 % versus 70 %; $p=0.02$), and Hispanics and blacks received fewer months of contraceptive coverage (9.3 versus 8.9 and 9.0, $p<0.001$). Compared to women receiving 3-month supplies, those receiving 1-month supplies had a higher likelihood of a gap (63 % versus 72 %, $p<0.001$), fewer months of coverage (9.3 versus 6.9, $p<0.001$), and lower likelihood of perfect adherence (22 % versus 11 %, $p<0.001$). In multivariable Cox regression analysis, Hispanics remained significantly more likely to experience a gap than white women (HR:1.18, 95 % CI:1.03–1.35). Women who received 1-month supplies also remained more likely to experience a gap than women who received 3-month supplies (HR:1.63, 95 % CI:1.39–1.99). In the adjusted logistic regression model for perfect adherence, there were no statistically significant differences by race/ethnicity. Women receiving 1-month supplies were significantly less likely to achieve perfect adherence than those receiving 3-months supplies (OR:0.45; 95 % CI:0.30–0.68).
CONCLUSIONS: Contraceptive adherence among women Veterans is poor. Interventions to enhance contraceptive adherence and lower the risk of unintended pregnancy among female Veterans are needed. Such strategies may include enhanced provision of long-acting, reversible methods that do not have adherence requirements (i.e., IUDs and implants) and/or dispensing more months of supply for hormonal methods.

COST SAVINGS ATTRIBUTABLE TO A CONTINUOUS MONITORING SYSTEM IN A MEDICAL-SURGICAL UNIT Sarah P. Slight[1,2]; Calvin Franz[3]; Michael Olugbile[1]; Harvey V. Brown[4]; David W. Bates[1,2]; Eyal Zimlichman[1,2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Eastern Research Group, Inc., Lexington, MA; 4UCLA, Los Angeles, CA. (Tracking ID #1628795)

BACKGROUND: As many as 80 % of critically ill patients will have had abnormal values for heart rate, respiratory rate and oxygenation in the 24 h prior to Intensive Care Unit (ICU) admission. Monitoring systems can help facilitate timely interventions for these high-risk patients by drawing attention to these signs of deterioration. This study evaluated the cost savings attributable to the implementation of a continuous monitoring system in a medical-surgical unit, and determined the return on investment (ROI) associated with its implementation.
METHODS: We performed a return on investment (ROI) analysis with the primary outcome measure of net cost savings per patient per year. The ROI model was framed from the perspective of the health care organization, and data on costs and outcomes obtained from a before-and-after controlled study conducted at a 316-bed community hospital. This hospital includes a 33-bed medical-surgical unit, which typically cared for medical, surgical or trauma patients. Costs and benefits were converted to 2011 U.S. dollars and discounted at a 7 % annual percentage rate. The ROI was calculated by subtracting the total discounted implementation costs from total discounted cost savings, then dividing the amount by total costs. The hospital research committee approved the study protocol for this analysis.
RESULTS: We constructed two models: a base case model (Model A) in which we estimated the total cost savings of intervention effects (i.e., reduction in length of stay (LOS), ICU LOS and treatment of pressure ulcers), and a conservative model (Model B) in which we only included the direct variable cost component for the final day of length of stay and treatment of pressure ulcers. In the 5-year Model, the hospital spent a total of approximately $273,570 on capital costs, one-time noncapital costs, and ongoing operational costs to implement the system. The system saved between $3,268,000 (Model B) and $9,089,000 (Model A), and resulted in a net benefit of between $2,687,000 and $8,508,000, respectively. An annual ROI of 292.8 % (Model A) and 92.5 % (Model B) was shown, with the hospital breaking even on the investment after 0.5 and 0.75 of a year, respectively. The average net benefit of implementing the system ranged from $224 per patient (Model B) to $710 per patient (Model A) per year. We performed a multi way sensitivity analysis, varying annual average admissions, the real discount rate, the rate of direct variable costs, and the proportion of patients in prospective payment systems, to reflect the rates of most U.S. community hospitals.
CONCLUSIONS: Implementation of a continuous monitoring system at one community hospital was associated with a highly positive ROI, when applying cost savings attributable to a reduction in LOS, ICU LOS, and pressure ulcers. Even greater cost savings may be realized if the hospital had high numbers of admissions and greater than 80 % prospective reimbursement rate. The use of such monitoring technologies has the potential to both improve safety and save money.

COST-EFFECTIVENESS OF NOVEL ORAL ANTICOAGULATION STRATEGIES FOR TREATMENT OF ATRIAL FIBRILLATION William Canestaro[1,2]; Amanda R. Patrick[2]; Jerry Avorn[2]; Kouta Ito[2]; Olga S. Matlin[4]; Troyen A. Brennan[3]; William Shrank[2]; Niteesh K. Choudhry[2]. [1]University of Washington, Seattle, WA; [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [3]CVS Caremark, Woonsocket, RI; [4]CVS Caremark, Northbrook, IL. (Tracking ID #1635728)

BACKGROUND: Oral vitamin K antagonists such as warfarin dramatically reduce the risk of thromboembolism in patients with atrial fibrillation (AF) but are challenging to use. The new anticoagulants and using genetic information to guide warfarin dosing appear to result in superior clinical outcomes but it is unclear whether their use is cost-effective.
METHODS: We created a Markov state transition to compare five scenarios in patients with newly diagnosed AF at high risk of thromboembolic stroke with no contraindications to warfarin: dabigatran 150 mg twice daily, apixaban 5 mg twice daily, rivaroxaban 20 mg once daily, genotypically-guided warfarin dosing and standard warfarin therapy. The effectiveness of these strategies was based upon data from randomized controlled trials. Other parameters were derived from the peer-reviewed literature. The model was run from a societal perspective with a lifetime horizon. Effectiveness was measured in quality-adjusted life-years (QALYs) and costs in 2011 US dollars.
RESULTS: Compared with standard warfarin therapy, genotypically-guided warfarin was more effective and less costly while the cost of apixaban, rivaroxaban, and dabigatran were $93 062, $111 465, and $140 557 per additional QALY gained, respectively. At a threshold of $100 000 per QALY, apixaban provided the greatest absolute benefit while still being cost-effective, although genotypically-guided warfarin would be superior if apixaban was 2 % less effective than observed in the ARISTOTLE trial. While apixaban was the optimal strategy in our base case, in probabilistic sensitivity analysis, genotypic warfarin was optimal in a greater number of iterations at a cost-effectiveness threshold of $100 000 per QALY.
CONCLUSIONS: While at a standard cost-effectiveness threshold of $100 000 per QALY, apixaban appears to be the optimal anticoagulation strategy, this finding is sensitive to assumptions about its efficacy and cost. In sensitivity analysis, genotypically-guided warfarin appears to be the optimal choice in the greatest number of simulations. As a result, the novel oral anticoagulants may not represent as good a value as strategies to improve INR control with warfarin.

COST-CONSCIOUS MEDICAL DECISION-MAKING: PATIENTS' PERSPECTIVES ON SCREENING AND PHYSICIANS' ROLES REGARDING COST BARRIERS David Grande[1,2]; Margaret Lowenstein[3]; Madeleine P. Tardif[4]; Carolyn C. Cannuscio[5,2]. [1]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA; [2]Leonard Davis Institute of Health Economics, University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA; [4]University of Pennsylvania, Philadelphia, PA; [5]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA. (Tracking ID #1641316)

BACKGROUND: As costs rise and high deductible health plans proliferate, patients increasingly face financial barriers to care. Prior research has shown that: patients want to have cost conversations with their doctors; doctors feel these conversations are important; and these conversations rarely happen. Little is known regarding how patients want

their doctors to consider cost-efficacy tradeoffs. We evaluated patients' preferences regarding novel strategies to screen for financial barriers to care. We also conducted an experiment to assess patients' preferences regarding physician engagement in cost-conscious medical decision-making.

METHODS: We conducted a mail survey with an embedded randomized experiment in a sample of 1,400 individuals who had applied for financial support from a patient assistance foundation (HealthWell Foundation). A total of 842 responded (107 incorrect addresses, 6 deceased; response rate: 65 %). Our instrument focused on three domains: a) patient comfort with health care team members screening for cost barriers; b) patient comfort with tools to screen for cost barriers; c) patient comfort with physician decision making styles in the context of cost barriers. For the latter, we randomized respondents to receive 1 of 3 vignettes depicting physician decision styles for initiating a new medication with a cost-efficacy tradeoff: 1) cost conscious choice (physician chooses cheaper) 2) cost indifferent choice (physician chooses more expensive) 3) patient directed choice (physician presents options and defers to patient). All respondents were then asked to rate a version of the vignette that was modified to reflect a shared decision style. On a 10-point Likert scale, scores >7 reflected that patients were "very comfortable" with the screening method or doctor's approach.

RESULTS: Among respondents, 81 % were very comfortable with their doctor asking about problems paying for medications. Fewer patients were very comfortable being asked by pharmacists (75 %, $p=0.002$), nurses (69 %, $p<0.001$), professional counselors (68 %, $p<0.001$), and trained volunteers (51 %, $p<0.001$). 59 % were very comfortable with their doctor's office reviewing medical records to screen for cost barriers. In comparison, 53 % were very comfortable with insurers ($p=0.026$), 62 % with pharmacies ($p=0.17$), 62 % with completing a form in their doctor's office ($p=0.16$), and 48 % with a screening email from their doctor ($p<0.001$). Overall, patients who trusted their doctor more were more likely to be comfortable with all team members and screening tools ($p<0.001$ for all). In our randomized experiment, respondents were uncomfortable deferring decisions to their physician. Only 25 % of patients were very comfortable with the vignette in which a physician made a cost-conscious decision to prescribe a less expensive drug. In comparison, 33 % of patients were very comfortable with the cost indifferent vignette, in which the doctor prescribed the most expensive drug ($p=0.055$) and 58 % were very comfortable with the vignette in which the patient directed the decision ($p<0.001$). 85 % reported that they were very comfortable with the doctor and patient making a shared decision.

CONCLUSIONS: In our sample of patients experiencing financial barriers to care, participants were generally comfortable with diverse strategies to screen for cost barriers. Regarding decisions with cost-efficacy tradeoffs, patients preferred to engage in shared decision-making with their doctors.

COST-CONSCIOUSNESS AMONGST INTERNISTS AT AN ACADEMIC TRAINING PROGRAM; A BRIEF SURVEY OF PRACTICES AND ATTITUDES Jonas Z. Hines[1,2]; Justin L. Sewell[2,1]; Claire Horton[2,1]; Niraj Sehgal[1]; Christopher Moriates[1]; Naama Neeman[3,1]; Alice H. Chen[2,1]. [1]University of California San Francisco, San Francisco, CA; [2]San Francisco General Hospital, San Francisco, CA; [3]Veteran Administration Medical Center, San Francisco, CA. (Tracking ID #1640465)

BACKGROUND: Healthcare expenditures in the U.S. are the largest in the world, a large portion of which is waste. Addressing such waste could decrease costs while improving healthcare quality. We sought to further evaluate characteristics associated with cost-consciousness within our three-hospital system, with a focus on elements of the Choosing Wisely campaign.

METHODS: We developed a survey with elements capturing practice, attitudes, behaviors and perceived drivers of unnecessary care and invited all internal medicine physicians at our institution to participate. Questions included 8 low-value diagnostic scenarios, 6 questions assessing attitudes toward cost-consciousness and 4 questions predicting personal and national patterns and drivers of unnecessary care. We also asked respondents how often they consider cost in decisions they make. We asked level of training, practice site, inpatient versus outpatient and generalist versus specialist. We used two-tailed t-tests and ANOVA for bivariate characteristics and performed a linear regression for factors associated with the composite unnecessary care score.

RESULTS: Among the 920 potential respondents, 279 (30 %) completed the survey. 110 (39 %) were trainees and 169 (61 %) were faculty. 171 (62 %) were generalists and 153 (56 %) primarily practiced in an inpatient setting. Cost-consciousness did not differ among generalists versus specialists, inpatient versus outpatient, or by site of practice. However, level of training was strongly associated with cost-consciousness, with faculty overall being more cost-conscious. In linear regression analysis, only level of training was associated with cumulative unnecessary care score (coefficient 3.14, $p<.001$). Attitudes concerning cost-consciousness were similar between trainees and faculty. However, trainees less frequently considered cost as a factor in patient care decisions (data not shown).

CONCLUSIONS: In our large university setting including three different practice sites (university, county, and Veterans Affairs), we found that level of training was a driver of perceived and actual cost-consciousness. While trainees believed they were less cost-conscious than faculty, they did not differ significantly in their attitudes toward cost-consciousness. One possible explanation for this difference is tolerance of uncertainty, which may increase with experience and would impact cost-consciousness. The survey indicated that internists are supportive of cost-consciousness, feeling quite strongly about the physicians' role in controlling cost and teaching trainees about cost, while eschewing that cost must be pitted against patient welfare. A low response rate and single institution limit the generalizability of the study. Moreover, cost-consciousness is complex and difficult to assess using a survey. However, our findings underscore the importance of integrating cost-consciousness into post-graduate medical training.

Table. Selected data from survey, Low-value diagnostic scenarios

	Trainee	Faculty	All respondents
Scenario 1 ECG in low-risk patients, mean (SD)	3.3 (1.4)	3.9 (1.4)*	3.6 (1.4)
Scenario 2 BNP in typical heart failure, mean (SD)	3.1 (1.4)	3.3 (1.3)	3.2 (1.3)
Scenario 3 Echo for syncope, mean (SD)	3.7 (1.3)	3.6 (1.4)	3.7 (1.3)
Scenario 4 Annual lipids in low-risk, mean (SD)	3.4 (1.4)	4.0 (1.3)*	3.7 (1.4)
Scenario 5 Imaging for nonspecific back pain, mean (SD)	3.4 (1.4)	4.0 (1.3)*	3.8 (1.4)
Scenario 6 ANA for non-specific symptoms, mean (SD)	3.3 (1.4)	3.8 (1.3)*	3.6 (1.4)
Scenario 7 Perioperative coagulation studies for low-risk patients, mean (SD)	3.2 (1.2)	3.5 (1.4)**	3.4 (1.3)
Scenario 8 Screening spirometry, mean (SD)	3.5 (1.6)	4.1 (1.5)*	3.8 (1.6)
Composite unnecessary care score (based on scenarios 1–8)	3.3 (0.8)	3.8 (0.9)*	3.6 (0.9)

COST-EFFECTIVENESS OF SINGLE- AND MULTI-COMPONENT VACCINATION PROGRAMS TO ELIMINATE DISPARITIES IN INFLUENZA AND PNEUMOCOCCAL VACCINATION RATES IN ELDERLY MINORITIES Constantinos I. Michaelidis[1]; Richard K. Zimmerman[2]; Mary Patricia Nowalk[2]; Kenneth J. Smith[3]. [1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA. (Tracking ID #1610220)

BACKGROUND: Although disparities exist in influenza and pneumococcal vaccination rates among elderly minority groups, there is little guidance as to which intervention or combination of interventions to eliminate these disparities is likely to be most cost-effective. We evaluate the cost-effectiveness of four hypothetical single- and multi-component vaccination programs designed to eliminate disparities in elderly influenza and pneumococcal vaccination rates in the practice setting.

METHODS: We developed a Markov cost-effectiveness model in which we assumed a societal perspective, 10-year vaccination program and

lifetime time horizon. The cohort was the combined African-American and Hispanic 65 year-old birth cohort in the United States in 2009. We evaluated five different vaccination strategies: no vaccination program and four vaccination programs that varied from "low intensity" (one intervention) to "very high intensity" (four interventions) based on the number of interventions deployed in each practice-based program, their cumulative cost and their cumulative impact on elderly minority influenza and pneumococcal vaccination rates. Three component interventions (patient reminders, practice standing orders and practice audit and feedback) were selected for inclusion because they are well-studied, effective and inexpensive. One intervention (practice vaccination champion) was selected for inclusion as a hypothetical solution to loss of gains in vaccination rates that can occur in later years of an initially high-performing vaccination program due to provider fatigue. We measured costs in 2011 U.S. dollars and effectiveness in quality-adjusted life years (QALYs).

RESULTS: The very high intensity vaccination program cost $24,479/QALY gained compared to the high intensity program and was the preferred strategy at willingness-to-pay-thresholds of both $50,000 and $100,000/QALY, preventing 37,178 influenza cases, 342 influenza deaths, 1,158 invasive pneumococcal disease (IPD) cases and 174 IPD deaths over the birth cohort's lifetime compared to no program. In one-way sensitivity analyses, the very high intensity program only became cost-prohibitive (>$100,000/QALY) at less likely values for the influenza vaccination rate achieved in the high (>73.5 %, base case estimate 71 %) or very high (<76.8 %, base case estimate 81 %) intensity vaccination programs. In probabilistic sensitivity analyses, varying all parameters simultaneously over distributions, the very high intensity program was preferred if willingness-to-pay thresholds were >$21,000/QALY gained.

CONCLUSIONS: For practices planning to deploy interventions to increase elderly minority vaccination rates and reduce disparities, a very high intensity vaccination program that includes four different interventions would be cost-effective. This analysis will provide assistance to community-based practices seeking cost-effective combinations of interventions targeting disparities in elderly minority vaccination rates.

COURTING MALPRACTICE RISK: FAILURES IN HIGH RISK OUTPATIENT TEST AND REFERRAL MANAGEMENT AND DOCUMENTATION Gordon D. Schiff[1,3]; Namara Brede[1]; Sara Singer[1,4]; Cathy A. Foskett[1]; Harry Reyes Nieva[1]; Caitlin A. Colling[1]; Diana L. Whitney[1]; Judy Ling[2]; Nicholas Leydon[2]; Endel J. Orav[1,3]; David W. Bates[1,3]; Madeleine Biondolillo[2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts Department of Public Health, Boston, MA; [3]Harvard Medical School, Boston, MA; 4Harvard School of Public Health, Boston, MA. (Tracking ID #1641768)

BACKGROUND: The PROMISES (Proactive Reduction of Outpatient Malpractice: Improving Safety, Efficiency, and Satisfaction) Project is an AHRQ-funded initiative to reduce malpractice risks in Massachusetts, one of seven national malpractice risk reduction projects, and the only one to focus exclusively on primary care. As part of the project's baseline evaluation component, chart review was conducted at 15 intervention sites (14 using electronic medical records and 1 using paper charts). Documentation was assessed in three key areas known to pose risks for malpractice suits in primary care: management of high risk medications, critical abnormal test results, and high risk referrals. Charts were retrospectively reviewed for a one-year study period preceding an 18-month PROMISES intervention. This report analyzes baseline findings related to test result and referral management.

METHODS: Practices identified an enriched sample of up to 100 patients triggered by the following abnormal test results: Cr > 1.8, K+ > 5.4, TSH > 10, INR > 4, and PSA > 5. Reviewers examined the charts to determine if results were noted and documentation of follow-up was present for these as well as other high-risk test results found in the charts (pulmonary nodule, abnormal colonoscopy, abdominal mass, positive stool guaiac, and abnormal pap smear). For high risk referrals, documentation of follow-up was assessed for the following clinical problems: suspicious breast mass, abnormal Pap smear, suspicious skin lesion, and chest pain or new cardiac arrhythmia. A Microsoft Access database was used for data entry and analysis. Charts were reviewed by trained reviewers and an experienced RN using previously validated instruments/criteria, and potential adverse findings were further assessed by a general internist and fed back to the practices in cases where there were active patient safety concerns.

RESULTS: Across 15 practices, 765 charts were reviewed, in which we identified a total of 1533 abnormal test results and 72 high-risk referrals. The practices varied in size from 1 to 9 physicians; the number of charts identified per practice ranged from 17 to 100. The most commonly encountered abnormal test results were Cr > 1.8 (521; 34 % of all tests), K+ > 5.4 (299; 19.5 %), TSH > 10 (255; 16.6 %), INR > 4, (214; 14 %), and PSA > 5 (158; 10.3 %). Of these abnormal tests, 107 (7 %) were not acknowledged by the responsible provider, and documentation of patient notification could not be found in 290 (18.9 %). No action or treatment plan was documented in 283 (18.5 %), and no indication of follow-up/treatment completion could be found (independent of plan documentation) in 256 (16.7 %). Documentation failure was even more common among high-risk referrals: a returned consultation note did not appear in the chart in 16 cases (22 %), the PCP failed to note specialist recommendations in 31 (43 %), and no action was taken on specialist recommendations in 32 (44 %).

CONCLUSIONS: We found serious gaps in documentation and follow-up of multiple abnormal lab tests and high risk referrals. Striking findings included no documentation of provider notification of patients for 1/5 of the abnormal test results, and a significant number (7 %) of tests entirely unacknowledged. This study highlights referral management as an important area of focus for quality improvement to reduce malpractice risk in the primary care setting, and provides the basis for various quality improvement interventions that we are undertaking in the PROMISES malpractice risk reduction project.

CROSSING BOUNDARIES: WHAT IS NEEDED TO REALIZE A COMPREHENSIVE MODEL OF ADVANCE CARE PLANNING? Sangeeta Ahluwalia[1,2]; David Bekelman[3,4]; Thomas J. Prendergast[5]; Alexis K. Huynh[1]; Karl Lorenz[1,6]. [1]Veterans Administration Greater Los Angeles, Los Angeles, CA; [2]UCLA Fielding School of Public Health, Los Angeles, CA; [3]VA Denver, Denver, CO; [4]University of Colorado, Denver, CO; [5]VA Portland, Portland, OR; 6UCLA School of Medicine, Los Angeles, CA. (Tracking ID #1624034)

BACKGROUND: Advance care planning (ACP) should optimally occur early and regularly over the course of an illness. Because patients with advanced illness are often cared for by multiple providers, effective ACP demands a level of coordination and information transfer across the healthcare system that has thus far proven difficult to achieve. We sought to identify the barriers and facilitators to an iterative and comprehensive model of ACP by characterizing the ACP experiences, practices, and perspectives of healthcare providers across settings and disciplines.

METHODS: We conducted multidisciplinary focus groups with providers at a single VA medical center. Participants were purposively sampled by discipline from the internal medicine, geriatrics, palliative care, social work, and intensive care departments. The following topics were covered with the aid of a semi-structured guide: provider conceptualization of and approach to ACP with their patients, beliefs about the objectives of ACP, challenges to engaging in ACP, and beliefs about gaps in ACP and on ways to improve ACP. Focus groups were audiotaped, transcribed, and qualitatively analyzed into categories and themes using the method of constant comparison.

RESULTS: Twenty providers (attending/resident physicians, nurses, chaplains, social workers) representing internal medicine, hospitalists, intensive care, geriatrics/continuing care, cardiology, and palliative care, participated in 2 focus groups (n=17) or individual interviews (n=3). Participants described divergent approaches to and definitions of ACP by specialty; e.g. while primary care providers described ACP as "life planning" and focused on eliciting their patients' values for healthcare, intensivists described it as part of end-of-life care and focused on identifying code status. Participants across specialties agreed that informa-

tion about their patient's broader life goals and values would be more useful at guiding decision-making than the narrowly specified treatment choices used in most living wills. Participants also agreed that primary care providers were best-suited to lead and coordinate the ACP process but acknowledged that in light of increasing workload in primary care, there is a need to test more efficient approaches to ACP, including group visits and the use of non-physician facilitators.

CONCLUSIONS: Differences in providers' understanding of and approaches to ACP may hinder a more seamless and coordinated model of ACP that happens regularly over the course of an illness. Healthcare providers across multiple specialties and disciplines recommend that primary care providers lead and coordinate ACP by eliciting information about patient values that can be usefully applied to a range of clinical scenarios. However, questions remain about how to do this efficiently and effectively, including how to usefully document and transfer qualitative information about patient values across providers, and how to design a more scalable approach to the time-intensive ACP process.

Exemplar Quotes Representative of Themes

Theme Exemplar Quote

Differences in approaches to ACP by specialty (Participant 2) I would say in the ICU we're most concerned with code status and code status only…I think we're certainly focused on the bottom line. (Participant 4) I think from the primary care perspective, it includes things like: where are you gonna live, what's your retirement gonna look like; what are your support services; what kinds of things do you need to make your life livable before you get to the point that you need to fill out a no code.

Utility of information on patient values (Participant 5) What I want is for that document to be about your life and what gets you through the day and what you look forward to. That would be a million times more helpful than those box-based like form that's there. (Participant 3) I think actually kind of a values statement- what do you value in life? What do you treasure in life? What would you not be willing to give up? What would you be willing to settle for? I think that those sorts of things are very helpful to providers about figuring out how far do we go with what we have available.

Critical role of primary care providers (Participant 12) We're often thrown into a situation where I don't know this patient. But I'm supposed to sit down and have this conversation with him about this most intimate and important topic. Most hospital providers feel that it's pro'lly a better thing to talk about in a primary care setting. And my guess is most primary care people feel that way too. (Participant 4) In an ideal world people would all have primary care providers with a long-term relationship and they would best hear it from them because this is the person that's going to be the one to break bad news if you will. And then tell you, \"this is where we're gonna go from here.\"

Need for more efficient approaches to ACP (Participant 1) I think it would be great if we could have some kind of educational visit. Heart patients come in and do a post-CBAG class. We could say \"You've been hospitalized three times for your disease, you've been slated to come in to this post-hospitalization like…the mandatory advanced care plan visit\". (Participant 2) And we probably could use our social workers more for some of those types of things. I could envision looking at a patient visit and saying, \"Well, maybe I'll have my social worker contact them and just, you know, get a sense of where they are.\" 'Cause they could at least talk about advanced directives -in a more kind of general way, but also be able to get sort of a sense of whether the patient started to think about those type of things.

DECISIONS ABOUT MEDICATION USE AND CANCER SCREENING AMONG ELDERLY ADULTS IN THE UNITED STATES Kathleen Fairfield[1]; Bethany Gerstein[3]; Carrie A. Levin[3]; Mary McNaughton-Collins[3,2]. [1]Maine Medical Center, Portland, ME; [2]Massachusetts General Hospital, Boston, MA; [3]Informed Medical Decisions Foundation, Boston, MA. (Tracking ID #1629383)

BACKGROUND: Elderly adults frequently encounter medical decisions, yet little is known about the process and quality of these decisions. Improved decision making about medication use and cancer screening may have relevance in preventing harm from over-screening, over-treatment, and polypharmacy.

METHODS: The TRENDS study is a survey of adults aged 40 and over in the US conducted in 2011 via an Internet panel. A "decision" for the purposes of this study includes whether the respondent had or discussed having a cancer screening test (breast, prostate, or colorectal cancer) or whether the respondent started or stopped, or discussed starting or stopping a medication for hypertension, cholesterol, or depression within the past 2 years. Respondents who made either one or two of the targeted medical decisions were asked a series of questions about each decision. Respondents who made three or more of the targeted medical decisions were asked about the two that are the least common based on U.S. prevalence rates. Respondents were queried about decision process (such as whether pros and cons were addressed, whether their opinion was sought, and who made the final decision), knowledge about the treatment, decisional regret, and perceived benefit and costs (including side effects, out of pocket costs, having to take medication, false alarms, and having to deal with a cancer that might not cause any harm). We calculated a net benefit value score from reported benefits and costs. Age was the primary variable of interest (<60, 60–74, 75+) for this analysis. We used ANOVA to analyze data as appropriate.

RESULTS: Among 2462 respondents, 1382 (56 %) were <60, 816 (33 %) were aged 60–74 and 265 (11 %) were aged 75+. Decision process scores were similar (and generally low) across age groups for medication and cancer screening indicating that all groups had poor involvement in medical decision making. Knowledge about medications was higher than for screening tests, yet did not vary significantly by age. For cholesterol medication decisions, respondents in the 75+ age group with no risk factors for heart disease had significantly higher net benefit value scores (mean 3.0, SD 2.6) compared with the <60 group (mean 1.7, SD 2.6), $p<0.001$ indicating that the oldest respondents perceived more possibility of benefit than harm. Similar trends were observed among respondents with 1 or more risk factors for heart disease, and for decisions about hypertension medication. We did not observe age differences in net benefit value scores for screening decisions, as all age groups tended to place positive value on screening. Decisional regret was generally low and did not vary by age group.

CONCLUSIONS: Elderly respondents to this national survey report weak decision processes when facing choices about common medications and cancer screening, despite little evidence of benefit for some interventions (cancer screening, cholesterol lowering medicines in low risk elderly) and possibility of harm (overdiagnosis, overtreatment, and polypharmacy in elders). Older adults also tend to place greater emphasis on benefit compared with harm when making medication choices. This represents an opportunity to educate elders and medical professionals who care for them more accurately about competing risks and estimated benefits for common medications and screening tests.

DECLINE IN INTERNAL MEDICINE RESIDENTS' ACLS EXPERIENCE IN THE MODERN TRAINING ERA Eric A. Young[1,2]; Kristin A. Stratton[1,2]; Michael Brin[1]. [1]Denver VA Medical Center, Denver, CO; [2]University of Colorado Denver, Aurora, CO. (Tracking ID #1633052)

BACKGROUND: Trainees must demonstrate competence in Advanced Cardiac Life Support (ACLS) to become board-certified in Internal Medicine. Duty hour restrictions may hinder the development of competence by minimizing exposure to "real world" codes. Our study seeks to quantify Internal Medicine residents' exposure to "real world" codes at a large academic training center and determine the relationship between that exposure and residents' confidence in code team leadership.

METHODS: We performed a cross-sectional email survey of second and third year Internal Medicine residents at the University of Colorado Denver, a large multi-site academic training center. Survey questions assessed the number of codes the residents had led in the past 12 months, their level of confidence in leading in-hospital codes on a 1–10 scale (10

being most confident), and when they most recently received ACLS training or a refresher course. A Spearman correlation coefficient was used to analyze the relationship between the number of codes the resident led in the last 12 months and self-reported confidence in ACLS leadership. Mean differences in self-rated confidence were compared among residents who had exposure to ACLS training in the last 1–6 months, 6–12 months, and over 12 months ago using Tukey's studentized range test.

RESULTS: A total of 71 residents responded for an overall survey response rate of 78 %. The mean number of codes run in the previous year was 3.4 with less than 10 % of residents running more than seven codes (SD 3.1; range 20). The mean confidence level was 6.1 (SD 2.0; range 9). Self-reported confidence was strongly correlated with "real world" code experience (R2 0.71; $p<0.0001$). Time since last ACLS training did not significantly affect level of self-reported confidence ($p=0.078$).

CONCLUSIONS: Our results suggest that Internal Medicine residents have limited exposure to "real world" code scenarios and that the amount of exposure is highly variable. The mean number of codes run annually (3.4) was lower than described in prior research. In a study by Hayes. et. al. in 2007, 80 % of surveyed Internal Medicine residents reported attending 1–5 codes per month during their 3–4 months of inpatient service. Our upper level residents complete 4–7 inpatient months annually. Thus, the average number of codes led per month was 0.6, well below the level reported by Hayes et. al. in 2007. The ideal number of codes one must lead to gain competence is not known. The mean confidence level in our cohort (6.1 out of 10) was also relatively low for such a critically important skill set. Self-reported confidence scores were highly correlated with "real world" code experience; however, this finding must be interpreted cautiously in the context of our study, as we did not directly assess competence. Previous research has demonstrated that there is not a direct correlation between confidence and competence in regards to ACLS leadership skills. Nevertheless, our results suggest that traditional residency training may provide inadequate opportunity to gain the ABIM-required competence in ACLS. In 2007, Wayne et. al. demonstrated that simulation-based training with deliberate practice was superior to traditional residency training in developing competence in ACLS leadership. Our study indicates that exposure to "real world" codes in traditional residency training has declined in the era of duty hour restrictions; therefore, the need for simulation-based training is even more pronounced.

DEFICIENT CANCER SCREENING DISCUSSIONS: RESULTS FROM A NATIONAL SURVEY Richard Hoffman[1]; Joann G. Elmore[2]; Kathleen Fairfield[3]; Bethany Gerstein[4]; Michael Pignone[5]; Carrie A. Levin[4]. [1]Albuquerque VA Medical Center, Albuquerque, NM; [2]University of Washington, Seattle, WA; [3]Maine Medical Center, Portland, ME; [4]Informed Medical Decisions Foundation, Boston, MA; [5]University of North Carolina, Chapel Hill, NC. (Tracking ID #1628074)

BACKGROUND: Cancer screening decisions are considered preference-sensitive, and providers are expected to help patients achieve informed decisions. We evaluated the content, processes, and outcomes of cancer screening discussions.

METHODS: The TRENDS study is an Internet-based survey of US adults aged ≥ 40 conducted in 2011. Respondents in this analysis reported discussing screening for breast (BrCa), colorectal (CRC), or prostate (PCa) cancer with a health care provider within the past 2 years. We queried respondents about the content of screening discussions (addressing pros and cons of screening), the decision-making process (did providers ask respondents whether they wanted a test, did providers explain that respondents could choose whether to have a test, did providers express opinions and recommend screening, who made the final decision), and discussion outcomes (testing decisions and whether respondents would make the same decision again). We analyzed data with descriptive statistics and chi-square tests.

RESULTS: Overall, 1382 respondents discussed cancer screening. The mean (SD) age was 59.9 (10.8), 74 % were non-Hispanic whites, 33 % were college graduates, and 46 % reported excellent/very good health. Nearly all discussions addressed the pros of screening, but only one-third addressed cons. Respondents reported that providers explained that they could choose whether to be screened in 67 % of the discussions, and were asked whether they wanted to be screened in 56 % of discussions. In 73 % of discussions, respondents reported that providers recommending testing. About 60 % reported that the decision was mainly their own, while 33 % made the decision together with their provider, and 7 % reported that the provider mainly made the decision. Only 8 % of discussions presented pros and cons of screening, explained that respondents had a choice whether to be screened, and asked respondents for their input. Overall, the majority of respondents underwent screening (77 %) and would definitely make the same decision again (69 %). The Table shows selected results by type of cancer screening discussion.

CONCLUSIONS: Cancer screening discussions often failed to provide balanced information by not addressing the cons of screening. Respondents did not routinely participate in shared decision-making, particularly for breast cancer screening. Supporting shared decision-making could improve the quality of cancer screening decisions and increase patient satisfaction.

Cancer screening discussions: content, processes, and outcomes

Survey item	Total (N=1382)	BrCa (N=516)	CRC (N=678)	PCa (N=188)	P-value*
Discussion Content and Processes					
Discussed pros	94 %	89 %	97 %	98 %	<0.001
Discussed cons	33 %	19 %	42 %	39 %	<0.001
Health care provider explained that respondents could choose whether to be screened	67 %	61 %	71 %	72 %	0.01
Health care provider requested input on screening decision	56 %	42 %	63 %	70 %	<0.001
Discussed pros/cons, explained choices, and requested input	8 %	5 %	9 %	11 %	<0.001
Decision made together by respondent and provider	33 %	26 %	38 %	44 %	<0.001
Outcomes					
Underwent screening	77 %	84 %	69 %	89 %	<0.001
Would definitely make same decision again	69 %	76 %	66 %	57 %	<0.001

DEMOGRAPHIC AND CLINICAL CHARACTERISTICS OF VETERANS WITH A HISTORY OF INCARCERATION Nicole Redmond[1]; Mark S. Litaker[2,3]; Michael Conner[3]; Stefan Kertesz[3,1]. [1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; 3Birmingham VA Medical Center, Birmingham, AL. (Tracking ID #1640495)

BACKGROUND: Prior studies show that recently released inmates have a 12.7 times higher risk of death in the 2 weeks after release (Binswanger IA et al., NEJM 2007) and report poor access to health care both pre- and post-incarceration (Conklin TJ et al., AJPH 2000). In the last quarter of 2007, the Veteran's Administration (VA) Healthcare for Homeless Veterans (HCHV) program began the Health Care for Re-Entry Veterans (HCRV) program. The goal of the HCRV program is to connect incarcerated veterans with treatment and rehabilitative services upon release as a strategy to prevent homelessness. To better understand potential health care and support service needs of the re-entering veterans, we compared demographics, indicators of socioeconomic vulnerability, and clinical characteristics of HCRV veterans with non-HCRV veterans.

METHODS: Using the Veterans Health Administration (VHA) Medical SAS datasets, which contain national administrative data on both inpatient and outpatient patient care encounters, all male veterans with at least 1 HCRV visit from January 1, 2008 through September 30, 2012 were identified as cases. A control group was randomly selected from the same age range as the cases by selecting male veterans without an HCRV visit during the study time period. Period prevalence of demographic characteristics and clinical diagnoses were compared between the cases and controls using t-tests or chi-square tests.

RESULTS: A total of 24,622 veterans had at least one HCRV visit during the study period. Compared to the control group (n=50,140), higher proportions of HCRV veterans were in their 40s (29 % vs. 11 %) and 50s

(40 % vs. 20 %) with fewer in their 60s (13 % vs. 25 %) and 70s (2 % vs. 17 %). Higher proportions of HCRV veterans were of Black race (31 % vs. 12 %). Vulnerability factors most evident among HCRV veterans were a greater prevalence of at least 1 episode of homelessness (47 % vs.5 %), divorced/unmarried/separated/widowed status (79 % vs.38 %), low annual income (<$10,000; 83 % vs. 42 %), and lack of insurance beyond VA benefits (84 % vs. 52 %) compared to the controls. HCRV veterans had slightly higher proportions with PTSD diagnoses (16 % vs. 13 %), but lower proportions with hypertension (33 % vs. 58 %) and diabetes (11 % vs. 25 %) diagnoses. $p<.001$ for all comparisons.

CONCLUSIONS: Consistent with prior literature on former non-veteran inmates, HCRV veterans are more likely to be younger and of Black race compared to their counterparts in the general veteran population. HCRV veterans have higher prevalence of PTSD but lower prevalence of hypertension and diabetes; this finding requires further analyses that control for key covariates including age and race. In addition, veterans with prior incarceration history have significant vulnerability factors that may influence their health care utilization including a) an almost 10-fold elevated prevalence of homelessness, b) a high prevalence of poverty, and c) lack of social support from a spouse or partner. Future work should focus on understanding what types of social and medical interventions may enable VHA, the sole source of health care for most HCRV veterans, to promote the healthy re-integration of these individuals into the community.

DEPRESSION CARE MANAGEMENT EFFECTIVELY SUPPORTS AND PROMOTES SELF-MANAGEMENT AMONG PATIENTS IN PRIMARY CARE Ramona S. DeJesus; Kristin Vickers Douglas; Lisa Howell. Mayo Clinic, Rochester, MN. (Tracking ID #1641876)

BACKGROUND: The collaborative care model, using allied health personnel, to act as care managers, has been consistently shown in studies to be effective in achieving sustained treatment outcomes in chronic disease management such as depression. Prior research had shown patient willingness to work with care managers but little is known on their satisfaction with this model. This study evaluated patient perceived satisfaction with care management and opinions on effectiveness of care management in promoting self-management.

METHODS: Adult patients seen at four primary care sites who had been enrolled in care management for depression and who has had at least 4 contacts with a care manager as identified through the registry, were asked to participate. A questionnaire with consent form was mailed out to 500 eligible patients. Qualitative and quantitative responses were collected from 125 responders. Qualitative responses were coded with methods of content analysis by two independent analysts.

RESULTS: Mean age of participants was 46 years (79 % female) and majority has a diagnosis of recurrent depression (65 %). Interestingly, the mean age among patients when they first experienced depression symptoms was 26 but mean age at time of initial diagnosis was 34. Results indicated that patients were satisfied with depression care coordination (M=8.5 [SD=2]; 10=very good). Predominant themes viewed care managers as caring and supportive. They created accountability for patients ("someone you can be accountable to"), and were knowledgeable experts ("knowledgeable in what you're struggling with") on depression care. Care managers were viewed as supporting self-management by collaborating to find solutions rather than fixing the issue for the patient. Although patients were satisfied with care management relationship and focus, logistical challenges associated with a telephonic intervention were problematic for some.

CONCLUSIONS: Patients with depression who worked with care managers under the collaborative care management program report very positive experience and high rate of acceptance to the model. There is a need to diagnose depression earlier and treat it using effective care models such as this. Barriers in care coordination, such as scheduling telephone calls, should be addressed in future care management implementation and study.

DESCRIPTIVE STUDY OF AFRICAN AMERICAN MEN SUCCESSFUL AT LONG-TERM WEIGHT LOSS MAINTENANCE Ann S. Barnes[1]; Rachel T. Kimbro[2]. [1]Baylor College of Medicine, Houston, TX; [2]Rice University, Houston, TX. (Tracking ID #1641804)

BACKGROUND: Overweight and obesity are highly prevalent in African American men: 70 % of non-Hispanic Black men have a BMI>25. However, there is limited data regarding weight loss and maintenance among this high risk group. The purpose of the current analysis is to describe a sub-sample of African American men who participated in a larger study about African American weight loss maintenance. The parent study (DK064898) identified a large sample of African American adults who intentionally achieved clinically significant weight loss of 10 % and maintained that weight loss for at least 1 year and compared them to individuals who achieved 10 % weight loss but regained the weight.

METHODS: A cross-sectional study design was used. Participants were recruited through various modalities. Eligible participants were asked to complete survey instruments about themselves and their weight history including demographic and weight characteristics, weight-loss and maintenance approaches. Participants completed the International Physical Activity Questionnaire. Responses from individuals who maintained weight and those who regained weight were compared using t-tests. All analyses were completed using STATA.

RESULTS: One thousand two hundred eighty African Americans completed surveys in the parent study. Of those, 133 were men (47 weight-loss maintainers and 86 weight-loss regainers). The average age for men was 42 years. Male weight-loss maintainers lost an average of 25 % of their body weight and maintained ≥ 10 % weight loss for an average of 6.8 years. Men who maintained most or all of the weight they lost reported limiting carbohydrates (42.4 % vs 22.7 %, $p\leq.05$) or using a food exchange or point system diet (15.6 % vs 4.0 %, $p\leq.05$) for initial weight loss when compared to those who regained weight. More male maintainers chose walking for physical activity for their initial weight loss than did regainers (77.8 % vs 47.7 %, $p\leq.010$). They also reported exercising at home (52.8 % vs 23.1 %, $p\leq.010$), outside in their neighborhood (38.9 % vs 18.5 %, $p\leq.05$), or during breaks on the job (33.3 % vs 13.9 %, $p\leq.05$) more frequently than did male weight-loss regainers. In terms of current maintenance habits, male weight-loss maintainers reported eating at fast food restaurants <1 time weekly more often than male regainers (59.6 % vs 30.2 %, $p\leq.001$). Likewise, more male maintainers are currently engaging high levels of physical activity as measured by the International Physical Activity Questionnaire when compared to regainers (66.6 % vs 32.6 %, $p\leq.001$).

CONCLUSIONS: Although small, this sample of African American men successful at long-term weight loss offers preliminary findings about weight-loss and maintenance in this understudied group. These limited findings suggest that low carbohydrate and/or exchange/point diet programs and walking in routine daily settings are relevant for initial weight loss in this group. Maintenance was associated with limiting fast food and engaging in high levels of physical activity. In clinical practice, providers may consider discussing one or more of these specific strategies for weight loss and maintenance with African American men.

DEVELOPING A CURRICULUM FOR MEDICINE RESIDENTS ON INCORPORATING PROGNOSIS IN THE CARE OF OLDER ADULTS WITH MULTIMORBIDITY Nancy L. Schoenborn; Matthew McNabney; Danelle Cayea; Cynthia M. Boyd. Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #1629769)

BACKGROUND: Multimorbidity (2 or more chronic conditions) is a common problem that affects over one in four Americans. Older adults are particularly affected, with half of older adults having three or more chronic conditions. Patients with multimorbidity (MM) are extremely vulnerable. Multimorbidity is associated with higher mortality, disability, institutionalization, decreased quality of life, and higher rates of adverse effects of treatment or interventions. Central to caring for patients with MM is adequate training specific to caring for this population. Guiding principles

for caring for older adults with MM were developed and published by the American Geriatrics Society. We describe a curriculum for internal medicine (IM) residents to teach these guiding principles, with a focus on prognosis.

METHODS: Our curriculum development process follows the 6-step method described by Kern et al. To assess general needs, we searched the literature for current approaches to teaching about caring for patients with MM and about assessing, discussing, or incorporating prognosis into clinical decision making. We assessed the needs of our targeted learners (IM residents at our institution) by gathering information on existing curricula, meeting with key stakeholders, and surveying a subset of residents at a teaching conference where we facilitated case discussions on MM and prognosis.

RESULTS: We found no described curriculum on caring for patients with MM. Some taught about caring for patients with chronic diseases, but focused on single diseases. The few that addressed prognosis existed within curricula on palliative care and oncology. None focused on assessing, discussing, and incorporating prognosis into managing patients with MM. Similarly, our targeted learners have had little teaching on integrating prognosis into caring for patients with MM. Fourteen IM residents attended the teaching conference [44 in program] and responded to our survey on using prognosis in the care of patients with MM. Two-thirds of the respondents reported that they did not regularly assess prognosis in their continuity clinic; none regularly discussed prognosis with patients. The main barriers cited were lack of knowledge and competing demands in clinic.

CONCLUSIONS: There are significant gaps in the education of clinicians on how to incorporate prognosis in the care of patients with MM. Residents who responded to our survey reported knowledge deficiency in this area. We are in the process of designing a curriculum to address this gap. We will focus on integrating prognosis into preventive care and management of certain common chronic diseases, and on recognizing when to consider palliative care. We plan to integrate didactic and case-based teaching methods, and reinforce learning longitudinally through supervised problem-solving in clinical practice.

DEVELOPING AN EFFICIENT SCREENER FOR TOBACCO, ALCOHOL, AND DRUG USE IN PRIMARY CARE: RESULTS OF QUESTION TESTING AND TEST-RETEST RELIABILITY STUDIES OF THE 'SUBSTANCE USE BRIEF SCREEN (SUBS)'

Jennifer McNeely[1,2]; Perry N. Halkitis[3,1]; Shiela Strauss[4]; Ariana Horton[4]; Rubina Khan[1]; Marc N. Gourevitch[1]. 1NYU School of Medicine, New York, NY; [2]NYU School of Medicine, New York, NY; [3]NYU Steinhardt School, New York, NY; 4NYU College of Nursing, New York, NY. (Tracking ID #1641225)

BACKGROUND: A major impediment to implementation of substance use screening and brief interventions in general healthcare settings is the lack of a truly efficient yet precise screening instrument that is compatible with clinical workflows. As a first step toward addressing this need, we developed the Substance Use Brief Screen (SUBS); a 4-item screener for tobacco, alcohol, illicit drugs, and nonmedical use of prescription drugs that is short, self-administered, and could be easily integrated with electronic health records.

METHODS: This was a two-phase instrument development study. Potential participants were approached consecutively in the waiting area of a large urban safety-net primary care clinic and screened for eligibility. Basic eligibility criteria were: current clinic patient, English speaking, age 18–65. In the initial phase, 27 participants completed a 30–40 min cognitive interview to assess item comprehension and acceptability. Detailed field notes were analyzed for comprehension of the screening items and participants' accuracy in classifying substances according to these categories, and the instrument was adapted based on these findings. In the following test-retest reliability phase, a second group of 61 participants completed the SUBS as a self-administered questionnaire on a touchscreen tablet computer, and were asked to return 1–2 weeks later to repeat it. Agreement between responses at the first versus second administration was evaluated with the phi coefficient and McNemar's tests.

RESULTS: The 88 total participants were 51 % male, with mean age 45 years (range 19–65, SD=12). 52 % were black, 22 % white, and 20 % Hispanic; 24 % were foreign born. 39 % had a high school education or less. Reported rates of past year use were 36 % for tobacco, 57 % for alcohol (4+ drinks/day), and 42 % for drugs (30 % illicit drugs only, 23 % prescription drugs only, 14 % both). Cognitive interviews in phase one (n=27) indicated that most participants were comfortable with the questionnaire, but many inaccurately estimated the quantity of alcohol in 'one drink' and misclassified medications without abuse potential (including over the counter medications) as nonmedical use of prescription drugs. In the test-retest reliability study (phase two, n=61), 54 (89 %) participants completed both visits. SUBS responses were 100 % complete. Correlation between screening results on the first and second administration was excellent for tobacco (phi=.96) and drugs (phi=.78), and good for alcohol (phi=.63). When illicit and prescription drugs were examined as independent categories of drug use, reliability was better for illicit drugs (phi=.73) than for prescription drugs (phi=.36). There were no significant differences between test administrations in detecting use, based on McNemar's tests, for any substance.

CONCLUSIONS: The Substance Use Brief Screen (SUBS) facilitated reporting of high levels of substance use, had good test-retest reliability, and was feasible in this sample of primary care patients. More work is needed to improve the clarity of the prescription drug misuse screening item, and further research is required to evaluate the validity of the SUBS for detecting unhealthy use and substance use disorders. If it is shown to have sufficient sensitivity and specificity for detecting clinically relevant substance use, this brief, self-administered instrument could facilitate routine integrated screening for tobacco, alcohol, and drug use in primary care settings.

DEVELOPMENT OF AN INSTRUMENT TO MEASURE THE QUALITY OF TREATMENT DECISIONS FOR ASYMPTOMATIC CAROTID ARTERY DISEASE

Ethan Halm[1]; Jasmin Tiro[1]; Colin Nelson[2]; Kim Batchelor[1]; Lei Xuan[1]; Carol Cosenza[3]; Karen R. Sepucha[4]. [1]Univ of TX Southwestern Med Ctr, Dallas, TX; [2]Informed Medical Decisions Foundation, Boston, MA; [3]Univ of Massachusetts, Boston, MA; [4]Massachusetts General Hospital, Boston, MA. (Tracking ID #1633408)

BACKGROUND: Patients (Pts) with asymptomatic carotid stenosis have 3 treatment options: carotid endarterectomy (CEA), carotid artery stenting (CAS), and medical therapy alone (Med)–each with its own benefits and risks. The quality of a decision about whether to undergo elective carotid revascularization depends on the extent to which the treatment reflects what's most important to an informed Pt. Valid measures of Pts' knowledge about treatments options and preferences are needed to assess decision quality and guide Pt education strategies about this common asymptomatic condition. We sought to identify a set of key facts, goals and concerns relevant to each treatment decision (CEA, CAS, Med) and assess differences in Pt and physician (MD) perspectives.

METHODS: We identified candidate 'Facts' (knowledge items about carotid disease, treatment options, and their associated short and long term benefits and risks) and 'Goals' (preferences for avoiding short/long term problems, invasive procedures) via literature review and qualitative work with Pts and MD experts. A written survey was mailed to Pts with carotid disease managed medically and surgically, and national experts (surgeons and non-surgeons). Respondents assessed and ranked the accuracy, importance and completeness of proposed decision quality instrument items with Likert scales.

RESULTS: We obtained 31 surveys from Pts with asymptomatic carotid disease-16 had CEA and 15 chose Med (69 % responded) and 30 surveys from international experts (US, Canada, UK) in vascular surgery, neurosurgery, neurology, and internal medicine (64 % responded). A core

set of 27 Facts (knowledge items) and 6 Goals (preference statements) were identified as important and comprehensive. The set of Facts were rated accurate, important and complete. For Facts, Pts rated as more important than MDs: explaining stenosis, trade-off of higher short term risk of stroke due to CEA/CAS in return for lower long term risk, need for Med after revascularization, short term risks of CEA/CAS, and lack of mortality benefit with CEA ($p<.05$). For Goals, Pts rated as more important than MDs avoiding invasive procedures and procedure complications ($p<.05$). Pts who had CEA had similar rankings as those who chose Med. Non-surgeons (compared to surgeons) rated as more important understanding that: carotid stenosis does not require CEA and treatment choice depends on medical factor and Pt preferences ($p<.05$) and trended towards having more concerns about risk of stroke due to CEA ($p=.08$).
CONCLUSIONS: A new decision quality instrument about asymptomatic carotid artery disease decision making was deemed by Pts and MDs to be accurate, important, and complete. Because Pts, surgeons, and non-surgeons perspectives are different, it is vital that a measurement tool include items reflecting all 3 views.

DEVELOPMENT OF THE TOOL TO ASSESS INPATIENT SATISFACTION WITH CARE FROM HOSPITALISTS (TAISCH) Haruka Torok[1]; Eric Howell[1]; Regina Landis[2]; Susrutha Kotwal[1]; Scott Wright[1]. [1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins Bayview Medical Center, Baltimore, MD. (Tracking ID #1632948)

BACKGROUND: Service excellence in U.S. hospitals, as measured by patient satisfaction scores, is receiving more attention with the results being reported publicly and affecting reimbursement rates. Ideally, accurate feedback could be given to individual providers to improve their performance; however the current survey data collection methods have significant limitations that lessen their usefulness.
METHODS: We developed an 18-item survey instrument, TAISCH, whose blueprint was built upon the theoretical underpinnings of the quality of care measures that are recommended by the Society of Hospital Medicine Membership Committee Guidelines for Hospitalists Patient Satisfaction. Other existing validated measures of the quality of patient care were reviewed and items related to the physician's care were included to further substantiate content validity. Input from experts was also solicited. The preliminary instrument was pilot tested on numerous inpatients and TAISCH was iteratively revised. The final version of TAISCH was administered to inpatients after they had been cared for by the same hospitalist provider for at least 2 consecutive days. The patients were enrolled only if they could correctly identify their hospitalist provider. TAISCH specifically asked the patients to rate their hospitalist provider's performance along multiple domains. Only hospitalist providers for whom at least 4 surveys were collected were included in the analysis. Reliability and validity testing were performed. Correlations between composite TAISCH score and Press Ganey (PG) physician score (comprised of 5 questions) were assessed.
RESULTS: Of 257 inpatients approached, 30 patients (12 %) refused to participate. Among the 227 consented patients, 24 (9 %) were excluded as they were unable to correctly identify their hospitalist provider. A total of 203 patients were enrolled and rated one of the 29 hospitalists. The patients' mean age was 60, 114 (56 %) were female, and 61 (30.5 %) were of a non-white race. Two hospitalists with fewer than 4 surveys collected were excluded from the analysis. Two hundred unique patients assessed one of the 27 hospitalists (Mean 7.4 surveys per hospitalist). The hospitalists' TAISCH score ranged from 55 to 69 (mean: 60.9, Standard deviation: 10.2, possible score range: 16–80). Reliability of TAISCH was very good (Cronbach's alpha=0.88). Pearson's correlation coefficient showed statistically significant correlation between TAISCH and the Jefferson Scale of Physician Empathy ($p<.001$, convergent validity). The correlation between TAISCH score and PG physician score was assessed for 20 out of 27 hospitalists for whom both data were available. The Pearson's Correlation coefficient was low at 0.15 ($p=.53$).
CONCLUSIONS: TAISCH allowed us to obtain patient satisfaction data that is undeniably attributable to specific hospitalist providers. TAISCH's strong correlation with the empathy scale and the lack of correlation with PG score calls into question our current methods for assessing patient satisfaction regarding hospitalist's quality of care. The timeliness of the TAISCH assessments also makes it possible for real-time service recovery which is impossible with other commonly used metrics evaluating patient satisfaction.

DIABETES CONTROL: IS TRAVEL TIME TO PRIMARY CARE PROVIDER ASSOCIATED WITH CHANGES IN HEMOGLOBIN A1C? A PRELIMINARY GEOSPATIAL ANALYSIS Andrew P. Wilper; Rick Tivis. University of Washington School of Medicine, Boise, ID. (Tracking ID #1643228)

BACKGROUND: Long term complications of diabetes are a major source of morbidity, mortality and cost. Diabetes management remains challenging even in the best circumstances. Continued search for modifiable variables associated with disease control is warranted. In our study, we analyzed the effect of drive time to primary care provider on diabetes control.
METHODS: We used data from the Veterans Integrated Service Network 20 Corporate Data Warehouse for this study. We identified diabetics by ICD-9 codes between 2008 and 2011. Our sample included 7,459 patients from the Boise VA catchment area. Using geocoded street address, we calculated both driving distance and drive time from the patient's home to their VA primary care facility. This distance and drive time analysis was calculated for each quarter year, as patient address is updated every 3 months. Therefore, change in address, and therefore change in drive time, is accounted for in this analysis. The Hemoglobin A1c (A1c) measures for an individual were averaged over each quarter of the year to coincide with the format of the distance data. Analysis was performed using a modified linear regression via SAS proc mixed to account for the repeated and variable nature of this data. Separate analyses were conducted for the 4th and 1st quarters (fall/winter) and the 2nd and 3rd quarters (spring/summer) as drive time in Idaho is more of a consideration in the winter months. We used SAS 9.2 (Cary, NC) for the statistical analysis. The distance and drive time analysis was provided by the Veterans Administration Planning Systems Support Group, Gainesville, Fl, using ESRI ARCGIS suite (Redlands, CA) and NAVTEQ street map premium (Chicago, Il). The Puget Sound IRB approved this study.
RESULTS: The study population was overwhelmingly male, 97 % ($n=$ 7,204), with an average age in 2008 of 65 years (standard deviation (SD)= 12 years). Sixteen percent died during the study period. The mean driving distance was 52 miles (SD=123 miles) miles and the mean drive time was 51 min (SD=143 min). The mean A1c was 7.2 (SD=1.4). Repeated measure regression analysis revealed a significant positive relationship between time traveled and A1c (F statistic 4.63, $p=0.0315$) in the fall/winter months while there were no significant relationship in the spring/summer months. This translates to a 0.03 increase in A1c for every hour of drive time. There was no significant ($p>.50$) relationship during the spring/summer quarters.
CONCLUSIONS: We demonstrate a small but significant relationship between diabetes control and drive time during the winter months. This suggests that increased travel time may be a risk factor for uncontrolled diabetes. Next steps in this analysis include adjustment for demographics and medical co morbidities, as well as analysis of mortality, blood pressure and lipid control. Should a relationship between drive time and disease control persist, we will search for a threshold drive time beyond which patients may need additional support for diabetes management.

DIAGNOSTIC UTILITY OF CTA CHEST IN "PE UNLIKELY" PATIENTS Kasaiah Makam[1]; Ashok Akula[1]; Alan Greenberg[2]. [1]University of Nevada School of Medicine, Las Vegas, NV; [2]University Medical Center, Las Vegas, NV. (Tracking ID #1642785)

BACKGROUND: Acute Pulmonary embolism (PE) affects approximately 69 persons per 100,000 people annually and is a major problem if not diagnosed in timely fashion. Clinical value of CTA (Computed tomography angiography) is similar to conventional angiography in diagnosing acute PE. Modified Wells score stratifies the patients at risk of acute PE into PE likely (score>4) and PE unlikely (</=4) groups. The combination of a score </=4.0 and a negative D-Dimer result may safely exclude PE in a large proportion of patients with suspected PE. We and others have observed frequent utilization of CTA in PE unlikely group. We wondered whether there is any clinical utility in obtaining CTA chest in PE unlikely patients.
METHODS: This was a single center, retrospective analysis based on results of CTA chest, CXR (chest x-ray) and chart review. Based on chart review modified Wells score was determined. Patients divided into PE likely and PE unlikely groups. For this study, "operationally" PE likely group was defined as score>4 or score </=4 with positive D-dimer and PE unlikely group was defined as score </=4 with negative D-dimer if available. The presence or absence of PE was determined based on CTA chest results. Clinically relevant alternative diagnoses (AD) made on CTAs were ascertained. CXR reports were reviewed and compared to CTA chest results. Prevalence of PE and net diagnostic utility were determined for defined PE unlikely group estimated as the outcome measures of the study. Prevalence of PE = Number of PE/total CTAs performed in defined PE unlikely group. Net diagnostic utility = AD-CXR/total CTAs performed in defined PE unlikely group (AD-CXR- Clinically relevant alternative diagnosis not discernible on CXR other than acute PE)
RESULTS: 268 patient charts were reviewed between age groups 18–65 who underwent CTA chest within 24 h of admission. Two patients were excluded from study. 16 patients were in PE likely group and 250 in PE unlikely group. D-dimer was performed in 51 patients of 250 in PE unlikely group and 43 were D-dimer positive. Therefore defined PE unlikely group included 207 patients. In this group 3 patients had acute PE and prevalence of PE was 1.44 % (3/207). 7 patients had clinically significant alternative diagnoses not discernible on CXR and Net diagnostic utility of CTA chest in PE unlikely group was 3.38 % (7/207, AD-CXR = Pneumonia-3, Pneumothorax-2, Lymphoma-1, skeletal metastasis-1). None of the patients in defined PE unlikely group had acute PE with negative D-dimer (8 patients = Wells score <4 and negative D-dimer).
CONCLUSIONS: Our results indicate that performance of CTA chest in the defined PE unlikely group has little diagnostic utility. In-fact only 1 in 33 CTAs has yielded clinically useful information, therefore our data does not support regular use of CTA chest in PE unlikely group. Routine incorporation of modified Wells score and D-dimer assay in the initial evaluation of patients in whom PE is diagnostic consideration should lead to significant decrease in CTA chest examinations.

DIFFERENCE OF SELF-REPORT COMPETENCY CONFIDENCE SCORES AND NUMBERS OF EXPERIENCED CASES BETWEEN TWO TYPE OF ROTATION PROGRAM AMONG JAPANESE JUNIOR RESIDENTS: NATION-WIDE SURVEY Sachiko Ohde; Osamu Takahashi; Gautam A. Deshpande; Tsuguya Fukui. St. Luke's International Hospital, Chuo Tokyo, Japan. (Tracking ID #1642966)

BACKGROUND: Japanese physicians experience their first clinical practice in the junior residency program (1st- and 2nd-year residents). The junior residency program has been mandatory for all physicians since 2004. From 2004 to 2009, this "core-based" curriculum required trainees to rotate in major departments (internal medicine, 6 months; surgery, 3 month;, anesthesiology, 1 month; OBGYN, 1 month; pediatrics, 1 month; psychiatry, 1 month; rural medicine, 1 month). In 2010, the Ministry of Health and Welfare allowed residents in some programs to choose a larger number of selectives ("selective-based curriculum"), reducing the number of required core departments. Despite resident freedom to choose preferred rotations, there are growing concerns about deterioration of basic clinical skills by young doctors.
METHODS: A nationwide cross-sectional study was conducted in March 2011. A standardized survey was distributed to all 2nd year residents in Japan, which included the type of curriculum (core-based or selective-based), self-reported competency scores for 98 clinical items, and number of cases experienced for 85 diseases. Competency scale scores and number of cases experienced was compared by curricular type.
RESULTS: Among a total of 7506 Japanese residents, 5052 residents replied to the survey (67.3 %); 3265 were males (64.6 %) and mean age was 283 years. 1206 (23.9 %) residents were in selective-based rotation programs. Out of 98 clinical competency items, residents in selective-based programs reported lower confidence scores in 12 items compared to those in core-based programs. Out of the 85 diseases assessed, selective-based residents reported less experience in 11 diseases. OBGYN- and pediatrics-related items and cases were particulary low.
CONCLUSIONS: Residents who are in selective-based curricula reported less confidence and less case experience, especially in OBGYN and pediatrics. To achieve primary care competency, junior residency program should maintain a core-based curriculum

DIFFERENCES IN CERVICAL CANCER KNOWLEDGE AMONG MINORITY WOMEN IN MIAMI Kumar Ilangovan[1]; Tulay Koru-Sengul[2,3]; Erin N. Kobetz-Kerman[2,3]; Olveen Carrasquillo[1]. 1University of Miami Leonard M. Miller School of Medicine, Miami, FL; [2]University of Miami Leonard M. Miller School of Medicine, Miami, FL; [3]University of Miami Sylvester Comprehensive Cancer Center, Miami, FL. (Tracking ID #1637087)

BACKGROUND: Minority women suffer disproportionately from cervical cancer incidence and mortality. Education initiatives aimed at improving cervical cancer knowledge may lead to increased appropriate screening and reductions in morbidity. Baseline data describing the variable levels of knowledge among specific minority and underserved communities will aid the design of such programs.
METHODS: The South Florida Center for Reducing Cancer Disparities is a comprehensive NCI initiative focused on the reduction and ultimate elimination of cervical cancer disparities in Miami-Dade County. As part of an ongoing randomized intervention study, we collected baseline data on cervical cancer knowledge among three minority communities: Little Haiti, Hialeah (90 % Latino), and West Perrine (mixed community). Eligibility criteria included women aged 30–65 years and not having had a Pap smear in the past 3 years. Knowledge was assessed using questions from the NCI's Health Information National Trends Survey (HINTS), which we translated and back translated into Haitian Kreyol and Spanish. We used Fisher's exact test to examine differences in knowledge across minority subgroups. We then used univariate and multivariate logistic regression models to control for additional sociodemographic correlates of higher cervical cancer knowledge.
RESULTS: Among the 202 women enrolled to date, 50 % are Latina, 40 % Haitian, and 10 % African American (AAs). We found 51 % of Latinas answered > 50 % of questions correctly versus 20 % of AAs and only 9 % of Haitians ($P<0.05$ for each group versus Latinas; see table 1 for examples of individual questions). Years of education and being married, but not age, were positively correlated with higher levels of knowledge ($P<0.05$). In multivariate analysis, adjusting for these potential confounders, Haitians remained less likely to answer > 50 % of questions correctly (OR 0.22, 95 % CI 0.08–0.63). The smaller sample size limited the statistical power of our comparison for AAs (OR 0.37, 95 % CI 0.10–1.39).
CONCLUSIONS: Among minority women in Miami who had not been adequately screened for cervical cancer, Haitians had the lowest levels of

cervical cancer knowledge. As more women are enrolled in our study (target 600) we will have greater power to detect potential differences among AAs. We have developed and are now testing culturally tailored educational interventions in these vulnerable groups.

Table 1

Question	Percent Answering > 50% Correctly		
	Latina	Haitian	African American
Do you think that most women diagnosed with cervical cancer die from the disease?	54%	6%	35%
Do you think that being hit in your lower abdomen can cause cervical cancer?	34%	6%	30%
Have you ever heard of HPV? HPV stands for Human Papillomavirus.	67%	20%	45%
* P <0.0001 for all group comparisons			

DIFFERENTIAL ADHERENCE TO MEDICATIONS BY OLDER ADULTS WITH MULTIPLE COMORBIDITIES Alex Federman[1]; Michael S. Wolf[2]; Anastasia Sofianou[1]; Melissa Martynenko[1]; Juan P. Wisnivesky[1]. [1]Mount Sinai School of Medicine, New York, NY; [2]Northwestern University, Chicago, IL. (Tracking ID #1636465)

BACKGROUND: Elderly patients with chronic diseases, such as asthma, frequently have multiple coexisting illnesses requiring daily adherence to medications. In this study we examined the extent of agreement of adherence across multiple medications in these patients.

METHODS: Asthmatics ages ≥60 were recruited from hospital and community practices in New York, NY and Chicago, IL (n=420). We administered the Morisky Medication Adherence scale, a validated 5-item assessment (score range, 0–4) to measure adherence to medications for up to 4 conditions: asthma (n=370, 88 %), hypertension (n=323, 77 %), hyperlipidemia (n=200, 48 %), and diabetes (n=128, 30 %). For patients on multiple medications for the same condition the average of scores was used. We utilized correlation analyses to assess the association of continuous adherence scores for asthma vs. other medications and calculated kappa statistics for agreement of adherence to these medications (good adherence defined as a score of 4).

RESULTS: Rates of medication adherence for each condition varied: for asthma, 41 %; hyperlipidemia, 70 %; diabetes, 66 %; and hypertension, 62 %. The correlation (r) of the continuous measures of adherence to asthma and hyperlipidemia, diabetes, and hypertension medications was relatively low (r=0.28, p=0.004; 0.13, p=0.35; 0.20, p=0.01; respectively). Similarly, k levels of agreement were low (0.17, 0.02, and 0.13, respectively; all p<0.01). In contrast, co-adherence was more likely for the non-asthma medications: hyperlipidemia and hypertension, k=0.45, r=0.50, p<0.0001; hyperlipidemia and diabetes, k=0.39, r=0.36, p<0.0001; diabetes and hypertension, k=0.27, r=0.36, p<0.0001.

CONCLUSIONS: Good adherence to hyperlipidemia, diabetes, and hypertension medications does not predict adherence to asthma medications. Optimizing the management of patients with multiple chronic diseases will require a better understanding of how and why patients adhere differentially to their medications.

DISABILITY BETTER PREDICTS LENGTH OF STAY THAN COMORBIDITY IN PATIENTS ADMITTED TO INTERNAL MEDICINE Chunzhen Tan[1,2]; Yee Sien Ng[2]; David Matchar[1]; Gerald Choon Huat Koh[3]; Young Kyung Do[1]. [1]Duke-NUS Graduate Medical School Singapore, Singapore, Singapore; [2]Singapore General Hospital, Singapore, Singapore; [3]Saw Swee Hock School of Public Health, Singapore, Singapore. (Tracking ID #1624134)

BACKGROUND: Clinical management and resource allocation for Internal Medicine (IM) patients are currently based on their presenting diagnosis, with little attention paid to the impact of disability and comorbidity. The primary aim of this study was to examine the association of disability and comorbidity with the length of stay (LOS) and their relative importance.

METHODS: Over 2 consecutive years, the study recruited consecutive unselected patients from an academic tertiary hospital who were admitted to the IM Department under a single medical team for a month. Explanatory variables charted included demographic, disease type, biochemical markers, social factors (e.g., financial difficulties and caregiver availability), comorbidities and functional disability. Our measure for functional disability was the Functional Independence Measure (FIM) recorded at inpatient discharge, a standardized measure consisting of 13 motor and 5 cognitive items ranging from 18 (totally dependent) to 126 (totally independent). Comorbidity was measured using the Charlson Comorbidity Index (CCI). Multiple regression analysis was conducted to examine independent associations of FIM and CCI with the length of hospital stay controlling for confounders such as demographics and social factors.

RESULTS: Among 248 patients included in the study (age 65.9 ±18.4, male 51.5 %), the mean LOS was 11.2±32.9 days with the median of 4.0 days. The average inpatient total FIM score was 92.3 ±37.2 with the mean motor FIM and cognitive FIM scores being 64.7±28.5 and 28.0±9.8, respectively. The mean unadjusted and adjusted CCI was 2.51±2.60 and 4.47±3.66 respectively. Sixty-three (34.1 %) patients had various social issues including financial difficulties and caregiver availability. The majority of patients (79.4 %) were discharged home. Multiple regression analysis results showed that greater functional dependence represented by a lower total FIM score (p=.006) and the

presence of social issues (p=.001) were positively and statistically significantly associated with the length of stay, while age (p=.119), gender (p=.555) and the CCI (p=.931) were not.
CONCLUSIONS: Disability may be a better predictive factor than comorbidity for the length of stay in IM patients. Optimal health care management could consider the benefit of incorporating disability in resource allocation in addition to the presenting diagnosis.

DISPARITIES IN SURGERY FOR EARLY STAGE LUNG CANCER: DO COMORBIDITIES AFFECT SURGICAL SURVIVAL DIFFERENTLY? Samuel Cykert[1]; Lloyd Edwards[2]; Paul Walker[3]; Franklin McGuire[4]; Peggye Dilworth-Anderson[5]. [1]University of North Carolina, Chapel Hill, NC; [2]University of North Carolina School of Public Health, Chapel Hill, NC; [3]Brody School of Medicine, Greenville, NC; [4]University of South Carolina School of Medicine, Columbia, SC; [5]University of North Carolina School of Public Health, Chapel Hill, NC. (Tracking ID #1637808)

BACKGROUND: Our recent, prospective cohort study confirmed the many reports using administrative data showing that African-Americans (AA) with early stage, non-small cell lung cancer receive potentially curative surgery less often than similar white patients (W). We found that AA with 2 or more comorbid illnesses only rarely went to surgery while W still proceeded to surgery regularly. As part of a lung cancer disparities intervention trial, we performed a retrospective chart review to determine the baseline rate of lung cancer surgery at the 3 participating institutions and to identify predictors of mortality for all patients. We also determined how comorbid conditions affected mortality in the surgical group. These data will be used for provider feedback as part of the multi-modal intervention approach.
METHODS: We performed a retrospective chart review of patients with biopsy proven early stage, non-small cell lung cancer at 3 academic institutions in the Southeast. Local cancer registries were used to identify patients then trained research associates extracted predetermined data. Note that one institution has a functional data warehouse and the data elements there were extracted in an automated fashion after which the RA performed regular sample checks to ensure accuracy. Elements of the chart review included demographic information, smoking status, pulmonary function tests, comorbid illnesses, date of death if applicable, surgical status, and cancer stage. Comorbid illnesses were used individually in the analyses when possible and were also compiled in other analyses as part of a Charlson Score. Descriptive statistics were compiled and bivariate analyses were performed with particular attention to receipt of surgery and 1 year mortality as outcomes. Regression analyses were performed using these same outcome variables and stratified analyses were done according to race and surgical status.
RESULTS: The cancer registries at the 3 institutions identified 714 early stage lung cancer patients during the 3 years of interest. 55 % of patients were male, 25 % AA, and the median age was 68 years. Although 68.5 % of W had lung cancer surgery compared to 65.7 % of AA, controlling for age, comorbidities, COPD, and other demographics the OR for surgery for AA was 0.64 (95 % CI 0.43, 0.96). The overall mortality rate was 14 % and did not differ by race. When considering the entire cohort, a Charlson Score>2 was associated with twice the chance of dying (OR 2.1, 95 % CI 1.4, 3.4) and surgery was associated with half the chance of dying (OR 0.55, 95 % CI 0.35, 0.89). When broken into individual components ef <40 % and known CAD were significantly associated with death. Examining the surgical group alone and the AA lung cancer group, these results remained consistent.
CONCLUSIONS: The tradeoff between surgery and comorbid illness continues to be the perplexing area in lung cancer surgery decision making. The diagnosis of COPD was not associated with an increase in 1 year mortality while cardiac illness was. AA did not differ in this regard. Instead of lower surgical rates among AA, perhaps more aggressive preoperative cardiac evaluation could optimize surgical outcomes and narrow disparities in care.

DO LETTERS OF RECOMMENDATION PREDICT SUCCESS IN MEDICAL SCHOOL? Elexis McBee[2,1]; Gretchen Rickards[2,1]; Nathalie Paolino[2,1]; Charles D. Magee[1,2]; Kent DeZee[1,2]. [1]Uniformed Services University, Bethesda, MD; [2]Walter Reed National Military Medical Center, Bethesda, MD. (Tracking ID #1641782)

BACKGROUND: Letters of Recommendation (LORs) are a time-honored aspect of the medical school application process, but their utility has been poorly studied. We sought to determine how well LORs predict performance during medical school.
METHODS: Three consecutive medical school classes (2007–2009) at the Uniformed Services University were retrospectively studied. Up to three LORs for each student in the top 1/6 of the class (Alpha Omega Alpha (AOA) graduates, n=27 per class) were compared to those in the bottom 1/6 of the class (determined by final grade point average, n=27 per class). Each letter was de-identified prior to independent coding by two investigators using a piloted data abstraction form, with differences resolved by consensus. Comparisons between AOA and bottom of the class LORs were made for 46 a priori categories using Chi square, Fisher's Exact Test, or Students' T-test, as appropriate.
RESULTS: We coded 437 letters (214 AOA and 223 bottom of the class LORs). Of the 46 categories coded, 7 categories were significantly different (p<0.05) between the two groups. AOA LORs were more likely than the bottom of the class LORs to have been written by an employer (including a research lab supervisor; 36 % vs. 22 %), to have recommended for employment promotion (16 % vs. none), to have stated the student was the "best" among their peers (41 % vs. 17 %), or to have indicated the student was known "very well" by the writer (41 % vs. 23 %). Conversely, AOA LORs were less likely to have been written by a classroom instructor (56 % vs. 65 %), to have a less than a top choice rating on a standardized LOR form (3 % vs. 19 %), or to have non-positive comments (6 % vs. 13 %).
CONCLUSIONS: In this hypothesis generating study, most variables in LORs did not forecast success during medical school. However, we identified several measures, such as being considered the "best" among peers, that may provide value in predicting medical school performance and warrant further investigation.

DO PHYSICIANS UNDER-RECOGNIZE OBESITY? Rachana Thapa[1]; Jennifer Friderici[1]; Reva Kleppel[1]; Janice Fitzgerald[1]; MIchael B. Rothberg[2]. [1]Baystate Medical Center, Springfield, MA; [2]Cleveland Clinic, Cleveland, OH. (Tracking ID #1641931)

BACKGROUND: Obesity is associated with adverse health outcomes including diabetes, sleep apnea, hypertension and osteoarthritis. Physician advice is among the strongest predictors of weight management effort by patients, yet only a minority of obese patients receive such advice. One contributor might be a failure to recognize obesity. Our objective was to assess physicians' ability to recognize obesity and identify factors associated with recognition and documentation of obesity.
METHODS: Cross-sectional survey of Internal Medicine and Family physicians at two urban, adult outpatient health centers. At the end of each session, physicians were instructed to categorize patients seen that session as normal weight (BMI<25 kg/m2), overweight (BMI 25–29.9) or obese (BMI≥30) based on recall. Physicians also provided personal demographics and answered 7 questions measuring attitudes about obesity and its treatment. The corresponding patient charts were abstracted for demographics, anthropometrics, and obesity-related comorbidities (diabetes, osteoarthritis, hyperlipidemia, coronary disease, and sleep apnea). We also reviewed whether patients had obesity documented as a problem within the last 3 visits. Proportion

comparisons were performed using Poisson regression, with standard errors adjusted to account for within-physician clustering. Each physician also received a proportion score (# of patients correctly identified as obese/# of obese patients seen). Proportion scores were compared by physician characteristic using Spearman's correlation (continuous) or Wilcoxon Rank Sum (binary). P-values of ≤0.05 were considered statistically significant.

RESULTS: A total of 62/62 physicians who were contacted completed weight assessments for 368 patients; 2 physicians declined to submit the attitudes questionnaire and 11 submitted incomplete questionnaires. The average patient was 50.7±16.1 years old; 56 % were female, 67 % were Hispanic, and 67 % had ≥1 obesity-related comorbidity. There were 175 (48 %) obese patients. Physicians identified 138 (67 %) of these as obese, 49 (28 %) as overweight and 9 (5 %) as normal weight. They identified as obese 85 % (82/96) of those with BMI ≥35, but only 44 % (35/79) of those with BMI of 30–34.9 ($p<0.0001$). Obese Hispanic patients were significantly less likely to be identified as obese than were non-Hispanic ones (62 % vs. 76 %, $p=0.03$). US-trained physicians recognized a higher proportion of obese patients than did international graduates (74 % vs. 53 %, $p=0.08$), and female physicians recognized more than males did (75 % vs. 55 %, $p=0.06$). No other physician factors or attitudes were associated with recognizing obesity. Physicians documented obesity as a problem for 99 (57 %, 95 % CI 49 %, 64 %) obese patients. Documentation was more likely among patients who physicians recalled as being obese (64 % vs. 41 %, $p=0.006$); Attending physicians documented obesity in the patient record more frequently than residents (67 % vs.50 %, $p=0.05$). Physicians documented obesity for 58 % of patients with at least 1 obesity related comorbidity vs. 52 % without ($P=0.59$).

CONCLUSIONS: Physicians have difficulty recognizing obesity unless the patients are morbidly obese. Physicians are less likely to identify Hispanic patients as obese than non-Hispanic patients. Residents documented obesity less often than attending physicians. Physicians should be trained in the recognition and documentation of obesity, especially in Hispanic patients.

DO PHYSICIANS AND PATIENTS DISCUSS THE HOSPITAL PLAN OF CARE? Zackary Berger; Sosena Kebede; Mary Catherine Beach. Johns Hopkins School of Medicine, Baltimore, MD. (Tracking ID #1636967)

BACKGROUND: Hospitalization presents a number of challenges to patients' exercise of autonomy. Little is known about the content of patient-physician dialogue concerning the hospital plan of care, and in particular whether physicians and patients discuss the plan explicitly. Our aim was to assess the discussion of the plan of care between inpatients on a hospitalist service and their physicians.

METHODS: We conducted a qualitative study of patient-doctor communication on an inpatient medicine hospitalist service. A research assistant digitally recorded and transcribed daily doctor-patient dialogue on walk rounds and daily semi-structured interviews with patients and doctors separately. Patient and physician statements were coded using a modified discourse analytic approach; coding categories were collaboratively determined by two of the authors.

RESULTS: Fifty-two encounters for 13 distinct patients were analyzed. Physicians did not discuss the plan of care at any point with seven patients, and acknowledged this in semi-structured interviews ("Sometimes I don't want to discuss everything about the plan because there is a fair amount of uncertainty…so I wouldn't want to be explicit with the patient every single time throughout their stay."). Physicians did discuss the plan of care with six patients (Physician: "I'm not sure that we need to put you through another stress test." Patient: "I want to at least, I want to at least be straight before I'm out of here." Physician: "Ok. Alright, so let me take a look at some of your other labs, and I'll get back to you on that."). In three of these six, the physicians indicated that in the discussion with the patient they obtained patient consent or agreement, but the audiorecorded dialogue revealed that this process was implicit. (Physician: "They are also cardiologists, they're specialists, so they will come and talk to you and then see whether you will [benefit] from the pills." Patient: "Ok." Physician: "Ok. So that's the plan for today.") No physicians discussed the discharge plan with patients.

CONCLUSIONS: While some physicians discuss the plan of care with patients, in some cases this is limited to patient agreement or consent. The discharge plan might be an area in which physicians can communicate more explicitly with patients. Further research should elucidate which communication practices, and characteristics of doctor and patient, act as facilitators or barriers for such explicit discussion.

DOES STRESS TESTING BEFORE ELECTIVE HIP FRACTURE SURGERY INCREASE LENGTH OF STAY AND/OR ALTER PATIENT MANAGEMENT? Elizabeth C. Gadziala[1,2]; Velair Walton[1]; Michael P. Carson[1]. [1]Jersey Shore University Medical Center, Neptune, NJ; [2]Axelrod Research Foundation, Neptune, NJ. (Tracking ID #1631170)

BACKGROUND: Retrospective studies suggested that pre-operative cardiac stress testing could identify patients at high risk for peri-operative myocardial infarction who might benefit from coronary revascularization, but a prospective randomized trial demonstrated that revascularization of high risk patients did not decrease mortality. The accepted approach to patients with acute non-traumatic hip fracture is surgery within 24–48 h of admission. Stress testing is unlikely to alter management, but could cause delays in patient care. The objective was to determine if a preoperative stress test administered to patients with acute hip fractures was associated with a longer length of stay (LOS), and if an abnormal result was associated with an alteration of the care plan.

METHODS: Retrospective case–control study of patients seen at our hospital 2006–2011. Patients were identified by ICD-9 for hip fracture and procedure codes for persantine or dobutamine stress tests. Patients were matched by age and gender.

RESULTS: 42 patients who had a pre-operative stress test (STRESS) were matched to 42 controls (CONTROLS). The mean age was 81 years in both groups, and 70 % were female. The respective mean values (days) for the STRESS group vs. CONTROLS were: LOS 8.3 vs. 4.7 ($p=0.0002$); Time to Operating Room 2.5 vs. 1.4; Time from surgery to discharge 5.7 vs. 3.2. The LOS was 3.6 days longer for the STRESS group [95%C.I. (1.7, 5.5)]. When a cardiologist was consulted 73 % had a stress test ($n=48$) vs. vs. 20 % when they were not (Risk Ratio 3.8 [95 % CI (1.9, 7.5)]), and the mean LOS was 7.9 vs. 4.5 days ($p=0.0004$). Among the STRESS group, the time to the operating room for those with ($n=5$) or without ischemia was 2.6 days, suggesting that an abnormal stress test result did not alter management. 60 % of patients were on beta-adrenergic blocking agents, and this was true for those with and without ischemia on the stress test. Neither of the patients who died had asthma or COPD, but only 1 was on a beta-blocker. The following were associated by Logistic Regression with stress testing: cardiology consultants, COPD, atrial fibrillation and hypercholesterolemia. Surprisingly, diabetes and a known history of coronary disease were not associated with testing.

CONCLUSIONS: In acute hip fracture patients, preoperative stress tests were associated with a longer length of stay, delays in getting to the operating room, and longer time from surgery to discharge. Abnormal results did not prompt alterations in management such as revascularization and beta-blockers were not prescribed to 2 patients with stress-induced ischemia. This study is limited by the retrospective design that could not identify other factors associated with testing or delays. This data suggests that such testing in this population increased LOS without affecting clinical decision making, and education of cardiologists could significantly decrease this "lets just be safe" practice style.

DOES THE MEANINGFUL USE OF ELECTRONIC HEALTH RECORDS IMPROVE CHRONIC CARE ABOVE STANDARD QI INTERVENTION? Samuel Cykert1,2; Ann Lefebvre2; Thomas Bacon2. 1University of North Carolina, Chapel Hill, NC; 2University of North Carolina, Chapel Hill, NC. (Tracking ID #1640879)

BACKGROUND: Care for chronic illness accounts for over 60 % of healthcare spending. Through the Health Information Technology for Economic and Clinical Health Act, 677 million dollars have been allocated to Regional Extension Centers (REC) to help primary care providers adopt electronic health records and achieve Stage 1 Meaningful Use (MU) functionality as defined by CMS. In this report, we consider the question, "Does adding Meaningful Use to quality improvement (QI) interventions achieve better chronic care results in disparate, independent primary care practices?"
METHODS: Through the Robert Wood Johnson funded Improving Performance in Practice Program (IPIP), rapid cycle QI techniques for chronic care improvement were disseminated to 180 North Carolina primary care practices by the end of 2009. The North Carolina Area Health Education Centers Program (AHEC) served as the organizational home for these efforts. Later, AHEC was also designated then funded as the REC for the state of North Carolina beginning February of 2010. Participating IPIP practices report diabetes population measures monthly to the AHEC database. Here, we report the results for practices that have reported these data for at least the last 6 months who have signed up for the REC. These practices are divided into 3 groups: Group 1 consists of practices that do not yet have automated quality reporting; Group 2 practices have instituted electronic prescribing + automated quality reporting; Group 3 practices have fully achieved Stage 1 Meaningful Use.
RESULTS: Participating practices average 3.8 providers per practice and 44 % were rural. Baseline percentages for population control (pre-IPIP) of diabetic care measures were 24 % for HGB A1c<7, 24 % for HGB A1c> 9,and 38 % for LDL-C<100. As of December of 2012, 21 practices were in Group 1. In these practices, HGB A1c<7 improved to 40.6 % while 23 % of patients still had HGB A1c>9. For Group 1 patients, LDL-C<100 remained at 38 %. Group 2 consisted of 26 practices covering 12,126 diabetics. Eleven practices covering 7,417 diabetics achieved full meaningful use and met Group 3 criteria. Diabetes chronic care results are shown in the Table.
CONCLUSIONS: Early data show that achievement of Stage 1 Meaningful Use through the REC program is associated with substantial gains in diabetes care measures in small, independent primary care practices who also engage in QI. These improvements are greater than those obtained through automated quality reporting alone and may be attributable to the organizational and workflow changes necessary to implement all facets of MU.
Diabetes Care Measures for Practice Groups 2 and 3
Group + Diabetic Care Measure Before EHR with Automated Reports After Automated Quality Reports After Achievement of MU
Group 2 HGB A1c<7 39.6 % 45.1 % -
HGB A1c>9 19.4 % 23.1 % -
LDL-C<100 42.7 % 45.7 % -
Group 3 HGB A1c<7 53.7 % 53.0 % 61.5 %
HGB A1c>9 25.4 % 15.5 % 13.9 %
LDL-C<100 46.5 % 52.4 % 62.0 %

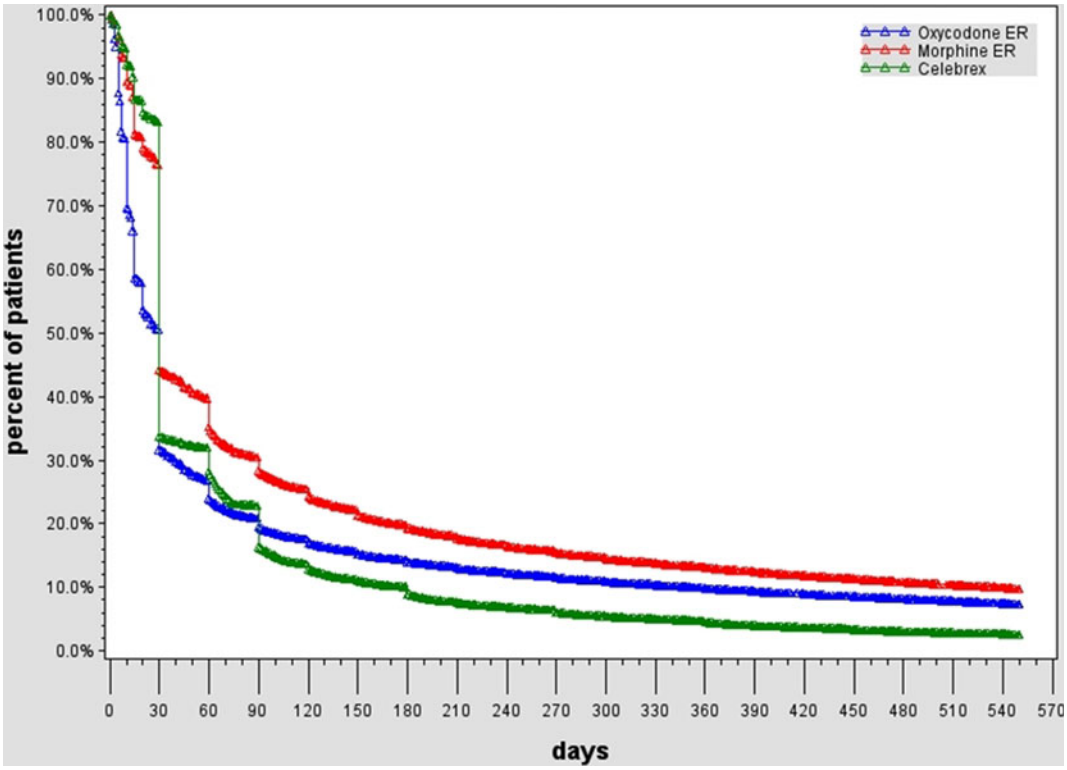
DOSE AND DURATION RELATIONSHIP BETWEEN PIOGLITAZONE AND ASSOCIATED RISK OF BLADDER CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS Sonal Singh[1]; Yoon Loke[2]; Chun Shing Kwok[2]; Chen Chen-Turner[2]; Richard M. Turner[2]; Chinedu A. Maduakor[2]. 1JHU, Baltimore, MD; [2]Norwich Medical School, Norwich, United Kingdom. (Tracking ID #1641914)

BACKGROUND: Pioglitazone is a widely used thiazolidinedione. There have been some concerns about its potential association with bladder cancer. To determine whether pioglitazone is associated with an increased risk of bladder cancer, we performed a systematic review and meta-analysis with a focus on investigating dose and duration effects, and whether risk with pioglitazone differs from rosiglitazone.
METHODS: We searched MEDLINE, EMBASE and regulatory documents in June 2012 and conducted meta-analysis on the overall risks of bladder cancer with pioglitazone or rosiglitazone and the risk with different categories of cumulative dose or duration of pioglitazone use
RESULTS: 14 studies were included: 5 RCTs (total >16,000 participants) and 9 observational studies (pooled cohort >1.5 million). There was a significantly higher overall risk of bladder cancer with pioglitazone (RCTs: OR 2.51, 95 % CI 1.09–5.80, p=0.03, I2=27 %; cohort studies: OR 1.20, 95 % CI 1.07–1.34, p=0.001, I2=0 %) but not rosiglitazone (RCTs: OR 0.84, 95 % CI 0.35–2.04, p=0.71, I2=0 %; cohort studies: OR 1.08, 95 % CI 0.95–1.23, p=0.24, I2=0 %). Subgroup analysis by cumulative dose showed the greatest risk with >28.0 g of pioglitazone (OR 1.64, 95 % CI 1.28–2.12, p=0.0001, I2= 0 %) which differed significantly from <10.5 g (p=0.02). Similarly, there was a significant difference with the risk of longer (>24 months) compared to shorter (<12 months) cumulative durations (p=0.004) of pioglitazone use. Direct comparison of pioglitazone and rosiglitazone yielded an OR of 1.25 (95 % CI 0.91–1.72, p=0.16).
CONCLUSIONS: A modest but clinically significant increased risk of bladder cancer with pioglitazone was found that appears related to cumulative dose and duration of exposure. We recommend prescribers consider alternative oral hypoglycaemics and limit pioglitazone use to shorter durations.

DURATION OF USE OF EXTENDED-RELEASE (ER) OXYCODONE, ER MORPHINE, AND CELECOXIB AMONG ADULTS WITH CANCER AND NON-CANCER PAIN Angela DeVeaugh-Geiss; Aditi Kadakia; Howard D. Chilcoat; Paul Coplan. Purdue Pharma LP, Stamford, CT. (Tracking ID #1618955)

BACKGROUND: Duration of use of extended-release (ER) opioids in US clinical practice has not been extensively published in the literature. The objective of this study was to assess duration of ER oxycodone and ER morphine use, two commonly used ER opioids, among cancer and non-cancer pain patients. Celecoxib was included as a non-opioid comparator.
METHODS: Using data from a national commercial insurance database (MarketScan; January 2008 through September 2011), patients ≥18 years old with a new ER oxycodone/ER morphine/celecoxib prescription and 24 months insurance enrollment (6 months before and 18 months after index prescription) were identified. Existing patients (those with prior prescriptions in the 6 month baseline period) were excluded. The primary measure was duration of continuous use (no gaps in supply ≥15 days; sensitivity analysis ≥30 days). Survival analysis was used to compare time to discontinuation of continuous use.
RESULTS: There were 43,519 new ER oxycodone users; 22,414 new ER morphine users; and 129,956 new celecoxib users. Cancer diagnoses were identified for 9 % of ER oxycodone, 10 % of ER morphine, and 5 % of celecoxib patients. Most patients discontinued use by 3 or 6 months (ER oxycodone: 80 % and 86 %, respectively; ER morphine: 72 % and 81 %, respectively; celecoxib: 84 % and 94 %, respectively). Time-to-event analysis across all drugs studied indicates a rapid drop in continuous use in the first month (>50 % decline), a less rapid decline between months 1 and 6 (approximately 15 % to 25 % decline), and appear relatively stable (approximately 5–20 %) thereafter, indicating that patients treated for 6 months will likely continue for up to 18 months (Figure). ER oxycodone and celecoxib results were similar regardless of cancer diagnosis; ER morphine patients without a cancer diagnosis were slightly more likely to continue longer term treatment than those with a cancer diagnosis.
CONCLUSIONS: Overall, most patients dispensed a new ER oxycodone, ER morphine, or celecoxib prescription had a non-malignant pain condition and fewer than one in five received continuous treatment for >6 months.

Time to event analysis: duration of continous use over 18 months



EFFECT OF COMORBIDITIES ON CLINICAL OUTCOMES IN LOW-RISK CURB-65 PATIENTS Luis C. Watanabe Tejada; David Paje; Qasim L. Shakeel; Abdul Kareem Uduman; Amit Vahia; Rafael Cabrera. Henry Ford Hospital, Detroit, MI. (Tracking ID #1633992)

BACKGROUND: The CURB-65 score is widely-used to risk stratify patients with community-acquired pneumonia (CAP). When the score is less than 3, the patient is considered to have a low mortality risk and current recommendations suggest that treatment may be provided in the outpatient setting. However, this tool only considers acute findings that reflect severity of illness; whether pre-existing clinical conditions significantly alter the risk of adverse outcomes in pneumonia patients is unknown. Our objective was to evaluate the effect of comorbidities on clinical outcomes in patients admitted with low-risk CURB-65.

METHODS: The medical records of consecutive patients admitted with CAP to a tertiary referral teaching hospital were reviewed to obtain the required clinical information to calculate the CURB-65 score and the age-adjusted Charlson Comorbidity Index (CCI). The performance of CCI in predicting 30-day mortality was plotted on a receiver operator characteristic (ROC) curve, from which a cutoff value was derived to define low and high-risk CCI. Patients with low-risk CURB-65 were stratified into low and high-risk CCI. The rates of 30-day mortality, 30-day readmission, intensive care unit (ICU) transfer, and length of stay (LOS) >7 days were compared between the two groups using Chi-square tests.

RESULTS: 538 patients were included in the analysis, 399 (74.16 %) had low-risk CURB-65. A CCI value of 7 was determined as the cutoff for the CCI risk groups based on the point of maximal sensitivity and specificity on the ROC curve for mortality. Of the patients with low-risk CURB-65, 269 (67.42 %) had CCI scores less than 7 and were classified as low-risk CCI; 130 (32.58 %) had CCI scores of at least 7 and were considered high-risk CCI. The rates of 30-day readmission and ICU transfer during the index admission were similar in both risk groups. The 30-day mortality rate was 19.2 % in high-risk CCI and 4.5 % in low-risk CCI (RR 4.31, 95 % CI 2.24 to 8.30, $p<0.001$). Prolonged hospitalization (LOS>7 days) was 35.4 % in high-risk CCI and 24.9 % in low-risk CCI (RR 1.42, 95 % CI 1.04 to 1.94, $p=0.029$)

CONCLUSIONS: Among patients admitted with community-acquired pneumonia with low-risk acute clinical findings, the presence of pre-existing comorbidities significantly increases the risks of mortality and of prolonged hospitalization. The age-adjusted Charlson Comorbidity Index appears to be a useful tool in further risk-stratifying patients that were identified to be low-risk based on their CURB-65 scores.

Rates of Clinical Outcomes in Patients with Low-Risk CURB-65 (Score<3)

EFFECT OF COMPUTERIZED CLINICAL DECISION SUPPORT ON APPROPRIATE LABORATORY MONITORING OF MEDICATIONS Amy Linsky[1,2]; Nivethietha Maniam[3]; Lynn A. Volk[3]; Steven R. Simon[1,4]. [1]VA Boston Healthcare System, Boston, MA; [2]Boston University School of Medicine, Boston, MA; [3]Partners Healthcare System, Wellesley, MA; [4]Brigham and Women's Hospital, Boston, MA. (Tracking ID #1641746)

BACKGROUND: Many medications require laboratory testing to assess efficacy or toxicity; however, this recommended monitoring is often not performed, potentially leading to adverse drug events. We sought to determine the effect of a computerized clinical decision support on adherence to recommended laboratory monitoring in ambulatory care settings.

METHODS: We conducted a randomized controlled trial of 11 community-based primary care practices (six randomized to intervention and five to control; $n=17$ clinicians participating) using an electronic health record with clinical decision support alert capability. Baseline period was 6/1/

2010–5/31/2011, and the intervention period was from 6/23/2011–12/22/2011. There were 32 target medications or medication classes, each of which required one to six distinct laboratory tests for appropriate monitoring. When one of these medications was prescribed, the clinical decision support determined if the indicated laboratory test(s) had been performed in the preceding 365 days. If appropriate testing was not found, an alert was presented to the clinician at the time of medication ordering. The primary outcome was the proportion of medications with appropriate laboratory monitoring, defined as the completion of all indicated laboratory testing from 365 days prior to the prescription date until 14 days after medication prescribing. Patient characteristics included age, sex, number of encounters during the time period and number of distinct medication classes of interest during the time period.

RESULTS: During the baseline time period, there were 10,541 unique patient-medication encounters in the control practices and 10,244 in the intervention practices; during the intervention time period, there were 9,535 and 8,066 in the control and intervention practices, respectively. At baseline, practices were generally similar on measured demographic and clinical parameters [e.g., mean age 60 years (SD14) in control practices, compared with mean age 60 years (SD 15) in intervention practices], although some differences were apparent (e.g., mean number of visits was 6.6 in control practices vs. 4.5 in intervention practices). During the baseline period, the primary outcome - complete laboratory monitoring - occurred for 70.7 % of medications in control practices and 79.4 % in intervention practices. In comparison, during the intervention, complete monitoring occurred for 62.4 % of medications in control practices and 77.7 % in intervention practices. For medications requiring three or more laboratory tests (n=555 during the entire study across both control and intervention practices) at most 17.7 % had evidence of complete laboratory monitoring. Medications with associated tests that are more specialized (e.g., digoxin level) similarly had lower rates of complete monitoring.

CONCLUSIONS: In this randomized controlled trial, adherence to laboratory monitoring recommendations decreased over time in both intervention and control practices, although the decline in adherence was less pronounced in the intervention group, suggesting some effectiveness. Interventions may need to target both patients and clinicians to improve the complex behavior of laboratory monitoring of medications.

EFFECT OF PAYMENT CHANGES FOR PRESSURE ULCERS FROM THE HOSPITAL-ACQUIRED CONDITIONS INITIATIVE: A STATEWIDE ANALYSIS Jennifer Meddings[1]; Heidi Reichert[1]; Kyle Grazier[2]; Laurence F. McMahon[1,2]. [1]University of Michigan Medical School, Ann Arbor, MI; [2]University of Michigan School of Public Health, Ann Arbor, MI. (Tracking ID #1641327)

BACKGROUND: Hospital-acquired pressure ulcers are painful, common, costly, and often preventable complications. Since the 2008 Hospital-Acquired Conditions (HAC) Initiative, Medicare uses claims data to deny extra hospital pay for treating certain HACs including pressure ulcers; this policy rapidly expanded to other payers. By the HAC Initiative, advanced stage pressure ulcers (stage 3 or 4) no longer can generate extra pay when hospital-acquired. A lesser-known detail of the HAC Initiative is that earlier stage (stage 1 or 2) and "unstageable" pressure ulcers no longer generate extra pay whether present-on-admission (POA) or hospital-acquired (HA). Whether hospital pay actually decreases with removal of pay for pressure ulcers depends on whether the patient has other comorbidities justifying the higher pay without the ulcer diagnosis. Our objective was to assess the impact of the pressure ulcer pay changes by evaluating pressure ulcer rates and hospital payments before and after the 2008 policy.

METHODS: Utilizing a before-and-after study of all-payer statewide claims data, we identified adult discharges with pressure ulcers (categorized as POA or HA) in >2.4 million annual discharges using the 2007 and 2009 Healthcare Cost and Utilization Project State Inpatient Datasets for 305 nonfederal acute care California hospitals. To assess financial impact, we used MS-DRG grouper software to assess how often and by how much did the HAC Initiative payment changes for pressure ulcers affect hospital pay.

RESULTS: Pressure ulcers were listed as POA diagnoses for 54,820 (2.27 %) discharges in 2007 and 73,908 (2.95 %) discharges in 2009; HA pressure ulcers were listed for 6,522 (0.27 %) discharges in 2007 and 6,573 (0.26 %) discharges in 2009. By clinical stage of pressure ulcer (available in 2009), stage 3 or 4 HA ulcers occurred in 586 cases (0.02 %); stage 1, 2 or unstageable ulcers (including HA or POA) occurred in 56,383 cases (2.25 %). Removal of pay for stage 3 or 4 HA ulcers reduced pay in 71 (12.1 %) pressure ulcer cases with an average pay decrease of $5503 per case, for a total statewide all-payer payment decrease of $390,698 (0.001 %) for all payers including $226,045 (0.002 %) for Medicare. Removal of pay for stage 1, 2, and unstageable ulcers reduced hospital pay in 19,123 (33.9 %) of cases including 17,867 (93.4 % of 19123) cases with present-on-admission ulcers; this resulted in a mean pay decrease of $3,213 per case for a total statewide pay decrease of $61,435,536 (0.20 %) for all payers including $46,156,024 (0.31 %) for Medicare.

CONCLUSIONS: The financial impact of the 2008 pay changes for pressure ulcers was very small on all-payer or Medicare statewide hospital payments. Unexpectedly, the largest proportion of pay change for pressure ulcers resulted from the lesser-known non-payment of all earlier stage and unstageable ulcers (including 93.4 % described as present-on-admission ulcers), which was two hundred times greater than the pay reductions for hospital-acquired stage 3 or 4 ulcers. Hospital-acquired pressure ulcers rates remained low and unchanged in claims data over the study period, but pressure ulcers recorded as present-on-admission increased. This study suggests that the most significant impact regarding pressure ulcers from the Hospital-Acquired Conditions Initiative was no extra pay for cases with present-on-admission earlier stage and unstageable pressure ulcers - rather than prevention or reduced pay for hospital-acquired advanced stage pressure ulcers.

EFFECT OF A MUSCULOSKELETAL OSCE USING SENIOR INTERNAL MEDICINE RESIDENTS AS STANDARDIZED PATIENTS Christina Harris; Johanna Martinez; B. Robert Meyer; Judy Tung; Cathy Jalali; Jessica Clemons. Weill Cornell Medical College, New York, NY. (Tracking ID #1642557)

BACKGROUND: Residents commonly express a lack of comfort evaluating patients with MSK complaints. Due to the complexities of teaching the musculoskeletal examination, traditional didactic teaching sessions are often inadequate and require supplementation with hands-on modeling. In an effort to improve the confidence and knowledge of internal medicine residents in their evaluation of patients with musculoskeletal complaints, we created an OSCE using our senior residents as standardized patients, teachers and evaluators of the interns.

METHODS: The musculoskeletal OSCE was integrated as a required component of the residents' ambulatory block. All senior residents selected a standardized patient scenario which focused on one of 5 common musculoskeletal complaints (neck pain, shoulder pain, back pain, hip pain, and knee pain). Senior residents were expected to: (1) deliver a 15 min hands-on session reviewing how to accurately evaluate a patient with the pain in their selected body region; (2) serve as a standardized patient for all interns rotating through the OSCE; (3) provide immediate formative feedback to each intern. Surveys assessing residents' self confidences in evaluating patients (history, physical examination and treatment) with the 5 common musculoskeletal complaints were completed before and after the OSCE. In addition, a medical knowledge assessment was completed, along with post-OSCE focus groups.

RESULTS: Prior to the OSCE, seniors were significantly more likely to report feeling more confident compared to the interns in all areas of a patient evaluation and across all 5 body areas. Despite this higher self-confidence, seniors did not perform better than the interns on the medical knowledge assessment. After the OSCE, there was an overall significant increase in the confidence level of all residents. Despite the seniors starting with a higher confidence level, post-OSCE data demonstrated an equalization of confidence between years. As a group, all residents universally felt more confident in performing an accurate history in all of the body areas, as compared to performing the physical examination or

delivering the treatment plan. In post-OSCE focus groups, 100 % of the residents reported feeling uncomfortable evaluating patients with musculoskeletal complaints and also felt that there was not enough time dedicated to this over medical school and residency. The majority of interns reported that they preferred learning from a resident rather than an attending as they viewed it as an extension of the intern-resident teaching dynamic in the hospital. Residents perceived the OSCE to be a nonthreatening learning environment for the interns.
CONCLUSIONS: A musculoskeletal OSCE utilizing senior residents as both the educators and the standardized patients is a unique and effective approach to educating residents in the evaluation of patients with musculoskeletal complaints. Interns appreciated the opportunity to learn from the seniors in a non-threatening environment. Future work will focus on methods to reinforce skills in hopes of promoting long-term retention.

EFFECT OF A HOSPITALIST-RUN POST-DISCHARGE CLINIC ON ADVERSE POST-DISCHARGE OUTCOMES Robert Burke[1,3]; Emily Whitfield[2]; Allan V. Prochazka[2,3]. 1Denver VA Medical Center, Denver, CO; [2]Denver VA Medical Center, Denver, CO; [3]University of Colorado School of Medicine, Denver, CO. (Tracking ID #1637820)

BACKGROUND: Hospitalist-run post-discharge clinics (PDCs) are being created to improve transitions in care. However, there are few data on their efficacy. The Denver VA Medical Center is unique in having a well-established hospitalist-run post-discharge clinic, in addition to urgent care and primary care clinics as post-hospitalization follow-up options. We aimed to assess the utility of the PDC compared with follow-up in primary care or with an urgent care provider, in terms of post-discharge outcomes at 30 days.
METHODS: The authors retrospectively reviewed all discharges from the Denver VA Medical Center's general medical service from January 2005 to August 2012 using the VA's Informatics and Computing Infrastructure (VINCI) database. Patients discharged to home in the Denver metro area who had a first follow-up visit with PDC, urgent care, or primary care within 30 days were included. The primary outcome was a composite of Emergency Department visits, hospital readmissions, and mortality in the 30 days following discharge. Outcomes were compared between the three groups in unadjusted analysis; outcomes were compared between PDC and primary care using propensity score-adjusted analyses to adjust for baseline differences in age, gender, comorbidity, previous hospital admissions, number of discharge medications, and time to first post-discharge visit.
RESULTS: 5085 patients were included; 538 who followed up in PDC, 2699 in urgent care, and 1848 in primary care. Patients were older (average age in PDC 67.8 years, urgent care, 67.1, primary care, 64.8, $p<0.0001$ for comparison) and predominantly male (95 %, p=NS). They also had high levels of baseline comorbidity as reflected in Elixhauser comorbidity index scores (PDC, 0.80, urgent care, 0.69, primary care, 0.75, $p=0.02$ for comparison), number of discharge medications (approximately 10 in each group, p=NS), and prior hospital admissions (18–23 % with an admission in the prior year, p=NS). Hospital length of stay (LOS) significantly varied between groups, with LOS 2.4 days shorter in PDC than primary care follow-up (PDC, 3.8 days, urgent care, 5.0 days, primary care, 6.2 days, $p=0.04$ for comparison). Despite this, outcomes at 30 days were not statistically different between the groups in unadjusted analysis (19.9 % in PDC, 18.3 % in urgent care, and 17.5 % in primary care, $p=0.42$); there was similarly no difference between PDC and primary care follow-up in propensity-adjusted multivariate analysis, adjusting for baseline differences between groups. The time to the first outpatient visit was 5.0 days in PDC, 9.4 in urgent care, and 13.7 in primary care.
CONCLUSIONS: Our results suggest a hospitalist-run post-discharge clinic is associated with an index hospital length of stay that is 2.4 days shorter, with equivalent outcomes at 30 days, to follow-up in primary care, despite an older and sicker population seen in the clinic. Increased access to early post-discharge follow-up may be linked to shorter lengths of stay. It is notable our results occurred in a healthcare system with robust primary care access and a shared electronic medical record (EMR); the effect of a hospitalist-run PDC may be increased in systems without these advantages. Further study of the impact of PDC clinics is needed.

EFFECTIVENESS OF AN INTERVENTION TO TEACH PHYSICIANS IN A MIDDLE-INCOME COUNTRY HOW TO HELP THEIR PATIENTS QUIT SMOKING Raul Mejia[2]; Celia P. Kaplan[1]; M. Alderete[2]; L. Peña[2]; Steve Gregorich[1]; V. Schoj[2]; Ethel Alderete[2]; Eliseo J. Perez-Stable[1]. [1]Division of General Internal Medicine, Department of Medicine, Medical Effectiveness Research Center for Diverse PopulationsUCSF, San Francisco, CA; [2]Universidad de Buenos Aires, Centro de Estudios de Estado y Sociedad, Buenos Aires, Argentina. (Tracking ID #1644240)

BACKGROUND: Physicians who routinely identify smokers and provide cessation advice with or without pharmacological treatment, can increase the quit rate of their patients. In Argentina, where 30 % of the adult population smokes, fewer than 30 % of primary care physicians have received any training in counseling patients on tobacco cessation. We tested whether a short evidence-based intervention to teach physicians how to help their patients who smoke quit, would result in higher cessation rates compared to usual care in Argentina, a middle-income country.
METHODS: General internists, family physicians and gynecologists were recruited from five clinical systems in the cities of Buenos Aires, La Plata and Olavarria (private practices, HMOs, and public clinics) and randomized to intervention or usual care. The physician intervention consisted of two three-hour sessions including a standard didactic curriculum and referral resources designed to teach them how to help patients quit smoking. Next, smoking patients who saw participating physicians within 30 days of physician training (index visit) were randomly sampled and interviewed by telephone at 1, 6 and 12 months after their visit to the physician. No single physician had more than 6 patients sampled. The main outcome was tobacco abstinence at 6 and 12 months; secondary outcomes were number of quit attempts, cigarettes per day, and use of pharmacological aides. Repeated measures on the same participants were accommodated via Generalized Estimating Equations.
RESULTS: 254 physicians (124 internists, 57 family physicians, 73 gynecologists) were randomized; average age was 44.6 years, 52 % women and 12 % smoked. While 24 % reported no previous training on tobacco cessation, 41 % reported good or excellent previous training. A total of 1,378 smoking patients were surveyed; 81 % were women, 46 % had >12 years of education, 81 % had rated their health status as good or excellent, and 63.1 % had access to Internet. At 1 month, most (76 %) reported daily smoking, 21 % smoked some days and 3 % had already quit smoking. Mean number of cigarettes per day was 12.9 (SD=8.8) and 63 % thought they would quit within the next 6 months. Outcomes at 6 months: Cessation Had Quit Attempt Used Meds Mean Cigs Intervention 13.8 % 12.2 % 9.9 % 12.4 Control 12.1 % 11 % 9.1 % 12.8 Quit rates at 12 months increased to 16 % in both groups; there was no intervention by month effect at 6 months ($\chi 2$ (df=2)=2.89, $p=0.24$. Pooling across intervention groups, patients seen by internists or family physicians were more likely to quit among daily and non-daily smokers ($\chi 2$ (df=1)=13.6, $p=0.0002$ and ($\chi 2$ (df=1)=10.03, $p=0.002$, respectively).
CONCLUSIONS: Providing standardized training in tobacco cessation to physicians did not improved the cessation rates among their patients at 6–12 months. It is necessary to explore other interventions to increase cessation rates of patients in primary care.

EFFECTIVENESS OF MAILED FECAL OCCULT BLOOD TEST CARDS AND OR A DETAILED COLON CANCER SCREENING BROCHURE VS A REMINDER LETTER FOR INCREASING COLORECTAL CANCER SCREENING RATES AT A PRIMARY CARE CLINIC SERVING MEDICALLY VULNERABLE PATIENTS. MICHAEL A. SOLIMAN, MD, DANNY MCCORMICK, MD, MPH AND WILLIAM ZINN, MD Michael Soliman; Danny McCormick; William Zinn. Cambridge Health Alliance, Cambridge, MA. (Tracking ID #1643000)

BACKGROUND: Colon cancer remains the 3rd most common cause of cancer mortality in the US. However, colorectal cancer (CRC) screening rates, particularly for medically vulnerable patients such as low income,

uninsured, racial/ethnic minority and immigrant patients are suboptimal. Previous studies have demonstrated the effectiveness of interventions using telephonic reminders at increasing CRC screening rates; however, such interventions are labor intensive and thus costly.

METHODS: We sought to identify an intervention that requires low labor intensity and cost but that is effective in increasing colon cancer screening rates among medically disadvantaged patients who previously did not respond to screening outreach attempts via mailed letter. The study setting was a single internal medicine primary care clinic at an urban public hospital in Massachusetts (MA) caring for a diverse and medically vulnerable population. The study sample consisted of 756 adults aged 51–75 who had no record of having had CRC screening (in the electronic medical record) according to current CRC screening guidelines. All patients had been contacted at least once by mail in the last year to encourage CRC screening. We conducted a comparative effectiveness randomized trial of 4 mail-based interventions using a 2×2 factorial design. Each intervention group received a letter encouraging CRC screening by fecal occult blood testing (FOBT) or colonoscopy. Group 1 received this letter only, Group 2 received 3 FOBT cards and pre-paid return envelope, Group 3 received a detailed 12 page CRC screening brochure with graphic depictions of a patient receiving colonoscopy and a description of FOBT that was produced by the MA state department of public health and Group 4 received the 3 FOBT cards and the brochure. At 6 months we assessed whether or not screening by FOBT or screening by colonoscopy had occurred.

RESULTS: The study sample consisted of 49.66 % women and 50 % >60 years of age. There were no statistically significant differences in patient characteristics among the 4 study groups. Patients receiving FOBT cards and a letter were more likely be screened by FOBT than patients receiving the letter alone (21 % vs. 13 %; P=0.038), but not by colonoscopy (6 % vs. 7 %, p=0.84). Patients receiving the brochure were neither more likely to be screened by FOBT (13 % vs. 13 %, p=1.0) nor colonoscopy (8 % vs. 7 %, p=0.69). Patients receiving FOBT and the brochure were neither more likely to be screened by FOBT (20 % vs. 19 %, p=0.79) nor colonoscopy (7 % vs. 7 %, p=1).

CONCLUSIONS: Although more resource intensive interventions that result in higher screening rates may be preferable, for resource-poor primary care practices mailed FOBT cards may be a feasible and effective option to improve CRC screening among medically disadvantaged patients who did not respond to previous outreach attempts. Detailed printed materials with graphic depictions of CRC screening procedures do no appear to be effective in this setting.

EFFECTIVENESS OF TRAINING MEDICAL STUDENTS AS TEACHERS USING THE STANFORD FACULTY DEVELOPMENT CENTER (SFDC) CLINICAL TEACHING CORE COMPETENCIES Jessica Schmitt; F Stanford Massie. University of Alabama School of Medicine, Birmingham, AL. (Tracking ID #1642100)

BACKGROUND: The University of Alabama School of Medicine (UASOM), Clinical Skills Teaching Associate (CSTA) program uses fourth year medical students (MS4s) as teachers for first year medical students (MS1s) in the Introduction to Clinical Medicine course. CSTA training has not been evaluated. We aimed to see if working as CSTAs increases MS4s' comfort with teaching. As training was changed prior to 2010, we wanted to compare final teaching comfort level for CSTAs of 2008–2009 to CSTAs of 2010–2012. Some CSTAs reviewed training material individually, giving us the ability to see if any difference exists in self-taught versus faculty-trained student teachers.

METHODS: MS4s were CSTAs for elective credit and were trained in components of the SFDC curriculum for Clinical Teaching. In 2008–2009, CSTAs attended 2 training sessions, covering 4 of 7 cores; in 2010–2012, they attended 3 sessions addressing 5 of 7 cores. Sessions were led by author FSM, a UASOM faculty member trained in the SFDC Clinical Teaching framework. CSTAs unable to attend sessions reviewed material alone and completed a questionnaire. CSTAs taught 9–10 small group sessions for their MS1s. CSTAs completed 2 surveys during the elective, an initial and final survey. CSTAs ranked their comfort level with 5 SFDC corse, their overall teaching ability and their overall comfort with teaching on a scale of 1–5. They specified which faculty-led training sessions they attended.

RESULTS: In 6 of 7 areas, the change from initial to final comfort level was significant. CSTAs in 2010–2012 were more comfortable evaluating students and giving feedback than CSTAs in 2008–2009. Whether self-taught or faculty-trained, final comfort levels in teaching skills were similar among CSTAs.

CONCLUSIONS: The increase from initial to final comfort level in most areas suggests that CSTA training is effective. Increased comfort for 2010–2012 CSTAs in critiquing students may be due to increased training with more time available. The data suggests, but cannot conclude absolutely due to small sample size, that student teachers can be adequately trained with handouts and questionnaires and do not require formal training by a faculty member.

Comparison of 2008–2009 and 2010–2012 CSTA Survey Results
2008–2009 vs 2010–2012 Initial Survey 2008–2009 vs 2010–2012 Final Survey
Overall teaching ability 0.17 (0.18) −0.01 (0.90)
Overall comfort with teaching 0.28 (0.14) 0.07 (0.41)
Creation of an appropriate learning climate NA −0.02 (0.88)
Communication of goals 0.00 (1.00) 0.03 (0.78)
Promotion of retention NA NA
Evaluation 0.14 (0.35) 0.25 (0.01)
Giving feedback 0.15 (0.32) 0.23 (0.02)
The table shows the difference in mean comfort level for the two groups. The first value is the mean comfort level of the CSTAs from 2010 to 2012 minus the mean comfort level of the CSTAs in 2008–2009. The p-value between the two groups is in parentheses. Significant values are bolded.

Initial and Final Trained Group and Self-Taught Group Results
Self-Taught vs Trained Group: Initial Results Self-Taught vs Trained Group: Final Results
Creation of an appropriate learning climate 0.11 (0.35) 0.11 (0.28)
Communication of goals 0.19 (0.15) 0.14 (0.35)
Promotion of retention −0.04 (0.76) −0.15 (0.43)
Evaluation 0.09 (0.44) −0.01 (0.91)
Giving feedback 0.16 (0.22) 0.00 (0.99)
The first value in each table cell is the mean comfort level of the Trained Group minus the mean comfort level of the Self-Taught Group. The p-value between the two groups is in parentheses.

EFFECTS OF PERCEIVED HEALTH DISCRIMINATION AMONG OLDER ADULTS Stephanie E. Rogers[1]; Angela D. Thrasher[2]; Yinghui Miao[1]; Alexander K. Smith[1]. [1]UCSF, San Francisco, CA; [2]UNC Gillings School of Global Public Health, Chapel Hill, NC. (Tracking ID #1626804)

BACKGROUND: Little is known about the relationship between perceived health discrimination and global geriatric health outcomes.

METHODS: We used data from the 2008 and 2010 waves of the Health and Retirement Study (HRS), a nationally represented longitudinal study of adults over age 50. A 2008 question assessed how frequently subjects perceived receipt of poorer service or treatment by doctors or hospitals than other people, and the reasons for perceived health discrimination. Based on conceptual considerations we divided our predictor into three levels: never perceived health discrimination, infrequently perceived (less than once per year), and frequently perceived (multiple times per year to almost every day). Our primary outcomes were: (1) report of a new or worsened disability at 2 years (difficulty or dependence in any of 6 activities of daily living [ADL = bathing, dressing, toileting, eating, transferring, and ambulating]); and (2) mortality over 2 years. We analyzed disability using a log-binominal regression and mortality using Cox proportional hazards.

Because it is unclear if conditions such as depression are confounders or mediators, we present models with and without adjustment for comorbidities (depression, high blood pressure, diabetes, cancer, lung disease, heart disease, and stroke). We used survey weights to produce national estimates.

RESULTS: There were 6,146 respondents (mean age 67, 56 % female, and 83 % white). Of the 19 % of the sample who reported discrimination in the healthcare setting, 13 % perceive discrimination infrequently and 6 % frequently. The most common reasons for discrimination were ageism (28 %), gender discrimination (12 %), and financial discrimination (12 %). Compared to subjects who never perceived health discrimination, those who reported any history of health discrimination were more likely to be younger (mean 65 years vs. 67), non-white (22 % vs. 16 %), depressed (32 % vs 18 %), diabetic (23 % vs 18 %), and have ADL difficulty at baseline (22 % vs 14 %) (all $p<.001$). Compared to the group that never perceived discrimination, there was no association between infrequently perceived discrimination and disability or mortality. Frequently perceived discrimination, however, predicted the development of new or worsened disability at 2 years in all models (RR adjusted for age, gender, race/ethnicity, and comorbidities 1.66, 95 % CI 1.13–2.44). Frequently perceived discrimination was associated with mortality in models adjusted for age, gender, and race/ethnicity (aHR 1.80, 95 % CI 1.14–2.84), but not after further adjustment for comorbidities (aHR 1.27, 95 % CI 0.81–2.00).

CONCLUSIONS: One out of 5 adults over age 50 reports experiencing discrimination in health care settings, most commonly ageism. One in 17 experience frequent health care discrimination and this is an independent predictor of new or worsened disability at 2 years, and possibly death.

EFFECTS OF WEIGHT LOSS ON PREVENTION OF TYPE 2 DIABETES MELLITUS IN SUBJECTS WITH PREDIABETES USING PHENTERMINE AND TOPIRAMATE EXTENDED-RELEASE FOR 2 YEARS Robert F. Kushner[1]; W. Timothy Garvey[2]; Craig A. Peterson[3]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]VIVUS, Inc., Mountain View, CA. (Tracking ID #1624578)

BACKGROUND: Obesity is associated with Prediabetes and an increased risk of progression to type 2 diabetes mellitus (T2DM). Weight loss in obese patients with Prediabetes reduces progression to T2DM. When used in conjunction with lifestyle changes, including reduced caloric intake and increased physical activity, phentermine and topiramate extended-release (PHEN/TPM ER) demonstrated significant weight loss and improvements in glycemic parameters in obese and overweight subjects with ≥2 weight-related comorbidities in a 56-week Phase 3 study (CONQUER). These benefits were maintained through an additional 52 weeks in the SEQUEL extension study.

METHODS: CONQUER completers at a subset of sites were offered participation in the SEQUEL extension study and remained on their original randomized, blinded treatment of placebo, PHEN 7.5 mg/TPM ER 46 mg (7.5/46), or PHEN 15 mg/TPM ER 92 mg (15/92). In this analysis, weight loss, fasting glucose, HbA1c, and annualized incidence rate of T2DM at week 108 were assessed in subjects with Prediabetes (fasting glucose ≥100 to ≤125 mg/dL or 2-h oral glucose tolerance test ≥140 to ≤199 mg/dL).

RESULTS: At baseline (CONQUER week 0), 316 of the 675 subjects (46.8 %) enrolled in SEQUEL had Prediabetes, mean age was 52.5 years, 63.3 % were female, 84.8 % were Caucasian, and mean weight was 103.1 kg. In these subjects, least-squares mean percent weight loss was significantly greater with PHEN/TPM ER vs placebo at week 108 ($P<.0001$; ITT-LOCF): −2.2 %, −11.1 %, and −12.7 % for placebo ($n=103$), 7.5/46 ($n=83$), and 15/92 ($n=130$), respectively. This translates to a least-squares mean absolute weight loss of −2.5 kg, −11.4 kg, and −13.1 kg for placebo, 7.5/46, and 15/92, respectively. This weight loss was associated with improvements in HbA1c and fasting glucose (Table) and with markedly reduced annualized incidence rates of T2DM by 49 % and 89 % in subjects receiving 7.5/46 and 15/92, respectively, compared with placebo ($P=.0125$ for 15/92 vs placebo; Table). Common adverse events in the Prediabetes SEQUEL safety population were constipation, dry mouth, and paraesthesia.

CONCLUSIONS: PHEN/TPM ER, when used as an adjunct to lifestyle modification, led to significant weight loss, which was sustained over 2 years. This weight loss was associated with improved HbA1c and fasting glucose and with reduced progression to T2DM in obese and overweight subjects with Prediabetes. Treatment of excess weight in obese and overweight patients with Prediabetes may help reduce new-onset T2DM in this at-risk population.

Table. Improvements in glycemia from baseline to week 108 (Prediabetes; ITT-LOCF).

EFFICACY AND CLINICAL RELEVANCE OF VILAZODONE IN THE TREATMENT OF MAJOR DEPRESSIVE DISORDER: A POOLED ANALYSIS OF PHASE III CLINICAL TRIALS Larry Culpepper[2]; Arif Khan[1]; Adam Ruth[3]; John Edwards[4]. [1]Northwest Clinical Research Center, Bellevue, WA; [2]Boston University School of Medicine, Boston, MA; [3]Prescott Medical Communications Group, Chicago, IL; 4Forest Research Institute, Jersey City, NJ. (Tracking ID #1640055)

BACKGROUND: Beyond efficacy, the clinical relevance of antidepressant treatment has been evaluated using measures such as response, remission, and the number needed to treat (NNT) or harm (NNH). Vilazodone, a serotonin reuptake inhibitor and 5-HT1A receptor partial agonist, is FDA approved for treatment of major depressive disorder (MDD) in adults. Data from two Phase III trials (NCT00285376; NCT00683592) were pooled to evaluate efficacy across depressive symptoms and clinical relevance relative to placebo.

METHODS: Data from 2 double-blind, randomized, placebo-controlled trials of similar design and conduct (one-week screening followed by eight-week double-blind treatment) were pooled for analyses. Participants were 18–70 years of age with DSM-IV-TR-defined MDD and a minimum score ≥22 on the 17-item Hamilton Depression Rating Scale (HAMD17). Patients randomized to vilazodone were titrated to a target dose of 40 mg, taken once daily (QD) with food, over a two-week period (10 mg QD for 7 days, 20 mg QD for the next 7 days, and 40 mg QD thereafter). The primary efficacy parameter was Montgomery-Asberg Depression

Rating Scale (MADRS) total score change from baseline to Week 8 analyzed using an analysis of covariance (ANCOVA) model based on the Intent-to-Treat (ITT) population and the last observation carried forward (LOCF) approach. Response (MADRS ≥50 % improvement from baseline; HAMD17 ≥50 % improvement from baseline; CGI-I score ≤2) and remission (MADRS ≤10; MADRS ≤12) were analyzed. Post hoc analyses estimated the treatment effect of vilazodone versus placebo on MADRS single items, the number needed to treat (NNT) for response (MADRS ≥50 % improvement) and remission (MADRS ≤10), and the number needed to harm (NNH) for adverse events (AEs) and AE discontinuations.

RESULTS: The ITT population comprised 431 vilazodone- and 432 placebo-treated patients. Vilazodone significantly improved MADRS total score relative to placebo with a least squares mean difference (LSMD) of −2.79 ($P<.0001$). Response was significantly greater for vilazodone versus placebo on all measures: MADRS (42 % vs 29 %, $P=.0002$); HAMD17 (44 % vs 33 %, $P=.0007$); and CGI-I (49 % vs 35 %, $P<.0001$). Remission was significantly greater for vilazodone versus placebo using both criteria; MADRS ≤10 (29 % vs 20 %, $P=.0041$) and MADRS ≤12 35 % vs 22 %, $P<.001$). Significant improvement in LSMD in favor of vilazodone versus placebo was seen in the change from baseline on every MADRS single item: apparent sadness, -0.24; reported sadness, −0.29; inner tension, −0.31; reduced sleep, −0.30; reduced appetite, −0.20; concentration difficulties, −0.24; lassitude, −0.27; inability to feel, −0.25; pessimistic thoughts, −0.35; suicidal thoughts, −0.29 ($P<.01$ for all). The NNT (95 % CI) for response and remission was 8 (5, 17) and 12 (7, 37), respectively (an NNT ≤10 for response is generally regarded as evidence for clinical relevance in depression treatment); the NNH (95 % CI) for AE discontinuations was 26 (15, 106).

CONCLUSIONS: Vilazodone showed broad efficacy across depression symptoms. Significantly better response and remission indicated clinical relevance for vilazodone; NNT and NNH analyses suggested a lower risk of AE discontinuation relative to clinically meaningful improvement for vilazodone.

ELDERLY ADULTS WITH DEMENTIA AND YOUNG ADULTS WITH DEVELOPMENTAL DISABILITIES: INTERNIST PERSPECTIVES ON SIMILARITIES AND DIFFERENCES IN CARE Sophia Jan[1,2]; Dava Szalda[2]; Manuel E. Jimenez[2,3]. [1]Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA; [3]Children's Hospital of Philadelphia, Philadelphia, PA. (Tracking ID #1643123)

BACKGROUND: Over 90 % of pediatric patients with special healthcare needs are living into adulthood necessitating internists to care for a new variety of diagnosis and disease processes. Many of these young adults share similar functional needs limitations and caregiver dependencies as elderly patients with dementia. We examine how clinical needs and practice supports by internists caring for this population may be similar or different from that of geriatric patients with dementia in order to identify barriers and possible interventions to improve care.

METHODS: We conducted semi-structured interviews with a convenience sample of internal medicine physicians. We purposively sampled participants based on their known or reported experience with young adults with pediatric onset chronic illness using a snowball strategy. Open-ended questions explored processes of care around the initial and subsequent visits to internal medicine practices of young adults with developmental disabilities and elderly adults with dementia. Interviews were recorded, transcribed, coded and continued until we reached thematic saturation. We identified themes using modified grounded theory.

RESULTS: Twenty-one practicing physicians in four different states in both academic and private practices were interviewed. Similarities identified include: reliance on caregivers for history; difficulties obtaining prior medical records or appropriate transfer summary for new patients; managing complex drug regimens and coordination among multiple specialists; needed assessments of cognitive skills, personal and family resources, and home living situation; consideration of guardianship, confidentiality, caregiver burden, and health literacy; need for expanded clinic resources, including extended visit time slots, availability of nurses between visits, social work and case management support; need for motility and other assistive technology supports; need for specific community services for transportation, respite care, and care coordination; and reliance on home health, rehabilitation services, and skilled nursing facilities. Differences include prevalence and presentation of specific diseases; predominance of Medicaid for young adult patients and Medicare for elderly patients; type of life stressors and community supports needed, such as vocational and educational for young adults and hospice and end-of-life care for the elderly.

CONCLUSIONS: There are many similarities and differences in needed practice supports for elderly adults with dementia and young adults with developmental disabilities. These similarities should be further explored to determine how the needs for this population of young adults can be served by or adapted from services and supports already available for elderly patients.

ELECTRONIC COMMUNICATION WITH PATIENTS: A KEY TO PATIENT-CENTERED, EFFICIENT CARE Tara F. Bishop; Matthew J. Press; Jayme Mendelsohn; Lawrence P. Casalino. Weill Cornell Medical College, New York, NY. (Tracking ID #1637069)

BACKGROUND: Principles of new primary care models imply that medical practices should use electronic communication more with patients and that this form of communication could sometimes substitute for office visits. However, this is rarely stated explicitly in the literature about these models. We performed a qualitative study to address the following questions: How do practices use electronic communication as a substitute for office visits? What are the perceived advantages and disadvantages of electronic communication with patients? What barriers and facilitators do practices face when implementing programs that substitute electronic communication for office visits?

METHODS: Using the literature and key informants, we identified 78 medical groups that potentially used electronic communication to substitute for office visits. Among the 35 group leaders who responded to our contact, 21 said they used electronic communication to substitute for office visits. We interviewed these leaders. We also interviewed 16 frontline physicians and staff in 6 of these groups (case-study groups) and interviewed a convenience sample of 6 leaders from health plans. We used a semi-structured interview tool and coded interview notes using the constant comparative method.

RESULTS: Among the 6 case-study groups, five were large (>100 physicians). Two were paid via capitation. The other 4 were paid via fee-for-service, but one charged an annual retainer fee and another received government funds to help support its operations. For 3 groups, their payment model (capitation and fee-for-service with a retainer) was a motivator to shift to electronic communication. One group had a formal e-visit program which they differentiated from informal electronic communication. Some private health plans paid for formal e-visits. Only 2 groups had time set aside in the workday for physicians to manage non-visit communication. Interviewees perceived more advantages than disadvantages of electronic communication with patients such as easier access to care for patients, that it saves patients time, and that it improves patient satisfaction. Physicians frequently said that electronic communication was more efficient than telephone communication. The most frequently cited disadvantage was that it created more work for physicians even in practices that had time set aside in the workday. When asked specifically whether electronic communication led to poor outcomes, respondents said no and some argued that care delivered electronically was safer than other modes of care. The most frequently cited barrier to implementation was patient and physician resistance to change. One practice that was paid only by fee-for-service cited lack of payment for electronic communication as a barrier. Interviews with leaders in the 15 additional groups yielded similar information. Interviews with health plan leaders revealed that few health plans reimburse for electronic communication and that some health plans consider hybrid models of payment (e.g. monthly PCMH payments) as the

mechanism to pay for electronic communication. One health plan leader felt there was little demand from physicians for payment for electronic communication.
CONCLUSIONS: The advantages of electronic communication appear to outweigh the disadvantages but physician workday redesign and new payment methods are likely necessary for electronic communication to be used more extensively.

ELIGIBILITY AND RECRUITMENT RATES BY VENUE TYPE FOR TWO COMMUNITY-BASED RANDOMIZED CONTROL TRIALS FOR OLDER BLACK MEN: IMPLICATIONS FOR HEALTH DISPARITIES RESEARCH Jordan Plumhoff. New York University School of Medicine, New York, NY. (Tracking ID #1641776)

BACKGROUND: Black men are often under-represented in research, decreasing the generalizability of results for many studies. Community-based settings such as barbershops and faith-based organizations are pillars of many Black communities, and are essential partners for institutions wishing to engage Black men in research. We comparestudy eligibility rates between various community-based settings in two large community-based randomized controlled trials and discuss implications for disparities research.
METHODS: We assessed 4,888 Black men over 50 at 154 community-based venues (including churches, mosques, barbershops, soup kitchens and food pantries, social services agencies, and community health fairs) in New York City to determine eligibility for two randomized trials to reduce disparities in blood pressure (BP) control and colorectal cancer (CRC) screening.Sites included barbershops, churches, mosques, soup kitchens, senior centers and health fairs. Eligibility included: 1) self-reported black male; 2) English-speaking; 3) uncontrolled BP; 4) in need of CRC screening, and 5) telephone access. Data was analyzed by recruitment location venue type and reason for ineligibility.
RESULTS: Eligibility rates differed by recruitment location. Barbershops and soup kitchens had the highest eligibility rates (29 % and 28 % respectively). Senior centers and churches had the lowest rates (12 % and 11 % respectively). We found a high prevalence of prior CRC screening at senior centers and churches (79 % and 69 % respectively). At health fairs, 68 % had prior CRC screening and 65 % had controlled BP. Mosques had the lowest rates of prior CRC screening (30 %) but had low eligibility rates due to language barriers (23 %).
CONCLUSIONS: To maximize recruitment efforts in community-based research, recruitment locations and characteristics of the populations served must be considered. Barbershops may provide access to participants of greater need compared to men recruited at churches or senior centers. Within faith-based organizations, soup kitchens and mosques may attract men with greater health needs compared to church congregations or health fairs. Future research to reduce health disparities among black men should prioritize high-need community-based settings.

EMAIL AS AN QUALITY IMPROVEMENT LEVER: EVIDENCE OF LACK OF EFFICACY FROM AN ACADEMIC INSTITUTION Ari Geliebter; Robert Sidlow. Jacobi Medical Center, Bronx, NY. (Tracking ID #1635656)

BACKGROUND: Proton pump inhibitors (PPIs) are widely used for the treatment of gastrointestinal disorders and for the prevention of gastrointestinal bleeding in hospitalized patients (i.e. “GI prophylaxis.”) However, studies have shown that there is significant inappropriate overuse of these medications. While PPIs are generally safe, they have been associated with the several complications, including nosocomial pneumonia, C. difficile infection, and increased fracture incidence, thus heightening the need to avoid their inappropriate use. A preliminary study at our institution revealed that approximately 50 % of inpatients had received esomeprazole therapy without having met any evidence-based criteria for PPI prescription. In an attempt to decrease the inappropriate use of these agents, we sought to assess the impact of a educational email intervention on the rate of esomeprazole (the only PPI on formulary) use at our teaching hospital. We hypothesized that, assuming a stable patient mix, overall inpatient esomeprazole usage would decrease as a result of an email-based educational intervention which targeted medical housestaff.
METHODS: Using a hospital-based pharmacy data warehouse, the weekly number of esomeprazole doses (either p.o. or i.v.) administered to patients on each of six inpatient medical units was determined over a 12 week period beginning in August 2012; prescription rates were normalized to the volume of admissions on each of those units. An email was then composed which a) highlighted the safety risks of inappropriate PPI administration in the hospital; and b) outlined evidence and consensus-based guidelines for PPI use in active GI disease and stress ulcer prophylaxis in hospitalized patients. During the intervention phase, the educational message was emailed from a departmental email server to all members of the internal medicine housestaff on a weekly basis for four consecutive weeks. Inpatient esomeprazole administration rates were then compared pre and post intervention.
RESULTS: The average rate of esomeprazole administration remained unchanged pre- and post- intervention (1.64 esomeprazole doses/patient vs. 1.89 esomeprazole doses/patient, $p=0.24$.)
CONCLUSIONS: An educational email intervention which sought to decrease the inpatient prescription of proton pump inhibitors by medical housestaff had no impact on their behavior. At our institution, email was an ineffective means to influence physician prescribing behavior, and thus should be used cautiously as a tool for quality improvement efforts.

ENSURING CULTURALLY COMPETENT FALLS QUESTIONS IN POPULATION-BASED SURVEYS Susan Huang[1]; Thu Quach[1]; Liss Ieong[1]; Joan Abrams[2]; Cary Sweeney[2]; Louise Aronson[2]. [1]Asian Health Services, Oakland, CA, CA; [2]University of California, San Francisco, San Francisco, CA. (Tracking ID #1637947)

BACKGROUND: Falls are the leading cause of injuries among older adults. Yet, relatively little is known about differences in falls among ethnic groups, even though differences have important implications for clinical care and resource allocation. A 2007 California Health Interview Survey (CHIS) study showed significantly lower fall rates in Asian elders than in other ethnic groups, 4.2 % in Chinese Americans vs. 12.4 % for All Races. We hypothesized that Chinese-specific language and/or translation issues might have led to under-reporting of falls. In Chinese, the single word for ‘falls’ is too narrow to capture the different types of falls; instead, the circumstances of the fall should be specified.
METHODS: As part of an academic-community partnership for a falls screening pilot project at a community health center in Oakland, CA, we surveyed 78 elderly Chinese patients about falls in the past year. The survey included the CHIS question “During the past 12 months, have you fallen to the ground more than once?” followed by questions that specified falls subtypes (falls, trip over, slip, faint, loss of balance, involuntary fall). Bilingual medical assistants (MA) conducted the survey as part of routine patient care. Instrument validation consisted of review by academic falls experts and bilingual, bicultural staff and pilot tested with study-eligible patients in the same practice. Questions were translated and back-translated to ensure linguistic accuracy.
RESULTS: All 4 participating MAs initially found the CHIS question impossible to articulate. Of the 78 participants, 12 (16 %) refused to answer the CHIS question because they did not understand it. In reporting whether they had fallen in the past year, 8 (10 %) answered “yes” to the CHIS question while 20 (26 %) answered “yes” to at least 2 falls subtypes. Of the 70 who answered “no” or refused to answer the CHIS question, 13 (19 %) answered “yes” to 2 subtypes and 2 (3 %) answered “yes” to 3 subtypes.
CONCLUSIONS: Falls prevalence in the elderly Chinese population may be under-reported in CHIS and other population-based surveys due to two types of translation issues: the phraseology used and cultural/linguistic differences in how falls are discussed. Providers should ensure that Chinese-speaking patients are asked about falls subtypes, and population-based surveys should ensure linguistic competency for greater accuracy in responses.

EVALUATING A MODIFIED INFORMED CONSENT FOR OLDER ADULTS IN CORRECTIONAL RESEARCH Anna Darby[1]; Cyrus Ahalt[2]; Irena Stijacic Cenzer[2,3]; Rebecca L. Sudore[2,3]; Brie Williams[2,3]. [1]Mount Sinai School of Medicine, New York, NY; [2]University of California San Francisco, San Francisco, CA; [3]San Francisco VA Medical Center, San Francisco, CA. (Tracking ID #1621278)

BACKGROUND: As the number of medically vulnerable older U.S. prison and jail inmates continues to grow, clinical research studies are needed to understand their health and healthcare needs. However, age- and circumstance-related vulnerabilities common in older inmates could lead to poor comprehension of the risks and benefits of participating in research and may necessitate safeguards beyond those required by the federal Office of Human Research Protections for all prisoners. This study assessed: (1) older jail inmates' comprehension of a research consent form designed for a population with low literacy; (2) the appropriateness of a teach-to-goal modified consent process; and (3) whether demographic or health-related characteristics confer added risk for poor consent comprehension in older jail inmates.

METHODS: Cross-sectional study of 251 adults age 55 or older in the San Francisco Jail. Participants were read a research consent form written at the sixth-grade level followed by 9 true/false comprehension statements. Those who could not answer all questions correctly on the first try were re-taught the material using a "teach-to-goal" methodology and re-tested up to three times. Demographic and health-related factors were analyzed for association with performance using bivariate analysis.

RESULTS: Of 251 participants, 55 % could not successfully respond to all comprehension statements on the first attempt. Of these, 75 (54.7 %) responded to more than one statement incorrectly and 18 (13.1 %) required the maximum allowed three passes to respond correctly to all statements. The modified consent process enabled 100 % participation of willing subjects and added <8 min to the consent process on average. No demographic or health-related factors were significantly associated with requiring additional, teach-to-goal education to complete the consent form.

CONCLUSIONS: Though 55.0 % of participants could not correctly respond to nine true/false comprehension statements on the first pass, and more than half of these (54.7 %) answered multiple questions incorrectly, the brief (<8 min) teach-to-goal intervention enabled 100 % participation with demonstrated comprehension of the consent forms. No demographic or health-related factors were significantly associated with poor comprehension, suggesting that a specific group of vulnerable older inmates is not easily identified. Therefore, all incarcerated older adults should receive the teach-to-goal consent process before participating in clinical research.

EVALUATION OF AHA RECOMMENDATIONS FOR CARDIAC MONITORING IN A NONCRITICAL SETTING Matthew T. Cerasale[1]; Carlos Calle[1]; David Paje[2]. [1]Henry Ford Hospital, Detroit, MI; [2]Henry Ford Hospital, Detroit, MI. (Tracking ID #1637364)

BACKGROUND: Cardiac monitoring is often overutilized. The 2004 American Heart Association (AHA) practice standards categorized indications for electrocardiographic monitoring in hospitalized patients based on the potential therapeutic benefit. This study sought to evaluate whether the AHA recommendations could safely guide the selection of patients for cardiac monitoring in a noncritical setting.

METHODS: Clinical data were extracted from the medical records of patients who were admitted to the telemetry unit of a suburban community hospital from January to March 2009. The indications for cardiac monitoring were classified based on the 2004 AHA practice standards: Class 1 includes clinical conditions where cardiac monitoring is indicated in most, if not all patients; Class 2 is when it may be of benefit for some patients, but not considered essential for all; and Class 3 is when it is not indicated. The outcome was the occurrence of new significant cardiac events during the period of monitoring, including acute coronary syndrome, symptomatic or malignant arrhythmias, QT prolongation and sudden cardiac death. Sensitivity, specificity and predictive values were calculated.

RESULTS: There were 505 admissions to the telemetry unit, 93 (18 %) had indications for intensive care and were excluded from further analysis. Of the remaining 412 patients, 186 (45 %) met Class 1 indications, 122 (30 %) were Class 2, and 104 (25 %) were Class 3. Of the Class 1 patients, 82 (44 %) had chest pain, and 73 (39 %) had acute coronary syndrome (ACS). Overall, the significant cardiac event rate was 1.46 % (6/412). The presence of a Class 1 indication was 67 % sensitive (95 % CI: 23–95 %) and 55 % specific (95 % CI: 50–60 %) for predicting an event. Reclassifying syncope from a Class 2 to a Class 1 indication resulted in sensitivity of 100 % (95 % CI: 54–100 %), specificity of 51 % (95 % CI: 47–56 %) and negative predictive value of 100 % (95 % CI: 98–100 %). The potential reduction in cardiac monitoring was 51 % (95 % CI: 46–56 %).

CONCLUSIONS: The overall incidence of significant cardiac events among patients currently placed on electrocardiographic monitoring in a noncritical setting is low. The 2004 AHA practice standards can provide safe and effective guidance on selecting patients who will benefit from monitoring, and may be enhanced if syncope is recategorized as Class 1. Applying these recommendations in clinical practice may help substantially reduce the use of cardiac monitoring.

Test Characteristics of the AHA Practice Standards for Predicting Significant Events on Cardiac Monitoring in a Noncritical Setting

Test Characteristic	Presence of Class 1 Indication Predicting Significant Cardiac Events			
	Original 2004 Practice Standards		Modified with Syncope as Class 1	
	Value, %	95 % CI, %	Value, %	95 % CI, %
Sensitivity	67	23–95	100	54–100
Specificity	55	50–60	51	47–56
Prevalence	1.46	0.54–3.14	1.46	0.54–3.14
Positive Predictive Value	2.15	0.60–5.42	2.96	1.10–6.33
Negative Predictive Value	99.12	96.83–99.87	100	98.23–100

EVALUATION OF CHARLSON COMORBIDITY INDEX AS A PREDICTOR OF ADVERSE OUTCOMES IN PATIENTS ADMITTED WITH COMMUNITY-ACQUIRED PNEUMONIA Qasim Shakeel; Rafael Cabrera; David Paje; Amit Vahia; Abdul Kareem Uduman; Luis C. Watanabe Tejada. Henry Ford Health Systems, Detroit, MI. (Tracking ID #1634966)

BACKGROUND: Patients diagnosed with community-acquired pneumonia (CAP) are commonly risk-stratified using either the validated CURB-65 criteria or the Pneumonia Severity Index (PSI), both of which primarily uses acute clinical findings to predict mortality. The role of chronic comorbidities in predicting outcomes in patients with CAP is unclear. Our goal was to evaluate the ability of the age-adjusted Charlson Comorbidity Index (CCI) to predict adverse outcomes in patients admitted with CAP to a general medical unit and we compared its performance with CURB-65 and PSI.

METHODS: The medical records of consecutive patients admitted with CAP to an urban tertiary referral teaching hospital were reviewed to obtain the required demographic characteristics, acute clinical findings and documented comorbidities to calculate the CURB-65, PSI and age-adjusted CCI scores. The performance of each severity score in predicting 30-day mortality, 30-day readmission, intensive care unit (ICU) transfer and length of stay (LOS) of at least 7 days was evaluated by producing receiver operator characteristic (ROC) curves. The areas under the ROC curves (AUC) were compared using Hailey and McNeil method based on the non-parametric two-sample Mann–Whitney U statistic.

RESULTS: 539 patients were included in the analysis, 85 (15.77 %) died within 30 days, 84 (15.58 %) were readmitted within 30 days, 76 (14.10 %) were transferred to the ICU during the index admission and 172 (31.91 %) had a LOS>7 days. The CURB-65, PSI and CCI scores were all highly significant predictors of 30-day mortality; the AUC for each were 0.735, 0.770 and 0.765, respectively, and were significantly greater than the line of no information ($p<0.001$). All three severity scores were also significant predictors of ICU transfer (CURB-65: 0.603, $p=0.002$; PSI: 0.652, $p<0.001$; CCI: 0.647, $p<0.001$) and of LOS>7 days (CURB-65: 0.578, $p=$

0.003; PSI: 0.607, $p<0.001$; CCI: 0.612, $p<0.001$). None of the severity scores significantly predicted 30-day readmission. When compared to each other, no severity score was significantly more predictive of mortality, readmission, ICU transfer or LOS>7 days than the other.
CONCLUSIONS: When predicting adverse outcomes in patients admitted with community-acquired pneumonia, risk assessment using comorbidities perform similarly when compared to measures that primarily include acute clinical findings. The age-adjusted Charlson Comorbidity Index significantly predicted important clinical outcomes in CAP patients. Future studies are necessary to determine if this tool may be universally applied to predict outcomes in other acute medical conditions.

EVIDENCE-BASED RISK COMMUNICATION: A SYSTEMATIC REVIEW Daniella A. Zipkin[1]; Elizabeth Allen[2]; Rebecca Beyth[3]; Scott Kaatz[4]; Nancy L. Keating[5]; Devin Mann[6]; Jeremy Sussman[7]; Connie Schardt[1]; Craig A. Umscheid[8]; Deborah Korenstein[9]; Avishek Nagi1; Richard Sloane[1]; David Feldstein[10]. [1]Duke University Medical Center, Durham, NC; [2]Oregon Health Sciences University, Portland, OR; [3]University of Florida, Gainesville, FL; [4]Hurley Medical Center, Flint, MI; [5]Harvard Medical School, Boston, MA; [6]Boston University School of Medicine, Boston, MA; [7]University of Michigan, Ann Arbor, MI; [8]University of Pennsylvania, Philadelphia, PA; [9]Mount Sinai School of Medicine, New York, NY; [10]University of Wisconsin School of Medicine and Public Health, Madison, WI. (Tracking ID #1636930)

BACKGROUND: Effectively communicating the risks and benefits of tests and therapies to patients is critical for shared decision-making. The method of communicating risk affects patients' comprehension and perceptions, but the best formats remain unclear. We systematically reviewed the literature on methods of communicating probabilistic information to patients to determine which presentations maximize patients' understanding, satisfaction, and decision-making.
METHODS: We searched Medline, CINAHL, Embase, and Cochrane CENTRAL from 1966 through December 2011 using terms related to patients, communication, risk, and outcomes of comprehension, preferences, and decision-making. We included all cross-sectional or prospective trials with an active control group that compared different methods of communicating the same risk. We excluded studies of health care providers and non-English language studies. One author reviewed titles and abstracts. Two authors independently reviewed full text and disagreements regarding inclusion were settled by consensus. Two authors independently abstracted information about the study population, interventions, and outcomes and assessed risk of bias using standard tools. Data were summarized with descriptive statistics. Study heterogeneity precluded meta-analysis.
RESULTS: Of 20,088 citations retrieved, 604 were selected for full text review. Seventy-six unique citations containing 85 studies (64 randomized trials) were included. The median number of participants was 266 (range 24 to 16,133). The most frequent comparisons were between variations of pictographs or icon arrays (IA) (15 comparisons), IA vs. natural frequencies (number of events out of stated denominator, NF) (8 comparisons), IA vs. bar graphs (7 comparisons), absolute risk reduction (ARR) vs. relative risk reduction (RRR) (6 comparisons), number needed to treat (NNT) vs. RRR (5 comparisons), and NF vs. NNT (4 comparisons). Studies comparing IA to NF and bar graphs had mixed results. With small risks, IA led to less overestimation of risk than NF. Compared with bar graphs, IA improved accuracy for incremental risks but results were split for overall risks. IA were associated with lower confidence in decisions, and sometimes considered confusing. Studies comparing IA presentations had several findings. IA displaying only sick subjects led to poorer risk understanding than those displaying sick and healthy subjects. For IA depicting total populations, there was less participant worry when incremental risk rather than overall risk was presented. Providing baseline and incremental risks in a single IA rather than two separate IA improved comprehension. A horizontal layout was more favorable than vertical. Participants perceived risks more accurately when presented with ARR compared with RRR. RRR was associated with a higher probability of accepting therapy or screening. NNT led to less accurate risk perceptions and less satisfaction with decision-making compared with RRR and NF.
CONCLUSIONS: The literature regarding methods of communicating risk is vast and heterogeneous in terms of formats, specific comparisons, outcomes, and outcome measurement. IA, NF and ARR appear best for overall accuracy of risk estimation, while bar graphs are better understood than IA in some instances. RRR has the greatest impact on behavior. A consensus statement to guide future study methodology would enhance consistency and reproducibility and optimize determinations of comparative effectiveness.

EXAMINING THE INFLUENCE OF A BEHAVIORAL CHANGE ACTIVITY ON SENIOR MEDICAL STUDENT ATTITUDES ABOUT MOTIVATIONAL INTERVIEWING Elizabeth Karwowski[1,2]; Teresa Cheng[1]; Jay D. Orlander[1,2]. [1]Boston Medical Center/Boston University School of Medicine, Boston, MA; [2]VA Boston Healthcare System, Boston, MA. (Tracking ID #1634009)

BACKGROUND: Despite its importance to clinical care and recognition as a core competency, many medical schools lack effective strategies to teach interpersonal communication. This study evaluated the impact of four communication workshops, along with a behavioral change activity, on senior students' valuation of communication and confidence in their communication skills.
METHODS: The curriculum for fourth-year students in a mandatory ambulatory medicine clerkship at Boston University School of Medicine included four communication skills workshops: setting the agenda (SA), motivational interviewing (MI), communication with peers (CP), and dealing with difficult patients (DD). All workshops included a short didactic session followed by skills practice totaling 90 min. Following only the MI workshop, students self-selected a behavioral change activity that they performed for 1 week, after which they completed a brief reflection. The behavioral change did not have to relate to the workshop content. Students completed a supplementary course evaluation at the end of the clerkship to assess the workshops using a seven-point Likert scale. Students rated their attitudes before and after the clerkship in two areas: the 'importance' of each communication skill and 'confidence' in their ability to perform it. Participation was voluntary and anonymous. No incentives were provided. Nonparametric tests including comparison of the means of the differences and Wilcoxon Signed Rank Test were used to analyze the data.
RESULTS: Forty-eight out of 60 (80 %) students completed the course evaluation. The data were not normally distributed. In aggregate, student scores improved for both the 'importance' and 'confidence' categories following each of the workshops. Nonparametric binomial testing showed that the mean positive change in student scores of 'importance' was greater in the MI workshop (1.13, 95 % CI 0.81–1.45) than workshops focused on SA (0.89, 0.62–1.16), CP (0.71, 0.46–0.96) and DD (0.58, 0.38–0.78), as well as the control query on the importance of general communication skills (mean 0.40, 0.21–0.59). Using Wilcoxon Signed Rank Test to compare the mean change in student scores among the workshops, the MI workshop improved scores significantly more than both the DD workshop ($p=0.003$) and the students' perceived importance of general communication skills ($p<0.001$). Binomial testing also showed that the mean positive change in student scores of 'confidence' was greater in the MI workshop (1.34, 95 % CI 1.08–1.60) than the workshops on SA (1.02, 0.76–1.28), CP (0.64, 0.42–0.86), and DD (1.16, 0.91–1.41), and the control query on general communication skills (0.60, 0.43–0.77). These differences in confidence scores were statistically significant for MI vs. SA ($p=0.027$), MI vs. CP ($p<0.001$), and MI vs. general communication skills ($p<0.001$).
CONCLUSIONS: Communications workshops targeting senior medical students improved their valuation of and confidence in these communication techniques. Relative to the other workshops, the larger increases in motivational interviewing scores suggest that continued application of these techniques outside the classroom through a simple activity may further increase student ratings of importance and confidence.

EYE IMAGES IMPROVE HAND HYGIENE COMPLIANCE IN AN EMERGENCY DEPARTMENT Sarah A. Stella1,2; Roger Stace3; Amber Miller1; Angela Keniston1; Marisha Burden1,2; Connie S. Price1,2; Richard K. Albert1,2. 1Denver Health Medical Center, Denver, CO; 2University of Colorado School of Medicine, Aurora, CO; 3University of Colorado Denver School of Business, Denver, CO. (Tracking ID #1638955)

BACKGROUND: Hand hygiene is thought to reduce hospital acquired infections, but multiple studies have found poor compliance with hand washing recommendations among health care workers. Interventions aimed at improving compliance, some requiring considerable effort and expense, have shown mixed results. A number of studies in behavioral science have shown that even subtle cues of 'being watched' appear to inhibit selfish behaviors and increase altruistic ones (e.g., increasing the amount of money contributed to an honor box: Bateson et. al., 2006, Biol.Lett.) and depiction of eye images has influenced these behaviors in both experimental and real-world settings. We hypothesized that displaying eye images in patient care settings would improve compliance with hand hygiene recommendations among health care workers.
METHODS: We placed posters depicting eye images or mountains (as a control), together with a message encouraging providers to wash their hands, next to foam product dispensers at the entrance to patient rooms in the emergency department of a university-affiliated safety net hospital. We employed an interrupted time series design varying the condition every three weeks as follows: baseline (no poster), eye images, washout period, mountains. Covert observation of hand hygiene opportunities was performed remotely via security surveillance cameras that were already in use. These allowed clear vision of the dispensers located outside the rooms but not of those located within all the rooms observed. Data were analyzed by segmented regression analysis.
RESULTS: During the period when no posters were utilized hand washing compliance was only 3.7 % and we saw no change in compliance over the 3 weeks period of assessment (P=0.60). After eye images were posted compliance increased to 11.1 % (P=0.02) and again, no change in compliance was observed over the 3 weeks observation period (P=0.10). At the beginning of the wash-out period compliance was 7.3 % which we did not find different from the 11.1 % measured when eye images were used (P=0.31), but compliance increased to a small extent during this period of observation (7.3 % to 9.2 %, P=0.03). Finally, we found no increase in hand hygiene from that measured at the beginning of the washout period and that measured after displaying the control images (7.3 % versus 7.4 %, P=0.48) and no change in compliance over the final period of measurement was observed (P=0.88). Surveillance cameras revealed multiple instances of misuse of latex gloves through all periods of observation.
CONCLUSIONS: Compliance with hand hygiene recommendations was very low in all periods of study but displaying eye images improved compliance (although still leaving compliance lower than expectations). Although not specifically tabulated, widespread misuse of latex gloves was observed, presumably in lieu of hand hygiene.

FACTORS AFFECTING THE HEALTH LITERACY OF HISPANIC ADULTS LIVING IN THE US Rosette Chakkalakal[1]; Lee Sanders[2]; Shonna Yin[3]; Eliana M. Perrin[4]; Russell L. Rothman[1]. [1]Vanderbilt University, Nashville, TN; [2]Stanford University, Palo Alto, CA; [3]New York University, New York City, NY; [4]University of North Carolina at Chapel Hill, Chapel Hill, NC. (Tracking ID #1643116)

BACKGROUND: Hispanic adults frequently score lower on assessments of health literacy than other racial/ethnic groups. However, individuals who identify as Hispanic often differ in terms of several socio-demographic factors such as acculturation and English proficiency; the extent to which these factors influence the health literacy of Hispanic adults is unknown. We therefore sought to explore the relationship between health literacy and these key factors among a sample of Hispanic adults living in the US.
METHODS: Using logistic regression models, we analyzed data collected from adult Hispanic caregivers participating in the Green Light Obesity Prevention Study to explore the effect of age, gender, education, income, place of birth (foreign-born versus US-born), acculturation, interview language preference, English proficiency, and city of residence on health literacy as measured by the Short Test of Functional Health Literacy in Adults (STOFHLA). We collapsed inadequate and marginal health literacy scores into a single "limited" health literacy category and compared individuals with limited and adequate health literacy. Acculturation was measured using the Short Acculturation Scale for Hispanics (SASH). We created 3 models so we could separately analyze the effect of acculturation, English proficiency, and interview language preference because of collinearity among these variables (model 1 included acculturation, model 2 included English proficiency, model 3 included interview language preference). Results were expressed as the adjusted odds of having adequate health literacy.
RESULTS: 430 Hispanic adults completed the STOFHLA; 14.9 % had limited health literacy and 85.1 % had adequate health literacy. In all 3 models the odds of having adequate health literacy were greater for Hispanic adults who were male, had a high school education or greater, had an income greater than or equal to $20,000, were born in the US, were more acculturated, spoke English, preferred to be interviewed in English, and lived in New York City, NY, Chapel Hill, NC or Nashville, TN. In model 1, the adjusted odds ratios for education (3.6, 95 % CI 1.8–7.2), income (7.2, 95 % CI 2.1–25.1), acculturation (2.1, 95 % CI 1.1–4.0) and city of residence (New York City versus Miami OR=3.6, 95 % CI 1.5–8.8, Chapel Hill versus Miami OR=4.3, 95 % CI 1.5–11.9, Nashville versus Miami OR=12.5, 95 % CI 3.6–43.1) were statistically significant. In model 2, the adjusted odds ratios for education (3.3, 95 % CI 1.7–6.4), income (5.0, 95 % CI 1.7–15.2), English proficiency (not well versus not at all OR=3.7, 95 % CI 1.8–7.6, very well or well versus not at all OR=3.6, 95 % 1.5–8.8), and city of residence (Nashville versus Miami OR=7.7, 95 % CI 2.3–26.3) were statistically significant. In model 3, the adjusted odds ratio for education (3.9, 95 % CI 2.0–7.5), income (6.3, 95 % CI 2.1–18.6), place of birth (5.5, 95 % CI 1.1–27.7), and city of residence (New York City versus Miami OR=2.3, 95 % CI 1.1–5.2, Chapel Hill versus Miami OR=3.6, 95 % CI 1.4–9.4, Nashville versus Miami OR=8.6, 95 % CI 2.7–27.8) were statistically significant.
CONCLUSIONS: Our project demonstrates the need to account for gender, education, income, place of birth, acculturation, language preference, English proficiency, and place of residence as we measure health literacy and design interventions to address literacy-related health disparities facing Hispanic populations.

FACTORS INFLUENCING INCREASING RACIAL DISPARITY IN DIABETIC LDL CHOLESTEROL CONTROL IN A CONTEXT OF ACTIVE QUALITY IMPROVEMENT Stephen D. Persell; Raymond Zhang; Ji Young Lee; Muriel Jean-Jacques; Tiffany Brown. Northwestern University, Chicago, IL. (Tracking ID #1639775)

BACKGROUND: The effects of general quality improvement (QI) approaches on racial disparities are not clear. After implementing multifaceted, physician-directed QI, we observed an increase in the disparity in rates of LDL cholesterol control between white and black diabetes patients. We sought to examine possible causes for the increasing racial disparity.
METHODS: We performed a retrospective observational study of a cohort of 962 black and white diabetes patients treated continuously at a large internal medicine practice between 2008 and 2010. The primary outcome was LDL cholesterol control defined as below 100 mg/dL measured in the past year. We obtained prescription regimens and patient characteristics from electronic health records. We performed multivariable logistic regression stratified by LDL cholesterol control status on 2/1/2008 to examine the association between race and LDL control on 2/1/2010 accounting for factors influencing LDL control including: baseline lipid-lowering medication prescription, medication changes, demographics, comorbidities and geocoded indicators of socioeconomic status. We used chart review to examine the prevalence of physician-documented non-adherence to lipid-lowering medication for patients with uncontrolled LDL cholesterol and examined reasons for non-adherence.

RESULTS: At baseline, 55.0 % of whites and 49.8 % of blacks were controlled (5.2 % disparity). The disparity in LDL cholesterol control increased during the first 2 years of the QI implementation, with 61.8 % of whites and 44.6 % of blacks having LDL cholesterol controlled in 2010, a 17.2 % disparity and a 12.1 % increase in the disparity between 2008 and 2010. Most of the cohort had an LDL test during the year prior to 2/1/2010, and this did not differ significantly by race (75.7 % of white patients and 72.4 % of black patients). Among patients uncontrolled at baseline, whites were more likely to become controlled. Among patients controlled at baseline, blacks were more likely to become uncontrolled. Accounting for patient characteristics and changes in lipid-lowering drug prescription regimens did not attenuate the relationship between black race and LDL control at follow-up for patients who were initially uncontrolled (aOR of 0.52, 95 % CI 0.34–0.80) or controlled (aOR of 0.46, 95 % CI 0.31–0.71). On chart review, among patients with uncontrolled LDL cholesterol in 2010, 40 % of black patients and 29 % of white patients had physician-documented non-adherence. Reasons for non-adherence did not significantly differ between black and white patients. Among those with non-adherence documented, the most common recorded reasons were patient-experienced adverse drug events (32 % for black patients, 35 % for white patients), patient preference to not use medication (27 % for black patients, 35 % for white patients), and financial barriers (24 % for black patients, 18 % for white patients).

CONCLUSIONS: The increased racial disparity was not explained by physician prescribing behavior or measured patient characteristics. Physician-facing, general QI interventions alone may be insufficient to produce equity in LDL cholesterol control. Helping patients maintain their prior success controlling their cholesterol appears to be as important for addressing this racial disparity as helping uncontrolled patients achieve control. Interventions that specifically address patients' perceptions of medication use and their experiences of adverse effects should be tested.

FINANCIAL STRAIN AND MEDICATION ADHERENCE AMONG DIABETES PATIENTS IN AN INTEGRATED HEALTHCARE DELIVERY SYSTEM Courtney R. Lyles[1]; Hilary K. Seligman[1]; Melissa M. Parker[2]; Howard H. Moffet[2]; Nancy E. Adler[3]; Dean Schillinger[1]; Andrew J. Karter[2]. [1]University of California San Francisco, San Francisco, CA; [2]Kaiser Permanente Northern California Division of Research, Oakland, CA; [3]UCSF, San Francisco, CA. (Tracking ID #1631061)

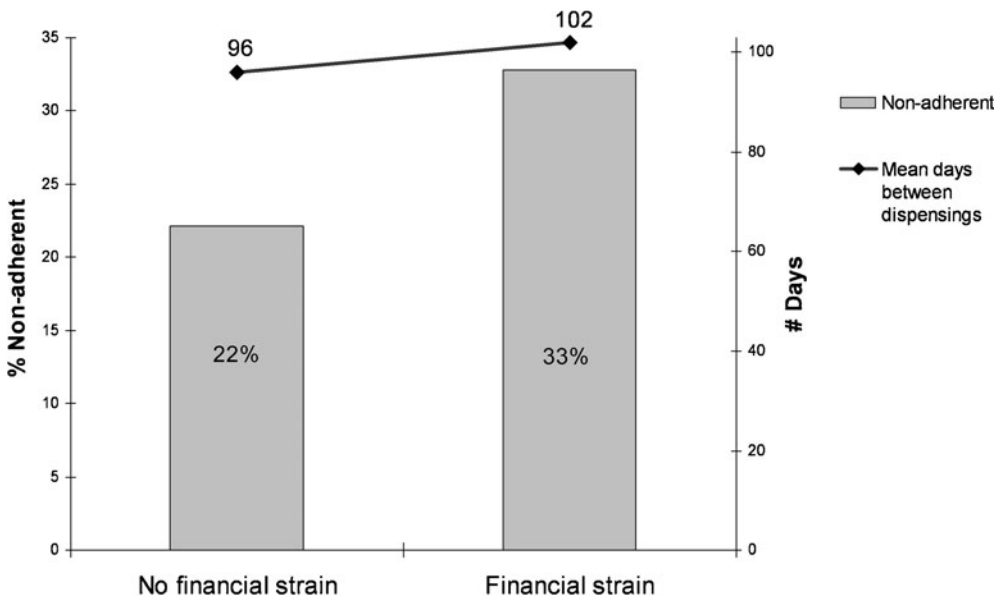
BACKGROUND: Financial strain, or the inability to afford necessary items such as food and clothing, is associated with poor glycemic control. It is hypothesized that this association is partially driven by decreased medication adherence resulting from an inability to afford medication. However, few studies have examined the association between financial strain and objectively-assessed medication refill behaviors.

METHODS: We conducted a race-stratified survey in 2005–2006 of diabetes patients receiving care at Kaiser Permanente Northern California, and linked responses to electronic medical record data. We examined self-reported financial strain ("How often did it happen that you did not have enough money to buy food, clothes or other things you needed?"), dichotomized as never vs. anytime in the previous year. Among patients with a newly prescribed cardiometabolic medication for a 100-day supply (the standard in this system), we examined pharmacy records to assess medication use in two ways. We counted the total days between dispensings and defined non-adherence as a second dispensing ≥2 weeks after the 100-day supply should have run out (i.e., ≥114 days between dispensings). We examined generalized linear models, adjusting for age, gender, education, race/ethnicity, medication type, and co-payment amount.

RESULTS: Among 7,773 individuals with a newly prescribed cardiometabolic medication, 8 % (n=609) reported financial strain. Overall, there were a total of 11,820 prescriptions among these individuals in 2006. Those reporting financial strain had an average of 102 days between dispensings, compared to 96 days among those not reporting financial strain (Figure, p-<0.01). In addition, 33 % of those reporting financial strain were non-adherent, compared to 22 % of those not reporting strain (Figure, p<0.01). These differences remained significant in adjusted models, with those reporting strain having a 4.1 days longer between dispensings (95 % CI: 0.3–7.9) and a 31 % increased likelihood of non-adherence (RR=1.31, 95 % CI: 1.12–1.53).

CONCLUSIONS: In this sample of diabetes patients in an integrated healthcare delivery system, we quantified the degree to which financial strain related to medication refill behaviors. There was a significant association between self-reported financial strain and non-adherence. This may suggest that those reporting difficulty affording necessary items may put off ordering medication refills, with the potential for long-term, negative implications on clinical risk factor control—especially when extrapolating poorer adherence over a longer (e.g., one-year) timeframe and across multiple cardiometabolic prescriptions (e.g., 4 medications, the average within this cohort).

Figure. Medication non-adherence and days between dispensings by financial strain



FRAMING EFFECTS INFLUENCE PHYSICIANS' SENSE OF PROFESSIONAL RESPONSIBILITY REGARDING HEALTH CARE COSTS Tim Mundell[1]; Katherine M. James[2]; Susan D. Goold[3]; Jon C. Tilburt[2,4]. [1]Willliam Beaumont School of Medicine, Rochester, MI; [2]Mayo Clinic, Rochester, MN; [3]University of Michigan, Ann Arbor, MI; [4]Mayo Clinic, Rochester, MN. (Tracking ID #1637538)

BACKGROUND: Health care reform aimed at reducing costs requires active physician participation. There is little, if any, literature regarding framing effects in health care reform language about physicians' responsibilities to reduce costs. We aimed to assess how framing effects might impact physicians' self-described responsibility to address cost issues. We hypothesized that physicians given "wise stewardship" language in a survey item would be most likely to agree with their responsibility, somewhat less likely to agree if given "cost-conscious" language, and least likely to agree if given overt use of "rationing" language in a dose-response fashion.
METHODS: In late May, June, and July of 2012, we mailed a self-administered, 8-page survey entitled, "Physicians, Health Care Costs, and Society" to 3,897 practicing US physicians representing all specialties. In this survey, we embedded an experiment using one survey item. The 3,897 participants were randomly assigned to one of the three following framings of physician obligations related to health care resources and asked to indicate their degree of agreement or disagreement based on a four point ordinal scale (strongly agree, somewhat agree, somewhat disagree, strongly disagree): the "wise stewardship" version ("It is my responsibility to exercise wise financial resource stewardship in my daily care of patients"), the "cost-conscious" version ("It is my responsibility to promote cost consciousness in my daily care of patients"), and the "rationing" version ("It is my responsibility to ration in my daily care of patients").
RESULTS: Overall, 1299 physicians received the "wise stewardship" version with 848 responding (RR=65.3 %); 1298 physicians received the "cost-conscious" version with 861 responding (RR=66.3 %); and 1300 physicians received the "rationing" version with 847 responding (RR= 65.2 %). Respondents in all three groups of the experiment were similar with respect to gender, age, region, specialty, practice setting, compensation model, and political affiliation. 88 % of physicians responding in the "wise-stewardship" language group agreed with the statement; 81 % of physicians responding in the "cost-conscious" language group agreed with the statement; and 22 % of physicians responding in the "rationing" language group agreed with the statement. Chi-square tests comparing distributions of responses to all three framing versions were statistically significant ("wise stewardship" v. "cost-consciousness" p-value=0.0003; "wise stewardship" v. "rationing" p-value<0.0001; "cost-consciousness" v. "rationing" p-value<0.0001).
CONCLUSIONS: Framing does appear to influences physicians' self-described responsibilities to reduce health care costs. Language describing physicians' ethical obligations to control health care resources is morally loaded and susceptible to political manipulation.

FRAMING EFFECTS CHANGE CLINICIAN RISK PERCEPTIONS MORE THAN IMPORTANT CHANGES TO A RISK'S TIME-FRAME AND OUTCOME Tanner Caverly[1]; Allan V. Prochazka[1]; Brian P. Lucas[2]; Shane Mueller[1]; Ingrid A. Binswanger[1]; Jean Kutner[1]; Brandon Combs[1]; Daniel Matlock[1]. [1]University of Colorado Denver, Denver, CO; [2]Stroger Hospital of Cook County, Chicago, IL. (Tracking ID #1631077)

BACKGROUND: In deciding whether the benefits of an intervention outweigh the harms, it is necessary to represent both in comparable formats. To do this a clinician must ask three questions: 1. are both benefits and harms framed as absolute risks? 2. are the time-frames the same? and 3. are the benefits and harms of similar importance to patients? The extent to which clinicians critically answer each of these questions when interpreting the meaning of a benefit or harm is not known. Thus, we conducted a survey to determine the extent to which clinicians modify their interpretation when specific changes are made to the framing, time-frame, and outcome.
METHODS: Survey items were developed and revised based on literature review, cognitive interviews, a focus group with survey experts, and pilot testing. The survey consisted of pairs of scenarios that were identical except for a single modification to framing, time-frame, or outcome (Table 1). Responses were on a 1–10 risk perception scale. Each pair was separated by unrelated survey questions and participants were not aware that items would be paired for scoring. However, participants were able to change responses to earlier questions if they noticed a connection. In this way, we hoped to capture how critically clinicians interpreted the risk information presented. We recruited 380 clinicians and trainees at educational conferences to take an anonymous, self-administered paper test: 115 nurse practitioners (NPs), 131 third year medical students, and 134 residents in internal medicine at 2 institutions. We calculated the mean difference between paired responses (within clinician) and used the paired t-test to assess statistical significance with a two-tailed p value threshold <0.05.
RESULTS: When identical risks were framed differently, clinician's responses differed by 1.5 to 2 points on the 10-point risk perception scale (Table 1). This corresponds to an increase of greater than half a standard deviation (SD) of the mean response on an individual question. In contrast, when clinicians were presented with meaningful increases in risk due to time-frame or outcome changes, responses paradoxically changed by 1 or less.
CONCLUSIONS: Clinicians and trainees do not appear to appropriately reformat risk information for comparisons. This leads them to view identical risks as different and equate importantly different risks.
Changes in clinicians' risk perception on a 10-point scale when responding to a pair of questions presenting risks that differ by framing, time-frames, or outcomes.
Question 1 Mean (SD) Question 2 Mean (SD) Mean within clinician difference (95 % CI)* *P*-value* Ideal difference
Framing Difference
Relative risk reduction of 33 % from baseline of 6 %** 7.0 (2.1) Absolute survival benefit from 94 % to 96 %** 5.0 (2.3) 2.0 (1.8 to 2.5)<0.0001 None, identical risk reduction
Disease kills 1 million people in the US every year*** 6.5 (2.5) Disease kills 0.3 % of the US population every year*** 5.0 (2.4) 1.5 (1.3 to 2.5)< 0.0001 None, identical risk
Time-Frame Difference***
3 % risk of dying from cancer over the next 10 years 6.1 (2.2) 3 % risk of dying from cancer over lifetime 5.1 (2.1) 1.0 (0.8 to 1.6) < 0.0001 > 0, same magnitude of risk over a shorter time-frame
Outcome Difference***
3 % lifetime risk of dying from cancer 5.1 (2.1) 3 % lifetime risk of getting cancer 4.8 (2.0) 0.3 (0.1 to 1.7) 0.0018>0, dying is a more important outcome
* Using the paired t-test, null hypothesis that the pooled mean difference equals zero. ** Response on a 10-point response scale that ranged from 1 to 10 with anchors at 1 ("no proof") and 10 ("good proof"). *** Based on a 10-point response scale that ranged from 1 to 10 with anchors at 1 ("not important") and 10 ("very important").

FREQUENCY OF LABORATORY TESTING AMONG GASTRIC BYPASS PATIENTS Adam G. Tsai[1]; Patrick Hosokawa[2]; Jonathan A. Schoen[3]; Allan V. Prochazka[1]. [1]University of Colorado, Aurora, CO; [2]University of Colorado, Aurora, CO; [3]University of Colorado, Aurora, CO. (Tracking ID #1636990)

BACKGROUND: Bariatric surgery for severe obesity is a common surgical procedure in the United States. An expert panel recommended that patients who have malabsorptive procedures (e.g., gastric bypass) undergo routine laboratory monitoring due to the risk of nutritional deficiencies. The frequency of lab monitoring can be considered a measure of quality of care in this patient population. We tested whether or not patients are undergoing this monitoring at the recommended frequency.
METHODS: Data came from the IMS LifeLink™ Health Plan Claims Database, which includes over 70 million patients. The database contains all records in which a lab test was billed to an insurance payer. Patients were identified by CPT codes for surgical procedure they had. The analysis

included all time after the time of the procedure code and where the patient was covered by one of the over 80 insurance payers in the database. We computed an expected number of tests per patient based on: 1) the duration in months of each patient's presence in the dataset after the index surgery; and 2) the minimum testing frequency recommended by the expert panel. We used adjustable gastric banding as a control group, as there is no recommended frequency of laboratory evaluation after this procedure. We examined testing for anemia, electrolytes, hemoglobin A1c (diabetes patients only), hepatic function, lipids, vitamin D, iron, and vitamin B12, as recommended by the expert panel. We conducted Cochrane-Mantel-Haenszel testing to assess for statistical significance of differences in testing frequency.

RESULTS: We calculated that on average, each gastric bypass patient should have 1.37 tests per year during their observation period in the database. However, the majority of patients (ranging from 50 % for vitamin B12 to 87 % for complete blood count) did not have lab tests done in a given year during the observation period. The percentage of gastric bypass patients that had at least one test per year were: 7.3 % for complete blood count, 29.5 % for iron deficiency, 13.3 % for electrolytes, 17.3 % for hemoglobin A1c, 22.8 % for vitamin B12, 12.5 % for vitamin D, 3.3 % for hepatic function, and 23.0 % for lipids. Gastric bypass patients had significantly more testing than gastric banding patients for vitamin D level, complete blood count, iron studies, electrolytes, and vitamin B12. The two groups had similar numbers of tests for diabetes, lipids, and hepatic function.

CONCLUSIONS: We found that patients who have undergone gastric bypass surgery are not routinely undergoing recommended laboratory monitoring. The results suggest that some patients are at higher risk of developing long-term nutritional deficiencies. However, the higher rate of testing for some nutritional deficiencies in the gastric bypass group suggests that these patients are undergoing some additional monitoring. Patients who undergo malabsorptive weight loss procedures have a lifelong risk of nutritional deficiencies and need long term monitoring. With the increasing frequency of bariatric surgery, surgical clinics will eventually be overwhelmed with follow-up. A better option might be to co-locate bariatric medical providers in surgical clinics, or for patients to be followed by physicians specializing in weight management. An alternative is to improve the education of primary care physicians regarding long-term monitoring of patient undergoing gastric bypass.

FREQUENT USERS OF THE EMERGENCY DEPARTMENT IN A COUNTRY WITH UNIVERSAL HEALTH COVERAGE: A PROSPECTIVE CONTROLLED CROSS-SECTIONAL STUDY
Patrick Bodenmann[1]; Fabrice Althaus[1]; Stephanie Stucki[2]; Corine Ansermet[2]; Sophie Guyot[3]; Katia Iglesias[4]; Sophie Paroz[2]; Lionel Trueb[3]; Olivier Hugli[3]; Jean-Bernard Daeppen[5]. [1]University of Lausanne, Lausanne, Switzerland; [2]University of Lausanne and Lausanne University Hospital, Lausanne, Switzerland; [3]University of Lausanne and Lausanne University Hospital, Lausanne, Switzerland; [4]University of Lausanne and Lausanne University Hospital, Lausanne, Switzerland; [5]University of Lausanne and Lausanne University Hospital, Lausanne, Switzerland. (Tracking ID #1625138)

BACKGROUND: A heterogeneous subgroup of patients account for a substantial proportion of all emergency department (ED) visits. Frequent users of the ED are a vulnerable population, and they are receiving attention in terms of characterisation and targeted interventions. The aim of this study was to systematically describe frequent users of the ED in Switzerland, a country with universal health care coverage.

METHODS: This prospective controlled cross-sectional study compared frequent users of the ED to non-frequent users (control group), and was conducted from November 2009 to June 2010 at the University Hospital of Lausanne, a tertiary care hospital with more than 50,000 annual ED visits. Frequent users were defined as patients with five or more visits to the ED in the previous 12 months. Patients who had not yet passed their 18th birthday at the time of the interview, or who had severe cognitive impairments were excluded from the study. Frequent users of the ED and controls (non-frequent users) were compared in terms of socio-demographic characteristics, medical indicators (somatic, mental and risk-behaviour) and health care use. Outcome measures were obtained through a robust questionnaire using previously validated scales.

RESULTS: During the study period, 24,277 patients attended the ED and 351 met the definition of frequent user (1.4 % of all ED patients). Frequent users made a total of 2,030 visits in the past year, which represented 6.3 % of the 32,441 visits made by all ED users during the same period. A total of 226 frequent users and 173 controls accepted an interview invitation. In a multivariate analysis, adjusted odds ratio of being a frequent user was 23.2 (95 % CI 9.1–59.2) for patients with three or more admissions to hospital, 8.4 (95 % CI 2.1–32.7) for patients who do not have a PCP, 4.4 (95 % CI 2.1–9.0) for patients living close to the ED (less than 5 km), 4.3 (95 % CI 2.0–9.2) for patients with a household income lower than 3,000 Swiss Francs/month (2,800 U.S. Dollars in 2009), 2.7 (95 % CI 1.2–6.1) for patients who had attended other EDs, 2.6 (95 % CI 1.1–5.9) for patients having a moderate to severe tobacco use, 2.3 (95 % CI 1.2–4.7) for patients having at least one mental problem according to the Prime-MD questionnaire (panic, anxiety, or mood disorder), 1.2 (95 % CI 1.1–1.4) with a change of one unit according to the Charlson Index (somatic co-morbidities). The risk of being a frequent user was decreased by 74.8 % (95 % CI 0.1–0.5) for patients with no admission to hospital, 72.5 % (95 % CI 0.1–0.9) for people attending for injuries, and 68.1 % (95 % CI 0.1–0.7) for patients having a chronic somatic condition. Adding marital status, education, country of birth, violence, social position, social support, French proficiency, income source, subjective somatic well-being, subjective mental well-being, chronic mental disease, moderate to severe alcohol consumption, illicit drug use, or number of visits to a specialist to the above model did not add predictive utility.

CONCLUSIONS: Frequent users of the ED are a socially and medically vulnerable population even in a universal health care coverage system. These results are helpful to better target the complex needs of frequent users of the ED: through better connection with a PCP, availability of ED-based case management teams, and as also by informing decisions about further services which should be provided to patients in the emergency department.

FROM ADMISSION TO DISCHARGE: PATTERNS OF INTERPRETER USE AMONG RESIDENT PHYSICIANS
Amy Shen[1]; Jenna Kruger[2]; Alicia Fernandez[1,2]. [1]University of California, San Francisco School of Medicine, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA. (Tracking ID #1627409)

BACKGROUND: Underuse of professional interpreters adversely affects quality of care to patients with limited English proficiency (LEP). Communication with hospitalized LEP patients relies on individual providers' decisions to use professional interpreters. Building on qualitative literature suggesting that resident physicians make conscious decisions about whether to use interpreters, we surveyed residents to determine if interpreter use varied by the type of hospital encounter.

METHODS: We conducted a cross-sectional survey study of internal medicine, general surgery, and family medicine resident physicians from one academic medical institution who care for LEP patients across four hospitals. Residents reported on interpreter use with their last hospitalized LEP patient with whom they experienced a language barrier. Regression models were used to determine the independent contribution of clinical site, patient characteristics, and physician characteristics to resident physician use of professional interpreters.

RESULTS: 149 residents (73 % response rate) completed the survey. 75 % of residents reported at least 1 h of prior interpreter training. 71 % of residents reported using professional interpreters for less than 60 % of hospital clinical encounters (mean 43 % (10,90) S.D. 26.35). 91 % of residents reported that their quality of communication with hospitalized LEP patients was "slightly worse" (62 %) or "much worse" (29 %) compared to their communication with clinically similar English speaking patients. Patterns of professional interpreter use varied substantially by type of clinical encounter, with more residents reporting getting by with their

own language skills or not talking to the patient due to time constraints during routine daily rounds than during patient admission or procedural consent discussions (28 % vs. 5 % vs. 2 %, p-value<0.005). Significant predictors of reporting greater professional interpreter use included specialty (family medicine and internal medicine greater than surgery), level of training (beta coefficient=15.7, p<0.001), more hours of interpreter training (beta=3.0, p=0.17), and self-report of growing up with a non-English language at home (beta=0.9, p=0.05). Despite known variation in access to interpreters by site, hospital site was not a predictor of professional interpreter use.
CONCLUSIONS: Residents use different modes of communication depending on the clinical situation and report considerable underuse of professional interpreters and worse communication with their hospitalized LEP patients compared to their communication with English speaking patients. Variation in professional interpreter use by type of clinical encounter and not clinical site underscores the importance of resident decision-making in determining whether LEP patients receive professional interpreter services. While training in interpreter use is associated with greater use of interpreters, more interventions are needed to improve the care of hospitalized patients with LEP, particularly for daily rounds.

FUNCTIONAL DISABILITY IN OLDER ADULTS ADMITTED TO AN URBAN SAFETY-NET HOSPITAL Rebecca T. Brown[1]; David Guzman[2]; Eric R. Kessell[2]; L. E. Goldman[2,3]; Urmimala Sarkar[2]; Edgar Pierluissi[1]; Jeffrey Critchfield[3]; Margot Kushel[2]. [1]University of California, San Francisco, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA. (Tracking ID #1636988)

BACKGROUND: Socioeconomically disadvantaged adults experience accelerated aging, developing geriatric conditions such as functional disability earlier than individuals of higher socioeconomic status. Among inpatients at safety-net hospitals, little is known about the prevalence of accelerated aging or the need for geriatric-focused care. We evaluated rates of functional disability in "young older" patients (age 55–64) and a traditional "geriatric" age group (≥65 years) admitted to an urban safety-net hospital.
METHODS: We enrolled 699 English, Spanish, and Chinese-speaking community-dwelling individuals aged 55 or older admitted to the medical, cardiology, and neurology services at an urban safety-net hospital. Participants completed in-person interviews during hospitalization that assessed demographics and the presence of self-reported functional disability 2 weeks before hospitalization (need for help with ≥1 Katz Activity of Daily Living (ADL); need for help with ≥1 Lawton Instrumental Activity of Daily Living (IADL)).
RESULTS: In both the younger group (N=402, mean age 60 years (standard deviation (SD) 3 years)) and older group (N=297, mean age 75 (SD 8)), slightly more than half of the participants were male, about one-fifth were white, and about half spoke a language other than English at home. Both younger and older participants had high rates of ADL disability (24 % and 34 %, respectively) and IADL disability (42 % and 63 %). The most commonly-reported ADL disabilities were bathing (18 % younger and 24 % older) and dressing (15 % and 26 %), and the most common IADL disabilities were shopping (30 % and 48 %) and meal preparation (27 % and 41 %).
CONCLUSIONS: Rates of functional disability were high among patients aged 55 and older admitted to a safety-net hospital; the rate of ADL disability in patients aged 55–64 was similar to that seen in community-dwelling adults with a mean age of 80, while the rate of ADL disability in the older age group was higher. Our results suggest that patients aged 55 and older admitted to safety-net hospitals may benefit from geriatric models of care that address functional disabilities.

FUNCTIONAL CAPACITY OF OLDER ADULTS UNDERGOING CORONARY ARTERY BYPASS GRAFT SURGERY: A 6 MONTHS FOLLOW-UP Marcio Niemeyer-Guimaraes[1]; Maysa S. Cendoroglo[2]; Clineu Mello-Almada[2]. [1]Quinta D'Or Hospital, Rio de Janeiro, Brazil; [2]EPM Unifesp, Sao Paulo, Brazil. (Tracking ID #1606777)

BACKGROUND: Preservation of autonomy and independence of cardiac older patients becomes the most important outcome, particularly those with borderline functional capacity. Improve function and quality of life should be key-targets, compared to the prolongation of life per se. The aim of study is to determine longitudinal changes in functional status by Functional Independence Measure (FIM) and activities of daily living scales (ADL/IADL) among older adults undergoing coronary artery bypass grafting (CABG).
METHODS: 364 patients aged ≥60 years with proposed cardiac surgery between Jan/2009 and Dec/2011 were prospectively selected according to risk factors for this observational study. It was conduct at 350-beds private hospital. Inclusion criteria were patients aged ≥60 years undergoing elective CABG without other approaches such as valves/aorta and carotid arteries. Thus, 73 patients were assessed before surgery, at discharge and after 1 and 6 months using FIM, ADL and IADL scales, and analyzed for subgroups with and without complications and cardio-pulmonary events during hospitalization. By assuming an estimated proportional change (decline) in FIM in the 6-months follow up, significance level of 5 % (α), statistical test power of 80 % (1-β), and an expected loss of individuals of 30 %, it was determined that an adequate sample should include 32 cases for each group, a total of 64 patients with complete data for the study. Repeated-measurement analysis of variance was used. Data are presented in median ± standard deviation. Significance level was set at 5 %.
RESULTS: Charlson Comorbidity Index was 2.05±1.64. FIM ranged from 121.9±5.1 (pre-admission) to 116±13.5 and 119.8±10.3 (1 and 6 months respectively) (P<.001); ADL from 5.9±0.26 to 5.65±0.82 and 5.90±0.48; IADL scales from 26±2.8 to 21.8±4.9 and 25.4±3.2 (P<.001). When subgroups with (34) and without (39) complications were compared there were no significant changes in FIM (P=.50); and so it was when subgroups with (49) and without (24) cardio-pulmonary events (P=.26). But when subgroups aged up to 70 (38) and less (35) were compared, FIM showed significantly different toward recovery over the time (P<0.02). Delirium (21.9 %); urinary tract infection (13.7 %) and blood transfusion (49.3 %) were intercurrent events found. There was correlation between scales and age (P<.02), mechanical ventilation time (P<.01), intensive care unit length of stay (P<.05).
CONCLUSIONS: FIM monitoring of older patients undergoing CABG surgery showed to be a promising tool of functional recovery over time, especially in subgroup of older people aged ≥70 years. That functional trajectory might help for planning recovery strategies in the 6-first months postoperatively, mainly in older seniors and those with frailty profile, based not only on increase in life expectancy proposal with cardiac surgery but also for functionality and quality of life.

GENDER DISPARITIES IN MEDICAL STUDENTS' COMFORT WITH LEADERSHIP SKILLS April S. Fitzgerald; Redonda G. Miller; David M. Levine; Bimal Ashar; Mary Catherine Beach. Johns Hopkins University, Baltimore, MD. (Tracking ID #1640891)

BACKGROUND: Prior studies have found gender differences in leadership styles, as well as disparities in career achievement for women in medicine. It is unclear if these differences are attributable to tendencies present before entering medical training, or a function of the learning environment and culture of the medical profession.
METHODS: We surveyed medical students from the Class of 2013–2016 at the Johns Hopkins School of Medicine at matriculation and then have thus far surveyed students from the Class of 2013–2014 2 years later upon entry into the clinical years. The questionnaire focused on student comfort in performing various skills related to leadership, including negotiating for oneself, negotiating for another, giving negative feedback, accepting criticism, networking, socializing, working on a team, leading a team, and following on a team. Students rated their level of comfort performing each skill on a 5-point scale from 0 (not at all comfortable) to 4 (extremely comfortable). We used t-tests to assess differences by student gender in comfort for each leadership skill.
RESULTS: Most (419/480) students completed the leadership survey at matriculation (87 % response rate) and most of those eligible (211/240)

from the Class of 2013–2014 completed the survey 2 years later (88 % response rate). At matriculation, the mean student age was 23 years (range 21–38); 47 % were female and 55 % reported having no previous leadership training. At matriculation, there were no differences by student gender in self-reported comfort to negotiate for others but female students were significantly less likely to feel comfortable negotiating for themselves (2.49 male vs. 2.15 female, $p<0.001$). At matriculation, female students were significantly less comfortable giving negative feedback (1.93 male vs. 1.61 female, $p=0.001$), accepting criticism (2.53 male vs. 2.18 female, $p=0.001$), and networking (comfort 2.21 male vs. 1.95 female, $p=0.009$), but had similar levels of comfort as male students in socializing with strangers. There were no significant differences by student gender in self-reported comfort leading or being a follower on a team upon matriculation. Two years later, female students continued to feel less comfort negotiating for oneself, giving negative feedback, and networking; however at this point, female students also felt less comfortable working on (3.06 male vs. 2.85 female, $p=0.042$) and leading a team (2.82 male vs. 2.45 female, $p=0.003$).
CONCLUSIONS: Gender differences in perceived comfort with leadership skills exist at the time of matriculation to medical school and may get worse over time. The pattern of results in which females feel less comfortable negotiating for themselves but not for others, and feel less comfort in networking but not in socializing, suggests that these gender disparities are not underlying differences in skill but are instead related to differences in self advocacy. Interventions to improve female medical student comfort with their own leadership ability are urgently needed, and further study is necessary to assess the impact of such interventions on gender disparities.

GENDER AND LEADERSHIP IN CARDIOPULMONARY RESUSCITATION Christine J. Kolehmainen[1,2]; Meghan Brennan[1,2]; Amarette Filut[1]; Carol Isaac1; Molly Carnes[1,3]. [1]University of Wisconsin, Madison, WI; [2]William S. Middleton Memorial Veterans Hospital, Madison, WI; [3]University of Wisconsin, Madison, WI. (Tracking ID #1642373)

BACKGROUND: In-hospital cardiopulmonary resuscitation (or a 'code') is an emergency requiring a multi-professional team to assemble efficiently and provide coordinated care. Ineffective leadership has been linked to team behaviors that could negatively impact a patient's likelihood of survival. Current guidelines recommend specific training in teamwork and leadership skills, but do not explicate the specific behaviors that comprise these competencies nor the learning methods. Automatic assumptions about what characteristics leaders will possess and how they will enact leadership are strongly influenced by cultural stereotypes. Research finds little if any difference in the effectiveness of male and female leaders. However, leader stereotypes are tightly aligned with "agentic" behaviors associated with male gender stereotypes (e.g. decisive, independent, authoritative) but not the "communal" behaviors associated with female gender stereotypes (supportive, dependent, weak). Based on this previous work and because leadership is critically important in CPR, we undertook the present study to explore leadership in CPR. In most teaching hospitals, internal medicine senior residents lead codes. We wanted to explore their experience with leadership in codes: How they learn to lead codes, what behaviors they associate with effective code leadership, how gender or other personal traits influences their experience with leadership.
METHODS: We conducted individual, semi-structured interviews from May-July 2012 with 23 internal medicine resident physicians at eight U.S. programs chosen to represent a range of geographic regions. We employed inductive and deductive qualitative analysis of text from the transcribed interviews to identify themes around effective code leadership. A total of 81 specific codes were ultimately organized into three major themes.
RESULTS: Several common themes about leadership emerged across all interviews. Leadership was viewed as a critical to a successful code. Residents described the ideal code leader as a person who has an authoritative presence, speaks with a deep, loud voice, uses clear, direct communication, and appears calm. Both men and women struggled to meet these ideals, but women described modifying their "normal day-to-day" behavior more to accommodate these standards. It created extra internal stress and some women worried they were perceived as "bossy". Several women talked about the importance of mentally preparing and "assuming a code persona" before leading. Women felt the institutional imprimatur of the white coat and holding the code pager helped legitimize their power. Some had ritualized behaviors to allow them to suspend their gender expectations to lead codes. Others apologized afterwards for their behavior to mitigate the impact of social reprisals.
CONCLUSIONS: Both men and women describe ideal code leadership behaviors similarly. The predominant view is that those characteristics that are more likely to belong to men, which is congruent with implicit assumptions that men are better leaders. While both men and women achieve those ideal behaviors in codes, women report intentionally altering their persona more. Some residents have adopted techniques to help negotiate gender roles. When residents are trained in how to direct codes, acknowledging the impact of gender stereotypes on expected behaviors might help mitigate female residents' stress from the need to mediate the competing identities of gender and code leader.

GENERIC STATIN PRESCRIBING IN AN INTERNAL MEDICINE RESIDENT CLINIC: IS TEACHING COST-CONSCIOUS MEDICINE IN RESIDENCY TOO LITTLE TOO LATE? Kira L. Ryskina[1]; Michael Pesko[2]; J. T. Gossey[1,3]; Erica Phillips[4]; Tara F. Bishop[2,3]. [1]New York Presbyterian Hospital—Weill Cornell, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Weill Cornell Medical College, New York, NY; [4]Weill Cornell Medical College, New York, NY. (Tracking ID #1635179)

BACKGROUND: Several national initiatives aim to teach high-value, cost conscious care at the resident level. While there is growing literature on independent physician ordering practices and factors that influence these practices, little research assesses factors that affect resident ordering practices. In this study, we evaluated brand name statin prescriptions by resident physicians in an academic primary care practice as a proxy of intensive healthcare utilization among internal medicine residents. The objective of this study was to determine whether there was variability in resident prescribing and what resident characteristics were associated with brand name statin prescriptions.
METHODS: We performed a retrospective, cross-sectional analysis of statin prescribing by resident physicians at an urban academic medical practice. We obtained data from our electronic medical record for patient encounters (including office visits, telephone encounters, and order-only encounters) between July 2010 and June 2011. We excluded prescriptions for statin refills and statin prescriptions for new patients because these patients may have been on brand name statins before the encounter. We characterized residents according to their year of training, gender, categorical vs. primary-care track, and their medical school's Hospital Care Intensity (HCI) index (above or below national average). Analyses were at the patient-encounter level. We used multivariate logistic regression with clustering to identify physician characteristics associated with brand name statin prescribing, adjusting for patient-level confounders.
RESULTS: Of the 121 internal medicine residents in the program, 93 met the inclusion criteria and were included in the study. Of the 319 unique patient-resident encounters where statin therapy was initiated, half had brand name statins prescribed. At the resident level, there was considerable variability in the proportion of statin prescriptions that was for brand name statins. Residents in the bottom quartile of brand name prescribing prescribed brand name statins in 13 % of encounters; while residents in the top quartile prescribed brand name statins in 87 % of encounters. There was an association between above-average HCI index for medical school attended and high utilization of brand name statins, however it was not significant (OR=1.58, $p=0.096$, 95 % CI 0.92–2.71). Being in the primary care track was associated with lower odds of prescribing brand name statins (OR=0.42, $p=0.027$, 95 % CI 0.20–0.91).
CONCLUSIONS: We found large variations in brand name medication utilization by residents. Our findings suggest that primary care track experience and possibly exposure to intensive healthcare utilization environments in medical school may influence resident physician prescribing behavior. A better understanding of the factors that influence practice patterns during training can help identify opportunities for educational

interventions which may have lasting implications for how physicians practice later in their careers.

GEOGRAPHIC COHORTING OF MEDICINE PATIENTS AT UMASS MEMORIAL MEDICAL CENTER - IMPLEMENTATION AND SUSTAINMENT Richard M. Forster[1,2]; Tze Chao Chiam[1,2]; LeRoi Hicks[1,2]; Lori Pelletier[1,2]. [1]UMass Memorial Health Care, Worcester, MA; [2]UMass Medical School, Worcester, MA. (Tracking ID #1643131)

BACKGROUND: This study describes the design and implementation of the geographic cohort project at UMass Memorial Healthcare. The project goals were to alleviate waste in the care delivery process and promote inter-professional care models for medicine patients. Previously, patients were assigned to a Hospitalist team before receiving a bed assignment, resulting in a team's patients being geographically scattered around the hospital. This potentially resulted in communication breakdowns, patient safety concerns, long walking distance by the physicians, reduced "touch time" with patients, and delayed discharge planning.
METHODS: A multidisciplinary team was formed to perform the assessment, design, implementation and sustainment of this effort. Multidisciplinary tools such as Lean methods, engineering tools, process design, and clinical expertise were used. A computer simulation (Discrete-event simulation) was used to study the feasibility and quantification of benefits of geographically cohorting patients and physicians. This simulation was also used to perform trade-off analysis of various configurations of geographic placement of Hospitalist/resident teams. Various challenges were faced upfront including data availability. These challenges were amplified due to the transition from a legacy patient record system to a newer electronic health record system. Upfront process design included patients' "port of entry" (e.g., ED, ICU, neighboring hospitals and clinic admits), and assignment algorithms (patient-to-bed and patient-to-physician). Communication and education were developed to ensure system-wide awareness of the new process. The Transitional Care Team (TCT) consisting of a Hospitalist, affiliate practitioner, Case Manager, and Triage Resident was formed and stationed in the ED. The major function of the TCT is to facilitate patients' admission process from the ED to acute care units and to ensure the admitted patient receives a bed assignment prior to a Hospitalist/resident team assignment. Three multidisciplinary rounds were performed daily on each medicine unit to discuss patients' care plans and disposition. Process data and performance feedback were reviewed weekly and improvement ideas were immediately tested.
RESULTS: Informal interviews with staff revealed positive feedback with regards to better communication among care teams and more efficient workflow. Quantitative results showed statistically significant improvement in several measures, including median time between ED admits to head-in-bed from 4.43 h to 3.82 h, with a p-value of 0.05; median length-of-stay from 2.73 days to 1.82 days, with a p-value of <0.001. Discharge time of Hospitalists teams also improved from a median of 5:28 PM to 4:45 PM with a p-value of 0.004.
CONCLUSIONS: Geographic cohorting of Medicine patients at UMass Memorial Healthcare was implemented in order to improve quality of care and workflow within the medical center among Hospitalist teams, nursing, and support staff while providing care for Medicine patients. Various measures put in place to ensure improved quality of care and process flow included the formation of the TCT, daily multidisciplinary rounds, as well as data-driven decision-making for background studies and sustainment. This work has demonstrated the successful use multidisciplinary tools to design process changes in order to improve quality of care and facilitating smoother patient flow in the medical center.

GLUCAGON-LIKE PEPTIDE-1-BASED THERAPIES AND RISK OF HOSPITALIZATION FOR ACUTE PANCREATITIS IN TYPE 2 DIABETES: POPULATION BASED MATCHED CASE-CONTROL STUDY Sonal Singh[1]; Hsien-Yen Chang[2]; Thomas M. Richards[2]; Jonathan Weiner[2]; Jeanne M. Clark[1,2]; Jodi B. Segal[1,2]. [1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD. (Tracking ID #1627572)

BACKGROUND: Acute pancreatitis has significant morbidity and mortality. Previous studies have raised the possibility that glucagon-like peptide-1-based therapies (GLP-1) including the GLP-1 mimetic (exenatide) and the dipeptidyl peptidase 4 inhibitor (sitagliptin) may increase the risk of acute pancreatitis. We aimed to test whether GLP-1 based therapies, such as exenatide and sitagliptin, are associated with an increased risk of acute pancreatitis.
METHODS: We conducted a population based case-control study in a large administrative database in the United States from 2005 to 2008. We included adults with type 2 diabetes aged 18–64; 1269 hospitalized cases with acute pancreatitis were dentified using a validated algorithm and 1269 controls matched on age category, sex, enrollment pattern, and diabetes complications. Conditional logistic regression was used to analyze the data.
RESULTS: The mean age of included individuals was 52 years and 57 % were male. Cases with pancreatitis were significantly more likely than controls to have hypertriglyceridemia (12.9 % vs 8.3 %), alcohol use (3.2 % vs 0. 2 %), gallstones (9.1 % vs 1.3) tobacco abuse (16.2 % vs 5.5 %), obesity (19.6 % vs 9.8 %) biliary and pancreatic cancer (2.8 % vs 0 %), cystic fibrosis (0.8 % vs 0 %) and any neoplasm (29.9 vs 18.0 %). After adjusting for available confounders and metformin use, both current use of GLP-1-based therapies within 30 days (adjusted Odds Ratio [aOR], 2.24, 95 % Confidence intervals 1.36–3.68) and recent use greater than 30 days and less than 2 years (aOR, 2.01, 95 % CI 1.27–3.18) were associated with significantly increased odds of acute pancreatitis relative to the odds in non-users.
CONCLUSIONS: Acute pancreatitis has significant morbidity and mortality. In this administrative database study of US adults with type 2 diabetes, treatment with GLP-1-based therapies, sitagliptin and exenatide, was associated with an increased odds of hospitalization for acute pancreatitis. Clinicians should carefully balance the known benefits of these agents on glucose-lowering along with the risk of acute pancreatitis to determine the optimal therapy for their patients in a shared decision-making context.

GLYCEMIC CONTROL AND URINARY INCONTINENCE IN NURSING-HOME ELIGIBLE PATIENTS WITH DIABETES MELLITUS Sei J. Lee[1]; Jessamyn Conell-Price[2]; Irena Stijacic Cenzer[1]; Catherine Eng[3]. [1]SFVAMC, UCSF, San Francisco, CA; [2]UCSF/UCB, San Francisco, CA; [3]On Lok Lifeways, San Francisco, CA. (Tracking ID #1633505)

BACKGROUND: Although poor glycemic control is thought to worsen urinary incontinence, few studies have explored this relationship in older patients with diabetes and functional disability. Thus we examined the relationship between Hemoglobin A1c (HbA1c) levels and urinary incontinence in nursing-home eligible community-dwelling older adults with diabetes.
METHODS: We examined 571 older adults with diabetes enrolled in On Lok Lifeways between 2002 and 2010. On Lok, like other Programs of All-Inclusive Care for the Elderly, enrolls nursing home-eligible elders and provides comprehensive medical and social services with the goal of delaying or preventing institutional care. HbA1c values (n=2745) were categorized as < 7, 7–7.9, 8–8.9, >9 %. Urinary incontinence was assessed every 6 months by nursing staff; "never" and "seldom" were combined into the No incontinence category and "often" and "catheter" were combined into the Yes incontinence category. Each HbA1c measure was linked to the closest assessment of incontinence and we performed mixed-effects logistic regression to account for clustering by patient. We also accounted for age, gender, race, cognitive status, dependence in ambulating and transferring, depression, diabetic medications and complications, and use of diuretic medications.
RESULTS: Participants were elderly, with a mean age of 81, and most were female (67 %) and Asian (65 %). Thirty-seven percent had moderate to severe cognitive impairment and 24 % had difficulty ambulating. The mean HgbA1c value was 7.4 and 11 % were taking insulin. We found that higher A1c levels were not associated with increased risk for urinary incontinence. In the unadjusted analysis, there was no significant relationship between HbA1c and incontinence. When we adjusted for confounding variables, there was no significant association between

HbA1c and incontinence, and the odds of incontinence was similar at every HbA1c level.

CONCLUSIONS: We found no evidence to suggest that glycemic control is associated with urinary incontinence in nursing-home eligible, community-dwelling older adults with diabetes.

Urinary Incontinence by Hemoglobin A1c Levels in Nursing-Home Eligible Older Adults

HIT HAPPENS: THE INPATIENT DILEMMA OF HEPARIN INDUCED THROMBOCYTOPENIA Pooja Kumar; Surekha Maddula; Robert E. Graham. Lenox Hill Hospital, New York, NY. (Tracking ID #1642232)

BACKGROUND: Heparin Induced Thrombocytopenia (HIT) is a dangerous and potentially life threatening complication of heparin therapy that results in both thrombocytopenia and severe arterial and venous thromboembolism. The diagnosis of HIT is based on both clinical assessment and laboratory testing. The clinical assessment is based largely on the 4 T score. The laboratory tests include ELISA to detect antibodies formed against a Heparin-PF4 complex, as found in HIT. Due to the high number of false negatives found with the ELISA test, the Serotonin Release Assay (SRA) is considered the gold standard diagnostic test to confirm HIT.

METHODS: Our objective was to review the diagnostic criteria of HIT with emphasis on the clinical assessment of HIT in the inpatient setting. In a retrospective review of 24 Internal Medicine patients with known or suspected HIT over a 4 month period, medical records were evaluated for the assessment of HIT using the 4 T score. The cases were also reviewed for management of HIT to include heparin listed as an allergy, heparin agent stopped, and alternative form of anticoagulation started.

RESULTS: In 12/24 patients, HIT Ab and/or SRA were appropriately sent. In 12/24 patients, HIT Ab and/or SRA were inappropriately sent. 0/24 patients had appropriate diagnosis and management of HIT. 7/24 patients had heparin product stopped, and only 2/24 patients had appropriate anticoagulation started. 0/24 patients had heparin listed as an allergy.

CONCLUSIONS: Based on our data, we plan to institute a HIT protocol that would appear once either the ELISA or SRA was ordered, and not allow for the two laboratory tests to be ordered simultaneously. The protocol would include a 4 T score calculator and mandate that all heparin products be stopped immediately if HIT was appropriately suspected. Heparin would be immediately listed as an allergy, and an alternative form of anticoagulation would be started. This HIT protocol will hopefully help us minimize such a large degree of both the misdiagnosis and the mismanagement of HIT. We hope that this will be cost effective in preventing superfluous laboratory testing and, more importantly, lifesaving by preventing deadly thromboembolism in those with HIT.

HABLAMOS JUNTOS (TOGETHER WE SPEAK): A BRIEF PATIENT-REPORTED MEASURE OF THE QUALITY OF INTERPRETERS Efrain Talamantes[1,2]; Gerardo Moreno[3]; Lourdes R. Guerrero[4]; Carol Mangione[2,4]; Leo Morales[5]. [1]UCLA and U.S. Department of Veterans Affairs, Los Angeles, CA; [2]University of California, Los Angeles, Los Angeles, CA; [3]University of California, Los Angeles, Los Angeles, CA; [4]University of California, Los Angeles, Los Angeles, CA; [5]University of Washington, Seattle, CA. (Tracking ID #1621987)

BACKGROUND: Although research supports the use of trained interpreters when providers care for patients with limited English proficiency(LEP), less is known about the quality of interpretation from the patient's perspective. This study examined the psychometric properties of a patient-reported measure of quality of interpreters and its association with patient's reports of doctor communication and satisfaction with care.

METHODS: We analyzed pooled, cross-sectional survey data collected in two waves between 2003 and 2006 from 1590 Latino adult women and men with LEP who participated in the Hablamos Juntos (HJ) national demonstration project. Quality of interpreters was assessed with four survey items that asked patients about their experiences with interpreters (item 1. listening carefully, item 2. repeating questions to doctor, and item 3. using words that are hard to understand, and item 4. spending enough time with patients). Doctor communication was examined with a multiple-item measure (listening carefully to patients, explaining things in a way patients can understand, showing respect for what patients have to say, and spending enough time with patients), and satisfaction with care was assessed with a single-item measure.

RESULTS: Sixty-nine percent (1,104) of patients surveyed used interpreters. Cronbach's alpha for the three items assessing interpreter quality was 0.31; dropping item 3 resulted in an alpha of 0.56. Items 1 and 2 were moderately correlated with doctor communication and satisfaction with care scores (r=0.21–0.39) supporting construct validity. The associations between interpreter quality and doctor communication and satisfaction with care remained significant in analyses adjusting for sex, gender, education, marital status, income, insurance coverage, health status, survey wave, and site of care.

CONCLUSIONS: Two of three items can be scaled to measure quality of interpretation from the patient's perspective. Quality of interpretation reported by patients is associated with doctor communication and satisfaction with care. More research is needed to fully elucidate how patients with LEP evaluate the quality of interpreters and how it relates to patient outcomes.

HAND HYGIENE BELIEFS AMONG PHYSICIANS IN A COMMUNITY HOSPITAL Amrita John; Aurora Pop-Vicas. Memorial Hospital of Rhode Island, Pawtucket, RI. (Tracking ID #1642777)

BACKGROUND: The cornerstone of infection prevention, hand-hygiene (HH) compliance remains challenging. Exploring physicians' perceptions toward HH can identify opportunities for performance improvement.

METHODS: Setting: 294 bed university-affiliated community hospital. Study design: cross-sectional multiple choice survey, measuring: perceived average physician HH compliance and reasons for non-compliance; perceived need for additional training; and suggested solutions to improve performance. Participants: House officers and attending physicians on staff at the study site.

RESULTS: Of the 119 respondents, 48 % and 52 % were house officers and attending physicians, respectively. Medical, surgical, and other specialties were represented by 81 %, 17 %, and 2 %, respectively. Alcohol-based hand disinfectants were preferred over soap and water (71 % vs. 29 %). The majority (78 %) believed our average HH physician compliance to be between 50 and 89 %. A total of 14 % believed it to be≥ 90 %, with attendings more likely to perceive it as such (OR 3.6, [1.01–15.9], P=0.027). Directly observed physician HH compliance during the 3 months preceding the survey had, in fact, averaged 77 %. The most common survey reasons cited for noncompliance were a high workload (49 %), inadequate access to sinks (31 %), forgetfulness (13 %), and inadequate access to alcohol-based hand disinfectants (10 %). House officers were more likely to believe that entering a patient's room without performing HH is acceptable when no direct patient contact is anticipated (OR 5.3, [1.3–31.5, P=0.008). Attendings were more likely to believe that trainees and other health-care workers model their HH practices after physician behaviour (OR 8.8, [1.8–82.6, P=0.001). A small majority (53 %) believed that further HH training would be of benefit, while surgeons were more likely to consider further HH training unnecessary (OR . 3.0 [1.0–9.4], P=0.02). Most physicians (92 %) believed the medical evidence associating HH with preventing nosocomial infections is excellent, while surgeons tended to rate the evidence as only fair or poor

(OR 3.9, [0.7–18.2], P=0.04). As interventions to increase compliance, most physicians would prefer a system of rewards (63 %) over penalties (17 %). Regular feedback on individual performance was the most common other intervention suggested. Electronic monitoring of HH compliance was favoured by only 48 % of respondents.

CONCLUSIONS: Most physicians in our study were realistic about HH compliance and recognized their role in modelling infection control behaviour to others. Misconceptions regarding HH practices, scepticism over the role of HH in infection prevention, and over-estimation of HH compliance were infrequently found. Addressing these concerns through further training and individualized performance feedback may improve overall HH performance.

HANDS ON THE HOOD, GRANDPA: ASSESSING THE NEED FOR GERIATRICS HEALTH TRAINING AMONG POLICE Rebecca T. Brown; Cyrus Ahalt; Michael A. Steinman; Brie Williams. University of California, San Francisco/San Francisco VA Medical Center, San Francisco, CA. (Tracking ID #1594932)

BACKGROUND: Police are first responders in a variety of emergencies with older adults in which age-related health or social problems play a critical role. For example, police are called for criminal or disruptive behavior related to cognitive impairment or substance use, or to respond to a lonely older adult who calls 911 to create an opportunity for social interaction. Although police play a front-line role in these encounters, their attitudes towards aging, knowledge of age-related health problems such as dementia, and ability to refer older adults to appropriate services are unknown.

METHODS: We administered questionnaires to San Francisco police officers attending mandatory crisis intervention training (participation rate, 92/123 (75 %)). Questionnaires assessed frequency of interactions with older adults, attitudes towards older adults (Geriatrics Attitudes Scale: score ≥3 indicates a positive attitude), and perceived knowledge deficits.

RESULTS: Although 89 % of police reported working with older adults at least monthly, only 33 % considered themselves knowledgeable about age-related health problems. Nearly all participants (95 %) had a positive attitude towards older adults (Geriatrics Attitudes Scale score ≥3), and a similar percentage considered geriatrics training important (95 %). Many police reported having knowledge of age-related health issues; for example, 73 % reported that they could explain the difference between depression, delirium, and dementia. However, several knowledge gaps were identified: 43 % of participants reported that they could not describe how depression, delirium, or dementia affect older adults, 54 % could not describe types of surrogate decision-makers for impaired older adults, and 61 % could not identify local organizations that provided social services for older adults.

CONCLUSIONS: Community police who interact frequently with older adults had positive attitudes towards older adults, but had several self-reported knowledge deficits about age-related health problems and resources. Although police are not traditional health care team members, they may benefit from geriatrics health training to address key knowledge deficits that could adversely affect their interactions with older adults.

HEALTH CENTERS CARE FOR A SICKER POPULATION WITH FEWER CLINIC VISITS AND FEWER HOSPITALIZATIONS Neda Laiteerapong[1]; James Kirby[2]; Yue Gao[1]; Tzy-Chyi Yu[3]; Ravi Sharma[4]; Sang Mee Lee[1]; Marshall Chin[1]; Aviva G. Nathan[1]; Quyen Ngo-Metzger[2]; Elbert S. Huang[1]. [1]University of Chicago, Chicago, IL; [2]Agency For Healthcare Research and Quality, Rockville, MD; [3]NORC, Bethesda, MD; [4]Bureau of Primary Health Care, Rockville, MD. (Tracking ID #1614983)

BACKGROUND: The Health Center (HC) program is a vital primary care safety net program supported by the Health Resources and Services Administration and cares for ~20.5 million people. Understanding how HCs influence utilization and quality of care for the primary care safety net is critical for the program's sustainability. Previous studies have been limited in how they identify HC patients and may not sufficiently address selection issues leading patients to be cared for at HC vs. other sites of care. We used unique geocoding data to more accurately identify HC patients and propensity score methods to address selection issues in order to compare utilization and preventive care receipt between HC patients and comparable outpatients.

METHODS: Pooling five, 2-year panels of Medical Expenditure Panel Survey data (2004–2008), we studied adults, ≥18 years, living ≤20 miles of a HC, with ≥1 outpatient visit in the first panel year. We identified HC patients if ≥50 % of their outpatient care was at HCs (n=1024). Using second panel year data, we compared utilization (office visits, hospitalizations and emergency room (ER) visits) and 10 preventive measures (routine visits, diet/exercise advice, influenza vaccination, dental care and hypertension, cholesterol, cervical/breast/colon cancer screening) between HC and other patients (non-HC, n=32,796). We modeled the overall population and non-dual Medicaid (HC, n=181; non-HC, n=1839), and uninsured (HC, n=349; non-HC, n=3622) subpopulations. Due to small sample sizes, hospitalizations could not be modeled for the Medicaid subpopulation and only 4 preventive measures could be modeled for the Medicaid and uninsured subpopulations. We calculated propensity scores to adjust for 38 characteristics (e.g., sociodemographics, insurance type, comorbidity, quality of life, disability). Analyses accounted for the complex survey design by including survey weights, which were multiplied by inverse probability treatment weights from propensity scores. We modeled utilization using negative binomial regression and preventive care receipt using logistic regression.

RESULTS: HC and non-HC patients differed in 37 out of 38 included characteristics. HC patients were less educated, poorer, more often minority, and had more diseases, more disability, and worse quality of life. Compared to non-HC patients, HC patients had lower rates of office visits (incidence rate ratio (IRR), 0.58, p<.001) and hospitalizations (IRR, 0.28, p<.001), but no difference was detected in ER visits. HC patients received more (2 out of 10 measures) or no different (7 out of 10 measures) preventive care. Among Medicaid patients, HC and non-HC patients had no difference in office visits, but HC patients had higher rates of ER visits (IRR, 1.60, p=.01). There was no difference in preventive care between Medicaid HC and non-HC patients for all measures. Uninsured HC patients had lower rates of office visits (IRR, 0.65, p=.01), but no difference in hospitalizations or ER visits was detected. Uninsured HC patients had more preventive care compared to non-HC patients for 3 out of 4 measures.

CONCLUSIONS: Health Centers care for a socially and medically disadvantaged population; however, HC patients have fewer clinic visits and hospitalizations and receive similar or more preventive care compared to other patients. Further study is needed to understand how Health Centers are able to provide high levels of preventive care with fewer clinic visits and fewer hospitalizations.

HEALTH LITERACY DID NOT INFLUENCE EFFECTIVENESS OF COMPUTER TELEPHONY-BASED POST-DISCHARGE SUPPORT Jessica A. Eng[1]; Joshua S. Richman[2]; Thomas Houston[3]; Christine Ritchie[1]. [1]UCSF/San Francisco VA Medical Center, San Francisco, CA; [2]UAB/Birmingham VA Medical Center, Birmingham, AL; [3]University of Massachusetts, Worcester, MA. (Tracking ID #1637471)

BACKGROUND: The use of technology has been advocated to enhance or replace resource-intensive post-hospitalization interventions for older adults with chronic disease. Interventions using the internet or smart phones are often challenging to those with low health literacy. In contrast, low-cost computer telephony interactive voice response systems (IVRS) allow for interaction between patients and databases using a simple telephone. Because technology-assisted interventions are often less effective in those with low health literacy, we tested to see if health literacy influenced the effectiveness of the intervention in a recent clinical trial using IVRS to support COPD patients.

METHODS: The E-Coach Intervention involved pre-discharge education by a care transition nurse (CTN) followed by post-discharge IVRS calls. The CTNs monitored patient IVRS responses through a web-based

dashboard, and provided telephone-based support as needed. Subjects with COPD at a tertiary care hospital were randomized to the IVRS intervention vs. standard care. Health literacy was measured prior to discharge using the Wallace Health Literacy Screener, which asks "How confident are you filling out medical forms by yourself?" We dichotomized health literacy to "adequate" (extremely/quite a bit) and "low" (somewhat/a little bit/not at all). The main outcome was days out of community (hospitalized or dead) within 30 days of initial hospital discharge. Generalized linear models were used, and adjusted analyses included age, sex, race, marital status, adequate finances, and comorbidity.
RESULTS: 132 subjects with COPD were randomized (46 % female, 33 % nonwhite, 34 % self-reported financial insecurity, 27 % with low health literacy, 99 % Medicare beneficiaries). Although the intervention decreased days out of the community, there was no association between health literacy and intervention effect in the unadjusted or adjusted models. Female sex and financial insecurity were independently associated with increased days out of community.
CONCLUSIONS: We found no difference in response to an IVRS-based post-discharge support intervention across health literacy. For interventions focused on Medicare populations with a broad array of health literacy, simple IVRS-based interventions may be more beneficial than more complex technology-based solutions.

HEALTH STATUS, HEALTH CARE UTILIZATION, AND LEGAL INCIDENTS FOLLOWING TRAUMATIC BRAIN INJURY IN HOMELESS AND VULNERABLY HOUSED ADULTS IN THREE CANADIAN CITIES Matthew To[1]; Kristen O'Brien[1]; Anita Palepu[2]; Anita M. Hubley[3]; Susan Farrell[4]; Tim Aubry[5]; Evie Gogosis[1]; Wendy Muckle[6]; Stephen Hwang[1,7]. [1]St. Michael's Hospital, Toronto, ON, Canada; [2]University of British Columbia, Vancouver, BC, Canada; [3]University of British Columbia, Vancouver, BC, Canada; [4]University of Ottawa, Ottawa, ON, Canada; [5]University of Ottawa, Ottawa, ON, Canada; [6]University of Ottawa, Ottawa, ON, Canada; [7]University of Toronto, Toronto, ON, Canada. (Tracking ID #1642665)

BACKGROUND: The prevalence of traumatic brain injuries (TBI) and its associations with health, subsequent health care utilization, and legal incidents in homeless and vulnerably housed populations have not been widely studied. The objectives of this study are to (1) determine the lifetime prevalence of TBI in homeless and vulnerably housed individuals across three Canadians cities (Toronto, Ottawa, and Vancouver), (2) characterize the associations between a history of TBI and health status at baseline, and (3) characterize the associations between a history of TBI at baseline and subsequent health care utilization, legal involvement, and victimization over a one-year follow-up period.
METHODS: Homeless and vulnerably housed persons aged 18 or older and were single were recruited. Data on demographic characteristics, health status and health conditions, health care utilization, and legal incidents were collected using structured, in-person interviews. Follow-up surveys were administered approximately 1 year after the baseline survey with questions on outcomes of interest including health care utilization (emergency department (ED) use, frequent ED use (≥3 visits per year) and hospital admission), legal incidents (arrests and/or incarcerations), and victimization (physical and sexual assault) over the previous 12 months. Descriptive statistics were used to compare participants with and without a history of TBI. Multivariate logistic regression models were developed to determine whether a history of TBI was associated with health care utilization, legal incidents, and victimization.
RESULTS: 1,182 homeless or vulnerably housed adults were included in the analysis and data for 964 participants were collected at follow-up. Overall, the lifetime prevalence of TBI in our sample was 61 %. Those with a history of TBI were significantly more likely to be male, White, born in Canada, completed some high school, and to have experienced more lifetime years of homelessness. Compared to those without a history of TBI, participants with a history of TBI had lower SF-12 Physical Component Summary scores (mean score 43.2 vs. 46.5, $p<0.001$), lower SF-12 Mental Component Summary scores (mean score 37.7 vs. 41.3, $p<0.001$) and were more likely to be living with another chronic health condition (82.0 % vs. 66.9 %, $p<0.001$). History of TBI was independently associated with ED use (AOR 1.5, 95 % CI 1.10–2.94) but not with frequent ED use (AOR 1.4, 95 % CI 0.96–2.10) or with hospital admission (AOR 1.50, 95 % CI 0.99–2.29) over the subsequent year. A history of TBI was independently associated with being arrested or incarcerated (AOR 1.79, 95 % CI 1.3–2.48) and with being a victim of physical assault (AOR 2.81, 95 % CI 1.96–4.03) but not with sexual assault (AOR 1.63, 95 % CI 0.86–3.09) over the subsequent year.
CONCLUSIONS: A history of TBI is very common among both homeless and vulnerably housed individuals. Individuals with a history of TBI had more comorbidity and poorer health status. Individuals with a history of TBI were also more likely to be ED users, arrested or incarcerated, and victims of physical assault over the subsequent year, highlighting the serious challenges to health and social function that these individuals face.

HEALTH COMMUNICATION QUALITY PREDICTS SELF-CARE BEHAVIORS AND TREATMENT SATISFACTION AMONG LOW-INCOME DIABETES PATIENTS IN A PUBLIC HEALTH SETTING Richard O. White[1]; Ken Wallston[2]; Sunil Kripalani[3]; Russell L. Rothman[3]. [1]Mayo Clinic, Jacksonville, FL; [2]Vanderbilt University, Nashville, TN; [3]Vanderbilt University, Nashville, TN. (Tracking ID #1642330)

BACKGROUND: Despite strong evidence about the optimal treatment of diabetes, care often remains suboptimal particularly for minorities and persons with limited resources. Ineffective health communication between providers and low-literacy patients may contribute to suboptimal care in these settings. The aim of this analysis is to examine the relationship between provider-patient communication and patient outcomes within the context of a low-literacy/numeracy-focused intervention to improve diabetes care and outcomes in a public health setting.
METHODS: Utilizing a cluster-randomized trial design, healthcare providers from 10 public health department clinics were exposed to training in effective health communication and the use of a low-literacy diabetes toolkit versus an active control condition based on content from the National Diabetes Education Program. Baseline patient assessments included: demographics, measure of health communication (Interpersonal Processes of Care Survey (IPC-18)), health literacy (STOFHLA), self-care behaviors (diet, foot care, blood glucose testing), medication adherence (ARMS), treatment satisfaction (DTSQ) and A1C. Continuous and categorical variables were described using means ± SD and percentiles. Multivariable linear regression models were used to evaluate the association between health communication quality (IPC-18) and, self-care behaviors, medication adherence, diabetes treatment satisfaction, and A1C. All models were adjusted for intervention status, age, race, gender, literacy status, income, insurance, insulin status and years since diagnosis.
RESULTS: To date 349 patients have been enrolled: mean age was 49.9± 9.5, 61 % were female, mean A1C was 9.6±2.1, and participants primarily self-reported three racial/ethnic categories (White 63 %, Black 17 %, and Hispanic/Latino 20 %). Most were uninsured (91 %), low income (83 % with <$20 k annually), and had moderate educational attainment (73 %≤ HS). According to the STOFHLA, 17 % had limited health literacy skills and 67 % had poor diabetes-related math skills (DNT). In adjusted analyses, lack of clarity was significantly associated with worse patient foot care ($\beta=-0.21$ [−1.02, −0.09], $p=0.02$), worse medication adherence ($\beta=0.43$ [1.1, 2.7], $p<0.001$), and lower treatment satisfaction ($\beta=-0.24$ [−2.9, −0.4], $p=0.009$). Eliciting concerns (EC), explaining results (ER), and deciding together (DT) were each independently associated with improved medication adherence (EC: $\beta=-0.19$ [−2.2, −0.01], $p=0.04$, ER: $\beta=-0.33$ [−2.8, −0.7], $p=0.001$, DT: $\beta=-0.23$ [−1.6, −0.2], $p=0.009$), and greater treatment satisfaction (EC: $\beta=0.25$ [0.44, 3.9], $p=0.01$, ER: $\beta=0.28$ [0.76, 3.9], $p=0.004$, DT: $\beta=0.15$ [−0.14, 2.1], $p=0.08$]. Communication quality was not significantly associated with glycemic control for any of the examined variables.
CONCLUSIONS: In a sample of adult diabetes patients seeking care in a public health department setting, the quality of provider communication

was independently associated with important self-care behaviors and overall treatment satisfaction after adjusting for potential confounders. Health communication quality may be an important modifiable factor that can help improve the delivery of diabetes care to vulnerable populations at risk of poor control.

HEALTHCARE SYSTEM SUPPORTS FOR INTERNISTS CARING FOR YOUNG ADULT PATIENTS WITH PEDIATRIC ONSET CHRONIC ILLNESS: A QUALITATIVE STUDY Sophia Jan[1,2]; Dava Szalda[2]; Manuel E. Jimenez[2,4]; Jeremiah Long[1]; Amelia Ni[1]; Judy A. Shea[1,3]. [1]Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA; [4]Children's Hospital of Philadelphia, Philadelphia, PA. (Tracking ID #1631375)

BACKGROUND: Over 90 % of pediatric patients with special healthcare needs are living into adulthood necessitating internists to care for a new variety of diagnosis and disease processes. Previous studies have identified patient and provider characteristics which limit care of these patients. We examined current practices in the care of adolescents and young adults with special healthcare needs by internists in order to identify barriers and possible interventions to improve care.
METHODS: We conducted semi-structured interviews with a convenience sample of internal medicine physicians. We purposively sampled participants based on their known or reported experience with young adults with pediatric onset chronic illness using a snowball strategy. Open-ended questions explored processes of care around the initial and subsequent visits to internal medicine practices. Interviews were recorded, transcribed, coded and continued until we reached thematic saturation. We identified themes using modified grounded theory.
RESULTS: Twenty-one practicing physicians in four different states in both academic and private practices were interviewed. Internists identified several factors that facilitated care for young adult patients with pediatric onset chronic illnesses. These included: requesting medical records and medical summary from pediatric providers at the initial referral contact; screening questions for all new patients by registration staff; having extended time slots for initial visits; setting family and provider expectations at the beginning of the patient-doctor relationship; email and other forms of electronic communications with both family and other members of medical team; availability and proficiency with electronic medical records within the practice; adequate call center, social work, and case-management support. Most providers also commented that being part of an academic practice, rather than private practice, helped shield providers from financial disincentives to accepting and continuing care for these complex patients.
CONCLUSIONS: Internists identified many potential interventions to help support providers caring for young adults with pediatric onset chronic illnesses. These interventions should be further studied to determine their impact on access and quality of care for these complex patients.

HEALTHCARE UTILIZATION BY INDIVIDUALS WITH CRIMINAL JUSTICE INVOLVEMENT: RESULTS OF A NATIONAL SURVEY Joseph W. Frank[1,2]; Jeffrey A. Linder[1,2]; William Becker[3,4]; David A. Fiellin[3]; Emily A. Wang[3]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Yale University School of Medicine, New Haven, CT; [4]VA Connecticut Healthcare System, West Haven, CT. (Tracking ID #1642108)

BACKGROUND: Individuals with criminal justice involvement —those arrested, on parole or probation —have increased morbidity and mortality yet barriers to healthcare exist. Community supervision in the form of parole or probation may positively impact need for and access to care, however. We sought to examine the association between recent criminal justice involvement and utilization of hospital and emergency department (ED) services and to estimate associated expenditures.
METHODS: We conducted a serial cross-sectional analysis of adult respondents in the 2008–2011 National Survey on Drug Use and Health (N=154,356), a nationally representative survey of the non-institutionalized U.S. civilian population. We created three mutually exclusive categories for self-reported past-year criminal justice involvement: 1) any parole or probation, 2) arrest only without community supervision, or 3) no involvement. Our two dependent variables were self-reported past-year hospital and ED utilization. We dichotomized each dependent variable (any vs. no utilization). We used the chi-square test to examine bivariate associations and multivariable logistic regression to adjust for sociodemographic and clinical characteristics. We then estimated annual expenditures using data from the 2008 to 2010 Medical Expenditure Panel Survey, a set of large-scale surveys that provides nationally representative cost estimates, adjusting for age, gender and calendar year.
RESULTS: In the United States, 2.5 % of adults (N=6212) reported past-year parole or probation and 1.7 % (N=4586) reported past-year arrest only. Individuals with any past-year criminal justice involvement (parole, probation or arrest) were more likely to be male (73 % vs. 47 %), members of minority groups (43 % vs. 32 %), publicly insured or uninsured (60 % vs. 28 %) and to report psychiatric (16 % vs. 9 %) and substance use diagnoses (38 % vs. 8 %) (P<.0001 for all comparisons). Hospitalization was more common among individuals with past-year parole or probation (12.3 %) or arrest only (14.3 %) compared to individuals with no past-year criminal justice involvement (10.5 %) (P<.0001). Similarly, ED utilization was more common among individuals with past-year parole or probation (39.3 %) or arrest only (47.2 %) compared to individuals with no past-year criminal justice involvement (26.9 %) (P<.0001). After adjustment for sociodemographic and clinical characteristics, past-year hospitalization was more likely for those with past-year parole or probation (odds ratio [OR] 1.33; 95 % confidence interval [CI] 1.14–1.54) and past-year arrest only (OR 1.51; 95 % CI 1.28–1.78) compared to individuals with no past-year criminal justice involvement. Similarly, past-year ED utilization was more likely among those with past year parole or probation (OR 1.25; 95 % CI 1.13–1.38) and past year arrest (OR 1.68; 95 % CI 1.50–1.88). Individuals with any past-year criminal justice involvement (parole, probation or arrest) accounted for 4.2 % of the U.S adult population but an estimated 7.2 % and 8.5 % of national hospital and ED expenditures, respectively.
CONCLUSIONS: In this nationally representative sample, past-year criminal justice involvement is associated with increased hospital and ED utilization as well as increased expenditures. Individuals with criminal justice involvement are a large, identifiable "high utilizer" group, who may benefit from strategies to decrease need for hospital and ED services.

HELPFUL VS. HARMFUL: SOCIAL NETWORKS AND THEIR ASSOCIATION WITH WEIGHT LOSS Ginger J. Winston; Erica Phillips; Mary Charlson. Weill Cornell Medical College, New York, NY. (Tracking ID #1643698)

BACKGROUND: Obesity has been shown to spread through social networks. However, further data are needed on social network structure and function in weight loss behaviors, particularly in race/ethnic minority populations. The aim of this analysis was to examine social network structure, its influence on eating habits and relationship to weight loss among adults enrolled in a behavior change weight loss study.
METHODS: The Small Changes and Lasting Effects (SCALE) trial is an ongoing 1 year weight loss intervention among non-Hispanic black and Hispanic adults, BMI≥25 kg/m2, living primarily in Harlem and the South Bronx, New York. Participants made small changes in their eating behaviors and set individual physical activity goals. Social network members were defined as people important in the participant's life; for example family, friends, coworkers. Data on participants' social network structure were collected at study close-out using the convoy model of social support. The convoy model consists of 3 concentric circles (Fig. 1); the closest network members were listed in the inner circle (circle 1), members not as close in the middle circle, and least close in the outer circle. Participants identified the network members who influenced their eating habits and if they helped or hindered their eating goals in SCALE. Weight

loss was calculated as the difference between weight measured at study enrollment and close-out. Data were analyzed using chi-square and ANOVA tests as appropriate.
RESULTS: There were 45 index participants included in the analysis (mean age 51 years, 38 % female, 40 % non-Hispanic black, 60 % Hispanic) and 469 social network members. The average network size was 10.4 members, with the largest percent of network members in circle 1 (60 %) followed by circle 2 (25 %) and circle 3 (15 %). The majority of network members were women (62 % circle 1, 77 % circle 2 and 74 % circle 3). 77 % of participants indicated that at least one social network member influenced their eating habits, these members were primarily in circle 1 (74 %). Among the social network members who influenced eating habits, 80 % helped participants with their SCALE eating goals, 8 % made it more difficult, and 11 % had no impact ($p<0.0001$). Network members who helped participants with their eating goals were primarily in circle 1 (74 %). Children and friends were identified as being more helpful than partners/spouses (25 %, 25 % and 8 % respectively). Network members identified as helpful lived primarily outside the home (70 %). There was a trend towards greater weight loss among participants who reported having social network members that helped them with their eating goals compared to those without help (−3.4 lbs vs. + 3.8 lbs, $p=0.06$).
CONCLUSIONS: In SCALE, the majority of participants indicated that social network members influenced their eating habits. There was a trend towards greater weight loss among participants who had social network help in their eating behavior goals compared to those without help. These data provide information on the structure of social networks among overweight/obese adults residing in an urban setting and provide evidence that social networks can be helpful in weight loss efforts.

HELPING FOURTH-YEAR MEDICAL STUDENTS ENGAGE ETHICS AND PROFESSIONALISM: USING THE CHARTER ON MEDICAL PROFESSIONALISM TO PROMOTE REFLECTION ON THE CLINICAL TRAINING ENVIRONMENT AND INDIVIDUAL CLINICAL EXPERIENCE Lauris C. Kaldjian[1,2]; Laura A. Shinkunas[2]; Ellen E. Gordon[1]; Jerold C. Woodhead[3]. [1]University of Iowa, Iowa City, IA; [2]University of Iowa, Iowa City, IA; [3]University of Iowa, Iowa City, IA. (Tracking ID #1631487)

BACKGROUND: We introduced a required Professionalism Seminar for fourth-year medical students, using the 3 fundamental ethical principles and 10 professional commitments of the Charter on Medical Professionalism (Ann Intern Med 2002;136:243–246) to help students assess their experience of the clinical training environment and guide written reflections on ethical and professional challenges encountered as sub-interns. The Seminar involved a pre-Seminar survey, written reflections, group discussion of some written reflections, and a post-Seminar evaluation.
METHODS: During sub-internships in internal medicine, pediatrics, or obstetrics-gynecology in 2011–12, students completed an anonymous, 13-item, pre-Seminar survey to assess the degree to which the principles and commitments in the Charter are taken seriously in their clinical training, using a 5-point Likert scale (all the time, most of the time, some of the time, rarely, never). Students wrote reflections describing and assessing an experience from their sub-internship involving a patient and raising an ethical or professional issue. To guide their writing, students were asked to review the Charter and comment on which principles and commitments seemed most relevant to the experience described. An anonymous, post-Seminar evaluation was conducted. Survey item and evaluation response frequencies were calculated. Directed content analysis of written reflections determined types of ethical and professional issues addressed, using a published taxonomy (J Med Ethics 2012;38:130–132); summative content analysis determined the frequency of references to the Charter's principles and commitments. The study was IRB-approved.
RESULTS: Of 70 eligible students, 67 completed the pre-Seminar survey, 65 completed the post-Seminar evaluation, and 65 written reflections were available for analysis. Survey results showed no students believed any of the principles or commitments are taken seriously in the training environment all the time. Most students believed the principles of primacy of patient welfare, patient autonomy, and social justice are taken seriously most or some of the time (98.5 %, 80.6 %, and 61.2 %, respectively). Commitments least likely to be perceived as being taken seriously most or some of the time were: improving quality of care (73.1 %), improving access to care (61.2 %), and just distribution of finite resources (47.8 %). Written reflections addressed treatment decisions (73.8 %), justice (52.3 %), professional duties (43.1 %), communication (30.8 %), miscellaneous issues (26.2 %), quality of care (13.8 %), and student specific issues (3.1 %). In reflections, references to the Charter's principles (primacy of patient welfare, 43.1 %; patient autonomy, 35.4 %; social justice, 33.8 %) were more frequent than the most commonly cited commitments (honesty with patients, 24.6 %; just distribution of finite resources, 23.1 %; improving quality of care, 21.5 %). The post-Seminar evaluation indicated 60.0 % of students agreed or strongly agreed that the Charter helped them identify more ethical and professional issues when writing their reflections.
CONCLUSIONS: Students are able to use the Charter to assess ethical and professional aspects of the clinical training environment and guide reflection on individual clinical experiences. The Charter should be seen as a practical resource in clinical education to facilitate critical observation, individual reflection, and multidisciplinary group discussion of ethics and professionalism.

HEPATITIS B AND PRISON OFFICERS: FEARS AND KNOWLEDGE ABOUT HBV TRANSMISSION Laurent Gétaz; Alejandra Casillas; Maria Pfefferle; Hans Wolff. University Hospitals of Geneva and University of Geneva, Geneva, Switzerland. (Tracking ID #1639499)

BACKGROUND: It is important to examine the health beliefs of caretakers who are in close contact with populations at high risk of infectious diseases, as is the case with prison officers. Incorrect beliefs among prison officers may affect the efficacy of risk reduction programs for all individuals. The goal of this study was to assess prison officers' knowledge, fears, and protection strategies specific to hepatitis B (HBV) in the prison setting.
METHODS: This descriptive study included prison officers from five prisons in Western Switzerland. Data on demographics, specific fears and knowledge concerning various infectious diseases were collected by an anonymous standardized questionnaire. Here, focusing on questions addressing HBV, we present descriptive analyses about HBV transmission knowledge and protective behaviors, and the associations between fear of infection and incorrect health beliefs.
RESULTS: In 2012, 170 prison officers (96 % participation rate) completed the questionnaire: 88 % were men and 56 % worked at a pre-trial prison; 72 % of correctional officers thought they had a higher risk of infection given their occupation. However, only 72 % thought that they could transmit a disease to an inmate, or ever possibly cause an infectious outbreak (65 %). While the majority (85 %) recognized that contaminated needles could spread HBV, a lower proportion was aware of the risks related to tattooing (72 %), unprotected sexual intercourse (62 %), sharing razors (69 %) and toothbrushes (49 %). Sterile needles and condoms were identified as useful preventive measures by 82 % and 67 % of prison officers, respectively. Concerning incorrect transmission modes, shaking hands, food, and coughing were recognized as false by 70 %, 36 % and 30 % of the prison officers, respectively. In terms of protective behaviors, 43 % of participants stated that they used gloves when intervening in a fight. Most importantly, only 46 % of participants said they were vaccinated, 16 % were sure not to be vaccinated, while 38 % did not know their HBV vaccine status. Regarding perceived fear of HBV, 44 % had a moderate to great fear of HBV infection. There were significantly higher rates of false beliefs among prison officers with moderate to great fear of contracting HBV versus those with little or no fear when asked about handshaking (RR 2.18, 95%CI 1.31–3.62), coughing (RR 1.26, 95%CI1.03–1.55), and sharing food (RR 1.40, 95%CI 1.10–1.77) as possible transmission risks.
CONCLUSIONS: HBV knowledge and protective behaviors are suboptimal among prison officers. As well, fear of HBV infection is associated with incorrect health beliefs. Improving knowledge of HBV transmission and protection modes can decrease fears, and lead to more

efficient health behaviors, such as systematic vaccination and use of gloves. As primary care physicians in prison also rely on prison staff for patient referrals and ancillary medical support, it is increasingly important to address and improve the health knowledge of these close-contact populations, for the benefit of vulnerable patients residing in the prison setting.

HIGH RATES OF DIABETES IN ASIAN SUBGROUPS: A CASE FOR USE OF THE ASIAN BMI CATEGORIES Jane Jih[1]; Alka M. Kanaya[1,2]; Tung T. Nguyen[1,2]. [1]University of California San Francisco, San Francisco, CA; [2]Asian American Research Center on Health (ARCH), San Francisco, CA. (Tracking ID #1624876)

BACKGROUND: Asians are the fastest growing racial group in the US. Their health data are often not disaggregated, and most population-based surveys are not conducted in Asian languages. The California Health Interview Survey (CHIS) provides statewide estimates of major racial/ethnic groups and is conducted in multiple languages including English, Mandarin, Cantonese, Vietnamese and Korean. We used CHIS to study the prevalence of heart disease and its risk factors by Asian American subgroups to inform clinical practice and prioritize targeted interventions.
METHODS: The 2009 CHIS is a population-based, cross-sectional, random-dial telephone survey of non-institutionalized Californians with oversampling of Vietnamese and Korean populations. We restricted this analysis to non-pregnant adults ≥18 years who self-reported being Asian or non-Hispanic whites. Key variables included sociodemographic characteristics, health status, body mass index (BMI) and prevalence of heart disease and risk factors. We conducted weighted analysis with jackknife standard errors according to CHIS guidelines and adjusted for age and gender. We compared rates of overweight and obesity using standard BMI categories and the World Health Organization (WHO) Asian BMI categories.
RESULTS: Table 1 shows prevalence of heart disease and risk factors for non-Hispanic whites, all Asians, and the six largest Asian subgroups. The heterogeneity among Asian subgroups for BMI, diabetes, hypertension and heart disease prevalence was obscured when data were aggregated for all Asians. Using the standard BMI categories, all Asian subgroups had lower rates of overweight/obesity than non-Hispanic whites (54.5 %), but, using the WHO Asian categories, Korean (59.5 %), Filipino (69.6 %), Japanese (62.1 %), South Asian (55 %), and all Asians (54.4 %) had similar or higher rates. All Asian subgroups had higher prevalence of diabetes than non-Hispanic whites (6.0 %), with Filipinos (13.7 %), South Asians (11 %) and Koreans (10.4 %) having much higher rates. Japanese (26.3 %), Vietnamese (27.7 %) and Filipino (37.5 %) reported rates of hypertension similar to or higher than non-Hispanic whites (26.2 %). Japanese (7.1 %) and South Asians (6.4 %) had similar heart disease prevalence to non-Hispanic whites (6.9 %).
CONCLUSIONS: We found marked heterogeneity in the prevalence of obesity, diabetes, hypertension and heart disease among Asian Americans. Findings from this linguistically appropriate population-based survey reveal that Asian Americans have higher rates of diabetes, with the rates about twice as high among Filipinos, South Asians and Koreans, compared to non-Hispanic whites. Asian WHO BMI categories are more consistent with this finding because they show much higher rates of overweight/obesity among Asian Americans than the standard categories. Our findings support the use of in-language surveys, data disaggregation, and the appropriate cutoff points for overweight/obesity in Asian Americans.

Table 1. Prevalence of Overweight/Obesity, Diabetes, Hypertension and Heart Disease from 2009 CHIS

	Non-Hispanic Whites (n=31,085)	Total Asian (n=5,062)	Vietnamese (n=1,413)	Chinese (n=1,055)	Korean (n=950)	Filipino (n=505)	Japanese (n=427)	South Asian (n=411)
Standard BMI (%) Overweight/Obesity (≥ 25)	54.5	34.1	21.7	25.3	33.0	47.3	38.7	39.9
Asian WHO BMI (%) Overweight/Obesity (≥ 23)	71.5	54.4	34.9	46.2	59.5	69.6	62.1	55.0
Diabetes (%)	6.0	9.7	7.0	7.9	10.4	13.7	7.8	11.0
Hypertension (%)	26.2	27.6	27.7	23.9	21.7	37.5	26.3	20.3
Heart Disease (%)	6.9	4.4	3.1	4.5	2.6	4.7	7.1	6.4

BMI = Body Mass Index; WHO = World Health Organization

HIGHER QUALITY COMMUNICATION AND RELATIONSHIPS ARE ASSOCIATED WITH IMPROVED PATIENT ENGAGEMENT IN HIV CARE Tabor E. Flickinger[1]; Somnath Saha[2]; Richard D. Moore[1]; Mary Catherine Beach[1]. [1]Johns Hopkins University, Baltimore, MD; [2]Portland VA Medical Center, Portland, OR. (Tracking ID #1638850)

BACKGROUND: Retention in HIV care is essential to receiving antiretroviral therapy, which dramatically improves morbidity and mortality for patients living with HIV and reduces HIV transmission as a key component of "test-and-treat" prevention strategies. Most prior work on retention in care has focused on patient factors as barriers to appointment adherence, with little attention to the role of patient-provider interactions. We hypothesized that patients' adherence to clinic appointments would be associated with the quality of communication and relationships with their HIV care providers.
METHODS: In an urban, academic HIV clinic, 1363 patients completed interviews assessing demographics, substance use, and patient ratings of the quality of communication and relationships with their providers on five domains: being treated with dignity and respect, being involved in decisions, being listened to, having information explained, and feeling known as a person. We calculated appointment adherence from clinic records as the number of completed appointments divided by the total number of routinely scheduled appointments over 1 year after the patient interview. We used linear regression analysis to investigate associations between appointment adherence and the five communication/relationship domains.
RESULTS: Mean age of the patient sample was 45.8 years; the majority of patients were male (65 %) and nonwhite (85 %). Sixty-six percent of patients were on antiretroviral therapy and 49 % had suppressed viral loads. For all patients in the study, the mean appointment adherence was 65 %. Appointment adherence was significantly higher for male versus female patients, white versus nonwhite patients, and those who had no recent substance use versus those who did. In analysis adjusted for patient race, sex, and substance use, patients kept more appointments if they had stronger relationships with their providers, as indicated by higher ratings on being treated with dignity and respect (p=0.022), being listened to carefully (p=0.009), having information explained in ways they could understand (p=0.003), and feeling known as persons (p=0.001). Being involved in decisions was not significantly associated with appointment adherence.
CONCLUSIONS: Appointment adherence was higher among HIV-infected patients who perceived higher quality communication and relationships with their providers. Enhancing providers' skills in effective communication and relationship-building may improve patient retention in HIV care.

HOME BASED AND OUTPATIENT PALLIATIVE CARE: CHALLENGES, OPPORTUNITIES AND MODELS OF CARE AMONG HOSPICE AGENCIES Allison Stark; Amy Kelley; Diane E. Meier; Melissa Aldridge Carlson. Mount Sinai School of Medicine, New York, NY. (Tracking ID #1638210)

BACKGROUND: The availability of outpatient palliative care services for patients who are not eligible for hospice is limited. This is despite tremendous growth in palliative care programs in U.S. hospitals. Hospice agencies are increasingly expanding service offerings to include palliative care for patients with advanced illness who do not qualify for hospice. The objectives of this study are to characterize models of non-hospice palliative care emerging from hospice agencies and to describe key challenges and opportunities.
METHODS: This study was conducted as a qualitative survey utilizing semi-structured interviews with hospice medical directors or administrators. The interview questionnaire focused on rationale for program development, program structure and strategy, and key challenges to development and sustainability. Hospice agencies in the New York City area were identified on the Hospice and Palliative Care Association of New York State website. A snowball sampling technique was utilized to identify

additional hospice agencies that offer non-hospice palliative care services. Interviews were audio recorded, coded and reviewed collectively to identify themes and trends.

RESULTS: Eighty-two percent (n=11) of hospice agencies contacted to date agreed to participate. Interviews have been conducted with eight hospice agencies thus far, representing both the not-for-profit and for profit sectors. Five of these hospice agencies are located in the New York City area. All hospices that provide non-hospice palliative care services cited meeting the unmet needs of patients with serious illness and improving their quality of life as the key drivers to the development of these services. Most also discussed the opportunity to increase hospice enrollment through transitioning patients from palliative care to hospice as an important value proposition. The most significant challenge described by hospice agencies providing non-hospice palliative care services is financial viability. Home based palliative care services are resource intensive without sufficient reimbursement. Outpatient palliative care services fare slightly better given the opportunity to see higher volumes of patients in a given time period. All agencies reported that their non-hospice palliative care services operate at a loss. Hospice agencies that do not provide palliative care services cited the lack of adequate reimbursement as their key deterrent. Several different models of palliative care service offerings have been developed by hospice agencies. Some offer a full continuum of palliative care services including hospital inpatient consultation, outpatient and home based care. Others have contractual agreements with payers, and in one case, with an accountable care organization, to provide palliative care services for high risk patients focusing on symptom management, advanced care planning and cost avoidance.

CONCLUSIONS: Hospice agencies are developing non-hospice palliative care services to meet the unmet needs of patients with advanced illness because they feel it is part of their underlying mission. The primary barrier to the development and sustainability of non-hospice palliative care programs is financial viability owing to a lack of adequate reimbursement. Selected hospice agencies are developing innovative models of non-hospice palliative care services that involve establishing contractual agreements with payers and accountable care organizations focused on demonstrating value through cost avoidance.

HOMELESSNESS, CIGARETTE SMOKING, AND DESIRE TO QUIT: A NATIONAL STUDY Travis P. Baggett[1,2]; Lydie A. Lebrun-Harris[3]; Nancy A. Rigotti[1,4]. [1]Massachusetts General Hospital, Boston, MA; [2]Boston Health Care for the Homeless Program, Boston, MA; [3]Health Resources and Services Administration, Rockville, MD; [4]Harvard Medical School, Boston, MA. (Tracking ID #1642559)

BACKGROUND: Cigarette smoking is common among homeless individuals, but whether the association between homelessness and smoking is independent of mental illness, substance abuse, and poverty is unknown. Homeless smokers are often assumed to be uninterested in quitting, although clinical experience and small studies suggest otherwise. We used data from a national survey to determine if homelessness is independently associated with current smoking or desire to quit.

METHODS: We analyzed data from the 2009 Health Resources and Services Administration Patient Survey (participation rate 72 %), a nationally representative survey of individuals using community health centers funded through Section 330 of the Public Health Service Act. These health centers target medically underserved populations, providing a sampling frame that includes both homeless and housed low-income individuals. We used multivariable logistic regression to examine the association between homelessness and (1) current cigarette smoking among all adults, and (2) past-year desire to quit among current smokers.

RESULTS: Of 2,678 adult respondents, 4 % were currently homeless and 11 % were formerly homeless. In unadjusted analyses, adults with any history of homelessness were more likely than never homeless respondents to be current smokers (57 % vs 27 %, $p<0.001$). In multivariable models, a history of homelessness was independently associated with current smoking (AOR 2.09; 95 % CI 1.49–2.93), even after adjusting for age, sex, race, veteran status, insurance, education, employment, income, mental illness, and alcohol and drug abuse. Housing status was not significantly associated with desire to stop smoking in unadjusted (p=0.26) or adjusted (p=0.60) analyses; 84 % of currently homeless, 89 % of formerly homeless, and 82 % of never homeless smokers reported wanting to quit in the past year.

CONCLUSIONS: A history of homelessness independently doubles the odds of being a current cigarette smoker. Despite this, homeless smokers do not differ from non-homeless smokers in their desire to quit. Our findings emphasize the need for creative efforts to reduce tobacco use disparities in this vulnerable population.

HORMONE THERAPY USE IN WOMEN VETERANS ACCESSING VA CARE: A NATIONAL CROSS-SECTIONAL STUDY Megan R. Gerber[1,2]; Suzanne Pineles[3]; Sandra Japuntich[3]; Bevanne Bean-Mayberry[4]; Matthew King[3]; Sally G. Haskell[5]. [1]VA Boston Healthcare System, Jamaica Plain, MA; [2]Boston University School of Medicine, Boston, MA; [3]VA Boston Healthcare System, Jamaica Plain, MA; [4]VA Greater Los Angeles Healthcare Sys, Los Angeles, CA; [5]VA Connecticut Healthcare System West Haven Campus, West Haven, CT. (Tracking ID #1638427)

BACKGROUND: The Women's Health Initiative (WHI) (2002) resulted in dramatic decline in hormone therapy (HT) use post menopause. National estimates (NHANES) showed a decline in HT use by women over 45 from 22.4 % in 1999–2000 to 4.7 % by 2009–2010. The sharpest drop occurred in 2003–04 immediately following WHI publication; a study of VA patients found similar rates of HT discontinuation for the same year. Current consensus guidelines advise short-term use of combined estrogen-progestin combinations primarily to treat vasomotor symptoms in women ages 50–59; more flexibility is granted for use of unopposed HT after hysterectomy. The current study aimed to establish the prevalence of 2009–10 HT use in VA and to examine whether co-morbid mental health conditions more common among Veterans, particularly PTSD, may be related to increased HT use in VA patients. We hypothesized that women with PTSD may be more likely to use HT compared to women without the diagnosis as they may perceive vasomotor symptoms as similar to hyperarousal symptoms of PTSD and find them less tolerable. Estrogen also impacts emotion regulation through sympathoadrenal responsiveness which could make discontinuation more difficult for women with mental illnesses.

METHODS: Women Veterans over the age of 45 receiving VA care were identified through the VA Pharmacy Benefits Management Program (PBM) data for 2009–10. HT use was defined as use of any systemic estrogen or estrogen/progestin-containing product. PBM data were linked to the VA National Patient Care Database (NPCD) for demographic and clinical variables. We examined bivariate associations between HT use and demographic/clinical variables using $\chi 2$ statistics for categorical and two-sided t tests for continuous data. To assess predictors of HT use, we estimated a hierarchical logistic regression model controlling for potential confounders including demographics, psychiatric and medical comorbidities.

RESULTS: The sample size was 157,195 women, mean age was 59 and 10.3 % received HT. Depression was the most common psychiatric diagnosis (21 %) followed by substance use disorders (16 %). Nearly 9 % of women had a diagnosis of PTSD. After controlling for demographics and hysterectomy, odds of HT use were increased in those diagnosed with depression (OR 1.5), osteoporosis (OR 1.4), bipolar disorder (OR 1.4) and PTSD (OR 1.3). Breast cancer had the strongest association with non-receipt of HT (OR 0.3).

CONCLUSIONS: The prevalence of HT use among women Veterans using VA care exceeds the general population rate of 4.7 % by more than two-fold. While prior work suggested that women Veterans were discontinuing HT at comparable rates to the general population, these data suggest that the decline was not sustained over time. In VA, mental health

diagnoses exhibited odds comparable to osteoporosis, a driver of HT use. Further study of the impact mental health comorbidity plays in patient decision making about HT could prevent adverse outcomes that may ensue when continuation is medically contraindicated. Quality improvement projects that review guidelines and risks for patients with comorbid mental illness on HT may be warranted.

HOSPICE ENROLLMENT PREFERENCES AMONG PHYSICIANS AND THE TIMING OF THEIR END-OF-LIFE CARE DISCUSSIONS WITH TERMINALLY-ILL CANCER PATIENTS Michael Pang-Hsiang Liu[2]; Garrett M. Chinn[1,3]; Nancy L. Keating[2,3]. [1]VA Boston Healthcare System, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA. (Tracking ID #1635188)

BACKGROUND: Physicians report preferences for care when they die that may be less aggressive than their patients generally receive, but few data are available about physicians' preferences for end of life care. In addition, evidence suggests that physicians often delay in discussing hospice with their terminally-ill patients despite guidelines recommending such discussions for patients expected to die within 1 year. We explored factors associated with physicians' reported preferences for hospice enrollment if they were terminally ill. We also assessed whether physicians who would enroll in hospice if terminally ill differed from other physicians regarding the timing of hospice discussions with their terminally-ill patients.
METHODS: We surveyed physicians caring for cancer patients enrolled in the multiregional population-based Cancer Care Outcomes and Research Surveillance study (response rate 61 %). Physicians indicated on a 5-point Likert scale how strongly they agreed or disagreed with the statement "If I were terminally ill with cancer, I would enroll in hospice." They were also asked to assume they were caring for an asymptomatic patient who they believed had 4–6 months to live and report whether they would discuss hospice with the patient: "now", "when the patient first develops symptoms", "when there are no more non-palliative treatments to offer", "only if the patient is admitted to the hospital", or "only if the patient and/or family bring it up." We used logistic regression to examine physician and practice factors associated with responding "strongly agree" that they would enroll in hospice. In a second model, we assessed if physicians who strongly agreed they would enroll in hospice were more likely than other physicians to report they would discuss hospice "now" with their terminally-ill patients.
RESULTS: The 4,368 respondents had a mean age of 49.4 (SD 10.2), 80 % were men, and 14 %, 6 %, 21 % and 59 % were medical oncologists, radiation oncologists, surgeons, and non-cancer specialists, respectively. Most physicians strongly (65 %) or somewhat agreed (21 %) that they would enroll in hospice if they were terminally ill. In adjusted analyses, physicians caring for a higher proportion of managed care and terminally-ill patients were more likely than other physicians to strongly agree they would enroll in hospice (both $P<.03$), as were female physicians (OR 2.0, 95 % CI 1.6, 2.4). Surgeons (OR 0.6, 95 % CI 0.5, 0.8) and radiation oncologists (OR 0.6, 95 % CI 0.4, 0.8) were less likely than medical oncologists to strongly agree they would enroll in hospice. Age, race, and teaching involvement were not associated with personal preferences for hospice. Overall, 26 % of physicians reported they would discuss hospice "now" with a patient who had 4–6 months to live. Physicians who strongly agreed they would enroll in hospice themselves were more likely than other physicians to report discussing hospice "now" (OR 1.7, 95 % CI 1.5, 2.0) with a terminally-ill patient.
CONCLUSIONS: Most physicians reported they would enroll in hospice if they were terminally ill- particularly female physicians, medical oncologists, and physicians caring for more terminally-ill and managed care patients. Physicians with strong personal preferences for hospice were more likely than others to report discussing hospice with their patients early. Personal preference for hospice may influence physicians' propensity to discuss hospice with their terminally-ill patients.

HOSPITAL READMISSION AND COMMUNICATION BETWEEN HOME HEALTH NURSES AND PHYSICIANS: A MIXED METHODS STUDY Matthew J. Press[1]; Linda M. Gerber[1]; Timothy Peng[2]; Penny H. Feldman[2,1]; Karin Ouchida[1]; Yuhua Bao[1]; Lawrence P. Casalino[1]. [1]Weill Cornell Medical College, New York, NY; [2]Visiting Nurse Service of New York, New York City, NY. (Tracking ID #1626761)

BACKGROUND: Each year, over 2 million episodes of home health care are provided for Medicare beneficiaries recently discharged from the hospital. To coordinate care and potentially prevent hospital readmissions, home health nurses must be able to communicate with their patients' physicians. Yet a few small studies suggest that home health nurses often have difficulty reaching physicians during the course of home care. Our objective was to analyze home health nurse-physician communication, identify failed communication attempts (that is, an unsuccessful attempt by the nurse to reach the physician), and to assess their association with hospital readmission.
METHODS: The study had three components: (1) qualitative analysis, (2) pilot quantitative analysis, and (3) comprehensive quantitative analysis. For the qualitative analysis, we conducted 9 individual physician interviews and 2 focus groups of 12 home health nurses each. For the pilot quantitative analysis, we analyzed electronic documentation of communication attempts made by home health nurses to physicians for 100 patients, 50 of whom were readmitted and 50 of whom were not readmitted. For the comprehensive quantitative analysis, we created a computerized text-processing algorithm to code failed communication attempts for approximately 8,000 Medicare beneficiaries with congestive heart failure who received post-acute home health care in 2008–2009 from a single agency. We will assess the association between failed communication attempts and the likelihood of risk-adjusted, 30-day hospital readmission by linking the agency data with inpatient Medicare claims.
RESULTS: Our qualitative analysis revealed several barriers to effective communication between home health nurses and physicians, which we grouped into three categories: responsibility (that is, identifying the physician who is responsible for the patient's home care), accessibility (that is, finding ways to reach the physician when he/she is unavailable), and collaborative strategy (that is, the attitude, skills, and tools nurses and physicians use to facilitate effective exchange of information). Nurses reported more problems with communication than did physicians. In the pilot quantitative analysis, 13 out of 50 readmitted patients had more than half of all communication attempts fail (89 total communication attempts). Of the 50 non-readmitted patients, only 5 had more than half of all communication attempts fail (108 total communication attempts; $p=0.07$). In the comprehensive quantitative analysis, preliminary results indicate that 2,500 (4.5 %) of 55,141 total communication attempts failed. Analysis of the association between failed communication attempts and hospital readmission is pending at this time but will be completed prior to the SGIM meeting.
CONCLUSIONS: Attempts by home health nurses to communicate with their patients' physicians are often unsuccessful, and our pilot analysis suggests that failed communication attempts may be associated with an increased likelihood of hospital readmission. Nurses and physicians report barriers to effective communication which may be amenable to intervention. Such improvements could enhance the capacity for home health nurses to coordinate care and potentially prevent hospital readmissions.

HOSPITAL READMISSIONS AMONG INDIGENT HIV-INFECTED PATIENTS: A MOVEMENT TOWARD MEDICAL HOME MODEL INTERVENTIONS Reshma Gupta[1]; Shireesha Dhanireddy[2]. [1]University of Washington, Seattle, Seattle, WA; [2]University of Washington, Seattle, Seattle, WA. (Tracking ID #1624160)

BACKGROUND: Hospital admissions related to advanced AIDS have significantly declined in the post-HAART era, though the rate of inpatient readmissions related to chronic illness among HIV positive patients

remains relatively high with a slow rate of decline. The medical home model has been used to improve chronic illness management. However, there are no studies evaluating the role of ambulatory medical homes on hospital readmission rates. In this quality improvement study, we will identify characteristics of hospital readmission to target future evaluation and intervention.
METHODS: We conducted a retrospective cohort study of 850 hospitalized adults from the Seattle Harborview Madison HIV Clinic and determined hospital admission and 30-day readmission rates at Harborview Medical Center between 1/1/2007 and 12/31/2012. Data were obtained via query of hospital MIND database. Readmission was defined as any hospitalization within 24 h to 30 days of hospital discharge.
RESULTS: Between 1/1/2007 and 12/31/12, 850 individual Madison clinic patients were admitted to the hospital, totaling 2234 hospital admissions. 534 of these admissions were considered readmissions occurring within 30 days of discharge. 61 (5.5 %) patients accounted for 669 (24 %) admissions. Six patients had more than sixteen admissions each, and three patients had more than twenty admissions each. Approximately 70 % of readmissions were related to chronic illness. Readmissions associated to chronic disease include respiratory disease, skin infections, mental illness, coronary disease, renal disease, substance use, and liver disease.
CONCLUSIONS: HIV patients are afflicted with multiple chronic illnesses, which are consistently affecting readmission rates. Identifying HIV patients within clinics who are at higher risk of hospital readmissions will help to target readmission prevention resources most efficiently. Developing ambulatory medical home-based interventions from this data will change readmission prevention paradigms so that there is a shared responsibility between clinics and inpatient teams. Ambulatory clinics will likely play a vital role in increasing quality and reducing costs during care transitions.

HOSPITALIST PHYSICIAN WORKLOAD: DOES IT MATTER? Daniel J. Elliott[1]; Paul Kolm[1]; Robert Young[2]; Ruth T. Aguiar[1]; Joanne C. Brice[1]. [1]Christiana Care Health System, Newark, DE; [2]Northwestern University Feinberg School of Medicine, Chicago, IL. (Tracking ID #1640315)

BACKGROUND: Hospital Medicine is the fastest growing medical specialty, in large part due to evidence that hospitalists provide high quality, efficient care. Current reimbursement structures generally incentivize or require increased hospitalist productivity. Increasing workload may negatively impact the quality and efficiency of care, but there is little empirical data to determine this association. We sought to determine the association between hospitalist workload and the quality and efficiency of care.
METHODS: We conducted a retrospective cohort study of inpatients over 18 admitted to a large, private hospital medicine service between February 1, 2008 and January 31, 2011. We excluded patients who were admitted directly to an intensive care unit, were not discharged prior to the end of the study period, or had a hospital length of stay (LOS) <0.5 or >30 days. The exposure was the total daily physician workload on the day of each encounter during the patient's hospitalization. Daily workload was calculated separately as 1) total work Relative Value Units (wRVU) standardized to 2011 values and 2) total patient census. The primary outcomes were hospital length of stay (LOS) and 30-day readmission rate. Key covariates included patient demographics and severity, physician continuity, and hospital occupancy. We used hierarchical time-to-event models clustered by patient and by physician. Workload and hospital occupancy were allowed to vary over the patient's hospitalization for the LOS models and fixed as the value on the day of discharge for readmission models. We tested an interaction term between workload and occupancy in all models.
RESULTS: Overall, 19,558 hospitalizations met study criterion. Median daily physician wRVU was 28.7 (IQR 21.3–35.1) and median daily census was 16 patients (IQR 10–20). Physician workload was strongly associated with LOS, but the effect varied across hospital occupancy. At low levels of hospital occupancy (<70 %), adjusted LOS was 1.5 days longer across the range of daily workload values when measured as wRVU and 2 days longer when measured by census. There was no association between workload and LOS at hospital occupancy above 90 %. The 30-day readmission rate increased from 15.5 % to 17.1 % (difference) as hospitalist workload measured by RVU on the day of discharge increased. The 30-day readmission rate did not vary across patient census on the day of discharge when hospital occupancy was below 80 %. However, at occupancy above 80 %, readmission rates ranged from 15.5 % to 17.2 % (difference).
CONCLUSIONS: Increased Hospitalist workload was associated with increased LOS and increased 30-day readmission rates in our cohort. Importantly, the association was modified by hospital occupancy such that LOS was most sensitive to workload at lower levels of occupancy and 30-day readmissions were most sensitive to workload at higher occupancies. Our findings suggest that hospitalist groups and hospitals need to work together to mitigate the impact of high volumes on the efficiency and quality of delivered care.

HOUSING FIRST AMONG HOMELESS PERSONS WITH CONCURRENT DISORDERS AMONG PARTICIPANTS OF THE VANCOUVER AT HOME STUDY Anita Palepu[1]; Michelle Patterson[2]; Akm Moniruzzaman[2]; Julian M. Somers[2]. [1]University of British Columbia, Vancouver, BC, Canada; [2]Simon Fraser University, Burnaby, BC, Canada. (Tracking ID #1635354)

BACKGROUND: There have been no randomized controlled trials of Housing First among chronically homeless persons with concurrent disorders. We, therefore, examined the relationship between substance use and residential stability among homeless adults with current mental disorders who participated in The Vancouver At Home study.
METHODS: The Vancouver At Home study is part of a multi-site pragmatic, randomized controlled trial of a Housing First intervention among homeless individuals with mental illness in five Canadian cities. Participants were eligible if they were 19 years of age or over, met criteria for a current mental disorder on the MINI 6.0 Neuropsychiatric Interview, and were absolutely homeless or precariously housed. We used the Residential Time-Line Follow Back Inventory to derive our primary outcome variable, residential stability, which we defined as the number of days in stable residences after randomization up to their 12 months visit. Substance dependence was identified at baseline using the MINI 6.0. At baseline self-reported frequency of substance use over the past month was captured using the Maudsley Addiction Profile. We dichotomized frequency of substance use to capture daily substance use versus less than daily or none; this variable was used to reflect severity of substance use and its potential impact on daily function. Mental health symptoms and severity were collected through the Colorado Symptom Index. Two negative binomial regression models were fit to examine independent association between the residential stability and the primary independent variables substance dependence and daily substance use.
RESULTS: A total sample of 497 participants were recruited between October 2009 and June 2011 with 58 % (N=288) meeting criteria for substance dependence and 29 % (N=143) reporting daily substance use. The follow-up rate at 1 year was 96 %. There was no difference in the number of days stably housed by substance dependence (182.1 versus 185.6 days, p=0.787). We found no significant association between substance dependence and residential stability (Adjusted IRR 0.94; 95 % CI 0.68–1.30) or between daily substance use and residential stability (Adjusted IRR 0.86; 95 % CI 0.61–1.22) after adjusting for the type of housing intervention, employment, sociodemographics and mental health.
CONCLUSIONS: People with mental disorders may achieve similar levels of housing stability from Housing First regardless of whether they experience concurrent substance dependence. In contrast to some interventions for homeless persons, HF does not require abstinence from drugs among clients. These findings raise important questions regarding the role and relevance of patient choice in the context of health service delivery and program design.

HOW BEST TO SUSTAIN IMPROVEMENTS IN GLYCEMIC CONTROL ACHIEVED IN DIABETES SELF-MANAGEMENT TRAINING PROGRAMS? A RANDOMIZED CONTROLLED TRIAL COMPARING PEER MENTORING WITH COMMUNITY HEALTH WORKER (CHW) OUTREACH Michele Heisler[1]; Brandy Sinco[1]; Gloria Palmisano[2]; Martha Funnell[1]; Tricia Tang[1]. [1]Ann Arbor VA/University of Michigan, Ann Arbor, MI; [2]Community Health and Social Services Center (CHASS), Detroit, MI. (Tracking ID #1642270)

BACKGROUND: Multiple studies suggest that without sustained follow-up support, diabetes self-management training programs only lead to short-term improvements (less than 6 months) in glycemic control. This is especially the case among low-income ethnic and racial minorities in resource-poor settings such as inner-city communities in which adults with diabetes face multiple challenges to diabetes self-management. Federally qualified health centers serving these communities often lack the resources to maintain intensive care management programs staffed by health care professionals to provide between-clinic visit outreach to adults with diabetes who have completed short-term diabetes self-management programs. Accordingly, we sought to compare a peer mentor program with periodic community health worker (CHW) telephone outreach as two possible means to maintain any gains achieved through an evidence-based diabetes self-management program that we have found in prior RCTs to improve glycemic control compared to usual care.
METHODS: The study was conducted at a federally qualified health center in the very low-income, predominantly Latino Southwest of Detroit. In a parallel randomized controlled trial, we randomized adults with poorly controlled diabetes (A1c>7.5 %) to one of two groups: 1) a six-month CHW-led diabetes self-management program and then 12 months of weekly drop-in group sessions or telephone outreach from an adult with diabetes ("peer mentor") who had completed the diabetes self-management program and 24 h of training in empowerment-based facilitation approaches; or 2) a six-month CHW-led diabetes self-management program and then 12 months of monthly CHW telephone outreach. We conducted intention-to-treat repeated measures assessments of changes in A1c between baseline, six-months (immediately after the diabetes self-management training program), 12-months, and 18-months follow-up. We also examined differences between the two groups.
RESULTS: 116 Latino adults with diabetes were randomized to one of the two arms. There were no significant differences in baseline characteristics between groups. Mean age was 49 years. 77 % had less than a high school education, and 94 % had an annual household income of less than $20,000. 95 % were on oral diabetes medications and/or insulin. In intention to treat analyses, mean A1c in the group randomized to the peer mentoring arm improved from 8.0 % to 7.3 % by the conclusion of the six-month diabetes self-management training, with mean A1cs of 7.5 % at 18-months follow-up, still a clinically significant 0.5 % less than at baseline. In the group receiving monthly CHW follow-up, baseline mean A1cs of 7.7 % decreased to 7.2 % at six-month follow-up and increased slightly to 7.3 % at 18-months, 0.4 % lower than at baseline. The differences between groups were not statistically or clinically significant.
CONCLUSIONS: Among these low-income inner-city Latino adults with diabetes, both peer mentoring in weekly group support sessions or fortnightly telephone outreach from volunteer trained diabetes patients and monthly community health worker telephone outreach led to maintenance of gains achieved in an evidence-based diabetes self-management training program. The sustained improvements in glycemic control we observed are equivalent to those achieved in more resource-intensive health professional-led care management programs. Both of the low-cost strategies evaluated in this RCT appear to be effective in sustaining achieved improvements.

HOW CAN ACADEMIC GENERALISTS CONTRIBUTE TO THE PATENT DEVELOPMENT OF INVENTIONS/INNOVATIONS?: EXPLORING THE U.S. PATENT DATABASE FOR PATENTS RELEVANT TO PRIMARY CARE James L. Wofford; Carolyn F. Pedley; Claudia Campos. Wake Forest University, Winston-Salem, NC. (Tracking ID #1641851)

BACKGROUND: Patents of inventions/innovations is an increasing important source of revenue for academic medical centers and represents a departure from the traditional academic paradigm of grant seeking and publishing. Patentable inventions are most often thought of as advanced technology for specialized settings, but the potential for improvement in health care delivery and revenue enhancement may be through invention/innovation in routine care activities in primary care setting. In an effort to explore how academic generalists in primary care settings can contribute to and collaborate in this new academic mission, we examined the United States patent database in order to determine the relevance of patent applications for the primary care setting .
METHODS: The US Patent and Trademark Office database contains the full text of nearly 200,000 patent applications issued from 1976 to the present. Each patent application has a separate, searchable web page that contains a detailed description and references of the invention/innovation. A search of all patent applications with the free text word "primary care" yielded 1194 patents from which a 10 % random sample was chosen for further review. Three investigators separately examined abstracts of patent applications to determine agreement on relevance to primary care (yes or no) and establish categories of the invention/innovation.
RESULTS: From the random sample of 119 patent applications reviewed, three were repeat applications. Filing dates for the applications ranged from Nov 27, 2000 to May 25, 2012. 59.5 % (69/116) of patent applications identified using the free text word search were actually relevant to primary care activities. The number of occurrences of the phrase "primary care" in the 116 patent documents ranged from 0 to 23, and patents relevant to primary care had more "primary care" occurrences than those judged as not relevant. (mean 1.7 vs 2.9). The most common invention/innovation categories were diagnostics (27.5 %, 19/69), therapeutics (24.6 %, 17/69), computer software 13.0 %, 9/69), health care administration (10.1 %), and communication systems (7.2 %). Specific patent documents better illustrate the relevance and potential for collaboration.
CONCLUSIONS: Primary care seems underrepresented in the U.S. patent database. Exploration of the database for the purpose of seeking primary care relevance is unwieldy. Still, identifiable patents relevant to primary care illustrate the potential for academic generalist to contribute and collaborate in the development of patentable inventions/innovations.

HOW PHYSICIANS' PRESENTATION OF INFORMATION ABOUT PCI TO PATIENTS WITH STABLE ANGINA MAY CONTRIBUTE TO THEIR BELIEF THAT IT IS A LIFE-SAVING INTERVENTION MIchael B. Rothberg[4]; Sarah L. Goff1,[2]; Kathleen M. Mazor[3]. [1]Baystate Medical Center/Tufts University School of Medicine, Springfield, MA; [2]CTSI/Tufts University School of Medicine, Boston, MA; [3]University of Massachusetts Medical School/Meyers PCI, Worcester, MA; [4]Cleveland Clinic, Cleveland, OH. (Tracking ID #1638724)

BACKGROUND: More than 600,000 percutaneous coronary interventions (PCI) are performed annually in the U.S. For patients with chronic stable angina, the benefit of PCI is limited to symptom reduction, yet many patients mistakenly believe that PCI will prevent myocardial infarction or death. We sought to illuminate how physicians' presentations of PCI may contribute to patients' misperceptions.
METHODS: Using the Verilogue Point-of-Practice Database (which includes visits with >600 physicians in 9 geographic regions throughout the U.S.), we searched outpatient/non-acute visit transcripts recorded between March 2008 and August 2012 for mention of PCI, cardiac catheterization, angiogram or stent placement. We included only transcripts of visits in which PCI was discussed with a cardiologist. After we developed an a priori codebook, one team member performed qualitative content analysis on all the transcripts, adding codes iteratively until theoretical saturation was achieved. A second member read a subset of transcripts and recommended revisions to the codebook. Codes were then revised and sorted into pertinent themes.
RESULTS: We analyzed 36 transcripts. Patients ranged in age from 44 to 88 years (median=67) and 9 (23 %) were women. "Rationale for recommending PCI" was identified as a major theme; sub-themes related

to how PCI benefit was presented included items that may contribute to patients' misperceptions. Many physicians informed patients that catheterization was the "only way to know for sure" about their coronary artery disease, suggesting that catheterization would be preferable to uncertainty about the presence, extent and location of disease. The implication was that once they "know for sure", an intervention could improve the patient's outcome; "That will show us for sure…then we can probably just [sic] go ahead….put in a stent… [and] have it taken care of ". Some physicians over-simplified the pathophysiology by using plumbing imagery "… sometimes we can also use a Roto-Rooter [to eliminate a blockage]". They also stated that PCI would "fix" the problem; "the next step forward is a cardiac catheterization, with the intent of fixing a problem if there is a problem". When patients questioned the need for PCI, some physicians overstated PCI benefits both implicitly and explicitly; "You sound good, you look good, but I want to keep it that way… I don't want things to happen to you while you're walking the steps or riding your bike," and "I wouldn't want you to have another heart attack." Only one physician explicitly stated that the only benefit of PCI for stable angina was symptom reduction and there would be no reduction in mortality or risk for MI. Although many physicians informed patients that they would need to take medication, few discussed maximizing medical management as an alternative to PCI. When discussions of alternatives to PCI did occur, it was generally only after a patient expressed hesitation about PCI.
CONCLUSIONS: In this study, some physicians presented information about PCI in a manner that may contribute to patients' misperception of the benefit of PCI for stable angina. A larger quantitative study is required to understand how often physicians may misrepresent the benefits of PCI when discussing it with patients.

HYPOACTIVE SEXUAL DESIRE DISORDER (HSDD): CONSISTENT EFFICACY AND SAFETY OF FLIBANSERIN TREATMENT IN BOTH PRE AND POSTMENOPAUSAL WOMEN James A. Simon[1,2]; Krista Barbour[2]; James Symons[2]. [1]George Washington University, Washington, DC; [2]Sprout Pharmaceuticals, Raleigh, NC. (Tracking ID #1629616)

BACKGROUND: Low sexual desire with personal distress (similar to HSDD) is the most common female sexual dysfunction affecting 10 % of pre and 20 % of postmenopausal women. Flibanserin is a novel 5-HT1A agonist/5-HT2A antagonist with secondary effects on dopamine and norepinephrine which is currently in development for HSDD.
METHODS: To generate long-term efficacy and safety data for flibanserin in pre- and naturally postmenopausal women with HSDD we conducted a 28-week, multicenter open-label extension study of women who completed one of three large, randomized, double-blind, placebo-controlled "parent trials" (n=2777, one in pre- and two in naturally postmenopausal women with HSDD). Subjects in the "extension" (premenopausal: n=346; postmenopausal: n=249) took Flibanserin 100 mg qhs.
RESULTS: Efficacy was assessed using the FSDS-R total score, and FSFI, validated scales for assessing sexual distress, and sexual function in HSDD, respectively. The study demonstrated a consistent reduction in distress (FSDS-R total and Q13), and increase in sexual function on the FSFI (total and desire) for pre- and post-menopausal women. Safety was determined using adverse events (AEs) and serious adverse events (SAEs). The majority of AEs were mild or moderate. None of the SAEs were considered related to treatment. The most common AEs (> 5 % of subjects) were (Pre/Postmenopausal): dizziness (8.7/10.8 %), somnolence (9.0/6.4 %), insomnia (5.2/5.2 %) and nausea (5.5/5.2 %).
CONCLUSIONS: Flibanserin 100 mg qhs was effective in increasing desire and decreasing distress associated with HSDD in both pre and postmenopausal women. Flibanserin's most common AEs are: dizziness, somnolence, insomnia, and nausea. No new AEs or SAEs were reported in this open-label extension. Flibanserin appears to be safe and effective for the treatment of HSDD in both pre and postmenopausal women. Additional studies are underway to confirm and extend these observations.

IDENTIFICATION OF HIGH-NEEDS PATIENTS DURING CARE HAND-OFFS Joshua T. Hanson[1,2]; Joanna Linsteadt1; Luci Leykum[1,2]. [1]UT Heath Sciences Center, San Antonio, San Antonio, TX; [2]South Texas Veteran's Healthcare System, San Antonio, TX. (Tracking ID #1642892)

BACKGROUND: After the 2003 ACGME Common Program Requirements limited duty hours, several studies estimated an increase in the number of patient care hand-offs from 11 % to 40 % in the hospital. It can be assumed that further duty hour restrictions have maintained or increased the number of these hand-offs. There is not a validated system for effective hand-offs despite these increased numbers of hand-offs and calls for such a system. There are widely used idealized systems, which do stress for the identification of patients that may require more attention. The skills necessary to identify these high needs patients have not been delineated. Our goal was to determine whether interns, residents, and attending physicians could identify these high use patients to the nighttime physician.
METHODS: Five housestaff teams were surveyed over eight days in a three-month span. Team members were asked to identify which patients would require the most attention by the nighttime physician responsible for their care. The following morning the nighttime physician would identify these high needs patients.
RESULTS: Complete data, as defined as patients identified from at least one member of the daytime team and the nighttime physician, were obtained from 52 out of a possible 160 encounters. At least one patient was appropriately identified in 37 of the 52 (71.2 %) encounters. Both high needs patients were correctly identified in 7 of 52 (13.5 %) encounters. Interns correctly identified at least one patient in 26 of 34 (76.4 %) encounters, while residents correctly identified at least one patient in 9 of 11 (81.8 %) encounters. Attending physicians correctly identified at least one patient in 2 of 7 (28.6 %) encounters.
CONCLUSIONS: These data suggest physicians may be able to identify some, but not all, of those patients that will require the most clinical care over the course of the night. Additionally, these data suggest that those physicians who provide the closest care, namely interns and residents, may be best able to identify those patient, though the attending data is too sparse to draw definitive conclusions. It would be important to gather this data from senior physicians working without housestaff in a clinical capacity to understand the intersection of experience and proximity to individual patient care. Furthermore, it would be interesting to examine the characteristics of the patients and how the physicians came to their conclusions regarding identification. This may lead to better understanding of how to teach these important skills for patient care transitions.

IDENTIFICATION OF LEARNER NEEDS TO CREATE A CURRICULUM IN HIGH-VALUE CARE Laura Loertscher; Tom Chau. Providence St. Vincent, Portland, OR. (Tracking ID #1641628)

BACKGROUND: Because escalating healthcare costs strain both individuals and society, physicians must curb wasteful practices and teach high-value, cost-conscious care to future providers. While uniquely positioned to advance this national priority, the medical education community knows relatively little about the current understanding and needs of physician trainees regarding cost-effectiveness. We describe resident practices and attitudes surrounding value-based care as well as their perceptions of the primary drivers of over-utilization.
METHODS: We conducted this study at a single, community-based internal medicine program with 26 residents. Prior to implementation of a new curriculum in high-value care, we performed a baseline survey of the residents in July 2012. The questionnaire was designed by the primary investigators with input from experts in medical education and clinical informatics. Responses to 5 case scenarios were used to stratify resident utilization of medical services along a scale of underuse, appropriate use, and overuse. Residents also rated a battery of healthcare utilization behaviors and attitudes on a Likert scale to identify the drivers of overuse. Mean responses are presented and the paired Mann–Whitney U test was used to compare groups of responses. The Binomial Exact Test was used to assess for overuse in the clinical scenarios.

RESULTS: Fourteen of 26 (54 %) eligible residents completed the survey. Residents agreed that health care costs in the US are too high (mean 4.9; 1=strongly disagree, 5=strongly agree) and waste represents a significant portion of the high cost (4.4). Residents reported that they and others frequently order unnecessary or cost-ineffective care, from occasional (about once a week) to often (several times a week). In response to sample clinical scenarios, residents over-ordered interventions more frequently than they under-ordered ($p<0.05$). They identified the most important drivers contributing to overuse as defensive medicine (mean 4.4), discomfort with uncertainty (4.2), patient demands (3.9), physician unawareness of cost (3.9), and reliance on sub-specialists (3.9).
CONCLUSIONS: Response to clinical scenarios and self-report indicate that residents frequently over-utilize interventions. A culture within medical education that rewards intellectual curiosity, thoroughness, and commitment to the individual patient may contribute to the liberal use of resources. However, our findings show that residents perceive defensive medicine, discomfort with uncertainty, patient requests, cost unawareness, and sub-specialty reliance as key drivers. Some of these factors may particularly affect less experienced physicians and represent critical targets when developing curricula for a generation of physicians that must learn to provide high-value care.

IDENTIFYING KEYS TO SUCCESS FOR REDUCING READMISSIONS: USING THE IDEAL TRANSITION IN CARE FRAMEWORK

Robert Burke[1,3]; Ruixin Guo[3]; Gregory J. Misky[2,3]. [1]Denver VA Medical Center, Denver, CO; [2]University of Colorado School of Medicine, Denver, CO; [3]University of Colorado School of Medicine, Denver, CO. (Tracking ID #1637876)

BACKGROUND: Failures during transitions of care from the hospital to the community are common and costly. Though many interventions to improve transitions of care and decrease hospital readmission have been tried, best practices are lacking. A framework for understanding transitions of care may help identify best practices. The Ideal Transition in Care framework proposes ten domains needed for safe transitions, allowing categorization of prior interventions. This framework was used to critically examine prior interventions aimed at reducing readmissions, and to evaluate which domains are most associated with successful interventions that reduce readmission rates.
METHODS: Prospective interventions to reduce readmissions published after January 1995 were reviewed (61 interventions). The authors independently assessed which of the ten domains of the Ideal Transition in Care each intervention included. The relationship between presence of each of the 10 domains aggregated over prior studies and a statistically significant reduction in readmission rates was evaluated in bivariate and multivariate analysis. Multiple logistic regression was used to analyze the relationship between the total number of domains included and reduction of readmissions, adjusted for study size, quality, and duration.
RESULTS: Prior interventions addressed 3.5 domains on average; 23 % addressed five or more. Domains most often included addressed patient education, programs for monitoring and managing symptoms after discharge, and care coordination. Advanced Care Planning was not included in any study, while enhancing communication with outpatient providers and recruiting community supports were rarely included. Educating Patients to Promote Self-Management, Monitoring and Managing Symptoms after Discharge, and Enlisting Help of Social and Community Supports were each associated with a significant reduction in readmissions ($p<0.05$), with the former two showing a trend towards significance after adjustment for multiple comparisons ($p=0.06$). In multivariate analysis, the number of domains included in an intervention was the only significant predictor of successfully reducing readmissions, when adjusting for quality, duration, and size ($R2=0.175$, $p=0.002$). Inter-rater reliability assessing whether a domain was present or not in a given intervention was moderate ($\kappa=0.47$).
CONCLUSIONS: Interventions to reduce hospital readmissions have historically been centered on a few select domains with relative neglect of others. The number of domains included in a given intervention is the most important factor in successfully reducing readmissions. These findings indicate the need for multi-component interventions to improve transitions of care, with particular focus on three key domains: Educating Patients to Promote Self-Management, Monitoring and Managing Symptoms after Discharge, and Enlisting Help of Social and Community Supports.

IDENTIFYING AND OVERCOMING THE BARRIERS TO BEDSIDE ROUNDS: A MULTI-CENTER QUALITATIVE STUDY

Jed Gonzalo[1,2]; Brian S. Heist[2]; Briar Duffy[3]; Liselotte Dyrbye[4]; Mark J. Fagan[5]; Gary S. Ferenchick[6]; Heather Harrell[7]; Paul Hemmer[8]; Walter N. Kernan[9]; Jennifer R. Kogan[10]; Colleen Rafferty[1]; Raymond Wong[11]; Michael Elnicki[2]. [1]Penn State College of Medicine, Hershey, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]University of Minnesota School of Medicine, Minneapolis, MN; [4]Mayo Clinic College of Medicine, Rochester, MN; [5]Alpert Medical School of Brown University, Providence, RI; [6]College of Human Medicine, Michigan State University, East Lansing, MI; [7]University of Florida College of Medicine, Gainesville, FL; [8]Uniformed Services University of the Health Sciences, Bethesda, MD; [9]Yale University School of Medicine, New Haven, CT; [10]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [11]Loma Linda University School of Medicine, Loma Linda, CA. (Tracking ID #1635018)

BACKGROUND: Bedside rounds in teaching hospitals have declined, despite recommendations from educational leaders to promote this effective teaching strategy. Literature suggests this decline is due to patient discomfort, perceived inefficiencies, and trainee apprehension. We interviewed current-day bedside teachers to identify: 1) actual barriers encountered during bedside rounds, 2) methods used to overcome trainee apprehension, and 3) potential strategies to promote bedside teaching.
METHODS: To address our research questions, we performed a qualitative thematic analysis of transcripts from digitally recorded, one-on-one telephone interviews with 34 bedside teachers. We recruited one co-investigator from 10 U.S. institutions and asked each to recruit three to six bedside teachers who actively served as inpatient attending physician and performed "bedside rounds" a minimum of 3 weekdays while on service. We defined "bedside rounds" as the team presenting the history or reviewing one physical exam component, while also discussing the management plan at the bedside; we explicitly excluded other forms of rounds not meeting these criteria, such as rounds occurring in the hallway. During data collection, the lead investigator took notes and using the process of constant comparative analysis, identified themes and categories and generated a preliminary codebook. Two investigators then analyzed transcripts independently, with regular adjudication sessions to compare codes and modify the codebook. Here we report the themes that emerged from analysis.
RESULTS: The 34 participants averaged 14 years of academic experience and were mostly associate or full professor (51 %). Rather than inefficiency or patient discomfort, the key barriers encountered during bedside rounds included time constraints (work-hour mandates), systems issues (eg. geographic admitting) and productivity demands. Six primary themes to overcome trainee apprehensions were identified: 1) Build a partnership to get "buy-in," 2) Create a safe, non-punitive environment, 3) Overcome with experience, 4) Make bedside rounds educationally worthwhile, 5) Respect house staff time, and 6) Highlight positive impact on patient care. Although numerous strategies to educate faculty on bedside rounds were suggested, one-on-one mentoring strategies, such as a "Two-Way Shadowing Program" allowing for experienced and inexperienced attending physicians to work together in an observatory-feedback relationship, was believed to be high yield.
CONCLUSIONS: Bedside teachers identified barriers encountered while performing bedside rounds, which are not fully commensurate with the

perceived barriers identified in the literature and reflect the increasing pressures of inpatient medicine. Although "trainee apprehensions" has been identified as a major barrier, our participants were less likely to encounter this barrier, likely explained by their employed strategies to focus efforts on trainees' concerns, adjustment period, and steps to increase odds of successful initial encounters. Likewise, prior studies have also found that trainees with more experience with bedside activities were more likely to prefer them. Although "time" was a major barrier identified by our participants, the gains of patient centered, point-of-service care and trainee education outweighed these concerns and did not preclude the occurrence of bedside rounds. These conclusions should inform faculty development efforts aimed at promoting bedside teaching.

IDENTIFYING AND REDUCING BARRIERS TO PAIN MANAGEMENT: A UNIQUE HOSPITALIST/PAIN MEDICINE COLLABORATION Cameron S. Page[1]; Dahlia Rizk[1]; Rebecca Calabrese[1]; Marilyn Bookbinder[2]; Steven E. Flores[2]; Russell Portenoy[2]. [1]Beth Israel Medical Center, New York, NY; [2]Beth Israel Medical Center, New York, NY. (Tracking ID #1642989)

BACKGROUND: Patient satisfaction scores will soon affect hospital reimbursement, and effective pain control is a key element of satisfaction with an inpatient experience. A recent study at a large urban hospital estimated that 40 % of inpatients have moderate-to-severe pain at least once during their stay. Despite many strategies devised to manage these episodes, inpatient pain remains a persistent challenge for hospitals. Categories of barriers to pain control have been identified, but the frequency of individual barriers has not been quantified. We describe the prevalence of barriers and their change over time.
METHODS: A Nurse Practitioner (NP) with experience in pain management visited inpatient units where most patients were cared for by hospitalists. For every patient with uncontrolled pain (defined as three scores greater than five in the past 24 h), the NP spoke with the attending physician, resident, and nurse, and reviewed the chart. This data was coded into discrete barriers to pain control.
RESULTS: Between February and April, 499 patients had pain on one or more days. 52 % were female, and the average age was 55. 44 % had a history of chronic pain, 18 % had a history of psychiatric disease, and 12 % had a history of substance abuse. A total of 56 potential barriers to pain control were initially identified. The most frequent barrier, "Presence of a pre-existing chronic pain syndrome," was recorded 256 times in February and 253 times in May 2012 (1.2 % decline). The second most frequent barrier, "Pain medication not changed due to need to observe current therapy" dropped from 113 occurrences to 2 (99.9 % decrease). 158 patients had uncontrolled pain for three or more days. During the study, the number of patients with uncontrolled pain for three or more days dropped from 47 in February to 33 in May (34 % decline, $p=0.083$). The total number of unique barriers declined from 32 in the first month of the study to 21 in the final month (34 %).
CONCLUSIONS: The presence of a dedicated pain management NP making rounds on patients was associated with a decrease in the recorded barriers to pain control. The large decline in physicians choosing to "observe current therapy" before escalating care has several possible explanations. Informal discussion with a NP experienced in pain management may have given the primary team confidence to more rapidly escalate care. There may also have been a Hawthorne effect, in which providers who know they are being observed are more attentive to pain control. Further research is needed to evaluate the association between change in barriers and pain scores.

Most Frequent Barriers to Pain Cotrol February 2012 May 2012 % Change
Presence of pre-existing chronic pain syndrome 256 253–1.2
Pain medication not changed due to need to observe current therapy 113 2–99.9
Pain control difficult due to severity of medical disease 91 134+48.6
Patient admitted on analgesic therapy 89 103+22.4
MD concerned about medication side effects 23 10–52.1

IDENTIFYING MEDICATION DISCREPANCIES THROUGH LINKED ADMINISTRATIVE PHARMACY CLAIMS Dominique Comer[1]; Joseph Couto[1]; Ruth T. Aguiar[2]; Edward Ratledge[3]; Daniel J. Elliott[2]. [1]Jefferson School of Population Health, Philadelphia, PA; [2]Christiana Care Health System, Newark, DE; [3]University of Delaware, Newark, DE. (Tracking ID #1640924)

BACKGROUND: Medication reconciliation can be used to identify medication discrepancies between what a clinician has documented and what a patient is actually taking. Dramatic improvements in the availability of administrative pharmacy claims in the electronic health record (EHR) may facilitate accurate medication reconciliation, particularly in the ambulatory care setting. The objective of this study is to identify and characterize medication discrepancies through the use of linked pharmacy claims data.
METHODS: We conducted a retrospective cross-sectional study of patients who were prescribed a new antihypertensive agent within a large primary care practice network. Patients were included if they had a diagnosis of hypertension or elevated blood pressure at the time of the new prescription and at least one visit within the previous 18 months. In our system the pharmacy fill history was imported on an ad hoc basis by clinicians and practice staff, so we excluded patients who had not had an imported pharmacy refill history on or after the index visit date. Additionally, because of concerns about the completeness of the pharmacy data, we excluded patients who did not have evidence of at least one claim in the pharmacy fill history prior to the index visit date. All pharmacy claims within the 120 days prior to the new prescription were compared to the medication lists from the physician EHR. Prescribed medications were considered active if the prescriber's history showed that the medicine was still to be taken at the time of the index visit. The primary outcome was the number of medication discrepancies, defined as a medication that appears on either the EHR medication list or the pharmacy fill claims list but not both. Differences in dose were not considered medication discrepancies. Key covariates include patient demographics, previous utilization and count of total medications.
RESULTS: We identified 269 patients who met study criterion. The average age (SD) was 58.5 years (13.8), 65 % were female, 23.1 % of patients were black, and 52.6 % were white, and 24.3 % were of another ethnicity or undetermined. There were a total of 2166 active medications in the EHR prescribed lists (average of 8.1 medications per patient) and 1344 medications in the fill history (average of 5.0 medications per person). Of the active medications in the physician list, 1002 (46.3 %) were matched to a claim in the pharmacy fill history; the remaining 1164 (53.7 %) were not matched to a medication in the fill history. Overall, patients had an average (SD) of 5.6 (4.0) medication discrepancies. Of the unmatched medications found in the pharmacy fill history, 57 (17 %) were controlled substances.
CONCLUSIONS: The real-time availability of pharmacy fill history to providers in clinical practice has the potential to dramatically enhance medication reconciliation by providing objective documentation of what a patient is filling at the pharmacy. In our cohort we identified frequent medication discrepancies between the pharmacy fill history and the prescriber's record. Importantly, there was a high prevalence of medications that patients had filled that were not recorded in the prescribing record, of which many were controlled substances. Our findings suggest that the availability of pharmacy claims may provide valuable information to providers as they conduct medication reconciliation.

IDENTIFYING SUPER DIFFUSERS OF HEALTH INFORMATION: ASSESSING THE RELIABILITY OF THE CONNECTIVITY, PERSUASIVENESS AND MAVEN SCALES AMONG SPANISH- AND ENGLISH-SPEAKERS Kenzie A. Cameron[1]; Vanessa Ramirez-Zohfeld[1]; Francisco Acosta[1]; Alfred W. Rademaker[2]; Franklin J. Boster[3]. [1]Northwestern University, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Michigan State University, East Lansing, MI. (Tracking ID #1641662)

BACKGROUND: Identifying influential individuals other than providers to promote health behavior change is an alternate route to commonly used

methods of patient education. The expanding use of patient navigators to augment the healthcare system is one prominent example. Individuals who are well-connected to others, are effective persuaders, and are viewed as having subject expertise (i.e., "mavens") may have the ability to reach diverse populations, and could serve as effective diffusers of information. This study assesses the reliability of three influence scales, originally developed and validated in English, which could be of assistance in identifying such influential individuals.

METHODS: Data were extracted from an ongoing study with English and Spanish-speaking patients. We modified existing Connectivity, Persuasiveness and Maven scales by reducing the number of items per scale from five to three, and rephrasing some items to reduce complexity. Items were translated into Spanish. Principal components analysis was used to identify independent factors in scales; Cronbach's alpha examined the reliability of the scales as a whole and by language. To assess ease of understanding of these new items, participants were asked to respond to the item: "Were these questions about how you interact with others easy to understand?" Participant responses were dichotomized (yes, no/don't know) and Fisher's exact test was used to compare ease of understanding of the questions by language.

RESULTS: Mean age among 486 participants was 57.8 (SD=6.1); 72.8 % were female. English-speakers comprised 57.6 % of the sample; 46.3 % were Hispanic/Latino, and 51.9 % African American. Regarding education, 30.9 % of patients reported 0–6 years, 47.5 % reported 7–12 years and 20.8 % had 13 or more years of education. Using principal components analysis (varimax rotation), three factors emerged overall: 1) persuasiveness (Eigenvalue=3.36, 37.3 % variance explained), 2) connectivity (Eigenvalue=1.34, 14.8 % variance explained), and 3) maven (Eigenvalue=1.26, 14.0 % variance explained). The same three factors were identified when assessing English and Spanish-speakers separately; eigenvalues and percentage of variance explained by each factor varied slightly. Scales demonstrated moderate to high internal consistency: persuasiveness Cronbach's α=0.77 (0.70 English subsample, 0.84 Spanish subsample), connectivity Cronbach's α=0.76 (0.68 English, 0.86 Spanish), and maven Cronbach's α=0.68 (0.62 English, 0.74 Spanish). Further, 88.1 % of participants indicated that scale questions were easy to understand, although English speakers were more likely to agree that the items were easy to understand (90.7 %) than were Spanish speakers (84.5 %, $p<0.05$). Mean scores on persuasiveness and connectivity increased with increasing education; a curvilinear relationship was found with maven items, such that participants with 0–6 and with 13+ years were significantly more likely to report higher mean scores than those with 7–12 years of education (all $p<0.005$).

CONCLUSIONS: This study of the modified and translated Persuasiveness, Connectivity, and Maven scales suggests the constructs are measured reliably in both English and Spanish. Being able to identify such super diffusers of health information may help to advance preventive health interventions, particularly those using peer facilitators or peer navigators as well as community based interventions.

IDENTIFYING THE RISKS OF ANTICOAGULATION IN PATIENTS WITH SUBSTANCE ABUSE Lydia M. Efird[2]; Donald R. Miller[1,3]; Arlene S. Ash[1,2]; Dan Berlowitz[1,2]; Al Ozonoff[1,4]; Shibei Zhao[1]; Joel Reisman[1]; Guneet Jasuja[1,3]; Adam Rose[1,2]. [1]Beford VA Medical Center, Bedford, MA; [2]Boston University School of Medicine, Boston, MA; [3]Boston University School of Public Health, Boston, MA; [4]Boston Children's Hospital, Boston, MA. (Tracking ID #1620372)

BACKGROUND: Warfarin is effective in preventing thromboembolic events but concerns exist regarding the risks of its use in patients with substance abuse. Clinicians often confront a dilemma and may choose not to prescribe anticoagulation, realizing that the patient will be at risk for thromboembolic events. Or clinicians may prescribe, without knowing the likelihood of successful anticoagulation control or the risk of hemorrhagic events. The goal of the study is to identify which patients with substance abuse might safely receive warfarin and in which it is best avoided.

METHODS: Among 103,897 patients who received warfarin from the Veterans Health Administration, ICD-9 codes identified 6,781 who abused drugs or alcohol. Specific substance abuse-related diagnostic codes (including number of times coded and outpatient and inpatient diagnoses), as well as lab values (including serum albumin, and highest recorded bilirubin, ALT, AST, ratio of AST:ALT) and other factors were examined as putative markers for disease severity. Outcomes included percent time in therapeutic range (TTR), a measure of anticoagulation control, and major hemorrhagic events. Major hemorrhages were obtained by ICD-9 codes meeting one of following criteria: associated with death within 30 days, blood transfusion, bleeding into a critical site, or cited as the main reason for hospitalization. TTR was compared among groups using ANOVA. Hazard Ratio for major hemorrhage over the 2-year study period was compared using Cox proportional hazards, controlling first for age, and then for age and TTR.

RESULTS: Nonusers had a higher mean TTR (62 %) than those abusing alcohol (53 %), drugs (50 %), or both (44 %, $p<0.001$). Specific diagnostic codes, number of times coded, and other laboratory values offered some ability to predict TTR or hemorrhagic events, but the most profound finding was AST:ALT ratio. Among alcohol abusers, increasing ratio of AST:ALT correlated with inferior control; a normal AST:ALT(<=1.5) predicted a relatively modest decline in TTR (54 %), while elevated ratios (AST:ALT 1.50–2.0 and >2.0) predicted progressively poorer control (49 % and 44 %, both $p<0.001$ compared to nonusers). Compared to nonusers, the age-adjusted hazard ratio for major hemorrhage was 1.93 in those with drug abuse and 1.37 in alcohol abuse ($p<0.001$); these hazard ratios remained significant after also controlling for anticoagulation control (HR 1.69 drugs $p<0.001$, and 1.22 alcohol $p=0.003$). Among patients who abuse alcohol, an elevated AST:ALT >2.0 was associated with a considerable increase in hemorrhagic events (HR 2.26, $p<0.001$), while a normal ratio AST:ALT <=1.5 predicted a hazard similar to that of nonusers (HR 1.03, $p=0.75$).

CONCLUSIONS: Anticoagulation control is particularly poor in patients with substance abuse. Major hemorrhages are more common, which is only partially explained by poorer anticoagulation control. Among alcohol abusers, the ratio of AST:ALT holds promise for distinguishing those at highest risk for adverse events from those whose risk may not differ meaningfully from that of the overall population.

IDENTIFYING THE RISKS OF ORAL ANTICOAGULATION IN PATIENTS WITH LIVER DISEASE Lydia M. Efird[2]; Adam Rose[1,2]. [1]Beford VA Medical Center, Bedford, MA; [2]Boston University School of Medicine, Boston, MA. (Tracking ID #1634419)

BACKGROUND: Chronic liver disease is thought to present a relative or even an absolute contraindication to warfarin therapy, but some patients with liver disease nevertheless will require long-term anticoagulation. The goal of this study is to identify which patients with liver disease might safely receive warfarin and in which patients it is best avoided.

METHODS: Among 102,134 patients who received warfarin from the VA from 2007 to 08, ICD-9 codes identified 1,763 with chronic liver disease. Laboratory values including lowest serum albumin, mean creatinine, highest AST, and lowest total cholesterol were examined as a means of identifying patients at higher risk among this group. Outcomes included percent time in therapeutic range (TTR), a measure of anticoagulation control, and major hemorrhagic events, as identified by ICD-9 codes. Hazard Ratio for major hemorrhage over the 2 year study period was compared using Cox proportional hazards, controlling first for age, and then for age and TTR.

RESULTS: Patients with liver disease of any kind had a lower mean TTR (53.1 %) compared with patients without such diagnosis (61.7 % $p<0.001$), as well as more hemorrhagic events (age-adjusted HR 1.93, $p<0.001$). Of the variables among patients with liver disease, the serum albumin level and the serum creatinine level were the strongest predictors of TTR and major hemorrhage. We created a 4-point composite score based on these

two variables: patients received one point each for mildly abnormal albumin (2.5–3.49 g/dL) or creatinine (1.01–1.99 mg/dL), and two points each for severely abnormal albumin (<2.5 g/dL) or creatinine (≥2 mg/dL). This composite score, which assigned each patient a risk score between 0 and 4 points, predicted both anticoagulation control and hazard for major hemorrhage (see Table). Compared to patients without liver disease, those with a score of zero had only a modest decline in TTR (59 %) and no significant increase in hemorrhagic events (HR 0.73, NS), while those with a score of four had very poor control (41.4 %) and more hemorrhages (HR 5.41 $p<0.001$). The risk of hemorrhage remained significant and was only mildly attenuated after controlling for anticoagulation control.

CONCLUSIONS: Overall, patients with liver disease have an elevated risk for major hemorrhage when receiving warfarin, which is only partly explained by poor anticoagulation control. Among patients with liver disease, a simple four-point composite scoring system using both serum albumin and creatinine identifies those at highest risk for poor anticoagulation control and major hemorrhagic events.

Composite Scoring System, Using Serum Albumin and Creatinine, to Predict the Risk of Major Hemorrhage in Patients with Liver Disease Receiving Warfarin

Liver Disease and Composite Risk Score Number of Patients Mean % Time in Therapeutic Range (TTR)* Number of Major Hemorrhages Hazard Ratio for Major Hemorrhage, Adjusted for Age (95 % CI) Hazard Ratio for Major Hemorrhage, Adjusted for Age and TTR (95 % CI)

ILLUSTRATED INSTRUCTIONS IMPROVE MEDICATION UNDERSTANDING: A RANDOMIZED CONTROLLED TRIAL Sunil Kripalani[1,2]; M Brian Riley[2]; Dane R. Boyington[2]; Arun Mohan[3,2]. [1]Vanderbilt University, Nashville, TN; [2]PictureRx, LLC, Chattanooga, TN; [3]Emory University, Atlanta, GA. (Tracking ID #1642577)

BACKGROUND: Many patients with chronic disease struggle to understand medication information, which contributes to poor adherence and outcomes. Patients with low health literacy or limited English proficiency are particularly at risk. We tested the effect of providing illustrated, plain language medication instructions on patients' medication understanding, adherence, and satisfaction.

METHODS: Latino patients with diabetes at 2 safety net clinics were randomized to receive usual care or usual care plus a PictureRx illustrated medication schedule. The PictureRx card showed the patient's full medication regimen, including a picture of each medication, its purpose, and a simple grid to show how much should be taken at each time of day (morning, noon, evening, and night). The PictureRx card included medication instructions in plain language, in both Spanish and English. Usual care patients received a list of their medications (text only), which was in their preferred language and also gave the drug indication. Outcomes were assessed by telephone interview approximately 1 week later. The Medication Understanding Questionnaire (MUQ) measured patients' ability to report the indication, strength, dosing, and frequency for up to 5 medications selected at random from their own medication regimen. Self-reported adherence and satisfaction were secondary outcomes. Analysis was performed by intention to treat, using independent samples t-tests.

RESULTS: Of 200 enrolled participants, 197 (98.5 %) completed follow-up. Participants had a mean age of 50 years, and 70 % were women. Most (71 %) had not completed high school, and 59 % had low health literacy. The mean number of prescribed medications was 4. Patients randomized to PictureRx cards had better overall understanding of their medications ($p<0.001$), including greater ability to report the drug indication ($p<0.01$), strength ($p<0.05$), dosing ($p<0.01$), and frequency of administration ($p<0.001$). Self-reported adherence did not differ significantly between study groups. Patients who received PictureRx cards were very satisfied. Nearly all (99 %) reported that the tool was clear and easy to read and that it helped them to remember which medicines to take (96.9 %) and when to take them (96.9 %). About 9 of 10 patients (90.9 %) said that they planned to take the PictureRx card with them to their next medical appointment.

CONCLUSIONS: In this randomized controlled trial, patients who received illustrated, plain language medication instructions demonstrated significantly greater understanding of their medication regimen. Such tools have potential to improve medication use and chronic disease control, as well as reduce health disparities.

IMPACT OF HYPOTHETICAL GENETIC BREAST CANCER RISK INFORMATION ON BEHAVIORAL INTENTIONS Monica Ferguson[1]; E. P. Wileyto[2]; Carrie Inge[3]; Marilyn M. Schapira[1]. [1]University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA. (Tracking ID #1640720)

BACKGROUND: Average lifetime breast cancer risk is approximately 13 % for women in the U.S. A sizeable number of women at increased risk for breast cancer are eligible for early detection and risk reduction strategies such as breast MRI or chemoprevention. Yet, very few women considered high risk adopt these strategies. Breast cancer risk is most often determined by a calculated 5-year or lifetime risk using the Gail or Claus models. However, genetic information is increasingly being used to further define breast cancer risk. The purpose of this study was to evaluate the impact of providing hypothetical genetic breast cancer risk information on early detection and risk reduction behavioral intentions.

METHODS: We conducted a randomized study using breast cancer risk scenarios based on hypothetical genetic test results. Subjects were recruited from seven radiology sites in southeastern, Pennsylvania after presenting for screening mammography. Breast cancer risk was calculated based on the Gail and Claus models and each subject submitted a biological sample to determine risk based on genetic testing. Subjects were contacted by phone 1 year after receiving a letter with their individualized risk profile based on the Gail and Claus models and then randomized to one of three risk scenarios based on hypothetical genetic test results. Subject were asked about their intentions to get an MRI, take tamoxifen, take raloxifene, or consider a prophylactic mastectomy if the genetic test showed their breast cancer risk was increased by 50 %, increased by 20 %, or decreased by 50 %. We used logistic regression to assess the effect of the hypothetical risk scenarios on the outcomes of interest.

RESULTS: Three hundred fifty-two subjects completed the telephone survey. Mean lifetime breast cancer risk was 12 % based on the Gail model and 14 % based on the Claus model. The average age of the subjects was 52 years (SD 8). Sixty-one percent of the subjects were Caucasian and 34 % were African-American. Subjects who were told the genetic test information increased their lifetime breast cancer risk by 50 % or 20 % were significantly more likely to report they would undergo MRI (OR 3.58, 95 % CI 1.86–6.93; OR 1.81, 95 % CI 1.03–3.9) than those who were told their risk was decreased by 50 %. Subjects who were told their risk increased by 50 % were also more likely to consider prophylactic mastectomy (OR 2.33, 95 % CI 1.25–4.36). In multivariate analysis, after controlling for race and baseline 5-yr Gail risk, these significant effects persisted. Black race had a significant association with each intention: MRI (OR 2.28, 95 % CI 1.24–4.19), tamoxifen (OR 2.31, 95 % CI 1.14–3.81), raloxifene (OR 2.11,95 % CI, 1.28–3.81, and prophylactic mastectomy

(OR 3.05, 95 % CI 1.79–5.21). There were no interactions between race and hypothetical risk assignment.
CONCLUSIONS: Our findings suggest that communication of genetic test results with relative risk information has a significant effect on behavioral intentions associated with breast cancer risk reduction. However, the findings were not uniform across interventions. Diagnostic and surgical interventions were more sensitive to the hypothetical genetic test results than intentions to use chemoprevention. The effect of race on the behavioral intentions suggests sociodemographic factors may also be important. These findings highlight the complex nature of communicating cancer risk and the challenges of optimizing personalized breast cancer risk reduction interventions.

IMPACT OF MASSACHUSETTS HEALTH CARE REFORM ON INSURANCE COVERAGE, ACCESS TO AND RECEIPT OF CARE AND HEALTH STATUS AMONG PATIENTS WITH CARDIOVASCULAR DISEASE OR RISK FACTORS Danny McCormick[1,2]; Amresh D. Hanchate[3,4]; Karen E. Lasser[4]; Mengyun Lin[4]; Meredith D'Amore[4]; Nancy R. Kressin[3,4]. [1]Cambridge Health Alliance, Cambridge, MA; [2]Harvard Medical School, Cambridge, MA; [3]VA Boston Healthcare System, Boston, MA; [4]Boston University School of Medicine, Boston, MA. (Tracking ID #1642485)

BACKGROUND: Cardiovascular disease (CVD) is the leading cause of morbidity and mortality in the US, and racial and ethnic disparities in CVD prevalence and treatment disproportionately shorten life expectancy for minorities. Massachusetts (MA) health care reform, the model for US national health care reform, increased insurance coverage rates; however, its impact on coverage, access to care and health status among patients with CVD or cardiovascular risk factors (CVRF) or racial disparities in these outcomes is unknown.
METHODS: We analyzed data from the Behavioral Risk Factor Surveillance System (BRFSS), representative statewide cross-sectional surveys from MA and seven "control" states that did not undergo health reform (RI, VT, NH, CT, NY, NJ and PA), before (2005) and after (2009) MA health reform implementation. The survey sample (n=6,698 in MA, and 28,455 in control states) consisted of adults age 18–64 (those targeted by the reform) who reported having CVD (history of myocardial infarction or stroke) or 2 or more CVRFs (current cigarette smoking, hypertension, hyperlipidemia, obesity [BMI >30] and age>50 for men and >55 for women). We estimated pre- to post- reform absolute differences (AD) and 95 % confidence intervals in MA in the proportion of individuals having insurance coverage, access to care, utilization of care and good/excellent health status using a "difference-in-differences" approach that accounted for secular trends in "control" states and patient demographic characteristics using linear probability models. We also examined changes in racial and ethnic disparities in these outcomes following reform.
RESULTS: We found increases in the proportion of MA respondents reporting having insurance (89.9 to 94.7 %; adjusted AD (aAD), 4.2 % [2.2, 6.2]), a personal doctor (90.6 to 94.2 %; aAD, 2.2 [0.37, 4.0]) and no financial barriers to seeing a doctor (89.1 to 91.4 %; aAD, 3.8 [1.6, 6.0]). We found no statistically significant changes in the proportion reporting a routine check up in the last year (79.9 to 83.4 %; aAD, −0.7 % [−2.8, 2.6]), taking a blood pressure medication among patients with hypertension (69.5 to 73.3 %; aAD, 0.7 % [−2.8, 4.2]), taking a lipid lowering medication among patients with hyperlipidemia (85.2 to 87.2; aAD; 0.35 [−2.6, 3.3]), having excellent/good health (80.0 to 79.8 %, aAD, −1.6 [−4.3, 1.0]), having no activity limitations due to health (75.0 to 73.7 %, aAD, 2.0 [−0.8, 4.8]) and not currently smoking cigarettes (46.1 to 42.3, aAD, −2.5 [1.3, −6.3]). There were no statistically significant changes or consistent trends in black-white or Hispanic-white disparities in insurance coverage (aAD, −4.0 [−13.2, 5.1] and 4.4 [−2.9, 11.7], respectively) or having no financial barriers to seeing a doctor (aAD, 2.7 [−5.3, 10.7] and −4.3 [−15.4, 6.7], respectively).
CONCLUSIONS: For patients with known CVD or CVRFs, MA health reform was associated with modest to small improvements in insurance coverage and access to care but no improvement in receipt of care or health status or in racial and ethnic disparities in coverage or access. Additional health care reform measures may be required to more substantially improve these outcomes for patients who are at high risk for or have CVD.

IMPACT OF MASSACHUSETTS HEALTH REFORM ON HOSPITALIZATIONS, LENGTH OF STAY AND COSTS OF INPATIENT CARE: DOES SAFETY-NET STATUS MATTER? Amresh D. Hanchate[1,2]; Danny McCormick[3]; Chen Feng[2]; Karen E. Lasser[2]; Nancy R. Kressin[1,2]. [1]VA Boston HealthcareSystem, Boston, MA; [2]Boston University School of Medicine, Boston, MA; [3]Harvard Medical School/Cambridge Health Alliance, Boston, MA. (Tracking ID #1641386)

BACKGROUND: There is widespread concern that large-scale insurance expansion—such as that anticipated from the Affordable Care Act—has the potential to cause sharp increases in health care utilization and costs. In the setting of Massachusetts' landmark 2006 health care reform, we estimated pre-reform to post-reform changes in inpatient care volumes and costs, contrasting the experience of safety-net hospitals (SNH) as the predominant providers of care for targeted reform beneficiaries, with that of non-SNH.
METHODS: We analyzed MA Hospital Inpatient Discharge Data on all non-federal MA hospital discharges from 2004 to 2010 for 2,636,326 non-elderly patients (age 18–64) - the population targeted by the reform—across all 66 short-term acute care hospitals. Safety-net hospitals were identified as those in the top quartile of hospitals (N=16) in the proportion of hospital admissions with Medicaid, Free Care (state-funded program for uninsured) and self-pay as the primary payer. Using the quarter as the unit of time, we examined longitudinal hospital-level changes in (a) number of admissions, (b) average length of stay (LOS; days), (c) average charge per day ($; 2010 prices) and (d) average charge per stay ($; 2010 prices), separately for SNH and non-SNH. We also examined changes for acute and non-acute admissions, and for subpopulations by race/ethnicity and socioeconomic status (SES; defined using patient zip code median income). We used linear regression models to estimate the average change between pre-reform (1/2004 to 6/2006) and post-reform (1/2008 to 6/2010) periods, adjusting for longitudinal changes in patient demographics and comorbidities at each hospital. To better isolate the impact of reform from secular state-wide trends, we treated the elderly (age 65+) as the "control" population and used a difference-in-differences model specification.
RESULTS: There was no significant post-reform change in the number of admissions; quarterly number of admissions per hospital were 1,480 pre-reform and 1,520 post-reform (p=0.68). A similar pattern was found for admissions at hospitals by safety-net status, for acute and non-acute admissions, and for minority and low-income subpopulations. Average LOS increased by a smaller amount among SNH (0.20 days; 95 % CI=[0.15, 0.25]) than among non-SNH (0.30 days; 95 % CI=[0.27, 0.33]). Average charges per day decreased among SNH ($-198; 95 %=[$-251, $-145]) and increased among non-SNH ($249; 95 %=[$215, $284]). A similar trend with a larger difference was found for average charges per stay (SNH=$-477; 95%CI=[$-768, $-187] and non-SNH=$1,442; 95%CI=[$1,248, $1,635]). Similar trends were found for both acute and non-acute admissions. Among blacks and Hispanics, none of the measures indicated larger increase in SNH compared to that in non-SNH; for low-income patients, increases in LOS and charges were smaller in SNH.
CONCLUSIONS: Following MA health reform, utilization of inpatient care did not increase at SNH, the predominant providers of inpatient care for populations targeted by the reform, compared to non-SNH. A similar trend was found for acute and non-acute admissions, and for minority and low-income subpopulations. Future analyses in the coming months will test robustness of these findings using the non-elderly patients from comparison states as the control population.

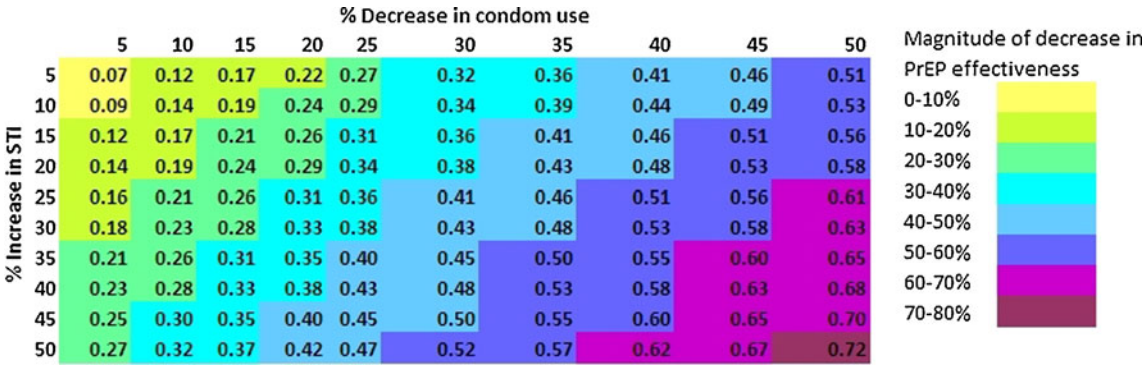
IMPACT OF ORAL HIV PRE-EXPOSUE-EXPOSURE PROPHYLAXIS IN MEN WHO HAVE SEX WITH MEN: A DECISION MODEL THAT INCORPORATES CHANGES IN CONDOM USE AND SEXUALLY TRANSMITTED INFECTIONS Anders Chen[1]; Geetanjali Chander[1]; David W. Dowdy[2]. [1]Johns Hopkins Medical Institutions, Baltimore, MD; [2]Johns Hopkins School of Public Health, Baltimore, MD. (Tracking ID #1632950)

BACKGROUND: In clinical trials, oral Pre-Exposure Prophylaxis (PrEP) reduced HIV transmission in men who have sex with men (MSM). However, condom use may decline in those using PrEP, which may in turn increase the prevalence of sexually transmitted infections (STI); both of these effects could paradoxically increase HIV transmission. We created a decision model that incorporates these effects in a simple framework designed to aid clinical decision-making as oral PrEP becomes more widely available.

METHODS: Using decision analysis, we constructed a model of HIV transmission in MSM ages 13–64 in high income countries. Our primary outcome was the annual probability of HIV infection, comparing PrEP to no PrEP among MSM, after accounting for changes in condom use and STI prevalence. Model parameters were obtained from the literature (including other highly-cited models of HIV transmission) and included baseline risk of HIV transmission per anal sex act (insertive vs. receptive); sexual frequency and partnership; antiretroviral use; and STI (HSV2, gonorrhea, chlamydia, syphilis, and HIV) prevalence. As the effect PrEP may have on condom use and STI prevalence outside of clinical trials is uncertain, we modeled a range of scenarios across a broad spectrum of values for these two parameters, thereby demonstrating the effects that these changes would have on the probability of HIV transmission. We present our results in a simple framework that can be used by clinicians in a variety of epidemiological and sociological conditions.

RESULTS: In the reference scenario, we assumed that oral PrEP reduces HIV transmission by 44 %, condom use reduces HIV transmission by 80 % per protected sex act, and prevalent STI in the HIV-negative partner increases HIV transmission by 3.5 fold. Under these assumptions, we estimated that a 20 % uptake of PrEP would reduce HIV transmission by 9 %, comparable to other models. However, if PrEP also reduced condom-protected sex acts by 10 % and increased STI prevalence by 10 %, this reduction fell to 7 % (a 14 % decrease in effectiveness). A 30 % reduction in proper condom use and a 10 % increase in STI would erase over one third of those gains. Figure 1 shows this anticipated reduction across a range of possible scenarios. On sensitivity analysis, these results were robust to changes in the prevalence of PrEP use, HIV prevalence and other key model parameters.

CONCLUSIONS: PrEP holds significant potential as a means of reducing HIV transmission in MSM, but this impact may be partially eroded by decreases in condom use and increases in STI prevalence. We use a readily-interpreted decision model to illustrate the expected magnitude of these losses in different clinical settings. Clinicians must proactively reinforce condom use, safe sex practices and other HIV prevention strategies in order to maximize the effectiveness of PrEP in reducing HIV transmission.



IMPACT OF PUBLIC REPORTING OF HOSPITAL READMISSION RATES ON EMERGENCY DEPARTMENT ADMISSION DECISIONS Matthew J. Press[1]; Zachary Meisel[2]; Michael Pesko[1]; Andrew Ryan[1]. [1]Weill Cornell Medical College, New York, NY; [2]University of Pennsylvania, Philadelphia, PA. (Tracking ID #1641645)

BACKGROUND: Beginning in July 2009, the Centers for Medicare and Medicaid Services began publicly reporting risk-standardized 30-day hospital readmission rates. Since approximately half of hospitalized patients are admitted through the emergency department (ED), hospitals may have responded to this policy in part by focusing their efforts to reduce readmissions on admission decisions in the ED. Our objective was to determine if public reporting of hospital readmission rates led to: 1) a decrease in the likelihood of admission to the hospital for patients seen in the ED following a recent hospitalization; or 2) an increase in the likelihood of admission to an observation unit for these patients.

METHODS: We performed a difference-in-differences analysis comparing the likelihood of admission to the hospital or to an observation unit for patients who presented to the ED within 7 days of a prior hospitalization versus patients who did not have a prior hospitalization within 7 days, before and after the implementation of public reporting of hospital readmission rates. We used data from 4 years before public reporting and 2 years after from the National Hospital Ambulatory Medical Care Survey, an annual, nationally representative survey of ED visits. We implemented our difference-in-differences model using logistic regression, controlling for patient demographic characteristics, clinical acuity, ED visit diagnosis, and secular trends in the outcomes for patients with and without a prior hospitalization.

RESULTS: We analyzed 97,991 ED visits by patients aged 18 or older, 4,106 of which were by patients who had a prior hospitalization within 7 days and 93,885 by patients who did not. For patients presenting to the emergency department within 7 days of a prior hospitalization, 34 % were admitted to the hospital and 3.4 % were admitted to an observation unit during the period prior to implementation of public reporting of readmission rates, versus 32 % and 2.7 %, respectively, for the period after. For patients without a recent hospitalization, 15 % were admitted to the hospital and 1.7 % were admitted to an observation unit prior to public reporting, versus 16 % and 2.5 %, respectively, after. Difference-in-differences estimates indicate that the changes in admissions to the hospital and to an observation unit for patients with a recent hospitalization compared to those without were not significant (admission to hospital: −0.5 percentage points, 95 % CI: −7.8, 6.9; admission to observation unit: −0.9 percentage points, 95 % CI: −3.1, 1.3). Results did not differ when the study sample was limited to patients with Medicare.

CONCLUSIONS: In the 2 years following its implementation, public reporting of hospital readmission rates did not lead to a change in admission decisions for patients who presented to the ED within 7 days of a prior hospitalization. National policies to reduce readmission rates that extend beyond public reporting—such as financial penalties—may lead hospitals to change processes of care in the ED. Evaluations of the impact of these policies should include an assessment of ED admission decisions.

IMPACT OF WORK CONDITIONS ON ERRORS AND QUALITY: A COMPARISON OF PRIMARY CARE CLINICS SERVING LARGE PROPORTIONS OF MINORITY PATIENTS TO THOSE THAT DO NOT Anita B. Varkey[1]; Linda Baier Manwell[2]; Said A. Ibrahim3; Roger Brown[2]; Neda Laiteerapong[4]; Mark D. Schwartz[5]; Eric Williams[6]; Diana Burgess[7]; Jacqueline Wiltshire[8]; Enid Montague[9]; Sara Poplau[10]; Mark Linzer[10]. [1]Loyola University Medical Center, Maywood, IL; [2]University of Wisconsin-Madison, Madison, WI; [3]VA Philadelphia Medical Center and Perelman University of Pennsylvania School of Medicine, Philadelphia, PA; [4]University of Chicago, Chicago, IL; [5]New York University School of Medicine and VA New York Harbor Health Care System, New York, NY; [6]University of Alabama-Tuscaloosa, Tuscaloosa, AL; [7]University of Minnesota Medical School and Minneapolis VA Health Care System, Minneapolis, MN; [8]University of South Florida, Tampa, FL; [9]Northwestern University, Chicago, IL; [10]Hennepin County Medical Center, Minneapolis, MN. (Tracking ID #1633878)

BACKGROUND: Racial disparities in care may be partly due to differences in work characteristics. We have reported that primary care clinics serving larger proportions of minority patients have less access to supplies, specialists and exam rooms. Also physicians in these clinics report more chaos, more time pressure, and less work control. Whether these work differences mediate quality of care in clinics with large minority populations is unknown. We compared chart audit data from clinics with larger versus smaller proportions of minority patients to assess associations between the work environment, medical errors and care quality.
METHODS: MEMO (Minimizing Error, Maximizing Outcome) is a 4-year longitudinal investigation involving primary care physicians and their adult patients with hypertension and/or diabetes. Chart audit data were contrasted between clinics with ≥30 % minority patients (Minority Clinics = MCs) versus <30 % (Non-Minority Clinics = NMCs). Work conditions considered as potential mediators of care quality included chaos, time pressure, work control, access to clinical resources, specialty referrals and exam rooms. In a series of two-level hierarchical (patient-physician) models, each work condition was tested as a potential mediator between minority clinic status and each error or quality outcome. Outcomes of interest included errors, quality, hypertension control, and diabetes control. An error score assigned a point for each missing care process (e.g., missed diagnosis, medication error, lack of cancer screening). A quality score assigned a point for each element of disease control according to national guidelines: hypertension control was defined as BP<140/90 for ≥50 % of recorded measurements and diabetes control was defined as a hemoglobin A1c ≤7.5 % for ≥50 % of recorded measurements in the 18-month audit period. Scores were normalized to a range of 0–100 by dividing the number of error/quality points by the number of applicable items and multiplying by 100. Models were adjusted for patient age, gender, and comorbidity, and physician age, gender, and specialty.
RESULTS: The sample included 287 physicians and 1207 patients in 73 clinics (26 MCs, 47 NMCs). Fewer rooms were available to physicians in MCs (2.1 vs 2.7 in NMCs, $p<0.001$). Overall adjusted error rates were almost 5 % higher in MCs than NMCs (29.6 % vs 24.8 %, $p<0.05$). While MC status predicted all mediators in the error models, only poor access to clinical resources (eg. supplies and equipment) completely mediated the relationship between MC status and total errors ($p<0.05$). Adjusted quality scores were not significantly different between MCs and NMCs (65.9 % vs 68.6 %, $p=0.38$). Exam room availability, however, was related to care quality in all clinics with each additional room increasing quality scores by almost 6 %. While hypertension control was similar between MCs and NMCs, BP control was lower in MCs with less specialist access (OR=0.33, 95 % CI 0.24, 0.46) and less room availability (OR=0.22, 95 % CI 0.16, 0.29). Diabetes control was worse for patients in MCs than in NMCs (OR= 0.51, 95 % CI 0.35, 0.73); with 24 % of this difference explained by less access to clinical resources.
CONCLUSIONS: Primary care work conditions, including lack of access to supplies, rooms, and referrals, was significantly associated with errors and quality, especially for MCs. Future work should assess if changes in work conditions can improve care quality and decrease medical errors for minority patients.

IMPACT OF A POPULATION MANAGEMENT SYSTEM ON PHYSICIAN PERCEIVED TIME DEVOTED TO PREVENTIVE CANCER SCREENING Jeffrey M. Ashburner[1]; Charlotte E. Ward[1]; Douglas Levy[1]; Adrian Zai[2]; Richard W. Grant[1]; Steven J. Atlas[1]. [1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA. (Tracking ID #1636311)

BACKGROUND: Advances in health information technology (HIT) allow the screening of patient populations independent of office visits. The impact of implementing such systems on the time physicians spend on these tasks during office visits is not known.
METHODS: We surveyed primary care physicians (PCPs) before and after implementation of a novel visit-independent, HIT population management system (TopCare—Technology for Optimizing Population Care in a Resource-limited Environment) for preventive cancer screening as part of a randomized trial involving 18 primary care (PC) practices within an academic PC network. PCPs in practices where the HIT intervention was implemented screened a real-time patient roster of their patients who were overdue for screening, and could choose the method of patient contact (reminder letter, refer directly to scheduling delegate or patient navigator) or defer screening. In control practices, PCPs were not involved in screening overdue patients using the HIT intervention. All PCPs (intervention and control) were asked to complete a survey about time devoted to cancer screening tasks before implementation of the HIT system and after 1-year. We hypothesized that the total amount of effort devoted to cancer screening tasks during office visits would decrease over 1-year among PCPs who used the HIT system. PCPs were asked how much time they spent during a typical half-day clinical session on each type of cancer screening (breast, cervical, colorectal), and what proportion of effort took place when the patient was not present. Post-implementation surveys included additional questions about satisfaction with the HIT system for PCPs in the intervention group. Pre and post-implementation survey responses were compared with McNemar's chi-square tests.
RESULTS: Response rates were 76 % (125 of 166) for pre-implementation and 52 % (87 of 166) for post-implementation surveys, with 46 % (76 of 166) PCPs completing both surveys. Among PCPs in the intervention group, the proportion who indicated they spent <10 min per clinical session devoted to cancer screening tasks increased over 1-year for breast (Pre: 49 %, Post: 58 %, $p=0.48$), cervical (Pre: 44 %, Post: 65 %, $p=0.01$), and colorectal (Pre: 26 %, Post: 47 %, $p=0.05$) cancer screening. There were no significant differences in pre and post-implementation survey responses for PCPs in control practices. Among of intervention PCPs who completed the post-implementation survey (47 of 90, 52 %), the proportion who believed the process for managing patients overdue for cancer screening improved over the past year increased from 21 % in the pre- to 79 % in the post-implementation survey ($p<0.001$). Among intervention PCPs who indicated they screened their roster (79 of 89, 89 %) and completed a post-implementation survey (41 of 79, 52 %), 68 % found the system to be easy to use, 63 % indicated it made their time managing cancer screening more effective, and 88 % were satisfied with the HIT system.
CONCLUSIONS: Primary care physicians who screened their roster of patients overdue for cancer screening using a visit-independent, population management HIT system for cancer screening reported less time spent devoted to cancer screening tasks during clinical sessions and no perceived increase in effort outside of a clinic visit.

IMPACT OF A FAMILY HISTORY COLLECTION TOOL, METREE©, IN IDENTIFYING INDIVIDUALS AT HIGH-RISK FOR CANCER AND THROMBOSIS Rebekah R. Wu[1,2]; Tiffany Himmel[3]; Adam Buchanan[4]; Karen Powell[5]; Elizabeth Hauser[6,7]; Astrid B. Agbaje[8]; Geoffrey S. Ginsburg[2,3]; Vincent Henrich[5]; Lori A. Orlando[2,9]. [1]VA Healthcare System, Durham, NC; [2]Duke Health System, Durham, NC; [3]Duke University, Durham, NC; [4]Duke Health System, Durham, NC; [5]UNC Greensboro, Greensboro, NC; [6]Duke University, Durham, NC; [7]VA Healthcare System, Durham, NC; [8]Cone Health System, Greensboro, NC; [9]Duke University, Durham, NC. (Tracking ID #1629461)

BACKGROUND: Family health history (FHH) is the single strongest predictor of disease risk and yet is significantly underutilized in primary care. The Genomedical Connection developed the Genomic Medicine Model for primary care (GMM) to improve collection of FHH and its use in guiding preventive health care strategies. At its core is a patient facing FHH collection tool, MeTree©, with embedded education and just-in time clinical decision support (CDS) for evidence based guideline-directed risk-stratified prevention strategies related to breast cancer, colorectal cancer, ovarian cancer, hereditary cancer syndromes, and thrombosis. To evaluate the impact of the GMM on patients, providers, clinic workflow, and patient care we integrated it into real world clinics and for this abstract we report on newly identifying patients who meet criteria for non-routine (more intensive) preventive care (i.e. at high risk for condition) and genetic counseling.

METHODS: Design: A hybrid implementation-effectiveness study. Setting: two primary care clinics in the Cone Health System. Participants: All non-adopted adult English speaking patients with upcoming appointments and their providers (PCP). Intervention: GMM education about and collection of FHH with entry of FHH into MeTree© prior to appointment, receive CDS and just-in time education about recommendations. Measures: Patient survey at baseline, 3 months, and 12 months. Physician survey at 3 months. Chart review at 1 year. Primary outcome: MeTree© identification as high risk in those not previously identified as high risk. Secondary outcomes: assignment to any non-routine strategy, previous screening performed or not.

RESULTS: Enrollment was 1,184. Participant demographics: age range 18–92 (mean 58.8, sd 11.79), 56 % male, and 75 % white. MeTree© recommended actions other than routine for: 68 in breast cancer; 14 in ovarian cancer; 221 in colon cancer; 42 for thrombosis. In addition MeTree© recommended genetic counseling for: 110 in breast cancer; 15 in ovarian cancer; 126 in colon cancer; 112 in hereditary cancer; 29 in thrombosis. For those who reached the one-year follow-up point and had non-routine recommendations, only 18.35 % (n=20) had received colonoscopies before 50 years old, the age of routine screening for colon cancer and only 16.4 % (n=10) of women had received mammograms before 50 years, the routine screening age for breast cancer. The following had been previously identified as high-risk by their providers: 2 of 68 for breast cancer; 0 of 9 for ovarian cancer; 3 of 126 for colon cancer, and 1 of 18 for thrombosis.

CONCLUSIONS: Collection of a structured FHH prior to a primary care visit uncovers a large number of people at higher than average risk for cancer and thrombosis, the vast majority of whom were previously unrecognized as being at high risk. In addition, most were not receiving the more intensive evidence-based risk-stratified preventive screening they meet criteria for. These data strongly support the need for tools that collect data for risk stratification prior to primary care appointments and provide CDS at the point of care to facilitate the implementation of evidence-based risk stratified primary prevention recommendations.

IMPACT OF THE DIABETES HEALTH PLAN ON CARDIOVASCULAR RISK FACTOR CONTROL AMONG RACIAL MINORITIES AND LOW SOCIOECONOMIC STATUS GROUPS Ekaterina Vaisberg; Carol Mangione; Susan Ettner; Norman Turk; Jinnan Li; Lindsay Kimbro; O. Kenrik Duru. UCLA, Los Angeles, CA. (Tracking ID #1642786)

BACKGROUND: Among patients with diabetes, disparities in A1c control persist for both racial minorities and individuals of lower socioeconomic status (SES). The Diabetes Health Plan (DHP) is a disease-specific health plan which aims to prevent diabetes complications by incentivizing preventive care with several innovative features. We hypothesize that the DHP will help mitigate racial and income-based disparities in A1c control.

METHODS: The DHP includes several enhancements to a standard plan, including financial incentives that minimize/eliminate co-pays to see primary care physicians and co-pays for many chronic medications. For these analyses, we used a longitudinal study design with a before/after comparison group. Patients with diabetes were defined as having any of the following: 1) at least one 250.xx inpatient, outpatient, or ED claim, 2) an A1c value≥6.5 %, or 3) use of insulin or an oral hypoglycemic medication other than metformin. We compared eligible diabetic patients within employer groups that provided the DHP and within employer groups that did not have access to the DHP (controls). We defined comparison groups by race/ethnicity (White, Latino, African American) as well as income (<$30 K, $30–49 K, $50–74 K, ≥$75 K). We applied propensity score matching, using matching variables including mean salary, member count, % female, and % with a chronic condition, to select 5 control employers for each DHP employer. We used a 2 year study window to measure A1c, with a 1-year "pre" period and 1-year "post" period for both the DHP samples but only included patients who had at least 9 months between their "pre" and "post" laboratory values in the analyses. We constructed multivariate linear regressions to estimate study outcomes, controlling for individual-level income, race, education, age and gender, and compared change in the last recorded laboratory value within each period using difference-in-difference analyses to estimate change for each race/ethnicity and income group. Results were expressed as predicted probabilities.

RESULTS: We identified 500 intervention and 751 control group patients with diabetes. In the DHP groups, the racial distribution was 64 % White, 19 % African American and 14 % Latino and the income/SES distribution was 12 % <$30 K, 31 % $30–49 K, 29 % $50–74 K and 27 %≥$75 K. In comparison, the control groups had fewer African Americans (9 %) and more patients with incomes > $75 K (47 %). Both Whites and Latinos in the DHP groups had a significantly greater reduction in A1c when compared to Whites and Latinos in the control groups (change in A1c −0.25, P<0.001 and −0.32, P=0.004, respectively). However, there was no difference in change in A1c among African Americans (p=0.21). When comparing patients by income categories, DHP patients with an income≥$75 K had larger reductions in A1c compared to controls with income > $75 K (change in A1c −0.33, P<0.001). There were no significant differences among the other SES groups.

CONCLUSIONS: Our results suggest that the DHP may potentially be associated with a reduction in disparities for Latinos, but not African Americans, as compared to whites. However, there is no similar effect for low-income patients, and the DHP may actually be associated with a greater effect among higher income groups. Additional studies over a longer follow-up period and examining a wider range of outcomes are needed for a complete evaluation.

IMPLEMENTATION OF INFORMATICS-SUPPORTED CARE MANAGEMENT INTERVENTION FOR HYPERTENSION Elaine M. Fleck[1]; Adam Wilcox[3]; Margaret McDonald[2]; Penny H. Feldman[2]. [1]Columbia University, New York City, NY; [2]Visiting Nurse Service of New York, New York City, NY; [3]Columbia University, New York City, NY. (Tracking ID #1641831)

BACKGROUND: WICER (Washington Heights/Inwood Informatics Infrastructure for Comparative Effectiveness Research) creates a research infrastructure for comparative effectiveness research (CER) with focus on patient centered care. As one of three (CER) studies through WICER, we are conducting a pilot for cross-institutional hypertension care management, supported by health information technology (HIT) and exchange. In this project, care managers at the Visiting Nurse Service of New York (VNSNY), help assess and manage patients with uncontrolled hypertension who are being treated in selected practices of the Columbia University Medical Center (CUMC)-New York Presbyterian (NYP) Ambulatory Care Network (ACN). The aim in this pilot is to asses the feasibility of a cross-institutional "informatics" supported care management intervention that

results in improved communication and coordination with the Primary Care Provider, resulting in more effective hypertension management of patients.
METHODS: Patients were identified with uncontrolled hypertension and a history of home health care service who also had a primary care provider in the CUMC/NYP/ACN. Eligible, consented patients were enrolled in a 6 month intervention and assessed comprehensively. The bilingual care manager (CM) implemented a self-management support program that included on going education and blood pressure monitoring in the home. Data were collected at baseline and at 6 months (results pending). The VNSNY CM then communicated the results of the assessment and home visits via the electronic health record of the patient at the CUMC/NYP-ACN practice. Components of HIT included creation of 1) CM access to electronic health record (EHR) of assigned patients 2) care management ability to transmit electronic secure health message 3) integration of a CM structured note in the electronic medical health record to allow PCP to monitor patient 4) CM ability to assess clinic for appointment 5) CM ability to generate an electronic alert to PCP.
RESULTS: Forty-six patients have been enrolled. Preliminary results show mean age of study participant is 67 years, 67 % female, 81 % Hispanic, 19 % non-Hispanic Black with average BP at enrollment at 153/83. CM components and communication platforms were created with physician input. Technical changes to the CU/NYP EHR were feasible. However, our limitations in facilitating smooth informatics communication were multiple. Due to organizational constraints, many informatics elements were completed via a work-around. A clinic nurse uploaded the information from the CM visit into the EHR for primary care team access. Using a secure web portal, the VNSNY CM has restricted access to the CU/NYP electronic health record, with reading rights only. Data exchange was one sided only. In addition, there was inability to generate visit alerts on the day of the visit.
CONCLUSIONS: This pilot demonstrates the challenge of creating a useful health "informatics" exchange to support care management of hypertension in the primary care setting between unique institutions. Although the technology is available for integration; the reality of aligning the health information technology for access within different organizations in a timely, efficient manner remains a challenge. Acknowledgement: This study was funded by R01 HS019853

IMPLEMENTATION OF A DIABETES SELF MANAGEMENT EDUCATION TEAM IN A PATIENT CENTERED MEDICAL HOME David E. Willens[1,2]; Kirbee Miller[2]; Rebecca L. Gammell[2]; Chandra Y. Osborn[2]; Ruth Lipman[4]; Joan Peterson[3]; Josh F. Peterson[2]. [1]Henry Ford Health System, Detroit, MI; [2]Vanderbilt University, Nashville, TN; [3]Vanderbilt University, Nashville, TN; [4]American Association of Diabetes Educators, Chicago, IL. (Tracking ID #1642406)

BACKGROUND: Type 2 diabetes is epidemic, projected to affect 1 in 3 Americans by 2050. The Patient Centered Medical Home (PCMH) model enhances resources for patient self-management and education. Diabetes Self-Management Education (DSME) improves diabetes knowledge, behaviors and control. A supervised peer coach may improve patient outcomes. We sought to determine the effectiveness, facilitators, and barriers to implementing a peer coach and Certified Diabetes Educator (CDE) team in an existing PCMH.
METHODS: The planning team consisted of a health psychologist, a diabetologist, a primary care physician and health services researcher, a nurse care coordinator (CC) and CDE, and a quality improvement fellow. A bachelor degree-level team member, without prior training in diabetes care, was trained in DSME and motivational interviewing and was added to the existing doctor-CC PCMH team. Each patient watched an educational video and received personalized instruction from the CC and then set a behavior change goal (e.g. diet, exercise, disease monitoring, smoking cessation) with the coach. Patient progress was assessed and coached telephonically to enhance problem solving and healthy coping skills monthly for 6 months. A prospective cohort design evaluated pre-post patient-level and program level outcomes. Eligible adult patients had a recent hemoglobin A1C greater than 7.0, age less than 85 years and no end stage comorbidities. The primary outcome was change in hemoglobin A1C between baseline and 6 months. Secondary outcomes were changes in self-care behaviors, perception of self-care support, diabetes knowledge, satisfaction, and self-efficacy. Patient and staff interviews assessed program implementation barriers and facilitators.
RESULTS: Of a convenience sample of 258 patients from six primary care practices at an academic tertiary care medical center, 102 were eligible and 41 (40.0 %) enrolled. Thirty (73.7 %) completed the six-month program. Most patients chose a goal related to diet or exercise. Hemoglobin A1C did not significantly change, median (IQR): 8.3 (7.4–9.5) to 7.8 (7.0–9.8). Days per week patients reported following a healthy diet improved, 3.5 (2.0–5.5) to 5.25 (4.25–6.0), $p<0.01$. Days following an exercise plan did not improve, 3.0 (1.0–4.5) to 3.0 (2.0–4.5). Scores on a 5 point Likert scale of patient perception of resources for self-management improved, 3.2 (2.6–3.9) to 4 (2.6–4.6), $p<0.05$]. Facilitators to program implementation were expert leadership, established PCMH infrastructure, and engaged CC/CDE and coach. The primary barrier to success was competing demands for patient engagement (e.g. caring for sick family member) causing variable proportions of successful follow-ups.
CONCLUSIONS: A pilot program to add a CDE-supervised diabetes peer coach to a PCMH improved patient self-care behaviors but did not significantly improve hemoglobin A1C over 6 months. Patients perceived the program implementation as a success. Level of patient engagement was variable, indicating that some subpopulations may benefit more than others. Facilitating factors were leadership with expertise in diabetes behavior change and a highly committed coach. Further research should focus on patient characteristics that predict full engagement, impact of intensity of patient contact on outcomes, and the cost-effectiveness of CDE-supervised peer coach programs.

IMPLEMENTATION OF A PROTOCOL FOR ABG USE INCREASES THE DIAGNOSTIC YIELD WHILE REDUCING UNNECESSARY TESTS Jeffrey DellaVolpe; Chayan Chakraborti; Kenneth Cerreta; Lizheng Shi; Nathan Nielsen. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1641638)

BACKGROUND: This study examined indications for arterial blood gas (ABG) use hypothesizing that implementation of a protocol of evidence based indications for ordering ABGs would result in a reduction of the total number of ABGs, ABGs "not indicated" according to the protocol, and routinely ordered ABGs without a specific clinical indication.
METHODS: We developed a protocol for ABG indications based on previously published guidelines and the needs of our institution. Exclusion criteria included age<18, stroke patients, and venous blood gases. Indications were recorded for 6 weeks by respiratory therapists prior to implementation. All staff and residents were then trained on the protocol and indications were recorded for six additional weeks.
RESULTS: After implementation of the protocol, there were significant reductions in total ABGs ($p<0.001$) and "not indicated" ABGs ($p<0.012$). The average ABG/patient/day decreased 24.8 % from 0.353 ABGs/patient/day to 0.265 ABGs/patient/day ($p<0.0003$), with no change in mortality between the study groups. Amongst non-ventilated patients, there was a significant reduction ($p<0.001$) in ABGs ordered for "difficulty oxygenating." In ventilated patients, there was a significant reduction in ABGs ordered for changes in PEEP ($p<0.03$), daily blood gases ($p<0.001$), and weaning trial ABGs ($p<0.004$) after implementation. ABGs ordered for change in minute ventilation increased by 15.6 % ($p<0.004$), while daily ABGs decreased by 14.4 % ($p<0.001$) and weaning trial ABGs decreased by 15.4 % ($p<0.004$). The number of abnormal ABGs increased 16 % when ordered for a change in minute ventilation ($p<0.006$) and decreased 13.5 % when ordered as a daily ABGs ($p<0.001$). There was no change in the number of normal ABGs.
CONCLUSIONS: Developing a clinical rationale for ordering ABGs is a shortcoming in the training of many clinicians. This project offers one approach, as well as empiric data on its effectiveness. Using this protocol, clinicians ordered fewer tests overall and ordered a higher proportion of ABGs based on changes in clinical status. Moreover, those ordered for changes in clinical status were more likely to be abnormal. In addition to facilitating more targeted and appropriate use of ABGs, this approach also reduced ABGs use 24.8 %. Cost minimization analysis estimated national cost savings to be $128 million annually for this intervention. For a test as

prevalent, invasive, and expensive as the ABG this study represents an important step towards judicious and meaningful use of medical resources.

IMPLEMENTATION OF AN EDUCATIONAL INTERVENTION AND AN ELECTRONIC DECISION SUPPORT MODEL WITH COMPUTERIZED ORDER ENTRY TO REDUCE INAPPROPRIATE RED BLOOD CELL TRANSFUSIONS Megha Rao; Jennifer Caceres; Andrew D. Timothy; Leslie Cotto; Salvador R. Garcia. University of Miami, Regional Campu, atlantis, FL. (Tracking ID #1643014)

BACKGROUND: Approximately 15 million red blood cell (RBC) units are transfused annually in the United States. Overuse of blood products is a common problem due to the lack of high quality evidence-based guidelines on RBC transfusions. While optimal RBC transfusions can be lifesaving, inappropriate non-emergent transfusions add to healthcare costs and expose patients to potential infectious and non-infectious risks. Hemoglobin levels between 7 and 9 g/dl require consideration of other clinical circumstances to determine the need for transfusion. We hypothesize that an educational intervention and a decision support (DS) model with computerized physician order entry (CPOE) for physicians will decrease inappropriate RBC transfusions in patients with hemoglobin levels in this range.
METHODS: The study was conducted at John F. Kennedy Medical Center between January 2011 - April 2012. A Phase I chart review of randomly selected patients who received blood transfusions between January 2011 - April 2011 was performed to determine if the RBC transfusions were appropriate following an evidence-based algorithm. In June 2011, the medical staff received a Medical Grand Rounds lecture to educate physicians on the current appropriate indications for transfusions and to introduce a DS model comprising an order set devised to help justify the need for transfusions with CPOE. Six months after the implementation of the DS model intervention with CPOE, a Phase II chart review of randomly selected patients who received RBC transfusions between January 2012 - April 2012 was performed. A subset analysis was performed to determine the predictors of the inappropriate blood transfusions. Patients with coronary artery disease or acute coronary syndrome were excluded due to the lack of consensus on treatment guidelines for this subgroup. We used chi square and multivariate logistic regression with interaction terms to test our hypothesis.
RESULTS: A total of 365 charts were reviewed in Phase I and 463 charts were reviewed during Phase II. Of these charts, 75.8 % (n=277/365) and 64 % (n=297/463) in Phase I and II, respectively, were in the hemoglobin range of 7–9 g/dl. Analysis of the charts within this range revealed that 67.4 % of RBC transfusions were inappropriate in Phase I compared to 43.0 % in Phase II. Hence, there was a 24.4 % reduction in inappropriate blood transfusions in those patients with a hemoglobin between 7 and 9 g/dl after the educational intervention and DS model with CPOE was implemented (p<0.01). Baseline characteristics of the subset analysis included age, gender, symptoms, cancer and chronic kidney disease. The analysis revealed that asymptomatic anemia was a statistically significant predictor of inappropriate blood transfusion with a P<0.01 and an odds ratio of 6.7 with 95 % CI (2.6–17.4)
CONCLUSIONS: The study demonstrated a statistically significant decline in the rate of inappropriate transfusions within the hemoglobin range of 7–9 g/dl. Asymptomatic anemia was a statistically significant predictor of inappropriate blood transfusion. This suggests that an educational intervention followed by implementation of a DS model with CPOE can guide the clinician further to validate the need for transfusion, thereby decreasing the number of inappropriate transfusions.

IMPLEMENTING CHANGE IN PRACTICE IN A FEDERALLY QUALIFIED COMMUNITY HEALTH CENTER: THE OFFICE-GUIDELINE APPLIED TO PRACTICE (OFFICE-GAP) MODEL Ade B. Olomu[1]; Venu Gourineni[1]; Steven Pierce[2]; Margaret HolmesRovner[3]. [1]Michigan State University, East Lansing, MI; [2]Michigan State University, East Lansing, MI; [3]Michigan State University, East Lansing, MI. (Tracking ID #1642726)

BACKGROUND: African Americans and persons with low socio-economic status (SES) suffer an unequal burden of morbidity and mortality from cardiovascular disease and receive less patient-centered care than less vulnerable patient populations. Our objective was to demonstrate the ability to accomplish change in a setting (Federally Qualified Community Health center {FQCHC}) that serves low income populations.
METHODS: This process evaluation tested the impact on medication adherence of a simple training process in routine care. The Office-GAP (Guidelines Applied to Practice) program included provider training, patient education in a group visit, and use of Guidelines Applied to Practice (GAP) checklist/tools during office visits. Two doctors, 1 nurse-practitioner (NP), 8 staff, and 96 patients with a diagnosis of CAD or diabetes mellitus in one FQCHC participated in this study from January 2009 to Dec 2011. After a group visit, patients followed up with physician visits using GAP tools. Multilevel logistic regressions tested whether the probability of aspirin, ACEI, beta blocker, and statin use changed over time.
RESULTS: All providers and staff attended the 90-minute training, 96 patients attended 90-minute group visit; Eighty (83.3 %) and 75 (78.1.0 %) patients completed their first and second follow up visits respectively. Forty-six percent were males, 48 % whites, 35 % blacks and 15 % were from other racial or ethnic backgrounds. The probability of aspirin/plavix use in all eligible patients was 44 % at pre-GAP and increased to 85 % at 3 months (p=.036, OR=6.9), to 95 % at 6 months (p<.001, OR=26.5), and 94 % at 12 months (p=.002, OR=19.5). For eligible diabetic patients, probability of aspirin/plavix use was 28 % in pre-GAP and was 84 % at 6 months (p=.020, OR=16.7) and 81 % at 12 months (p=.045, OR=11.0). Predicted ACEi/ARB use went up from 88 % at pre-GAP visit to 99 % at 6 months (p=.024, OR=15.2) and 99 % at 12 months (p=.042, OR=11.6) in diabetic patients. Statin use was 99 % at 12 months (p=.019, OR=17.2), compared to 86 % at pre-GAP visit. Logistic regression revealed that age and Office-GAP visits predicted aspirin use and having Medicaid/Medicare insurance predicted statin use at 12 months.
CONCLUSIONS: This approach to implement change in a FQCHC using provider/patient training and Office-GAP tools appears feasible. It has the potential to improve evidence-based medication use for patients with heart disease and diabetics. The Office-GAP Program could serve as a model for implementing guideline based care for all chronic diseases in outpatient clinical settings. There is a need to determine effectiveness and cost-effectiveness of this approach.

IMPLEMENTING A TRACKING AND FEEDBACK REGISTRY INNOVATION TO IMPROVE COORDINATION OF ADJUVANT THERAPIES IN BREAST CANCER Nina A. Bickell[1]; Rebeca Franco[1]; Allie Moss[2]; Zoe Lawrence[1]; Ann S. McAlearney[2]. [1]Mount Sinai School of Medicine, New York, NY; [2]The Ohio State University, Columbus, OH. (Tracking ID #1640042)

BACKGROUND: As adjuvant breast cancer treatments are delivered by different specialists, underuse may be worsened by fragmented care, but could be improved by implementing a tool that improves coordination across outpatient specialty care settings. Despite the apparent effectiveness of an innovative Tracking & Feedback (T&F) intervention tool to eliminate racial disparities in and reduce underuse of needed adjuvant breast cancer treatments, uptake and implementation of the tool was poor. We aimed to assess the challenges to and feasibility of implementing a web-based T&F innovation in hospitals that serve large proportions of minority women with breast cancer as a first step toward improving coordination and delivery of needed adjuvant therapies.
METHODS: We interviewed 49 key informants (n=29 clinical; n=20 administrative) from 6 inner-city hospitals with high volumes of minority breast cancer patients to better understand how organizational characteristics might impact coordination of care, implementation and success of the T & F innovation. We used the constant comparative method of qualitative data analysis and standard techniques to code the interview data.
RESULTS: We found considerable variability across hospitals with respect to their reported abilities and approaches to coordinate tracking and delivery of adjuvant therapies for women with breast cancer. All sites have multi-disciplinary Tumor Boards meetings and active Quality Improvement

with many departments focused on improving transitions in care. Yet, for several, specialty care remains siloed and systems for communicating across specialties are poor. Many hospitals have patient navigators, but navigator functions differ across sites. All hospitals have electronic medical records (EMRs) but not all EMRs can "talk" to scheduling software to track requested referrals. Many physicians rely on follow-up appointments to ascertain adjuvant treatment receipt, but sites vary in their abilities to address "no-shows." Several sites rely on staff to identify and follow up with "no-shows," but many of these individuals are overwhelmed with ever-increasing tasks and management responsibilities. Lack of resources, compounded by patient populations who often differ from their providers in language and cultural beliefs, coupled with frequent incorrect contact information make it difficult to follow up with no-shows. While quality and change were important to all, several interviewees felt they were bucking an inflexible system and devised ways to work around the obstacles. Perceived successful coordination factors included strong clinical leadership, designated accountabilities, and flexibility for both clinicians and administrators to work within and around inflexible organizational systems of care.

CONCLUSIONS: As care integration across sites and specialties are encouraged by federal law and regulation, specialty care silos and rigid communication systems still pose barriers to change. Our results suggest that implementing a web-based T&F innovation must be responsive and tailored to individual hospital characteristics, and flexible enough to permit modification of care processes at the organization level.

IMPLICATIONS OF POVERTY, HOSPITAL TYPE, AND A GRASSROOTS COMMUNITY INTERVENTION ON DISSEMINATION OF PHYSICIAN ORDERS FOR LIFE SUSTAINING TREATMENT IN CALIFORNIA HOSPITALS Takehiro Sugiyama[1,2]; David Zingmond[1]; Karl Lorenz[3]; Allison Diamant[1]; Kate O'Malley[4]; Judy Citko[5]; Victor Gonzalez[1]; Neil Wenger[1]. [1]University of California, Los Angeles, Los Angeles, CA; [2]University of Tokyo, Tokyo, Japan; [3]Greater Los Angeles VA Medical Center, Los Angeles, CA; [4]California HealthCare Foundation, Oakland, CA; [5]Coalition for Compassionate Care of California, Sacramento, CA. (Tracking ID #1626524)

BACKGROUND: Clinicians must identify and document patients' goals and wishes in order to assure appropriate treatment in late life. However, decisions such as do not resuscitate (DNR) orders are commonly lost in transition between care venues. Physician Orders for Life-Sustaining Treatment (POLST) is a tool to facilitate continuity of end-of-life decisions across care venues and became legal in California in January 2009. A novel grassroots community coalition intervention was used to disseminate POLST into California hospitals and nursing homes. We surveyed California hospitals to evaluate dissemination of POLST and factors associated with POLST uptake in hospitals.

METHODS: We surveyed all acute care hospitals in California between August 2011 and January 2012. We then linked survey responses with community coalition reports of interaction with hospitals and hospital characteristics from the California Office of Statewide Planning and Development (OSHPD) and Census ZIP Code Tabulation Areas (ZCTAs). Main outcome measures were hospital report of stocking blank POLST forms, staff education about POLST, and appropriate handling of POLST both in the emergency department (ED) and on admission. We described the extent of POLST dissemination and then performed multiple logistic regression analyses to evaluate the independent association of the intervention (community coalitions-hospital interaction) and hospital factors (ownership, size, hospital-area poverty [i.e., proportion of residents with income less than 200 % of federal poverty level], rurality, and proportion of older inpatients with early DNR orders in 2009) associated with POLST uptake in the hospital. We converted odds ratios into risk ratios (RRs) to facilitate interpretation of the results with bootstrapping to compute confidence intervals (CIs).

RESULTS: Of 349 hospitals, 286 (81.9 %) responded to the survey. Eighty-seven percent of hospitals had available blank POLST forms, 84 % had educated staff about POLST and 91 % handled POLST properly in the ED and on hospital admission. In multivariable analyses, the proportion of residents in the area with income below 200 % of the federal poverty level was negatively associated with stocking blank POLST forms (RR 0.97 per 10 % increase in the proportion in poverty, 95 % CI 0.94–0.99), educating staff about POLST (RR 0.96, 95 % CI 0.92–0.99), and appropriate handling of POLST (RR 0.98, 95 % CI 0.94–0.998). For-profit (compared to nonprofit) hospitals were less likely to stock blank POLST forms (RR 0.86, 95 % CI 0.70–0.997) and to have educated staff (RR 0.86, 95 % CI 0.71–0.98). Hospitals with community coalition interaction were more likely to handle POLST forms appropriately (RR 1.09, 95 % CI 1.004–1.21).

CONCLUSIONS: Although POLST is widely used in California hospitals, a significant minority of hospitals remain unprepared to appropriately employ POLST forms 3 years after implementation. Future efforts to improve POLST implementation should emphasize dissemination in hospitals in poorer areas and among for-profit hospitals. A grassroots community-based intervention appeared to facilitate POLST dissemination in California hospitals.

IMPROVEMENT OF DEPRESSION SYMPTOMS WITH VILAZODONE TREATMENT: MADRS SINGLE ITEM SHIFT ANALYSES Larry Culpepper[1]; Anjana Bose[2]; Maju Mathews[2]; John Edwards[2]. [1]Boston University School of Medicine, Boston, MA; [2]Forest Research Institute, Jersey City, NJ. (Tracking ID #1640707)

BACKGROUND: Vilazodone (VLZ) is a serotonin reuptake inhibitor and 5-HT1A receptor partial agonist approved by the FDA for the treatment of major depressive disorder (MDD) in adults. The Montgomery-Asberg Depression Rating Scale (MADRS) is a validated, clinician-rated scale used to measure MDD symptom severity and improvement following treatment; it comprises 10 items (Apparent Sadness, Reported Sadness, Inner Tension, Reduced Sleep, Reduced Appetite, Concentration Difficulties, Lassitude, Inability to Feel, Pessimism, Suicidal Thoughts). Each item score ranges from 0 to 6 with higher score indicating greater severity. The present analyses assessed clinically relevant symptom improvement in MADRS individual items by evaluating baseline to end of study (EOS) shifts from more to less severe symptom categories.

METHODS: The analyses were conducted on pooled data from 2 positive, Phase III, eight-week, double-blind, randomized, placebo (PBO)-controlled trials (NCT00285376, NCT00683592) in outpatients (18–70 years) with DSM-IV-TR-defined MDD. VLZ dose was titrated over a two-week period from 10 mg to a 40-mg target dose taken once daily with food. Post hoc analyses were conducted on study completers with 8 weeks of treatment. The shift analyses were done at two levels: patients with baseline score ≥2 (eg, sad but brightens without difficulty, slightly reduced sleep, occasional edginess) to an EOS score <2 ('minimal to no symptoms') and patients with baseline score ≥4 (eg, unhappy most of the time, sleep reduced by at least 2 h, continuous tension/intermittent panic) to EOS score ≤2. Odds ratios were estimated and Fisher's exact test was used to obtain the 2-sided nominal P values for comparisons between VLZ and PBO.

RESULTS: The percentage of patients with severity category shift from baseline ≥2 to EOS <2 was significantly higher for VLZ vs PBO on all MADRS single items (OR range, 1.4–1.7; $P \leq .05$) except Reduced Appetite (OR 1.3; $P = .232$). In patients with greater symptom severity (baseline ≥4), more VLZ than PBO patients shifted to ≤2 at EOS. Differences were statistically significant for VLZ vs PBO on items of Apparent Sadness (60 % vs 47 %; OR, 1.7; $P = .003$), Reported Sadness (60 % vs 48 %; OR, 1.6; $P = .003$), Inner Tension (58 % vs 41 %; OR, 2.0; $P = .003$), Reduced Sleep (51 % vs 36 %; OR, 1.8; $P = .002$), and Lassitude (57 % vs 47 %; OR 1.5; $P = .029$). For Item 10 (Suicidal Thoughts), OR was not evaluable.

CONCLUSIONS: Significantly greater proportion of patients treated with VLZ compared with PBO achieved a shift from a baseline score ≥2 to EOS score <2 on all MADRS single items except Reduced Appetite. For patients with more severe symptoms (baseline score ≥4), significant improvements were noted on the items of Reported Sadness, Apparent Sadness, Inner Tension, Reduced Sleep, and Lassitude. Shifts to the 'minimal to no symptom' severity category demonstrated that VLZ treatment is associated with clinically meaningful improvement in symptoms of MDD.

IMPROVEMENTS IN QUALITY OF LIFE BY MAGNITUDE OF WEIGHT LOSS IN OBESE AND OVERWEIGHT SUBJECTS
Timothy Church[1]; Barbara Troupin[2]. [1]Louisiana State University System, Baton Rogue, LA; [2]VIVUS, Inc., Mountain View, CA. (Tracking ID #1623811)

BACKGROUND: Obesity has been shown to have a negative impact on quality of life (QOL). Weight loss has demonstrated improvements in QOL among obese and overweight patients. In the EQUIP and CONQUER studies, phentermine and topiramate extended-release (PHEN/TPM ER), when used in combination with lifestyle modifications (including reduced caloric intake and increased physical activity), resulted in significant weight loss over 56 weeks in obese and overweight subjects with comorbidities. This post hoc analysis evaluated weight loss and its effects on QOL over 56 weeks.
METHODS: EQUIP evaluated PHEN 3.75 mg/TPM ER 23 mg (3.75/23) and PHEN 15 mg/TPM ER 92 mg (15/92) vs placebo in 1267 patients with body mass index (BMI) ≥35 kg/m2. CONQUER evaluated PHEN 7.5 mg/TPM ER 46 mg (7.5/46) and 15/92 vs placebo in 2487 patients with BMI ≥27 kg/m2 and ≤45 kg/m2 and ≥2 weight-related comorbidities. A standardized lifestyle intervention consisting of caloric reduction and increased physical activity was introduced for all subjects. In this post hoc analysis, Impact of Weight on QOL-Lite Questionnaire (IWQOL-Lite; EQUIP and CONQUER) and Medical Outcomes Study Short Form (SF-36; CONQUER only) were administered to subjects achieving <5 %, ≥5 % to <10 %, ≥10 % to <15 %, and ≥15 % weight loss at week 56.
RESULTS: In both trials, least-squares mean percent weight loss was significant with PHEN/TPM ER treatment vs placebo at week 56: in EQUIP, −1.6 %, −5.1 %, and −10.9 % for placebo, 3.75/23, and 15/92, respectively at week 56; and in CONQUER, −1.2 %, −7.8 %, and −9.8 % for placebo, 7.5/46, and 15/92, respectively ($P<.0001$ vs placebo, all comparisons). Across all treatment groups, in EQUIP, 57.5 % of subjects lost <5 % of their body weight by week 56, 16.8 % lost ≥5 % to <10 %, 9.8 % lost ≥10 % to <15 %, and 15.9 % lost ≥15 %. In CONQUER, across all treatment groups, 51.2 % of subjects lost <5 % of their body weight by week 56, 19.3 % lost ≥5 % to <10 %, 12.9 % lost ≥10 % to <15 %, and 16.5 % lost ≥15 %. Improvements in QOL increased incrementally with the degree of weight loss. In EQUIP and CONQUER, greater weight loss led to greater numerical improvements in IWQOL-Lite total score (Table). SF-36 Physical Component Summary and Mental Component Summary scores were also numerically improved with increasing weight loss in CONQUER (Table). Numerical improvements were observed in all IWQOL-Lite (EQUIP and CONQUER) and SF-36 (CONQUER) domain scores, with greater weight loss leading to greater numerical improvements (data not shown). PHEN/TPM ER was generally well tolerated, with the most common adverse events being dry mouth, paraesthesia, and constipation in each study.
CONCLUSIONS: Weight loss was associated with improved QOL as assessed by IWQOL-Lite and SF-36, with greater weight loss leading to greater improvements in QOL parameters. Improvements in QOL, through lifestyle modifications alone or in conjunction with a weight-loss therapy such as PHEN/TPM ER, may provide an additional benefit for obese patients.

Table. Improvements in IWQOL-Lite and SF-36 by magnitude of weight loss from baseline to week 56 (ITT-LOCF).

	<5% Weight Loss	≥5% to <10% Weight Loss	≥10% to <15% Weight Loss	≥15% Weight Loss
EQUIP IWQOL-Lite Total Score (n=496, 176, 117, 186)*	7.0	10.6†	15.1‡§	20.0‡§¶
CONQUER IWQOL-Lite Total Score (n=972, 424, 298, 394)*	8.6	13.1‡	15.8‡§	20.2‡§¶
CONQUER SF-36 Physical Component Summary (n=963, 414, 300, 390)*	1.7	4.0‡	5.2‡§	6.7‡§¶
CONQUER SF-36 Mental Component Summary (n=963, 414, 300, 390)*	-0.5	-0.4	0.6†	0.8†§

*n values represent those subjects in the <5%, ≥5% to <10%, ≥10% to <15%, and ≥15% weight loss groups, respectively
†$P<.05$ vs <5% weight loss; ‡$P<.0001$ vs <5% weight loss; §$P<.05$ vs ≥5% to <10% weight loss; ¶$P<.005$ vs ≥10% to <15% weight loss

IMPROVING BED MANAGEMENT BY UTILIZING EARLY INTERDISCIPLINARY DISCHARGE PLANNING
Surekha Bhamidipati[1]; Andrew Abraham[1]; Edith Johnson[2]. [1]Christiana Care Health System, Newark, DE; [2]Christiana Care Health System, Newark, DE. (Tracking ID #1644080)

BACKGROUND: Daily discharge predictions are a necessary activity in busy hospitals and the accuracy of such predictions contributes to hospital preparedness for challenges to bed capacity. Last-minute discharge planning leading to a lack of coordination in the discharge process can lead to inefficiencies and bed management constraints during this vital transition point of patient care. Our study was designed to assess the effect of a 24 h discharge planning tool and a discharge liaison on early discharges while maintaining patient preparedness for discharge.
METHODS: The study was conducted on a single medical unit that is supported by one hospitalist group, i.e. a geographically cohorted patient unit, over a 6 month period. Over 50 % of the patients on the unit were staffed by a single rotating hospitalist and a nurse practitioner. A pre-study assessment of 457 patients was performed to establish baseline parameters that included demographics and hospital metrics such as readmission rates and length of stay. A total of 326 patients were involved in the study. During the study, an interdisciplinary team including the attending physician of record, charge nurse, case manager, social worker and a discharge liaison met at a daily huddle to discuss next day's potential discharges. A checklist tool was created and utilized at the huddle to target patients deemed safe for discharge before 2 PM the next day. The checklist was a list of responsibilities for staff members and consisted of tasks necessary for discharge the next day. The targeted patients were assigned the discharge liaison, and all other patients were discharged as usual and served as a control group. The discharge liaison was a nurse practitioner with clinical responsibilities and helped facilitate the implementation of the tasks on the checklist and spent about 1 h a day performing this job. The study also measured patient preparedness for discharge using a validated and nationally tested survey tool, CTM III. Both the control and the intervention groups received the survey.
RESULTS: The number of early daily discharges (before 2 pm) increased significantly from an average of 2.2 to 4.0 ($p<0.001$) from baseline for the intervention group with no significant change for the control group. No

increase in length of stay or readmission rates was noted during the study period. The discharge survey scores in the intervention group compared to the control group revealed the following: 1. Attention to patient and family preferences increased, 3.26 vs. 3.70 (p=0.002), 2. Patient understanding of their responsibilities regarding personal health management improved 3.26 vs. 3.70 (p=0.002) and 3. Knowledge regarding the purpose of medications increased from 3.27 vs. 3.70 (p=0.002).
CONCLUSIONS: Our 24 h discharge planning tool and use of a discharge liaison are ways to improve staff preparedness for efficient discharges and can facilitate earlier discharges and improve patient preparedness for this important transition. Such an intervention can also result in improved patient flow, hospital bed management and can be easily replicated at any acute care hospital without significant additional expenditure.

IMPROVING RATES OF ANNUAL COLORECTAL CANCER SCREENING AMONG LATINO PATIENTS David W. Baker[1,2]; Tiffany Brown[1,2]; David R. Buchanan[3]; Jordan Weil[3]; Kenzie A. Cameron[1,2]; Lauren Ranalli[3]; M. Rosario Ferreira[4]; Kate Balsley[3]; Shira N. Goldman[1,2]; Ji Young Lee[1]; Michael S. Wolf[1,2]. 1Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Erie Family Health Center, Chicago, IL; [4]Northwestern University Feinberg School of Medicin, Chicago, IL. (Tracking ID #1636721)

BACKGROUND: Only 61 % of U.S. adults are adequately screened for colorectal cancer (CRC); rates are lower among Blacks, Latinos, and the poor. Fecal occult blood testing (FOBT) is one recommended screening modality; its effectiveness is contingent on repeating the test every 1–2 years. Many individuals in vulnerable groups face barriers to annual FOBT screening, including lack of a regular source of care, less frequent medical visits, frequent changes in residence, and lack of awareness of the need for annual screening. We describe interim results from a comparative effectiveness study of an intervention to maximize the rate of annual FOBT compared to usual care among vulnerable patients.
METHODS: This is a randomized controlled trial conducted at an urban federally-qualified health center network serving a primarily poor, Latino population. At the start of the study, 42 % of patients were up to date on CRC screening; the rate of annual (repeat) screening (within 18 months of the previous FOBT) was 23 %. We excluded patients with medical conditions that would make CRC screening by FOBT inappropriate. All patients who had a negative FOBT in the previous year and were due for repeat FOBT were identified using electronic health records and randomized (with an IRB-approved waiver of informed consent) to receive either usual care or a multifaceted intervention. Usual care includes computerized reminders, standing orders for assistants to give out a fecal immunochemical test (FIT), and provider feedback on CRC screening rates. The intervention group also receives: 1) a mailed reminder letter to patients from their provider, including a free FIT, low-literacy instructions for completing the FIT, and a postage-paid return envelope, 2) automated phone and text messages after the initial mailing, 3) an automated phone and text reminder 2 weeks later for those who fail to return the FIT, and 4) outreach by a CRC screening coordinator to patients who fail to return the FIT within 3 months. The primary outcome is completion of FOBT within 6 months of the date due.
RESULTS: 175 patients have been randomized to the intervention group; they are primarily Latino (87 %), female (70 %), and Spanish-speaking (83 %), with a mean age of 60 years (SD=6.1). The mailing was returned to sender for 3 %. For the initial automated calls, 57 % were answered in person, 35 % were answered by machine, and 9 % were not completed. The initial text message was sent successfully to 51 % of patients. To date, 134 (77 %) intervention patients completed a repeat FOBT within 6 months; 16 (9 %) completed the FIT prior to their due date (i.e., after a clinic visit); 54 (31 %) completed it within 2 weeks of the mailing and initial call and text, 53 (30 %) between 2 weeks and 3 months (following the reminder call and text), and 11 (6 %) between 3 and 6 months (after the coordinator outreach). Six (5 %) patients had positive FITs.
CONCLUSIONS: This multifaceted intervention has achieved rates of adherence to annual CRC screening far above pre-intervention levels. Moreover, adherence reached the high level needed for FOBT to reduce CRC mortality. Most of the screenings were achieved by the FIT mailing and the automated reminders without the need for the CRC screening coordinator. These interim data suggest that it is possible to dramatically improve annual CRC screening for vulnerable populations with relatively low-cost strategies that can be supported by increasingly available health information and consumer technologies.

IMPROVING RESIDENT UNDERSTANDING OF THE HEALTH LITERACY OF THE COMMUNITY THROUGH THE LAY HEALTH EDUCATOR PROGRAM Panagis Galiatsatos; Rebeca Rios; William D. Hale; Jessica Colburn; Colleen Christmas. Johns Hopkins Bayview Medical Center, Baltimore, MD. (Tracking ID #1638644)

BACKGROUND: Health literacy is defined as "the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions about one's medical care". While health literacy of individuals has been shown to correlate with positive health outcomes, recognizing health literacy is not rigorously taught in most residency training programs. The Lay Health Educator Program (LHEP), established and hosted by Johns Hopkins Bayview Medical Center, invited religious congregations from nearby communities to send representatives to learn about common medical conditions and health care topics taught in weekly seminars and bring that expertise back to their congregations. The seminars were delivered by residents, followed by a question-and-answer portion so that residents may receive immediate feedback about the community members' comprehension of the seminar. The purpose of this study is to assess if this community engagement impacts residents' perspectives of health literacy and if such an impact is valuable in their medical training.
METHODS: The LHEP was conducted over 10 weeks, one evening a week for 2 hours, covering specific health topics. Resident physicians researched their health topics and presented the information in a PowerPoint format with handouts, speaking for 45 min followed by a 15 min question-and-answer portion with the participants. Prior to the sessions, if requested, coaching was provided for the residents. The impact of these sessions was evaluated with pre- and post-surveys with each question rated on a 1–10 Likert scale (1=not at all, 10=completely).
RESULTS: Twelve residents elected to participate in the LHEP seminars. Resident survey results are presented as a mean (± standard deviation). Prior to the LHEP, the residents rated their comfort in recognizing health literacy as 7.07±0.91. After LHEP, they rated that the LHEP changed their perspective in recognizing health literacy as 8.00±1.34, that knowing their patient's health literacy would influence how they would manage patients at 9.15±1.07, and the degree to which they felt more should be done in residency training to improve learning a patient's and community's health literacy at 9.0±1.36.
CONCLUSIONS: Per the surveys, even though the residents participating in the LHEP initially felt confident in recognizing a patient's health literacy, the LHEP changed their perspectives on the importance of health literacy in patient care. Residents revealed that knowledge of patients' health literacy would impact management. All residents agreed more should be done in residency training to learn about a community's health literacy.

IMPROVING THE QUALITY OF ASTHMA CARE USING THE INTERNET Christopher Sciamanna; Jennifer M. Poger; Andrew Pool; Heather Stuckey; Erik B. Lehman; Timothy Craig. Penn State Hershey, Hershey, PA. (Tracking ID #1621261)

BACKGROUND: Asthma is a significant health burden, as approximately 7 % of Americans are currently diagnosed with this condition. Despite widespread dissemination of evidence-based guidelines, more than half of adults with asthma are uncontrolled. The purpose of this randomized

control trial was to test the efficacy of an intervention designed to help patients know what questions to ask their provider, as well as to know when they need a provider visit sooner than scheduled by providing them with access to an asthma module of a patient activation website.
METHODS: 408 participants were randomized 1:1 to one of two conditions: Participants in the Intervention Condition (IC) received feedback about their asthma control, including questions to ask their asthma care provider at their next visit. Participants in the Control Condition (CC) received feedback about questions regarding preventive services (e.g., cancer screening) that they should ask their primary care provider. The main outcome measure is the change in the percentage of patients in each group whose asthma is controlled (ACT≥20), according to the Asthma Control Test (ACT) and NAEPP guidelines.
RESULTS: 325 participants completed 12 month follow up measures (IC: N=157; CC: N=168). Participants in the IC reported a significantly greater mean change in the overall ACT score than participants in the CC (2.1 vs 1.2; p=.012). Similarly, significant between group differences were observed in the mean change in rescue inhaler/nebulizer use frequency (0.6 vs 0.3; p=.005). Regarding medication use, participants in the IC reported a significant between group mean change in the number of inhaled asthma medications they used between baseline and 12 months (0.4 vs 0.2; p=0.021).
CONCLUSIONS: Participants randomized to the IC reported greater improvement in asthma control compared to the CC. Results indicate that individuals with chronic conditions, such as asthma, may benefit from using patient activation websites with tailored feedback.

IN THE PRESENCE OF A MENTAL HEALTH COMORBIDITY, WHAT PREDICTS GUIDELINE ADHERENCE FOR A CHRONIC CONDITION (TYPE 2 DIABETES)? Leigh H. Simmons[2]; Lisa C. Welch[1]; David M. Pober[1]; Felicia L. Trachtenberg[1]; John B. McKinlay[1]. [1]New England Research Institutes, Watertown, MA; [2]Massachusetts General Hospital, Boston, MA. (Tracking ID #1641823)

BACKGROUND: Evidence-based guidelines are often considered the standard for facilitating and assessing clinical care. Most guidelines are constructed for individual illnesses, but patients often present with multiple comorbidities. This study examines the predictors of guideline adherence for type 2 diabetes in the presence of a mental health comorbidity.
METHODS: A randomized balanced factorial experiment was conducted with 256 primary care physicians who observed video vignettes of an established patient presenting with type 2 diabetes with worsening glycemic control, weight gain, and elevated blood pressure. Vignette patients were systematically varied by age, gender, race, and comorbidity type (depression, schizophrenia with normal affect [SNA] or bizarre affect [SBA], and eczema as control). Verbal presentation was standardized. After viewing the vignette, respondents took part in a structured interview about clinical management, attitudes toward patient, practice culture, disease management tool use, and professional satisfaction. The outcome (higher/lower adherence to diabetes guidelines) was scored on a 0–100 scale summing whether respondents would attend to constructs of published diabetes guidelines: diabetes treatment (glycemic control, self-management, psychosocial care); prevention/management of diabetes complications (cardiovascular disease, nephropathy, retinopathy, foot care/neuropathy); and additional physical and laboratory evaluations for comprehensive diabetes evaluation. A multivariate ANCOVA model with backwards elimination tested for significance of predictors and meaningful interactions with comorbidity, with control for potential confounders.
RESULTS: The average level of guideline adherence was 43.6 (range: 3.0–92.5). Guideline adherence was significantly higher among physicians who reported using more disease management tools (p=.009) and general use of guidelines in their practice (44.9 vs 36.5; p=.048). Compared to patients with eczema, guideline adherence was only 2.1 points higher for patients with depression (95%CI: −9.6,13.9) but lower for patients with SNA (−4.0; 95%CI: −16.6,8.6) or SBA (−4.5; 95%CI: −16.3,7.4). Further, for patients with SBA, physicians ranking schizophrenia higher than diabetes on their problem list exhibited somewhat lower adherence to diabetes guidelines compared to those ranking diabetes higher (−10.6; 95%CI: −18.9, −2.3); for patients with SNA, the trend was the same. Though physician view of patients' ability to self-manage health explained some of the difference in adherence among comorbidities (p=.02), the effect of comorbidity remained significant (p=.008).
CONCLUSIONS: On average, respondents reported low adherence to diabetes guidelines in the presence of a comorbidity (mental health or eczema). That some physicians scored above 90 supports that the outcome variable captured relevant clinical actions, suggesting that low average adherence may reflect substantial clinical inertia. The finding of slightly lower guideline adherence in the presence of comorbid schizophrenia is consistent with literature showing that patients with serious mental illness risk lower quality of care and higher mortality from diabetes. Results identify two practice patterns—using more disease management tools and general use of guidelines in clinical practice—that support guideline adherence for patients with diabetes, providing actionable strategies that healthcare organizations and policymakers can target to enhance guideline implementation.

INCARCERATION IS ASSOCIATED WITH WORSE HEALTH OUTCOMES AND ANTIRETROVIRAL ADHERENCE AMONG HIV-INFECTED PATIENTS Emily A. Wang[1]; Kathleen A. McGinnis[2]; Kathleen M. Akgün[1]; Jennifer Edelman[1]; Amy C. Justice[1,3]; David Rimland[4]; Karen Wang[3]; David A. Fiellin[1]. [1]Yale University, New Haven, CT; [2]VA Pittsburgh Healthcare System, Pittsburgh, PA; [3]VA CT Healthcare System, West Haven, CT; [4]Atlanta VAMC and Emory University School of Medicine, Atlanta, GA. (Tracking ID #1639971)

BACKGROUND: One in seven individuals infected with HIV is incarcerated each year. Compared with HIV-infected individuals who are never incarcerated, individuals released from correctional facilities have worse HIV disease control and increased mortality, although the specific mechanisms for this are unknown. We aimed to measure the impact of incarceration on HIV disease control in released patients and determine whether worse adherence to antiretroviral therapy and/or poor engagement in primary care are contributing to worse disease outcomes following release from correctional facilities.
METHODS: We examined the association between incarceration and measures of HIV disease severity using data from the Veterans Aging Cohort Study (VACS). VACS is a longitudinal, prospective, 8-site observational study of HIV-infected patients seen in Veterans Administration Medical Centers using a combination of self-reported, administrative, and clinical data. During the most recent follow-up examination (2010–2011), participants answered questions about their sociodemographics, history of incarceration, alcohol and illicit drug use, homelessness, and depression. Using multivariate regression, we explored the independent association between having a history of incarceration and low CD4 counts (<200 cells/mL), detectable viral RNA loads (> 500 copies/mL), and the VACS Index, a validated biomarker predictive of morbidity and mortality. We then performed a Baron and Kenny statistical mediation analysis to examine whether antiretroviral drug adherence or engagement in primary care (2+ primary care visits in 12 month period) mediated observed associations, expecting an attenuation of the association after adjustment for the candidate mediators.
RESULTS: Among 1599 HIV-infected male patients, 48 % reported having been incarcerated, 73 % were on HAART and 98 % had 2+ primary care visits in the past 12 months. In unadjusted analyses, participants who reported a history of incarceration were more likely to have a low CD4 count (odds ratio (OR) 1.41, 95 % confidence interval (CI) 1.05, 1.89), a detectable viral load (1.39 OR, 95 % CI (1.02, 1.74), and a higher (worse) VACS Index score, (β 4.11, 95 % CI (2.19, 6.05)) compared with participants who did not endorse a history of incarceration. Adjustment for covariates associated with low CD4 count, including drug use, income, homelessness in the past 4 weeks, attenuated the association (adjusted odds ratio (AOR), 1.19, 95 % CI 0.86, 1.65). Similarly, adjustment for covariates associated with detectable viral load (age, race, drug use, income, homelessness in the past 4 week) attenuated the association of between

incarceration and detectable viral load (AOR 1.12, 95 % CI 0.84, 1.52)). However, adjustment for covariates associated with VACS Index (race, income, drug use, homelessness in the past 4 weeks) attenuated but did not eliminate the association between incarceration and the VACS Index (β 2.2, 95 % CI, 0.16, 4.31). Mediation analysis revealed that HAART adherence attenuates the association by 13 % (β 1.9, 95 % CI −0.29, 4.23) while engaging in primary care does not change the association between incarceration and VACS index (β 2.3, 95 % CI 0.08, 4.59).

CONCLUSIONS: Incarceration is associated with worse health outcomes among HIV-infected veterans. Clinicians should assess incarceration history in HIV-infected patients in order to improve clinical outcomes through improved adherence to antiretroviral therapy.

INCORPORATING A PANEL MANAGEMENT ASSISTANT AND TOOLKIT INTO VA PATIENT ALIGNED CARE TEAMS Katelyn Bennett[1,2]; Ashley E. Jensen[1,2]; Jaclyn Fox[1,2]; Stella Savarimuthu[1,2]; Rachel Blitzer[1,2]; Anne Dembitzer[2,1]; Scott Sherman[2,1]; Mark D. Schwartz[1,2]. [1]NYU School of Medicine, New York, NY; [2]Veterans Affairs New York Harbor Healthcare System, New York, NY. (Tracking ID #1641229)

BACKGROUND: Panel management (PM) is an important tool in patient centered medical home (PCMH) models, but few studies have examined how to implement it effectively. The Program for Research on the Outcomes of VA Education (PROVE) seeks to understand the impact of PM and clinical microsystem education on hypertension and smoking outcomes through the incorporation of a Panel Management Assistant (PMA) into VA's PCMH model, Patient Aligned Care Teams (PACT). We developed a toolkit to address gaps in patient care identified through stakeholder interviews. PMAs used toolkit strategies to enhance primary care for smoking and hypertensive patients. Strategies included broad educational outreach such as mailings about VA resources and self-management tips for hypertension; targeted phone outreach such as follow-up calls to patients with a new smoking cessation medication; and connect to care strategies such as contacting patients who are eligible for programs such as telephone monitoring. We sought to determine which PM strategies were preferred by providers and nurses, and to describe barriers to implementing PM and incorporating PMAs into teams.

METHODS: We hired and trained 6 part-time PMAs and randomly assigned each to 2 teams to perform toolkit strategies for 9 months. Before and after intervention, we surveyed primary care providers and nurses about PM and PROVE implementation. PMAs also completed weekly surveys to capture their use of the PM strategies and on their teams' responses to the interventions.

RESULTS: Most primary care providers (76 %) and nurses (89 %) reported the PM toolkit and PMA were helpful resources. Over 9 months, PMAs performed an average per month of 24 PM interventions per team of which "targeted phone outreach" (33 %), "connection to care" (30 %) and "broad education" (22 %) were most frequent. Most providers and nurses (83 %) found the targeted and broad educational outreach strategies helpful and 80 % found connecting patients to care helpful. Time constraints posed a considerable barrier to toolkit implementation. Each PMA was employed part-time and assisted 2 teams. In 20 h per week, PMAs spent most of their time running data queries (19 %), calling patients (17 %), preparing mailings (17 %), and developing patient materials (15 %). In 9 months, the 6 PMAs completed 793 phone calls (54 % of which reached patients) and 5,024 mailings. On average, PMAs spent about 11 min on the phone per patient and 2 min mailing per patient. Limited interaction between teams and PMAs was an important challenge; both PMAs and teams said more time was needed to establish roles, relationships, and trust.

CONCLUSIONS: Primary care teams preferred that the PMAs focus on preparing educational mailings and connecting patients to care. Increasing intervention length and contact time between PMAs and teams may increase toolkit acceptance and effectiveness. While this toolkit was developed to address care gaps specific to hypertensive and smoking populations, the strategies are generalizable to other diseases and offer PCMH models a more comprehensive method of conducting panel management.

INITIATING A STUDENT-FACULTY COLLABORATIVE PRIMARY CARE PRACTICE FOR CHRONIC DISEASE MANAGEMENT Mitalee M. Patil[1]; John Hegde[1]; Tomi Jun[1]; Sun Yoo[1]; Jane M. Zhu[1]; Jennifer Katz-Eriksen[2,1]; Rebecca Berman[3,1]; Pamela Vohra-Khullar[4,1]; Kristin Remus[4,1]; Amy R. Weinstein[4,1]. [1]Harvard Medical School, Boston, MA; [2]Brigham & Women's Hospital, Boston, MA; [3]Brigham & Women's Hospital, Boston, MA; [4]Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #1640846)

BACKGROUND: We conducted a needs assessment of the primary care practice at Beth Israel Deaconess Medical Center (BIDMC) and found areas for improvement in chronic disease management, specifically through patient education. Since patient education is not a core focus in our medical school curriculum, particularly in the pre-clinical years, we developed a new student-faculty collaborative practice to train medical students to become more effective patient educators and to improve chronic care management for patients.

METHODS: Based on results from the needs assessment, we developed care management models for patients with hypertension, diabetes, COPD and obesity in collaboration with the patients' primary care physicians and specialists. Patients are recruited from existing BIDMC patient panels, with a focus on those who may benefit from additional attention to lifestyle modifications, medication titration and adherence, and behavioral counseling. Patients are seen in a weekly evening clinic by a team consisting of a first- or second-year medical student, a third- or fourth-year medical student, and an attending physician. This unique team structure allows the senior student to assume a teaching role and offers the junior student an opportunity to witness disease management prior to clinical rotations. Each hour-long appointment prioritizes patient education.

RESULTS: During the four-month fall clinic period, our practice ran at 78 % capacity, with a no-show rate of 13 % and a same-day cancellation rate of 7 %. Student committees implemented a number of programs to improve and evaluate patient care while educating students. The student education committee instituted a pre-clinic chronic disease lecture series. The chronic care management committee developed disease-specific checklists to optimize and standardize care. Our patient education committee trained student clinicians about methods of motivational interviewing. The research committee identified patient outcomes for evaluation and submitted research protocols currently under review.

CONCLUSIONS: Our collaborative practice has adopted a time-intensive, counseling-intensive approach focused on patient education needs. Next steps in evaluation include analyses of patient outcomes, student educational impact, and patient satisfaction data. However, our practice is not yet running at full capacity. Improving patient recruitment and appointment attendance remains a priority. Longitudinally, this clinic demonstrates a model for student-faculty co-management of patients who have difficult-to-manage chronic diseases and offers students educational opportunities that complement the traditional medical school curriculum.

INITIATING BUPRENORPHINE MAINTENANCE FOR OPIATE-DEPENDENT HOSPITALIZED PATIENTS: A RANDOMIZED CONTROLLED TRIAL Jane M. Liebschutz[1,2]; Denise Crooks[2]; Debra S. Herman[3,4]; Bradley J. Anderson[3,4]; Lidia Meshesha[2]; Shernaz Dossabhoy[2]; Michael D. Stein[3,4]. 1Boston University School of Medicine, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]Butler Hospital, Providence, RI; [4]Brown University School of Medicine, Providence, RI. (Tracking ID #1634852)

BACKGROUND: Opioid agonist treatment (OAT) with methadone or buprenorphine has been shown to reduce mortality and morbidity in opioid-dependent persons; however, barriers exist to entering OAT. Lack of availability of office-based buprenorphine OAT and difficulty keeping outpatient appointments can impede entry into OAT. This study examined whether offering opiate-dependent persons hospitalized for medical conditions initiation and linkage to office based buprenorphine OAT would facilitate entry to and increase engagement in buprenorphine OAT at 6 months post initial hospitalization.

METHODS: A daily chart review of all hospital admissions and clinical interview by an addiction specialist nurse or physician identified opiate-dependent patients admitted to a general medical hospital and not currently in substance abuse treatment. Eligible (not alcohol dependent, no benzodiazepine misuse), and consenting patients were randomized to either a 5-day buprenorphine detoxification protocol (DETOX) or buprenorphine induction, intra-hospital dose stabilization, and post-discharge transition to maintenance buprenorphine OAT (LINKAGE) at an outpatient buprenorphine program affiliated with the hospital's primary care clinic. Intention to treat outcomes at 6 months included entry into outpatient buprenorphine OAT, days receiving OAT, and OAT retention at 6-months. Data were collected via hospital electronic medical records and participant interviews at baseline, 1, 3, and 6 months. Opioid dependency was verified through the Structured Clinical Interview for DSM Disorders (SCID).
RESULTS: Among 119 participants, the mean age was 40.1 (±11.8) years, 85 (71.4 %) were male, 50 (42.0 %) were non-Hispanic Caucasian, 35 (29.4 %) were African-American, and 25 (21.0 %) were Latino. LINKAGE and DETOX arms did not differ significantly (all p values>.4) on demographic characteristics. Compared to those in DETOX (n=58), participants randomized to LINKAGE (n=61) were significantly ($\chi 2$= 43.3, p<.001) more likely to enter buprenorphine OAT (73.8 % vs. 13.8 %) by 6-months. Among persons who entered buprenorphine OAT, mean buprenorphine treatment days were 93.2 (± 57.0) and 57.0 (± 56.7) in the LINKAGE (n=45) and DETOX (n=8) arms, respectively. Six months post enrollment, 2 (3 %) of the DETOX group and 14 (23 %) of the LINKAGE group were actively engaged in buprenorphine OAT ($\chi 2$=9.7, p=0.002).
CONCLUSIONS: LINKAGE was able to enroll 74 % of out-of-treatment, opiate-dependent hospitalized persons in buprenorphine OAT. Compared to standard inpatient detox, initiation of and linkage to buprenorphine treatment is an effective mean for engaging medically hospitalized patients who are not actively seeking care for their substance dependence in long-term addiction treatment. Integrating OAT into inpatient medical care is a promising avenue to reach persons with opioid dependence.

INTENSITY OF OPIOID ANALGESIC PRESCRIBING AND URGENT CARE SERVICES: A NATIONAL COHORT STUDY
Barbara J. Turner[1]; Yuanyuan Liang[1,2]; Christopher L. Louden[2]; Benjamin R. Ehler[2]; KoKo Aung[1,2]. [1]University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX. (Tracking ID #1636460)

BACKGROUND: Opioid analgesic (OA) prescribing for chronic non-cancer pain (CNCP) has proliferated in recent years. Death from drug overdose is associated with higher dose OA therapy. We hypothesized that 'risk' categories based on both dose and duration of OA therapy would be associated with costly utilization of urgent care services in a national cohort.
METHODS: We examined data from Aetna's health maintenance organization that has approximately 2.1 million enrollees. We identified 279,049 persons aged 18 to 64, enrolled for at least 12 months, from January 2009 to July 2012, receiving pharmacy benefits, and filling at least 2 prescriptions for non-injectable Schedule II or III OAs. We excluded 57,986 persons with: no diagnostic data on claims, a non-basal cell cancer diagnosis within 6 months of an OA prescription; prescriptions for methadone or buprenorphine-naloxone for opioid dependence; or incomplete demographics. Claims and enrollment data included: demographics [age, gender, US region (per CDC categories)], inpatient and outpatient encounters, ICD-9 codes and filled prescriptions for OAs. We classified CNCP as: neuropathic, musculoskeletal, chronic headache, unspecific chronic pain, or multiple. We also identified persons with depression, anxiety disorder, or posttraumatic stress disorder. We characterized OA therapy in 6-month intervals from first OA prescription within the study period to end of enrollment or July 2012. For each 6-month interval, we defined 4 OA risk categories (OARC): NO risk (0d), LOW risk (1–60d at <40 morphine equivalent daily dose in mg (MED)), MEDIUM risk (1–60d at [40–100] MED or >60d at <40 MED), HIGH risk (>=100 MED or >60d at [40–100] MED). We identified our 3 primary outcomes as any hospitalization, any emergency department (ED) visit, and any drug overdose. Using repeated measures logistic regression, we examined the adjusted association of OARC with each outcome adjusting for clinical, demographics, and time interval.
RESULTS: The 221,063 persons in the cohort were characterized by: 57 % female, median age of 45 (IQR: 35–54), and residence in the South (47 %) West (18 %), Midwest (6 %) and Northeast (29 %). The cohort had 881,555 6-month intervals after first OA prescription of which 7 % had at least one hospitalization, 14 % had at least one ED visit and 0.2 % had at least one drug overdose. After adjusting for demographics, clinical conditions and interval, increased OARC was significantly associated with greater likelihood for all 3 outcomes compared with NO Risk as shown in the table.
CONCLUSIONS: Dose and duration of OA therapy are both strongly associated with adverse events in a national privately insured cohort including costly hospitalization and ED visits as well as drug overdose. These risk categories may be useful to prospectively identify patients who need additional support to avoid these adverse events and ideally to reduce the risk of OA therapy.
Adjusted Odds Ratios for Opioid Analgesic Risk Categories and Outcomes
OARC (% of 6-month intervals) Adjusted Odds Ratios (95 % CI)
Hospitalization ED Visit Overdose
High Risk (26 %) 8.19 (7.83–8.56) 3.45 (3.36–3.55) 1.78 (1.46–2.18)
Medium Risk (18 %) 5.67 (5.42–5.94) 3.64 (3.55–3.74) 1.14 (0.90–1.45)
Low Risk (13 %) 2.81 (2.66–2.96) 3.08 (3.00–3.18) 1.04 (0.80–1.36)
No Risk (43 %) 1.00 1.00 1.00

INTERNAL MEDICINE RESIDENTS' TRAINING IN SUBSTANCE USE DISORDERS
Sarah Wakeman[1,2]; Meridale Baggett[1]; Eric Campbell[2,3]; Genevieve Pham-Kanter[3,4]. [1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Mongan Institute for Health Policy, Boston, MA; [4]University of Colorado Anschutz Medical Campus, Denver, CO. (Tracking ID #1643074)

BACKGROUND: Resident physicians are the direct care providers for many patients with Substance use disorders (SUD). Physicians have reported not feeling competent to manage addiction. Lack of post-graduate training and limited attending physician role modeling has been highlighted as reasons for this lack of preparedness.
METHODS: A survey was e-mailed to 184 internal medicine residents. The survey was designed to assess residents' self-reported preparedness to diagnose and treat addiction, their evaluation of the quality of instruction in addictions, and their knowledge of addiction.
RESULTS: Responses were obtained from 101 (55 %) of the residents. Residents estimated that 22 % of inpatients were admitted for a condition directly related to addiction and 26 % met criteria for substance use disorder. 25 % of residents felt unprepared to diagnose addiction and 62 % felt unprepared to treat addiction. Only 13 % felt very prepared to diagnose addiction. No residents felt very prepared to treat addiction. Preparedness to diagnose or treat addiction did not differ significantly across PGY level. 55 % rated the overall instruction in addictions as poor or fair. In the outpatient clinical setting, 72 % of residents rated the quality of addictions training as poor or fair. In the inpatient setting, 56 % rated the quality of instruction as poor or fair. No resident answered all six knowledge questions correctly. Slightly more than half correctly identified the mechanism of buprenorphine and 19 % correctly answered a question regarding the use of naltrexone. 9 % of residents responded that someone had expressed concern about their drinking or drug use.
CONCLUSIONS: Internal medicine residents provide care for a substantial population with active substance use disorders, yet a quarter of residents feel unprepared to diagnose addiction and 62 % feel unprepared to treat it. More than half of residents rate the quality of instruction they receive related to addiction as fair or poor. Structured and comprehensive addictions curriculum and faculty development are needed to address the deficiencies of the current training system.

INVITING PATIENTS TO READ THEIR DOCTOR'S NOTES: WHO READS THEM AND WHAT HAPPENS OVER TIME? John N. Mafi[1]; Roanne Mejilla[1]; Henry J. Feldman[1]; Jan Walker[1]; Long Ngo[1]; Jonathan Darer[2]; Christina C. Wee[1]; Tom Delbanco[1]. [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Geisinger Health System, Danville, PA. (Tracking ID #1638175)

BACKGROUND: Helping patients engage more actively in managing their health and healthcare represents one of the most important challenges of modern medicine. In the OpenNotes project, primary care physicians (PCPs) invited those patients registered to use secure patient portals to read their notes by e-mail once the note was signed, and initial findings suggest enormous patient enthusiasm with little effect on PCP workflow. We evaluated factors that might predict patients viewing their notes and examined to what degree their interest in viewing notes persisted over time.
METHODS: Using data from the Geisinger Health System cohort of the OpenNotes trial, we designed a repeated-measures analysis to evaluate predictors of viewing notes during the 12 month period from 7/1/10 to 7/1/11. Our unit of analysis was the patient visit, and our primary outcome was notes viewed, defined as patients reading their PCP's note within 30 days of receiving an electronic notification inviting the patient to read the note. Using a generalized linear model, we evaluated age, sex, time (in months) since the start of the OpenNotes trial, the lag time between the visit and when the PCP signed the note, and the number of visits prior to a given visit under analysis. We also accounted for clustering by patient visits. In addition, we conducted a separate analysis of those patients who responded to our baseline survey (44 % response rate) in order to adjust for (self-reported) race, education, employment status, and perceptions of general health.
RESULTS: We analyzed 14,323 visits (23 PCPs, 5,816 patients) over 12 months. The mean patient age was 53 years, and 55 % were female. The median number of visits per patient was 2 (IQR 1, 3). PCPs signed their notes a mean of 2 days after the visit (median=1). Among patients with more than one visit (62 %), the unadjusted rate of viewing notes declined by 1 % between the first and last note available, and patients who read at least one note tended to read subsequent notes (R=43 %). Our table summarizes significant predictors of viewing notes. Female and older patients were more likely to view notes, while a more than 2 week delay in PCPs signing their notes reduced the probability of note viewing by nearly 8 %. Patients were also slightly less likely to view their notes with each subsequent visit. In our sub-analysis of survey respondents, we observed similar results, except that visit count's effect on viewing notes no longer reached statistical significance, RR 0.989 [0.978, 1.001]. Patients with fair to poor health were also less likely to read their notes, RR of 0.951 [0.910, 0.994].
CONCLUSIONS: Illness burden and delay in physician note signing independently reduced the likelihood of patients viewing their notes. Although patients in our study were less likely overall to read their doctor's notes with each successive visit, the magnitude of decline was remarkably small, suggesting that patients have a durable interest in accessing their clinical notes.

IS SATISFACTION WITH ELECTRONIC MEDICAL RECORDS ASSOCIATED WITH OVERALL JOB SATISFACTION IN PHYSICIANS? Christine D. Jones; George M. Holmes; Sarah E. Lewis; Kristie Thompson; Darren A. DeWalt. University of North Carolina at Chapel Hill, Chapel Hill, NC. (Tracking ID #1639737)

BACKGROUND: Electronic medical records (EMRs) are being increasingly adopted nationwide in primary care practices. Though previous work has suggested that the initial implementation of an EMR can be a difficult transition for physicians, little is known about whether physician satisfaction with an EMR is associated with overall job satisfaction. We sought to evaluate whether satisfaction with an EMR is associated with job satisfaction in physicians.
METHODS: A survey was emailed to 738 unique email addresses of practice contacts for 825 primary care practices in North Carolina. Three subsequent reminder and follow up emails were additionally sent. The survey content had been previously been designed to evaluate medical home transformation within primary care clinics actively enrolled in quality improvement initiatives. Physicians who indicated that their practice had an EMR were asked to rate their agreement with three additional statements to assess satisfaction with the EMR: 1) "My clinic's EMR is a big help to me in providing quality care to my patients," 2) "The EMR is well integrated into the practice's daily work flow," and 3) "I can trust the validity of the data in our EMR." Answers to these questions were on a 5-point Likert scale ranging from "Strongly Disagree" to "Strongly Agree." The three EMR items were transformed into a summed score. Job satisfaction was assessed with the question "Overall, I am satisfied with my current job." Those who agreed or strongly agreed with this statement were considered to have high job satisfaction. We used least squares regression to compare EMR satisfaction (independent variable) with high job satisfaction (dependent variable).
RESULTS: Surveys were returned from 283 individuals across 214 practices (26 % response rate for practices). Among the respondents, 150 (65 %) were physicians, 55 (24 %) were non-physician clinicians, and 24 (10 %) were administrative employees. We excluded physicians from our analysis who were either missing data (n=6) or who indicated that they did not use an EMR (n=21). Among the remaining 123 physicians who indicated they had an EMR in their practice, 67 % were female, 77 % were

in a private practice, 29 % were Hispanic or nonwhite, and they graduated from medical school an average of 18 years ago. Overall, a majority of physicians (81 %) indicated high job satisfaction. EMR satisfaction was correlated with high job satisfaction (beta=0.359, $p<0.0001$). After adjusting for gender, race/ethnicity, graduation year, and whether the physician was in private practice, EMR satisfaction remained correlated with high job satisfaction (beta=0.344, $p<0.0001$).
CONCLUSIONS: Among primary care physicians who responded to a survey in North Carolina, satisfaction with their EMR was associated with overall job satisfaction, even after adjusting for multiple potential confounders. As EMRs become more prevalent and more integral to daily clinical operations for primary care physicians, satisfaction with EMRs will likely be an increasingly important contributor to overall job satisfaction.

IT'S MIDNIGHT, DO YOU KNOW WHO YOUR PATIENTS ARE? A SURVEY OF HOUSESTAFF ATTITUDES TOWARDS NIGHTTIME HOSPITAL CARE Joshua T. Hanson[1,2]; Sahand Rahnama[1]; Tareq Nassar[1]; Luci Leykum[1,2]. 1UT Heath Sciences Center, San Antonio, San Antonio, TX; [2]South Texas Veteran's Healthcare System, San Antonio, TX. (Tracking ID #1642696)

BACKGROUND: In recent years, increasing attention and efforts have been paid to providing safe and effective care in hospitals during nights and weekends. In academic settings, physician trainees provide the majority of this care. Many investigators have studied the attitudes of trainees towards education and patient care during nightfloat rotations. Furthermore, attempts have been made to measure adverse outcomes during nightfloat rotations. However, there is a paucity of information on the beliefs of physician trainees regarding their role as the nighttime physician and whether the daytime physicians provide adequate information in the care of the patients in the hospital. Our goals were to understand these attitudes and behaviors among the internal medicine housestaff at single academic medical center.
METHODS: A questionnaire was administered to the trainees of a university based internal medicine residency-training program. Respondents could submit their answers electronically or on paper. The questionnaire focused on behaviors and attitudes of housestaff toward transitions in care, nighttime medicine, and the clinical tools that have been implemented in efforts to assist their activities.
RESULTS: Responses from 53 of 89 (59.6 %) residents were obtained from all levels of training. The majority of residents (39/53 [62.3 %]) agreed or strongly agreed that having a nightfloat intern provided safer patient care when compared to the call team and that the checkout procedure currently in place was safe (41/53 [77.4 %] responded frequently or always.) Furthermore, the vast majority (47/53 [88.7 %] responded frequently or always) felt responsible for the patients at night. A minority of respondents were informed of the patient's care plan for the next day (6/53 [11.3 %] responded frequently or always), were given a list of actions to not perform (11/53 [13.21 %] responded frequently or always), and felt that the checkout process informed them of the current clinical care of each patient (14/53 [26.4 %] responded frequently or always.) Thirty-one of fifty-three (58.5 %) respondents stated that they document frequently or always in the electronic medical record (EMR) new events that required action. Finally, 35 of 53 (66.0 %) respondents described the checkout list as a time-saver when compared to finding information in the EMR.
CONCLUSIONS: Reassuringly, physician-trainees felt responsible for the clinical care of patients at night. However, it is striking that the checkout procedure is believed to be safe when the care plans are rarely communicated fully and the written signout is not believed to be an efficient data source when compared with the EMR by more than a third of the respondents. This finding correlates to other findings of written signout usage at this institution. It is also surprising that so many respondents report such a high degree of documentation when a different study of this residency-training program demonstrated an extremely low rate when behaviors were measured in real time. These findings suggest that if hospitals are to achieve safe and effective care around the clock, the behaviors and attitudes of physicians must be examined and adjusted, while efforts to better support nighttime medicine must be undertaken.

KEEPING PATIENTS SAFE: PATIENT SAFETY RESULTS AFTER TWO YEARS OF AN ENHANCED CLINIC HANDOFF Megan Prochaska[1]; Marcus Dahlstrom[3]; Wei Wei Lee[1]; Kimberly Beiting[4]; Shana Ratner[2]; Julie L. Oyler[1]; Lisa M. Vinci[1]; Vineet Arora[1]; Amber Pincavage[1]. [1]University of Chicago, Chicago, IL; [2]University of North Carolina-Chapel Hill, Chapel HIll, NC; [3]University of California San Francisco, San Francisco, CA; [4]University of Illinois-Chicago, Chicago, IL. (Tracking ID #1642350)

BACKGROUND: Internal Medicine resident clinic handoffs are a vulnerable period for patients, and yet few interventions exist to reduce risk during this transition. Two years after implementation of an enhanced handoff protocol, we evaluated its effectiveness and sustainability on patient outcomes for high-risk patients.
METHODS: Based on a needs-assessment in 2010, we formalized a 2011 handoff protocol including resident education, improved scheduling coordination, automatic missed visit rescheduling, safety audits and time for PGY2s to establish care during telephone visits. To facilitate handoffs, graduating residents listed their "high-risk" patients on sign-outs. High-risk patients included patients who have multiple complex problems, frequent hospitalizations, non-adherence, missed visits or challenging social situations. This protocol was again used in 2012. In 2010, 2011, and 2012 we performed chart audits to examine when patients were scheduled, if they saw the correct PCP, if they were lost to follow-up after 6 months, and acute care visits (emergency room visits or hospitalizations) 3 months after the handoff. Descriptive statistics, including chi squared tests and trend analysis for proportions were used to examine differences across years in outcomes of interest.
RESULTS: Nearly all patients ($n=258$ in 2010; 323 in 2011; 264 in 2012) [97 % (250/258) vs. 98 % (217/323) vs. 93 % (246/264)] received follow-up appointments in all 3 years. After 2 years, there was a continued improvement in the number of patients with acute visits in the emergency room or hospital 3 months post-handoff compared with 2010 (26 % (68/258) in 2010 vs. 20 % (64/323) in 2011 vs. 16 % (42/264) in 2012, $p=0.003$). There were significantly fewer patients who were lost to follow up at 6 months by 2012 (19 % (50/258) in 2010 vs. 22 % (71/323) in 2011 vs. 12 % (32/264) in 2012, $p=0.03$). In 2011, significantly more patients saw the correct PCP assigned to them who received the handoff (44 % (113/258 vs. 82 % (265/323), $p<0.001$) and this improvement was sustained in 2012 (71 % (188/264), $p<0.001$ compared to baseline). More patients in 2012 had a "no show" to a PCP visit in the past year then in 2011 and 2010 (42 % (109/258) in 2010 vs. 60 % (192/323) in 2011 vs. 80 % (210/264) in 2012, $p<0.001$) while the numbers of patients missing their first visit with a new PCP after the handoff was unchanged (29 % (75/258) in 2010 vs. 43 % (139/323) in 2011 vs. 31 % (82/264) in 2012, $p=0.65$).
CONCLUSIONS: Two years after implementation of an enhanced clinic handoff quality improvement intervention in an internal medicine residency clinic led to sustained improvements in patient outcomes. Although residents selected a higher risk population with more missed visits each year, the intervention was associated with a significant decline in acute care visits and significantly fewer patients lost to follow up 6 months after the handoff. Given the current national need to reduce health care costs for the sickest patients and improving access to primary care for the newly insured, redesigning clinic handoffs in an urban residency program may be an effective way to improve care for a high-risk patient population.

KNOWLEDGE GAP: LACK OF AWARENESS OF THE CANCER RISK ASSOCIATED WITH OBESITY Ginger J. Winston; Erica Phillips; Carla Boutin-Foster; Mary Charlson. Weill Cornell Medical College, New York, NY. (Tracking ID #1636168)

BACKGROUND: Data are limited regarding knowledge of the health risks of obesity among overweight/obese black and Hispanic adults residing in underserved urban communities, a population disproportionately affected by the obesity epidemic. Education is a cornerstone of health behavior change, therefore, data on obesity risk knowledge are important in order to develop tailored weight loss interventions. The aim of this analysis

was to measure knowledge of the health risks of obesity among non-Hispanic black and Hispanic adults enrolled in a weight loss trial in New York City.

METHODS: The Small Changes and Lasting Effects (SCALE) trial is an ongoing 1 year behavior change weight loss intervention among non-Hispanic black and Hispanic adults with body mass index (BMI)≥25 kg/m2 living primarily in Harlem and the South Bronx, New York. At enrollment participants were asked if obesity increased the risk of hypertension, diabetes, high cholesterol, joint pains/arthritis, breast cancer and obstructive sleep apnea. One point was given for each correct answer, and a risk knowledge score was calculated as a summation of points. Bivariate data were analyzed using student T tests and chi-square tests as appropriate. A multivariate regression model was used to assess the relationship between the risk knowledge score and the following covariates: age, gender, race/ethnicity, BMI at enrollment, education, insurance status and the Charlson comorbidity index. The interaction between race/ethnicity and education was assessed in the fully adjusted model.

RESULTS: Data were available for 275 participants (88 % women, 50 % non-Hispanic black, 50 % Hispanic, mean BMI 34.3 kg/m2, mean age 48 years). The majority of participants indicated that obesity increased the risk of hypertension (95 %), diabetes (97 %), high cholesterol (91 %), joint pains/arthritis (89 %) and sleep apnea (91 %). Only 44 % of participants reported that obesity increased the risk of breast cancer. Hispanics had a higher mean risk knowledge score compared to non-Hispanic blacks (5.3 vs. 4.8, $p<0.002$), though a lower percent of Hispanics completed high school (44 % vs. 75 %, $p<0.0001$). A greater percent of Hispanics compared to non-Hispanic blacks reported that obesity increased the risk of diabetes (99 % vs. 96 %, $p=0.05$), high cholesterol (95 % vs. 85 %, $p<0.01$), breast cancer (51 % vs. 37 %, $p=0.02$), and sleep apnea (96 % vs. 84 %, $p<0.001$). In the fully adjusted regression model, race/ethnicity ($p<0.0001$), gender ($p=0.02$) and education ($p=0.01$) were associated with the risk knowledge score. Specifically, female gender and education beyond high school were associated with a higher score. There was an interaction by race/ethnicity in the relationship between the risk knowledge score and education ($p=0.002$). Non-Hispanic black participants with less than high school education had the lowest mean risk knowledge score.

CONCLUSIONS: In the SCALE trial, a smaller percent of participants were aware of the breast cancer risk associated with obesity than the cardiovascular risks. Hispanics had a higher mean risk knowledge score compared to non-Hispanic blacks, despite lower educational levels. These results indicate a need for increased public health education regarding the non-cardiovascular risks associated with obesity in underserved urban communities. Our results also suggest non-formal sources of obesity risk education among Hispanics, a finding that deserves further investigation.

KNOWLEDGE AND PERCEPTIONS OF NON-PHYSICIAN PRIMARY CARE TEAM MEMBERS REGARDING END OF YEAR PCP TRANSITIONS IN A RESIDENT CONTINUITY CLINIC Emily S. Wang[1,2]; Michelle Conde[1,2]; Bret Simon[2]; Luci Leykum[1,2]. [1]South Texas Veterans Health Care System, San Antonio, TX; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX. (Tracking ID #1640242)

BACKGROUND: Transitioning to a new primary care physician (PCP) is a stressful time for patients; it is also a potential time for increased harm and risk. These risks are amplified in Internal Medicine resident continuity clinics due to the yearly cycle of residents finishing their training and new residents assuming care for this cohort of patients. With the nation-wide movement to the Patient-Centered Medical Home (PCMH), opportunities exist for the team to have a greater role in assisting with this transition, but there are no studies documenting perspectives of the non-physician team members on resident PCP transitions. The objective of this study was to determine the baseline knowledge and perceptions of the non-physician Patient-Aligned Care Team (PACT) members, the Veterans Health PCMH model, regarding the end of year hand-off in a resident continuity clinic.

METHODS: We report a cross-sectional study of clinic member perceptions. An anonymous survey was issued to 24 non-physician PACT team members (physician assistants, nurse practitioners, nurses, medical assistants, pharmacists, psychologists, dieticians, social workers, clerical staff) at the hospital based Internal Medicine Clinic at South Texas Veterans Health Care System in the summer of 2012. Demographic data were obtained including clinic role, number of years working in the clinic, and amount of time spent with patients whose PCPs were residents. Perceptions and attitudes on the transition process were measured based on a 5-point Likert scale ranging from strongly disagree to strongly agree. Questions such as "It is the PCP's responsibility to inform the patient when he/she will be leaving" and "I can help with making the transition easier" were rated.

RESULTS: The response rate was 92 %(22 of 24). All PACT team members were aware the IMC is a resident teaching clinic, but 18 % were unaware that residents had graduated from medical school. This unawareness did not correlate with the length of time working in the clinic. Many of the respondents (13/24) identified that patients voiced frustration with the hand-off process and most (17/24) affirmed there should be a formalized approach of ushering patients through this period. 96 % felt it was the resident PCPs' responsibility to inform the patients they would be getting new PCPs, but 64 % believed they could help make the end of year transition to new PCPs easier.

CONCLUSIONS: While majorities of PACT team members identified problems with end-of-year PCP transitions, nearly all considered the resident responsible for managing these changes. However, two-thirds of PACT team members did recognize that they had the potential to facilitate this process. With the constant changes in PCPs occurring annually in resident continuity clinics, it seems natural for PACT members to assume a greater role in supporting patients through this transition, particularly since they hear concerns from patients about this process. However, an incomplete understanding of residency training is a barrier to overcome. A team approach to collective responsibility for the transition process could be an important strategy for improving the transition process and might reinforce the emphasis on team function, an essential element of the PCMH philosophy. Future studies should investigate possible interventions that can be implemented with clearly defined roles and functions for all members of the PACT to improve patient satisfaction and ultimately, quality of care during transition periods.

KNOWLEDGE IS POWER: PILOT TESTING A BROCHURE TO IMPROVE THE COMMUNICATION OF MAMMOGRAM RESULTS TO URBAN BLACK WOMEN Erin N. Marcus[1]; Tulay Koru-Sengul[2,3]; Feng Miao[3]; Ada P. Romilly[4]; Olveen Carrasquillo[1]. [1]University of Miami Miller School of Medicine, Sylvester Comprehensive Cancer Center, Miami, FL; [2]Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL; [3]Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL; [4]Jackson Health Systems, Miami, FL. (Tracking ID #1640172)

BACKGROUND: Approximately 1 in 10 women are asked to return early for additional imaging after a single routine screening mammogram. Research indicates many women are unaware of the frequency of early recall and experience anxiety when asked to return early. When surveyed, many women voice an incorrect understanding of their mammogram result and follow up. These "result communication failures" are more common among ethnic minority women. With focus group input, we developed a culturally targeted brochure to improve awareness of the frequency of abnormal results and the importance of timely follow-up among black, English-speaking women. In this pilot study, we assess reactions to the brochure and evaluate its effect on women's understanding of their result and mammography-related anxiety.

METHODS: A randomized, two-arm controlled trial is ongoing among black women ages 40–69 with a BI-RADS 0 (incomplete, requiring additional follow-up) screening mammogram result in an urban safety net breast health center. Our pilot study will enroll a minimum of 45 women.

Women randomized to the intervention receive the culturally targeted brochure in addition to the standard result notification letter. Women randomized to the control arm receive the standard result notification letter. Two weeks after the letter is mailed, prior to the scheduled return visit, all participants are asked to complete a phone survey. Frequencies and percentages are calculated for all patients as well as by groups. Chi-square or Fisher's exact test are being used to examine differences in group proportions. Univariate logistic regression models for intervention/control are being fitted to calculate odds ratios (OR) and 95 % confidence intervals (CI).

RESULTS: To date, 33 of a target 45 women have been surveyed, including 15 interventions and 18 controls. 61 % self-identified as African-American and 39 % as Caribbean. 64 % were uninsured and 24 % received Medicaid. 27 % had not completed high school, and 40 % screened positive for low health literacy. Income, education, literacy and ethnicity are similar between the intervention and control groups. Thus far, all respondents have correctly stated their result and follow-up plan. However, 60 % of the intervention group and 22 % of controls said they had not felt anxious since their mammogram (OR 0.19, 95 % CI 0.04, 0.87; p=0.032). Women in the intervention group were also less likely to report perceiving follow up mammograms as "scary" (20 % vs. 78 %, OR 12.8, 95 % CI 2.36, 69.72; p=0.003). Among the intervention group, 12 (of 15) women stated that the brochure increased their knowledge of what happens after a mammogram "a lot" and 3 "somewhat"; 13 (of 15) said they thought the pamphlet should be mailed to all women who need to follow up early after an abnormal mammogram. Representative comments included, "the pamphlet was like a light on me. Now I feel a little better"; and "I didn't know about the numbers. It was good to see the numbers."

CONCLUSIONS: Pilot data suggests that a simple, culturally targeted brochure explaining the frequency of abnormal mammograms is effective in reducing anxiety among low-income black women asked to return early for more imaging studies. Women have been amenable to receiving the brochure along with the result notification letter. Additional pilot testing of the brochure and other mammography educational media, including a web page and video, are ongoing.

LANGUAGE INTERPRETATION ERRORS AND THEIR CLINICAL SIGNIFICANCE IN THE MEDICAL ENCOUNTERS OF SPANISH-SPEAKING LATINOS. Jasmine Santoyo-Olsson; Anna M. Napoles; Leah Karliner; Eliseo J. Perez-Stable. UCSF, San Francisco, CA. (Tracking ID #1637070)

BACKGROUND: Limited English proficient (LEP) patients with language concordant clinicians experience better outcomes of care than LEP patients with discordant clinicians. Due to shortages of language concordant physicians, there is a need to understand the impact of language interpretation on physician-patient communication and quality of care. Across three interpretation modes: professional in-person (PI), remote professional via videoconferencing (VMI), and ad hoc (non-professional, untrained; AH) interpreters, this study compared: 1) the frequency of interpreter communication behaviors, and 2) ratings of the clinical significance of interpretation errors.

METHODS: Selected patients, representing 3 modes of language interpretation (PI=5, VMI=22, AH=5), were recruited from a public hospital primary care clinic in Northern CA between May-Oct 2005 and audio recorded. Verbatim transcripts were independently coded by two investigators using a coding scheme that classified interpreter behaviors into one of eight categories: two positive (non-error) or six negative (error) codes: accurately interprets (+), asks for clarification (+), makes an addition (−), makes a substitution (−), answers for patient or clinician (−), makes an omission (−), editorializes (−), and uses incorrect words (−). The unit of analyses was an identifiable segment of continuous speech or text unit (TU). Two general internists verified the coding of the first two coders and applied independently another coding scheme to the negative behaviors (errors) that assessed their clinical significance on a 1=clinically insignificant to 4=highly clinically significant scale. All coding was adjudicated until consensus was reached.

RESULTS: Mean age of patients (n=32) was 53 years (SD 15.8), 75 % were women, 88 % had < high school education, and 56 % were uninsured. Mean age of clinicians (n=14) was 51 years (SD 11.5), 71 % women, 50 % non-Latino White, 80 % general internists, and 50 % had no previous training on using interpreters. A total of 2,945 TUs were coded; 30 % (N=872) of text units were coded as errors, with an average of 27 errors per visit. Errors of omission were 65 % of all errors coded. Accurate interpretation occurred less frequently in AH interpreted visits (38 % vs. PI=66 % and VMI=65 %; p<.05). The distribution of types of interpreter errors by mode of interpretation was similar except for makes an omission (AH=33 %, vs. PI=16 % and VMI=16 %; p<0.05) and answers for patient or clinician (AH=16 %, vs. PI=1 % and PVC=1 %; p<0.05), which occurred more frequently in AH interpreted visits. Clinically significant errors occurred frequently, (59 % of all errors, although only 7 % were rated as moderately or highly clinically significant). The mean clinical significance rating of errors was 1.67 (SD 0.61).

CONCLUSIONS: Clinically significant errors in medical interpretation are fairly common in primary care visits of Spanish-speaking patients. Ad hoc interpreted visits result in more interpreter errors of omission and answering for patients or clinicians, indicating lower quality interpretation. Expansion of professional interpreter services for LEP patients either through in-person or videoconferencing modes is warranted.

LATINO POPULATION CHANGE AND UNCOMPENSATED CARE IN CALIFORNIA HOSPITALS, 2000–2010 Matthew O'Brien[1]; Jie Chen[2]; Jeremy Mennis[1]; Victor Alos[1]; David Grande[3]; Alex Ortega[4]. [1]Temple University School of Medicine, Philadelphia, PA; [2]University of Maryland School of Public Health, College Park, MD; [3]University of Pennsylvania School of Medicine, Philadelphia, PA; [4]UCLA Fielding School of Public Health, Los Angeles, CA. (Tracking ID #1643376)

BACKGROUND: Uncompensated care provided in hospitals imposes a significant financial burden on the U.S. health care system that is expected to persist after implementation of the Patient Protection and Affordable Care Act. Latinos are more likely than any other demographic group to lack health insurance, and therefore represent a potential driver of uncompensated hospital care. The size of the Latino population and hospitals' uncompensated care costs continue to grow nationally and in many states; however, no studies have examined their potential relationship. The objective of this study was to determine the association between the Latino population growth rate in California, the state with the largest Latino population, and the change in hospitals' uncompensated care costs between 2000 and 2010.

METHODS: Data on all general, acute, short-stay hospitals in California were obtained from the 2000 and 2010 California Office of Statewide Health Planning and Development's hospital survey (100 % response rate). These data were merged with population data from the U.S. Census, which were aggregated into hospital service areas. We adjusted our analysis for hospital characteristics (ownership type, system membership, urban vs. rural location, teaching status, annual emergency department visits, and receipt of Disproportionate Share Hospital payments), market factors (location in a competitive market, presence of other hospitals), and population demographics (poverty, uninsurance, elderly, unemployment, and education). Our main outcome measure was hospitals experiencing the largest change in uncompensated care costs between 2000 and 2010. Chi-square tests were used in bivariate analyses. Logistic regression was used to calculate the odds of hospitals located in communities of medium and high Latino population growth having the largest increase in uncompensated care costs.

RESULTS: During the study period, California's Latino population grew from 31 % to 36 % (p<0.001) and total uncompensated care costs in hospitals rose from $2.7 billion vs. $4.1 billion (in 2010 dollars) (P<0.001). After adjusting for hospital characteristics, market factors, and population demographics, there was no significant association between the Latino population growth rate in California and hospitals' change in uncompensated care costs [medium and high Latino growth, respectively: odds ratio [OR], 2.03; 95 % confidence interval [CI] 0.84–4.88; and OR, 1.97; 95 % CI 0.64–6.03).

CONCLUSIONS: Our study found no association between the growth of California's Latino population and hospitals' uncompensated care costs. This finding provides current evidence to inform rapidly evolving health reform efforts at the state level. Understanding the factors that do and do not impact uncompensated care is important as policymakers explore the financial implications of expanding insurance coverage through the Affordable Care Act.

LATINO STROKE SURVIVORS ARE MORE LIKELY TO EXPERIENCE DEPRESSION Kezhen Fei; Emma K. Benn; Rennie Negron; Stanley Tuhrim; Carol Horowitz. Mount Sinai School of Medicine, New York, NY. (Tracking ID #1641894)

BACKGROUND: Literature suggests that White Americans experience more depression in general, and post-stroke depression than non-White Americans, but depression disparities have not been well-explored. We aimed to characterize this association by applying a novel 'Rank and Match' secondary analytic method, based on the Institute of Medicine's disparity framework to a multi-racial/ethnic stroke cohort.
METHODS: We recruited a cohort of community-dwelling adults who had a stroke in the past 5 years, from Harlem and the South Bronx in New York City, to a recurrent stroke prevention intervention. At baseline, we measured depression using the PHQ-8 scale, and patients' health status, demographics, comorbidities and socioeconomic status (SES), including income and education. We used multivariate logistic regression to evaluate the impact of race/ethnicity, after adjusting for health status and SES, on having depression (using a score≥10 as depressed). Then based on the IOM's disparity framework, we used our "Rank and Match" method to assess racial/ethnic differences in depression after matching Latinos and non-Latinos by their health status rank.
RESULTS: The cohort included 600 participants, with a mean of 1.9 years after stroke, mean age of 63 years, 42 % were Black, 39 % Latino, 60 % female, 56 % lived below poverty, 29 % had Medicaid and 31 % had less than a high school degree. Participants with depression (n=178; 30 %) were more likely young (p=0.002), Latino (p<0.0001), receive Medicaid (p<0.001), and had more comorbidities (p=0.004) than non-depressed participants. The adjusted odds of depression for Latinos was 3.45 (95 % CI: 1.48–8.07) times higher than for Whites and 2.22 (95 % CI: 1.45–3.38) times higher than for Blacks. After applying the "Rank and Match" method, the difference between Latinos and Whites became stronger (OR= 4.65; 95 % CI: 1.91–11.30), and the difference between Latinos and Blacks sustained (OR=2.19; 95 % CI: 1.41–3.40).
CONCLUSIONS: This study newly reveals a high depression burden among Latino stroke survivors, particularly in comparison with non-Latinos. Future research is needed to further study this disparity, and to address depression in this population.

LEARNING ENVIRONMENT ASSESSMENT OF ONE CURRICULUM BEING TAUGHT AT MEDICAL SCHOOLS 10,000 MILES APART Sean Tackett[1]; Robert Shochet[2]; Jorie Colbert-Getz[2]; Krishna Rampal[3]; Nicole A. Shilkofski[3]; Scott Wright[1]. [1]Johns Hopkins Bayview Medical Center, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Perdana University Graduate School of Medicine, Kuala Lumpur, Malaysia. (Tracking ID #1638739)

BACKGROUND: American academic medical centers are expanding their international activities, including those in medical education. Creating an effective learning environment is critical for success in medical education but this may be difficult when cultures collide. Johns Hopkins Medicine is currently building Perdana University Graduate School of Medicine (PUGSOM) near Kuala Lumpur, Malaysia, making PUGSOM the 3rd American medical school situated beyond our borders. In the fall of 2011, the first class of PUGSOM students matriculated. The goal of this study was to compare students' assessment of the learning environment at PUGSOM to that at Johns Hopkins University School of Medicine (JHUSOM), where the curriculum was created and from which most PUGSOM faculty came. A secondary goal of the study was to assess a new learning environment assessment tool, the Johns Hopkins Learning Environment Scale (JHLES), in another context.
METHODS: Students responded anonymously to online surveys during the summer after their first year of medical school. Surveys contained demographic questions and 2 learning environment scales, the Dundee Ready Educational Environment Measure (DREEM) and the JHLES. The DREEM is the most widely-used survey to assess the learning environment; students respond across a 5-point Likert scale with their level of agreement with 50 items, grouped into 5 categories: (1) perception of teachers, (2) perception of teaching, (3) academic self-perception, (4) perception of atmosphere, and (5) social self-perception. DREEM scores range from 0 to 200, and in prior studies, often average ~125. The JHLES is a 28-item survey, also using 5-point Likert scale response options developed at JHUSOM. Factor analysis resulted in 7 domains: (1) community of peers, (2) faculty relationships, (3) academic climate, (4) engagement, (5) mentorship, (6) acceptance and safety, and (7) physical space. Potential scores on JHLES can range from 28 to 140.
RESULTS: Complete surveys were collected from 100/120 (83 %) students at JHUSOM, and 24/24 (100 %) at PUGSOM. A greater proportion of PUGSOM respondents were female (71 % vs. 50 %), but gender did not influence scores on learning environment scales in subgroup analyses. The quality of the learning environment was perceived to be better at PUGSOM than JHUSOM on scores on the DREEM (155 (SD 19) vs. 143 (SD 23), p=0.011) and JHLES (117 (SD 12) vs. 112 (SD 12), p=0.078). Statistically significant differences (p<0.05) between JHUSOM and PUGSOM student responses occurred on 17/50 individual items on the DREEM. PUGSOM students gave more favorable ratings on 13 of these 17 items, including 8 in the "perception of teaching" category. On JHLES, responses differed significantly for 6/28 items; 5 of these 6 had PUGSOM students providing more favorable ratings. Correlation coefficients for scores on the DREEM and JHLES were r=0.80 for PUGSOM and r=0.64 for JHUSOM.
CONCLUSIONS: The DREEM and JHLES were highly correlated in both settings and indicated that the learning environments at PUGSOM and JHUSOM are positive. The high appreciation of the learning environment at PUGSOM, where an American curriculum has been introduced by American faculty, should reassure that high quality education can translate across countries and cultures. Future work will be needed to determine if the quality of the learning environment is maintained over time and how it relates to educational outcomes such as exam scores, residency placement, and quality of patient care.

LET'S TALK! PATIENT ATTITUDES ABOUT TELEPHONE-BASED ALTERNATIVES TO FOLLOW-UP OFFICE VISITS WITH SPECIALISTS Jessica A. Eng[1,2]; Cecily J. Hunter[1]; Laura B. Cantino1; Caterina Yuan[1]; Sunny Lai1; Evie Kalmar[1]; Christy K. Boscardin[1]; Margaret A. Handley[1]; Ralph Gonzales[1]; Sara Ackerman[3]. [1]UCSF School of Medicine, San Francisco, CA; [2]San Francisco VA Medical Center, San Francisco, CA; [3]UCSF School of Nursing, San Francisco, CA. (Tracking ID #1633158)

BACKGROUND: The number of specialty care visits in the US is rising, contributing to increased health care costs and delayed access to specialty care. There is a need for new models of care that are less costly and offer alternatives to office visits. However, if not designed with patient attitudes in mind, new models of care could result in significant patient resistance and dissatisfaction. In the context of a clinical operations project aimed at increasing the availability of new patient appointments by reducing unnecessary follow-up visits, we explored patient attitudes about telephone-based specialty follow-up.
METHODS: We observed physician-patient interactions in an urban academic endocrinology clinic from June to October 2012. Observations were discussed at regular team meetings. We subsequently conducted semi-structured interviews from October to November 2012. Interviews were conducted in clinic with a convenience sample of patients following their physician encounter. Interviews included questions on satisfaction with clinic experience and attitudes about a new pilot program consisting of patients leaving office visits with a scheduled follow-up phone call with the clinic medical assistant (MA) instead of a scheduled office visit with the physician. Interviewers explained that information gathered during the MA phone call would be conveyed to the physician, who would then decide whether patients should have another scheduled MA phone call or office visit. Interviewed patients were provided free parking as compensation. Interview notes were iteratively reviewed and discussed by 5 research team members, followed by a conference in which consensus was reached on key findings and themes.
RESULTS: Team members spent 43 h observing physician-patient interactions, and 24 patients (71 % female, aged 22 to 64) were interviewed. Overall, patients were very satisfied with their clinic experiences, in particular their interactions with physicians and office staff. Patients also expressed enthusiasm for alternatives to office-based follow-up. The dominant theme that emerged about the telephone-based follow-up program was patient convenience, including the possibility of saving time and money for travel and not

missing work. Other themes supporting this program included communication facilitation—the anticipation of improved communication with the clinic and altruism—the potential to contribute to increased office visit access for other patients. Patient endorsement of telephone-based follow-up was predicated upon the expectation that physicians continue to have primary responsibility for clinical care. A minority of patients expressed reservations about MA phone follow-up, including concerns about their care potentially "falling through the cracks" and whether the physician would continue to be in charge of medical decisions. Another consideration that emerged was the value of family members or friends in office encounters and how their participation in care might be affected by telephone-based follow-up.

CONCLUSIONS: This study reveals positive patient attitudes towards the concept of telephone-based alternatives to specialty clinic follow-up. Unexpected findings include patient interest in the program's ability to facilitate communication with the clinic and improve clinic access for other patients. Future studies of telephone-based follow-up visits should examine physician attitudes and include patient collaboration in redesign efforts to ensure acceptability.

LIMITED HEALTH LITERACY IS COMMON IN FORMER PRISON INMATES Mim Ari[1]; Joel Hirsh[2]; Brenda Beaty[1]; Ingrid A. Binswanger[1]. [1]University of Colorado School of Medicine, Aurora, CO; [2]Denver Health Medical Center, Denver, CO. (Tracking ID #1638884)

BACKGROUND: Former inmates are a medically vulnerable population. While studies of prisoners have shown limited literacy proficiency, health literacy has not been extensively assessed in this population. The goals of this study were 1) to describe health literacy in former prison inmates, 2) to assess the association between health literacy and demographic variables, self-reported health status, access and barriers to care, and high-risk behaviors.

METHODS: Sixty-eight individuals were recruited within 6 months of release from prison. Participants were interviewed in person using a survey that included questions from well-established and commonly-used data collection instruments, including the Addiction Severity Index, the Short Form-36, and the National Health Interview Survey, as well as questions related to criminal justice history, risk behaviors, past and anticipated health care, and the presence of medical complications of drug use. Additionally, individuals completed two validated health literacy instruments: a single item literacy screener (SILS) that asked participants "how confident are you filling out medical forms by yourself" and the Medical Term Recognition Test (METER) which asked participants to correctly identify 40 medical terms (i.e. kidney, hepatitis, anemia) from a list of 70 terms that included non-medical terms that were similar to medical terms (i.e. blout, cerpes, malories). The health literacy instruments were analyzed using descriptive statistics. The relationships between health literacy and self-reported health status, health care coverage, having a primary care physician, barriers to care, and tobacco use were also explored.

RESULTS: Participants (n=68) were a mean age of 42 years old (SD 10). The median number of months involved in the criminal justice system was 108. Sixty-four percent considered their health to be good to excellent, while 36 % reported poor to fair health. The two health literacy measures revealed a large range of scores. On the SILS, only 48 % felt extremely or quite a bit confident filling out medical forms. The mean adjusted METER score was 29 (SD 8.7). Using a categorization system based on score, 28 % had functional health literacy while 57 % had marginal health literacy, and 15 % had low health literacy. Functional vs. marginal/low health literacy did not show an association with age, sex, education, or time involved in the criminal justice system. On the METER, non-white participants were more likely to have marginal/low health literacy (p= 0.02). A higher percentage of those with functional health literacy reported good to excellent self-reported health status (p=0.07).

CONCLUSIONS: Limited health literacy is common in former prison inmates and, along with other complex social factors, may contribute to decisions related to access to care, participating in high-risk behaviors, and their overall health. A discussion of interventions to improve health outcomes and increase access to care in individuals recently released from prison would be incomplete without taking into account health literacy given the wide breadth of health literacy skills in this population. Our study was limited by small sample size, which makes understanding the contribution that health literacy plays more challenging.

LIMITED PROVIDER RESPONSE TO ABNORMAL MICROALBUMIN TEST RESULTS: IMPLICATIONS FOR THE UTILITY OF SCREENING RATE AS A QUALITY OF CARE METRIC Sonia T. Bajwa-Dulai; Parambir S. Dulai; Kelly A. Kieffer. Dartmouth Hitchcock Medical Center, Lebanon, NH. (Tracking ID #1637899)

BACKGROUND: Annual urine microalbumin testing is recommended in diabetic patients to screen for nephropathy. The rate at which this testing is performed is a process of care quality metric used by health care systems, accrediting organizations, and payors. It is unclear how effectively screening generates meaningful clinical outcomes. Therefore, we studied outcomes of microalbumin testing in the diabetic population of an academic primary care practice, with aims of quantifying the overall frequency of abnormal results and the proportion of patients with abnormal results in whom testing led to a meaningful change in care.

METHODS: The study population included patients receiving primary care from one clinical team at an academic medical center or from a satellite clinic of the medical center. Identical systematic, team-based processes of chronic disease care are utilized at both sites. Our chronic disease registry and laboratory database were searched to identify diabetic patients who had microalbumin testing ordered by a provider on the primary care team during a 1-year period. Retrospective chart reviews were performed for patients with abnormal results to determine whether a meaningful clinical response occurred within 6 months after the test. A meaningful response was defined as: repeat microalbumin testing; addition or increase in angiotensin converting enzyme inhibitor (ACE), angiotensin receptor blocker (ARB), beta-blocker(BB), or calcium channel blocker (CCB); further evaluation of renal function (urine protein/creatinine ratio, renal ultrasound), or nephrology referral.

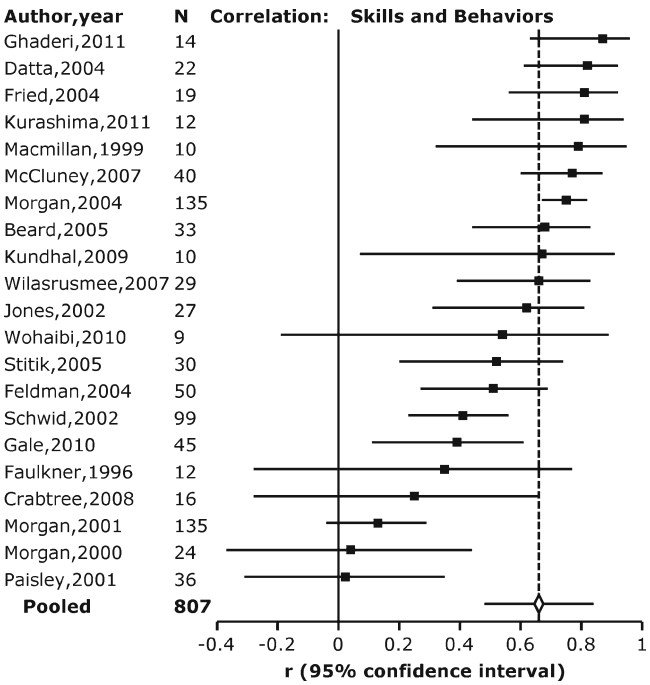
RESULTS: Of 959 diabetic patients in the practice, 50 % (n=478) had at least one microalbumin test in the primary care setting during the study period. 27 % of those tested (n=131/478) had abnormal results; the proportion of patients with abnormal results was similar between clinic sites. A meaningful clinical response occurred in 9 % of patients tested (n=42/478), in 32 % (n=42/131) of patients with abnormal results, and in 28 % (n=19/68) of patients newly diagnosed with microalbuminuria. Clinical responses included: repeat testing (n=21), addition (n=6) or increase (n=8) in ACE/ARB, increase in CCB (n=1), urine protein/creatinine ratio testing (n=6), renal ultrasound (n=2), and/or nephrology referral (n=4). In 43 % (n=56) of patients the ACE/ARB dose was continued without adjustment. Patients in whom a meaningful clinical response occurred had higher baseline creatinine levels (1.14 vs. 0.95; p=0.005), were more often male (p=0.059) and more likely to have macroalbuminuria (p=0.103). On multivariate regression analysis, a meaningful clinical response was more likely in patients with a baseline creatinine >1.4 (OR 3.10, 95 % CI 1.02–9.49) or a resident primary care provider (OR 2.59, 95 % CI 1.06–6.52).

CONCLUSIONS: Abnormal microalbumin results were relatively common in our diabetic population, but rarely led to meaningful changes in care. This may be due to the provider missing the test result, not appreciating its significance, or feeling that a change in care was not appropriate. Any of these factors, if present, would represent opportunities to increase the value of patient care. In our population, an elevated creatinine was more likely to prompt a response, suggesting clinicians may delay action until disease progression has begun. Further interventions focusing on provider education, follow-up protocols, and improved patient selection may allow for this screening measure to be more effectively utilized.

LINKING SKILLS ASSESSMENT WITH PATIENT OUTCOMES: A SYSTEMATIC REVIEW AND META-ANALYSIS David A. Cook[1]; Ryan Brydges[2]; Benjamin Zendejas[3]; Rose Hatala[4]. [1]Mayo Clinic College of Medicine, Rochester, MN; [2]University of Toronto, Toronto, ON, Canada; [3]Mayo Clinic College of Medicine, Rochester, MN; [4]University of British Columbia, Vancouver, BC, Canada. (Tracking ID #1643171)

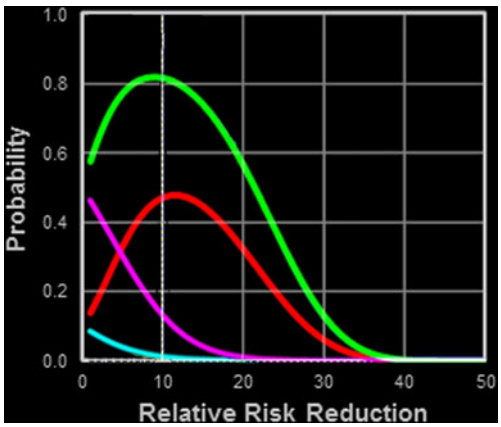
BACKGROUND: Evaluating the patient impact of health professions education is a societal priority, yet directly measuring patient outcomes is often impractical. Establishing links between patient outcomes and easier-to-measure knowledge and skills enables researchers to primarily use these surrogates, reserving for selected situations the more difficult measurement of patient outcomes. However, the strength of such links and the quality of the evidence remain largely unknown. We aimed to explore empiric links between patient outcomes and skills assessed using technology-enhanced simulation, and to identify validity evidence reported.

METHODS: We systematically searched MEDLINE, EMBASE, Scopus, and prior reviews through May 2011. We included all original research studies involving health professionals that a) evaluated the validity of a simulation-based assessment and b) reported a patient outcome. We worked in duplicate to select studies and abstract information on validity evidence and magnitude of correlation. We distinguished patient outcomes of learner behaviors (LB; eg, instructor ratings of learners during patient care), procedure time (PT), and actual patient effects (PE; eg, complications). We pooled correlation coefficients using random effects meta-analysis.
RESULTS: From 10,911 articles screened we identified 34 eligible studies enrolling 1127 participants. Topics included laparoscopic surgery, gastrointestinal endoscopy, airway management, bronchoscopy, and anesthesiology. Participants included resident physicians (*N*=28 studies), practicing physicians (*N*=12), medical students (*N*=4), and nurses (*N*=3). 29 studies reported LB outcomes, 9 reported PT, and 4 reported PE, although not all reported correlation with simulation-assessed skills. For 21 studies that did report correlation of skills with LB, the pooled correlation was 0.65 (95 % CI, 0.48–0.84; see Figure). The pooled correlation for PT was 0.71 (0.43–1.00; *N*=5 studies), and for PE was 0.37 (−0.31 to 1.00; *N*=2 studies). Looking at the validity evidence for patient outcomes, most studies (*N*=28) reported evidence of relations with other variables, while evidence of content (10 studies) and internal structure (*N*=9) were reported less often.
CONCLUSIONS: Simulation-based assessments usually (but not always) correlate with learner behaviors during patient care, with a moderately large pooled correlation. While surrogate outcomes are imperfect, they may be useful in many situations. Validity evidence for patient outcomes is sparse.



LIPID LOWERING THERAPY AND RISK OF PANCREATITIS: A BAYESIAN ANALYSIS TO DISTINGUISH BETWEEN THE CLINICAL IMPORTANCE AND STATISTICAL SIGNIFICANCE KoKo Aung[1]; Sonal Singh[2,3]; George A. Diamond[4]. [1]University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Johns Hopkins University School of Public Health, Baltimore, MD; [4]Cedars-Sinai Medical Center and University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, CA. (Tracking ID #1635074)

BACKGROUND: A recently published meta-analysis of 28 large randomized trials concluded that use of statins, but not fibrates, was associated with a lower risk of pancreatitis in patients with normal or mildly elevated triglyceride levels. There was no significant heterogeneity among the trials. The combined risk ratio averaged 0.79 (*P*=.01) in statin trials and 1.39 (*P*=.053) in fibrate trials. The objective of this study was to determine if lipid lowering therapy is associated with a clinically important reduction in the risk of pancreatitis using Bayesian analysis.
METHODS: We re-analyzed the individual trials in the meta-analysis using a formal Bayesian algorithm (Arch Intern Med 2009;169:1431). We quantified clinical importance as the probability of a relative risk reduction (RRR) >10 % using a range of prior distributions (skeptical and enthusiastic).
RESULTS: The table and figure below summarize the range of probability of RRR >10 % (threshold of clinical importance) for a worst case skeptical prior (Pworst) and a best-case enthusiastic prior (Pbest) according to our Bayesian classification algorithm. Nine of the 21 statin trials exhibited insufficient evidence of benefit (Pworst<Pbest<0.5) and 12 exhibited inconsistent evidence of benefit (Pworst<0.5<Pbest) in reducing the risk of pancreatitis. The meta-analytic summary of all 21 statin trials exhibited similarly inconsistent evidence of benefit. In comparison, 5 of the 7 fibrate trials exhibited insufficient evidence of benefit and 2 exhibited inconsistent evidence of benefit. The meta-analytic summary of all 7 fibrate trials exhibited insufficient evidence of benefit.
CONCLUSIONS: The totality of evidence is inadequate to conclude that lipid lowering therapy reduces the risk of pancreatitis to a clinically important degree. Our observations support wider use of Bayesian analysis to distinguish between the clinical importance and statistical significance of conventional meta-analyses.
Lipid lowering therapy and incident pancreatitis
Source Sample Size Risk ratio (95 % CI) Pworse Pbest
Statin vs placebo trials 113,800 0.77 (0.62–0.97) 0.39 0.78
Intensive vs moderate dose statin trials 39,614 0.82 (0.59–1.12) 0.19 0.61
All statin trials 153,414 0.79 (0.65–0.95) 0.47 0.82
All fibrate trials 40,162 1.39 (1.00–1.95) 0.01 0.13
Sensitivity analysis of the probability of a clinically important benefit (y-axis) as a function of the threshold for a clinically important RRR in statin trials (green = enthusiastic prior, red = skeptical prior) and fibrate trials (magenta = enthusiastic prior, cyan = skeptical prior)



LOSING WEIGHTS: FAILURE TO RECOGNIZE AND ACT ON WEIGHT LOSS DOCUMENTED IN AN ELECTRONIC MEDICAL RECORD Robert El-Kareh[1]; Valeria C. Pazo[2]; Adam Wright[2,3]; Gordon D. Schiff[2,4]. [1]UC San Diego, La Jolla, CA; [2]Brigham and Women's Hospital, Boston, MA; [3]Partners HealthCare System, Wellesley, MA; [4]Harvard Medical School, Boston, MA. (Tracking ID #1625879)

BACKGROUND: Involuntary weight loss may be a sign or symptom of a serious or undiagnosed illness. When significant weight loss is unrecognized, an opportunity to make a timely diagnosis may be missed. Routine capture of electronic weight data is a requirement for meaningful electronic health record (EHR) use; however, limited data exist estimating how frequently recorded weight loss is recognized. We sought to use EHR data to estimate the frequency of unrecognized involuntary weight loss and its implications.
METHODS: We analyzed weights recorded in our EHR of a random sample of 100,000 adult outpatients. We found 14,680 patients who had at least one pair of weight measurements showing a 10 pound loss within a year and identified a random subset of 1000 of them. We developed a linear regression-based algorithm to identify the start and end of periods of weight loss at rates of at least 10 % per year.

Within each loss period, we identified an "index visit," defined as the first visit at which the patient had lost 10 % of weight from the start of the loss period. Board-certified internists reviewed 170 charts of patients who experienced these weight loss periods to determine whether: 1) the weight loss was involuntary; 2) the weight loss was recognized and documented by the clinician at the index visit or at the first visit with the primary care provider (PCP) following the index visit; and 3) possible explanations for involuntary weight loss could be identified at the index visit or emerged in the subsequent 2 years. To calculate agreement between reviewers, both reviewed a random subset of 20 of the charts and we calculated kappa statistics for the three main assessments.

RESULTS: We identified 577 weight loss periods in 543 unique patients in the random sample of 1000 patients with a 10 pound weight loss within 1 year. We estimated that 18 % of the adult patient population in our sample had at least one weight loss period meeting our criteria. Of the 170 randomly selected weight loss periods that were reviewed, 22 (13 %) were involuntary, 36 (21 %) were voluntary and 112 (66 %) could not be determined at the index visit. We found that 66 (39 %) weight loss periods were recognized by the clinician at the index visit based on documentation in the chart and an additional 3 (2 %) recognized at the next PCP visit. In the subsequent 2 years following the index visit for 134 non-voluntary weight loss periods, 66 (49 %) were found to have possible explanations involving medical conditions, 19 (14 %) involving psycho-social conditions, 9 (7 %) due to erroneous data entry, 8 (6 %) were actually voluntary, and 6 (4 %) were due to postpartum weight loss. No possible explanations were found in 26 (19 %) of cases. Reviewer agreement as measured by kappa statistics regarding assessment of whether weight loss was voluntary, whether it was recognized, and category of possible explanation in the subsequent 2 years were 0.83, 0.90, and 0.60 respectively.

CONCLUSIONS: Periods of weight loss were common in our adult medical population. These losses were often involuntary and clinicians frequently did not recognize or document them. Many patients with involuntary weight loss had potential explanations at the time of the visit or in the subsequent 2 years. Use of electronic data coupled with clinical decision support to alert for clinically significant weight loss may provide opportunities for earlier detection and thereby reduce delays in the diagnosis or treatment of important underlying conditions.

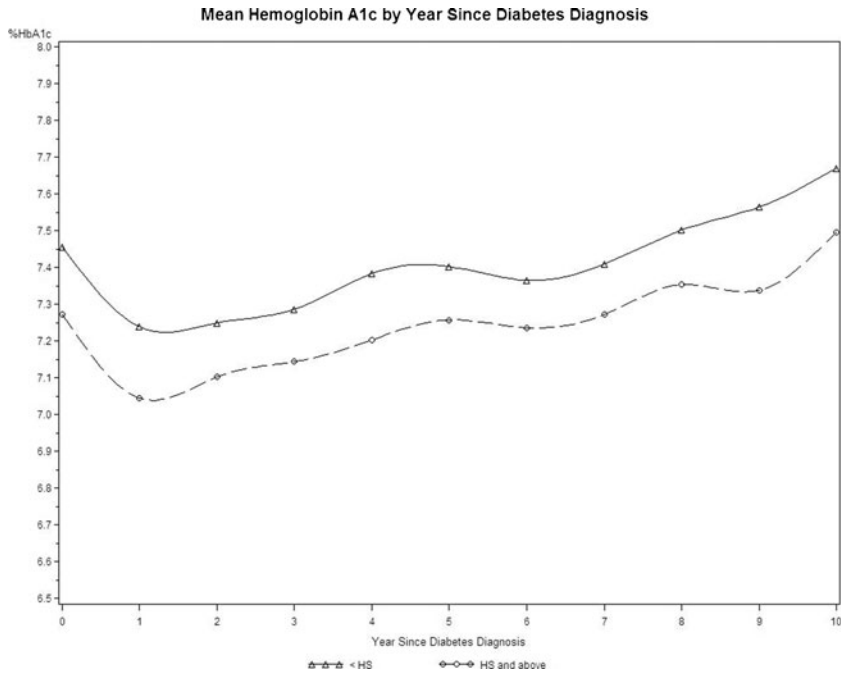
LOW EDUCATIONAL ATTAINMENT IS ASSOCIATED WITH GREATER TIME OUT OF GLYCEMIC CONTROL AND INCREASED KIDNEY DISEASE IN DIABETES PATIENTS: A LONGITUDINAL ANALYSIS Seth A. Berkowitz[1]; Wei He1; Yuchiao Chang[1]; Steven J. Atlas[1]; James Meigs[1]; Deborah J. Wexler[2]. [1]MGH, Boston, MA; [2]MGH, Boston, MA. (Tracking ID #1634575)

BACKGROUND: Patients with low educational attainment, a correlate of low socioeconomic status, have increased diabetes prevalence. However, it is unclear if these patients have worse disease control or microvascular outcomes. We hypothesized that lower education would be associated with worse longitudinal glycemic control and increased risk of developing renal disease.

METHODS: We constructed a cohort of adult patients with diabetes within an 18-practice primary care research network from Jan 1 2003 to Dec 31 2011. Patients diagnosed before age 40 or started on insulin at diagnosis were removed to exclude type 1 diabetes patients. We classified self-reported educational attainment as less than high school diploma (<HS) or high school diploma or greater (≥HS). The primary outcome was proportion of total follow-up time spent with a hemoglobin A1c (HbA1c) above 8.0 %. We defined incident chronic kidney disease stage 5 (CKD5) as at least 1 eGFR<15 ml/min by the CKD-EPI equation occurring for the first time after the diagnosis of diabetes. We performed unadjusted analyses with t-tests, and adjusted analyses with linear regression and Cox regression.

RESULTS: Over a mean follow-up duration of 5.5 (range 0.1–9) years, 13,234 patients contributed 73,424 years of follow-up time. The mean age at cohort entry was 61.1 (SD 11.5) years and 18 % had<HS education. Patients with <HS education were more likely to be non-white, female, and have Medicaid, Medicare, or no, compared to commercial, insurance ($p<$ 0.001 for all comparisons). Figure 1 depicts trends in mean HbA1c. Patients with <HS education spent 23.1 % of their follow-up time with an HbA1c>8.0, compared to 19.6 % of patients with≥HS ($p<.001$) with no difference in number of HbA1c tests per year between the two groups (4.05 in <HS vs. 4.09 in≥HS, $p=0.93$). In a linear regression model adjusted for age at cohort entry, gender, race/ethnicity, duration of diabetes, HbA1c tests per year, and insurance status, <HS remained associated with more time above HbA1c of 8.0 % (adjusted mean 24.8 % vs. 22.9 %, $p=.01$). In time-to-event analyses adjusted for age at cohort entry, gender, race/ethnicity, insurance, HbA1c tests per year, proportion of follow up time with HbA1c>8.0 %, and duration of diabetes, <HS education was associated with increased risk of incident CKD5 (HR 1.31, 95%CI 1.06–1.60).

CONCLUSIONS: Low education is associated with increased hyperglycemia and risk of CKD5, even after adjustment, including for glycemic control. Patients with low education are a high risk subgroup that may benefit from population health interventions to reduce health inequities.



MAJOR BLEEDING RISK IN ANTICOAGULATED PATIENTS RECEIVING CONCOMITANT ANTIPLATELET THERAPY: A PROSPECTIVE STUDY Jacques Donze[1,2]; Nicolas Rodondi[3]; Gerard Waeber[4]; Jacques Cornuz[5]; Drahomir Aujesky[3]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Bern University Hospital, Bern, Switzerland; [4]Lausanne University Hospital, Lausanne, Switzerland; [5]Lausanne University Hospital, Lausanne, Switzerland. (Tracking ID #1623873)

BACKGROUND: There is strong evidence that patients on both oral anticoagulant and antiplatelet therapy have a higher risk of bleeding than patients on antiplatelet therapy alone. However, there are few data comparing the risk between a combination of oral anticoagulant plus antiplatelet therapy, and oral anticoagulant alone. Current data are limited to retrospective studies or specific populations only. We aimed to prospectively evaluate whether unselected medical patients on oral anticoagulation have an increased risk of bleeding when on concomitant antiplatelet therapy.
METHODS: We prospectively studied consecutive adult medical patients who were discharged on oral anticoagulants between 01/2008 and 03/2009 from a Swiss university hospital. The primary outcome was the time to a first major bleeding on oral anticoagulation within 12 months. Major bleeding was defined as a fatal bleeding, a symptomatic bleeding in a critical organ or a bleeding causing a fall in hemoglobin level≥20 g/L or leading to a transfusion≥2 units of packed red cells. Multivariable analyses were performed using the Cox proportional hazards method with the first major bleeding event as the dependent variable and antiplatelet therapy (no one vs. at least one antiplatelet agent) as the independent variable. All important confounders based on a priori knowledge were included in the model: age, target INR at the time of enrollment, total number of medications, history of major bleeding event, and history of myocardial infarction.
RESULTS: Among the 515 included anticoagulated patients, the incidence rate of a first major bleed was 8.2 per 100 patient-years. Overall, 161 patients (31.3 %) were on both anticoagulant and antiplatelet therapy, and these patients had a similar incidence rate of major bleeding compared to patients on oral anticoagulation alone (7.6 vs. 8.4 per 100 patient-years, P=0.81). In a multivariate analysis, the association of concomitant antiplatelet therapy with the risk of major bleeding was not statistically significant (hazard ratio [HR] 0.89, 95 % confidence interval, 0.37–2.10). Only the number of medications (HR 1.13, 95%CI 1.02–1.25) and a higher target INR (HR 3.67, 95%CI 1.56–8.62) remained significantly associated with major bleeding event.
CONCLUSIONS: In this prospective cohort of internal medicine patients, the risk of bleeding in patients receiving a concomitant antiplatelet therapy was similar to patients without antiplatelet therapy, suggesting that the use of antiplatelet therapy in addition to oral anticoagulant in the general population may not be as high as found in previous studies of specific populations.
Cox Bivariate and Multivariable-Adjusted Analyses (n=515)
HR (95%CI)
Variable Bivariate Analyses Adjusted Model*
Concomitant antiplatelet therapy 0.91 (0.42–1.98) 0.89 (0.37–2.10)
Age, per 10 years 1.11 (0.84–1.47) 1.16 (0.85–1.56)
Target INR (≥ 3.0 vs. < 3.0) 3.83 (1.65–8.89) 3.67 (1.56–8.62)

MAKING THE EHR SMARTER: PATIENT AND PROVIDER REPORTED DATA IMPROVE PERFORMANCE ON PREVENTATIVE HEALTH QUALITY MEASURES Michael E. Bowen[1,2]; Jason Fish[1]; Deepa Bhat[1]; Brett Moran[1]; Temple S. Howell-Stampley[1]; Lynne Kirk[1]; Kim Batchelor[1]; Ethan Halm[1,2]. 1UT Southwestern Medical Center, Dallas, TX; [2]UT Southwestern Medical Center, Dallas, TX. (Tracking ID #1639832)

BACKGROUND: Although Electronic Health Records (EHRs) facilitate data collection and management, the ability to capture services delivered in other health systems and patient-centered information is limited. The frequency of such occurrences and impact on performance metrics is unknown. We describe the frequency of provider-reported exceptions to preventative health best practice alerts (BPAs) and examine the impact of patient-centered data exceptions on performance metrics.
METHODS: We implemented 5 visit-based BPAs in our Epic EHR targeting preventative health metrics in 3 general medicine clinics between July 2011 and June 2012. BPAs included: mammography (MAM), colorectal cancer (CRC), cervical cancer (CERV), and osteoporosis (OP) screening, and pneumonia vaccine (PNA). BPAs allowed providers to report patient preferences and medical contraindications to BPAs. BPAs satisfied outside the health system were documented in the BPA or the health maintenance section of the EHR. The study sample included established patients eligible for age-appropriate preventative services with at least one primary care visit in the past year. Baseline performance was calculated as the proportion of eligible patients satisfying measures based on EHR data. Post-BPA measurements were calculated using 3 approaches: 1) Standard: EHR data/measure eligible; 2) Exception: (EHR data + completed elsewhere)/(measure eligible-patient reason-medical reason); 3) Patient-centered: in this approach, patient refusals or medical contraindications counted towards measure completion rates. (EHR data + completed elsewhere + patient reason + medical reason)/measure eligible. Performance before and after BPA implementation was examined for each approach using a chi-square analysis with bonferroni adjustment. A cross-sectional comparison of post-BPA performance between the 3 approaches was also done.
RESULTS: Between July 2011 and June 2012, 23805 encounters were completed by 9780 patients who were eligible for at least one health maintenance measure. A total of 21757 alerts fired. Baseline performance rates were as follows: MAM 71 %, CRC 67 %, CERV 53 %, OP 72 %, and PNA 67 %. For each metric, between 2 and 9 % of patients had services completed elsewhere and between 0.7 and 2.4 % of BPAs were not completed for patient reasons such as patient refusal or medical reasons such as limited life expectancy. In the standard approach, significant improvement from baseline was observed after BPA implementation for CRC (74 %), PNA (73 %), and OP (72 %) (p<0.05 for all). Mammography and cervical cancer screening rates did not change. In the exception approach, all measures improved significantly from baseline: MAM 75 %, CRC 84 %, CERV 62 %, OP 80 %, and PNA 82 % (p<0.05 for all). Similar improvements from baseline were noted with the patient-centered approach: MAM 76 %, CRC 84 %, CERV 63 %, OP 80 %, PNA 81 % (p< 0.05 for all). While no difference in post-BPA performance between the exception and patient-centered approaches was observed in cross-sectional analysis, performance rates in the exception (p<0.05 for all measures) and patient-centered approaches (p<0.05 for all measures) were significantly higher than the standard approach.
CONCLUSIONS: Inclusion of patient and provider-reported data improved performance on preventative health metrics. Service completion in outside systems is common, and failure to account for outside data may underestimate performance.

MANAGING YOUR MEDICATION FOR EDUCATION AND DAILY SUPPORT: THE VALUE OF A CLINICAL PHARMACIST IN PRIMARY CARE PRACTICES TO IMPROVE DIABETES CARE Ekaterina Vaisberg[1]; Gerardo Moreno[2,1]; Chi-Hong Tseng[1]; Douglas Bell[1]; Robin Clarke[1]; Shirley Wong[1]; Jeffery Y. Fu[1]; Carol Mangione[1]. [1]University of California, Los Angeles, Los Angeles, CA; [2]University of California, Los Angeles, Los Angeles, CA. (Tracking ID #1642189)

BACKGROUND: Inclusion of clinical pharmacists on the primary care team has potential for improving the care of complex chronic conditions such as diabetes. A limited number of randomized trials have examined the incorporation of clinical pharmacists to patient care with mixed results, but few pragmatic studies have investigated the impact of the pharmacists in real world settings or community primary care practices. Our objective is to test the value of embedding a clinical pharmacist into the care team in four heterogeneous community-based primary care practices, by evaluating the effect of such a program on cardiovascular risk factors for complex patients with diabetes.

METHODS: We conducted a pre-post cohort study of a clinical pharmacist medication therapy management intervention for patients with type 2 diabetes. Patients were eligible if they fit one of the following criteria: hemoglobin A1c (A1c) >9 %, blood pressure (BP)>140/90 mmHg, LDL-cholesterol (LDL-c) >130 mg/dL or five or more prescribed chronic medications. One-on-one consultations with patients were conducted by the pharmacist at primary care practices in the community. The main components of the consultations were motivational interviewing for personal adherence barriers, medication reconciliation, and medication therapy management. We compared pre-post intervention values for A1c, LDL-c and SBP. We used t-tests and Wilcoxon rank sum tests to compare continuous variables between two groups and chi-squared tests to compare categorical variables. Control subjects have been chosen from 9 additional primary care practices in the same health system but without a clinical pharmacist. If selected for presentation, propensity score analysis comparing the change from pre and post measurements between experimental and matched control subjects will be presented.

RESULTS: Patients that saw the clinical pharmacist (N=89) were 47 % female and had a mean age of 62 ±12 years. The mean baseline A1c was 8.1 % (±12), SBP was 132 mmHg (±32), and the LDL-c was 99 mg/dL (±30). Medication reconciliation was conducted on all patients and the average number of prescribed medications was eight. Patients that consulted with a clinical pharmacist had a mean decrease in A1c of −0.42 % (95 % CI −0.78 to −0.06, P=0.02) while among patients with a baseline A1c>9 %, the decrease in A1c was −1.88 % (n=25, 95 % CI −2.69 to −1.07, P<0.001). There were no significant decreases in overall mean LDL-c and SBP. Among patients with a baseline LDL-c>130 mg/dL, the decrease in LDL-c was −52.75 mg/dL (n=12, 95 % CI −80.94 to −24.56, P=0.002). Among patients with a baseline SBP> 140 mmHg, the decrease in SBP was −6.54 mmHg (n=21, 95 % CI −11.21 to −1.87, P=0.008).

CONCLUSIONS: Clinical pharmacists may be an important addition to clinical care teams in community primary care practices and may help improve intermediate cardiovascular risk factors and glycemia among a subset of patients with uncontrolled diabetes. More pragmatic research studies are needed to investigate the effectiveness of different ways of embedding clinical pharmacists into care teams and to increase our knowledge about which patients benefit the most from consulting with clinical pharmacist.

MEASURING CLINICIAN INFORMATION LITERACY: EXPERIENCES WITH A PANEL MANAGEMENT INTERVENTION

Brian E. Dixon[1]; Ashley E. Jensen[2,3]; Katelyn Bennett[2,3]; Scott Sherman[2,3]; Mark D. Schwartz[2,3]. [1]Indiana University-Purdue University Indianapolis, Indianapolis, IN; [2]New York University School of Medicine, New York, NY; [3]Veterans Affairs New York Harbor Healthcare System, New York, NY. (Tracking ID #1640511)

BACKGROUND: Medicine is an information science. Clinicians receive reams of information from an array of sources that they must process into decisions and prioritized tasks for the clinical team and patient. Health reform policies incentivize clinicians to use health information technologies to coordinate care across a highly fragmented delivery system. For example, the VA is currently implementing a patient-centered medical home initiative known as PACT (Patient Aligned Care Teams) in which primary care teams manage panels of patients. PACT and similar models require clinicians to access, analyze, and apply information from a number of different electronic systems. The information literacy skill of clinicians is unknown and there is little evidence on the impact of programs designed to teach information literacy. We sought to develop a measure of information literacy and describe its variability and change in response to a controlled panel management intervention aimed at PACT.

METHODS: We investigated information literacy among primary care providers (PCPs) and nurses (RNs), as a component of PROVE (Program for Research on the Outcomes of VA Education). The goal of PROVE is to assess the impact of panel management support and education on hypertension and smoking outcomes through the addition of a non-clinical panel management assistant (PMA) randomly allocated to PACT at the VA New York Harbor Health Care System. PMAs served as a liaison to their PACT, providing information on teams' hypertensive and smoking patient panels using VA's panel management tools: PC Almanac and PACT Compass. We surveyed 44 PCPs and 17 RNs, pre- and post-intervention, about their use of the two data tools (each 1 item, 5-point Likert scale). For the post-survey we developed an 8-item measure about use and attitudes toward electronic information resources as a measure of information literacy (mean of 8-items, 5-point Likert scale, Cronbach's α=0.84). We compared scores between study arms and clinician type (PCP and RN) using one-way analysis of variance. To test our hypothesis that the intervention increased the use of panel management data tools, we compared responses pre- and post-intervention using paired t-tests.

RESULTS: Survey response rates were 76 % overall. The mean score for information literacy post-intervention was 3.4 (SD 0.82) out of 5. The mean information literacy was similar for PCPs (3.3, SD 0.83) and RNs (3.8, SD 0.66, p=0.57 for difference), and for intervention (3.6) and control groups (3.1, p=0.12 for difference). Compared to baseline, reported use of the PC Almanac increased from 2.6 to 3.2, mean change (95 % CI) of 0.5 (0.09, 0.94, p=0.02). Reported use of the PACT Compass increased from 2.3 to 3.2, mean change of 1.2 (0.7, 1.6, p<0.001). Information literacy was positively correlated with usage of both panel management tools (r= 0.83 for Almanac, r=0.87 for Compass, p=0.001 for both).

CONCLUSIONS: To be effective innovators and leaders, clinicians must have the information literacy skills necessary to access, analyze, and apply information from electronic clinical systems. This research moves our field closer to measuring information literacy, and it suggests that education interventions and information liaison roles might support access and utilization of technologies designed to enhance care coordination.

MEDICAL EDUCATION IN HEALTH POLICY BEFORE AND AFTER THE AFFORDABLE CARE ACT

Mitesh Patel[1]; Monica L. Lypson[2]; Matthew M. Davis[2]. [1]University of Pennsylvania, New York, NY; [2]University of Michigan, Ann Arbor, MI. (Tracking ID #1634961)

BACKGROUND: The Affordable Care Act is one of the most important pieces of health policy reform to be enacted in US in decades. Meanwhile, our previous work has found that less than 50 % of graduating medical students felt appropriately trained in topics relating to health policy such as medical economics and health care systems.

METHODS: The objective of this study is to determine if medical education in health policy has changed since the Affordable Care Act was passed. The Medical Student Graduation Questionnaire (MSGQ) was obtained from the Association of American Medical Colleges (AAMC) for national data from 2006 to 2012. Responses for perceptions of training relating to topics in health policy were compared to clinical care and clinical decision making using classification methods from our prior work. Pearson chi square statistics were conducted to evaluate changes between 2008 (before) to 2012 (after).

RESULTS: From 2006 to 2012, the percentage of graduating medical students that reported appropriate training was stable for clinical care (83–85 %) and clinical decision making (89–90 %). During that same period, perceptions of training in health policy steadily rose from 58.0 % to 63.9 %. Compared to 2008, chi square analysis found statistically significant changes in 2012 for all 13 components of health policy except medical economics (36.4 to 37.2 %) and law and medicine (48.9 to 48.9 %). The most significant increases were in public health (64.0 to 75.9 %), managed care (47.4 to 57.9 %), and biostatics (72.3 to 79.4 %).

CONCLUSIONS: While the aggregate perceptions of training in health policy increased slightly after the Affordable Care Act was passed, the overall rate of 64 % is still quite low when compared to clinical care or clinical decision making. More study is necessary to evaluate whether these small change are due to improvements in medical school curricula or other reasons.

Graduating Medical Students' Perceptions of Being Appropriately Trained

MEDICAL STUDENT EMOTIONS EVOKED BY A CURRICULUM IN HEALTH CARE DISPARITIES April S. Fitzgerald; Pamela Lipsett; Mary Catherine Beach; Patricia A. Thomas. Johns Hopkins University, Baltimore, MD. (Tracking ID #1641014)

BACKGROUND: The existence of disparities in health care is a known problem that persists despite many years of active research and intervention. Well-documented reasons for healthcare disparities include patient, provider, and system factors. What is missing from the literature is an understanding of how information gained by students taking a course in healthcare disparities emotionally impacts those students. The goal of our study is to provide educators with guidance and examples of how the healthcare disparities course impacts first year medical students in terms of their emotional response.
METHODS: The Health Care Disparities (HCD) intersession is the first course matriculating students complete at Johns Hopkins University School of Medicine. At the end of the 2010 intersession, students were asked to write a reflective essay describing emotions evoked by the 3-day learning experience. Of the 120 students who completed the course, 25 essays were randomly selected for qualitative evaluation.
RESULTS: In the post-course evaluation, more than 99 % of students reported having a better understanding of social, behavioral, and economic factors affecting the healthcare disparities in Baltimore. Students' reflections described both positive and negative emotions evoked by participating in the course. Recurring negative reactions included feeling alarmed at the degree of disparities "impressed and shocked by the statistics", overwhelmed by the scope of the issues "dizzying array of issues began to obscure my answers", and guilty about their own life circumstances "made me feel ashamed … I have so much." Recurring themes of positive reactions included the thought-provoking nature of the topic "cause me to question my belief system and my concept of self", personal transformation in perspective "challenged my understanding of me," and inspiration to make a difference "motivate us as students to work for change."
CONCLUSIONS: Students have both positive and negative emotional reactions to learning about the existence of healthcare disparities. These strong emotional responses should be considered by educators when presenting health disparity information to students. Educators who better understand the emotional responses of students can better facilitate the cognitive dissonance evoked by this new information and help students constructively adapt to these feelings over time.

MEDICAL AND LEGAL CONSEQUENCES OF ONGOING DRUG USE AMONG YOUNG INJECTION DRUG USERS INFECTED WITH HEPATITIS C VIRUS Joshua A. Barocas[1]; Shawnika J. Hull[3]; James M. Sosman[1,2]; Ajay Sethi[4]; John J. Fangman[5]; Ryan Westergaard[1,2]. [1]University of Wisconsin-Madison, Madison, WI; [2]University of Wisconsin-Madison, Madison, WI; [3]University of Wisconsin-Madison, Madison, WI; [4]University of Wisconsin School of Medicine and Public Health, Madison, WI; [5]Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #1641796)

BACKGROUND: Non-sterile injection practices and unprotected sexual contact place injection drug users (IDUs) at high risk for contracting and transmitting Hepatitis C virus (HCV). Injecting drugs has numerous other infectious and non-infectious medical consequences, which may be preventable with education about safer injection practices and/or addiction treatment. We hypothesized that IDUs who are tested for and receive a diagnosis of HCV may adopt safer behaviors and lower their risk of further negative health consequences.
METHODS: We invited clients at a multisite, free needle-exchange program in Southeastern Wisconsin to complete an anonymous, 88-question, computerized, interviewer-administered survey. The survey assessed frequency of injection, self-reported HCV status, recent hospitalization, incarceration, overdose, and other major injections (e.g. skin abscess, endocarditis). Participants were included if they were over 18, reported active injection drug use in the past week, and could provide informed consent. Respondents were asked to report consequences of their drug use that occurred during the preceding 6 months. Multiple logistic regression was used to assess the association between HCV status and the occurrence of consequences of drug use among HCV positive participants while controlling for potential confounders such as age, gender, and drug use frequency.
RESULTS: The survey was completed by 553 IDUs, of whom 69 % were male, 83 % white, 11 % black and 6 % Hispanic. The median age was 28, and 54 % resided in the Milwaukee metropolitan area. Active HCV infection was reported by 74 participants (13.4 %). Controlling for age, gender, and high frequency drug use, during the preceding 6 months, HCV-positive respondents were more likely to have overdosed on drugs (adjusted odds ratio (OR) 2.67, confidence interval (CI) 1.59–4.47), been put in jail for less than 30 days (OR 1.99, CI 1.19–3.32) or incarcerated for more than 30 days (OR 3.50, CI 1.91–6.33) than their HCV-negative counterparts. The HCV positive and negative groups did not differ significantly with respect to the incidence of passing out while driving (18.9 % and 16.7 %, respectively), infective endocarditis (2.7 % and 0.97 %, respectively), contracting a skin or soft tissue infection (41.9 % vs 27.6 %, respectively), or being hospitalized for another severe infection (12.2 % and 6.8 %, respectively).
CONCLUSIONS: Among this cross-sectional sample of mostly-young, urban IDUs, we found that those known to be infected with HCV were more likely to report recent overdose and becoming incarcerated. Our data do not support the hypothesis that IDUs adopt safer behaviors after receiving an HCV diagnosis. Rather, HCV appears to be a marker of ongoing high-risk drug use. It is not known whether previous or ongoing treatment for HCV correlates with safer practices. Medical providers and prevention specialists should recognize that HCV-infected IDUs remain at high risk for negative consequences of drug use. Prevention strategies should emphasize strategies to reduce overdose and incarceration in addition to avoiding transmission of bloodborne pathogens through the sharing of injection equipment.

MEDICAL DECISION-MAKING PREFERENCE IN VIETNAMESE INPATIENTS VERSUS ENGLISH-SPEAKING, NON-VIETNAMESE INPATIENTS Dan-Vinh Nguyen; Cheryl Ho; Ahmad Kamal; Sara Doorley. Santa Clara Valley Medical Center, San Jose, CA. (Tracking ID #1626382)

BACKGROUND: Santa Clara County, California is home to over 130,000 individuals of Vietnamese origin, comprising a significant portion of inpatients at the county hospital, Santa Clara Valley Medical Center. When hospitalized, patients often face important and complicated medical decisions. Traditionally, physicians have used a paternalistic or physician-directed approach to guide decisions. Yet, a shared model in which patients play a more collaborative role has been increasingly emphasized. To evaluate if culture may influence medical decisions, this study compared Vietnamese patients' preferences of a shared or physician-directed model with English-speaking, non-Vietnamese patients.
METHODS: A validated survey using a modified version of Ende et al's "Autonomy Preference Index" was administered in English and Vietnamese to assess two domains: information-seeking desire and decision-making preference. Powered to reveal a difference in the decision-making domain, two age-matched groups of 30 Vietnamese and non-Vietnamese inpatients

were surveyed. Each domain consisted of a series of statements graded by a five-point Likert Scale. For decision-making, four questions gauged individual preference and four measured preferences with family involvement for a total of eight questions. Individual and family sub-domain scores ranged 4–20 each, totaling 8–40. A median score of 24 (12 in each sub-domain) denoted neutrality, as if all questions were answered with a 3. Scores above or below the median represented a preference for paternalistic or shared decision-making, respectively. The information-seeking domain had seven questions and scores ranged 7–35. Higher scores indicated greater desire for knowledge about one's illness. T-tests were used to evaluate for significance.

RESULTS: Both groups had 16 males, an average age of 59, and approximately three household members. With 17 Vietnamese and 24 non-Vietnamese individuals completing 12th grade or higher, average years of education differed, 11.47±3.40 and 13.47±2.23 years (p=0.05), respectively. Vietnamese patients had a preference for the physician-directed model, scoring 31.13±4.90, while their counterparts scored 24.23±5.93, $p<$ 0.01. This remained significant in both the individual (15.87±2.30) and family (15.27±2.73) sub-domains, $p<0.01$. The non-Vietnamese group had a slight inclination towards paternalism in the individual sub-domain, 12.70±2.64. But a shared model was favored when considering family, 11.53±3.77. Total decision-making scores of gender and education subgroups are seen in the table. With information-seeking, both Vietnamese (30.73±3.45) and non-Vietnamese (32.27±2.36) groups scored highly, p=0.10.

CONCLUSIONS: Vietnamese inpatients preferred a paternalistic style of medical decision-making compared to the non-Vietnamese, even when controlling for gender and education. This may ultimately reflect culture shaping patients' views on medical decisions and the patient-provider relationship. Rather than encourage broad generalizations, providers should be challenged to engage more fully with patients and their families. By understanding a patient's needs and values, patient-centered care can be achieved, regardless of the decision-making model.

	Vietnamese	Non-Vietnamese	p value
Male	31.31±5.23	26.13±6.28	0.08
Female	30.93±4.52	22.07±4.80	<0.01
Education≥12th grade	30.12±5.95	23.79±5.84	0.02
Education≤11th grade	32.46±3.88	26.00±5.33	0.04

MEDICATION USE AFTER DEMENTIA DIAGNOSIS IN AN OBSERVATION COHORT OF DIABETES PATIENTS: THE DIABETES AND AGING STUDY Urmimala Sarkar[1]; Courtney R. Lyles[1]; Michael A. Steinman[2]; Elbert S. Huang[3]; Howard H. Moffet[3]; Rachel Whitmer[3]; Margaret Warton[3]; Andrew J. Karter[3]. [1]University of California, San Francisco, San Francisco, CA; [2]University of Chicago, Chicago, IL; [3]Kaiser Permanente, Oakland, CA. (Tracking ID #1640424)

BACKGROUND: The diagnosis of dementia in older patients requires patients and their doctors to revise the goals of preventive care, due to the high risk of adverse drug events and shortened life expectancy associated with the diagnosis. In particular, dementia diagnosis may alter the role of diabetes and cardiovascular medications designed to prevent long-term complications. Little is known about changes in medication use following diagnosis of dementia. As part of the Diabetes and Aging study, we (1) examined number of medications, and (2) characterized glycemic, blood pressure (BP), and lipid control before and after a diagnosis of dementia, compared to a reference population.

METHODS: Using a pre-post design with controls, we studied diabetes patients aged ≥50 from a race-stratified survey cohort in an integrated healthcare delivery system (Kaiser Permanente). Identification of incident dementia was based on ICD-9 codes 294.1, 294.2, 290.XX, 331.0, 331.1, 331.2, 331.82, and excluded dementia due to substance use or trauma. We excluded subjects with <12 months of continuous follow-up following diagnosis, evidence of prevalent dementia (previous dementia diagnoses), or type 1 diabetes. Using risk-set sampling we randomly selected 4 control subjects per dementia case, group matched on date of dementia diagnosis ("baseline date") to account for temporal variations, 5-year age categories, and sex. We assessed cardio-metabolic medication count and poor risk factor control (hemoglobin A1c >9 %, LDL >130 mg/dL, blood pressure (BP) >140/90 mmHg) at baseline and 12 months post-baseline. We plan to examine specific medication changes and conduct a formal difference-in-differences analysis of changes in medication count and clinical control.

RESULTS: In the eligible cohort (n=1,158 patients), the 4-to-1 matching yielded 193 (17 %) clinically recognized dementia cases. The vast majority (93 %) had diabetes for 5+ years, 75 % were aged 70+, 47 % were female, 50 % had a high school education or less, and 76 % were non-white (25 % Asian, 19 % black, 17 % Latino). At baseline, dementia patients were taking significantly more medications than controls (6.8 vs. 6.3 medications, respectively). One year later the number of medications decreased more in dementia patients vs controls (1.3 and 0.5 fewer medications, respectively). In terms of risk factor control, those with dementia entered the cohort with higher A1c compared to those without dementia, but there were no differences between the groups 1 year post-baseline. In contrast, there were no differences at baseline in lipid or BP control but poorer control among those with dementia at one-year follow-up, when compared to those without dementia.

CONCLUSIONS: Patients in this cohort decreased the number of medications taken over time; moreover, there was a greater decrease in polypharmacy after the recognition of dementia. These findings suggest that providers may be modifying some treatment goals subsequent to recognition of dementia. Future research is needed to understand how dementia affects the thinking of patients and physicians as they confront specific decisions regarding target goal selection and medication use for cardiometabolic control.

	Baseline		12 month follow-up	
	No dementia	Dementia	No dementia	Dementia
Number of meds	6.3	6.8	5.8	5.5
A1c>9	6.5 %	12.4 %*	7.6 %	8.6 %
LDL>130	5.8 %	9.0 %	5.7 %	11.5 %*
SBP>140/90	22.2 %	25.2 %	19.6 %	26.2 %†

MISSED COMMUNICATION - AN ANALYSIS OF UNREAD MESSAGES THROUGH A PATIENT WEB PORTAL Bradley H. Crotty; Bruce E. Landon. Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #1642688)

BACKGROUND: Web-based patient portals offer patients a view of their medical record and the opportunity for secure messaging with physicians. Asynchronous communication such as secure messaging outside of visits may be more preferable and efficient to phone calls, and may be an important component of accountable care. Little data are available as to whether these messages are read and received by the recipient. We sought to study unread messages in a mature patient portal to understand their prevalence and patient factors associated with having unread messages.

METHODS: After allowing for a four-year equilibration period, we analyzed messages between attending physicians and patients between 2005 and 2010, evaluating the prevalence of unread messages, and the patient factors associated with these 'missed communications.' Duplicate messages from carbon copies were purged. Messages that were automatically forwarded within a practice were considered read once opened by any staff member. We developed logistic regression models with data from the most recent year to estimate having any unread messages after adjusting for race, age, sex, insurance type, socioeconomic status, and length of portal participation.

RESULTS: Patients and providers both had unread messages, and these decreased each year before plateauing after 6 years for patients and 4 years for physicians. In 2010, 7.3 % of patient messages were unread by the recipient physician, and 18 % of physician messages were unread by the recipient patient. Forty percent of patients who received a message from their doctor in 2010 had at least one unread message. After adjustment, sex, ethnicity, age, and income were significant predictors of having unread messages.

CONCLUSIONS: In a mature patient portal, unread messages are alarmingly prevalent. After adjustment, differences by race, age, and income persist, suggesting a difference in how different patient groups use the tool. These data suggest that physicians and patients should discuss

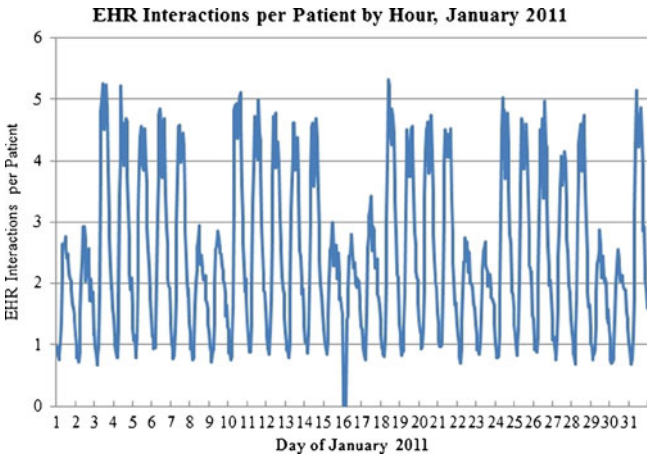
their communication preferences before engaging in messaging. In addition, high rates of unread messages initially suggest that there is an adjustment period for both physicians and patients as they begin using the portal. Further work to characterize the unread messages and reasons for lack of follow-up may shed light on this important communication failure.

MISSED OPPORTUNITIES FOR BREAST CANCER PREVENTION AMONG PRIMARY CARE PROVIDERS Jennifer Corbelli; Melissa McNeil. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1642038)

BACKGROUND: Breast cancer is among the most feared diagnoses of women of all ages. Prior research has suggested that tools to calculate (Gail model) and minimize (chemoprevention) breast cancer risk are infrequently used in primary care. It is unknown whether this practice has persisted in recent years, despite the widespread attention brought to these issues by changes in breast cancer screening guidelines. The primary aim of this study is to examine and compare current attitudes and practices of internists, family physicians, and gynecologists with respect to breast cancer risk assessment and prevention.
METHODS: We conducted a cross-sectional study at a large academic medical center. Both resident and attending physicians in three primary care specialties (gynecology, internal medicine, and family medicine) were electronically surveyed. Our survey was adopted with permission from National Survey of Primary Care Physicians' Cancer Screening Recommendations and Practices. Survey items assessed respondents' practices and attitudes regarding the Gail model and chemoprevention in women of different ages and breast cancer risks. We used descriptive statistics to generate response distribution for each survey item. We used Chi-square tests to compare survey responses across specialties.
RESULTS: Our overall response rate was 55 % (316/575). 40.8 % of providers reported ever having calculated a Gail score. A higher proportion of gynecologists (60.0 %) used the Gail model as compared to internists (36.9 %) and family physicians (33.3 %) (p=0.0018). Among all providers who have used the Gail model, 19.4 % reported regular use ("regular" defined as in >60 % of the time) in women over age 60, and 22.8 % reported regular use in women with a family history of breast cancer. Within the subset of providers who report ever having used the Gail model, the only significant difference among specialties was observed for women over 60, in whom gynecologists (29.7 %) were more likely than internists (13.3 %) to regularly use the Gail model (p=0.048). Only 13.2 % of providers reported ever having prescribed chemoprevention. Gynecologists (30.3 %) reported more frequent prescribing than both internists (8.5 %), and family physicians (8.0 %) (p=<0.001). Eleven percent of all providers who never prescribed chemoprevention agreed with the statement "I do not believe that chemoprophylaxis benefits most women who are eligible to receive it."
CONCLUSIONS: An overall minority of providers across primary care specialties use the Gail model to assess, and chemoprevention to decrease, breast cancer risk. This finding is significantly more pronounced among internists and family physicians as compared to gynecologists. Although the reasons for these findings are multifactorial, provider education is clearly a key factor. Until providers are more informed and comfortable in their use of the Gail model and chemoprevention, opportunities to identify and intervene in women at increased risk for breast cancer will continue to be missed.

MONITORING THE PULSE OF HOSPITAL ACTIVITY: ELECTRONIC HEALTH RECORD UTILIZATION AS A MEASURE OF CARE INTENSITY Saul Blecker; Jonathan Austrian; Daniel Shine; R. Scott Braithwaite; Martha J. Radford; Marc N. Gourevitch. NYU School of Medicine, New York, NY. (Tracking ID #1633574)

BACKGROUND: Hospital care on weekends has been associated with reduced quality and poor clinical outcomes, suggesting that decreases in overall intensity of care may have important clinical effects. Initiatives to address this important safety issue would be strengthened if a shared metric existed to describe the intensity of care provided at a given time of day or day of the week. We describe a new measure of hospital intensity of care based on utilization of the Electronic Health Record (EHR).
METHODS: We measured global intensity of care at our academic medical center by monitoring use of the EHR in 2011. Our primary measure, termed EHR interactions, was the number of accessions of a patient's electronic record by a clinician, adjusted for hospital census, per unit of time; our secondary measure was percent of total available central processing unit (CPU) power used to access EHR servers at a given time. We graphically displayed moment-to-moment intensity of care and calculated the coefficient of correlation between the two measures. Negative binomial regression models were used to determine the relative rate of weekday to weekend EHR interactions per patient for three daily time periods: day, morning/evening, and night.
RESULTS: Tracking EHR usage produced a detailed graphic picture of the hospital day and week, clearly demarcating rounding hours, lunch hours, hospital holidays, and other landmarks (Figure). EHR interactions were lower on weekend days as compared to weekdays at every hour (p<0.0001) and the daytime peak in intensity noted each weekday was blunted on weekends (Figure). The relative rates (RR) of census-adjusted record accessions per patient on weekdays compared with weekends were (95 % CI): RR 1.76 (1.74–1.77), RR 1.52 (1.50–1.55), and RR 1.14 (1.12–1.17) for day, morning/evening, and night hours, respectively. Percent CPU usage correlated closely with EHR interactions (r=0.92).
CONCLUSIONS: EHR usage is a sensitive, convenient and easily reproduced measure of intensity of care in the hospital. Using this measure we identified large, hour-specific differences between weekend and weekday intensity. EHR interactions may serve as a useful measure for tracking and improving temporal variations in care that are common, and potentially deleterious, in hospital systems.
January 1, 2, 8, 9, 15, 16, 22, 23, 29, 30 were weekend days; January 17 was a federal holiday. EHR downtime for maintenance occurred in the early morning of January 15.



MOTIVATION, SELF-EFFICACY, AND WEIGHT LOSS IN A CLINIC-BASED WEIGHT LOSS PROGRAM Stephanie A. Rose[1]; Dominique Zephyr[2]; Tyler Smith[2]; Chrisanthi Masero[1]; Kelly H. Webber[3]. [1]University of Kentucky, Lexington, KY; [2]University of Kentucky, Lexington, KY; [3]University of Kentucky, Lexington, KY. (Tracking ID #1640574)

BACKGROUND: Level and type of motivation can predict completion and success in weight loss programs. We explored motivation, self-efficacy, and perceived autonomy support for patients enrolled in a weight loss program, and assessed BMI change in a subset of patients.
METHODS: Patients enrolled in a 12-week clinic-based medically-managed weight loss program based on the Diabetes Prevention

Program between January 2011 and April 2012 completed a baseline quantitative survey including questions from the Treatment Self-Regulation Questionnaire, the Health Care Climate Questionnaire, the Perceived Competence Scale, and questions regarding their primary care physician's (PCP) obesity treatment practices.
RESULTS: 36 overweight and obese patients (body mass index (BMI) ≥25 kg/m2) agreed to participate. 88.9 % reported having seen their PCP at least once in the past year. All but one reported their PCP had ever told them they needed to lose weight. 62 % felt that their PCP was able to help them with weight loss, but only 44 % felt it was their PCP's responsibility to do so. Mean autonomous motivation (AM) was 6.02 (SD 0.79) (scale of 0 to 7), mean controlled motivation (CM) was 2.70 (SD 1.21), mean self-efficacy was 4.78 (SD 1.32), and mean perceived PCP support of AM was 4.58 (SD 1.69). There was a positive correlation between self-efficacy and AM (r=0.30); and a negative correlation between self-efficacy and CM (r=−0.17), PCP support of AM and AM (r=−0.08), and perceived PCP support of AM and CM (r=−0.39). Patients with linked outcome and survey data (n=8) demonstrated a mean BMI change of −1.44 kg/m2 (range −4.3 to +0.7). For these patients, there was a negative correlation between BMI and AM (r=−0.27), CM (r=−0.10), and self-efficacy (r=−0.14); and a positive correlation between BMI and perceived PCP support of AM (r=0.39).
CONCLUSIONS: Patients reported higher mean levels of AM versus CM and a positive correlation between self-efficacy and AM. The small subset demonstrated an overall mean weight loss. Higher levels of AM and self-efficacy were linked to decrease in BMI, as was higher levels of CM, although the correlation was not as strong. Future goals include expanding the sample size to strengthen the results and an intervention to promote patient and provider self-efficacy and AM.

MOTIVATORS AND BARRIERS TO BEHAVIOR CHANGE AMONG POSTPARTUM WOMEN WITH PRIOR GESTATIONAL DIABETES. Joyce W. Tang[1]; Ronald T. Ackermann[1]; Javiera Pumarino[1]; Alan Peaceman[2]; Kenzie A. Cameron[1]. [1]Northwestern University, Chicago, IL; [2]Northwestern University, Chicago, IL. (Tracking ID #1641703)

BACKGROUND: Gestational diabetes mellitus (GDM) affects approximately 4 % of women, of whom 50 % will develop type 2 diabetes (DM2) within 10 years. Developing effective interventions to prevent development of DM2 among this high risk cohort requires an understanding of the barriers and facilitators to behavior change and preferred sources of support.
METHODS: We conducted semi-structured interviews with a purposive sample of women who were diagnosed with GDM during a recent pregnancy and were within 1 year of delivery; patients diagnosed with DM2 after delivery were excluded. We recruited participants from 3 obstetrics clinics affiliated with Prentice Women's Hospital (Chicago, IL). A programmer analyst identified eligible patients through query of the Electronic Health Record for women with positive glucose tolerance tests. Women were asked open ended questions to elicit knowledge, attitudes, and behaviors related to diabetes prevention. This abstract focuses on women's descriptions of: 1) motivators of and barriers to adopting healthy behaviors and 2) preferences for additional support. All interviews were digitally recorded and transcribed. We developed a set of a priori codes based on our study questions. Using a modified grounded theory approach, we added additional codes that emerged. Two coders independently coded all interviews using NVivo 9. Discrepancies were resolved by discussion.
RESULTS: We interviewed 24 women (8 Hispanic, 8 African-American, 8 Caucasian). Concern for DM2 was an important motivator for behavior change (i.e., desire to avoid use of insulin and avoid complications such as amputation and blindness). Children were frequently mentioned as both motivators of behavior change (e.g., need to stay healthy to care for children; desire to serve as a role model to children), as well as barriers to behavior change (e.g., no time to exercise or cook due to caring for children/lack of reliable childcare; fatigue due to nighttime awakenings; children not liking healthy foods). Lack of motivation was also a commonly raised barrier; however, women infrequently mentioned lack of monetary resources, poor access to healthy foods, or poor knowledge of healthy choices. Although many women desired assistance with child care, some women expressed lack of trust in care provided by non-family members. Even those with relatives available to help with child care often stated they would not ask them for assistance in order to exercise due to concern for overburdening them and guilt for taking time away from their child. Many women described plans to delay behavior change (e.g., until children are sleeping better, until children are old enough to exercise with me). Women expressed interest in receiving information on how to exercise with their baby/children, and for assistance with meal planning/weight loss.
CONCLUSIONS: For women with a history of GDM, important motivators for behavior change include avoiding DM2, staying healthy for their children, and modeling healthy behaviors for their children. Child care appears to be the primary barrier to behavior change. Efforts to engage these women in diabetes prevention interventions should leverage these intrinsic motivators and address both child care needs and women's lack of prioritization of their own health.

MULTIMORBIDITY AND HEALTH CARE UTILIZATION AMONG HIGH-COST PATIENTS: IMPLICATIONS FOR CARE COORDINATION Donna Zulman[1,2]; Jean Yoon[3]; Danielle M. Cohen[1,2]; Todd H. Wagner[3,4]; Christine Ritchie[5,6]; Steven Asch[1,2]. [1]VA Palo Alto Health Care System, Menlo Park, CA; [2]Stanford University, Stanford, CA; [3]VA Palo Alto Health Care System, Menlo Park, CA; [4]Stanford University, Stanford, CA; 5University of California, San Francisco, San Francisco, CA; [6]San Francisco VA Medical Center, San Francisco, CA. (Tracking ID #1637266)

BACKGROUND: Within the U.S. and many subpopulations, the most costly 5 % of patients often account for close to half of total health care expenditures. A number of innovative health care delivery models have recently emerged that aim to enhance these patients' care and optimize their use of services. We sought to inform these programs by investigating multimorbidity patterns, and associated health care utilization, among the costliest 5 % of patients in the Veterans Health Administration (VHA) system.
METHODS: We obtained total health care costs and sources of costs (inpatient, outpatient, pharmacy, and VHA purchase care) for 5.2 million patients who received care within the VHA system in fiscal year (FY) 2010. We identified the costliest 5 % of patients, and examined the proportion of care they received in the inpatient and outpatient setting, as well as their insurance status and sociodemographics (including age, sex, and race/ethnicity). Using Chronic Condition Indicators (CCI) and body system groupings established by the Agency for Healthcare Research and Quality, we assessed the prevalence of 33 chronic conditions and rates of multi-system multimorbidity (presence of conditions affecting more than one body system). We then used multivariate linear regression to examine the association between multi-system multimorbidity and origins of health care costs (i.e., inpatient versus outpatient), after adjusting for age, sex, and health insurance.
RESULTS: The most costly 5 % of patients (n=261,699) accounted for 47 % of total VHA costs in FY 2010. The mean (SD) age of these patients was 63 (13) years, and 41 % were≥65 years. Median and mean (SD) health care costs were $52,807 and $72,977 ($64,040) (total), $26,979 and $42,179 ($58,680) (inpatient), and $12,699 and $19,182 ($30,269) (outpatient), respectively. The most common chronic conditions included hypertension (63 %), diabetes (34 %), ischemic heart disease (27 %), cancer (25 %), and low back pain (21 %), and close to half (47 %) of patients had a mental health condition. Multi-system multimorbidity was extremely common: 85 % had conditions affecting ≥2 body systems (e.g., coexisting cardiovascular and mental health conditions), and 18 % had conditions affecting ≥5 body systems (e.g. coexisting cardiovascular, respiratory, gastrointestinal, genitourinary, and endocrine conditions). There was a positive association between multi-system multimorbidity and total cost of health care, with most of the increased costs originating in the outpatient setting. The mean absolute and relative costs generated in the outpatient setting increased with each additional system affected by chronic conditions (p<0.001), from $16,495 (29 % of total costs) among patients

with one affected system to $22,440 (35 % of total costs) among those with ≥5 affected systems. In contrast, multi-system multimorbidity was associated with a decrease in costs originating in the inpatient setting ($p<0.001$). These relationships persisted when analyses were stratified by age (<65 and ≥65 years).

CONCLUSIONS: Multimorbidity is extremely common among VHA's 5 % highest-utilizing patients, who account for nearly half of the system's total health care expenditures. The observed association between multi-system multimorbidity and proportion of costs originating in the outpatient setting suggests a role for interventions that coordinate primary and specialty care for high-utilizers with multiple chronic conditions.

MULTIPLE BARRIERS ASSOCIATED WITH DELAYS IN CARE AMONG WOMEN WITH ABNORMAL CANCER SCREENING IN THE BOSTON PATIENT NAVIGATION RESEARCH PROGRAM Ambili Ramachandran[1]; Karen Freund[3]; Sharon Bak[1]; Timothy Heeren[2]; Clara Chen[2]; Azadeh Nasseh1; Tracy A. Battaglia[1,2]. [1]Boston University/ Boston Medical Center, Boston, MA; [2]Boston University School of Public Health, Boston, MA; [3]Tufts University School of Medicine, Boston, MA. (Tracking ID #1620566)

BACKGROUND: Patient navigation (PN) programs were designed to address barriers to care among underserved populations as a means to improve access to timely cancer care. While there is widespread dissemination of patient navigation programs nationwide, there is a paucity of research examining the impact that barriers have on time to resolution of an abnormal screening test.

METHODS: We conducted a secondary analysis of the Boston PN Research Program, a quasi-experimental PN intervention across six federally qualified inner-city community health centers (CHCs) conducted from 2007 to 2010. Eligible subjects were women with breast and cervical cancer screening abnormalities in the navigation arm. We examined the effect that the presence of barriers (0, 1, 2, 3+) had on time to diagnostic resolution, defined as the number of days from the index screening event to a final diagnosis of cancer or no cancer. Unadjusted analyses compared the percent of women with diagnostic resolution at 365 days through chi-square tests. Adjusted analyses used multivariable Cox proportional hazards regression with time to diagnostic resolution as the outcome to examine the effects of the number of barriers, controlling for demographic covariates and clustered by patients' primary navigator. Adjusted HR (aHR) less than 1.0 indicated a lower likelihood of timely diagnostic resolution.

RESULTS: There were 1481 women who received navigation; mean age was 40 years, 32 % were White, 27 % were Black, and 31 % were Hispanic. Only 28 % had private health insurance, and 38 % did not speak English. Overall, half of all patients ($n=745$, 50 %) had documentation of one or more barriers to care identified during navigation contacts. Women with barriers were more likely to be older (mean age 41 versus 38 years), non-White race (77 % versus 60 %), non-English language speakers (46 % versus 29 %), and to have public or no health insurance (79 % versus 65 %) compared to women without barriers ($p<0.001$ for all comparisons). At 365 days after the index screening event, 94 % of women without barriers had achieved diagnostic resolution, compared to 90 %, 84 %, and 69 % of women with one, two, or three or more barriers, respectively ($p<0.0001$). Using the multivariable model, we found the likelihood of timely diagnostic resolution decreased as the number of barriers increased [one barrier, aHR 0.81 (95 % CI 0.56–1.17), $p=0.26$; two barriers, aHR 0.55 (95 % CI 0.37–0.81), $p=0.0025$; three or more barriers, aHR 0.31 (95 % CI 0.21–0.46, $p<0.0001$)].

CONCLUSIONS: Within a patient navigation program with proven ability to reduce delays in care, we found that navigated patients with documented barriers to care experience a decreased likelihood of timely resolution of their screening abnormalities; this effect is more pronounced when multiple barriers are present. In the era of accountable care and limited resources, these findings suggest the need to target navigation to those most vulnerable individuals, in this case, those with identifiable barriers.

NATIONAL EVALUATION OF THE EFFECTS ON HEALTHCARE UTILIZATION AND COSTS OF THE VA PATIENT CENTERED MEDICAL HOME INITIATIVE Paul Hebert; Chuan-Fen Liu; Edwin Wong; Susan Hernandez; Adam Batten; Sophie Lo; Jackie Lemon. VA Puget Sound Health Care System, Seattle, WA. (Tracking ID #1633566)

BACKGROUND: The Veterans Health Administration (VA) has committed $2 billion toward transforming healthcare delivery. The centerpiece is an initiative to implement a version of the patient-centered medical home model, entitled patient-aligned care teams (PACT) at each of its 972 outpatient clinics nationwide, beginning in 2010. We evaluated the effects to date of the initiative on health care utilization and costs.

METHODS: Because all VA clinics participated in the PACT initiative the study design is an interrupted time-series analysis. The study sample included 8.5 million patients assigned to a primary care provider at any time from January 2003 through October 2012 at 972 clinics. Utilization outcomes included outpatient visits for primary care, specialty care, urgent care, and mental health; hospitalizations for ambulatory care-sensitive conditions (ACSC); and emergency department visits. Quarterly utilization rates were aggregated to the facility level and modeled as a function of patient demographics and risk factors, time-invariant facility characteristics, the facility-specific area unemployment rate, and time. Statistically significant changes in the intercept and time trend in the post PACT period was interpreted as evidence of an effect of PACT. Separate models were estimated for Veterans age <65 and 65+ to account for non-VA utilization by Veterans with Medicare benefits.

RESULTS: Following initiation of PACT, significant departures from long-run trends in utilization were observed for several categories of utilization. Primary care visits increased by 1.0 % (age <65=−1.2 %, age >65=3.5 %; $p<0.01$), and specialty care visits increased by 2.0 % (age <65 =2.0 %, age>65=2.0 %; $p<0.01$). Utilization decreased by −7.3 % for mental health visits (age<65=−7.8 %, age>65=−5.2 %; $p<0.01$) and by −1.7 % for hospitalizations for ACSC (age<65=−4.2 %, age>65=−0.2 %; $p=0.02$). No significant effects were observed for emergency or urgent care visits, or specialist-provided procedures. $498 million in health care costs were avoided compared with an incremental investment to-date of $822 million (i.e., on top of "baseline" funding), for a net discounted cash flow of −$308 million. We found similar results for all categories of utilization when the study sample was restricted to patients who had at least two primary care encounters. There are important limitations. The lack of a control group of Veterans who were not exposed to the PACT initiative necessitated an interrupted time-series design. The PCMH initiative is not yet fully implemented at all facilities. Variations in coding over time and among VA facilities likely contributed to null findings for emergency department and urgent care visits.

CONCLUSIONS: Modest but statistically significant departures from long run trends in utilization were found in several utilization categories over the first 2 years of the VA PCMH initiative. These changes are consistent with previous studies that found increased access to care and decreased hospitalizations for ambulatory care sensitive conditions associated with the adoption of PCMH. Although the PCMH initiative is still progressing, it has not yet yielded a positive return on investment.

NATIONAL PHYSICIAN SURVEY REGARDING ADULT VACCINE DELIVERY: MISSED OPPORTUNITIES AND A CALL FOR A SYSTEMATIC APPROACH Laura Hurley[1,2]; Carolyn Bridges[3]; Rafael Harpaz[3]; Mandy Allison[4,2]; Sean O'Leary[4,2]; Lori A. Crane[2,5]; Shannon Stokley[3]; Brenda Beaty[2]; Michaela Brtnikova[2]; Andrea Clinger[2]; Faruque Ahmed[3]; Craig M. Hales[3]; Allison Kempe[4,2]. [1]Denver Health, Denver, CO; [2]Children's Hospital Colorado, Aurora, CO; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]University of Colorado Anschutz Medical Campus, Aurora, CO; [5]Colorado School of Public Health, Denver, CO. (Tracking ID #1633030)

BACKGROUND: Public health experts are recommending more vaccines for adults, and many of these vaccines are being delivered outside the medical home. Our objectives were to assess among general internists

(GIM) and family medicine physicians (FM): 1) practices regarding assessing need for and stocking recommended adult vaccines; 2) barriers to stocking and administering vaccines; 3) characteristics of physicians who perceive greater financial barriers to delivering vaccines, and 4) practices, experiences and attitudes regarding vaccination outside the medical home.

METHODS: We administered an Internet and mail survey 3/2012–6/2012 to a national network of 443 GIM and 409 FM representative of the American College of Physicians and American Academy of Family Physicians. In addition to descriptive analysis, we created a financial barriers scale and used it in a multivariable analysis to determine physician and practice characteristics associated with perception of greater financial barriers.

RESULTS: Response rates were 79 % (352/443) for GIM and 62 % (255/409) for FM. Less than 1/3 reported routinely assessing vaccination status at every visit. A minority is using Immunization Information Systems (GIM 8 %, FM 36 %, $p \leq 0.0001$). The table shows FM and GIM practices regarding assessing need for and stocking recommended vaccines. The most commonly reported barriers were financial. Physicians practicing in the South, private practice, practices with <5 providers, and practices with more patients with Medicare Part D had a greater perception of financial barriers to delivering vaccines ($p<0.05$). 50 % of providers considered difficulty determining receipt of vaccines a barrier to stocking and administering vaccines (10 % major barrier, 40 % moderate barrier). The majority of providers reported they refer patients elsewhere for vaccines they did not stock and most commonly refer to a pharmacy/retail store (25 % Often/Always, 26 % Sometimes) or public health department (21 % Often/Always, 40 % Sometimes). However, the most commonly reported reasons for referring patients elsewhere for vaccines included the patient's insurance not covering the vaccine (18 % Often or Always/ 43 % Sometimes) and patient's insurance covers the vaccine, but reimbursement is inadequate (11 % Often/Always, 29 % Sometimes). The majority of physicians reported receiving information regarding vaccines administered by other vaccinators <50 % of the time.

CONCLUSIONS: Several categories of problems hinder effective adult vaccine delivery. Systematic approaches to assessing vaccination needs and recommending needed vaccines at all visits, as well as improving communication between vaccine providers, are needed. Provisions in the Affordable Care Act will likely lessen financial barriers; however, more work to address barriers perceived to be created by Medicare Part D is warranted.

NATIONAL SURVEY OF PHYSICIANS' COST CONSCIOUSNESS Susan D. Goold[1,3]; Katherine M. James[2]; Matthew Wynia[5]; Bjorg Thorsteinsdottir[2,7]; Robert Sheeler[6]; Jason Egginton[8]; Mark Liebow[4]; Jon C. Tilburt[4,2]. [1]University of Michigan, Ann Arbor, MI; [2]Mayo Clinic, Rochester, MN; [3]University of Michigan, Ann Arbor, MI; [4]Mayo Clinic, Rochester, MN; [5]American Medical Association, Chicago, IL; [6]Mayo Clinic, Rochester, MN; [7]Mayo Clinic, Rochester, MN; [8]Mayo Clinic, Rochester, MN. (Tracking ID #1632864)

BACKGROUND: Many have called upon physicians to reduce waste and exercise wise resource stewardship. We examined US physicians' views about their roles and responsibilities in addressing rising health care costs, and whether physician and practice characteristics are associated with those views.

METHODS: In mid-2012, we mailed a self-administered, 8-page survey to a random sample of 3,897 practicing US physicians representing all specialties in the AMA Physician Masterfile. We developed the survey through an iterative process of literature review, focus groups with physicians about cost considerations in their practice, and cognitive interviewing with physicians. We reviewed histograms, calculated skew and kurtosis, then proceeded with principle components factor analysis with varimax orthogonal rotation. We retained factors based on criteria $\lambda>1$ or the scree test, initially reviewing 1,2,3 and 4-factor solutions. Items that failed to load >0.3 on any factor were dropped, and other items used to interpret underlying domains; analyses were repeated in an iterative fashion. In all analyses, Factor 1 had $\lambda>2$, often $\lambda>2.5$, with other factors $\lambda<1$ resulting in a one-factor solution with 11 items and good internal consistency ($\alpha=0.77$). Cost consciousness scores were used as a continuous dependent variable in simple and multiple linear regression to detect associations with physician and practice characteristics.

RESULTS: Of 3897 potential respondents, 2556 returned completed surveys for a response rate (AAPOR RR2) of 65 %. Response rates differed somewhat by age (50 years and older: 67 %; less than 50 years: 64 % (X 2=5.4; $p=0.02$) but not by sex, region, race, or specialty. A majority of physician respondents were white (77 %), male (70 %), and over 50 (58 %). Physicians were evenlydistributed in self-reported political leaning (10 % very conservative, 28 % somewhat conservative, 29 % independent, 20 % somewhat liberal/progressive, 10 % very liberal/progressive). Half (53 %) reported receiving a salary or salary plus bonus as their primary practice compensation type. Respondents' scores in the 11-item cost-consciousness scale ranged from 11 to 44, with mean and median scores of 31. In multivariate models, parameter estimates reflect a 1-unit increase in scores. Older age, practice setting, compensation type, political ideology and region of practice were all associated with differences in cost consciousness in unadjusted analyses. Older age ($\beta=0.06$, $p<0.0001$), reporting a practice setting other than small/solo (Group/HMO $\beta=1.16$, $p<0.0001$; city/state/federal government $\beta=1.4$, $p=0.0004$; medical school $\beta=2.15$, $p=0.005$), reporting compensation other than "billing only" (salary plus bonus $\beta=1.03$, $p<0.0001$; salary only $\beta=0.80$, $p=0.01$), and reporting a political ideology of somewhat ($\beta=1.75$, $p<0.0001$) or very liberal/progressive ($\beta=2.90$, $p<0.0001$) were all associated with higher cost-consciousness scores. Practicing in the South ($\beta=-0.67$, $p=0.02$) or Northeast ($\beta=-1.42$, $p<0.0001$) was associated with lower cost-consciousness scores.

CONCLUSIONS: Results suggest there are sub-pockets of the profession with distinct identities and professional self-conceptualizations that drive their judgments about their perceived role in addressing health care costs. This contemporary, large-scale and comprehensive survey of US physicians provides important empirical insight into the contours of professional sentiments about addressing health care costs at a crucial juncture in US health care.

NATIONAL TRENDS IN THE MANAGEMENT OF BACK AND NECK PAIN John N. Mafi; Ellen P. McCarthy; Roger B. Davis; Bruce E. Landon. Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #1627954)

BACKGROUND: Back and neck pain are among the most common reasons for visiting a physician and cost the healthcare system approximately $86 billion annually. Studies suggest that the treatment of back pain frequently involves the overuse of diagnostic or treatment modalities that are not supported by national guidelines including use of advanced imaging, referrals to other physicians, and narcotics. Few studies have evaluated national trends in the quality of the management of spine-related disease.

METHODS: We evaluated trends in guideline concordant and discordant treatment of routine spine problems over 10 years from 2001 to 2010 using nationally-representative data on visits to physicians from the National

Ambulatory Medical Care Survey and National Hospital Ambulatory Medical Care Survey. We studied outpatient visits with a chief complaint or primary diagnoses of back or neck pain, as well as those with secondary complaints and diagnoses of back or neck pain, but unrelated primary reasons for the visit (e.g., hypertension). We excluded visits with concomitant red flag diagnoses or complaints including fever, neurologic symptoms, and cancer as well as diagnoses or complaints with similar treatments (e.g. knee pain or trauma). Our primary outcome was guideline discordant care defined as prescriptions for narcotics, referrals to another physician, or radiologic testing including plain films or advanced imaging such as MRIs or CT scans. We also studied guideline concordant care defined as prescriptions for NSAIDs or acetaminophen, or referral to physical therapy and none of the discordant indicators. To examine trends, we used SUDAAN to estimate logistic regression models focusing on a linear trend for the survey year, and adjusting for age, sex, race, insurance status, physician specialty, whether the visit was with the patient's PCP, located in a metropolitan area, and region. Results are weighted to reflect national estimates.

RESULTS: We identified 17,438 visits for spine problems, representing an estimated 306 million visits. Mean age was 51.1 years and 57 % were female, with both remaining stable over time. The proportion of visits reflecting guideline concordant care remained stable from 22 % and 27 % in 2001–2002 to 28 % and 29 % in 2009–2010 (p=0.1987 for trend). The proportion of visits with guideline discordant care increased from 46 % and 40 % to 47 % and 52 % for the same time period (p=0.0006 for trend). The Table presents trends in the outcome's components. In a sub-analysis, the odds of ordering a CT or MRI over the 10-year interval increased by 1.78 [1.35, 2.33]. A sensitivity analysis restricted to visits with a chief complaint of new onset back or neck pain revealed similar results.

CONCLUSIONS: Despite numerous published national guidelines, management of spine problems has increasingly relied on advanced diagnostic imaging and narcotic prescriptions. Improvements in management of spine-related disease represent an area of potential costs savings for the health care system while also maintaining or improving the quality of care.

Utilization Rates Over Time

NATIONAL TRENDS IN OPIOID PRESCRIBING AMONG PATIENTS AT RISK OF OPIOID MISUSE: 2001–2010 Marc Larochelle; Fang Zhang; Dennis Ross-Degnan; James F. Wharam. Harvard Medical School, Boston, MA. (Tracking ID #1635376)

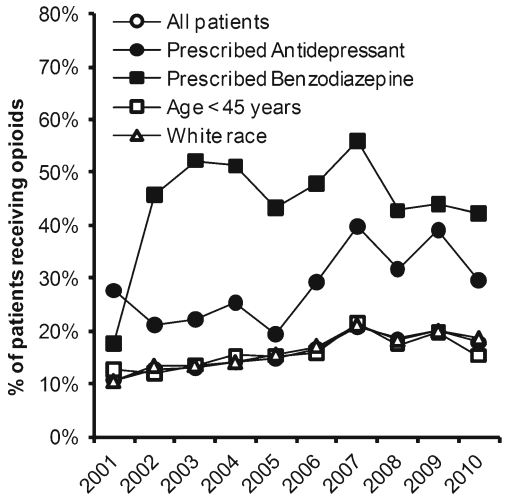
BACKGROUND: Rates of opioid prescribing, overdose, and overdose-related mortality are all increasing in the United States. Previously reported risk factors for opioid misuse include younger age, white race, coexisting mental health disorders, and concomitant use of benzodiazepines. Recent guidelines recommended caution in prescribing opioids to patients at high risk of misuse; however, it is not known if physicians responded by reducing prescribing to such patients.

METHODS: We used the National Ambulatory Care Survey (NAMCS) and analyzed visits of patients with a complaint of musculoskeletal pain annually from 2001 to 2010. The outcome was prescription of an opioid pain medication. We analyzed four risk factors for opioid misuse: age less than 45 years, white race, concomitant antidepressant prescription, and concomitant benzodiazepine prescription. We analyzed trends in the rate of opioid prescribing overall and among patients at risk of opioid misuse using the Cochran-Armitage trend test. We included the four opioid misuse risk factors as candidate predictors of opioid prescription in a multivariable logistic regression. We controlled for gender, payer, region, and indicators of the patient-physician relationship. We used SAS with SAS-callable SUDAAN to account for the complex survey design.

RESULTS: We analyzed 29,103 visits for musculoskeletal pain over the decade. The estimated number of visits nationally increased from 102 million in 2001 to 119 million in 2010. Opioids were prescribed in 10.8 % of visits in 2001, increasing to 17.9 % in 2010 (p<0.0001). From 2001 to 2010, the prevalence of opioid prescribing increased among each group at risk of misuse (p<0.0001 for each risk factor; Figure). Young patients and white patients were no less likely to receive opioids than older and non-white patients (OR 1.0; 95 % CI 0.9–1.1, and OR 1.2; 95 % CI 1.0–1.4 respectively). Patients being treated with an antidepressant had significantly higher odds of being prescribed an opioid (OR 1.9; 95 % CI 1.6–2.2) as did patients receiving a benzodiazepine (OR 4.0; 95 % CI 3.3–4.9).

CONCLUSIONS: Opioid prescribing for musculoskeletal pain increased by more than 50 % in the last decade and increased among patients with risk factors for opioid misuse. Research is needed to determine if these patterns are driving the increase in opioid-related mortality nationwide. Policy- and practice-level interventions are needed to improve patient safety.

Trends in opioid prescribing among groups of patients at risk of opioid misuse.



NATIONAL TRENDS IN PROCESSES AND OUTCOMES OF CARE FOR ELDERLY PATIENTS HOSPITALIZED FOR PNEUMONIA Jonathan S. Lee[1]; Wato Nsa[2]; Leslie R. Hausmann[1,3]; Amal N. Trivedi[4]; Dale W. Bratzler[5]; Dana Auden[2]; Kate Goodrich[6]; Fiona M. Larbi[6]; Michael J. Fine[1,3]. [1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Oklahoma Foundation for Medical Quality, Oklahoma City, OK; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA; [4]Alpert Medical School of Brown University, Providence, RI; [5]Oklahoma University Health Sciences Center, Oklahoma City, OK; [6]Centers for Medicare and Medicaid Services, Baltimore, MD. (Tracking ID #1638089)

BACKGROUND: Measuring and reporting performance rates for disease-specific processes of care are important features of Medicare quality improvement and pay for performance initiatives. Our aim was to assess secular trends in performance rates of processes and outcomes of care for elderly patients hospitalized for community-acquired pneumonia (CAP).

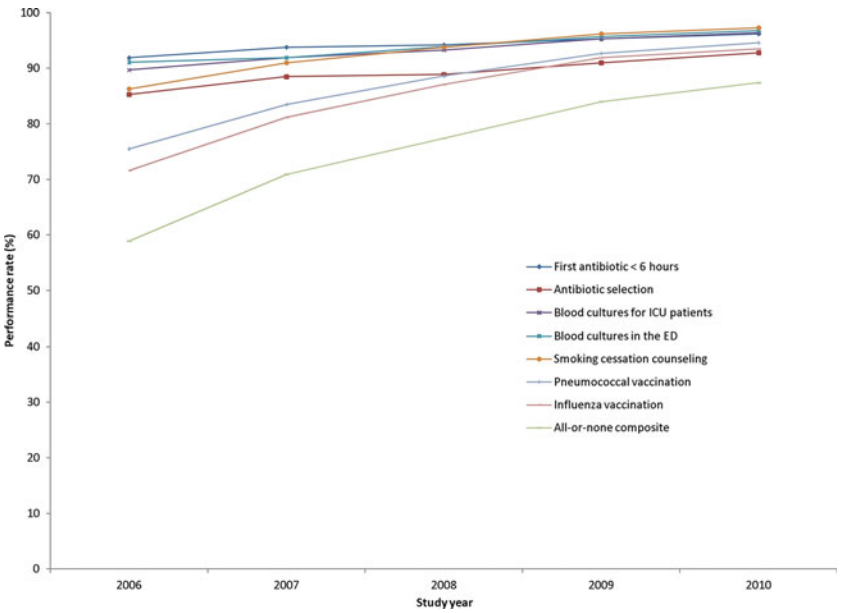
METHODS: We studied elderly patients (age≥65) hospitalized for CAP in U.S hospitals participating in the Centers for Medicare and Medicaid Services (CMS) Inpatient Quality Reporting program during calendar years 2006 to 2010, who met eligibility criteria for the CMS inpatient pneumonia process measures. Our outcomes were performance rates for these 7 publicly-reported pneumonia process measures (i.e., timely initiation and appropriate selection of antibiotics, performance of blood cultures in the emergency department and for intensive care unit patients, smoking cessation counseling, and pneumococcal and influenza vaccination); an

all-or-none composite of all process measures; and 2 medical outcomes (i.e., all-cause mortality and hospital readmission at 30 days). We used linear regression analyses to assess changes in these outcomes by study year.

RESULTS: From 2006 to 2010, 1,818,979 elderly patients with CAP were hospitalized (range 326,956 to 399,243 per year) at 4,740 unique hospitals (range 4,353 to 4,504 per year). As shown in the Figure, performance of all 7 processes of care and the all-or-none composite increased significantly over the 5-year study period ($p<0.01$ for trend, all measures). In 2010, each individual process of care was performed in more than 90 % of all patients, with the largest increases in performance rates over time occurring for pneumococcal (+19.1 %) and influenza (+21.9 %) vaccinations, the 2 process measures performed least frequently in 2006 (75.5 % and 71.6 %, respectively). Performance of the all-or-none composite measure showed the greatest 5-year improvement (+28.5 %), from 58.9 % to 87.4 %. Among all patients, mortality was 10.4 % (range 9.2 to 11.4 % per year) and readmission was 20.4 % (range 19.5 to 20.7 % per year), with neither outcome demonstrating a significant change ($p>0.2$ for trend, both outcomes) over time.

CONCLUSIONS: National performance rates for all pneumonia processes of care improved significantly from 2006 to 2010, with current rates exceeding 90 % for all publicly-reported measures. Despite these improvements in pneumonia processes of care, no significant changes in patient mortality or readmission were observed during this 5-year period.

Figure. National trends in performance of processes of care for pneumonia, 2006 to 2010.



NAVIGATING PUBLIC HOUSING RESIDENTS INTO CARDIOVASCULAR PREVENTION PROGRAMS: A MULTI-SITE INTERVENTION STUDY Tracy A. Battaglia[1]; Jo-Anna L. Rorie[2]; Sarah W. Primeau[1]; Sarah E. Caron[1]; Sarah G. Bhosrekar[2]; Bing L. Chen[1]; Sharon Bak[1]; Timothy Heeren[6]; Gerry Thomas[4]; Rachel Goodman[5]; Eugenia Smith[3]; Deborah J. Bowen[2]. [1]Boston University School of Medicine, Boston, MA; [2]Boston University School of Public Health, Boston, MA; [3]Community Committee for Health Promotion, Boston, MA; [4]Boston Public Health Commission, Boston, MA; [5]Boston Housing Authority, Boston, MA; [6]Boston University School of Public Health, Boston, MA. (Tracking ID #1622701)

BACKGROUND: Residents of urban public housing are among the most vulnerable to early morbidity and mortality from cardiovascular disease. Our prior work demonstrated the impact of a Resident Health Advocate in engaging residents into health screenings, yet interventions are needed to promote participation into care to improve health outcomes.

METHODS: The Boston University Partners in Health and Housing Prevention Research Center, a community-public health partnership, conducted a quasi-experimental intervention study 2011–2012 across six public housing developments in Boston. Three developments were assigned a Patient Navigator (a resident health advocate with advanced training) and three served as control sites. Eligible residents were 18+ years of age, English or Spanish speaking, and screened positive for one or more risk factors (overweight/obese, hypertension, hypercholesterolemia, diabetes, or smoking) at monthly, on-site health screenings. Navigated residents received in person and telephone support to ensure clinical and community referrals were completed. A baseline and follow-up survey collected socio-demographics and healthcare utilization outcomes: visit with primary care provider, participation in community prevention programs (i.e. walking group/smoking cessation program) in prior 3 months. McNemar's tests were used to measure significant changes between outcome measures pre-post intervention.

RESULTS: Among 610 residents participating in screenings, 451 were eligible and 326 (72 %) enrolled ($n=152$ intervention, $n=174$ control). Of those enrolled, the mean age was 50, 75 % female, mostly Non-White (28 % Black, 51 % Hispanic, 10 % Other), public/no health insurance (94 %), had a PCP visit in the past 3 months (64 %), and nearly half never graduated high school (44 %) and were foreign born (47 %). Overall, 79 % were overweight or obese, 78 % reported or diagnosed hypertension, 66 % reported or diagnosed diabetes, 47 % reported high cholesterol, and 32 % reported current tobacco smoking. Compared to intervention residents, controls were more likely to be older (mean age 52 vs. 46, $p<0.01$), non-English speaking (56 % vs. 39 %, $p=0.01$), foreign born (53 % vs. 40 %, $p=0.02$) yet more likely to have seen a primary care provider in the past 3 months (72 % vs. 55 %, $p<0.01$). Preliminary analyses ($n=184$ with completed outcomes) found navigated subjects reported a significant increase in outcome utilization pre-post intervention: attending a primary care visit (51 % to 71 %, $p<0.01$), participating in community programs (34 % to 55 %, $p<0.01$), and over-all attending a community program or a primary care

visit (66 % to 88 %, $p<0.01$). Control group residents reported no significant change in healthcare utilization: attending primary care visit (74 % to 75 %, $p=0.84$), participating in community programs (23 % to 18 %, $p=0.35$), and over-all attending a community program or a primary care visit (79 % to 78 %, $p=0.84$).
CONCLUSIONS: This multi-site navigation intervention study documents the impact of a patient navigator on improving healthcare utilization among a vulnerable population living in public housing.

NEEDLE AND SYRINGE EXCHANGE PROGRAMS: ACCEPTABILITY AND SAFETY OF RETRACTABLE SYRINGES FOR IV DRUG USERS IN THE LARGEST PRE-TRIAL PRISON IN SWITZERLAND
Hans Wolff; Javier Barro; Alejandra Casillas; Thierry Favrod-Coune; Anne Francois; Jean-Pierre Rieder; Mariem Baroudi; Laurent Gétaz; Barbara Broers. University Hospitals of Geneva, Geneva, Switzerland. (Tracking ID #1636223)

BACKGROUND: Transmission of blood-borne infections is important to address in prison, given the prevalence of HIV and hepatitis, overcrowding, and high levels of risky behavior in this setting. Needle and Syringe Exchange Programs (NSP) have proven their feasibility, efficacy and safety in prison settings, but less than 1 % of prisons worldwide have NSP. One identified barrier is organizational concern for needle stick injuries and use of soiled syringes as weapons among inmates. We evaluated 1) incarcerated drug users' experiences with retractable syringes in an NSP, and 2) beliefs and knowledge about NSP among prison officers (PO) and healthcare staff (HS) in prison.
METHODS: From May to October 2010, we replaced usual (insulin-type) syringes with retractable needle devices as part of the NSP in the prison of Champ-Dollon, Geneva; Switzerland. We examined the demographics, clinical profiles for and NSP use among NSP participants, and asked about the ease and safety of the retractable needle device use, in face-to-face interviews. We distributed ninety-eight questionnaires to prison officers and to healthcare staff (HS), surveying individuals on their knowledge and opinions regarding drug use and harm reduction measures.
RESULTS: 284 retractable syringes were distributed to 28 inmates, with a return rate of 70 %. Twenty-six of them accepted to participate in the study. Thirteen were selected for interview and 10 interviews were completed. Most participants were male (96.4 %); mean age was 32 years (SD 4.8). They had a median of 2 previous incarcerations (range 1–45) with a median duration of 70.7 days (range 5–690). Median duration of IV drug use was 54 months (0–324). Seropravelence of HIV was 3 %, HBV 7.1 % and HCV 60.7 %. The majority of participants expressed that retractable syringes were acceptable alternatives, but complained about difficulties due to the weight of the syringe and needle quality, as well as the difficulty to install and use the syringe filter. Of the 98 questionnaires distributed to PO and HS, 70 % of PO and 100 % of the HS estimated harm reduction policies as an effective means to reduce the risk of transmission of blood-borne infections. However, 90.3 % of PO and 9.6 % of HS were still concerned about the use of syringes as weapons; and 76.1 % of PO (4.8 % of HS) feared that NSP would increase drug abuse.
CONCLUSIONS: This is the first study evaluating experiences with retractable syringes for NSP in a correctional setting. NSP was perceived as an acceptable alternative for incarcerated IV drug users. Acceptance may be increased by improving the quality and ease of use of the retractable device as suggested by prisoners. Despite the safe 15-year existence of NSP in the Geneva Champ-Dollon prison, fear of syringes as a weapon still exists among prison officers and health staff. Nevertheless, it is useful to gain this information– as addressing PO and HS safety concerns are an important step towards more disseminated NSP implementation.

NEGATIVE HEALTH CARE EXPERIENCES AND THEIR CONSEQUENCES IN 3 RACIAL AND ETHNIC GROUPS
Rebecca J. Schwei; Elizabeth A. Jacobs. School of Medicine and Public Health, University of Wisconsin, Madison, WI. (Tracking ID #1641611)

BACKGROUND: It has been hypothesized that a previous negative health care experience may lead to changes in a usual source of care. Changes in a usual source of care have been associated with decreased health care use, access, and quality, and greater health costs. Our objectives were to better understand (1) who reports having a negative experience in health care, (2) whether or not they change their behavior if they report a previous negative experience, and (3) whether or not reporting a change in behavior is associated with race/ethnicity.
METHODS: We studied a convenience sample of 472 adults from Chicago area grocery stores who self-identified as African American, Mexican-Hispanic, or White. We used chi-square analyses to evaluate differences in sociodemographic characteristics (race/ethnicity, gender, marital status, employment status, income, education level), access to care (insurance status, avoidance of care due to cost), and overall health status between participants reporting a negative health care experience and those who did not. We used the 10-item Negative Health Care Experience Scale; participants were asked "In the past 5 years, have you had a health care experience you considered to be bad or negative?" and, if they said yes, "How often have you done the following (10) thing(s) because of that bad experience?": decided not to follow your doctor's advice; did not return for your next medical appointment; changed doctors or went for treatment elsewhere; stayed with the same doctor but trusted him or her less; stopped going to the doctor as often as you should; stopped treatment or going to the doctor entirely; did not go for treatment next time you were ill; changed hospitals or clinics; and only go to the emergency room for treatment. Possible reponses for each question included "never", "rarely", "sometimes" or "always". We used frequencies to describe responses to items.
RESULTS: 157 (33.3 %) participants reported having a negative health care experience in the past 5 years. The only sociodemographic, access to care and overall health status variables that differed between those reporting a negative health care experience and those who did not were a self report of avoiding needed care due to cost (49.7 % vs. 31.3 % $p<0.001$), visiting the doctor more than 6 times per year (24.4 % vs. 14.9 % $p=0.044$) and poor health (7.8 % vs. 2.9 % $P<0.001$). The Negative Health Care Experience Scale had high reliability ($\alpha=.82$). The frequency of report of each of the ten behavior changes did not differ by race/ethnicity. Of the people reporting a negative health care experience, 89 % of participants reported "sometimes" or "always" changing at least one behavior in response to a negative health care experience. The frequency of reporting "sometimes" or "always" for the individual items ranged from 35 % for "only go to the emergency room for treatment" to 64 % for "changed doctors or went for treatment elsewhere".
CONCLUSIONS: A third of our sample reported having at least one negative experience in health care in the last 5 year and those who did significantly differed from those who did not in terms of access to care and overall health status. The participants' responses on the Negative Health Care Experience Scale suggest that a previous negative health care experience may influence a patient's subsequent health care behaviors. Further research is needed to understand how health care providers and organizations can prevent these negative experiences and consequences.

NEIGHBORHOOD DISADVANTAGE AND DISORDER AND ADOLESCENT WEIGHT CHANGE OVER TIME
Adebowale Odulana[1,2]; Asheley C. Skinner[2]; Crystal W. Cene[1]; Tamera Coyne-Beasely[2]; Andrew J. Perrin[4]; Giselle Corbie-Smith[1,3]; Eliana M. Perrin[2]. [1]UNC at Chapel Hill School of Medicine, Chapel Hill, NC; [2]UNC at Chapel Hill School of Medicine, Chapel Hill, NC; [3]UNC at Chapel Hill School of Medicine, Chapel Hill, NC; [4]UNC at Chapel Hill, Chapel Hill, NC. (Tracking ID #1640896)

BACKGROUND: Neighborhood disorder, the perceived lack of order and social control in a neighborhood, is associated with lower physical activity and obesity in adults, but less is known about the association in adolescents. Low neighborhood socioeconomic conditions, neighborhood disadvantage, may increase access to obesogenic foods and might promote sedentary lifestyles in adolescents. However, the relationship between neighborhood disorder and disadvantage, and adolescent weight remains unclear. In this study we aim to evaluate the association of neighborhood factors with adolescents' weight changes as they transition into adulthood.
METHODS: Data from waves 1–3 of the National Longitudinal Study of Adolescent Health (Add Health) were used for adolescents aged 12–18 years at wave 1 and 19–25 years at wave 3. Household level variables (e.g., income)

were based on parent responses in wave 1. Neighborhood-level variables included measures of disadvantage, safety, and disorder. We calculated changes in weight category for adolescents and adults (higher, lower, or the same) using measured height and weight from wave 2 to wave 3. We assessed associations between household and neighborhood characteristics at wave 1 and weight changes from wave 2 to 3 using chi-square tests.
RESULTS: Of 10,548 adolescents (mean age 15.5 year., 50 % male, 68 % white, 14 % black, 18 % other) 69 % were healthy weight, 16 % overweight, and 12 % obese at wave 2. Most (57 %) stayed in the same weight category from wave 2 to 3, 31 % went to a higher category, and 11 % lower. Household use of public assistance was associated (p=0.03) with greater weight instability (loss and gain) in adolescents while higher parental education (p=0.002) was associated with lower weight instability. Neighborhood disadvantage variables, poverty (p=0.001) and unemployment (p=0.002), were associated with more weight instability in adolescents.
CONCLUSIONS: Household characteristics and neighborhood disadvantage are strongly associated with weight instability, weight increases and decreases over time. Further study should elucidate the reasons for instability in weight and determine if weight decreases in disadvantaged neighborhoods are healthy or are unhealthy (i.e. the result of food insecurity, substance abuse, or poor health). These findings emphasize the importance of environmental factors on adolescent weight. Whether neighborhood disorder and safety mediate the effects of disadvantage deserves deeper consideration.

NET EFFECT OF AGGRESSIVE BLOOD PRESSURE CONTROL ON STROKE AND FALLS IN OLDER COMMUNITY-DWELLING ADULTS Lillian Min[1,2]; Caroline Blaum[3]; Kenneth M. Langa[1,2]; Deborah A. Levine[1,2]; Eve A. Kerr[1,2]. [1]University of Michigan, Ann Arbor, MI; [2]VA Healthcare Systems, Ann Arbor, MI; [3]New York University, New York, NY. (Tracking ID #1637119)

BACKGROUND: Systolic hypertension affects two-thirds of older adults. Despite cardiovascular benefit of systolic blood pressure (SBP) control demonstrated in trials of selected older patients, it is unclear when benefit of aggressive SBP control outweighs the risk of falls - a known risk of multiple cardiovascular medications.
METHODS: In a longitudinal secondary analysis of 6,280 participants age 65 or older with treated hypertension or SBP measurement >140 mmHg in the Health and Retirement Study in 2006, the frequency of new fall injuries (fall requiring medical care) and new stroke (told of stroke by physician) were assessed as a multinomial variable with the following 4 outcomes: stroke and fall, stroke only, fall only, and no stroke/no fall. We examined the effect on the outcome over 2 years by four levels of increasing SBP control: (1) untreated SBP ≥160 mmHg, (2) treated SBP ≥160 mmHg, (3) treated SBP 121–159 mmHg or untreated SBP 140–159 mmHg, and (4) treated SBP<120 mmHg, controlling for baseline age and sex using multinomial logistic regression. We selected high and low SBP cutoffs as a ±20 mmHg interval around currently-recommended SBP of 140 mmHg.
RESULTS: New injurious falls were more probable (n=799, 14 %) than new stroke (n=243, 4 %) during the two-year follow-up, a difference that increased with age: 7 % falls and 2 % stroke at age 65 versus 25 % falls and 5 % stroke at age 90. More aggressive BP control by a 1-level increase in aggressiveness was associated with increased falls (RR fall only=1.1, p=.05), but not strokes (RR stroke only=.9, p=.2) or both (RR both=1.2, p=.4). The predicted effect on falls, stroke, and the net effect on both outcomes are displayed by age and degree of increase in BP control (Table). The absolute effect sizes of harm for increasing from poorly controlled BP to overly controlled BP are of clinical significance comparable to other clinical tradeoff situations (e.g., warfarin versus aspirin for atrial fibrillation).
CONCLUSIONS: In older adults, more aggressive SBP control increased the risk of falls and did not decrease the risk of stroke. Controlling SBP less than 120 mmHg is associated with net harm. We need to individualize treatments for older adults based on risk and benefits for important clinical and geriatric outcomes.
Net effect on falls and stroke, by age and varying intensification of SBP control
Age Degree of increase in SBP control (From less control to more control) Effect on falls* Effect on stroke* Net effect** (95 % CI)

* Absolute difference in probability between the two levels of BP control, in percentage points. A negative value indicate decrease in risk (a benefit).
** Net increase in probability of either event, in absolute percentage points.

NEW GRADUATE MEDICAL EDUCATION TEACHING STRATEGIES IN A POST-ACGME WORK-HOUR MANDATED ENVIRONMENT. Christa Nevin[1]; Donald M. Dempsey[1]; Martin Rodriguez[1]; Andrea Cherrington[1]; Mukesh Patel[1,2]; Niveditha Thota[1]; Erin Snyder[1]; Angelo L. Gaffo[1]; Joseph Barney[1]; Matthew Wyatt[1]; Brita Roy[1]; David Daly[1]; James H. Willig[1]. [1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Maryland, Baltimore, MD. (Tracking ID #1631208)

BACKGROUND: In 2003 and 2011, the Accreditation Council of Graduate Medical Education (ACGME) introduced guidelines limiting resident duty hours, resulting in a decrease in educational opportunities for residents. We explored resident attitudes regarding the educational impact of ACGME guidelines and openness to new educational strategies. With these data, and applying principles of Gamification (the use of game elements in non-game applications), we developed a web-based application to supplement medical resident training.
METHODS: Eight focus groups of internal medicine residents at the University of Alabama at Birmingham (UAB) were conducted between 6/2012 and 7/2012 to explore attitudes towards the 2011 ACGME duty hour guidelines. Focus group transcripts were reviewed and common themes identified using a deductive/inductive approach. Participants also completed a survey on openness to new teaching strategies. Using Gamification principles, we developed an online software application (Kaizen-IM), accessed via desktop or mobile device, to improve medical knowledge by allowing residents to compete with their peers to answer clinically relevant questions in structured multispecialty-focused seasons throughout the academic year.
RESULTS: 34 residents participated in focus groups (16 PGY-1, 12 PGY-2, 6 PGY-3). Residents reported a decline in teaching by attending physicians and by PGY-2/PGY-3 residents to interns since implementation of the ACGME guidelines. 79 % reported that they would use an application that allowed them to compete with peers to improve medical knowledge. Kaizen-IM, named after the Japanese business principle of continuous improvement, was launched on 8/20/2012. During Season One of Kaizen-IM (8/20/2012-10/14/2012), 110 questions developed by UAB faculty were administered (2/day) to participating internal medicine residents. 97 (76 %) of UAB internal medicine residents actively participated in Season One, responding to 77 % of administered questions (8,140 total responses).
CONCLUSIONS: Residents are concerned about the educational impact of the ACGME work-hour restrictions and are open to new learning strategies. Novel educational methodologies, like Kaizen-IM, may provide additional learning opportunities for residents. Kaizen-IM is actively being used and has been enthusiastically embraced by UAB Internal Medicine residents.

NO-SHOW TO PRIMARY CARE APPOINTMENTS: WHY PATIENTS DO NOT COME? Emma R. Kaplan-Lewis; Patrick R. Cronin; Sanja Percac-Lima. MGH- Massachusetts General Hospital, Boston, MA. (Tracking ID #1631951)

BACKGROUND: Failure to show up to a primary care appointment leads to disruption of the core purpose of primary care- continuous quality care over time. Missed appointments are a source of inefficiency in the medical system and lead to poor control of chronic disease, later presentation to care and wasted health care dollars. No-shows are higher in primary care clinics taking care of underserved populations and could be a contributing factor to poorer health outcomes in this group. Understanding the factors associated with primary care clinic no-shows and exploring methods to reduce the no-show rate are important to increase access to quality primary care and reduce health disparities. The objective of this study was to determine who were the patients not showing to primary care appointments and to explore their reasons to no-show.
METHODS: A retrospective study was conducted at a community health center (CHC) affiliated with a large academic medical center serving a predominantly Latino, immigrant, low-income population. The majority of patients are Spanish speaking. Poverty levels are more than twice the average in the state. Adult patients >18 yo who did not show up to primary care appointments at the adult medicine practice on 51 days from 3/23/12 to 9/4/12, were called by a bilingual (English and Spanish) patient service coordinator. The patient's reported reason for missing the appointment was documented. Using two-sided t-test of proportions we compared demographic characteristics of the patients that showed to their appointments to patients that did not, as well as patients that could not be reached post no-show.
RESULTS: During the study period there were 7, 508 scheduled appointments at the adult medicine practice, and 1,904 cancellations, reschedules and bumped appointments were excluded. Of the 5,604 appointments that were evaluated, 927 (16.5 %) patients did not show up for their appointments. Of the patient's who missed an appointment, 735 (79 %) were called and of these 273 (37 %) were reached. When compared to patients who came to their appointment, patients who no-showed were younger ($P<0.01$), more likely to be Black ($P=0.04$) or Hispanic ($P<0.01$), and to have Medicaid or be self insured ($P<0.01$), or to have unknown insurance ($P<0.01$). Of patients who no-showed, those who were reached by phone were more likely to be >65 yo ($P<0.01$) and have Medicare insurance ($P=0.02$). The three most common reasons patients cited for missing an appointment were: Forgot ($n=97$, 35.5 %), miscommunication regarding the appointment ($n=86$, 31.5 %) and acute illness (pt too sick to come in or hospitalized) ($n=21$, 7.7 %).
CONCLUSIONS: No-show rates interfere with quality primary care. The patient population in this study cites forgetting and miscommunication as their two most common reasons for missing appointments. Interventions designed to target these reasons are needed to help reduce the no-show rate, improve access and decrease health disparities in this underserved patient population.

NOTE QUALITY AND QUALITY OF CARE: IS THERE AN ASSOCIATION? Samuel T. Edwards[1,2]; Pamela M. Neri[3]; Lynn A. Volk[3]; Gordon D. Schiff[4,5]; David W. Bates[4,5]. 1VA Boston Healthcare System, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Partners Healthcare System, Wellesley, MA; [4]Brigham and Women's Hospital, Boston, MA; [5]Harvard Medical School, Boston, MA. (Tracking ID #1599957)

BACKGROUND: While physician notes are essential to outpatient care, note content is variable, and note quality lacks rigorous definition. Electronic health record (EHR) adoption can result in more complete documentation, but there are concerns that notes are becoming longer, increasingly redundant, and suffer from poor formatting. Documentation style varies between specialties, and the relationship between note quality and clinical quality has not been defined. We describe the composition of specialists' and primary care physicians' outpatient notes for diabetes and coronary artery disease. We identify what data elements are recorded in notes and elsewhere in the EHR. We also assess subjective note quality and compare this to disease specific quality scores.
METHODS: Two physicians reviewed a random sample of notes of outpatient visits to a PCP or medical specialist in 2010 with a diagnosis of coronary artery disease or diabetes mellitus. Data collected included documentation method, note structure, presence of outdated or erroneous copy/pasted text, and visit-specific items relating to the management of diabetes and coronary artery disease. Note quality was assessed using the 9-item Physician Documentation Quality Instrument. Quality scores were generated using the meaningful use criteria. Categorical variables were compared using Fisher's exact test.
RESULTS: Our analysis included 239 notes, written by 111 physicians; 110 notes were written by primary care physicians, 52 by cardiologists and 77 by endocrinologists. PCPs used templates and free text predominantly (42.3 % and 40.9 % respectively). Cardiologists used free text predominantly (65.2 %) followed by dictation (34.8 %), and endocrinologists primarily used free text, followed by templates (58.8 % and 35.3 %, respectively). Mean note length was 619 words for PCPs, 536 words for cardiologists and 659 words for endocrinologists ($p=0.04$). Reason for visit was absent in 10.8 % of notes, medication list was absent in 19.7 %, and timing of follow-up was absent in 18.0 % of notes. Outdated or erroneous copy/pasted material was present in 10.8 % of notes overall, was more common in endocrinology notes (19.5 %) and less common in cardiology notes (1.9 %). Laboratory quality indicators were more likely to be present in the EHR than in the physician note (lipid panel in last year for diabetes: 56.4 % in note vs. 84.9 % in EHR), while medication-based quality indicators were more likely to be present in the note than elsewhere in the EHR (beta blocker for CAD: 67.3 % in note vs. 59.1 % in EHR). Between specialties, there were few differences in documentation of quality metrics. Composite quality scores for diabetes and CAD showed no significant association with subjective note quality (correlation coefficient −0.13, $p=0.065$).
CONCLUSIONS: We found significant differences between specialties regarding documentation method and note length. Typical note sections such as reason for visit and follow-up timing were frequently missing from physician notes, and erroneous/outdated copy/pasted text was frequently present. Key clinical data to support quality patient care are often missing from physician notes, although they often can be found elsewhere in the EHR. Subjective assessment of note quality did not correlate with clinical quality scores. As EHRs continue to be adopted, studies of what documentation improves care and clear policies which support this are needed.

OFF-LABEL USE OF ONDANSETRON IN HOSPITALIZED MEDICAL PATIENTS: PREVALENCE, PATTERNS AND PREDICTORS Sarah Hartley[1]; Latoya Kuhn[2]; Staci Valley[1]; Nabil Fallouh[1]; Kathleen Dussan[1]; Stephanie Judd[1]; Susan L. Murphy[4,3]; Sanjay Saint[2,1]; Vineet Chopra[2,1]. 1University of Michigan, Ann Arbor, MI; [2]Ann Arbor Veterans Affairs Medical Center, Ann Arbor, MI; [3]Ann Arbor Veterans Affairs Medical Center, Ann Arbor, MI; [4]University of Michigan, Ann Arbor, MI. (Tracking ID #1619089)

BACKGROUND: Hospitalists frequently prescribe ondansetron for nausea and vomiting. However, the Food and Drug Administration (FDA) has approved this agent only for prophylaxis of nausea and emesis related to chemotherapy, radiation therapy or for postoperative patients. The purpose of this study was to evaluate the prevalence and predictors of off-label ondansetron use in hospitalized medical patients.
METHODS: We conducted a case–control study of adult medical patients admitted to a single university hospital from the emergency department (ED) between 1 May 2008 and 30 September 2009 who received ondansetron, prochlorperazine, or promethazine as the first anti-emetic after admission. Exclusion criteria included anti-emetic therapy at home, allergy to anti-emetics, pregnancy, admission to the intensive care unit, or use for an indication other than nausea or vomiting. Our sample was initially obtained using an administrative data set; a random sample of 75 patients was selected for medical record review in order to calculate a kappa statistic. A total of 158 patients who received non-FDA approved ondansetron were compared to 151 patients who received promethazine or prochlorperazine (either of which were considered standard treatment). Patterns of non-FDA approved use were analyzed using descriptive statistics. Multivariable logistic regression models were then fit to identify predictors of such use.
RESULTS: We found that ondansetron as first-line treatment for nausea outside of FDA-approved indications was 5 times more prevalent than standard

therapy (4169 doses versus 750 doses). Patients treated with ondansetron tended to be older (54.6 versus 48.8 years, $P<0.01$), more likely to be hypertensive (50.6 % vs. 39.7 %, $P=0.05$), and less frequently prescribed multiple anti-emetics at the time of admission (32.3 % vs. 43.7 %, $P=0.04$) (Table 1). Receipt of prochlorperazine or promethazine in the ED was associated with the decreased likelihood of receiving non-FDA approved ondansetron therapy during admission (odds ratio 0.27, 95 % confidence interval 0.11, 0.66) (Table 2). Inter-rater reliability for data abstraction between the two raters showed excellent agreement ($k=0.89$).

CONCLUSIONS: Although ondansetron therapy for non-FDA approved indications is highly prevalent in hospitalized medical adults, use of standard anti-nausea treatment in the ED was associated with a decrease in this practice. Implementing policies for "upstream" use of medications in the ED may substantially influence inpatient practice

Table 1. Descriptive Characteristics of the Study Sample (N = 309)

Characteristic	Ondansetron n=158	Prochlorperazine / Promethazine n=151	P value
Age, mean (SD)	54.6 (18.3)	48.8 (15.0)	<0.01
Male	56 (35.4%)	56 (37.1%)	0.76
Number of admission, mean (SD)	1.0 (2.5)	1.2 (2.0)	0.44
Hypertension	80 (50.6%)	60 (39.7%)	0.05
Diabetes	40 (25.3%)	31 (20.5%)	0.32
Cirrhosis	11 (7.0%)	6 (4.0%)	0.25
Renal insufficiency	26 (16.5%)	20 (13.2%)	0.43
Discharged on an anti-emetic	32 (20.2%)	35 (23.2%)	0.53
More than one inpatient anti-emetic ordered	51 (32.3%)	66 (43.7%)	0.04

Table 2. Multivariable Logistic Regression Showing Predictors of Ondansetron Therapy

Predictor variable	Odds Ratio	95% Confidence Interval
Age	1.02	1.00-1.03
Cirrhosis	1.51	0.54-4.27
Number of admissions	0.97	0.87-1.08
Admitting service		
Hematology/Oncology	0.54	0.21-1.36
Hospitalists	1.10	0.67-1.83
Other*	Reference	
Emergency Department Treatment		
Ondansetron	1.04	0.60-1.80
Prochlorperazine or Promethazine	0.27	0.11-0.66

*Other admitting service includes Internal Medicine, Cardiology, Family Medicine and Pulmonary

OFF-LABEL ANTIPSYCHOTIC PRESCRIPTIONS IN IRAQ AND AFGHANISTAN VETERANS WITH POSTTRAUMATIC STRESS DISORDER IN VA HEALTHCARE, 2001–2011 Beth Cohen[1,2]; Ying Shi[1]; Thomas Neylan[1,2]; Karen H. Seal[1,2]. [1]San Francisco VA Medical Center, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA. (Tracking ID #1641921)

BACKGROUND: Over one quarter of veterans who have returned from Iraq and Afghanistan and entered VA care have received a diagnosis of posttraumatic stress disorder (PTSD). PTSD has been associated with metabolic abnormalities and cardiac risk factors, even in these younger age veterans. Antipsychotics have been increasingly prescribed for off-label uses, including treatment of PTSD. Given concern about the potentially harmful metabolic side effects of antipsychotics as well as recent trials that failed to demonstrate efficacy for PTSD symptoms, we used a large national VA sample to explore the use of off-label antipsychotics among Iraq and Afghanistan veterans with PTSD. We evaluated the prevalence of off-label antipsychotic use and identified sociodemographic factors, military service characteristics, and psychiatric comorbidities that were associated with their use.

METHODS: We used de-identified Department of Defense data and national VA electronic medical records to select Iraq and Afghanistan veterans who had enrolled in VA care between 10/1/2001 and 12/31/2010, and followed them through 12/31/2011. We used ICD-9 codes to determine mental health and medical diagnoses and pharmacy records to evaluate medication use. We only included medications that were prescribed after the date of PTSD diagnosis and had a supply of at least 30 days. We excluded patients that used antipsychotics but had comorbid diagnoses indicating on-label use (i.e. schizophrenia, bipolar disorder, depression with concurrent use of an antidepressant medication). To evaluate factors independently associated with off-label antipsychotic use, we used Poisson regression models that included age, gender, race, marital status, military component (Active Duty vs. National Guard/Reserve), rank (officer vs. enlisted), branch, multiple deployments, and rural vs. non-rural location. We developed similar models evaluating the association of psychiatric comorbidities with off-label antipsychotic use.

RESULTS: The mean age of our study population was 29.2 years (SD 9) and 9.6 % were women. Of the 155,926 patients with PTSD examined, 22 % (34,142) received no psychiatric medications, 66.2 % (103,276) received psychiatric medications other than antipsychotics, and 11.9 % (18,508) received off-label antipsychotics. In fully adjusted models, several factors were independently associated with off-label antipsychotic use, including male sex (adjusted relative risk 1.47, 95 % CI 1.39–1.55), Active Duty status (1.32, 1.28–1.37), enlisted vs. officer (1.71, 1.55–1.87), and rural vs. non-rural location (1.11, 1.08–1.14). Several comorbid psychiatric diagnoses were also associated with increased likelihood of off-label use, including personality disorder (2.05, 1.91–2.19), drug use disorder (1.77, 1.69–1.86), panic disorder (1.57, 1.48–1.67), and alcohol use disorder (1.43, 1.37–1.50).

CONCLUSIONS: A substantial minority of Iraq and Afghanistan veterans with PTSD diagnoses received off-label antipsychotics. Male veterans, those who were Active Duty, lower rank, or lived in rural locations, and those with psychiatric comorbidities were more likely to receive off-label antipsychotics. Off-label antipsychotics may be prescribed to more symptomatically complex and behaviorally challenging patients, who may be more difficult to engage in conventional psychotherapy. Still, providers should be cautious about off-label antipsychotic use given their known metabolic risks and questionable benefits for PTSD.

OPTIMAL TIMING TO ADMINISTER THE PHQ-9 FOLLOWING A POSITIVE PHQ-2 DEPRESSION SCREEN AMONG HOSPITALIZED PATIENTS WITH HEART FAILURE Tatiana Deveney[1,2]; Bea Herbeck Belnap[2]; Sati Mazumdar[3]; Fanyin He[3]; Bruce L. Rollman[2]. [1]University of Rochester School of Medicine, Rochester, NY; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]University of Pittsburgh, Pittsburgh, PA. (Tracking ID #1641551)

BACKGROUND: An American Heart Association (AHA) Science Advisory recommends that patients with cardiac disease be routinely screened for depression with the 2-item Patient Health Questionnaire-2 (PHQ-2), with the PHQ-9 questionnaire administered to patients screening positive to diagnose depression. However the optimal time to administer the follow-up PHQ-9 is unknown. To address this question, we compared the prevalence of depression and incidence of 12-month all-cause mortality among hospitalized patients with systolic heart failure (HF) when the PHQ-9 was administered either: (1) immediately following a positive PHQ-2 screen; or (2) at 1-month following hospitalization.

METHODS: Trained study nurses enrolled 371 hospitalized HF patients with an ejection fraction (EF) <40 % and NYHA functional class II-IV symptoms who screened positive for depression on the PHQ-2 administered prior to discharge from 4 Pittsburgh-area hospitals (12/07 to 6/09). Afterwards, they administered the PHQ-9 both immediately following the PHQ-2 and via telephone at 1 month post-hospitalization. Sociodemographic and clinical information were collected at baseline. Using accepted convention, we defined depression as a PHQ-9 score ≥10, then used Kaplan-Meier analyses to calculate the incidence of all-cause mortality at 1-year follow-up by depression status, with log rank tests used for statistical significance.

RESULTS: The study sample was predominantly Caucasian (85 %) and male (64 %) with a mean age of 65±13 years. At baseline, their mean PHQ-9 score was 11.3±4.5, and 63 % of the cohort (232/371) scored ≥10. Of the 316 (85 %) patients who completed the PHQ-9 at 1-month follow-up, 24 % (76) scored ≥10 (8 (3 %) died prior to 1-month follow-up). We confirmed vital status on 100 % of the study cohort at 1-year and identified 76 deaths (20 %). 12-month all-cause mortality was similar between patients who scored ≥10 vs. <10 on the PHQ-9 at baseline (21 % vs. 19 %; p=0.73) and at 1-month follow-up (14 % vs. 15 %; p=0.87). Overall, 21 % (49/232) of those who scored PHQ-9 ≥10 at baseline and 14 % (11/76) of those who scored ≥10 at 1-month died by 12-month follow-up. (Table).

CONCLUSIONS: Among hospitalized HF patients who screen positive for mood symptoms on the PHQ-2, the estimated prevalence of depression is lower when the PHQ-9 is administered 1-month after hospital discharge rather than immediately following the PHQ-2. Furthermore, as neither the baseline nor the 1-month level of PHQ-9 score was associated with alterations in 1-year mortality, delaying administration of the PHQ-9 may safely reduce the risk of over-diagnosis of depression while better focusing treatment resources on HF patients with persistent depressive symptoms who might be more likely to benefit from treatment.

PHQ-9 Score ≧ 10 PHQ-9 Score <10 p-Value*

OUTCOMES AMONG BUPRENORPHINE-NALOXONE PRIMARY CARE PATIENTS AFTER HURRICANE SANDY Babak Tofighi[1]; Arthur R. Williams[2]; Rana Biary[3]; John Rotrosen[4]; Joshua D. Lee[5]; Ellie Grossman[6]. [1]New York University School of Medicine, New York, NY; [2]New York University School of Medicine, New York, NY; [3]New York University School of Medicine, New York, NY; [4]New York University School of Medicine, New York, NY; [5]New York University School of Medicine, New York, NY; [6]New York University School of Medicine, New York, NY. (Tracking ID #1628814)

BACKGROUND: Post-disaster studies evaluating outcomes among substance using patients enrolled in treatment reveal an increase in relapses. However, outcomes among opiate dependent patients enrolled in office-based buprenorphine treatment have yet to be studied. In October 2012, Bellevue Hospital Center (BHC) and all its primary care services were temporarily closed as a result of Hurricane Sandy. BHC's primary care office-based buprenorphine clinic was temporarily closed and later relocated to an affiliate public hospital. The hospital outpatient pharmacy, which supplies low-cost buprenorphine to uninsured patients, was also temporarily closed. We surveyed enrolled patients for self-reported buprenorphine adherence, illicit substance and alcohol use, as well as disaster-related personal consequences post-Sandy.

METHODS: A quantitative and qualitative semi-structured survey was piloted and administered to patients scheduled for follow-up in BHC's primary care buprenorphine clinic starting in November 2012. This 15-minute survey was administered by one of four physicians either by telephone or in-person in clinic. Survey domains included: housing and employment disruptions, social and economic support (disaster relief), treatment outcomes (buprenorphine adherence, missed medication doses, ability to get care), and tobacco, alcohol and drug use. Open-ended questions probed general patient experiences related to the storm and associated disruptions. Baseline demographic characteristics and insurance status was available from the medical record. Analysis was descriptive (counts, proportions) and qualitative, coding open-ended responses for emergent themes.

RESULTS: There were 146 patients enrolled in the clinic at the time of the storm; of those, we have been able to reach 79 to invite them to participate in the survey. 73 patients have completed the survey (92 % of those invited). The clinic population's mean age is 42 years (range 21–67 years), and it is 82 % male, 14 % African American, 41 % Hispanic, and 44 % Caucasian. Twenty percent are uninsured, and 73 % are enrolled in Medicaid. Illicit opioid misuse was rare, with 4 patients reporting increased illicit heroin or prescription opioid use since Sandy. 49 % of respondents reported disruption of their buprenorphine-naloxone medication supply (n= 36). Of this group, 83 % reduced their daily dose to prolong supply (n=30), 53 % eventually obtained telephone or written refills from relocated Bellevue providers, 24 % obtained buprenorphine from friends/family, and 13 % reported buying buprenorphine from others/dealers. All patients reported difficulty obtaining emergency buprenorphine prescriptions elsewhere (emergency rooms, new outpatient programs).
CONCLUSIONS: Disruption to buprenorphine supply was the norm among a cohort of primary care buprenorphine patients at a large public hospital clinic abruptly closed due to Hurricane Sandy. Common coping strategies were self-directed dose reduction, remote (telephone) refills, and obtaining buprenorphine from friends/family or drug markets. Few respondents reported significantly increased illicit opioid or other drug or alcohol use pre/post-Sandy. Public sector office-based buprenorphine delivered in a primary care setting appears relatively adaptable to severe environmental and service disruptions following a natural disaster.

OVERDOSE HISTORY AND WILLINGNESS TO USE NALOXONE AMONG FORMER PRISON INMATES Ingrid A. Binswanger[1,2]; Brenda Beaty[1]; Shane Mueller[1]; Karen F. Corsi[3]; Sung-joon Min[1]. [1]University of Colorado School of Medicine, Denver, CO; [2]Denver Health, Denver, CO; [3]University of Colorado School of Medicine, Aurora, CO. (Tracking ID #1619705)

BACKGROUND: Former prison inmates are at high risk for overdose death after release from prison. Naloxone is an opioid antidote traditionally used in medical settings to prevent the fatalities from opioid induced respiratory depression. Naloxone is provided to former prison inmates to reverse opioid overdoses in some community-based programs in the United States and European countries. The goal of this study was to examine the history of self-reported overdose and witnessed overdose among former prison inmates and their attitudes towards naloxone for bystander use after release from prison. Understanding the perspective of former prison inmates on naloxone use post-release is important because they may be subject to bystander administed naloxone in future overdoses.
METHODS: As part of a prospective longitudinal cohort study of former prison inmates released to the Denver area, we interviewed 193 former inmates about overdose and their perspectives on naloxone. Participants were recruited from community and re-entry agency sites. Prior to asking questions about naloxone, we provided an introduction with the following statement: "Naloxone or Narcan is a drug used to counter the effects of opioid overdose. It is either given in the nose or as an injection. It has been distributed as part of emergency kits to heroin users in some US cities." We used descriptive statistics to examine prior reported overdoses leading to health service utilization, witnessed overdoses, actions taken at the last witnessed overdose, and willingness to be trained in and use naloxone. To assess positive attitudes towards naloxone in this context, we asked participants if they thought people leaving jails and prisons should be given naloxone. We conducted univariable (chi-square, Mantel-Haenszel chi-square and Fisher's exact tests) and multivariable logistic regression to examine the association of baseline characteristics with positive attitudes towards naloxone.
RESULTS: Among 193 participants, 43.0 % had ever injected drugs. Cocaine/crack was the drug of choice for 29.5 % of the sample, whereas heroin or speedball was the drug of choice for 8.8 %. Nearly one third (32.1 %) had ever been to an emergency department or hospitalized for an overdose from any drug, and 53.4 % had ever witnessed a heroin overdose. At the last witnessed overdose, only 52.9 % of the sample reported that someone called 911. Most (85.5 %) were willing to be trained to use naloxone, and 90.0 % reported that they were willing to give naloxone to someone having an overdose. Overall, 76.7 % thought people leaving prisons and jails should be given naloxone. In unadjusted and adjusted analyses, white race (p=0.04) was the only significant baseline characteristic associated with a more positive attitude towards naloxone.
CONCLUSIONS: In this community-recruited sample of former prison inmates, a high proportion reported past health care utilization for a personal history of overdose. The majority had witnessed overdoses but emergency services were not called in many witnessed overdoses. These findings suggest bystander-administered naloxone could prevent opioid overdose fatalities in this population, in addition to increasing education about calling 911 and legislation to prevent arrest at the scene of an overdose. This high-risk population had favorable impressions of naloxone, but widespread implementation of naloxone distribution to criminal justice populations will require further clinical, research and policy efforts.

OVERUSE, UNDERUSE, AND MISUSE OF COLORECTAL CANCER SCREENING TESTS Gina R. Kruse[1]; Sami M. Khan[2]; Alan M. Zaslavsky[3]; John Z. Ayanian[2,3]; Thomas D. Sequist[2,4]. 1Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]Harvard Vanguard Medical Associates, Boston, MA. (Tracking ID #1637776)

BACKGROUND: The recent rise in the use of colorectal cancer (CRC) screening exams has led to concerns regarding the efficiency of population-based screening programs. We assessed underuse, overuse, and misuse of CRC screening and surveillance exams among an average-risk adult population.
METHODS: We studied 2,653 adults age 50–65 with no personal history of CRC who initiated screening in 2001 in a large multispecialty group practice. We used electronic health record data to identify all CRC screening exams (home fecal occult blood testing [FOBT], flexible sigmoidoscopy [FS], and colonoscopy) between 2001 and 2011, and reviewed pathology reports of all colon biopsies. We used 2008 screening guidelines and 2006 surveillance guidelines from the US Multi-Society Task Force to classify use. We defined UNDERUSE as any exam performed > 1 year after recommended intervals and OVERUSE as any endoscopy exam performed > 1 year before recommended intervals. We did not measure OVERUSE of FOBT exams given the short (1 year) interval. MISUSE included FOBT or FS exams performed following the removal of colorectal adenomas or FOBT performed within 10 years of a normal colonoscopy. We excluded 15 (0.5 %) patients diagnosed with CRC during the study period. We used Kaplan-Meier methods to calculate the time to follow-up exam by initial findings (no polyps; hyperplastic polyps; 1–2 small adenomas [<10 mm]; or adenomas with high risk features [3+ adenomas/large adenoma >10 mm/ high-grade dysplasia/ villous adenoma]).
RESULTS: Most patients were women (53 %), white (80 %), and commercially insured (81 %). Baseline screening exams in 2001 included 1,812 FOBT exams (69 %), 377 FS exams (14 %), and 449 colonoscopies (17 %). Subjects continued receiving primary care in the multispecialty practice for a median of 10 years (interquartile range [IQR] 6–10 years) following the baseline exam; during which time an additional 5,184 screening and surveillance exams (2,318 FOBT exams [45 %], 506 FS exams [10 %], and 2,360 colonoscopies [46 %]) were completed by 224 primary care providers and 26 endoscopists. 2 % of FOBT exams were positive; while 11 % of endoscopic exams identified 1–2 small adenomas and 6 % of exams identified adenomas with high risk features. Among follow up FOBT exams, 338 (15 %) represented UNDERUSE and 674 (29 %) represented MISUSE. Among FS exams, 1 (0.2 %) represented UNDERUSE, 7 (1 %) represented OVERUSE, and 6 (1 %) represented MISUSE. Among colonoscopies, 414 (18 %) represented UNDERUSE and 921 (39 %) represented OVERUSE. The median time to next screening after negative FOBT was 1.3 years (IQR 1.0–2.4 years) and after FS was 5.5 years (IQR 4.5–9.4 years). The median time to next colonoscopy varied based on the previous exam findings (log-rank p< 0.001), including previous exams with no polyps (6.4 year, IQR 5.0–9.0 years), hyperplastic polyps (5.6 years, IQR 4.8–8.9 years), 1–2 small adenomas

(5.0 years, IQR 3.3–6.3 years), and adenomas with high risk features (3.0 years, IQR 2.3–4.0 years).
CONCLUSIONS: We identified substantial inefficiencies, with over one-third of colonoscopies performed too early and one third of FOBTs performed either late or inappropriately. These use patterns may reduce the tests' effectiveness, subject patients to unnecessary risks, and increase healthcare costs. Healthcare providers developing tools to increase CRC screening rates should address the simultaneous potential for underuse, overuse, and misuse.

PART-TIME PRIMARY CARE PHYSICIAN ACCESS AND CONTINUITY IN THE PATIENT CENTERED MEDICAL HOME Ann-Marie Rosland[1,2]; Sarah Krein[1,2]; Myra Kim[1,3]; David Ratz1; Darcy Saffar[1]; Eve A. Kerr[1,2]. [1]VA Ann Arbor Healthcare System, Ann Arbor, MI; [2]University of Michigan Medical School, Ann Arbor, MI; [3]University of Michigan School of Public Health, Ann Arbor, MI. (Tracking ID #1636595)

BACKGROUND: Patient Centered Medical Home (PCMH) models prioritize same-day access to and continuity with one assigned primary care provider (PCP). At the same time, PCPs are increasingly seeing patients on a part-time schedule. Likewise, the VHA is emphasizing same-day access and continuity in its nation-wide PCMH program. Yet many VHA PCPs, particularly those in academically affiliated medical centers, are not in clinic every day because they work part-time or have other duties. We sought to determine how limited availability ("part-time") and full availability ("full-time") VHA PCPs differed in same-day access and continuity.
METHODS: We examined primary care clinic appointment data from July 2010 to October 2012 in one VHA healthcare system. PCP availability was measured through assigned patient panel size, which is directly proportional to the number of half-day sessions the PCP is in clinic. Part-time was defined as having less than 5 half-day sessions per week. Continuity was measured by whether a primary care appointment or non-acute ED visit was completed with the patient's assigned PCP. The main measure of access was whether a request for a same-day appointment was accommodated on the same-day with the assigned PCP. We also examined whether same-day requests resulted in an appointment with the assigned PCP within 1 week or an appointment on the same-day with any PCP. Multilevel models (MLM) evaluated the impact of PCP availability on continuity and access, controlling for demographic and clinical characteristics of the requesting patients, number of same-day requests the patient made in the month, and site of care.
RESULTS: 1312 total PCP-months of care were examined; 49.7 % were from part-time PCPs. Across 128,376 visits, patients had an AOR for 'continuity'—seeing their assigned PCP - of 1.25 (95 % CI 1.21, 1.30) per each additional session increase in PCP weekly availability. The expected probabilities of continuity were 67 % for patients of PCPs with 2 sessions/week, 79 % for patients of PCPs with 5 sessions/week, and 92 % for patients of PCPs with 10 sessions/week. Across 21,862 same-day appointment requests, the AOR of being seen on the same day with the assigned PCP was 1.07 (1.03, 1.10) per additional weekly session of availability; expected probabilities were 18 % for 2 sessions/week, 21 % for 5 sessions/week, and 27 % for 10 sessions/week. The AOR of being seen within 1 week by the assigned PCP was similar (1.07 (1.03, 1.10) per additional weekly session), but with higher overall expected probability: 27 % for 2 sessions/week, 31 % for 5 sessions/week, and 38 % for 10 sessions/week. Differences in the odds of being seen same-day by any PCP were slightly attenuated (AOR 1.05 (1,02, 1.09)) with high expected probabilities of 54 % for 2 sessions/week, 56 % for 5 sessions/week, 61 % for 10 sessions/week.
CONCLUSIONS: Patients of part-time PCPs experienced significantly less continuity and, to a smaller extent, less same-day access, than patients of full-time PCPs. Given the growing prevalence of part-time PCPs and the projected shortage of providers in the future, PCMH programs will need to structure care teams that include part-time providers while enhancing levels of access and continuity.

PARTICIPATING IN DIABETES (CARE): THE ART OF ACCOMPANIMENT, ENACTMENT OF ILLNESS, AND CROSS-CULTURAL CARE Arlene M. Katz[2]; Victoria Koski-Karell[1]; Marie-Louise Jean-Baptiste[1]; Kermshlise C. Picard[1]. [1]Cambridge Health Alliance, Cambridge, MA; [2]Harvard Medical School, Boston, MA. (Tracking ID #1642527)

BACKGROUND: Haitian immigrants with Type 2 Diabetes Mellitus (DM2) encounter complex social and structural forces that influence their health indicators and their familiarity with concepts of prevention, chronic disease management, and capacity for self-care. In 2003, Dr. Jean-Baptiste and her team began convening an innovative monthly open group of Haitian DM2 patients at Windsor Clinic in Cambridge, MA. The program strives to enhance "good care" for Haitians living with DM2 and other chronic diseases by promoting practice-based cross-cultural care. This research project strove to understand the ways that patients experience, participate in, and enact their disease; the ways that healthcare professionals accompany these individuals during their illness experiences; and how care practices might be "tweaked" to improve the health, lifestyle, and wellbeing of Haitian patients living with DM2.
METHODS: This project employed qualitative ethnographic methods over the course of 24 months. Investigators attended, observed, and participated in monthly Diabetes Group meetings, taking fieldnotes and speaking informally with health professionals and participants in the Group. Filmed formal interviews were conducted with 4 professionals, 10 Haitian patients, and other participants. Qualitative data of participants' illness experiences and Group meetings was analyzed for themes and insights into what is "at stake" for Haitian DM2 patients, the benefits and challenges of DM2 care, the art and role of accompaniment, and factors influencing Group attendance and participation. Secondary and intermediate outcome measures of self-management, self-sufficiency, knowledge, and social engagement were also considered. Quantitative data was also collected through routine blood glucose, cholesterol, blood pressure, and HbA1c tests.
RESULTS: Participation in monthly Diabetes Group meetings increased steadily since 2003 and over the course of this research project. The initial Group expanded from one group of 10–14 patients to three distinct monthly groups of 15–25 patients each. Footage was used to create a videotape presented to participants. It was a central way to include patients in the proceedings and outcomes of the project, which they found empowering. Patients discussed strategies for chronic disease management and definitions of health terms; asked and answered each other's questions; engaged in a walking group; and participated in food demonstrations. This motivated mutual behavioral change and expanded providers' sensitivities to social and cultural determinants of health and care. In 12 months, regular participants' HbA1c levels dropped from 12 to 8.4. While a number of patients consistently participated in the Diabetes Group, others attended less regularly and were more likely to face challenges in their self-care and had poorer health indicators.
CONCLUSIONS: The Diabetes Group embodies accompaniment; the collaboration between patient, doctor, and the community; integrated cross-cultural healthcare; and the relational aspects of global health and social change. Results demonstrate the importance of caregivers responding to the complexities of their patients' lived experiences of disease and situated knowledges by continuously tweaking goals, educational lessons, and interventions. Social support and consistent participation in the Group shows sustained positive health impact. Further ethnographic research is needed to understand why some patients participate more consistently than others.

PARTNER NOTIFICATION PRACTICES AMONG HIV-INFECTED MEN E. J. Edelman[1]; Kirsha S. Gordon[2]; Matthew Hogben[3]; Stephen Crystal[4]; Kendall Bryant[5]; Amy C. Justice[1,2]; David A. Fiellin[1]. [1]Yale University, New Haven, CT; [2]VA Connecticut Healthcare System, West Haven, CT; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]Rutgers, New Brunswick, NJ; [5]National Institute on Alcohol Abuse and Alcoholism, Potomac, MD. (Tracking ID #1642472)

BACKGROUND: Partner notification (PN), the process during which partners of an HIV-infected (HIV+) individual are notified of their exposure, is an important component of efforts to seek, test and treat all potentially HIV+ individuals. However, there are few data available assessing PN practices in national samples of HIV+ patients.
METHODS: We performed a cross-sectional analysis of the Veterans Aging Cohort Study, an observational study conducted at 8 urban centers nationally. We used data from 2003 to 2004. The analytic sample was restricted to HIV+ men who had available survey data and were sexually active in the past 12 months. To determine PN practices, we used the following question: Since you were diagnosed with HIV, have you told your sexual partners so that they can get tested and treated as well? We collapsed response options accordingly: 1) I told every partner/I had the health department notify my partners for me (categorized as PN performed); and 2) I told some partners, but not all of them/I did not tell any of them/I tried to notify my partners but could not find them/I prefer not to answer this question (categorized as PN not performed). Covariates were assessed using self-report and laboratory data. Sexual risk items assessed behaviors during the past 12 months. Multiple partners was defined as at least 3 partners in the past 12 months; casual partners was defined as having sex with a partner who was not known ahead of time. Depressive symptoms were assessed using the Beck Depression Inventory; alcohol consumption was based on the Alcohol Use Disorders Identification Test (AUDIT). Descriptive statistics were used to compare the characteristics of those who did and did not conduct PN. Multivariable logistic regression analysis was used to determine factors associated with PN.
RESULTS: In our sample (n=912), 336 (37 %) of patients had not performed PN. In bivariate analyses, in comparison to those who performed PN, patients who did not perform PN were similar based on age (mean[SD]=49[9]), race/ethnicity (white 22 %, black 63 %, Hispanic 11 %, other 4 %), education (95 % high graduate or more), HCV-infected (45 %), suppressed HIV-1 viral load (defined as <500 copies/mL) (54 %), CD4 count (median[IQR]=414 [278, 586]), years since HIV diagnosis (median[IQR]=6 [3,8]), depression score (median[IQR]=3 [1,7]) and AUDIT score (median[IQR]=2 [0,4]). Men who did not perform PN were more likely to be not married (92 % vs. 82 %), have casual partners (44 % vs. 14 %), have sex with men 64 % vs. 43 %), have at least 3 sex partners (41 % vs. 19 %), exchange money or drugs for sex (19 % vs. 8 %), been diagnosed with a sexually transmitted infection (STI) (16 % vs. 11 %), endorse non-condom use (31 % vs. 17 %), and have sex under the influence of alcohol/drugs (23 % vs. 17 %); all $p<0.04$. In the final model, HIV-infected men with casual partners (OR [95 % CI]=0.45 [0.29, 0.70]), men who reported having sex with men (OR [95 % CI]=0.63 [0.45, 0.87]), multiple partners (OR [95 % CI]=0.60 [0.41, 0.88]), exchanged money or drugs for sex (OR [95 % CI]=0.53 [0.31, 0.89]), or who endorsed non-condom use (OR [95 % CI]=0.65 [0.44, 0.95]) were less likely to conduct PN. Notably, HIV-1 RNA<500 copies/mL was not associated with whether patients had performed PN.
CONCLUSIONS: Among a sample of HIV+ patients, PN is suboptimal and associated with ongoing sexual risk behaviors. Interventions to improve PN, particularly in the setting of sexual risk behaviors, are needed.

PATIENT EXPERIENCES WITH INVOLUNTARY OUT-OF-NETWORK CHARGES Denise D. Pong[3]; Kelly A. Kyanko[1]; Kathleen Bahan[4]; Leslie Curry[2]. 1NYU School of Medicine, New York, NY; [2]Yale School of Public Health, New Haven, CT; [3]Duke University School of Medicine, Durham, NC; [4]Columbia University Mailman School of Public Health, New York, NY. (Tracking ID #1630768)

BACKGROUND: Approximately 40 % of individuals using out-of-network physicians experience involuntary out-of-network care, leading to unexpected and sometimes financially burdensome charges. Despite its prevalence, research on patient experiences with involuntary out-of-network care is limited. Greater understanding of patient experiences may inform policy solutions to address this issue. We sought to characterize the experiences of patients who encountered involuntary out-of-network physician charges.
METHODS: Qualitative study using 26 in-depth telephone interviews with a standardized interview guide. Participants were a purposeful sample of privately insured adults from across the U.S. who experienced involuntary out-of-network care. They were diverse with regard to income level, education, and health status.
RESULTS: Four recurrent themes characterize the perspective of individuals who experienced involuntary out-of-network physician charges: 1) responsibilities and mechanisms for determining network participation are not transparent; 2) physician procedures for billing and disclosure of physician out-of-network status are inconsistent; 3) serious illness requiring emergency care or hospitalization precludes ability to choose a physician or confirm network participation and 4) resources for mediation of involuntary charges once they occur are not available.
CONCLUSIONS: Our data reveal that patient education may not be sufficient to reduce the prevalence and financial burden of involuntary out-of-network care. Participants described experiencing involuntary out-of-network healthcare charges due to system level failures. As policymakers seek solutions, our findings suggest several potential areas of further consideration such as standardization of processes to disclose that a physician is out-of-network, holding patients harmless not only for out-of-network emergency room care but also for non-elective hospitalization, and designation of a mediator for involuntary charges.

PATIENT EXPERIENCES WITH LIFESTYLE COUNSELING IN AN ONLINE LIFESTYLE SUPPORT SYSTEM John J. Rief. University of Pittsburgh, Pittsburgh, PA. (Tracking ID #1643142)

BACKGROUND: While online counseling offers a variety of tools for tailoring the delivery of lifestyle interventions and collapsing the physical distance between practitioners and participants, it also augurs major changes in the communicative strategies and styles of both. Shifting counseling to an online environment may yield positive benefits (e.g., increased participant adherence and more timely problem-solving) but also create the conditions for anxieties regarding, for example, the quality of patient-provider interaction. Thus, additional research is needed to assess the ways in which different modalities of online communication cultivate and/or enervate patients' ability to develop strong relationships with their providers and effective self-management skills. My primary objective was to evaluate the experiences of primary care patients participating in an evidence-based online lifestyle intervention, especially their sense of the quality of their interaction with online lifestyle coaches who assisted in delivering the intervention.
METHODS: I utilized qualitative methods (i.e., the rhetorical technique of close reading based on shared word choices, themes, and frames) to analyze interview responses from 35 participants who completed exit interviews after completion of a 1-year-long online lifestyle intervention. This analysis focuses on a set of 8 questions regarding participant experiences with online lifestyle coaching and, in particular, with the two styles of asynchronous contact used by lifestyle coaches to interact with participants: "as needed" (in response to specific problems faced or questions posed by participants) and "scheduled" (automated). The previously transcribed passages from these interviews were analyzed and then mapped based on shared thematic characteristics.
RESULTS: Throughout the participant responses, four primary themes emerged: (1) the need for dialectical engagement (i.e., back and forth dialogue and deliberation), (2) the role of collaboration in problem solving (i.e., combining the grounded experiences of individual participants with the expertise of lifestyle coaches to address specific barriers to success), (3) the need to address the specific context of the participant in terms of communication style and healthcare needs, and (4) the extent to which "as needed" and "scheduled" notes variously enhance or undermine participant perception of genuine human interaction. Many participants noted the importance of receiving "as needed" notes to the development of their partnership with their lifestyle coach. These themes provide key inflection points for additional research including the importance of human (as opposed to fully automated) interaction in online lifestyle interventions and the potential importance of patient-centered communication strategies in the online environment.

CONCLUSIONS: The emergent themes provide a starting point for understanding how the participants experienced online interaction with their lifestyle coaches in the context of an online lifestyle support system aimed at assisting them in losing weight and increasing their physical activity. This study suggests that the personalization of online interaction as well as the extent to which it avoids full automation may be essential to its successful adoption in lifestyle interventions.

PATIENT NAVIGATION FOR SCREENING MAMMOGRAPHY: A RESIDENT CLINIC QUALITY IMPROVEMENT INITIATIVE
Swati Shroff[1]; Molly McCoy[2]; Mariuca Tuxbury[2]; Bonnie Sherman[2]; Sharon Bak[2]; Tracy Battaglia[2]. [1]Boston Medical Center, Boston, MA; [2]Boston Univeristy School of Medicine, Boston Medical Center, Boston, MA. (Tracking ID #1637221)

BACKGROUND: In an era of accountable care, health system innovations are necessary to achieve equity in quality healthcare delivery. Patient navigation (PN) has been used to address breast cancer disparities; however, its use has not been evaluated in resident training practices. This study aims to evaluate the use of PN in resident primary care clinics to improve mammography screening rates.
METHODS: We conducted a pre-post evaluation of a breast cancer quality improvement (QI) initiative from September 2011-July 2012 at the largest ambulatory resident clinic at Boston Medical Center (BMC). The initiative began with a didactic session introducing residents to the concept of PN, including existing telephone, written, and electronic protocols navigators use for scheduling and tracking mammograms. Eligible patients for the QI initiative included: women aged 51–70 years of age, assigned to a resident provider, and seen by a BMC internal medicine provider within the past 2 years. The outcome of interest was mammography adherence, defined by the Healthcare Effectiveness Data and Information Set (HEDIS) measure as completion of a screening mammogram within the past 24 months. The QI initiative was designed so that all women whose last documented screening mammogram was 18 months ago or greater received one-on-one navigator outreach and tracking over time to ensure 24 month adherence to screening mammography. Those whose last documented mammogram was <18 months ago received usual care. Clinical and demographic data were extracted from the electronic medical record. McNemar's test was used to compare pre- and post-adherence rates. An electronic self-administered post-intervention survey was given to the residents to assess their experiences with PN.
RESULTS: 66 residents had 552 patients eligible for the QI initiative. The majority of the women were Non-White (Black 64 %, Hispanic 13 %), publicly insured (60 %), and non-US born (62 %). Pre-intervention, only 293 women (53 %) were adherent to screening mammography according to the HEDIS measure. Adherent women were more likely to be Black (70 % v. 58 %, p= 0.002), insured (74 % v. 65 %, p=0.05), and have a previous mammogram report on record (96 % v. 28 %, p<.0001). Post-intervention adherence rates significantly improved after 9 months of implementation of PN (66 % v. 53 %, p<0.0001). Improvements were observed across all sociodemographic groups. Among the navigation-targeted group (n=278), 55 % were unable to be contacted by phone, while only 10 % actually declined mammography services. Of the 27 (41 %) residents who completed the survey, 75 % reported at least one communication with the navigator, yet only 14 % knew the navigator's name. 35 % of respondents felt PN decreased their workload, and 100 % would like to see PN's role expanded within their ambulatory practices.
CONCLUSIONS: PN has potential to improve the equitable delivery of quality care, in this case, mammography adherence rates among resident practices serving vulnerable populations, despite challenges in contacting eligible patients. Resident trainees perceived having PN in their ambulatory practice to be beneficial.

PATIENT PERCEPTIONS ABOUT ANTIBIOTIC TREATMENT FOR ACUTE COUGH: A QUALITATIVE STUDY
Patrick P. Dempsey[1]; Alexandra C. Businger[1]; Lauren E. Whaley[1]; Jeffrey A. Linder[1,2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Cambridge, MA. (Tracking ID #1641422)

BACKGROUND: Although national guidelines discourage antibiotic prescribing for acute cough, patients continue to seek care and clinicians continue to prescribe antibiotics for acute cough. To understand knowledge and attitudes of patients regarding the evaluation and treatment of acute cough, we conducted a series of interviews with patients at a large, diverse primary care practice.
METHODS: We conducted a qualitative analysis of semi-structured, in-depth interviews with 14 patients that had a primary care physician at the Phyllis Jen Center for Primary Care in Boston. Patients were eligible if they had a visit to the practice in the past 2 years, were aged 18–64 years old, and did not have chronic lung disease. Patients received US$50 for their participation. Interview questions addressed: patient knowledge of antibiotics; patient attitudes toward inappropriate prescribing of antibiotics for acute cough; patient desire and demand for antibiotics for acute cough; patient perceptions of antibiotic prescribing guidelines and patient education materials; patient ideas for improving antibiotic prescribing through changes in the practice environment and provider behavior. Each interview was recorded, transcribed verbatim, and analyzed utilizing a standard comprehensive qualitative analysis method using structural then thematic coding.
RESULTS: Participants had a mean age of 46 years, 7 of 14 were white, and 8 of 14 were women. Participants had a varied understanding of the appropriateness of antibiotic prescribing. When asked if antibiotics were necessary for their cough, participants said: yes (4); no (4); they are necessary for bacterial infections (1); they are necessary for bronchitis or pneumonia (1); they are not sure (1); they follow what the doctor says (1). Participants mentioned different consequences of unnecessary antibiotics such as: building resistance (5), allergic reactions (5), increasing susceptibility to future infections (5), and opening yourself up to more problems and getting sicker (5). Of the 14 participants, 10 reported never directly asking their physician for antibiotics for acute cough. Participants universally agreed that patient education materials (posters, pamphlets) about when antibiotics should be prescribed would be helpful; 10 participants said they would read and follow them. To help providers decrease inappropriate antibiotic prescribing, 9 participants endorsed phone triage by nurses to educate patients on over-the-counter remedies and guide patients on when it is necessary to come to the office. Three participants responded that clinicians need to spend more time with the patient rather than rushing to judgment and prescribing antibiotics. Four participants responded that physicians should educate patients about over-the-counter remedies and help set expectations for the typical duration of symptoms.
CONCLUSIONS: The majority of participants were aware of the ineffectiveness of antibiotics for acute cough and of the potential for adverse reactions. To reduce inappropriate antibiotic prescribing for acute cough, patients universally agreed that patient handouts and posters would be beneficial. Several patients thought clinicians should spend more time with patients and provide education on prevention strategies, over-the-counter remedies, and reasons why antibiotics would not help acute cough.

PATIENT SAFETY AND INTERPROFESSIONAL COLLABORATION ASSESSMENT: A DISTINCT SKILLS SET FOR MEDICAL STUDENTS
Jennifer Adams[1]; Marc Triola[1]; Maja Djukic[2]; Linda Tewksbury[1]; Sabrina W. Lee[1]; Sondra Zabar[1]; Kathleen Hanley[1]; Colleen Gillespie[1]. [1]NYU School of Medicine, New York, NY; [2]NYU College of Nursing, New York, NY. (Tracking ID #1640550)

BACKGROUND: Interprofessional collaboration (IPC) is increasingly recognized as fundamental to patient-centered medical care. Interprofessional education (IPE) is shown to improve patient outcomes and collaboration in practice. Still, many medical schools have limited training in IPE. The NYUSOM and NYUCON, with support from the Josiah Macy Jr. Foundation, developed and implemented a comprehensive IPE curriculum for its students. To better understand the impact of the curriculum, an OSCE (Objective Structured Clinical Examination) was completed to assess medical students' baseline skills in IPC and to assess whether these abilities were associated with other core clinical skills.

METHODS: An IPE case was authored and implemented as part of a high-stakes, end-of-third-year comprehensive clinical skills OSCE. The case prompted students to create an interprofessional care plan with a nurse for the patient they saw in a previous case, a 15-minute interview with a patient who came into urgent care with chief complaint of shortness of breath. Students were expected to use the SBAR (situation, background, assessment and recommendation) technique to communicate with the Standardized Nurse and to use CUS (concern, unsafe and safety issue) if the nurse relayed any incorrect information. The Standardized Nurse was trained to make a specific mistake to ensure the student had the opportunity to use CUS. A behaviorally anchored checklist was developed to assess IPC, including 4 items to assess use of SBAR, 1 item focused on using CUS to respond to the Standardized Nurse's information error, and 3 items focusing on core dimensions of collaborative practice (introducing professional role, collaborating in identifying next steps and implementing an interprofessional team care plan). Each of these used a 3-point response scale of "not done", "partly done", and "well done" and a composite score of % "well done" for the 8 items was calculated to measure overall IPC skill. Finally, a 4-point item assessed the degree one would recommend the student as a physician based on overall IPC. The Standardized Nurse completed the checklist at the conclusion of the case.
RESULTS: 168 third year medical students completed the case. 72 % of students used SBAR to present a patient-centered situational assessment; half used SBAR to comprehensively present the patient's background; 41 % used SBAR to provide their assessment of the situation. Only 27 % used CUS in a skillful and respectful way in response to the nurse's error. 17 % of students fully introduced self and role and less than a third (28 %) of students collaborated with the nurse in developing a plan of action. Overall, the 8-item IPC score appeared to be internally consistent (Cronbach's alpha=.70); average % well done=35 % (SD=26 %). Also, 41 % of students received a "recommend with reservations" rating for their overall IPC; 38 % received a "recommend" and 22 % received a "highly recommend" rating. Finally, IPC was not significantly associated with other core clinical skills assessed in this high-stakes 8-station OSCE (correlation with overall communication scores=.05, p=.54; history-gathering r=.04, p=.59; physical examination r=.03, p=.71; clinical reasoning r=.09, p=.24).
CONCLUSIONS: Medical students' IPC skills need targeted development. This particular skill set was not associated with other core clinical skills, suggesting that IPC practice is a distinct skill set that requires specific curricula and training experiences.

PATIENT SELF-REPORT OF COLORECTAL CANCER SCREENING DISCUSSIONS WITH PRIMARY CARE PHYSICIANS: WHAT SCREENING OPTIONS ARE BEING DISCUSSED AND WHAT OPTIONS ARE BEING MISSED? Vanessa Ramirez-Zohfeld[1]; Alfred W. Rademaker[2]; Nancy C. Dolan[1,3]; M. Rosario Ferreira[1,4]; William L. Galanter[6]; Jonathan M. Radosta[6]; Dachao Liu[2]; Milton "Mickey" Eder[5]; Francisco Acosta[1]; Kenzie A. Cameron[1]. [1]Northwestern University, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Northwestern Medical Faculty Foundation, Chicago, IL; [4]Jesse Brown VAMC, Chicago, IL; [5]ACCESS Community Health Network, Chicago, IL; [6]University of Illinois Hospital & Health Sciences System, Chicago, IL. (Tracking ID #1641499)

BACKGROUND: Past research has indicated the critical importance of clinician discussion and recommendation of colorectal cancer (CRC) screening. Recent research also indicates that providing patients a choice of screening options (alerting patients that there are multiple U.S. Preventive Services Task Force (USPSTF)-accepted screening modalities) may increase CRC screening completion, particularly among racial and ethnic minorities. Objective: To assess the frequency with which CRC screening is discussed during non-acute general internal medicine (GIM) visits, as well as to assess which screening tests are being discussed in a population of average risk, 50–75 year-old, racially/ethnic minority patients.
METHODS: Data were extracted from an ongoing randomized-controlled study to promote CRC screening at seven federally qualified health centers and one academic health center in a large, urban area. English and Spanish-speaking patients who were not up to date with CRC screening and were seeking care at one of these health centers participated in an interviewer-administered survey before and immediately after their physician visit. Descriptive statistics were used to identify whether or not discussion of screening occurred during the visit and if so, what type of screening option(s) were discussed.
RESULTS: Among 485 patients who completed an interviewer-administered survey immediately following their physician visit, the mean age was 57.8 years (SD=6.1); 355 (73.2 %) were female; 221 (45.6 %) identified themselves as Hispanic/Latino and 245 (50.5 %) as Non-Hispanic Black; 149 (30.7 %) reported 0–6 years of education, 231 (47.6 %) reported 7–12 years of education and 101 (20.8 %) had 13 or more years of education. Almost one-third of patients (33.1 %) reported being uninsured. Two hundred forty-one (49.7 %) of patients reported that their physician discussed CRC screening with them during their visit. Of those 241 patients who recalled a discussion regarding CRC screening, 190 (78.8 %) reported that they had discussed specific CRC screening tests with their doctor (19.1 % indicated that a discussion had occurred, but no specific tests had been discussed, and 2.1 % could not recall if specific tests had been discussed or not). When asked which tests had been discussed, 25.8 % reported stool tests (FOBT or FIT); 83.2 % reported colonoscopy; and 3.2 % could not recall the specific tests that had been discussed. Of the 158 participants who reported discussions of colonoscopy, only 23 (14.6 %) reported that the physician had also discussed stool tests.
CONCLUSIONS: In the majority of patient visits during which CRC screening was discussed, only one screening option was presented; most often that option was colonoscopy. In addition to increasing the frequency of discussion of CRC screening within non-acute GIM visits, clinicians should consider offering patients a choice of CRC screening modalities, which appears to occur infrequently. Increased discussion of screening options may ultimately serve to increase screening completion, particularly among racial and ethnic minorities as well as those who are uninsured or underinsured.

PATIENT ACTIVATION BY DTCA INFLUENCES PRIMARY CARE PHYSICIANS' PRESCRIPTIONS OF CELEBREX FOR OSTEOARTHRITIS Michael Fischer[1]; Jeffrey N. Katz[1]; Lisa D. Marceau[2]; Felicia L. Trachtenberg[2]; Jing Yu[2]; John B. McKinlay[2]. [1]Brigham & Women's Hospital, Boston, MA; [2]New England Research Institute, Watertown, MA. (Tracking ID #1629268)

BACKGROUND: Direct to consumer marketing of medications is intended to "activate" patients to request the advertised medication from their physicians. There is limited data on the extent to which physicians alter prescribing patterns in response to specific requests from activated patients.
METHODS: We performed a factorial experiment in which primary care physicians viewed clinically authentic videotapes of "patients" presenting with symptomatic knee osteoarthritis (OA). The "patients" were played by professional actors who differed by sex, race (white, Black, Hispanic) and SES (higher, lower). 192 primary care physicians working primarily in Illinois were recruited to participate. Each physician viewed one vignette of a patient with typical symptoms of knee OA lasting for several months. In one half of vignettes the patient was 'activated' and asked: "I've seen ads for Celebrex and it looks just like what I need…A woman I work with takes it and she said it really works for her…so, I really want to try that." The non activated patients requested help with their pain but did not ask for any specific medications: "I just want something to make it better." Activated and nonactivated vignettes were balanced on sex, race and SES. Physicians were balanced by sex and years of experience. After viewing the videotape, the physicians completed a questionnaire in which they indicated the treatment(s) they would likely order. We examined the association between patient characteristics, particularly activated vs. non-activated, and the medications the physicians said they would prescribe (celecoxib, non-selective NSAIDs, other) using a multivariate ANOVA model.

RESULTS: 53 % of the PCPs presented with a vignette including an active request for celecoxib reported that they would prescribe celecoxib, as compared with 24 % of physicians seeing the identical vignette without an active medication request ($p<0.0001$; Table). Physicians receiving an active request for celecoxib were less likely to report that they would prescribe a non-selective NSAID (29 %) than physicians whose simulated patients did not request celecoxib (42 %; $p=0.06$). Most of the non-selective NSAIDs specified are available as generics. Further, physicians who received an active request for celecoxib prescribed either a COX-2 OR a traditional NSAID for 82 % of vignettes, compared to 66 % of physicians who did not receive an active request ($p=0.004$). The associations between active request and physician prescribing patterns were not influenced by patient characteristics (gender, race, SES) or physician characteristics (gender, experience).

CONCLUSIONS: Physicians presented with an activated request for celecoxib by a patient with typical knee OA were more than twice as likely to prescribe celecoxib compared to physicians encountering a non-activated patient who provided the same clinical history and they were also considerably more likely to prescribe any NSAID (selective or non-selective). Given the higher price, increased risk of cardiovascular toxicity and similar efficacy of celecoxib compared to non-selective NSAIDs, these findings suggest that some types of patient activation may increase health care costs and compromise appropriateness of prescribing.

Prescription of celecoxib and other NSAIDs for OA: Stratified by active patient request

Active Request	Celecoxib	NSAID, not Cox-2	Celecoxib OR non-selective	Neither
Yes	51 (53 %)	28 (29 %)	79 (82 %)	17 (18 %)
No	23 (24 %)	40 (42 %)	63 (66 %)	33 (34 %)

PATIENT AND PHYSICIAN GENDER CONCORDANCE IN PREVENTIVE CARE IN UNIVERSITY PRIMARY CARE SETTINGS Vanessa Virgini[1]; Simone Krähenmann-Müller[1]; Manuel R. Blum[1]; Bruno R. da Costa[2]; Tinh-Hai Collet[3]; Stefan Weiler[1]; Yonas Martin[3]; Jacques Cornuz[3]; Edouard Battegay[4]; Jean-Michel T. Gaspoz[5]; Douglas Bauer[6]; Eve A. Kerr[7]; Drahomir Aujesky[1]; Nicolas Rodondi[1]. [1]Inselspital, University Hospital of Bern, Bern, Switzerland; [2]Inselspital, University Hospital of Bern, Bern, Switzerland; [3]University Hospital of Lausanne, Lausanne, Switzerland; [4]University Hospital of Zurich, Zurich, Switzerland; [5]University Hospital of Geneva, Geneva, Switzerland; [6]University of California, San Francisco, CA; [7]University of Michigan, Ann Arbor, MI. (Tracking ID #1623711)

BACKGROUND: The proportion of female physicians working in primary care medicine has increased for several decades. Several studies have reported physician gender differences in preventive health care received by patients, especially for gender-specific preventive services. However, limited data exist on the role of patient and physician gender and gender concordance in the broad spectrum of preventive care. Therefore, we assessed the association between physician gender, patient-physician gender concordance, and the quality of preventive care in Swiss university primary care settings.

METHODS: We performed a retrospective cohort study of 1001 randomly selected patients aged 50–80 years from four Swiss university primary care settings. We used indicators derived from RAND's Quality Assessment Tools indicators and calculated percentages of recommended preventive care (such as behavioral counseling and cancer screening) according to physician and patient gender. We conducted a hierarchical multivariate logistic regression model to derive point estimates and p-values while accounting for the hierarchical structure of our dataset. Analyses were adjusted for patients' age, civil status, occupation, legal status and for physicians' age, function and centre (both as random factors).

RESULTS: Overall, 1001 patients (mean age 63.5 years, 557 male) treated by 189 physicians (mean age 34.2 years, 90 male, 94.7 % residents) were included in this study. Female patients received less recommended preventive care than male patients (65.2 % vs. 72.1 %, $p<0.001$). Female physicians provided significantly more preventive care than male physicians to both female (66.7 % vs. 63.6 %) and male patients (73.4 % vs. 70.7 %, $p=0.01$). Results were similar after multivariate adjustment. We found no evidence that preventive care differed among gender concordant and discordant patient-physician pairs (p for interaction=0.70). Female physicians provided particularly more recommended cancer screening (colon cancer, breast cancer) than male physicians (38.5 % vs. 30.9 %, $p=0.01$).

CONCLUSIONS: In Swiss primary care settings, female patients receive less preventive care than male patients. Furthermore, female physicians provide significantly more preventive care than their male colleagues, particularly for cancer screening. This study suggests that greater attention should be paid to female patients in preventive health care. Further studies are needed to understand why female physicians tend to provide better preventive care.

PATIENT AND PHYSICIAN SATISFACTION WITH AN ELECTRONIC MEDICAL RECORD (EMR): CORRELATIONS WITH COMPUTER ACTIVITY Neil J. Farber[1]; Yunan Chen[3]; Alan Calvitti[1,2]; Richard L. Street[4,5]; Danielle Zuest[2]; Lin Liu[1]; Kristin Bell[2]; Mark Gabuzda[2]; Barbara Gray[2]; Zia Agha[2,1]. 1University of California, San Diego, La Jolla, CA; [2]San Diego VAMC, La Jolla, CA; [3]University of California, Irvine, Irvine, CA; [4]Texas A & M University, College Station, TX; [5]Baylor College of Medicine, Houston, TX. (Tracking ID #1638783)

BACKGROUND: The use of electronic medical record (EMR) systems by primary care physicians has increased in recent years. Although there are clear benefits to EMRs, such as better availability of medical information and potentially decreased medical errors, some have expressed concerns about an increased workload for physicians, as well as problems with patient-physician interaction. However, no studies have examined the association of patient or physician satisfaction with physician EMR usage intensity. The data reported in this abstract, part of a larger study involving EMR use in a VAMC, look at correlations between actual computer use by physicians during the patient-physician interaction and the satisfaction of patients and physicians during that interaction.

METHODS: General internal medicine physicians in VAMC continuity practices located in one West Coast city were recruited to be part of this study. Each participating physician identified up to six patients to participate in the study. All patients were visiting the physician for either a follow-up or an acute visit. Physician use of the computer and the patient-physician interaction in the exam room were captured in real time via videotape of the interaction, videotape of the computer screen, and through the use of the Morae system that records physician clicks and scrolls on the computer. Physicians and patients completed satisfaction surveys (patients with their physicians, physicians with the EMR system and patient-physician interaction). Spearman correlation coefficients were used to analyze the correlations between patient satisfaction with the physician, and the amount of physician time spent viewing the computer; and for the correlations between the physician satisfactions with the EMR system and various computer activities.

RESULTS: Video and Morae data, and satisfaction surveys, were collected on a total of 126 individual patient office visits for the 23 participating physicians. The total time spent using the EMR during the clinical visit negatively correlated with the satisfaction of the perceived interactional skills of the physician ($p=0.05$), and patient-centered communication was positively associated with the time spent by the physician with the patient and companion ($p=0.01$). Physician satisfaction was negatively correlated with the total number of clicks and scrolls using the EMR (a measure of the time using the EMR), including adequacy of data collection ($p=0.0024$), use of time in the interaction ($p=0.0017$), physician-patient relationship ($p=0.0368$), and the cooperative nature of the patient ($p=0.0317$).

CONCLUSIONS: In this study of VA general internists' use of the EMR, patient satisfaction with the physicians' interactional skills, and physicians' satisfaction in several spheres of the clinical interaction were negatively correlated with an increased physician use of the EMR during the

clinical visit. EMR systems need to be designed in a more physician friendly manner that allows for increased physician time during the interaction for face-to-face communication with the patient, and to ease the workload of EMR documentation. In the meantime, physicians should be coached about how to expedite their use of the EMR during the clinical visit as well as outside of the exam room in order to improve both theirs and their patients' satisfaction.

PATIENT AND PROVIDER ATTITUDES TOWARD OBESITY CARE IN THE PRIMARY CARE SETTING Stephanie A. Rose[1]; Joseph Conigliaro[2]; Nancy Schoenberg[3]. [1]University of Kentucky, Lexington, KY; [2]North Shore-LIJ, New Hyde Park, NY; [3]University of Kentucky, Lexington, KY. (Tracking ID #1640747)

BACKGROUND: Despite published guidelines, physicians are not routinely screening and counseling for obesity. We evaluated attitudes and opinions, the perceived role of the provider in weight loss care, and barriers and facilitators to weight loss care in primary care.
METHODS: Using previous findings, we developed a qualitative survey of adult primary care providers (PCPs) and adult (≥18 years of age) patients (pts) at four separate rural and urban primary care settings. Groups of PCPs and pts were invited to participate in separate 90-minute focus groups run by a trained focus group leader and were asked questions that included 1) reasons for discrepancies in prevalence of PCP and pt report of discussion of weight loss (100 % vs 44 %); 2) reasons for differences in sense of PCP responsibility for pt weight loss (93 % vs 41 %); 3) types of weight loss programs recommended by PCPs; 4) barriers to PCP provision of weight loss; and 5) ideas for improvement for PCP provision of weight loss to pts. Focus groups sessions were audiotaped and transcribed and assessed for repeated themes.
RESULTS: We conducted four PCP and three pt focus groups. PCPs felt that pts underreported PCP weight loss counseling due to lack of patient information retention and explicit discussion by the provider. Pts felt that PCPs may overreport counseling and may be reluctant to provide counseling due to concern of offending pts. PCPs reported giving tips such as food diaries, calorie counting, and referrals to programs such as Weight Watchers. Pts generally reported receiving small tips such as specific dietary advice and exercise promotion or no tips at all. PCP-reported barriers to weight loss counseling included sedentary lifestyle due to socioeconomic and environmental changes, and a lack of office tools for weight loss. Pt-reported barriers to weight loss included lack of time and lack of communication between PCPs and pts, as well as socioeconomic and lifestyle barriers promoting weight gain. PCP ideas for improvement included changes promoting access to a healthy lifestyle, while pts focused on specific weight loss goals, incentives, frequent follow-up, and increase in provider-patient communication.
CONCLUSIONS: PCPs report more pt weight loss counseling than reported by pts. Pts report a positive correlation between weight loss advice and weight loss attempt. PCPs appear to be missing opportunities for guideline-concordant obesity care. Further analysis will be based on grounded theory analysis of the transcripts of the multiple sessions, with the development of codes, categories, and concepts to develop tools for weight loss in primary care.

PATIENT AND REGIMEN CHARACTERISTICS PREDICT MEDICATION ERRORS AFTER HOSPITAL DISCHARGE Amanda Salanitro[1,2]; Amy P. Myers[3]; Courtney Cawthon[4]; Cardella L. Leak[4]; Julia M. Jacobsen[4]; Joanna S. Lee[4]; Samuel K. Nwosu[5]; Jonathan S. Schildcrout[5]; John F. Schnelle[1,4]; Ted Speroff[1,4]; Sunil Kripalani[2,4]. [1]VA Tennessee Valley Healthcare System, Nashville, TN; [2]Vanderbilt University, Nashville, TN; [3]Vanderbilt University, Nashville, TN; [4]Vanderbilt University, Nashville, TN; [5]Vanderbilt University, Nashville, TN. (Tracking ID #1636712)

BACKGROUND: Medication errors persist in spite of medication reconciliation being performed at hospital discharge. Furthermore, when patients return home there may be differences between what medications patients think they should be taking and what is ordered. Medication errors in this setting place patients at risk for harmful adverse drug events and hospital readmission. We examined patient- and medication-related factors associated with medication errors following hospital discharge.
METHODS: We analyzed data from a prospective cohort study of patients hospitalized with acute coronary syndromes and/or acute decompensated heart failure who were enrolled in the Vanderbilt Inpatient Cohort Study. Medication errors were determined by comparing discharge medication lists to what patients reported taking during a phone interview in the week following discharge. We utilized standard Bernoulli logistic regression for binary endpoints (i.e., presence/absence of an error) and binomial logistic regression for count endpoints (i.e., number of errors) to examine the association between pre-specified risk factors and types of medication errors (discordance between the presence of a medication on the discharge list and the patient-reported list; errors of omission and commission; and for cardiac medications, discrepancies in indication, dose, and frequency). Risk factors included demographic characteristics, health literacy, subjective numeracy, marital status, cognitive function, social support, education, income, depression, global health status, and medication adherence.
RESULTS: Patients took a mean of 13 medications after discharge. Among 473 patients, 51 % had at least one discordant medication (i.e., it did not appear on both the discharge list and the patient-reported list). Over one-quarter (27 %) of patients were not taking a medication that they were supposed to be taking per the discharge list (an omission), while over one-third (36 %) were taking a medication not listed on the discharge list (error of commission). Nearly 60 % of patients reported a discrepancy in indication, dose, or frequency for at least one cardiac medication on the discharge list. In adjusted analyses, the greater the number of medications taken, the higher the odds were for having a medication being discordant (odds ratio=1.10, 95 % confidence interval 1.05–1.15), having an error of commission (OR=1.09, CI 1.04–1.14), or having a discrepancy in indication, dose, or frequency (OR=1.38, CI 1.17–1.62). No risk factors were significantly associated with errors of omission. Older age (OR=1.215, CI 1.07–1.38) and more cardiac medication changes between admission and discharge (OR=1.05 per medication change, CI 1.00–1.10) were associated with higher odds of discrepancies in indication, while female gender (OR=0.683, CI 0.52–0.89), higher health literacy (OR=0.972, CI 0.96–0.99), and higher subjective numeracy (OR=0.863, CI 0.78–0.96) were protective. Worse cognitive function was associated with higher odds of discrepancies in frequency (OR=1.407, CI 1.08–1.84), while female gender was protective for discrepancies in dose (OR=0.649, CI 0.47–0.91).
CONCLUSIONS: Medication errors were identified frequently in patients recently discharged. Patients with advanced age, lower health literacy and numeracy, cognitive impairment, and who take more medications are at risk for experiencing more post-discharge medication errors and subsequent potential harm due to these errors.

PATIENT REQUESTS FOR SPECIFIC NARCOTICS INFLUENCE PHYSICIAN PRESCRIBING FOR SCIATICA Michael Fischer[1]; Jeffrey N. Katz[1]; Lisa D. Marceau[2]; Felicia L. Trachtenberg[2]; Jing Yu[2]; John B. McKinlay[2]. [1]Brigham & Women's Hospital, Boston, MA; [2]New England Research Institutes, Watertown, MA. (Tracking ID #1633192)

BACKGROUND: Sciatica is one of the most common presenting complaints in primary care. Physicians struggle to manage pain adequately while avoiding overuse of narcotic medications that can cause adverse clinical effects or are subject to misuse and diversion. It is unknown to what extent patient expectations or requests for pain medication drive physician prescribing decisions.
METHODS: We performed a factorial experiment in which PCPs viewed clinically authentic videotapes of "patients" presenting with symptoms strongly suggestive of sciatica. The "patients" were played by professional actors who differed by sex, race (white, Black, Hispanic) and SES (higher, lower). 192 PCPs working primarily in Illinois were recruited. Each PCP

viewed one vignette of a patient presenting with a few weeks of daily right-sided lower back pain with radiation down the posterior right leg but with no weakness or other generally accepted "red flag" symptoms. The patient described driving as an important work requirement that was adversely affected by the pain. In half of the vignettes the patient made a specific request for oxycodone: "my wife/husband had some oxycodone left over from some dental surgery and I took one last night and … I mean, it really worked. I was amazed—It was the first time I've had relief since this all started. So, I'd like to try some of that." The other half of patients presented an open-ended request: "I just want something to make it better." Activated and open-ended requests were balanced on sex, race and SES. PCPs were balanced by sex and years of experience. After viewing the videotape, the PCPs completed a questionnaire in which they indicated the treatment(s) they would likely order. We examined the association between patient attributes, particularly type of request, and PCP decisions about prescribing narcotics using a multivariate ANOVA model.

RESULTS: 20 % of PCPs presented with an active request for oxycodone reported that they would prescribe a form of oxycodone, compared to only 1 % of PCPs presented with an open-ended request ($p<0.001$; Table). PCPs presented with active requests were more likely to report that they would prescribe a strong narcotic (56 % vs 30 %; $p<0.001$) and less likely a weak narcotic (13 % vs 26 %; $p=0.01$). Patients with higher SES were more likely to receive a narcotic (69 % vs 52 %; $p=0.01$). Patient sex and race were not associated with narcotic choice.

CONCLUSIONS: PCPs presented with a patient request for oxycodone were almost twice as likely to prescribe a strong narcotic, driven mostly by increased prescribing of oxycodone specifically, while PCP's presented with an open-ended request for pain relief rarely selected oxycodone. PCPs were more likely to prescribe narcotics for patients with higher apparent SES, suggesting potential disparities in pain management. Given current concerns about overuse or diversion of narcotic pain medications and the safety concerns related to the patient in the vignette driving for work, these findings suggest that active patient requests may lead to overuse of strong narcotics.

Prescription of oxycodone and other narcotics for sciatica: Stratified by active patient request for oxycodone

Active Request	Oxycodone	Strong narcotic	all (1)	Hydrocodone	Weak narcotic (2)	Any narcotic (3)	No narcotic
Yes	19 (20 %)	54 (56 %)	35 (36 %)	12 (13 %)	63 (66 %)	33 (34 %)	
No	1 (1 %)	29 (30 %)	28 (29 %)	25 (26 %)	53 (55 %)	43 (45 %)	
p-value	<0.001	<0.001	0.35	0.01	0.11	0.11	

1 hydrocodone, oxycodone 2 codeine, propoxyphene, tramadol 3 four physicians prescribed both a strong and weak narcotic

PATIENT SATISFACTION WITH HOSPITALIZATION: ADDRESSING PATIENT'S MOTIVATING CONCERNS FOR ADMISSION AND PERCEPTIONS OF READINESS FOR DISCHARGE Mohan B. Palla; Muralidhar R. Idamakanti; Amber Khan; Muhammad A. Shahzad; Mangai Kishore; Diane L. Levine. Wayne State University, Detroit, MI. (Tracking ID #1642246)

BACKGROUND: Many patients are dissatisfied with how their health care complaints are handled and are disappointed and frustrated when their expectations are not met. Patients often have different perspectives about readiness for discharge compared with their physicians. Acknowledging and addressing expectations has a positive influence on satisfaction. To explore patient expectations and their impact on satisfaction, we studied the motivating concerns of patients at the time of admission (TOA) and their perceptions of timing of discharge.

METHODS: This was a prospective cohort study of hospitalized patients. The Readiness for Hospital Discharge Scale (RHDS) was modified to create a scale addressing patient's motivating concerns at the TOA. A pilot was conducted to validate the scale. The Motivating Concern at Admission Scale (MCaAS) focused on exploring concerns at TOA distinct from the chief complaint. Patient's age, gender, health insurance, prior hospitalization and readmission within 30 days was collected. On admission, patients rated each item on the MCaAS using a Likert Scale (1-unimportant, 5-very important). Patients were interviewed daily regarding readiness for discharge. On the day of discharge, patients were asked whether their motivating concerns at TOA were addressed and how satisfied they were with their hospital stay on a Likert scale (1-very satisfied, 4-very dissatisfied). Mann–Whitney U-Test was used to compare ordinal data and patient satisfaction. Scale items were grouped into categories (physical, emotional, socioeconomic and medical). Continuous data was analyzed using the independent t-test.

RESULTS: 241 patients, mean age of 50.5 (± 15.4), were interviewed (58 % men, 85 % African American). 87.7 % anticipated admission. 199 (82.6 %) were very satisfied with their hospitalization. Functional limitation was a more important motivating concern at TOA in patients≥ 65 years ($Z=-1.99$, $P=0.04$). Socioeconomic concerns: need for shelter ($Z=-2.48$, $P=0.01$), food ($Z=-2.48$, $P=0.01$), and warmth ($Z=-2.36$, $P=0.01$) were more important in patients <65 years. Patients without health insurance considered socioeconomic ($Z=-2.93$, $p=0.003$) and medical issues ($Z=-5.66$, $p=0.00$) more important motivating concerns at TOA than those with. Patients with prior hospitalization ($t=2.19$, $P=0.03$) and readmissions ($t=2.04$, $P=0.04$) within 30 days considered physical limitations more important than those without. Overall, 93.4 % of patients felt their motivating concerns at TOA were addressed. Patients whose motivating concerns were addressed were more satisfied ($Z=-9.37$, $P=0.00$). The mean patient expected length of stay (LOS) was 3.6 days (± 2.2); mean actual LOS was 4.4 (± 3.1). Mismatch regarding readiness for discharge between patient and physician was seen in nearly one quarter of cases. Discharge timing mismatch was associated with patient dissatisfaction ($Z=-6.20$, $P=0.00$). Satisfaction was not dependent on patient concerns at admission but was dependent on whether concerns were met. There were no differences in patient's motivating concern at admission with discharge timing mismatch. Finally, there was no relationship between satisfaction and prior hospitalization or readmission.

CONCLUSIONS: In this study we found patient satisfaction was lower when patient's motivating concerns for admission were not addressed and their readiness for discharge was incongruent with day of discharge. Concentrating on these areas provides an opportunity to further improve patient satisfaction.

PATIENTS HAVE SOMETHING TO SAY: ANALYSIS OF 514 PATIENT SAFETY AND QUALITY COMMENTS FROM THE PROMISES PATIENT SURVEY Namara Brede[1]; Sara Singer[3,5]; Harry Reyes Nieva[1]; Judy Ling[2]; Nicholas Leydon[2]; Caitlin A. Colling[1]; Patricia Satterstrom[4,3]; Catherine Yoon[1]; Endel J. Orav[1,3]; Joel S. Weissman[1,5]; Donald Goldmann[6]; Madeleine Biondolillo[3]; Gordon D. Schiff[1,5]. 1Brigham and Women's Hospital, Boston, MA; [2]Massachusetts Department of Public Health, Boston, MA; [3]Harvard School of Public Health, Boston, MA; [4]Harvard Business School, Boston, MA; [5]Harvard Medical School, Boston, MA; [6]Institute for Healthcare Improvement, Boston, MA. (Tracking ID #1641452)

BACKGROUND: The PROMISES (Proactive Reduction of Outpatient Malpractice: Improving Safety, Efficiency, and Satisfaction) project is an AHRQ-funded quality improvement initiative to assess and reduce malpractice risks in primary care practices in Massachusetts. As part of the project's baseline evaluation component, a patient survey was administered that included a free-response question. This paper draws on responses to that question to describe patients' ideas about how their providers and practices could improve the care and services they received.

METHODS: Data were collected by a professional research firm using a newly developed mail survey tool that combined elements of CAHPS and AHRQ patient safety culture instruments. In each of 25 practices across Massachusetts, we recruited from 81 to 150 patients seen over several weeks. Patients were given the opportunity to opt out of the survey, and the survey was administered to the remaining 3582 patients. Qualitative comments were transcribed by the research firm and then coded thematically by PROMISES investigators into categories reflecting broad themes; each individual comment was placed into one or multiple categories. Comments falling into each category were coded as either positive or negative, and we summarized the number of responses in each group.

RESULTS: Of those surveyed, 1648 patients (47 %) responded to the survey; 514 of these surveys (31 %) contained patient comments. 182 patients offered positive comments about their care, 251 voiced negative comments, and 70 noted both positive and negative aspects of care. About half of the comments (228) included concrete suggestions for improvements, e.g., "follow through on referrals," "provide for STAT appointments," and "let me bypass the automated phone system." The single most common theme was communication with physicians (114 comments: 20 positive/94 negative); e.g., "[my doctor] is attentive to my needs, thorough in her explanations," and "they need to spend more time with patients and listen." Patients also commented on communication with office staff (103 comments: 64+/39−), overall satisfaction with care (99: 60+/39−), office waiting time (79: 11+/68−), timely appointment scheduling (68: 16+/52−), professional caregiver competency (52: 34+/18−), communication with NPs/PAs (43: 18+/25−), test result management (36: 2+/34−), office visit time (28: 1+/27−), referral management (26: 7+/19−), office facilities (23: 2+/21−), insurance/billing (21: 1+/20−), office organization (19: 3+/16−), medication management (19: 3+/16−), and trust of providers (12: 9+/3−).
CONCLUSIONS: Patients provided an unexpected abundance of comments, revealing some striking patterns. While the most common themes related to communication, other concerns, including waiting time and test and referral management, were also frequently cited. Some themes were almost always mentioned in a negative light (insurance/billing and test result management), while others were more positive or mixed (communication with staff and professional competency of caregivers). These comments provided useful feedback to individual practices, and also illuminated areas of importance for patients. This rich and complex dataset highlights possible areas of focus for future malpractice risk reduction and quality improvement work in the primary care setting.

PATIENTS IN A COMMUNITY HEALTH CENTER CONSIDER PATIENT PORTALS IMPORTANT BUT FACE BARRIERS TO ADOPTION Mita S. Goel; Rachel O'Conor; Liliana Aguayo; Anne M. Boyd; David W. Baker. Northwestern University, Chicago, IL. (Tracking ID #1642530)

BACKGROUND: Patient portals (PPs) allow patients electronic access to their health records and may facilitate communication with health care providers. Implementation of PPs is likely to accelerate because PP use is essential for garnering federal financial incentives for achieving meaningful use of electronic health records. We sought to identify attitudinal and access barriers to PP adoption among patients seeking care at a federally qualified community health center (FQHC) preparing to implement a PP.
METHODS: We contacted a random sample of 150 patients, stratified by age and gender, with 2 or more visits in the past 18 months to an urban FQHC. We conducted a 20 min telephone interview soliciting (1) attitudes toward PP features, such as secure messaging and viewing test results using a 5 point Likert Scale, (2) use of internet-enabled technology and (3) demographic characteristics. In addition to simple descriptive statistics, we examined the relationship between demographics, attitudes towards PP features and use of internet-enabled technology.
RESULTS: A total of 104 participants consented for the study (response rate 69 %). Mean age was 47 years (age range 18–72); 66 % were women, 85 % were Latino, 71 % preferred to speak in Spanish and 45 % had less than a high school education. More than 80 % reported key features of the PP were important or very important (medication refills, viewing test results, viewing medication lists and dosing, seeing when screening tests are due, receiving text alerts when due for screening, online scheduling, emailing about new medical problems, asking questions about existing medical issues and sharing medical records with other providers). Younger age (18–34 years) was positively correlated with rating PP features as important ($p<0.05$); ratings of PP features did not vary by preferred language. Many respondents lacked access to internet-enabled technology; 34 % did not own a computer and 45 % did not have an internet-enabled mobile phone. In all, 46 % did not have access to any internet-enabled technology. Increasing age was negatively associated with access to internet-enabled technology; 85 % of respondents aged 18–34 years had access vs. 22 % of those 65 years and older ($p<0.05$). Similarly, Spanish language preference was associated with poorer access to internet-enabled technology; 43 % of Spanish speakers had access vs. 80 % of English speakers ($p<0.05$). When asked why they lacked internet-enabled devices ($n=54$), 50 % reported they did not know how to use a computer and an additional 25 % reported they were unable to afford the technology. However, 95 % of all participants had access to a mobile phone and of those, 75 % used text messaging.
CONCLUSIONS: Although patients seeking care at an FQHC consider key PP functions important, many lack access to, or proficiency with using, internet-enabled devices. Adoption of PP technology in this context is likely to be slow and may place safety net institutions at risk of losing important federal financial incentives. Further work should explore the prevalence of these barriers more broadly in FQHCs. Text messaging may be a more feasible vehicle for patient-centered interventions in FQHCs at present.

PATIENTS WHO FEEL SAFE TO DISCLOSE LGBT RELATED ISSUES TO THEIR HEALTHCARE PROVIDERS ARE MORE MOTIVATED TO TAKE CARE OF THEIR OWN HEALTH Richard E. Greene; Benjamin Cox; Jonathan Gursky; Nicole Rosendale; Benjamin Solomon; Jaclyn Fox; Colleen Gillespie. NYU School of Medicine, New York, NY. (Tracking ID #1641126)

BACKGROUND: Lesbian, gay, bisexual and transgender (LGBT) health centers exist to meet the special health needs for members of the LGBT community. It remains unclear whether patients attending these clinics take better care of themselves or have better health outcomes than patients who are seen in other, mainstream clinics. We surveyed patients at a new LGBT clinic embedded in a city-funded outpatient facility that serves an urban, diverse, underserved population on the Lower East Side of NYC. Our aim was to better understand why patients sought out care at an LGBT clinic, assess patient satisfaction with these clinics, and evaluate how these clinics may change patient attitudes about their own health.
METHODS: We designed and administered an 18-question survey to the patients at the new LGBT Clinic; the first 15 questions used True/False and Likert scale formats to assess participants' attitudes about LGBT-health centers, views about their own health, and satisfaction with the care received at the clinic. Three questions were open-ended and allowed the patient to name their sexual identity and include additional comments about their healthcare experiences. The survey was sent to all LGBT-identified patients who sought primary care services at the LGBT clinic since its opening. Between May and June 2011, patients received an email that described the purpose of the study and included a link to the anonymous on-line survey. Three weekly reminder emails were sent. People who attended the clinic but did not identify as LGBT (i.e. who had been scheduled erroneously), who came seeking Sports Medicine advice exclusively (a side interest of the lead clinician), or did not have access to e-mail were excluded from the study. We used descriptive statistics to analyze the results and performed Chi-Square analyses to examine for associations between key variables of interest.
RESULTS: Of the 87 patients who were invited, 38 (44 %) responded. Overall, patients reported they had a "good experience" at the clinic (36/38 (94 %) agreed or strongly agreed with this statement). Patients named as reasons they chose the LGBT clinic: safety and freedom from discrimination, confidence they would have their specific needs addressed, and assurance of LGBT sensitive providers. 30/38 respondents (79 %) reported that they strongly agree that since receiving care at the LGBT Clinic, they are now taking better care of their own health. Respondents' taking better care of their own health since seeking care at the LGBT clinic was positively associated with having shared health concerns there that they previously had not shared with providers (Chi Sq=8.70, $p=.034$). Both of these elements (better self-care and newly sharing health concerns at the LGBT clinic) were also positively associated with feeling that the staff at the LGBT clinic created a safe place ($p<.05$).
CONCLUSIONS: LGBT patients are more likely to share details of their lives with providers they perceive to be open and sensitive to the LGBT related aspects of their lives. Our data implies that by sharing these details, patients may be activated to take better care of their own health once engaging in a system they feel to be free of bias against LGBT individuals.

PATIENTS' UNDERSTANDING OF CARDIOVASCULAR DISEASE RISK MESSAGES Tiffany Brown[1,2]; Namratha R. Kandula[1,2]; Muriel Jean-Jacques[1,2]; Ingrid N. Guzman[1]; Stephen D. Persell[1,2]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL. (Tracking ID #1640450)

BACKGROUND: Although effective for primary prevention in individuals at high risk for cardiovascular disease (CVD), statins are underused, especially among vulnerable populations. One factor in underuse may be that patients do not understand their CVD risk and the potential benefits of taking a statin. As part of a randomized trial aimed at increasing statin use in high risk patients, we developed education materials that described a patient's personalized 10-year CVD risk and encouraged patients to talk about statins with their health care provider. This qualitative study describes patients' reactions to these messages and subsequent modifications to the messages during pilot-testing.
METHODS: We developed a targeted message for patients with a 10-year risk for myocardial infarction or coronary death of ≥10 % (based on Framingham Risk Score) and hyperlipidemia. The message contained 3 main points: (1) the patient's current risk score (2) the average risk score for a person of the same age with normal risk factors; and (3) the patient's adjusted risk if statin treatment was initiated. The same message was presented using two different visual formats: a pictogram or a vertical thermometer with stoplight colors. We conducted semi-structured qualitative interviews with a convenience sample of patients in an urban federally qualified health care center serving a predominantly homeless population. Participants were shown both variations of the message for a hypothetical patient. The order that the 2 different formats were shown in was randomly varied. After the first round of interviews, we simplified the message and conducted additional interviews.
RESULTS: Participants' (n=53) mean age was 46 years old, 72 % were male, 62 % were African-American, 36 % had less than a high school education, and 57 % reported some form of health care coverage. In the first round of interviews (n=39), fewer than half of participants were able to accurately explain the message in their own words. Participant responses highlighted comprehension challenges (e.g., "Just say 'you are in bad shape' the other stuff I don't need" and "I'm a little confused to be honest. Is this [pictogram] supposed to be happy?"). Participants felt that the information on the same age patient with low risk and also the adjusted risk score after treatment was too much information and confusing. They preferred the thermometer to the pictogram. Based on the initial feedback, we simplified the message from three main ideas to only one: the patient's current high risk score. In the second round of interviews (n=14), three-quarters correctly explained the main idea of the message. Participants also said the message should mention lifestyle change in addition to statin treatment as a way to lower CVD risk. A brief sentence about lifestyle was added to the final message.
CONCLUSIONS: Pilot-testing of messages about CVD risk and statin treatment identified important comprehension challenges which patients might encounter. Participants had difficulty interpreting messages that compared their own high risk score to the lower risk score of a patient with controlled risk factors. Participants said that the most important and understandable messages were to focus on their individual high risk and to include information about lifestyle. Educational messages aimed at increasing statin use should be simple and focus on the patient's current high risk and what action should be taken.

PATTERNS OF EXPENDITURES AND ADHERENCE TO MEDICATIONS AMONG LOW AND NON-LOW INCOME BENEFICIARIES ENROLLED IN MEDICARE PART D Arleen Brown; Stella M. Yala; Norman Turk; Carol Mangione; Susan Ettner; O. Kenrik Duru; Neil Steers; Lindsay Kimbro. David Geffen School of Medicine at UCLA, Los Angeles, CA. (Tracking ID #1628744)

BACKGROUND: The Medicare Part D low-income subsidy (LIS) provides full or partial waivers for out-of-pocket (OOP) medication, has cost-sharing requirements and eliminates gap coverage. Under the Affordable Care Act (ACA), more Medicare beneficiaries will receive LIS. However, it has not been established the effect of Part D LIS on expenditures and its association with medication adherence. The objectives of this study were to examine, among Part D beneficiaries, the effect of LIS on expenditures and to determine if the subsidy is associated with adherence to medications for hypertension, diabetes or hypercholesterolemia.
METHODS: In this cross-sectional, retrospective analysis, non-LIS beneficiaries without coverage in the gap (Non-LIS/Non-GC) were compared to non-LIS beneficiaries with gap coverage (Non-LIS/GC) and to LIS beneficiaries with gap coverage. Data from a national Medicare insurance provider included participants in 12 states continuously enrolled from January 1, 2005 through December 31, 2006. Patient information was linked to 2000 US Census tract data. Logistic regression models were constructed to assess the association between LIS status and the following outcomes: (a) expenditures that exceeded the gap threshold and (b) adherence to hypertensive, diabetes, or cholesterol-lowering medications. Generalized linear models were used to assess the association between LIS status and total, OOP, or plan expenditures. All models included as covariates demographic characteristics (age, gender), co-morbid conditions, residential census tract characteristics (median household income, education, race/ethnicity, linguistic isolation), and state of residence. Models of medication adherence included only beneficiaries with the condition of interest.
RESULTS: Of the 344,817 eligible beneficiaries, 290,302 were non-LIS/Non-GC, 29,289 were non-LIS/GC, and 25,226 were LIS. Adjusted estimates for expenditures, prescription drug use, and medication adherence are presented in the table.
CONCLUSIONS: Relative to Non-LIS/Non-GC beneficiaries, LIS beneficiaries had higher total costs and lower OOP costs; were more likely to reach the gap expenditure threshold; and had slightly higher medication adherence. Non-LIS/GC beneficiaries had modest differences in expenditures and adherence compared to Non-LIS/Non-GC beneficiaries. Our findings suggest that gap coverage may be associated with improved adherence for LIS participants and that attempts to reduce or eliminate gap coverage may result in lowered medication adherence among the most vulnerable beneficiaries, leading to increased costs and poorer health outcomes. Further research is needed to understand how the extension of ACA benefits will influence expenditures and adherence among Medicare beneficiaries who are not currently eligible for the subsidy.
Regression-Adjusted Estimates of Expenditures, Prescription Drug Use, and Adherence by LIS and Gap Coverage Status
Non-LIS/Non-Gap Coverage (Ref.) N=290,302 Non-LIS/Gap Coverage N=29,289 LIS N=25,226
Total expenditures $1,341 $1,360* $1,887**
Plan expenditures $776 $822** $1,708**
OOP expenditures $570 $546** $148**
Brand OOP expenditures $369 $374* $96**
Expenditures that exceeded \"Gap\" threshold 16.9 % 17.4 %* 27.6 %**
Total number of prescriptions 26.5 25.1** 38.1**
Diabetes drug adherence 57.4 % 57.7 % 62.5 %**

PATTERNS OF HOSPICE CARE AMONG VETERANS AND NON-VETERANS Melissa W. Wachterman[1,2]; Steven R. Simon[1,2]; Stuart R. Lipsitz[2]; Nancy L. Keating[3,2]. [1]VA Boston Healthcare System, Jamaica Plain, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA. (Tracking ID #1639941)

BACKGROUND: Historically, hospice use by military Veterans lagged behind that of non-Veterans. Responding to this disparity, in 2002–2003, the Veterans Health Administration (VHA) expanded Veterans' access to end-of-life care services, and rates of hospice use increased substantially. Meanwhile, general US hospice patterns have shifted in recent decades, moving beyond the traditional focus on treating patients with cancer living at home. We compared

Veteran and non-Veteran hospice users to determine whether demographics, primary diagnosis, location of care, and service utilization differed for these two populations.

METHODS: Using data from the 2007 National Home and Hospice Care Survey (NHHCS), administered by the National Center for Health Statistics, we identified 1415 male hospice users (95 % of Veterans in NHHCS were male). We used chi-square and t-tests to compare Veterans and non-Veterans by demographic characteristics, primary diagnosis, and location of hospice care. We used multivariate regression to assess whether differences in primary diagnoses and location of care between Veterans and non-Veterans existed after adjustment for demographic and clinical factors. We also compared measures of service utilization-length of stay (LOS) in hospice and number of visits by hospice nurses, social workers, and home health aides-between Veterans and non-Veterans, using multivariate regression. All analyses accounted for the complex sampling design; results were weighted to reflect national estimates.

RESULTS: Among 483 Veteran and 932 non-Veteran male hospice users, representing 287,620 hospice enrollees nationally in 2007, Veterans were significantly older than non-Veterans (mean age 77.0 vs. 74.3 years, p=0.02). Most Veteran and non-Veteran hospice users were non-Hispanic whites (81.7 % and 82.0 %, p=0.72) and married (70.1 % vs. 61.0 %, p=0.10), respectively. Veteran hospice users were significantly more likely to live at home while receiving hospice (68.4 % vs. 57.6 %, p=0.047), although this difference was not statistically significant after adjustment for demographic and clinical factors (p= 0.06). Cancer was a more common diagnosis among Veterans in hospice than non-Veterans (56.4 % vs. 48.4 %), but this difference was not statistically significant (unadjusted p=0.07, adjusted p=0.06). In analyses adjusting for demographic and clinical factors, mean hospice LOS was significantly longer for Veterans than non-Veterans (60 vs. 48 days, p=0.0499). In adjusted analyses, the number of nurse or social worker visits did not differ by veteran status (both p> 0.10), but Veterans received significantly fewer visits from home health aides than non-Veterans (1 every 3.3 days vs. 1 every 2.0 days, p=0.005).

CONCLUSIONS: In a nationally-representative cohort of male hospice users, Veterans were older than non-Veterans, but other characteristics were similar. We found suggestive evidence that Veterans may be more likely than non-Veterans to have cancer and receive hospice at home (a more traditional pattern of hospice use), though these differences were not statistically significant. The longer LOS for Veterans suggests that Veterans are being referred to hospice earlier than non-Veterans, perhaps as a result of the VHA's efforts to expand awareness of and access to hospice. However, Veterans had fewer home health aide visits than non-Veterans. Further study is needed to understand the sources of this difference and to assess if it is associated with worse experiences among Veteran hospice users.

PEER MENTORSHIP AT A METHADONE MAINTENANCE TREATMENT PROGRAM: DEVELOPING SELF-EFFICACY THROUGH PROJECT GROW Magni Hamso[1]; Hillary Kunins[1]; Janet Smith[2]; Melissa Stein[2]. [1]Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1629970)

BACKGROUND: Women with opioid dependence face many gender-specific challenges as they enter treatment, including poorer physical and mental health than their male counterparts, low self-efficacy, and, in the case of methadone maintenance, a highly structured and hierarchical system comprised of more male than female clients. The aim of this study was to evaluate the peer-mentoring arm of Project GROW (Giving Resources and Options to Women), an HIV prevention program serving women enrolled in methadone maintenance treatment programs (MMTP) in the South Bronx, an impoverished New York City neighborhood with high rates of HIV and substance use. The goal of the peer-mentoring program was to create a cadre of female peers who could help engage other women in treatment and HIV prevention activities. The purpose of this analysis was to assess how being a peer mentor might affect the women's sense of self-efficacy, both inside and outside of the MMTP.

METHODS: All current Project GROW peer mentors were invited to participate in a semi-structured interview. The interview included questions about the women's understanding of peer mentorship, their perceptions of self-efficacy (how they viewed themselves and their future, and how they thought they were viewed by MMTP staff, other clients and family since becoming peers), their experience of methadone maintenance (both the idea and logistics of being on methadone), and their attitude toward and engagement in high-risk behavior. The interviews were audio-taped, transcribed, and analyzed using the principles of grounded theory.

RESULTS: All ten current Project GROW peer mentors participated in the interviews. The women ranged in age from 40 to 60 years old, were African American or Latina, and attended a MMTP of the Albert Einstein College of Medicine's Division of Substance Abuse. The most prominent theme that featured in all of the interviews was the importance of peer mentorship in their lives. Central to all of the women's self-definition was being a peer mentor. The women suggested that other clients and staff saw them as Project GROW peer mentors, rather than as clients and substance users. They defined their future around remaining peer mentors and continuing to help others both inside the MMTP and outside, among their family and friends. Contrary to our expectations, women did not share increased frustration with the logistics of methadone maintenance after becoming peers; instead, they were grateful for methadone, which had helped keep them substance-free, and more patient with the hierarchical structure of the MMTP.

CONCLUSIONS: Participation in a peer-mentoring program for women in methadone maintenance provided these women with an important identity as a peer mentor that superseded their identities as substance users and MMTP clients. This identity helped promote their self-efficacy to remain substance free, to continue treatment with methadone, to help other female substance users, and to participate more fully in their families' lives. Training to become a peer mentor may have important benefits for women enrolled in a MMTP, with regard to both functional and substance use related outcomes.

PERCEIVED DISCRIMINATION AMONG PATIENTS WITH SICKLE CELL DISEASE: ASSOCIATION WITH CLINICAL OUTCOMES Mary Catherine Beach[1]; Carlton Haywood[1]; Sophie Lanzkron[1]; Gladys Onojobi[2]; Shawn M. Bediako[3]; Charles Jonassaint[1]; Marie Diener-West[1]; Jennifer Haythornthwaite[1]. [1]Johns Hopkins University, Baltimore, MD; [2]Howard University, Washington, DC; [3]University of Maryland Baltimore County, Baltimore, MD. (Tracking ID #1638809)

BACKGROUND: The predominantly black race of persons with sickle cell disease (SCD) is perceived by healthcare providers and patients to impact the quality of care. Furthermore, as a historically stigmatized disease, it is possible that persons with SCD perceive discrimination on the basis of their disease status. While perceived racial discrimination is associated with clinical outcomes in other patient populations, little is known about the effects of discrimination among SCD patients. We compared the extent to which persons with SCD perceive discrimination due to their race or disease, and examine the impact of perceived discrimination on patient outcomes.

METHODS: Using audio self-interviews, we administered questionnaires to SCD patients receiving ambulatory care at two urban hospital centers. Independent variables were the extent to which respondents perceived discrimination from doctors due to their race or their disease over the past 12 months, and over the past 2 years. Outcomes were the respondent's self-reported adherence to doctor's advice, levels of trust in the medical profession, distrust in the healthcare system, and sickle cell specific self-efficacy.

RESULTS: 279 SCD patients participated in our survey. The respondents were 97 % black, 53 % female, and had a mean age of 34.9 years. In thinking about experiences over the previous 2 years, 25 % of respondents perceived discrimination based on race, and 28 % perceived discrimination based on having SCD. In thinking about experiences over the previous 12 months, respondents perceived a greater level of disease- vs. race-based discrimination (mean scores=2.1 vs. 1.6, p<0.0001). Both disease- and race-based discrimination perceptions were associated with lower self-efficacy, lower trust in medical professionals, and greater distrust of health care systems. Perceptions of disease-based, but not race-based, discrimination were associated with less adherence to doctor's advice. Both race-based and disease-based perceived discrimination maintained independent associations with trust in medical professionals and distrust in the health care system after controlling for each other, respondent sex, and respondent

age. Only disease-based discrimination maintained an independent association with self-efficacy and adherence with doctor's advice.
CONCLUSIONS: Patients with SCD perceive discrimination based both on their race and their disease status. Both types of perceived discrimination have negative consequences for SCD patient trust in medical professionals and distrust in the health care system. Furthermore, disease-based discrimination appears to have negative consequences for patient's self-efficacy and their adherence to treatment. The effects of perceived discrimination should be the subject of greater attention in the SCD community.

PERCEIVED RISK FOR TYPE 2 DIABETES AMONG WOMEN WITH A HISTORY OF GESTATIONAL DIABETES Joyce W. Tang[1]; Kenzie A. Cameron[1]; Javiera Pumarino[1]; Alan Peaceman[2]; Ronald T. Ackermann[1]. [1]Northwestern University, Chicago, IL; [2]Northwestern University, Chicago, IL. (Tracking ID #1641834)

BACKGROUND: Gestational diabetes (GDM) is a striking, yet modifiable risk factor for the development of type 2 diabetes mellitus (DM2). Nearly 50 % of women diagnosed with GDM develop DM2 within 10 years of initial diagnosis. It is unclear whether or not most women with a history of GDM are aware of their increased risk for developing DM2 and the extent to which they seek primary care follow-up after delivery. Prior studies in this area are limited and have not included ethnic minorities, who are disproportionately affected by GDM.
METHODS: We conducted structured interviews with women who were diagnosed with GDM during a recent pregnancy and were within 18 months of delivery; patients diagnosed with DM2 after delivery were excluded. We recruited participants from 4 obstetrics clinics (2 academic, 1 private, 1 community) and 1 endocrinology clinic affiliated with Prentice Women's Hospital (Chicago, IL). A programmer analyst identified eligible patients through query of the Electronic Health Record (EHR) for positive glucose tolerance tests (GTT). Women rated their risk for DM2 over 10 years (4 point scale) and compared their risk to those of other women their age (5 point scale). Reasons for risk ratings were elicited (open-ended response). Women rated the effect of GDM on risk for DM2 (5 point scale). Interest in receiving wellness information from physicians was rated on a 3 point scale. Receipt of follow-up care and postpartum GTT were self-reported. Chi-square tests were used to test potential differences by race.
RESULTS: Of 124 eligible patients, 74 women completed interviews (33 Caucasian, 34 Hispanic, and 7 African-American); mean age was 33.8 (SD 5.7). Ninety-one percent of women felt they had at least a slight chance of developing DM2, but only 12 % perceived their risk to be high. Forty-one percent of women rated their risk for DM2 as higher than for other women their age; Hispanic women were less likely than African American or Caucasian women to perceive higher risk for DM2 (24 % Hispanic, 52 % Caucasian, 71 % African-American, $p=0.01$). Most women believed that GDM increased their risk for DM2, but only 17 % felt it increased their risk by a lot. Reasons for perceived higher risk included family history of DM2, elevated weight, and history of GDM. In contrast, reasons for perceived low risk included a healthy or improved lifestyle and lack of family history of DM2. Ninety-six percent of women reported seeing a physician after delivery (with 31 % seeing a primary care physician other than their OB/GYN); yet, 45 % of women reported not undergoing guideline recommended postpartum GTT. Sixty-three percent of women reported seeing a primary care physician at least once a year and 77 % of women reported interest in receiving information on how to stay healthy from their primary care physician.
CONCLUSIONS: Most women with a history of GDM perceive themselves to be at risk for DM2, but few perceive themselves to be at high risk; Hispanic women were least likely to perceive their risk as higher than that of their peers. GDM is felt to increase risk for DM2, but only mildly. After pregnancy, women commonly obtain follow-up in primary care, and may benefit from a coordinated handoff from obstetric care to improve continuity of care and ensure continued emphasis on the importance of diabetes prevention.

PERCEPTIONS OF CLINICAL RESEARCH AMONG PERSONS WITH SICKLE CELL DISEASE Mary Catherine Beach[1]; Carlton Haywood[1]; Sophie Lanzkron[1]; Shawn M. Bediako[3]; Gladys Onojobi[2]; Charles Jonassaint[1]; Jennifer Haythornthwaite[1]; Marie Diener-West[1]. [1]Johns Hopkins University, Baltimore, MD; [2]Howard University, Washington, DC; [3]University of Maryland Baltimore County, Baltimore, MD. (Tracking ID #1638694)

BACKGROUND: There is only one FDA-approved disease-modifying therapy available to treat sickle cell disease (SCD); therefore participation of individuals with SCD in clinical trials of new therapies is vital to improve the health of this population. Unfortunately, many clinical investigators report difficulty in recruiting sufficient numbers of SCD patients to participate in trials, and a number of major studies in SCD have closed down due to insufficient enrollment. Despite this, little is known about the attitudes that persons with SCD have about clinical trials. We examined attitudes towards clinical trials among persons with SCD, and the extent to which demographic, attitudinal, clinical characteristics, previous clinical trial history, and perceptions of the quality of prior healthcare experiences is associated with SCD patient attitudes.
METHODS: Using audio self-interviews, we administered questionnaires to SCD patients receiving ambulatory care at two urban hospital centers in Baltimore, MD and Washington, DC. Independent variables were patient demographics (age, sex, receipt of medical assistance, household income, and education), patient attitudes (trust in medical professionals and distrust in the healthcare system), the perception of the severity of their own SCD compared to others, previous participation in a clinical trial, and quality of prior healthcare experiences (Stewart et al.'s Interpersonal Processes of Care measure). Outcomes were the respondent's attitudes towards clinical research and clinical trials as measured by a modified version of the Perceptions of Participation in Clinical Research scale.
RESULTS: 279 SCD patients participated in our study (response rate of 92.5 %). Respondents were 97 % black, 53 % female, and had a mean age of 34.9 years. Most (74.9 %) respondents reported having being asked to participate in a clinical trial; of those, most (67.5 %) also reported participating in a clinical trial at some point in their life. Most SCD patients (84 %) agreed or strongly agreed that clinical trials are a necessary way to learn about treatments, 81 % agreed or strongly agreed that it is important for people to take part in clinical trials, 77 % agreed or strongly agreed that participation in a clinical trial can help them and their family, and 92 % agreed or strongly agreed that participation in a clinical trial can help future generations. In a regression model, previous participation in a clinical trial and having the perception that one's SCD was not as severe as others both independently predicted having more positive attitudes toward clinical trials.
CONCLUSIONS: Contrary to what is commonly and anecdotally reported, we found very positive attitudes toward clinical trials among persons with SCD. In our study, patients who perceived that their SCD was less severe than others, and patients who have previously taken part in clinical trials, reported the most positive attitudes towards clinical trials. These results suggest that difficulties that are encountered in recruiting SCD patients to take part in clinical trials may be less likely due to SCD patient attitudes, and perhaps more likely due to the logistical requirements/burdens of participation, to researcher attitudes and/or their methods of approaching potential participants, or to research design considerations (such as overly stringent or inappropriate inclusion/exclusion criteria).

PERSPECTIVES ON PHYSICAL ACTIVITY AMONG IMMIGRANTS AND REFUGEES TO MINNESOTA Mark L. Wieland[1]; Kristina Tiedje[2]; Sonja J. Meiers[3]; Ahmed A. Mohamed[4]; Christine M. Formea[1]; Jennifer M. Ridgeway[1]; Gladys B. Asiedu[1]; Ginny Boyum[5]; Jennifer A. Weis[1]; Julie A. Nigon[6]; Christy A. Patten[1]; Irene G. Sia[1]. [1]Mayo Clinic, Rochester, MN; [2]Université Lumière Lyon 2, Lyon, France; [3]Winona State University, Rochester, MN; [4]Michigan State University College of Human Medicine, East Lansing, MI; [5]Rochester Community and Technical College, Rochester, MN; [6]Hawthorne Education Center, Rochester, MN. (Tracking ID #1634408)

BACKGROUND: Immigrants and refugees to the United States exhibit relatively low levels of physical activity and this disparity likely contributes to the escalation in cardiovascular risk (obesity, hyperlipidemia, hypertension, diabetes) observed after immigration. Reasons for this disparity are poorly understood.
METHODS: Through an established community-based participatory research partnership, 16 gender and age-stratified focus groups were conducted among 127 participants from heterogenous immigrant and refugee groups (Cambodian, Latino, Somali, Sudanese) in Rochester, Minnesota. Focus group questions were informed by community participation and by a social cognitive (learning) theory framework. Transcripts of audio recordings were coded independently by two analysts using inductive analysis to generate code lists. The final code list (agreed upon by all eight analysts) was used for paired coding of materials. Through coded material, themes and sub-themes emerged as an explanatory model for perceived barriers and facilitators to physical activity among participants. Analytic memos and data tables were derived to inform presentation of results. Analysis was facilitated by NVIVO-9 software.
RESULTS: We found many similarities in perceived barriers and facilitators to physical activity between heterogenous immigrant and refugee groups. Knowledge of physical activity principles was high, but physical activity was conceptualized and practiced in many different ways, including intentional exercise, sports, and chores around the house. Further, participants conveyed many advantages of being physically active that extend beyond the biomedical (e.g., lower risk of diseases, longevity) to the psychosocial (e.g., enhanced self-confidence, happiness, and lower stress). Participants described more barriers to physical activity in the US than in their home country and said that they are in a process of transition and learning how to overcome the barriers to being physically active in their new country. Importantly, lack of familiarity and comfort with taking the first steps towards being physically active are the most significant barriers to behavior change. However, once these initial hurdles are cleared, participants were optimistic about their ability to be physically active. Structural barriers included lack of time, lack of transportation to exercise facilities, lack of motivation or interest in formal exercise, competing time spent with electronics, and a lack of places to gather as groups for physical activities that are affordable and linguistically welcoming. Participants were motivated by social support from family, friends, and communities to be physically active.
CONCLUSIONS: We found many similarities in perceived barriers and facilitators to physical activity between heterogenous immigrant and refugee groups, suggesting that these shared experiences of immigration and associated social, economic, and linguistic factors (rather than cultural norms) may be primary drivers of physical activity after arrival to the US. These findings may inform intervention work among immigrants and refugees to the United States to promote physical activity.

PERSPECTIVES ON SUFFERING IN THE PRIMARY CARE SETTING Catherine Trimbur[1]; Timothy Quill[2]; Sally Norton[2]. [1]Montefiore Medical Center, Bronx, NY; [2]University of Rochester School of Medicine, Rochester, NY. (Tracking ID #1637990)

BACKGROUND: The experience of suffering is widespread and important aspect of patients' health and health care. An expression of internal distress, suffering can be a simultaneously physical, emotional and existential experience. Primary care physicians carry a great responsibility in identifying and managing suffering. However, few studies have looked at provider experiences in caring for patients who are suffering, or strategies they use to address suffering in the outpatient setting.
METHODS: This study examines the perspectives of primary care physicians on caring for suffering patients, particularly how they develop the skills necessary to observe, diagnose and address suffering in the context of an otherwise demanding outpatient setting. We used a semi-structured qualitative descriptive design. Participants were physicians working in primary care practices in upstate NY, including family practitioners, general internists and pediatricians. The sample had even representation from providers in urban, suburban and rural practices and were evenly distributed in number of years in practice. We conducted 20 semi-structured, face-to-face interviews with questions focusing on types of suffering observed, ways in which formal and informal education prepared them to address suffering and approaches they used in their own practice to meet these patient needs. Suffering was purposefully not defined for respondents to allow for respondents' own perspectives to emerge. Physicians were first recruited by criterion sampling and then snowball or referral sampling. Interviews were audiotaped, transcribed and analyzed by an iterative process to identify and analyze major themes, concepts and events relevant to the research question.
RESULTS: Providers in this study articulated a deep ideological commitment to patient-centered care and to being aware of suffering in their patients. They identified a clear sense of how they wanted to interact with patients and made deliberate choices to cultivate the type of practice that would support this ideology. However, they also identified significant structural challenges in doing this. The primary challenges identified were lack of medical training around patient suffering, and constraints around office visits (including number of visits per session, length of time scheduled for visits, location of visits, and reimbursement structures). They described these factors as barriers to their ability to exhibit empathy, elicit concerns and create healing relationships with patients. Innovative approaches for overcoming these challenges was also an important theme that emerged. These approaches included seeking out continuing education (both formal and informal), flexibility in scheduling visits (length and location of visits and using appointments for family meetings) and accepting lower salaries.
CONCLUSIONS: This study explores the challenges and rewards of caring for suffering patients in the primary care setting and the unique approaches one group of providers use to overcome these challenges. As many of the strategies described are financially uncompensated, providers were instead motivated by an ideological commitment to their patients and to relieving suffering. The results of this study point to the need for increased structural support for this type of work and more robust training around recognizing and exploring suffering at all stages of medical education.

PHARMACY-BASED INTERVENTIONS TO REDUCE PRIMARY MEDICATION NON-ADHERENCE Niteesh K. Choudhry[1]; Michael Fischer[1]; Katsiaryna Bykov[1]; Gregory Brill1; Gregory Bopp[2]; Aaron M. Wurst[2]; William Shrank[1]. [1]Brigham & Women's Hospital, Boston, MA; [2]CVS-Caremark, Woonsocket, RI. (Tracking ID #1629255)

BACKGROUND: Non-adherence to essential chronic medications is common and leads to substantial morbidity, mortality, and avoidable healthcare costs. Recent studies have recognized the frequency of primary non-adherence, when patients do not fill their first prescription for a new medication. Little is known about what interventions could reduce rates of primary non-adherence. We evaluated two interventions implemented by a large pharmacy chain attempting to reduce primary non-adherence to cardiovascular medications.
METHODS: In 2007 CVS retail pharmacies began making automated reminder phone calls to patients who had not picked up new prescriptions within 3 and 7 days after the prescription was initially processed. In 2009 pharmacists and pharmacy technicians began making personal calls to patients who had not picked up their prescriptions within 8 days after initial processing. For each intervention a 1–2 % random sample of patients, selected based on birthdate, did not receive the intervention and served as a control group. We used pharmacy and insurance data from CVS-Caremark to identify the rate at which prescriptions for cardiovascular medications were not filled within 30 days after they had first been processed.
RESULTS: The automated intervention included 852,629 patients and 1.2 million prescriptions, with a control group of 9,282 patients and 13,179 prescriptions. The live intervention included 121,155 patients and 139,502 prescriptions with a control group of 2,976 patients and 3,407 prescriptions. The control and intervention groups were balanced by age, gender, and patterns of prior prescription use. For the automated intervention, the rate of unfilled prescriptions was 4.2 % in the intervention

group and 4.5 % in the control group ($p>0.1$). For antihypertensives the unfilled prescription rate was 3.6 % in the intervention group and 4.0 % in the control group ($p>0.1$) while for statins the rates were 5.4 % in the intervention group and 5.6 % in the control group ($p>0.1$). The live intervention was used in a group that had not filled prescriptions after 8 days and thus had much higher rates of primary non-adherence. In this setting the rate of unfilled prescriptions was 36.9 % in the intervention group and 41.7 % in the control group, a difference of 4.8 % ($p<0.0001$). The difference in unfilled prescription rate for antihypertensives was 6.9 % ($p<0.0001$) but for statins was only 0.5 % ($p>0.1$).

CONCLUSIONS: Automated reminder calls encouraging patients to fill their prescriptions had no significant effect on rates of primary medication adherence. Personal calls from pharmacists and pharmacy technicians to patients at high risk for primary non-adherence significantly increased primary adherence to prescriptions for cardiovascular medications, although many patients still did not fill their prescriptions. The findings were driven by improved adherence to anihypertensive medications, with no effect on adherence to statins. Our findings indicate that 20 personal calls from the pharmacy would be needed to yield one additional filled prescription, or 15 calls per prescription filled if the results were limited to antihypertensives. Future analyses of long-term adherence and clinical outcomes will be needed to assess the cost-effectiveness of these interventions for pharmacies or health systems.

PHYSICIAN RACE AND THE CARE OF MEDICALLY DISADVANTAGED PATIENTS: A NATIONALLY REPRESENTATIVE ANALYSIS

Lyndonna M. Marrast[1,2]; Leah Zallman[1,2]; David Himmelstein[1,3]; Steffie Woolhandler[1,3]; David Bor[1,2]; Danny McCormick[1,2]. [1]Harvard Medical School, Boston, MA; [2]Cambridge Health Alliance, Cambridge, MA; [3]City University of New York at Hunter College, New York, NY. (Tracking ID #1642396)

BACKGROUND: Studies from 20 to 30 years ago suggested that minority physicians were more likely to care for medically disadvantaged patients. Diversifying the physician workforce was, therefore, seen as a method to lessen widespread health disparities. Since then, the share of black and Hispanic physicians in the workforce has increased marginally. The US population has become more racially and ethnically diverse and disparities in access to care persist. It is not known, however, whether minority physicians currently care for a higher proportion of vulnerable patients than white physicians; if so, renewed efforts to diversify the physician workforce might improve access to care for these populations.

METHODS: We analyzed the 2010 Medical Expenditure Panel Survey (MEPS) which collects data annually on a nationally representative sample of non-institutionalized US residents regarding demographics, insurance status, use of health services and the characteristics of respondents' physicians, including race. Our study sample consisted of adults (age >=18) who reported having a physician as their usual source of care and who identified their physician's racial/ethnic background ($n=7070$). We examined the association between physician race/ethnicity and the care of vulnerable patient populations by estimating the odds ratios (and 95 % confidence intervals [CI]) for being cared for by a minority (black, Hispanic, Asian) vs. a non-Hispanic white physician for respondents who were low income, defined as living below 200 % of poverty (vs. higher income), had Medicaid (vs. other insurance types), were uninsured (vs. insured), spoke a language other than English at home (vs. English spoken at home) or were of minority race/ethnicity (vs. white). We also estimated the association between the specific race of the patient and that of his/her physician (white, black, Hispanic or Asian). Finally, we repeated these analyses using multivariable logistic regression to control for other characteristics of the provider (age, gender, office setting, region of the country and metropolitan statistical area).

RESULTS: The odds of being cared for by a minority physician were higher for low income (OR, 1.65; 95%CI [1.37, 1.98]), Medicaid (OR, 2.8; 95%CI [2.30, 3.40]), non-English speaking (OR, 9.53; 95%CI [7.05, 12.88]), uninsured (borderline significance, with OR, 1.26; 95%CI [0.98, 1.62]) and racial and ethnic minority (OR, 7.04; 95%CI [5.81, 8.52]) patients. Adjustment for physician characteristics in multivariable models did not alter these findings. The association between patient and physician specific race/ethnicity were stronger: relative to non-Hispanic white patients, black patients were more likely to be cared for by a black than a white physician (OR, 23.24; 95 % CI [16.28, 33.17]), Hispanic patients were more likely to be cared for by a Hispanic than a white physician (OR, 19.04; 95 % CI [13.47, 26.93]) and Asian patients were more likely to be cared for by an Asian than a white physician (OR, 25.73; 95 % CI [16.92, 39.13]).

CONCLUSIONS: Physicians of minority race and ethnicity currently play a disproportionately large role in the care of medically disadvantaged patients. Increasing the racial and ethnic diversity of the physician workforce could ameliorate persistent disparities in access to care for medically disadvantaged patients.

PHYSICIAN VIEWS OF COST-CONTAINMENT STRATEGIES

Susan D. Goold[1,2]; Jon C. Tilburt[3,4]; Matthew Wynia[8]; Katherine M. James[4]; Robert Sheeler[6]; Jason Egginton[5]; Mark Liebow[1]; Bjorg Thorsteinsdottir[4,7]; Marion Danis[9]. [1]University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Mayo Clinic, Rochester, MN; [4]Mayo Clinic, Rochester, MN; [5]Mayo Clinic, Rochester, MN; [6]Mayo Clinic, Rochester, MN; [7]Mayo Clinic, Rochester, MN; [8]American Medical Association, Chicago, IL; [9]Clinical Center, NIH, Bethesda, MD. (Tracking ID #1633204)

BACKGROUND: Given physicians' key role in the health system, we examined their enthusiasm for cost containment strategies and how this varied by physician and practice characteristics.

METHODS: In mid-2012 we surveyed a random sample of 3,897 practicing US physicians from all specialties in the AMA Physician Masterfile. Respondents rated their enthusiasm (not, somewhat, very enthusiastic) for cost-containment strategies. Multivariate logistic regression analyzed relationships between physician and practice characteristics and enthusiasm for each strategy.

RESULTS: 2556 of 3897 returned completed surveys (RR 65 %). Physicians responded most favorably to a strategy promoting continuity of care. (Table). Surgeons and procedural and non-procedural specialists were less enthusiastic than primary care physicians about reducing compensation for highly paid specialties (ORs 0.1, 0.2 & 0.5; 95 % CIs 0.1–0.2, 0.1–0.2 & 0.4–0.7). Specialists reported more enthusiasm for penalizing avoidable readmissions (ORs 1.7 & 1.3; 95 % CIs 1.3–2.1 & 1.1–1.7); procedural specialists reported less enthusiasm for bundled payment (OR 0.6; 95 % CI 0.5–0.8). Physicians paid salary or salary plus bonus were more enthusiastic about electronic health records (ORs 1.9 & 2.3; 95 % CIs 1.4–2.4 & 1.8–2.9) and bundled payment (ORs 2.2 & 1.7; 95 % CIs 1.7–2.8 & 1.4–2.1); salary only physicians were more enthusiastic about eliminating fee-for-service payment (OR 4.0; 95 % CI 3.1–5.3). Physicians in group/HMO settings reported more enthusiasm than those in solo/small groups for electronic health records (OR 2.3; 95 % CI 1.8–2.9), eliminating fee-for-service (OR 2.2; 95 % CI 1.6–2.9), quality and safety data (OR 1.5; 95 % CI 1.1–2.2), limiting access to expensive treatments (OR 1.8; 95 % CI 1.3–2.4), chronic disease coordination (OR 1.9; 95 % CI 1.0–3.7) and using cost-effectiveness data (OR 1.7; 95 % CI 1.2–2.3). Those in governmental settings responded similarly to group/HMO physicians. Independents and liberals were more enthusiastic than conservatives about most strategies except for high-deductible health plans and higher co-pays.

CONCLUSIONS: US physicians expressed enthusiasm for cost-containment strategies that could enhance quality, e.g., decision support, continuity of care, and improving conversations with patients. Linking evidence with decision-making and reducing insurance coverage for marginally-beneficial, high-cost services found some support. There was less enthusiasm for financing reforms, although that varied by specialty, compensation and practice setting.

PHYSICIANS CARING FOR PHYSICIANS - A QUANTITATIVE SURVEY J. H. Isaacson; Kathryn Teng; Sarah Schramm; Sam Butler; Michael Felver; Craig Nielsen; Carmen Paradis; MIchael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Tracking ID #1641480)

BACKGROUND: How physicians provide longitudinal primary care to physician-patients has not been well studied. In focus groups, we identified that physicians perceived that caring for physician-patients differed from caring for other patients. The objective of this study was to explore these differences. Specifically, we looked at the 5 themes: differences in care; benefits; challenges; specific strategies employed; and the perceived importance of each specific strategy.
METHODS: We surveyed all Cleveland Clinic Medicine Institute primary care physicians (pcps) using an anonymous, web-based application. The survey consisted of 18 Likert-scale questions, five Yes/No questions, and two open-ended questions grouped into the five themes listed above. Data was analyzed using the Wilcoxon-Mann–Whitney two sample test and the yes/no responses were analyzed using either a chi-square or a Fisher's exact test.
RESULTS: Of 210 physicians, 88 (42 %) responded. Mean age was 47.6; mean years in practice was 16.6. 47 % were women. Regarding differences in care, participants agreed or strongly agreed they were more likely to follow the same protocol for chart documentation (88 %), communicate results in the same way (54 %), and change their schedule to accommodate physician-patients (44 %). They disagreed/strongly disagreed that they ordered more tests or procedures (58 %) or had trouble maintaining boundaries (66 %). Benefits of providing care to physician patients included feeling their work was valued (60 % agree/strongly agree) and greater ease in discussing complex issues (68 % agree/strongly agree). Challenges included more anxiety or self-doubt when caring for physician patients (49 % agree/strongly agree). Participants felt it was important to use the following strategies when caring for physician-patients: make recommendations based on evidence-based medicine (83 %) follow routine assessment and examination protocols (87 %), follow routine scheduling and communication protocols (50 %), recommend the same follow up visit schedule (60 %), and define boundaries of the relationship (45 %). In practice, most respondents reported using the same strategies when caring for physicians and non-physicians except for scheduling and communication protocols. Physicians with greater experience reported less anxiety (−0.2 per decade in practice, p=0.04), felt that their work was more valued (0.3 per decade, p=0.003), and agreed more strongly that caring for physician-patients was not different from caring for other patients (0.3 per decade, p=0.01). They were also less likely to follow routine assessment and examination protocols (−0.2 per decade, p=0.04) and to define boundaries of the relationship (−0.3 per decade, p=.04). Similarly, for each 10 unit increase in number of physician-patients seen, the need to define boundaries decreased by 0.2 (p=0.04).
CONCLUSIONS: Physicians perceive caring for physicians as different and rewarding, though some find it anxiety-provoking. Many are willing to make concessions regarding scheduling and testing. With increasing experience, anxiety decreased, as did the need to follow protocols and maintain boundaries.

PHYSICIANS USING MODERN PRACTICES FOR EXCELLENT DOCUMENTATION AND CARE IN HEART FAILURE (PUMPED CHF) Annia Cotorruelo-Martinez[1]; Jay N. Patel[1]; Nicole Gill-Duncan[1]; Philippe Leveille[1]; Julie M. Pearson[2]; Kell Julliard[2]; Archana Saxena[1]. [1]Lutheran Medical Center, Brooklyn, NY; [2]Lutheran Medical Center, Brooklyn, NY. (Tracking ID #1641659)

BACKGROUND: The goal of this study was to test the effectiveness of a multifaceted intervention, including a novel online training program, designed to improve resident documentation and knowledge related to congestive heart failure (CHF).
METHODS: We developed a web-based educational curriculum with two main goals in mind; to educate residents on CHF diagnosis and management based on the ACGME core competencies and to emphasize the importance of appropriate chart documentation. The course reviewed what should be included in documentation of a CHF patient by walking the learner through the various sections of a patient chart. A pre- and post-test administered immediately before and after the online course assessed knowledge that changed as a direct result of the course (maximum score 14 points) and allowed residents to identify individual areas for improvement. The study team also individually coached residents who completed the course in the proper assessment, treatment and management of one CHF patient while on the medicine floors. To measure the application of the online course and one-on-one coaching on actual chart documentation, charts from patients with systolic CHF with left ventricular ejection fraction (LVEF) less than 50 % were scored using a 39-point scoring system. The scoring system included: CHF symptoms, signs, behaviors, functional class, LVEF assessment, discharge medications, patient education, and other transition of care resources. Chart documentation scores from the intervention group of residents were compared with a historical control of patient charts meeting the same inclusion criteria.
RESULTS: Knowledge of CHF documentation significantly increased after the online educational course from a mean of 10.6 (76 %) to 12.6 (90 %) (p<0.001). The mean documentation score of the patient charts (n=50) in the historical control group was 46 % compared to 58 % in the charts reviewed after the educational intervention (n=47).
CONCLUSIONS: Despite a significant increase in knowledge scores following the online educational course, there was only a slight increase in documentation scores—even with ongoing mentoring. The data from the chart review suggests that the online component was not sufficient to create sustained change. Additional teaching modalities to use in conjunction with online learning need to be identified in this setting to foster resident education and improvement on a continuous basis to ultimately result in sustained behavior change.

PHYSICIANS' PROPENSITY TO DISCUSS PROGNOSIS ON PATIENTS' PROGNOSIS AWARENESS FOR METASTATIC LUNG OR COLORECTAL CANCER Michael Pang-Hsiang Liu[1]; Mary Beth Landrum[1]; Jane C. Weeks[2]; Haiden A. Huskamp[1]; Katherine L. Kahn[3]; Yulei He[1]; Jennifer W. Mack[2]; Nancy L. Keating[1,4]. [1]Harvard Medical School, Boston, MA; [2]Dana-Farber Cancer Institute, Boston, MA; [3]University of California at Los Angeles, Los Angeles, CA; [4]Brigham and Women's Hospital, Boston, MA. (Tracking ID #1641780)

BACKGROUND: Understanding one's prognosis is essential for terminally-ill patients, as it will influence their treatment preferences. However, many patients have a limited awareness of their prognosis, and little is known about the impact of physicians' propensity to discuss prognosis on patients' prognosis awareness. We collected information from a large cohort of advanced-cancer patients and their physicians to explore the potential association of physicians' propensity to deliver prognostic information with patients' perceptions of their prognosis.

METHODS: We investigated 686 patients with metastatic lung or colorectal cancer at diagnosis who participated in the Cancer Care Outcomes Research and Surveillance study, a multiregional population-based prospective cohort study of lung and colorectal cancer patients. We included patients who were alive and reported their life expectancy at the baseline interview conducted 3–6 months after diagnosis. Patient-reported life expectancy of ≤2 years for lung cancer and ≤5 years for colorectal cancer was considered generally accurate. These patients were linked with 486 doctors who were identified by these patients as filling important roles in their cancer care and responded to the physician survey. Physicians were asked to assume they were caring for an asymptomatic patient with a life expectancy of 4–6 months and report when they would initiate discussion about prognosis with this patient. Using multivariable logistic regression, we assessed whether patients of physicians who reported discussing prognosis "now" reported more accurate awareness of their life expectancy, adjusting for patient and physician characteristics.
RESULTS: Few patients with metastatic cancers (16.5 %) reported an accurate awareness of their prognosis. Patients whose most-important-doctor reported discussing prognosis with terminally-ill patients early were more likely than those whose doctors deferred these discussions to have an accurate prognosis awareness (adjusted proportion, 18.5 % vs 7.6 %; odds ratio, 3.23; 95 % confidence interval, 1.39–7.52; P=0.006). Patients whose physician cared for more terminally-ill patients were more likely than other patients to report an accurate prognosis awareness. Individuals who died within 3 months after the interview were most likely to be aware of their prognosis, and those who lived more than 2 years were least likely to be (28.6 % vs 9.8 %; P<0.001).
CONCLUSIONS: Although few patients with advanced cancer reported an accurate prognosis awareness, physicians' propensity to discuss prognosis early was associated with more accurate reports of prognosis. This finding suggests that physicians' communication behaviors may play an important role in explaining the very low rate of prognostic understanding we observed among patients with incurable cancers. Some patients may be hindered from having an accurate understanding of their prognosis if the doctors whom they are relying on for their key decisions about their cancer tend to delay or are reluctant to discuss prognosis with them. Enhancing the communication skills of providers with important roles in cancer care may help to improve patients' understanding of their prognosis.

PHYSIOLOGIC MEASURES OF MINDFULNESS MEDITATION IN OLDER ADULTS Natalia Morone[1,2]; Sagar Kamprath[1]; Ronald Glick[1]. [1]University of PIttsburgh, Pittsburgh, PA; [2]Veterans Affairs Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1634917)

BACKGROUND: Mindfulness meditation has been associated with subjective reports of relaxation in older adults, but physiologic changes have been less well studied. Most commonly noted in the literature is an increase in the high frequency component of heart rate variability (HRV), which has been associated with an increase in parasympathetic cardiac activity via the vagus nerve. Other changes noted include decrease in heart rate (HR), blood pressure (BP), and respiratory rate (RR), which are also associated with relative predominance of parasympathetic over sympathetic nervous system cardio-respiratory control. Currently, there is little data in older adults that describe their response to mindfulness meditation. The objective of this study was to collect physiologic changes associated with mindfulness meditation in older adults. Our hypothesis was that BP, HR, and RR would significantly decrease during mindfulness meditation while HRV would significantly increase as compared to not meditating.
METHODS: Older adults participating in a clinical trial of mindfulness meditation for chronic low back pain were asked to complete an electrocardiogram (EKG). Physiologic measures were recorded after completion of the eight-week mindfulness meditation program. HRV, HR, and RR were recorded with an EKG, and BP was recorded with an automated blood pressure monitor. Participants were asked to perform a "vanilla" task (watch a documentary) for 15 minutes and then asked to meditate for 15 min while an EKG was being recorded. They were also asked to rate the quality of their meditation immediately after the meditation session (0=poor to 10=excellent). Data analyses focused on within-participant changes that occurred between meditation and the comparison (vanilla) task. To determine the effects of meditation on HRV EKG data was analyzed with Mindware HRV Software modules. It computes HR and RR from the EKG and outputs a file of interbeat interval values which were used to compute time-based statistics of standard deviation of the normal-to-normal interval (SDNN) and the square root of the mean squared differences of successive NN intervals (RMSSD).
RESULTS: Eighteen participants completed physiologic data collection. The mean age of the sample was 74 years, 12/18 (67 %) of participants were female, 14/18 (78 %) were white, 13/18 (72 %) had a least some college education, and 11/14 (79 %) made less than $40,000 per year. Participants rated the mean quality of their meditation as 8.1 (range 4–10). Participants had a significant decrease in their systolic BP measured before the neutral task and after the 15 min meditation session (123.1 vs. 114.9, P=0.002) and a significant decrease in their diastolic BP (70.9 vs. 65.2, P=0.004). They also had a significant decrease in their RR (16.1 vs. 14.3, P=0.046). HRV changed in the expected direction but did not reach statistical significance (SDNN 62.4 vs. 99.9, P=0.12; RMSSD 81.9 vs. 115.7, P=0.11).
CONCLUSIONS: A brief mindfulness meditation session significantly reduced BP and RR in older adults with chronic low back pain. Heart rate variability improved during the short session but did not reach statistical significance.

PICTURE GOOD HEALTH: A CHURCH-BASED, PHOTOVOICE INTERVENTION FOR LATINOS WITH DIABETES Arshiya A. Baig[1]; Amanda Giese[1]; Cara A. Locklin[2]; Yue Gao[1]; Sang Mee Lee[1]; Michael T. Quinn[1]; Marla C. Solomon[2]; Lisa Sanchez-Johnsen[2]; Deborah L. Burnet[1]; Marshall Chin[1]. [1]University of Chicago, Chicago, IL; [2]University of Illinois at Chicago, Chicago, ID. (Tracking ID #1635193)

BACKGROUND: Clinical trials assessing the impact of church-based programs on diabetes outcomes among Latinos are lacking. We compared the effect of a low-intensity (LI) versus high-intensity (HI) church-based diabetes self-management intervention on clinical outcomes among low-income Latino adults.
METHODS: Using CBPR, we partnered with two Latino churches in an urban, low-income neighborhood. We recruited adults with self-reported diabetes, who were non-pregnant and English or Spanish-speaking from community and church events in Chicago. Participants were randomized to the LI or HI intervention group and followed for 6 months. In the LI group, participants received mailed metabolic assessments (MMA) and a 90-min lecture on diabetes self-management at the church. In the HI group, participants received MMA and were invited to an eight-week church-based intervention of weekly diabetes self-management classes led by lay leaders trained in motivational interviewing. In weekly photovoice exercises, participants discussed photos of their lives with diabetes and shared challenges and successes in self-care. Patient navigators assisted participants in finding a physician and connected them to local resources. The primary outcome was change in A1c. Secondary outcomes included change in LDL, blood pressure, BMI, diabetes self-care, self-rated health, and self-empowerment.
RESULTS: One-hundred participants enrolled and were randomized. Their mean age was 54±12 years and 81 % were female, 98 % were Latino,

70 % only spoke Spanish at home, 87 % had a household income below $30,000, and 51 % were uninsured. Average baseline A1c was 8.0 %±2.0. HI participants attended an average of 4.6±3.3 classes; 82 % of LI participants attended the lecture. The 6-month follow-up rate was 80 %. Both groups improved in 3 self-care measures from baseline to 6-months, but the HI group had improvements in 6 more self-care areas, including mean days in past week eating a healthy diet (1.06 days, 95 % CI:0.13–1.99), eating high fat diet (−1.20, 95 % CI:−1.84- -0.56), days exercising (1.21, 95 % CI:0.36–2.07), days checking feet (1.15, 95 % CI:0.25–2.05) and a trend for days adhering to medication regimen (0.72, 95 % CI:−0.03–1.47). Improvements in 2 diet and exercise measures remained significant for the HI group when assessing for change by group over time. All participants significantly improved their self-rated health status (1.55 mean increase, 95 % CI:1.15–1.95) and diabetes self-empowerment (0.22 mean increase, 95 % CI:0.01–0.43) but differences between groups were not significant. There was a significant overall decrease in A1c at 3-months (−0.31 %, 95 % CI:−0.62- -0.01) which was not sustained at 6-months (−0.15 %, 95 % CI:−0.54-0.25); differences between groups over time were not significant. There were no significant changes in other secondary outcomes within or across arms. There was a trend for the HI group to have less contact with their physician during the study period (−1.08±−4.06 total visits and calls, p=0.10) compared to baseline than the LI group (−0.10±3.23, p=0.77). Interventions were well-received in both groups.

CONCLUSIONS: Among low-income Latino adults with diabetes, a church-based intervention can improve diabetes self-care, self-empowerment, self-rated health and, in the short-term, A1c. A high intensity intervention may improve more aspects of diabetes self-care and be a lower-cost substitute for an additional physician visit.

PILOT CLINICAL TRIAL OF A COLLABORATIVE CARE INTERVENTION TO IMPROVE SYMPTOMS AND QUALITY OF LIFE IN CHRONIC HEART FAILURE David Bekelman[1,2]; Carolyn T. Nowels[2]; Debbi Main[7]; Paul Heidenreich[5]; Brack Hattler[1,2]; Karl Lorenz[6]; Paula Meek[4]; Connor McBryde[1,2]; Stephanie Hooker[3]. [1]VA Eastern Colorado Heath Care System, Denver, CO; [2]University of Colorado School of Medicine, Aurora, CO; [3]University of Colorado, Denver, CO; [4]University of Colorado College of Nursing, Aurora, CO; [5]VA Palo Alto Health Care System, Palo Alto, CA; [6]VA Greater Los Angeles Health Care System, Los Angeles, CA; [7]University of Colorado, Denver, CO. (Tracking ID #1635628)

BACKGROUND: People with chronic heart failure suffer from numerous symptoms that worsen quality of life. We developed the CASA (collaborative Care to Alleviate Symptoms and Adjust to illness) intervention to improve symptoms and quality of life by integrating palliative and psychosocial care into chronic care. The objectives of this study were to determine the feasibility and acceptability of CASA and identify necessary improvements prior to an efficacy trial.

METHODS: The study was designed as a prospective, mixed-method, pilot clinical trial. Patients with chronic heart failure meeting eligibility criteria were recruited from outpatient cardiology clinics and inpatient medical wards of the Denver VA Medical Center and the University of Colorado Hospital. Enrolled patients were randomly allocated to CASA or another intervention also being pilot tested. The CASA intervention included: (1) Nurse phone visits with structured symptom assessments and guidelines to alleviate breathlessness, fatigue, pain, or depression; (2) a social worker who provided structured phone counseling targeting adjustment to illness and depression if present; and (3) brief weekly team meetings with a palliative care specialist, cardiologist and primary care physician who made medical recommendations to patients' primary care providers to improve symptoms. Measurements included: (1) Enrollment and retention rates, (2) medical recommendation implementation rates and quality of care measures, (3) baseline and 3 month self-report outcome measures, and, (4) an end-of-study semi-structured participant interview to collect feedback on the helpfulness of the intervention and recommendations for changes.

RESULTS: Forty-two percent of approached eligible patients enrolled, and the 17 CASA pilot participants were male with a median age of 63 years. One subject withdrew from the study early and there were <5 % missing data. Participants reported that the nursing component of the intervention was a "good source of information" about self-management and included the right number of and timing of phone visits. Some found symptoms besides those targeted by the intervention to be "most bothersome" at baseline, such as cough (12 %) and numbness/tingling in hands/feet (12 %). Participants recommended reducing the nurse phone symptom survey length. Most enjoyed speaking to the social worker, although some felt the content of the psychosocial component did not fit with their situation "because I'm not depressed." Overall, 71 of 87 (82 %) CASA collaborative care team medical recommendations were implemented (medication changes, 40/41; tests, 14/22; consults, 17/21). In terms of quality of care, all participants who screened positive for depression were either treated for depression or thought not to have a depressive disorder. Both participants who endorsed thoughts of dying were reassessed and found not to be suicidal.

CONCLUSIONS: The CASA intervention was feasible based on participant enrollment, cohort retention, minimal missing data, implementation of CASA medical recommendations, and acceptability of the intervention. Several intervention changes were made based on participant feedback, including shortening nurse symptom assessments, addressing symptoms beyond the four target symptoms, modifying the psychosocial language to make it less depression-focused, and increasing the flexibility around which psychosocial modules are provided.

POLYPHARMACY AMONG VETERANS WITH AND WITHOUT HIV INFECTION IN THE VETERANS AGING COHORT STUDY E. J. Edelman[1,2]; Kirsha S. Gordon[2]; Kathleen M. Akgün[1,2]; Cynthia Gibert[3,4]; Vincent Lo Re[5]; Ian R. McNicholl[6]; David Rimland[7,8]; Janet P. Tate[1,2]; Julie Womack[1,2]; Christina Wyatt[9]; Amy C. Justice[1,2]. [1]Yale University, New Haven, CT; [2]VA Connecticut Healthcare System, West Haven, CT; [3]George Washington University School of Medicine, Washington, DC; [4]Washington DC Veterans Affairs Medical Center, Washington, DC; [5]University of Pennsylvania School of Medicine, Philadelphia, PA; [6]UC-San Francisco, San Francisco, CA; [7]Emory School of Medicine, Atlanta, GA; [8]Atlanta Veterans Affairs Medical Center, Atlanta, GA; [9]Mount Sinai School of Medicine, New York, NY. (Tracking ID #1640956)

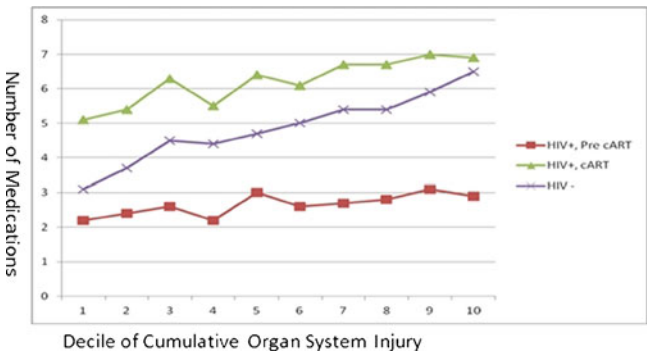
BACKGROUND: Guidelines recommend identical primary care screening and treatment criteria for HIV infected individuals (HIV+) and those without HIV (HIV−) despite greater cumulative organ system injury (and risk of adverse drug effects) and absolute burden of medication among HIV+. Because polypharmacy, defined as prescriptions for >5 medications at once, has established risks among HIV- we used data from the Veterans Aging Cohort Study (VACS) to characterize and compare rates of polypharmacy among HIV+/− Veterans. We hypothesized that combination antiretroviral therapy (cART), older age, and greater organ system injury would be associated with higher medication counts

METHODS: VACS includes HIV+ and age and race/ethnicity matched HIV- Veterans seen within the National Veterans Healthcare System. The VACS Index is composed of age and 8 routine clinical biomarkers reflecting organ system injury including: immune dysfunction, and bone marrow, liver, and renal injury—weighted to predict all cause mortality. It predicts mortality among HIV+/− with equal accuracy (C statistic 0.71). Using cross sectional data from fiscal year 2010, we calculated active medications and VACS Index scores for HIV+/− closest to the midpoint of the year. We used pharmacy fill/refill data to determine active long-term medication counts (> 90 days), including combination antiretroviral therapy (cART). Using the VACS Index score, we grouped subjects into deciles of organ injury (injury groups), and calculated median number of medications by HIV status and cART use (defined as being on >3 antiretroviral medications from

at >classes). We fit a linear regression model predicting number of medications based upon HIV status, cART exposure, age, race/ethnicity, and VACS Index score.

RESULTS: Our analysis included 53,147 subjects (16,148 HIV+ on cART; 3,235 HIV+ not on cART; and 33,764 HIV-). Association between medication count and organ injury group was strong among HIV- with median medication count doubling from 3 to >6 from the lowest to highest injury group (figure). In contast, all HIV+ on cART risk groups were on a median of ¬>5 medications and none of the HIV+ not on cART risk groups crossed this threshold. In regression models adjusting for age, race/ethnicity, and VACS Index score, compared to HIV+ not on cART, HIV- patients were on a mean of 2.2 (95 % CI 2.1–2.4) more medications and HIV+ on cART were on a mean of 3.7 (95 % CI 3.5–3.8) more medications.

CONCLUSIONS: Compared to HIV- and to HIV+ not on cART, HIV+ on cART are at substantially higher risk of polypharmacy regardless of age or organ system injury. Risk increases further with age and organ injury. Providers should be cautious when applying primary care guidelines to HIV+ on cART, given risks associated with polypharmacy among those without HIV, especially among those with decreased organ system reserve, and the lack of evidence of long-term benefit among HIV+.



POLYPHARMACY IS ASSOCIATED WITH AN INCREASED RISK OF MAJOR BLEEDING IN ELDERLY PATIENTS WITH VENOUS THROMBOEMBOLISM Waltraud Leiss[1]; Marie Méan[1]; Andreas Limacher[2]; Marc Righini[3]; Kurt A. Jäger[4]; Hans-Jürg Beer[5]; Joseph Osterwalder[6]; Beat Frauchiger[7]; Christian M. Matter[8,9]; Nils Kucher[10]; Anne Angelillo-Scherrer[11]; Jacques Cornuz[12]; Martin Banyai[13]; Bernhard Lämmle[14]; Marc Husmann[15]; Michael Egloff[5]; Markus Aschwanden[4]; Henri Bounameaux[3]; Nicolas Rodondi[1]; Drahomir Aujesky[1]. [1]Bern University Hospital, Bern, Switzerland; [2]University of Bern, Bern, Switzerland; [3]Geneva University Hospital, Geneva, Switzerland; [4]Basel University Hospital, Basel, Switzerland; [5]Cantonal Hospital of Baden, Baden, Switzerland; [6]Cantonal Hospital of St. Gallen, St. Gallen, Switzerland; [7]Cantonal Hospital of Frauenfeld, Frauenfeld, Switzerland; [8]University of Zurich, Zurich, Switzerland; [9]Zurich University Hospital, Zurich, Switzerland; [10]Bern University Hospital, Bern, Switzerland; [11]Lausanne University Hospital, Lausanne, Switzerland; [12]University of Lausanne, Lausanne, Switzerland; [13]Cantonal Hospital of Lucerne, Lucerne, Switzerland; [14]Bern University Hospital, Bern, Switzerland; [15]University of Zurich and Zurich University Hospital, Zurich, Switzerland. (Tracking ID #1630445)

BACKGROUND: Venous thromboembolism (VTE) often affects multimorbid older patients who take multiple concomitant drugs (polypharmacy). Although drug interactions with vitamin K antagonists are a potential cause of excessive anticoagulation and bleeding, whether polypharmacy increases bleeding risk in elderly patients with VTE is uncertain.

METHODS: In a multicenter Swiss cohort study, we prospectively enrolled consecutive patients aged ≥65 years who received vitamin K antagonists for acute VTE between September 2009 and March 2012. The presence of polypharmacy, defined as the use of more than four different drugs, was assessed at baseline. The outcome was the time to a first major bleeding, defined as fatal bleeding, symptomatic bleeding in a critical site, or bleeding causing a fall in hemoglobin ≥20 g/L or leading to the transfusion ≥2 units of red blood cells. We assessed the association between polypharmacy and the time to a first major bleeding using Cox proportional hazard analysis, adjusting for known bleeding risk factors (age, gender, history of major bleeding, active cancer, chronic liver disease, chronic renal disease, cardiac disease, thrombocytopenia, cerebrovascular disease, diabetes mellitus, anemia, arterial hypertension, recent major surgery and presence of symptomatic pulmonary embolism).

RESULTS: Of 830 enrolled patients, 413 (49.8 %) had polypharmacy. The mean ± SD follow-up duration was 17.8±9.3 months. The overall incidence of major bleeding was 6.4 % per person-year. Patients with polypharmacy had a significantly higher incidence of major bleeding than patients without (9.0 % vs. 4.1 % per person-year; p=0.002). After multivariate adjustment, polypharmacy remained significantly associated with major bleeding (hazard ratio 2.1, 95 % confidence interval 1.2–3.5; p=0.007). Patients with polypharmacy did not spend a higher percentage of time with an excessive international normalized ratio (>3.0) than patients without (17.7 % vs. 16.0 %; p=0.18).

CONCLUSIONS: Polypharmacy is common in elderly patients receiving vitamin K antagonists for VTE, and is an independent predictor of major bleeding. Further studies need to explore by which mechanism polypharmacy increases the bleeding risk in elderly patients with VTE.

POORLY INFORMED DECISION MAKING FOR CANCER SCREENING: RESULTS FROM A NATIONAL SURVEY Richard Hoffman[1]; Joann G. Elmore[2]; Kathleen Fairfield[3]; Bethany Gerstein[4]; Michael Pignone[5]; Carrie A. Levin[4]. [1]Albuquerque VA Medical Center, Albuquerque, NM; [2]University of Washington, Seattle, WA; [3]Maine Medical Center, Portland, ME; [4]Informed Medical Decisions Foundation, Boston, MA; [5]University of North Carolina, Chapel Hill, NC. (Tracking ID #1633671)

BACKGROUND: Cancer screening requires individuals to obtain and process key information in order to make informed decisions. We examined ratings of information sources and feeling informed about screening, cancer knowledge, and goals and concerns about screening for breast (BrCa), colorectal (CRC), and prostate (PCa) cancer.

METHODS: The TRENDS study is an Internet-based survey of US adults aged≥40 conducted in 2011. All respondents reported having experienced and/or discussed screening either for breast, colorectal, or prostate cancer in the past 2 years. Respondents rated the importance (from 0=not all to 10=extremely important) of various information sources for decision-making (health care providers, media, family), how informed they felt about cancer screening (0=not all to 10=extremely well informed), and the importance (0=not all to 10=extremely) of goals and concerns relevant to the screening decision (value of early detection and knowing cancer status). Respondents also reported the main reason for their cancer screening decision, their perceived cancer risk, and answered knowledge questions. We analyzed data with descriptive statistics (mean [SD]), ANOVA, and chi-square tests.

RESULTS: Overall, 1768 eligible respondents were surveyed: 683 BrCa, 795 CRC (491 women), and 290 PCa. The mean (SD) age was 59.9 (10.7), 76 % were non-Hispanic whites, 34 % were college graduates, and 50 % reported excellent/very good health. Respondents considered health care providers the most important information source (7.5 [2.9]), followed by family/friends (5.2 [3.3]), and then media (4.0 [3.2]). While personal preference was the main reason for BrCa decisions, provider recommendations were the main reason for PCa and CRC testing decisions. Overall, 40 % considered themselves to be at low risk for cancer and 14 % at high risk. Most respondents felt informed about cancer screening, with a mean value of 7.5 (2.2), though respondents felt less informed about PCa (6.6 [2.4]) than CRC (7.4[2.1]) or BrCa (7.9 [2.0]), P<0.001. However, respondents performed poorly on knowledge questions; only 17 % correctly answered all 3 questions while 12 % correctly answered none. Most respondents correctly answered questions about whether there was evidence for the benefit of screening (78 %), but only 29 % knew the

lifetime risk for cancer diagnosis (15 % BrCa, 44 % CRC, 20 % PCa, $P<0.001$) and only 38 % knew the risk of cancer mortality (26 % BrCa, 42 % CRC, 44 % PCa, $P<0.001$). Respondents substantially overestimated incidence and mortality risks. Respondents rated finding cancer early (9.0 [2.1]) and knowing cancer status (9.1 [2.0]) as highly important decision factors for all cancer screenings. Compared to PCa respondents (CRC respondents were not queried), BrCa respondents more highly valued avoiding false positive tests (8.5 [2.6] vs. 7.6 [2.8]), the reassurance of a negative test (9.2 [1.8] vs. 8.5 [2.3]), and avoiding dealing with harmless cancers (7.8 [3.3] vs. 6.9 [3.4]), all P-values <0.001.
CONCLUSIONS: Respondents rated early detection and knowing cancer status as highly important decision factors when considering cancer screening. Although respondents considered themselves well informed, they performed poorly on key knowledge questions. These findings highlight the need for providing information to better support informed decision-making. Health care providers, who were considered the most important source of information, are well positioned to facilitate this decision support.

PREDICTORS OF U.S. PHYSICIAN REACTIONS TO THE AFFORDABLE CARE ACT Jon C. Tilburt[2,5]; Ryan M. Antiel[1]; Katherine M. James[2]; Jason Egginton[3]; Robert Sheeler[4]; Mark Liebow[5]; Susan D. Goold6. [1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN; [3]Mayo Clinic, Rochester, MN; [4]Mayo Clinic, Rochester, MN; [5]Mayo Clinic, Rochester, MN; [6]University of Michigan, Ann Arbor, MI. (Tracking ID #1637599)

BACKGROUND: Reactions to the Patient Protection and Affordable Care Act (ACA) have been mixed. Little is known about how U.S. physicians' political affiliations, specialties, or other demographic or practice characteristics relate to their reactions to health care reform legislation. We sought to describe physicians' views about the direction the ACA might take U.S. health care, their perception of the fairness of reimbursement under the ACA, and to examine physician characteristics associated with those judgments.
METHODS: In the summer of 2012, we mailed an 8-page paper survey entitled "Physicians, Health Care Costs, and Society" to a random sample of 3897 U.S. physicians drawn from the AMA Masterfile. The survey contained two items related to the ACA: "The Affordable Care Act, if fully implemented, would turn United States health care in the right direction" (with 4-point Likert scale response categories: "strongly disagree" to "strongly agree"); and "The Affordable Care Act, if fully implemented, would make physician reimbursement…" (response categories "more fair", "less fair", "neither more nor less fair", and "not sure"). We used multivariate logistic regression in SAS 9.2 (Cary, NC) to look for associations between physicians' demographic characteristics including age, sex, region of practice, their political self-characterization, clinical specialty (categorized as primary care, surgery, procedural specialty, nonprocedural specialty, nonclinical specialty, and other), practice compensation type, and their responses to the two survey items related to the ACA.
RESULTS: Among the 2556 physicians who responded (AAPOR RR2: 65 %), two out of five (41 %) believe that the ACA will turn U.S. health care in the right direction. Only 7 % believe the law will make physician reimbursement more fair, while 44 % believe it will make physician reimbursement less fair. Physician respondents were split in self-reported political affiliation (38 % conservative, 29 % independent, 30 % liberal), the majority were male (70 %) and age 50 years or older (58 %). Compared to political conservatives, self-identified liberals and independents were both substantially more likely to endorse the ACA (OR 36.6 [95 % CI, 27.2–49.3]; OR 5.3 [95 % CI, 4.1–6.9], respectively) and to believe it will make physician reimbursement more fair (OR 12.8 [95 % CI, 6.7–24.2]; OR 5.0 [95 % CI, 2.5–9.8]; respectively) after adjusting for age, sex, race, region, and specialty. Surgeons and procedural specialists were significantly less likely than primary care providers to agree that the ACA will benefit U.S. health care (OR 0.6 [95 % CI, 0.4–0.8], OR 0.6 [95 % CI, 0.5–0.8], respectively), and were significantly less likely to believe that the ACA will render physician reimbursement more fair (OR 0.2 [95 % CI, 0.1–0.4], OR 0.4 [95 % CI, 0.3–0.7], respectively) when adjusting for age, sex, race, region, and specialty.
CONCLUSIONS: Significant subsets of U.S. physicians express concerns about the direction of U.S. health care under the ACA. Those opinions appear intertwined with political affiliation and type of medical specialty.

PREDICTORS OF CROSS-CULTURAL CARE PREPAREDNESS AMONG PHYSICIANS AND NURSES IN LAUSANNE, SWITZERLAND Alejandra Casillas[1,3]; Sophie Paroz[1]; Alexander Green[2]; Hans Wolff[3]; Patrick Bodenmann[1]. [1]Lausanne University Hospital, Lausanne, Switzerland; [2]Harvard Medical School, Boston, MA; [3]Geneva University Hospital, Genève, Switzerland. (Tracking ID #1630454)

BACKGROUND: Representing new challenges for providers, Switzerland has seen a rapid influx of migrant and at-risk patients into the safety net. We evaluated provider preparedness for commonly encountered vulnerable patient profiles, and examined determining predictors. Rather than utilize awareness or knowledge of particular cultures for self-assessment, we focused on cross-cultural preparedness- an all-encompassing and reliable indicator of cultural competence.
METHODS: This secondary data analysis comes from a broader survey on cross-cultural care at Lausanne University Hospital and Department of ambulatory care and community medicine. A 64-item questionnaire, including translated/back-translated items from the validated survey, "Residency training in cross-cultural care," was mailed in November 2010 to residents, chief residents and nurses. Preparedness items asked "How prepared do you feel to care for…?" referring to patient-profiles, such as "patients with distrust of the health care system" on an ascending 5-point Likert scale. We examined proportions of "4-well/5-very well prepared," and the mean composite score for the eight items. We used simple and multivariate linear regression to examine the effect of the following variables on the composite: demographics (gender, non-French dominant language), work (provider role, time at institution, work-unit "sensitized" to cultural-care), and items on reported cultural-competence training, and cross-cultural care problem-awareness. We determined which were significant before and after adjustment. We present results significant at the $p=0.05$ level.
RESULTS: Of 885 mailed questionnaires, 371 individuals (41.2 %) returned the completed survey: 123 (33.6 %) physicians and 239 (66.4 %) nurses, reflecting the distribution of providers in the institution. The mean composite score was 3.30 (SD 0.70) with the highest proportion of "well/very well-prepared" responses for the item referring to patients with "cultures different from your own" (67.2 %) and the lowest for "whose religious beliefs affect treatment" (21.9 %). Prior to adjustment, having a non-French dominant language ($p=0.004$), working in a sensitized department ($p=0.003$), five of eight training experience items and four of six problem-awareness items were significantly correlated with higher preparedness. After multivariate adjustment, having a non-French dominant language ($\beta=0.25$, $p=.012$), working in a sensitized department ($\beta=0.21$, $p=.007$), having received training on the history/culture of a specific group ($\beta=0.25$, $p=.03$) remained significantly associated; as did problem-awareness about the lack of practical experience caring for diverse populations ($\beta=0.25$, $p=.004$) and about inadequate cross-cultural training ($\beta=0.18$, $p=.04$). Nurse provider role ($\beta=0.221$, $p=.03$) was also associated with higher preparedness, after adjustment.
CONCLUSIONS: Self-assessed preparedness among Lausanne providers leaves room for improvement. But, speaking a non-native dominant language, working in a sensitized department, and possessing specific training experiences and problem-awareness were associated with preparedness. The positive effect of nurse role on preparedness is consistent—Swiss nurses have historically led the charge on cultural competency. These findings highlight strategies for improving provider preparedness and thus high-quality cross-cultural care: emphasizing the experience of nurses, and the institution's role in creating a diverse and culturally sensitive work environment.

PREDICTORS OF EARLY ENROLLMENT IN HOME BASED PRIMARY CARE AMONG VETERANS WITH DIABETES Samuel T. Edwards[1,2]; Julia Prentice[3,4]; Donglin Li[3]; Steven R. Simon[1,5]; Dayna Cooper[6]; Thomas Edes[6]; Steven D. Pizer[3,4]. [1]Boston VA Healthcare System, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]VA Boston Healthcare

System, Boston, MA; [4]Boston University Schools of Medicine and Public Health, Boston, MA; [5]Brigham and Women's Hospital, Boston, MA; [6]Veterans Health Administration, Washington, DC. (Tracking ID #1639784)

BACKGROUND: Intensive primary care and home-based services have the potential to reduce costs and improve quality for patients with extensive care needs, but appropriate patient selection is critical to ensure efficacy and cost effectiveness. In this study, we describe patient selection into one such program by examining predictors of early enrollment in Home Based Primary Care (HBPC), a national home care program operated by the US Department of Veterans Affairs (VA).
METHODS: We identified all Veterans who filled a prescription for any antihyperglycemic medication through VA in 2005 or 2006, who subsequently enrolled in HBPC. We extracted baseline patient data from VA and Medicare claims, and included demographics, comorbidities and inpatient bed days in the prior year. Early HBPC enrollment was defined as enrollment within 6 months of study entry, while enrollment after 6 months was defined as late enrollment. We compared baseline characteristics using descriptive statistics and performed logistic regression to determine factors that predict early versus late enrollment in HBPC.
RESULTS: We identified 25,737 diabetic Veterans enrolled in HBPC, and 6,477 enrolled within 6 months. Early HBPC patients were older (early HBPC 75.9 years vs. late HBPC 73.6 years, $p<0.001$), and more likely to be non-white race (77.6 % vs. 74.5 % $p<0.001$). Early HBPC patients had a higher prevalence of heart failure (38.5 % vs. 22.8 %., $p<0.001$), chronic lung disease (39.3 %, vs. 30.3 % $p<0.001$), paralysis (7.1 % vs. 3.4 %, $p<0.001$), depression (28.1 % vs. 18.8 %, $p<0.001$), psychosis (23.3 % vs. 16.2 %, $p<0.001$) and metastatic cancer (1.6 % vs. 0.8 %, $p<0.001$). Early HBPC patients also were also more likely to spend over 15 days in the hospital in the prior year (22.1 % vs. 10.5 %, $p<0.001$), and less likely to spend no time in the hospital in the prior year (48.9 % vs. 65.0 %, $p<0.001$). Early and late enrollees had similar rates of obesity (22.8 % vs. 22.9 %, $p=0.89$), lymphoma (1.0 % vs. 0.8 %, $p=0.13$ and alcohol abuse (4.16 % vs. 4.14 %, $p=0.92$). Drug abuse was less common in early HBPC patients (1.6 % vs. 2.2 %, $p=0.003$). Multivariate predictors of early HBPC (OR>1) or not receiving early HBPC (OR<1) are shown in the table.
CONCLUSIONS: Older patients with multiple serious chronic diseases, and those with prior hospitalization are more likely to be early enrollees in HBPC. Metastatic cancer and paralysis were strong predictors, suggesting HBPC serves those with terminal illness and physical disability. Depression and psychosis were also strong predictors, reflecting HBPC's role in mental health care. Patients with drug abuse were less likely to be early enrollees, suggesting a possible barrier to enrollment. Overall, HBPC serves elderly Veterans with multiple comorbidities and high hospital utilization. These results are consistent with appropriate patient selection and will facilitate future work to assess the impact of HBPC on utilization and health.

Multivariate predictors of early HBPC enrollment

Predictor	OR	95 % Confidence Interval
Age (per year)	1.04	1.03–1.04
> 15 inpatient hospital days	1.55	1.40–1.71
CHF	1.63	1.52–1.76
Paralysis	1.92	1.68–2.19
Metastatic Cancer	1.65	1.25–2.16
Depression	1.52	1.41–1.63
Psychosis	1.51	1.40–1.63
Drug Use	0.66	0.51–0.84
White Race	0.76	0.70–0.82

PREDICTORS OF POSTPARTUM PRIMARY CARE UTILIZATION FOR WOMEN WITH MEDICALLY COMPLICATED PREGNANCIES: AN ANALYSIS OF MEDICAL CLAIMS DATA Wendy L. Bennett[1]; Hsien-Yen Chang[2]; David M. Levine[1]; Lin Wang[3]; Donna Neale[4]; Erika Werner[4]; Jeanne M. Clark[1]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Johns Hopkins HealthCare, LLC, Glen Burnie, MD; [4]Johns Hopkins School of Medicine, Baltimore, MD. (Tracking ID #1643459)

BACKGROUND: Pregnancy complications, such as gestational diabetes mellitus (GDM) and hypertensive disorders of pregnancy (HDP), are risk factors for type 2 diabetes (DM) and cardiovascular disease. Guidelines recommend postpartum DM screening for women with GDM and reassessing blood pressure for women with HDP. We determined predictors of postpartum utilization of primary and obstetric care in the 1 year after delivery.
METHODS: We conducted a retrospective cohort study using claims data 2003–10 from a private health insurance plan and a Medicaid Managed Care Organization in Maryland. Our sample included women with ≥ one pregnancy and insurance claims 6 months prior to conception through 12 months after delivery. We compared utilization between women with complicated pregnancies (GDM, pregestational DM or HDP) and a comparison group of women who had a pregnancy without any of these complications, using ICD9 and CPT codes. The primary outcome was a primary care visit within 12 months and the secondary outcome was an obstetric visit within 3 months after delivery. We used multivariate logistic regression models to assess the association between the pregnancy complications and sociodemographic predictor variables, and utilization of care at 3 and 12 months after delivery, stratified by insurance type.
RESULTS: 37,751 deliveries accounted for 8,389 complicated pregnancies (7,741 women) and 28,054 comparison pregnancies (23,559 women). 87.2 % had Medicaid insurance. Rates of HDP, GDM and pregestational DM were 17.0 %, 9.1 % and 1.4 %, respectively. Compared to the group without complications, women with a complicated pregnancy were older at delivery (24.8 vs. 26.5 years, $p<0.001$), had higher rates of cesarean delivery (38.0 % vs. 24.6 %, $p<0.0001$) and preterm delivery (13.7 % vs. 8.0 %, $p<0.0001$). Among women with private health insurance 60.0 % in the complicated delivery and 49.5 % in the comparison group attended a primary care visit within 12 months postpartum. Half of women with Medicaid lost coverage 3–6 months after delivery. Among those with coverage≥6 months postpartum, 56.6 % in the complicated group and 51.7 % in the comparison group attended a primary care visit within 12 months. Nearly half of all women with private health insurance and 60 % of women with Medicaid attended a postpartum obstetric visit within 3 months. Among women with Medicaid, statistically significant predictors of receiving a primary care visit within 12 months postpartum included non-Black race, older age, preeclampsia or pregestational DM (but not GDM) and depression. Among women with private health insurance, statistically significant predictors of receiving primary care within 12 months included co-morbid diagnoses of thyroid disease and asthma, being a current smoker and having a mental health disorder, but not pregnancy complications.
CONCLUSIONS: Compared to women without pregnancy complications, women with GDM, HDP or pregestational DM were more likely to attend primary care visits within 1 year after delivery. Except for women with pregestational DM, fewer than 60 % of women with complicated deliveries attended a visit. Because many women lose insurance coverage within 3 months of delivery, Medicaid expansion policies have potential to improve women's post-pregnancy preventive health care, especially for women at risk of developing chronic diseases.

PREDICTORS OF POTENTIAL BLOOD PRESSURE OVERTREATMENT IN OLDER VETERANS WITH DIABETES Lillian Min[1,2]; TImothy Hofer[1,2]; Robert Holleman[2]; Adam S. Wilk[3,2]; Eve A. Kerr[1,2]. [1]University of Michigan Medical School, Ann Arbor, MI; [2]VA Healthcare Systems, Ann Arbor, MI; [3]University of Michigan School of Public Health, Ann Arbor, MI. (Tracking ID #1636412)

BACKGROUND: We have previously shown that an 80-year-old veteran with diabetes is three times more likely than a 55-year-old veteran to receive potential overtreatment for hypertension. However, we know little about how geriatric-specific co-morbidities and patterns of health care use are associated with overtreatment in older veterans with diabetes.
METHODS: We identified 280,396 veterans age 75+ with diabetes receiving ambulatory care in the Department of Veterans Affairs (VA) over 2 years (8 quarters, July 2009-June 2011) using VA National Central

Data Warehouse data. For the last visit of each quarter, we indexed low blood pressure (BP) visits with BP <130/65 mmHg. To measure the degree of potential overtreatment. for each veteran, we used anti-hypertension medication data to count the number of low-BP visits during which the veteran was also prescribed >=3 classes of BP medications continuously OR had BP regimen intensification within 3 months of the low-BP visit (a count of 8 possible opportunities per veteran). We then examined, using zero-inflated binomial regression, how specific comorbidity and utilization variables were associated with degree of potential overtreatment. Variables were age (in years, range 75–100), count of 21 general medical conditions (e.g., heart disease), count of 8 geriatric conditions (e.g., dementia), ambulatory care use (total specialty and primary care visits), and the intensity of geriatric care utilization (4 categories: general medicine with/without one geriatric consultation visit, geriatric primary care [2+ geriatric clinic visits comprising >50 % of primary care visits], or other combination of geriatric and general primary care visits). We adjusted for time exposure. On a subset of 7,227 of the older veterans who received any new geriatric care (consultation or onset of new primary care) during the 2-year time period, we performed a longitudinal analysis to measure the time relationship between potential overtreatment and onset of new geriatric care.

RESULTS: Nearly one-third (31 %) of the older veterans had a low-BP visit associated with potential overtreatment. Multivariable regression results (Table) showed that each additional year above age 75, both types of co-morbidity, and utilization all predicted greater potential overtreatment ($p<.001$ for all variables). The only protective factor was intensity of geriatric care involvement. Veterans with geriatricians as primary care providers had the least potential overtreatment compared to those with no geriatric care (.44 versus .54 visits with potential overtreatment, on average). All variables were strongly statistically significant ($p<.001$). In the longitudinal analysis, overtreatment risk was increased in the 3 quarters leading up to new geriatric care and decreased in the 3 quarters after new geriatric care.

CONCLUSIONS: Increased age, greater healthcare use, and co-morbidity all contribute to overtreatment. Short-term protection from overtreatment following geriatric clinic care suggests strategies employed by geriatricians may be useful in preventing potential overtreatment of older diabetic patients.

Variables (Effect sizes) Effect on predicted number (mean) of low-BP visits with overtreatment
Age (95 vs 75 years) .63 vs .50
Number of visits (9 vs 2) .54 vs .38
Number of general medical conditions (6 vs 3) .60 vs .40
Number of geriatric conditions (2 vs 0) .54 vs .53
Geriatric care involvement (geriatrics as primary care versus no geriatric care) .44 vs .54
$p<.001$ for all variables in the model

PREDICTORS OF SCHOLARLY SUCCESS AMONG INTERNAL MEDICINE RESIDENTS Leonardo Tamariz; Deidre T. Campbell; Mary Moore; Stephen Symes; Ana M. Palacio. University of Miami, Miami, FL. (Tracking ID #1639967)

BACKGROUND: Many residency programs have structured research curriculums that have reported scholarly success. However, the components that predict this success in a research curriculum are unknown. The aim of this study was to evaluate predictors of scholarly success in a research curriculum among internal medicine residents.

METHODS: We collected information from categorical internal medicine residents and their mentors. Resident data consisted of self-reported demographics, research knowledge using the biostatistical test survey, and USMLE scores. Mentor data consisted of number of publications and federally funded grants. We defined scholarly success as the presentation of the research project on a national meeting or publication in a peer-review journal. We calculated predictors of scholarly success using logistic regression.

RESULTS: We collected information on 156 residents and 53 mentors. The majority of the residents were males (61 %) from 26 to 30 years of age. Third year residents had the highest presentation or publication rate (71 %). Resident data like USMLE and biostatistical knowledge scores were not predictive of scholarly success ($p>0.05$). Number of papers published by the mentor (OR of 1.02; 95 % CI 1.0–1.05; $p=0.03$) and having federally funded grants (OR 6.4; 95 % CI 2.8–14.5; $p<0.01$) predicted scholarly success.

CONCLUSIONS: A research curriculum aids in achieving pre-determined milestones. Mentors play were critical in scholarly success.

Predictors of scholarly success
Predictor Odds ratio (95 % CI) p-value
PYG3 level 8.2(3.2–8.9)<0.01
Female gender 0.63(0.32–1.2)0.19
Foreign medical graduate 0.68(0.33–1.3) 0.28
USMLE score step 1 0.99(0.98–1.0) 0.26
USMLE score step 2 0.99(0.98–1.0) 0.26
Number of publications by mentor 1.02(1.0–1.05) 0.03
Number of mentor federally funded grants 6.44(2.85–14.5) <0.01

PREGNANCY INTENTION AND AMBIVALENCE IN OBESE AND NON-OBESE WOMEN Cynthia H. Chuang[1,2]; Junjia Zhu[2]; Kristen Kjerulff[2]. [1]Penn State College of Medicine, Hershey, PA; [2]Penn State College of Medicine, Hershey, PA. (Tracking ID #1643092)

BACKGROUND: Obese women have been described to be less likely to use contraception, although the reasons for this are unclear. Ambivalence toward future pregnancy (i.e., not sure if you want a future pregnancy or not) has been associated with contraceptive non-use and increased risk for unintended pregnancy. The objective of this study was to describe the future pregnancy intentions and ambivalence toward future pregnancy in obese and non-obese women.

METHODS: Participants of the First Baby Study, a cohort of 3,006 women recruited during the pregnancy of their first child, were interviewed during the 3rd trimester. Women were asked if they were intending another pregnancy in the future (Y/N) and how certain they were about those intentions (certain vs. ambivalent). Logistic regression analysis modeled the outcomes of intention and ambivalence, adjusting for age, race/ethnicity, education, marital status, pregnancy complications, and intendedness of index pregnancy.

RESULTS: There were 607 (20.4 %) obese women participating in the First Baby Study. Intention for future pregnancy did not differ by weight status, with 85.5 % of the sample intending to get pregnant again at some time in the future. However, obese women were more likely to be ambivalent about future pregnancy intentions than non-obese women (48.9 % vs. 42.7 %, $p=0.006$), which persisted in multivariable analysis (adjusted odds ratio 1.23, 95 % CI 1.01–1.50).

CONCLUSIONS: Obese women were more likely to report ambivalence regarding future pregnancy. Since ambivalence has been linked to inconsistent contraceptive behavior, this could partly explain why obese women are at higher risk for contraceptive failure and unintended pregnancy.

PRELIMINARY FINDINGS FROM A RANDOMIZED TRIAL OF A COMMUNITY HEALTH WORKER LED INTERVENTION TO IMPROVE DIABETES INTERMEDIATE OUTCOMES AMONG LATINOS WITH POORLY CONTROLLED DIABETES Olveen Carrasquillo; Sonjia Kenya; Ana M. Palacio. University of Miami, Miami, FL. (Tracking ID #1643294)

BACKGROUND: Diabetes disproportionately impacts Latino population. Community Health Workers are repeatedly highlighted as one approach that may improve cardiovascular and diabetes intermediate outcomes in this population. However, evidence from rigorous RCTs supporting this approach is very limited. We present preliminary findings from our ongoing randomized trial testing this strategy among Latinos with poorly controlled diabetes living in Miami.

METHODS: The Miami Health Heart Initiative is a NHLBI sponsored study that seeks to examine the impact of a comprehensive community health workers intervention on systolic blood pressure among poorly controlled diabetics (A1c >=8.0 %). Following a comprehensive 90 min study intake and phlebotomy eligible Latino patients ages 35–65 year are randomized to usual health care plus health education literature or the CHW intervention. The intervention consists of home visits, phone calls and group education, nutrition and community based exercise sessions. CHWs use a social determinants approach to assist with social/family needs, patient navigation and culturally tailored evidence based health education. At 1 year an RA blinded to group assignment conducts a follow-up evaluation. All three hundred patients have been randomized. In this abstract we present preliminary data on the first 120 who have been followed for 1 year. We use t-testing and linear mixed models to statistically test for the impact of our intervention on our primary outcomes.

RESULTS: Of the first 120 patients, 30 % were from Cuba and others coming from a wide variety of Latin American countries. Study attrition has been 18 % with slightly greater attrition in the control group. Intervention patients have received an average of 6 home visits, 21 completed phone calls and participated in 1.5 groups sessions. Over 80 % of intervention patients have had at least 10 CHW contacts over the course of a year. Feedback from CHWs has been that the program is making a tremendous impact on the lives of many patients. At "graduation ceremonies" held for patients completing the intervention, all have expressed overwhelming support for the program many with emotional testimonials of the major difference the program has made in their lives. As shown in table 1, as compared to the control group, in the intervention arm we have seen slight improvements in SBP and less worsening of A1C and LDL. However, these are very small differences of questionable clinical impact and our study will not be adequately powered to detect such small effect sizes.

CONCLUSIONS: In a highly heterogeneous Latino population, we are not detecting a significant impact of a comprehensive and rigorous CHW intervention on CVD and diabetes clinical outcomes. Our data does not support perceptions by our study staff, subjects randomized to the intervention, and overwhelming expert consensus in support of CHW interventions among Latino diabetics.

MMHI Preliminary findings

PREOPERATIVE HYPERNATREMIA PREDICTS INCREASED PERIOPERATIVE MORBIDITY AND MORTALITY Alexander A. Leung[1]; Finlay A. McAlister[2]; Samuel R. Finlayson[1]; David W. Bates[1]. [1]Brigham and Women's Hospital, Boston, MA; [2]University of Alberta, Edmonton, AB, Canada. (Tracking ID #1624359)

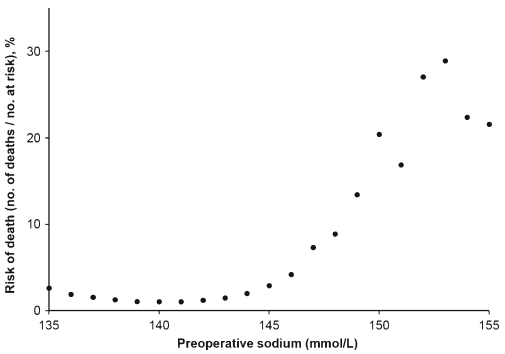
BACKGROUND: Hyponatremia has been linked to adverse perioperative outcomes. However, the prognostic implications of preoperative hypernatremia are unknown. We sought to determine whether preoperative hypernatremia is a predictor of 30-day perioperative morbidity and mortality.

METHODS: We conducted a cohort study using the American College of Surgeons-National Surgical Quality Improvement Program (ACS-NSQIP), and identified 908 869 adult patients undergoing major surgery from approximately 300 hospitals from the years 2005 to 2010, and followed them for 30-day perioperative outcomes, which included death, major coronary events, wound infections, pneumonia, and venous thromboembolism. Multivariable logistic regression was used to estimate the odds of 30-day perioperative outcomes according to the presence of preoperative hypernatremia.

RESULTS: The 20 029 patients (2.2 %) with preoperative hypernatremia (>144 mmmol/L) were compared with the 888 840 patients with a normal baseline sodium (135–144 mmmol/L). Hypernatremia was associated with a higher risk for 30-day mortality (5.2 % vs. 1.3 %; adjusted odds ratio [OR], 1.44; 95 % confidence interval [CI], 1.33–1.56), and this finding was consistent in all subgroups. The risk increased according to the severity of hypernatremia ($p<0.001$ for pairwise comparison for mild [145–148 mmol/L] vs. moderate to severe [>148 mmol/L] categories). Furthermore, hypernatremia was associated with a greater risk for perioperative major coronary events (1.6 % vs. 0.7 %; adjusted OR, 1.16; 95 % CI, 1.03–1.32), pneumonia (3.4 % vs. 1.5 %; adjusted OR, 1.23; 95 % CI, 1.13–1.34), and venous thromboembolism (1.8 % vs. 0.9 %; aOR, 1.28; 95 % CI, 1.14 to 1.42).

CONCLUSIONS: Preoperative hypernatremia is associated with increased perioperative 30-day morbidity and mortality.

Risk of 30-day perioperative mortality according to preoperative sodium level



PREPARING PRACTICES TO BE PATIENT-CENTERED MEDICAL HOMES: PATIENT INTEREST IN SELF-MANAGEMENT SUPPORT PROGRAMS Christopher Sciamanna[1]; Vijay A. Patel[1]; Jennifer Kraschnewski[1]; Dino A. Messina[2]; Heather Stuckey[1]; William J. Curry[1]; Cynthia H. Chuang[1]; Lisa L. Sherwood[1]; Stacy L. Hess1. [1]Penn State Hershey, Hershey, PA; [2]Danbury Hospital, Danbury, CT. (Tracking ID #1623965)

BACKGROUND: To qualify as a Patient-Centered Medical Home, practices will need to support patient self-management, yet few studies have examined the interest of primary care patients. This study determined the interest of primary care patients in participating in a range of self-management programs.

METHODS: Cross-sectional survey of 483 consecutive primary care patients, assessing interest in six self-management programs, focusing on weight, stress and physical activity.

RESULTS: Interest in programs ranged from 36.3 % (group walking) to 55.3 % (group strength training). The average patient was interested in 2.7 (Standard Deviation; SD=2.2) programs and 71 % were interested in at least one program. Those reporting more days of poor physical health were more interested in the strength training program [OR=2.3 (95 % CI; 1.1–4.5)], those reporting more days of poor mental health were more interested in the online stress reduction program [OR=6.5 (95 % CI; 3.1–13.7)] and obese individuals were more interested in a group weight control program [OR=22.0 (95%CI; 9.5–50.7)], than those with a normal weight. Individuals with hypertension, diabetes and high cholesterol were no more interested in participating in any program, after adjusting for potential confounders.

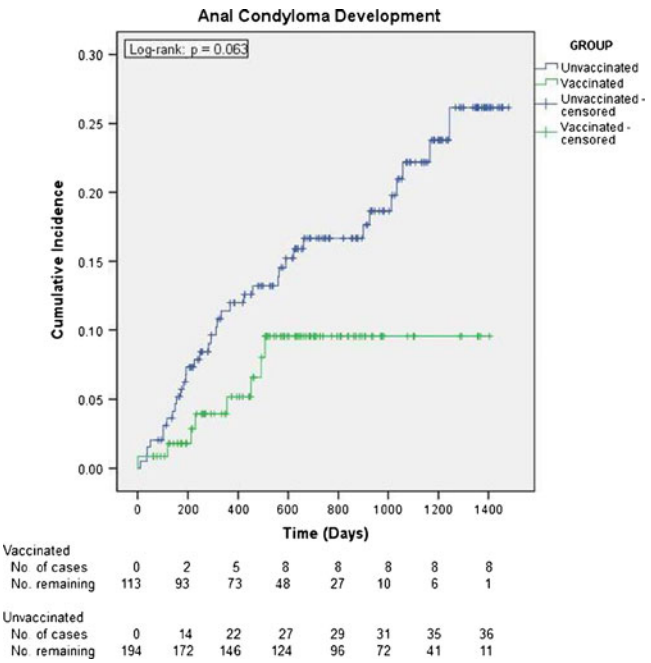
CONCLUSIONS: Self-management programs are of great interest to primary care patients and should be considered as a method for addressing the self-management support standards for Patient-Centered Medical Homes. Self-referral may be more appropriate for some programs (e.g., stress reduction for patients with poor mental health) than for others (e.g., physical activity for patients with hypertension).

PRESCRIBING PEDOMETERS IN A SAFETY-NET HEALTH SYSTEM: PILOT AND FEASIBILITY STUDY RESULTS Ann S. Barnes. Baylor College of Medicine, Houston, TX. (Tracking ID #1642408)

BACKGROUND: Physical inactivity is associated with obesity, cardiovascular disease, diabetes, and some cancers. Evidence suggests that even modest levels of light to moderate physical activity can reduce cardiovascular disease risk. While most Americans do not engage in adequate physical activity levels, low-income individuals are even less likely than their more affluent counterparts to report adherence to recommended levels. Studies have shown that physician counseling, prescriptions for exercise, and pedometers have resulted in increases in patient physical activity levels. Likewise, studies have shown that pharmacists can successfully be a part of multi-modal efforts to counsel patients on healthy lifestyle changes. The purpose of this pilot study was to determine the feasibility of 1) having physicians in a busy, safety-net, out-patient clinical practice prescribe pedometers to adult patients deemed safe for low-level physical activity (walking); 2) having patients redeem a pedometer prescription (free of charge) at the on-site pharmacy; and 3) having pharmacists engage in physical activity and pedometer counseling with patients.
METHODS: An uncontrolled clinical trial design was used for this pilot and feasibility project. All physicians from 2 out-patient health centers within a large safety-net health system in the southeast United States were invited to introduce the benefits of walking to their adult patients and to prescribe a pedometer to help their patient monitor and carry out the physical activity recommendation. The pedometer prescription was embedded within the electronic medical record formulary so that the intervention fit within usual provider work-flow. Patients filled the pedometer prescription as they would any other prescription within the health center pharmacy system. Pharmacists provided brief counseling on how to use the pedometer, how to increase steps, and they provided patients with a flier about physical activity classes offered within the health system and a step-log with a self-addressed stamped envelope that could be returned to the study's principal investigator. Both the physicians and the pharmacists were provided with brief scripts to assist them with communicating with their patients. Neither physicians, nor pharmacists, nor patients were provided with incentives for participation.
RESULTS: Between February 2010 and December 2010, 750 pedometers were prescribed by the two participating clinics. All physicians caring for adult patients wrote at least one pedometer prescription during the study period. Of the 750 prescriptions written, 603 were filled in the pharmacy (80 % filled). Eleven percent of participating patients returned their completed step log by mail.
CONCLUSIONS: This small pilot study demonstrates that it is feasible in a safety-net health system for busy, primary care providers to engage their patients in counseling about physical activity and to prescribe a pedometer. It also shows that the majority of patients who are given a pedometer prescription by their doctor will fill the prescription to get the device. Lastly, the pilot shows that non-traditional health promotion providers– pharmacists– are willing and able to offer health promotion advice about physical activity to patients in the context of filling patient pedometer prescriptions.

PREVENTION OF ANAL CONDYLOMA WITH QUADRIVALENT HUMAN PAPILLOMAVIRUS VACCINATION OF OLDER MEN WHO HAVE SEX WITH MEN: A NONCONCURRENT COHORT STUDY Kristin Swedish[1]; Stephen E. Goldstone[2]. [1]Montefiore Medical Center, Bronx, NY; [2]Mount Sinai School of Medicine, New York, NY. (Tracking ID #1641467)

BACKGROUND: The quadrivalent human papillomavirus vaccine (qHPV) is FDA-approved for use in males 9 to 26 years old to prevent anogenital condyloma. QHPV has been shown to decrease anal and cervical high-grade dysplasia recurrence post treatment. The objective of this study is to determine if qHPV is effective at preventing anal condyloma among MSM 26 years of age and older.
METHODS: This nonconcurrent cohort study evaluated HIV-negative MSM patients aged 26 and older seen in a single anorectal surgery practice in New York City during 2007–2010. Patients either had no history of anal condyloma or had previously-treated anal condyloma recurrence-free for at least 12 months prior to vaccination/time zero. We determined the recurrence rate of anal condyloma in vaccinated versus unvaccinated patients.
RESULTS: Of 308 eligible patients, 114 (37 %) patients had received the full 3-dose qHPV vaccine electively; 194 (63 %) were unvaccinated. One hundred ten (35.7 %) patients had history of anal condyloma. Vaccinated patients were significantly younger than unvaccinated patients (vaccinated mean age 38.5 +/− 7.4 years, unvaccinated mean age 44.2 +/−10.4, $p<0.001$) and were more likely to test positive for oncogenic HPV within 8 months prior to study entry (vaccinated 43.9 %, unvaccinated 33.5 %, $p=0.03$). Groups were comparable in respect to race/ethnicity; insurance type; smoking status; history of anal condyloma; history of high-grade anal intraepithelial neoplasia; and history of gonorrhea, chlamydia, and syphilis. The incidence of anal condyloma among vaccinated patients was 4.6 per 100 person-years; the incidence among unvaccinated patients was 8.7 per 100 person-years. After adjustment for history of anal condyloma and oncogenic HPV status, qHPV was associated with decreased risk of anal condyloma development, though did not reach significance (hazard ratio 0.47; 95 % confidence interval 0.22–1.04; $p=0.063$).
CONCLUSIONS: Among MSM 26 years of age and older with and without history of anal condyloma, qHPV appears to reduce the risk of anal condyloma development and the risk of recurrence in those who had been condyloma-free for at least 1 year prior to vaccination. A randomized controlled trial is needed to confirm these findings in this age group.
Time to development of anal condyloma among vaccinated and unvaccinated MSM 26 years of age and older, New York City, April 2007 - April 2011 ($N=308$).



PRIMARY CARE CLAIMS EXPERIENCE OF MASSACHUSETTS MALPRACTICE INSURERS: LESSONS FOR IMPROVING SAFETY AND REDUCING RISK Gordon D. Schiff[1,5]; Ann Louise Puopolo[3]; Anne Huben-Kearney[4]; Carol Keohane[3]; Peggy McDonough[4]; Ellis R. Bonnie[4]; David W. Bates[1,5]; Madeleine Biondolillo[2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts Department of Public Health, Boston, MA; [3]CRICO/Risk Management Foundation, Boston, MA; [4]Coverys, Boston, MA; 5Harvard Medical School, Boston, MA. (Tracking ID #1641654)

BACKGROUND: Despite prior focus on high-impact inpatient cases, the outpatient setting, particularly primary care, is increasingly recognized as a major contributor to malpractice claims and risk. In order to study outpatient malpractice experience and identify areas for improvement, the Massachusetts Department of Public Health, leading academic and safety partners, and the state's two leading malpractice insurers came together to share data and lessons from primary care malpractice cases as part of an AHRQ-funded malpractice reduction initiative.
METHODS: Databases from the two insurers were queried for all claims closed during the 5 years between 2004 and 2009 that involved adult primary care physicians and practices. For each year, statistical analyses were performed on the number of closed claims, patient diagnosis, physician named, disposition of case, classification of breakdown in the process of care (e.g. diagnosis, medication), and subclass of the alleged breakdown (e.g. for diagnosis: history/physical/evaluation of symptoms, ordering of tests, test interpretation, etc.). Statistical t-tests of comparison between outcomes of primary care vs. non-primary care cases were also performed using SAS.
RESULTS: During the study period, an average of 3,305 general medical staff/fellow physicians were covered by the two insurers, and 551 malpractice claims involving 595 physicians were registered, giving an overall rate of 3.3 cases per year per 100 physicians covered. A total of 595 physicians were named in these 551 cases. Breakdown in care processes occurred most frequently in the following areas: diagnosis (397 cases; 72.1 %), medication management (66 cases; 12.3 %), other medical treatment (41 cases; 7.4 %), communication (15 cases; 2.7 %), patient rights (8 cases; 1.5 %), and patient safety/security (8 cases; 1.5 %). Leading diagnoses involved in cases were cancer (190), heart diseases (48), blood vessel diseases (27), infections (22), and CVA (16). Notably, among cancer cases, 129 (68 %) were one of four cancers: colorectal, lung, prostate, and breast. Each of these leading cancers had a distinctive pattern and frequency of breakdown points and patient characteristics; for example, among 56 colorectal cancer cases with allegations related to diagnosis error 9 patients (16 %) were 49 years old or younger. Ambulatory cases were also significantly more likely to be settled (35 % vs. 20 %), or result in plaintiff verdict (2 % vs. 1 %) compared to non-general medical malpractice claims.
CONCLUSIONS: Review of malpractice claims for primary care physicians in Massachusetts showed that such cases represent a substantial burden, and point to key areas of system failure and patient risk. Failure or delays in diagnosis, particularly breast, lung, colorectal, and prostate cancers, accounted for the most cases, and each had its own patterns of failure distribution. Targeting routine outpatient processes that create vulnerabilities to these types of adverse patient outcomes represents a priority for preventing both patient harm and associated malpractice lawsuits, especially as they appear to be more difficult to defend.

PRIMARY CARE INTERNAL MEDICINE WORKLOAD OUTSIDE THE CLINIC ENCOUNTER: A VOLUME/TIME STUDY Lori A. Brown; Neil J. Farber; Jessica J. Chen; John Fontanesi. UCSD, La Jolla, CA. (Tracking ID #1631884)

BACKGROUND: Primary care practices are besieged by increasing demands including changes of workflow and scope of work brought about by electronic medical records (EMRs). Previous studies have examined the changes in physician workload and scope of work using survey instruments or administrative data to examine these changes. However, these studies likely under-represent what is now expected of academic practicing physicians. This study attempts to capture a more complete picture of the workload and scope of work of physicians working with an EMR in an academic setting by combining direct workflow observations with time analysis of activities outside of the clinic.
METHODS: This study was part of larger data acquisition for a quality improvement initiative conducted at the Internal Medicine Group (IMG) of the University of California, San Diego in March, 2011. The study included standardized direct workflow observations of patients, staff, and physician. Data included detailed time-motion analyses of EMR activities including E-prescriptions, E-mail, lab imaging consultations, and documentation functions. Volume of extra-clinical patient care activities are logged into and date and time-stamped by the EMR, captured via administrative logs for each physician for a 90 day period. Data reflecting each physician's percent of time in clinical activities was converted to a full time equivalent (FTE), and a multiplier of the FTE was applied to the number of tasks performed. The converted numbers of tasks then converted to hours per categorical task per 90 day period. Using U.S. Bureau of Statistics, the 90 day periods were converted into annualized hours per task category. Using the assumption of 18.5 workdays/ month, with each workday 8.1 h long, the annualized hours were converted to an average clinical workday. The gender and part-time vs. full-time status of the physicians were compared with the results of the workload data via student's T-tests.
RESULTS: For every 8 h of direct patient care time, physicians spent an average of 3:55 h (3:00–4:10 h) engaged in various forms of documenting and responding to clinical communications. Phone call accounted for 1:40 h of time (1:33–1:68 h), with assessing laboratory results accounting for 0:73 h (0:57–0:95 h) and e-prescriptions accounting for 0:54 h (0:51–0:66). No significant effects were seen for gender or work status of the physicians in this study.
CONCLUSIONS: Academic primary care general internal medicine physicians in this study spend a significant percentage of time in responding to communications and documenting the management of their patient's health outside of the clinical encounter when utilizing EMRs and workload is unrelated to gender of the physician and work status. Particularly with impending shortages of U.S. primary care physicians and data indicating burnout in primary care, there is an urgent need to address the large amount of physician's workload occurring outside the clinical encounter. In addition, competing demands on academic general internists with teaching and scholarly pursuits can make it difficult to continuously monitor patient care activities occurring outside the patient visit. Academic general internal medicine clinic directors should consider addressing potential changes in workflow particularly in this setting.

PRIMARY CARE PHYSICIAN-DEFINED COMPLEXITY AND OUTPATIENT CHARLSON SCORE AS PREDICTORS OF HEALTH CARE UTILIZATION Clemens S. Hong[1]; Richard W. Grant[2]; Yuchiao Chang[1]; Jeffrey M. Ashburner[1]; Wei He[1]; Timothy Ferris[1]; Steven J. Atlas[1]. [1]Massachusetts General Hospital, Boston, MA; [2]Kaiser Permanent, Division of Research, Oakland, CA. (Tracking ID #1642668)

BACKGROUND: Health system redesign efforts increasingly focus on patients with complex health needs. We evaluated a previously validated predictive algorithm for physician-defined complexity (PDC), alone, and in combination with complexity defined using outpatient Charlson score, as predictors of primary care (PC) and acute care utilization.
METHODS: We applied the PDC predictive algorithm and outpatient Charlson score to a 2007 cohort of 143,372 PC patients in an academic primary care network. We defined complex patients using each algorithm. We used a risk score threshold for PDC that reflected maximized model accuracy (15.7 % of patients complex), and an outpatient Charlson score threshold of ≥3 (18.9 % of patients complex). We investigated PC and acute care utilization outcomes over the subsequent 4 years comparing three classifications of patient complexity: 1) complex by Charlson, but not PDC (Ch), 2) complex by PDC, but not Charlson (P), and 4) complex by both Charlson and PDC (ChP).
RESULTS: Over 75 % (108,081) of PC patients were not complex by either algorithm; 14.6 % (20,977) of patients were complex by only one algorithm (8.8 % in the Ch group and 5.8 % in the PDC group); 10.0 % (14,314) were complex by both algorithms. Table 1 shows patient characteristics of the 4 complexity groups. Compared to the Ch group (12.7 visits), P group patients (8.8 visits, $p<0.01$) visited their PC practice less and ChP patients (14.7 visits, $p<0.01$) visited their PC practice more frequently over 4 years. On average, PDC patients made a greater number of ED visits (0.8 v 0.5 visits, $P<0.01$) and were hospitalized more (0.5 v 0.4 admits, $P<0.01$), but there was no difference in the number of 30-day readmissions (0.06 v 0.05 $P=0.10$) in 4 years of

follow-up. However, a statistically significant difference in 30-day readmissions with the same directional trend was seen at 2 and 3 years (data not shown). ChP patients made a greater number of ED visits (0.9 v 0.5 visits, $P<0.01$), were hospitalized more often (1.2 v 0.4 admits, $P<0.01$) and had more frequent 30-day readmission (0.20 v 0.05 admits, $P<0.01$).

CONCLUSIONS: Physician-defined complexity is a distinct construct from complexity defined by Charlson score, with 14.6 % of all patients defined as complex by only one of the two algorithms. PDC is correlated with decreased primary care engagement and increased acute care utilization in unadjusted analyses compared to Charlson-defined complexity. The complexity cohort defined by both algorithms appears to be at even higher risk for acute care utilization. PDC may enhance current risk prediction approaches and help identify complex patients that are both at high risk for future acute care utilization and challenging for physicians to manage.

Table 1: Patient Characteristics and Healthcare Utilization Outcomes in 3 Complexity Groups

Variable	Complex By Charlson (Ch) N=12,723	Complex By PDC (P) N=8,254	Complex by Both (ChP) N=14,314	P-value PDC vs Ch	P-value ChP vs Ch

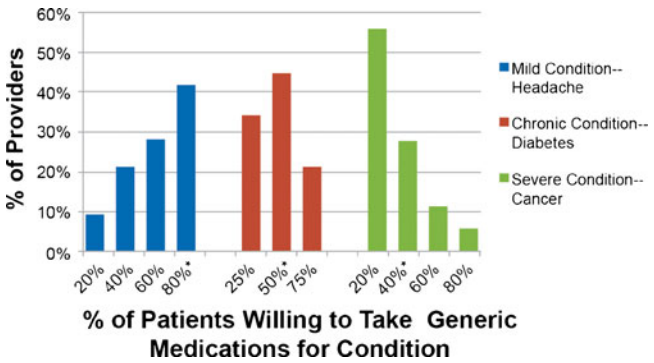
PRIMARY CARE PROVIDER AWARENESS OF THE PREVALENCE OF BELIEFS ABOUT GENERIC MEDICATIONS AMONG PATIENTS Kristin Whitely; Susan J. Andreae; Monika Safford. University of Alabama at Birmingham, Birmingham, AL. (Tracking ID #1637328)

BACKGROUND: Medication adherence plays a vital role in the effective treatment of chronic illness, yet previous studies suggest that more than half of patients with chronic illnesses do not take their medications as directed. Among the hypothesized barriers to adherence include cost. This is especially relevant in the Southeast, where both chronic disease and poverty are more prevalent than elsewhere in the U.S. Findings from our previous study, which surveyed a sample of Southeastern patients with chronic diseases, indicated that many patients in this population might hold misconceptions regarding generic medications despite their cost-related benefits. Primary care providers could address such concerns directly, yet no studies have examined provider awareness of these misperceptions. Therefore, we surveyed practicing primary care physicians in the Southeast to assess provider awareness regarding patient misperceptions of generic medications.

METHODS: We developed an online, case-based, educational module on generic medications as part of an ongoing continuing medical education (CME) program targeted at a network of primary care physicians, physicians' assistants, and nurses practicing in Mississippi and Alabama that receive monthly education modules for CME credits. Based on a previously completed survey of beliefs of Southeastern primary care patients with chronic medical conditions, the 11-item pre-test assessed providers' estimates of the prevalence of beliefs in their patients. Completed prior to the education module, the survey asked providers to estimate the prevalence of patient beliefs about issues such as the efficacy and side effects of generic medications and patients' willingness to use generics for various medical conditions. We contrasted primary care provider estimates with the actual prevalence reported on the patient survey.

RESULTS: There were 161 respondents to the provider survey. Overall, only 43 % of providers correctly estimated the prevalence of patient beliefs: 50 % of patients believed that generics were less efficacious than brand name medications, and 49 % of providers correctly estimated this prevalence; 50 % of patients believed that generics have more side effects, and 58 % of providers correctly estimated this prevalence (see also Figure).

CONCLUSIONS: Fewer than half of these Southeastern primary care providers accurately estimated the prevalence of beliefs about generic medications among Southeastern patients. Greater awareness of patient beliefs about generic medications among these providers could enhance the uptake of generic medications in this population. These findings may be useful for the design of future interventions aiming to increase utilization of generic medications in the rural Southeast, which would alleviate cost as a barrier to medication adherence.



PRIOR INCARCERATION IS ASSOCIATED WITH DISTRUST IN THE HEALTH CARE SYSTEM BUT NOT WITH TRUST IN HEALTH CARE PROVIDERS Aaron D. Fox; Joanna L. Starrels; Chinazo Cunningham. Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1640728)

BACKGROUND: To optimize engagement in health care, patients must trust their provider and the health care system. In buprenorphine treatment for opioid dependence, patients must trust their providers enough to disclose sensitive information such as ongoing drug use. Frequently in the United States, incarceration co-occurs with opioid dependence, and the negative experiences of incarceration may engender mistrust. Further, experts recommend that patients who are court-mandated to substance abuse treatment be treated in integrated care where treatment providers report directly to the criminal justice system; however, this may also compromise trust. In this study, we investigated prior incarceration and levels of trust, hypothesizing that trust would be lower in those with a history of incarceration than in those without.

METHODS: We conducted a cross-sectional study of opioid-dependent individuals who initiated buprenorphine treatment at an urban community health center. Treatment providers did not report directly to the criminal justice system. Questionnaires assessed demographic information, substance use, health status, prior incarceration, and two measures of trust. Dependent variables were: (1) trust in health care provider and (2) distrust in the health care system. For each trust variable, participants rated seven statements using a 5-point scale (1=strongly disagree, 5=strongly agree), and we used the mean of these seven items as a summary score. There were two main independent variables: (1) any incarceration (≥ 3 days within lifetime; yes/no) and (2) recent incarceration (≥ 1 day in the previous 30 days; yes/no). We tested the associations between each independent and dependent variable using four separate linear regression models, adjusting for demographic and clinical covariates that were associated with the independent variables in bivariate testing.

RESULTS: Of the 91 participants, most were male (74 %), Hispanic (69 %), and unstably housed (62 %). Thirty percent were HIV-positive, and the mean age was 44 years. Any incarceration occurred in 64 (70 %), and of these, 14 (15 %) had recently been incarcerated. Those with any incarceration were more likely to be male and unstably housed than those

without. Overall, trust in health care provider was high (3.48±0.56, mean ± SD) but distrust in the health care system (3.30±0.94) was also high. In unadjusted analyses, any (vs. no) incarceration was associated with greater distrust in the health care system (3.45±0.95 vs. 2.95±0.83, p=0.01), but was not associated with trust in health care provider (3.60±0.60 vs. 3.66±0.57, NS). Recent (vs. no) incarceration was also associated with distrust in the health care system (3.84±0.74 vs. 3.21±0.94, p=0.02), but was not associated with trust in health care provider (3.36±0.64 vs. 3.66±0.69, NS). Adjustment for covariates did not change significance.
CONCLUSIONS: Prior incarceration was common in this cohort of buprenorphine-treated patients. Distrust in the health care system was high and significantly associated with prior incarceration, while trust in one's health care provider was high regardless of prior incarceration. The potential for negatively impacting this high level of trust by requiring providers to report directly to the criminal justice system should be evaluated before integrated models of court-mandated substance abuse treatment are fully implemented.

PRIVATE FOR-PROFIT OPIOID TREATMENT PROGRAMS PROVIDE FEWER COMPREHENSIVE SERVICES THAN NON-PROFIT AND PUBLIC PROGRAMS Marcus A. Bachhuber[1]; William Southern[2]; Chinazo Cunningham[1]. [1]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1625676)

BACKGROUND: Skyrocketing rates of opioid addiction in the US have triggered a renewed interest in opioid treatment programs (OTPs). In addition, health reform may result in increased funding for OTPs. This funding could be distributed to private for-profit and private non-profit OTPs, or used for expansion of government-run (public) OTPs. Private for-profit OTPs may increase profits by withholding potentially beneficial services that are not reimbursed by insurance plans. To examine the relationship between ownership and services offered, we compared private for-profit, private non-profit, and public OTPs.
METHODS: We conducted a cross-sectional analysis of the 2010 National Survey of Substance Abuse Treatment Services, a voluntary nationwide survey of all US drug treatment programs. We examined five services by self-reported OTP ownership, (1) screening for co-occurring infectious diseases (HIV, sexually transmitted infections, and viral hepatitis), (2) provision of mental health care, and ancillary support with (3) social services, (4) employment, and (5) housing. We first conducted bivariate analyses comparing services offered by ownership status; then, we developed multivariable logistic regression models to examine whether differences found were due to differing epidemiologic needs. When examining whether OTPs screened for co-occurring infectious diseases, we adjusted for county-level rates of HIV, sexually transmitted infections, hepatitis C, and treatment admissions for injection drug use. For provision of mental health services, we adjusted for measures of county mental health (mean number of emotionally unhealthy days for adults and percent reporting inadequate social/emotional support) and number of mental health professionals per 100 000 persons. For provision of ancillary support, we adjusted for county-level social (proportion of persons with disabilities, veterans, high school graduates, and single-parent households), economic (proportion unemployed, under the poverty line, receiving public assistance, and receiving food assistance), and housing measures (proportion of persons who moved in the past year, renters spending >35 % of income on rent, and proportion of vacant housing units).
RESULTS: Of 1 039 OTPs offering outpatient services, 56.0 % were for-profit, 34.4 % were non-profit, and 9.6 % were public. In logistic regression models, public OTPs were more likely than for-profit OTPs to screen for infectious diseases (OR: 4.0, 95 % CI: 2.5–6.5), provide mental health assessment and treatment (OR: 21.4, 95 % CI: 12.4–36.9), provide assistance with social services (OR: 3.1, 95 % CI: 1.9–5.3), employment (OR: 1.9, 95 % CI: 1.2–2.9), and housing (OR: 2.0, 95 % CI: 1.2–3.4). Non-profit OTPs were also more likely than for-profit OTPs to screen for infectious diseases (OR: 2.1, 95 % CI: 1.5–2.8), provide mental health assessment and treatment (OR: 7.2, 95 % CI: 4.6–11.3), and provide assistance with social services (OR: 2.8, 95 % CI: 2.0–3.8), but not more likely to provide assistance with employment (OR: 0.9, 95 % CI: 0.6–1.2), or housing (OR: 1.2, 95 % CI: 0.9–1.7).
CONCLUSIONS: For-profit OTPs were less likely to provide comprehensive services than both non-profit and public OTPs. These differences persisted after adjusting for measures of epidemiologic need. Our findings suggest that investment in non-profit and public OTPs may more effectively increase the availability of comprehensive services to opioid-dependent patients.

PROACTIVE TOBACCO TREATMENT AND POPULATION-LEVEL CESSATION: A PRAGMATIC RANDOMIZED CONTROLLED TRIAL Steven Fu[1,2]; Michelle van Ryn[5]; Scott Sherman[3,4]; Diana Burgess[1,2]; Siamak Noorbaloochi[1,2]; Barbara Clothier[1]; Brent C. Taylor[1]; Anne Joseph[2]. [1]Minneapolis VA Health Care System, Minneapolis, MN; [2]University of Minnesota Medical School, Minneapolis, MN; [3]New York Harbor VA Health Care System, New York City, NY; [4]New York University School of Medicine, New York City, NY; [5]University of Minnesota Medical School, Minneapolis, MN. (Tracking ID #1637966)

BACKGROUND: Current tobacco use treatment approaches are reactive and require smokers to initiate treatment or depend on the provider to initiate smoking cessation care. As a result, most smokers do not receive evidence-based treatments for tobacco use that include intensive behavioral counseling and pharmacotherapy. Proactive tobacco treatment integrates population-based and individual-level treatment strategies to address both patient and provider barriers to tobacco cessation care. The primary objectives of this study was to assess the effect of a proactive care intervention on population-level smoking abstinence rates (i.e., abstinence among all smokers including those who use and do not use treatment) and on use of evidence-based tobacco treatments compared to reactive/usual care among a diverse population of current smokers
METHODS: We identified a population-based registry of current smokers from four Veterans Health Administration (VHA) facilities using the VHA electronic medical record health, who were randomized to proactive care or usual care. The proactive care intervention combines: (1) proactive outreach and (2) offer of choice of smoking cessation services (telephone or face-to-face). Proactive outreach included a mailed invitations followed by telephone outreach (up to 6 call attempts) to motivate smokers to seek treatment with choice of services. Because this study was testing proactive outreach, smokers were randomized prior to contact and a baseline survey was administered after randomization using a multiple-wave mailed questionnaire protocol. Outcomes from both groups were collected 12 months post-randomization from participant surveys and from VHA administrative databases. The primary outcome was population-level cessation at 1 year using a self-reported, 6-month prolonged smoking abstinence measure.
RESULTS: Current smokers (N=6400, 1600 per site) as identified by the electronic medical record were randomly assigned to proactive care or usual care with an allocation ratio of 1:1 within each site and mailed a baseline survey. The sample was diverse; 28 % African American, 62 % Caucasian, 4 % other race, and 4 % unknown race. Seven percent were of Hispanic ethnicity. In the proactive care intervention group, 2519 were mailed outreach invitation materials. During telephone outreach, 1556 (62 %) were successfully contacted. Of the participants mailed an outreach invitation packet, 392 (16 %) elected VA telephone coaching and 77 (3 %) elected in-person smoking cessation services at their VA Medical Center. The follow-up survey response rate was 67 %. We observed a significant increase in the population-level cessation rate of 2.6 %. The population-level cessation rate at 1 year was 13.4 % for proactive care compared to 10.8 % for usual care (p=0.025). In generalized linear mixed model analysis, proactive care resulted in increased odds of population-level cessation, OR=1.274 (1.033, 1.571). In additional analyses incorporating multiple imputation to estimate missing outcome measures and adjusting

for baseline group differences in age of smoking initiation, and length of prior quit attempts, the effect of proactive care on population-level cessation persisted, OR=1.220 (1.002, 1.484).
CONCLUSIONS: Population-based proactive tobacco treatment using proactive outreach to connect smokers to evidence-based telephone or in-person smoking cessation services is effective for increasing long-term population-level cessation rates.

PROGRAM LEVEL PREDICTORS OF INTERNAL MEDICINE BOARD PASS RATES Manas Kaushik[1]; Malavika Subramanyam[2]; Ashish Upadhyay[1]; Ananya Roy[3]. [1]Boston Unviersity School of Medicine, Boston, MA; [2]Indian Institute of Public Health, Gandhinagar, India; [3]Yale School of Public Health, New Haven, CT. (Tracking ID #1621950)

BACKGROUND: Aggregate pass rate of residents in American Board of Internal Medicine (ABIM) certifying exam is an indicator of residency program performance. We explored state wise and regional variation in pass rates and hypothesized that program level factors influence the aggregate performance of residents.
METHODS: We utilized prospectively collected administrative data by American Medical Association and Accreditation Council for Graduate Medical Education (ACGME) on 359 non-military, internal medicine residency programs from which residents appeared on the American Board of Internal Medicine examination in 2004–2006 and 2007–2009. We used generalized estimating equations (GEE) in SAS 9.2.
RESULTS: Mean program board pass rates varied significantly by region (West: 89.1 %, South: 90.3 %, Midwest: 92.1 %, Northeast: 92.6 %). In fully adjusted model, the program level pass rates were 2 % lower for each withdrawn sub-specialties and 0.8 % lower for each PD change. ACGME accreditation cycle length and proportion of preliminary residents were significantly associated with program pass rates.
CONCLUSIONS: Program size can limit the utility of board pass rates to be used as continuous program accreditation. Stability in program leadership and sub-specialty programs is associated, independent of ACGME's summary accreditation evaluation, with better resident preparation for delivering better patient outcomes and care.

PROMOTING COLORECTAL CANCER SCREENING AMONG URBAN AMERICAN INDIAN AND ALASKA NATIVE ELDERS: IDENTIFYING AND ADDRESSING CULTURAL ISSUES, KNOWLEDGE AND BELIEFS RELATED TO COLORECTAL CANCER AND SCREENING Shin-Ping Tu[3]; Deborah Bassett[1]; Emily R. Van Dyke[2]. [1]University of Pennsylvania, Philadelphia, PA; [2]University of Washington School of Public Health, Seattle, WA; [3]University of Washington, Seattle, WA. (Tracking ID #1624529)

BACKGROUND: Colorectal cancer (CRC) is a leading cause of cancer deaths among American Indian/Alaska Natives (AI/ANs). AI/ANs are twice as likely to be diagnosed with advanced CRC compared to non-Hispanic Whites. 50–60 % of CRC deaths can be prevented if adults aged 50 or older receive routine screening. While overall cancer mortality has declined between 1.4 and 3 % per year over the last decade, cancer mortality has not declined among AI/ANs. To promote CRC screening among AI/ANs, we examined cultural context, knowledge, and beliefs about CRC and CRC screening among urban AI/AN Elders.
METHODS: Seven focus groups were conducted in two urban settings in the Pacific Northwest (N=46) to adapt an evidence-based CRC screening intervention to urban AI/AN patients. Facilitators used field guides to discuss participant awareness and concerns about CRC and CRC screening. Our analyses consisted of examining each communicative event using ethnography of communication and Hymes' 1962 SPEAKING framework, which is a heuristic aid that enables analysis of various components of a communicative interaction. This method has been used effectively in many cultural settings to elucidate a rich understanding of communicative events. Focus group transcripts and contextual notes comprised the datasets that were analyzed using speech codes theory (SCT). Based on six propositions, SCT asserts that in any instance of communicative conduct, elements of a speech code are present and are identifiable through the speech of its users. This code reveals beliefs, premises, and rules about psychology, sociology, and the appropriate use of communicative conduct within a given speech community. Findings from the analysis of these datasets were based on the observation of repeated occurrences of components of communicative conduct, which suggest a pattern in the data rather than a single instance. We then distilled elements of speech codes that were used and understood by the focus group participants into a set of themes that elucidate a shared way of speaking about colorectal cancer among these urban AI/AN Elders.
RESULTS: Based on descriptive content thematic analysis, Table 1 summarizes common focus group themes. We identified several shared cultural norms with respect to talking about health, CRC, and cancer screening. These included norms about the use of silence and of humor by both men and women as an indicator of discomfort with a topic. These norms also revealed the importance of contextualizing CRC screening as a means of preserving AI/AN culture by prolonging the lives of AI/AN Elders so that they can share their traditions with future generations.
CONCLUSIONS: Themes identified through pre-intervention focus groups guided each step of the patient educational materials development process. Using this applied CBPR model, we created unique and compelling culturally-appropriate educational materials to encourage CRC screening among AI/AN Elders.
Table 1: Themes Identified in Seven Pre-Intervention Patient Focus Groups
Desire for educational materials specifically about AI/ANs and designed by AI/ANs
Importance of emphasizing the potential benefits of CRC screening to the patient's family and community rather than focusing on the potential to reduce individual mortality
Importance of showing that traditional ways of living in harmony on the Medicine Wheel can be achieved through health maintenance including a \"traditional\" diet, exercise, and cancer screening
Fear of death and dying leading to preference for not knowing earlier than necessary about cancer diagnosis
Aversion to CRC screening modalities due to previous abuse and resultant shame and embarrassment
Among male respondents, assumption that CRC screening requires digital rectal exam, which leads to fear that getting screened for CRC might cause questioning of their sexuality
Tension between knowing that a healthy diet, regular exercise, and regular health care will promote long-term health and difficulty accessing and affording healthy food, safe exercise spaces, and medical care
Anger over lack of access to colonoscopies given high cancer mortality among AI/ANs
Need and desire for patient advocates and outreach services to make CRC screening more readily accessible

PROMOTING LEARNER-CENTERED EDUCATION IN MORNING REPORTS Leah Tudtud-Hans; Sam Baz; Lawrence Loo. Loma Linda University School of Medicine, Loma Linda, CA. (Tracking ID #1633809)

BACKGROUND: In November 2011, the Liaison Committee on Medical Education (LCME) revised its Educational Standard (ED-5-A) stating "A medical education program must include instructional opportunities for active learning. . . to provide medical student with opportunities to develop lifelong learning skills." The LCME continues to require Schools of Medicine and departments to provide resources to enhance the teaching skills of their residents (ED-24). Our morning reports include medical students, interns, senior residents and faculty. Structuring educational conferences to meet the learning needs of this diverse group poses a challenge even for the most experienced teacher.
METHODS: We designed two worksheets to improve the educational value of our resident led morning reports. Our goals were to enhance the teaching skills of our senior resident presenters, improve self-reported learner perceptions, and to set a higher educational standard for these conferences. The first worksheet entitled "Promoting Principles of Adult & Active Learning" asks each presenter to systematically organize the conference focusing on a learner-centered approach. Each presenter is asked to (1) specify learning objectives for each major group in the audience (i.e. medical student, intern, and senior resident); (2) describe the intended interactive process to facilitate individual and or group participation; (3) utilize audiovisual aids to appeal to different learning styles; and (4) ensure the learning climate will foster participation and inquiry. The second worksheet entitled the "Value of Morning Reports" asks each member of the audience to (1) name the top 3 learning objectives addressed in the conference; (2) evaluate the conference on a 5 point Likert-like scale on clarity of presentation, degree of interaction, practical usefulness of the content, and overall learning value; and (3) open-ended comments solicited on areas of strength, areas to improve and other. Feedback is provided to the resident presenter immediately after the conference by key faculty.
RESULTS: To date, 404 total evaluations were collected. Conference evaluations before and after our educational intervention found no differences in the "overall learning value" of our morning reports when all participants were included. This is most likely due to a ceiling effect since our morning reports were already highly rated (Year 2011–4.63 versus Year 2012 4.64, p=0.93). Subgroup analysis, however, revealed that medical students consistently rated these conferences higher in all 4 categories evaluated and for "clarity of presentation," this reached statistical difference (Year 2011 4.10 versus Year 2012 4.71, p=0.001).
CONCLUSIONS: Residents often receive little training in their roles as teachers and medical educators. Our teacher's guide worksheet outlines a basic organizational approach that promotes learner-centered education and active learning. The impact of this intervention appears to be the greatest with the medical students. Our senior residents uniformly reported that the presenter worksheet helped them focused their learning goals and objectives for the different levels of learners and increased their confidence when leading morning reports. Our simple to use educational intervention can be readily applied to other institutions and helps meet both medical school (LCME) and residency (ACGME) accreditation standards for teaching and learning

PROMOTING SMOKING CESSATION AFTER HOSPITAL DISCHARGE: THE HELPING HAND RANDOMIZED CONTROLLED COMPARATIVE EFFECTIVENESS TRIAL Nancy A. Rigotti[1,2]; Sandra Japuntich[3]; Susan Regan[1]; Jennifer H. Kelley[1]; Yuchiao Chang[1]; Michele Reyen[1]; Joseph C. Viana[1]; Elyse R. Park[2]; Douglas Levy[2]; Molly Korotkin[1]; Joanna Streck[1]; Daniel E. Singer[1]. [1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Boston VA Health Care System, Boston, MA. (Tracking ID #1626274)

BACKGROUND: Hospitalization provides an opportunity for smokers to quit. Smokers who quit after hospital discharge reduce their subsequent morbidity and mortality rates and might reduce their risk of readmission. Hospital-initiated tobacco treatment is effective only if it continues for more than 1 month after discharge. Sustaining the treatment of chronic conditions like tobacco dependence from hospital to home is a challenge for health care systems to accomplish. We tested a model system to facilitate the delivery of evidence-based smoking cessation counseling and medication to hospitalized smokers after hospital discharge.
METHODS: A randomized controlled trial at 1 large urban teaching hospital compared 2 post-discharge treatments, Extended Care (EC) vs. Standard Care (SC), for smokers who were counseled during their hospital stay and wanted to quit smoking after discharge. EC provided 3 months of free medication of the patient's choice at discharge (nicotine replacement, bupropion, or varenicline) and 5 automated outbound interactive voice response (IVR) phone calls at 2, 14, 30, 60, and 90 days after discharge. IVR calls reminded smokers to stay quit, promoted medication adherence and offered medication refills and a return call from a live counselor for further support. SC patients were given advice to contact a free telephone quitline and use smoking cessation medication after discharge. Outcomes (use of treatment, smoking status, readmission rate) were assessed 1, 3, and 6 months post-discharge.
RESULTS: 397 smokers who were admitted from 7/2010 to 4/2012 were randomly assigned to EC (n=198) or SC (n=199). Groups were comparable at baseline (49 % male, 85 % white, mean age=52 y; mean cig/day=17). Follow-up rates were 91 % (1 month), 85 % (3 month), and 82 % (6 mo). EC, compared to SC, increased smokers' post-discharge use of pharmacotherapy (87 % vs 66 %, p<.001, at 1 month; 91 % vs. 73 %, p<.001, at 3 month) and counseling (41 % vs 26 %, p=.002 at 1 month; 67 % vs. 47 %, p<.001 at 3 month). EC, compared to SC, increased self-reported continuous abstinence at 1 mo (46 % vs 34 %, p=.010), 3 mo (34 % vs 24 %, p=.024), 6 month (28 % vs 16 %, p=.007) after discharge and tobacco abstinence for the past 7 days at 1 month (53 % vs 40 %, p=.011), 3 month (46 % vs 37 %, p=.092), and 6 month (42 % vs 29 %, p=.007) after discharge. Analysis of readmission rates is in process.
CONCLUSIONS: A multi-component telephone-based intervention designed to facilitate hospitalized smokers' access to tobacco treatment after discharge improved the use of counseling and pharmacotherapy and increased smoking cessation rates for 6 months after hospital discharge. This promising model could be adopted by hospitals to provide post-discharge treatment and help meet tobacco quality of care standards.

PROSPECTIVE ASSOCIATION OF PHYSICAL ACTIVITY AND MARKERS OF INFLAMMATION AND INSULIN RESISTANCE IN OUTPATIENTS WITH CORONARY HEART DISEASE: DATA FROM THE HEART AND SOUL STUDY Jennifer L. Jarvie[1]; Mathilda C. Regan[2]; Beth Cohen[1,2]. [1]University of California, San Francisco, San Francisco, CA; [2]San Francisco VA Medical Center, San Francisco, CA. (Tracking ID #1635366)

BACKGROUND: Higher levels of physical activity are associated with lower rates of coronary heart disease (CHD). Prior studies have suggested this is in part secondary to lower rates of inflammation and insulin resistance in active versus sedentary individuals, but conclusions are limited by their cross-sectional designs. Additionally, little is known about how changes in physical activity can alter levels of inflammation and insulin resistance. Using a population of patients with known CHD, we sought to determine whether activity level was associated with markers of inflammation and insulin resistance over a 5-year period.
METHODS: We used data from 656 participants in the Heart and Soul Study, a prospective cohort study of outpatients with documented CHD. Physical activity was evaluated at baseline and Year 5 by self-report of frequency of "activities such as 15–20 min of brisk walking, swimming, general conditioning, or recreational sports." We classified participants with low versus high levels of activity based on prior definitions from this cohort that were associated with objective treadmill exercise capacity and risk of future CHD events. Comparing activity from baseline to Year 5 yielded 4 groups: stable low activity (n=151), high activity to low activity (n=110), low activity to high activity (n=60), and stable high activity (n=335). We compared Year 5 markers of inflammation (C-reactive protein [CRP], interleukin-6 [IL-6], and fibrinogen) and insulin resistance (insulin, glucose, and A1c) in the 4 activity groups using t-tests and developed linear regression models serially adjusted for potential confounding and mediating variables.

RESULTS: At Year 5 there were significant differences between the 4 activity groups in mean CRP, IL-6, fibrinogen, insulin, A1c, and glucose (see Table), with those who increased their physical activity over time having lower levels of inflammation and insulin resistance than those with stable low or decreasing activity. Those with high activity at both time points had the lowest levels of these biomarkers. The differences in CRP, IL-6, fibrinogen, and glucose were not explained by adjustment for age, gender, aspirin use, BMI, smoking, and depression.

CONCLUSIONS: In this novel population of men and women with known CHD followed for 5 years, higher physical activity was associated with lower levels of inflammation and insulin resistance. These findings provide possible mechanisms for lower rates of CHD events in individuals who are more physically active compared to their more sedentary peers and optimistically highlights that individuals with CHD who increase their frequency of physical activity may improve their biological profile and reduce risk of further CHD events.

Association of exercise status with Year 5 biomarkers

PROVIDER PERCEPTIONS OF INTENTIONAL MEDICATION DISCONTINUATION Amy Linsky[1,2]; Steven R. Simon[1,3]; Barbara G. Bokhour[4,5]. 1VA Boston Healthcare System, Boston, MA; [2]Boston University School of Medicine, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA; 4ENRM VA Medical Center, Bedford, MA; [5]Boston University School of Public Health, Boston, MA. (Tracking ID #1641699)

BACKGROUND: Adverse outcomes from inappropriate medication use, whether measured as adverse clinical events, increased health care costs or decreased quality of life, are pervasive, even within an integrated health care system such as the Veterans Health Administration (VA). While medication adherence and medication reconciliation receive considerable attention, there has been less focus on improving intentional, proactive discontinuation of medications that may no longer be necessary or whose benefits no longer outweigh associated risks. Therefore, our objective was to identify provider beliefs and attitudes associated with medication discontinuation.

METHODS: We conducted 45–60 min semi-structured qualitative interviews with 20 Primary Care providers with prescribing privileges, including physicians, nurse practitioners and clinical pharmacists, at two VA Medical Centers. Providers were asked about their perceptions of medication management, polypharmacy and clinical decision making related to intentional medication discontinuation. Fully transcribed interviews were analyzed based on the principles of grounded theory, including open coding, theme development and constant comparative analysis of cases.

RESULTS: Study participants had varying years of clinical experience and mixed exposure to prior practice in non-VA settings. We identified five domains that affected how clinical providers make and act upon decisions to discontinue medication: 1) Polypharmacy—perceptions of its definition, prevalence and importance ; 2) Understanding of the patient—developed relationships, established trust and open communication enabled better understanding of patients' knowledge of and adherence to their medication regimens, establishing a foundation upon which decisions could be based; 3) Clinical reasoning and decision making—the rationale and professional jurisdiction that support medication discontinuation; 4) Clinical practice activities—actions required in patient care, often requiring providers to multitask or feel time pressures; and 5) Structural factors such as personnel (e.g., provider roles and care-team composition), system (e.g., coordination across multiple providers and locations) and information technologies. Specifically, providers had various definitions of polypharmacy and expressed that patients frequently were prescribed many more than five medications. Medication reconciliation, necessary for making discontinuation decisions, was viewed as time-consuming. A common source of frustration was inadequate exchange of information with non-VA providers, leading to uncertainties about prior evaluations and management. Some physicians reported a sense of control over the medication regimens that empowered them to discontinue prescriptions. Pharmacists enjoyed their expanded role in the Patient Aligned Care Team model (i.e., a medical home); they appreciated spending dedicated time with patients and conducting medication reconciliation to enable prescribing decisions.

CONCLUSIONS: Clinicians express a wide variety of opinions and viewpoints related to medication management decisions, and especially discontinuation. In order to develop and implement effective interventions that improve prescribing practices, whether targeted at the clinician or organization of care delivery, additional research is needed on the full range of attitudes and beliefs harbored by clinical providers as well as the environments in which they practice.

QUALITY OF CARE AND RACIAL DISPARITIES AMONG POTENTIAL MEDICARE ACCOUNTABLE CARE ORGANIZATIONS Ryan E. Anderson[2,3]; John Z. Ayanian[1,4]; Alan M. Zaslavsky[1]; J. Michael McWilliams[1,4]. [1]Harvard Medical School, Boston, MA; [2]Harvard Kennedy School of Government, Cambridge, MA; [3]Washington University School of Medicine, St. Louis, MO; [4]Brigham and Women's Hospital, Boston, MA. (Tracking ID #1642510)

BACKGROUND: The Medicare Accountable Care Organization (ACO) programs reward larger provider groups for improving quality of care and containing spending, but not for reducing health care disparities. This study sought to examine sociodemographic differences between Medicare beneficiaries served by provider groups sufficiently large to participate in ACO programs (≥5,000 assigned beneficiaries) and those served by smaller groups; the association between group size and racial disparities in quality for cardiovascular disease and diabetes; and the association between quality and disparities among larger groups.

METHODS: Using 2009 Medicare claims and linked American Medical Association Group Practice data, we assigned 3.3 million beneficiaries with cardiovascular disease or diabetes to primary care provider groups. Six quality measures were evaluated for this population, including four process measures adapted from the Healthcare Effectiveness Data and Information Set, hospitalization for ambulatory care-sensitive conditions (ACSCs) related to cardiovascular disease or diabetes, and hospitalization for any ACSC. We compared racial differences in these quality measures for provider groups that were small (<5,000 assigned beneficiaries), medium-sized (5,000–14,999), and large (≥15,000), adjusting for sociodemographic and clinical characteristics. Among medium-sized and large groups, we used multilevel models to estimate correlations between group performance on quality measures for white beneficiaries and black-white disparities within groups.

RESULTS: Beneficiaries assigned to medium-sized and large provider groups were more likely to be white (88.5 vs. 84.5 %; $P<0.001$), less likely to be eligible for Medicaid (13.3 vs. 18 %; $P<0.001$), and lived in areas with fewer people below poverty (8.7 vs. 9.6 %; $P<0.001$). Large groups were associated with smaller disparities in retinal exams compared with small groups (3.7 vs. 1.2 %; $P<0.001$) for beneficiaries with diabetes, but not with smaller disparities in other process measures or hospitalization for ACSCs. Among medium-sized and large groups, lower rates of hospitalization related to cardiovascular disease or diabetes among white beneficiaries were correlated with smaller racial disparities ($r=0.30$; $p=0.005$), but better quality was not correlated with smaller disparities in other measures.

CONCLUSIONS: Provider groups sufficiently large to participate in ACO programs were more likely to serve white beneficiaries and those living in more socioeconomically advantaged areas. The size of provider group was not consistently associated with smaller racial disparities in care for

Medicare beneficiaries with cardiovascular disease or diabetes. These findings suggest that benefits achieved by ACOs may accrue disproportionately to white patients in more affluent areas. To the extent that new payment incentives improve the quality of care provided by ACOs, our findings suggest these potential gains may not be consistently associated with reduced racial disparities across the quality measures included in ACO contracts. Additional incentives and novel payment arrangements may be required for ACOs to promote greater equity in care.

QUALITY OF INPATIENT DOCUMENTATION OF CODE STATUS DISCUSSION Rashmi K. Sharma; Andrew Thurston; Diane Wayne. Northwestern University, Chicago, IL. (Tracking ID #1642626)

BACKGROUND: Although a code status discussion (CSD) provides an opportunity for physicians to assess patient preferences regarding end-of-life care, prior studies have shown that these conversations are infrequently documented in the medical record. Little is also known about the quality of these discussions. We sought to examine the content and quality of documented inpatient CSDs.
METHODS: Using the electronic medical record (EMR), we identified all patients admitted to a single academic medical center between January 1 and June 30, 2011 with a do-not-resuscitate (DNR) order written or cancelled at least 24 h after admission. We then used an electronic text search query to identify all clinical notes, written 24 h before and after the DNR order, that referenced discussion of code status or resuscitation. We excluded notes written by consulting physicians. Using published guidelines for CSD content, supplemented by key domains from an institutional communication skills training program, we developed a chart abstraction tool to evaluate the quality of CSD documentation. One coder abstracted the following quality elements: a) who the discussion was held with (e.g., patient, surrogate); b) review of patient goals and values; c) discussion of prognosis; d) review of treatment options e) likely outcomes of resuscitation, and f) presence of a healthcare power of attorney (HCPOA). A second coder reviewed a subsample to assess for inter-rater reliability.
RESULTS: We identified 395 patients with a new or cancelled DNR order of whom 237 (60 %) had a note documenting a CSD. We reviewed a random sample of 131 notes (55 %) of which 26 were excluded (consultant notes) leaving 105 notes for abstraction. Percent agreement between the two coders for each of the key abstraction elements ranged from 70 to 100 %. Mean patient age was 63.5 +/− 18 years; 37 % of patients were male and 57 % were white. Median length of stay was 10 days, 88 % of patients had been admitted to the hospital within the previous 6 months, one patient had a documented DNR order on a previous hospitalization, and 42 % of patients died in the hospital. Thirty four percent of notes were written by an internal medicine resident, 34 % by a non-internal medicine resident, and 28 % by a hospitalist. Discussion of prognosis was documented in 18 % of notes, outcomes of resuscitation in 2 %, patient values and goals in 8.6 % and 48 % respectively, and presence of HCPOA in 24 %. Sixty-nine percent of notes contained documentation of who the discussion was held with. There were no significant differences in documentation between medicine and non-internal medicine residents. Hospitalists were more likely to document who the discussion was held with (89 % vs. 61 %, p=0.006) and patient goals (67 % vs. 39 %, p=0.02) than residents.
CONCLUSIONS: Review of inpatient CSD notes revealed poor documentation of several key content domains. Our findings suggest that education in CSD documentation is needed for residents as well as supervising faculty. Further research is also needed to clarify factors affecting the quality of CSD documentation and to identify ways to improve documentation in the inpatient setting.

QUALITY OF LIFE AND THE VALUE OF WEIGHT LOSS AMONG OBESE PRIMARY CARE PATIENTS Christina C. Wee; Roger B. Davis; Karen W. Huskey; Mary Beth Hamel. Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #1640513)

BACKGROUND: Obesity has wide-ranging adverse consequences including its adverse impact on health and quality of life (QOL). Not surprisingly, a majority of obese adults desire and attempt weight loss each year. Few studies, however, have examined the degree to which obese patients value weight loss, the risks patients are willing to assume to lose weight, and the contribution obesity-related QOL makes on how much patients value weight loss.
METHODS: We interviewed 338 obese patients (BMI ≥35 from 4 diverse primary care practices (58 % response rate) to assess their health, QOL (via the Impact of Weight on QOL-lite/IWQOL-lite), and preferences for weight loss. We assessed patients' health utility (preference-based quality life measure) via a series of standard gamble scenarios assessing patients' willingness to risk death to lose various amounts of weight or achieve perfect health (range 0 to 1; 0=death and 1=most valued health/weight state). We developed sequential multivariable models to assess the association between sociodemographic (age, sex, race, education), clinical (i.e. BMI, comorbidities) and QOL factors and patients' utility as a continuous outcome using linear regression and as a dichotomous outcome (utility less than 1.0) using logistic regression.
RESULTS: Our sample had mean age of 49 years, 68 % were women and by design 50 % were nonwhite. Pts had a mean weight of 257 lbs (BMI 40.7) and desired an ideal weight of 172 lbs (33 % weight loss). Their mean utility was 0.94, reflecting the group's average willingness to accept a 6 % risk of death to achieve their most desired health/weight state. Pts were more willing to assume a risk of dying for higher levels of weight loss and were more willing to risk death to achieve their perceived ideal weight than to achieve perfect health (see Table). In initial linear regression models that evaluated the role of age, sex, race, BMI, and education, education was the only significant correlate of pt utility; college graduates had a utility 0.04 units higher than those with no more than a high school education. However, this difference was no longer significant after full adjustment. After full adjustment, QOL score was the only factor significantly associated with utility; a 10 point higher score on the IWQOL-lite was associated with a 0.01 unit increase in utility. Comorbid conditions were not significantly associated with pt utility even prior to adjusting for QOL. Results from logistic regression models were consistent with our primary findings.
CONCLUSIONS: Moderately to severely obese primary care patients in our study report health utilities similar to those living with mild depression reported elsewhere. As anticipated, obesity-related quality of life was significantly associated with utility. Surprisingly, patients' utility did not appear to be influenced by BMI or comorbid conditions.
Table. Patient Preferences and Utility for Weight Loss and Perfect Health

Current 10 % weight loss 20 % weight loss BMI of 25 Perceived ideal weight Perfect health - 25.8 36.6 39.3 45.0 25.2 - 3.9 8.9 9.6 9.6 9.4 0.943 0.952 0.966 0.976 0.979 0.960

QUALITY OF OSTEOPOROSIS CARE AMONG OLDER MEDICARE FRAGILITY FRACTURE PATIENTS 2006–2010 John Mecchella[1,2]; Stephen K. Liu[1,2]; Jeffrey C. Munson[1,3]; John-Erik Bell[1,3]; Rebecca L. Zaha[1]; Anna N. Tosteson[1,3]; Nancy E. Morden[1,3]. [1]The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH; [2]Geisel School of Medicine at Dartmouth, Hanover, NH; [3]Dartmouth-Hitchcock Medical Center, Lebanon, NH. (Tracking ID #1637217)

BACKGROUND: Osteoporotic fractures result in substantial morbidity and mortality; fracture risk is highest among fragility fracture survivors. Appropriate osteoporosis treatment reduces recurrent fractures. We studied osteoporosis care in a national cohort of older, community dwelling Medicare fragility fracture survivors to assess the uptake of care guidelines and post-fracture care quality among U.S. adults.
METHODS: Using Medicare administrative inpatient, outpatient (2003–2010) and prescription data (2006–2010), we studied patients 68 years of age or older with a fracture of the hip, distal radius or proximal humerus. Poisson regression modeled factors, including patient characteristics, comorbidities and hospital referral region (HRR) of residence, were

associated with our main outcome: bone density testing and/or anti-resorptive pharmacotherapy in the 6 months following fracture. In secondary analyses, these models were repeated for patients without osteoporosis care prior to index fracture ("attention naïve"), for women only, by fracture location and allowing 12 months to achieve the outcome.

RESULTS: Among 61,832 fracture patients (37.3 % hip, 19.9 % humerus, 42.9 % radius), mean age was 80.6; 87.0 % were female; 88.5 % were white; 2.6 % were Black; 62.1 % were "attention naïve" at the time of fracture. Overall 21.8 % received testing and/or pharmacotherapy in the 6 months following fracture. In adjusted models, factors associated with significantly lower likelihood of receiving this care were: Black race, male sex, and an upper extremity fracture (vs. hip). In models restricted to "attention naïve" patients the same factors were associated with lower RRs of achieving care. Adjusted HRR-level care rates ranged from 14.7 % to 22.9 %. The proportion receiving care increased from 2006 to 2009 (16.8 % vs. 30.5 %). Secondary analyses paralleled the main models. Overall, the proportion achieving the main outcome within 12 months of index fracture was only slightly higher: 28.4 %.

CONCLUSIONS: In this national cohort, post-fracture osteoporosis care was uncommon, especially for Blacks and men. Osteoporosis care increased over time, but for most patients without prior osteoporosis attention, a fragility fracture was insufficient to trigger treatment and/or testing in this fully-insured cohort. Clinicians and policy makers must consider effective remedies for this persistent care gap.

QUANTIFYING THE IMPACT OF UNNECESSARY IONIZED CALCIUM MEASUREMENTS Paul Di Capua; Michael A. Pfeffer. UCLA, Los Angeles, CA. (Tracking ID #1638244)

BACKGROUND: Lack of standardization in physicians' ordering practices contributes to the wide variability in both outcomes and costs of health care. For example, based on our clinical experience, house staff routinely order daily ionized calcium on a majority of patients despite the limited benefit in all but a subset of patients, with potential cost savings for the hospital. However, serum calcium measurements are part of a routine basic metabolic panel and serve as an adequate proxy for concentration of ionized calcium, the biologically active calcium cation. The correlation between the serum and ionized calcium concentrations changes in certain patient populations—end stage renal disease, hyperparathyroidism, hypercalcemia of malignancy, crtically ill and after blood transfusions—wherein it may be more justifiable to order this specialty test. This exploratory research sought to measure the number of unnecessary ionized calcium measurements in our hospital and quantify the financial and clinical costs of these measurements.

METHODS: Two hospital-specific databases were linked to quantify unnecessary ionized calcium measurements: a billing database included laboratory orders (without lab values) and patient co-morbidities, and a laboratory database provided lab values. The billing database included all adult inpatient admissions over a calendar year. Patients with any of the five criteria which preclude using serum calcium as a proxy for ionized calcium were excluded. A subset of 1000 patients from the billing database were linked to the laboratory database. An ionized calcium measurement was considered superfluous if the patient did not meet any of the five comorbid criteria and if an ionized calcium measurement had been normal within the previous 30 days. The clinical laboratory director and staff provided logistic and financial information to quantify the costs of ionized calcium measurements.

RESULTS: There were a total of 32,566 inpatient admissions over the examined calendar year. Of these, 24 % had any kind of malignancy, 5 % had CKD (defined as stage 4, 5 or end stage renal disease) and 1 % had any kind of parathyroid disease. 20,822 (64 %) patients had an ionized calcium measured at least once and 15,735 (48 %) had multiple ionized calcium measurements. Of the 1000 patients in the subset for which we had clinical data, 43 % had a normal ionized calcium within 30 days and 18 % had a prior normal ionized calcium and none of the comorbid criteria. The marginal cost of an ionized calcium measurement is $0.74, for serum calcium, $0.13. We estimate the total direct annual cost of superfluous ionized calcium measurements to be $58,746 and total blood loss of 234,637 L of patient blood unnecessarily drawn.

CONCLUSIONS: Variability in physician ordering underlies part of the quality gap in the American healthcare system; laboratory orders can be window into this gap. Even under the broadest exclusion criteria, many patients unnecessarily have their ionized calcium levels measured routinely in our system without clinical indication. This example may be specific to our hospital system, but the larger lesson of cost-conscious healthcare can be applied more broadly. This analysis has served as a backbone for an educational intervention aimed at reducing unnecessary lab ordering and a guide in changing laboratory order templates.

RACE, WEIGHT LOSS, AND CHANGE IN PATIENTS' UTILITY AFTER WEIGHT LOSS SURGERY Christina C. Wee[1]; Edward R. Marcantonio[1]; Karen W. Huskey[1]; Daniel B. Jones[1]; George L. Blackburn[1]; Caroline Apovian[2]; Roger B. Davis[1]; Mary Beth Hamel[1]. [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Boston Medical Center, Boston, MA. (Tracking ID #1640225)

BACKGROUND: While weight loss surgery (WLS) is one of few treatments that produce substantial and sustained weight loss, it is neither universally effective nor risk free and WLS outcomes often fall short of patients' (pts') initial expectations. Moreover, few data are available on WLS' effectiveness in racially diverse populations in the U.S. and the "value" pts derive from undergoing WLS.

METHODS: We interviewed 538 consecutive pts who sought and underwent WLS at 2 centers (70 % response rate) to examine outcomes of WLS and the value pts place on these outcomes. We determined the "value" pts derived from WLS by prospectively assessing pts' health value or health utility (preference-based quality of life measure) via a series of standard gamble scenarios assessing pts' willingness to risk death to lose various amounts of weight or to achieve perfect health; calculated utilities ranged from 0 to 1 where 0=death and 1=most valued health/weight state before and after WLS. Weight loss was abstracted via chart review. We conducted preliminary multivariable analyses to examine the influence of sex and race on weight loss and change in utility 1-year post-WLS on the first 372 pts who completed our 1-year post-op interview (72 % retention).

RESULTS: The mean pre-WLS BMI was 46.6, the mean age was 45.1 years, 76 % were women, 69 % were Caucasian, 17 % were African American (AA) and 9 % were Hispanic; 55 % underwent Gastric Bypass and 45 % underwent Gastric Banding. The mean patient utility was 0.88 prior to WLS, representing patients' willingness to assume a 12 % average risk of dying to achieve their most valued weight/health state. One year post-WLS, pts lost a mean of 26 % of initial weight. After adjustment for age, sex, baseline BMI, education, recruitment site, and surgery type, AA [21.5 % (95 % CI 19.3, 23.7) of initial weight] and Hispanic [22.2 % (19.2, 25.1)] pts lost significantly less weight than Caucasian pts [26.4 % (25.1, 27.7)]. After adjustment, pts' utility on average improved among Caucasian pts [+0.056 (0.023, 0.090)], remained unchanged among Hispanic pts [+0.0004 (−0.076, 0.075)] and deteriorated among AAs [−0.057

(−0.114, −0.001)]. Men and women had comparable weight loss [22.9 % (20.9, 25.0) vs. 24.3 (22.8, 25.8)] and change in utility [0.0003 (−0.052, 0. 053) vs. 0.019 (−0.019, 0.058)] 1 year after WLS. We did not detect significant interactions between sex and race nor between surgery type and sex or race.
CONCLUSIONS: Caucasian patients lost more weight than AA or Hispanic pts 1 year after WLS; nonetheless, AA and Hispanic pts still achieved fairly substantial weight loss. The utility change among Caucasian pts post WLS is comparable to a transition from mild clinical depression to perfect health reported elsewhere. However, despite sustaining fairly substantial weight loss, health utility deteriorated among AA patients and did not change among Hispanic patients after WLS. Future studies should evaluate longer-term clinical and utility outcomes after WLS and the factors that drive health value derived by patients.

RACIAL DIFFERENCES IN CANCER SCREENING WITH ELECTRONIC HEALTH RECORDS AND ELECTRONIC PREVENTIVE CARE REMINDERS Rebecca G. Mishuris[1,2]; Jeffrey A. Linder[1,2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA. (Tracking ID #1637529)

BACKGROUND: Racial disparities in cancer screening are well documented. Health information technology may reduce these disparities. We investigated whether the use of electronic health records (EHRs) or electronic preventive care reminders (e-reminders) had an impact on racial disparities for cancer screening.
METHODS: We measured the difference in rates of age-appropriate cancer screening between whites and non-whites at primary care visits with and without EHRs and, at visits with EHRs, with and without e-reminders. We used the representative surveys, National Ambulatory and National Hospital Ambulatory Medical Care Surveys, from 2006 to 2009. We examined mammography for women age 40–75; Pap smears for women age 21–65; and sigmoidoscopy or colonoscopy for patients age 50–75. We developed logistic regression models with each type of cancer screening as the dependent variable to determine if the use of EHRs or e-reminders independently modified differences in screening rates between whites and non-whites.
RESULTS: We analyzed an estimated 93 million cancer screening visits in the US from 2006 to 2009. Practices had EHRs at 49 % of these visits, and, at visits with EHRs, e-reminders at 62 %. For mammography, there was no difference in screening between whites and non-whites overall (p=0.79). At practices with EHRs, there was no difference in mammography screening between whites and non-whites (6.4 % vs. 6.1 %, p=0.79). At practices with e-reminders, there was no difference in mammography screening between whites and non-whites (6.6 % vs. 5.8 %, p=0.61); at practices without e-reminders there was no difference between whites and non-whites (6.2 % vs. 6.6 %, p>0.05); and the presence of e-reminders did not modify the lack of a difference in mammography between whites and non-whites (p=0.70 for the adjusted interaction). For Pap smears, there was no difference in screening between whites and non-whites overall (p= 0.05). At practices with EHRs, there was no difference in Pap smear screening between whites and non-whites (5.8 % vs. 5.8 %, p=0.75). At practices with e-reminders there was no difference in Pap smear screening between whites and non-whites (6.4 % vs. 6.4 %, p=0.60); at practices without e-reminders there was no difference in screening between whites and non-whites (4.9 % vs. 5 %, p>0.05); and the presence of e-reminders did not modify the lack of a difference in Pap smear screening between whites and non-whites (p=0.68 for the adjusted interaction). For colon cancer screening, whites were more likely to receive screening than non-whites overall (4.2 % vs. 3.4 %, p=0.003). At practices with EHRs, whites received colon cancer screening less often than non-whites (2.4 % vs. 4.3 %, p=0.006); the presence of EHRs did not modify the difference between whites and non-whites (p=0.22 for the adjusted interaction). At practices with e-reminders, whites received colon cancer screening less often than non-whites (2.3 % vs. 4.7 %, p=0.02); at practices without e-reminders, there was no difference in screening between whites and non-whites (2.4 % vs. 3.5 %, p=0.09); and the presence of e-reminders did not modify the difference in colon cancer screening between whites and non-whites (p=0.43 for the adjusted interaction).
CONCLUSIONS: Non-whites were less likely to receive colon cancer screening overall, but this disparity was reversed at practices using EHRs and e-reminders. At practices with EHRs or e-reminders, we found no racial disparities in cancer screening.

RACIAL DISPARITIES IN HPV VACCINATION. Sonya Borrero; Amanda Gelman; Elizabeth Miller; E. Bimla Schwarz; Aletha Y. Akers; Kwonho Jeong. University of Pittsburgh, Pittsburgh, PA. (Tracking ID #1642094)

BACKGROUND: HPV vaccination is a safe and effective method for primary prevention of cervical cancer yet US rates of HPV vaccination remain suboptimal. Given that cervical cancer is more common in African-American and Hispanic women than in white women, it is important to determine whether there are racial/ethnic disparities in the utilization of the HPV vaccine and to understand potentially modifiable factors contributing to observed disparities. The objective of this study was to examine the independent effect of race/ethnicity on HPV vaccine initiation in adolescents and young women in the US and to determine whether access to healthcare influences this relationship.
METHODS: We used nationally representative data collected by the National Survey of Family Growth from 2007 to 2010 to compare HPV vaccine initiation among white, African-American, and Hispanic females aged 15–24. We conducted a multivariable regression analysis to determine the independent effect of race/ethnicity on HPV vaccine initiation after controlling for socio-demographic variables found to be significant in bivariate analysis. We then examined the role of healthcare access as a confounder for the relationship between race/ethnicity and HPV vaccination by adding several access-related variables into the model. These included insurance status during the last 12 months, place of residence (urban, suburban, or rural), and receipt of at least one reproductive health service within the last 12 months. Given that existing national studies report prevalence rates for either younger or older vaccine-eligible women, we also conducted age-stratified analyses (ages 15–18 and 19–24 years) to enable comparisons with existing data. STATA survey procedures were used for all analyses to account for the NSFG's complex survey sampling design.
RESULTS: The sample consisted of 3,073 women: 62.7 % were white, 19.7 % Hispanic, and 17.6 % African American. Overall, only 24.0 % of girls and women reported HPV vaccination. There were significant racial/ethnic differences in rates of vaccination with 28.7 % of white females reporting vaccination compared to 15.0 % of African-American women and 16.9 % of Hispanic women (p<0.001). After adjusting for age, religion, birth country, marital status, parent education, household income, and number of lifetime male sexual partners, African-Americans and Hispanics remained less likely to have been vaccinated against HPV (adjusted OR: 0.46; 95 % CI: 0.33–0.66 and adjusted OR: 0.56; 95 % CI: 0.38–0.83, respectively). Adding healthcare access measures did not substantially change the odds of vaccination for African-Americans or Hispanics (adjusted OR: 0.43; 95 % CI: 0.31–0.59 and adjusted OR: 0.61; 95 % CI: 0.41–0.89, respectively). The age-stratified analyses revealed that this disparity affected African-American females in both age groups (ages 15–18 and 19–24) and Hispanic adolescent girls (ages 15–18).
CONCLUSIONS: There are significant racial/ethnic disparities in HPV vaccination that do not appear to be explained by access to healthcare. Research is needed to further elucidate the reasons for under-vaccination among girls and young women of color and identify ways in which providers and healthcare systems may improve vaccine uptake for these vulnerable populations.

RACIAL DISPARITIES IN THE USE OF CATHETER ABLATION FOR ATRIAL FIBRILLATION AND FLUTTER Leonardo Tamariz; Alexis P. Rodriguez; Robert Myerburg; Hua Li; Ana M. Palacio. University of Miami, Miami, FL. (Tracking ID #1639828)

BACKGROUND: Atrial fibrillation (AF) is the most common arrhythmia seen in clinical practice that requires therapy. Catheter ablation is an expensive but potentially curable treatment of AF. We explored racial

disparities in the use of catheter ablation for AF in the State of Florida, and compared the findings to ablation for atrial flutter (AFlut).
METHODS: We conducted a cross-sectional analysis of all ambulatory and hospital discharge procedures between 2006 and 2009 in the State of Florida. We identified all subjects with AF and AFlut, using ICD-9 code 427.31 and 427.32, and all catheter ablation for AF and AFlut, using ICD-9 procedure codes 37.34, along with the race/ethnicity of each individual. We used logistic regression to determine the odds ratio (OR) of having a catheter ablation per disease by race and ethnicity adjusted for Charlson score, insurance status and year of the procedure.
RESULTS: We identified 923,590 subjects with AF and 28,714 with atrial flutter. Blacks had the highest comorbidity scores compared to Whites and Hispanics ($p<0.01$). Catheter ablations were more commonly used in AFlut than in AF. Figures 1 and 2 show the temporal trends of catheter ablation use by ethnicity. The adjusted OR of having catheter ablation for AF for Blacks was 0.67; 95 % CI 0.60–0.75 ($p<0.01$) and for Hispanics was 0.82; 95 % CI 0.75–0.91 ($p<0.01$) when compared to Whites. The adjusted OR of having an ablation for atrial flutter for Blacks was 1.08; 95 % CI 0.96–1.21 ($p=0.16$) and for Hispanics was 0.90; 95 % CI 0.78–1.08 ($p=0.20$) when compared to Whites.
CONCLUSIONS: In the state of Florida, during the years of 2006 and 2009, Black and Hispanics subjects with AF received less catheter ablations while the same minority subjects with atrial flutter received a similar number of ablations compared to White subjects with the same insurance and comorbidity burden.

RANDOMIZED INTERVENTION TO PROMOTE PHYSICAL ACTIVITY OF INTERNAL MEDICINE RESIDENTS Anne N. Thorndike; Sarah Mills; Lillian Sonnenberg; Deepak Palakshappa; Tian Gao; Cindy T. Pau; Susan Regan. Massachusetts General Hospital, Boston, MA. (Tracking ID #1623837)

BACKGROUND: Physicians' long, intense work hours reduce time for healthy behaviors and contribute to burnout. Promoting physical activity of medical residents could help create better role models for patients and improve physician health during and after residency.
METHODS: We tested 2 strategies using an activity monitor to increase physical activity of internal medicine residents over 12 weeks in 2011 at a hospital in Boston, MA. In Phase 1 (6 weeks), residents were randomly assigned to an activity monitor with visual feedback (intervention) or to a blinded monitor (control). Phase 2 (6 weeks) was a team competition with all monitors unblinded. In both phases, residents were given free access to an on-site fitness center. Primary outcomes were: 1) median steps/day to assess activity levels and 2) proportion of days on which the activity monitor was worn to assess compliance with wearing the monitor. Secondary analyses looked at mean steps/day on days when the monitor was worn (>500 steps), comparing steps in Phase 2 vs. Phase 1, steps during inpatient vs. outpatient rotations, and steps by residency year of training. Baseline weight, BMI, blood pressure, and fasting lipids of residents were compared to measurements at study end.
RESULTS: A total of 104 residents were randomized in Phase 1, and 99 continued into Phase 2. The mean age of residents was 29; 54 % were female; 66 % were white; and the mean BMI was 24.1. During Phase 1, intervention and control groups recorded similar steps/day (6369 vs. 6063, $p=0.16$) and compliance with wearing the monitor (77 % vs. 77 % of days, $p=0.73$). During Phase 2 (team competition), residents assigned to intervention in Phase 1 recorded more steps/day (5382 vs. 3698, $p<0.001$) and were more compliant (63 % vs. 56 %, $p<0.001$) compared to control. Including only days with >500 steps recorded, residents logged more steps/day during Phase 2 (team competition) than Phase 1 ($p=0.009$) and more steps/day during outpatient than inpatient rotations ($p<0.001$). During the team competition, senior residents recorded more steps per day than juniors or interns ($p=0.02$). Compared to baseline, at study end the mean systolic blood pressure decreased ($p=0.004$), HDL cholesterol increased ($p<0.001$), and weight did not change.
CONCLUSIONS: This is the first randomized intervention to our knowledge to promote physical activity among physicians. We found that a relatively simple intervention was feasible, moderately effective for improving activity, and associated with improvement in cardiovascular risk factors of internal medicine residents. Future research will be needed to determine if improving physician lifestyle habits can help prevent burnout and improve health outcomes.

REACH OF AN EFFECTIVE, NATIONALLY-AVAILABLE, LOW-COST, PEER-LED, NONPROFIT WEIGHT LOSS PROGRAM IN MEDICALLY UNDERSERVED AREAS Nia S. Mitchell[1]; Ariann F. Nassel[2]. [1]University of Colorado Anschutz Medcial Campus, Aurora, CO; [2]University of Colorado Anschutz Medical Campus, Aurora, CO. (Tracking ID #1640695)

BACKGROUND: Obesity disproportionately affects underserved populations, and physicians struggle to help underserved patients lose weight because of a lack of affordable and accessible weight loss programs. Take Off Pounds Sensibly (TOPS) is a nationally-available, low-cost, peer-led, nonprofit weight loss program that can be implemented in any setting. Although a large study of the effectiveness of TOPS showed that participants lost 5 % or more of their initial weight and maintained the weight loss for up to 3 years, there was no information about the reach of TOPS into underserved areas. Understanding the reach of TOPS in underserved communities is an important step in addressing the health disparity of obesity because it informs providers of its widespread

availability for their underserved patients. We hypothesized that TOPS would be available in 25 % of medically underserved areas (MUAs) because of its low cost, peer-led format, and ease of implementation. We also hypothesized that the racial and ethnic makeup of the locations of TOPS chapters would reflect the diversity of the country and include lower income categories.

METHODS: To determine the reach of TOPS into underserved populations, we integrated TOPS chapter addresses from the TOPS administrative database with data from Health Resources Services Administration (HRSA) designated MUAs using geographic information systems. MUAs are determined based on the ratio of primary care physicians per 1000 population, infant mortality rate, percentage of population with income below the poverty level, and percentage of population age 65 and over. To determine the racial demographics and median income of the TOPS chapter locations, we incorporated data from US Census tracts.

RESULTS: In the United States, there are 3,461 HRSA-designated MUAs, and there are 6,765 TOPS chapters with over 115,000 members throughout the country. The number of chapters per state varies from 3 in Hawaii to 403 in California. Thirty percent of MUAs have at least one TOPS chapter, and one MUA has 20 chapters. Twenty-four percent of TOPS chapters are in MUAs. The US population is 75 % Caucasian, 14 % African American, and 16 % Hispanic. The average racial distribution in the census tracts for the TOPS chapter locations was 82 % (range 18–96 %) Caucasian, 7 % (range 0.3–27 %) African American, and 9 % (range 1–47 %) Hispanic. The average median income for the census tracts with TOPS locations is $48,931 (range $35,822–$82,623).

CONCLUSIONS: TOPS, an effective, low-cost weight loss program, is available in 30 % of MUAs in the United States. Although the racial distribution of the locations of the TOPS chapters does not match the distribution in the country, TOPS operates in racially and economically diverse communities, including those that are underserved, those with large ethnic minority populations, and those with low median incomes. Given its effectiveness, locations in communities at risk for obesity, and ease of implementation, TOPS is poised to be part of the broader solution to treat obesity among medically underserved populations. Physicians should consider recommending TOPS to their underserved overweight and obese patients.

READMISSION AND MORTALITY ASSOCIATED WITH HYPONATREMIA AT THE TIME OF DISCHARGE IN PATIENTS WITHOUT HEART FAILURE OR END-STAGE LIVER DISEASE

Brittany Fuller; Michael F. Harrison; Juan Cesar Fernandez Castillo; Sreekanth Uppuluri; Harish Kinni; Karen Olarte-Merida; David Paje. Henry Ford Hospital, Detroit, MI. (Tracking ID #1642556)

BACKGROUND: Hyponatremia at the time of hospital discharge is common. Previous studies show that it is associated with increased risks of rehospitalization and of both short-term and long-term mortality. However, these studies included patients with either heart failure (HF) or end-stage liver disease (ESLD), conditions where hyponatremia is known to be indicative of poor prognosis. The purpose of this study was to evaluate the association between hyponatremia at the time of discharge and the rates of readmission and mortality in patients without HF or ESLD.

METHODS: Administrative and clinical data were retrospectively abstracted from the medical records of consecutive patients discharged alive from an urban tertiary referral teaching hospital. Patients with a history of HF or ESLD were excluded. The primary outcomes included the following 30-day events: all-cause readmission, mortality, and composite of readmission or mortality. Independent *t*-test and chi-squared test were used to compare baseline characteristics between patients discharged with hyponatremia (serum sodium concentration <135 mEq/L) and those discharged with eunatremia (135–145 mEq/L). Pearson's chi-squared tests were used to compare outcomes between both groups. Kaplan-Meier graphs were also plotted and compared using the log-rank test.

RESULTS: Overall, 950 patients were included in the analysis. At the time of discharge, 418 (44 %) had hyponatremia and 532 (56 %) had eunatremia, with mean serum sodium concentrations of 132.1±1.5 mEq/L and 138.2±2.2 mEq/L, respectively ($p<0.01$). Compared to patients with normal serum sodium, those with hyponatremia had higher age-adjusted Charlson Comorbidity Index (3.6±3.2 vs. 2.6±2.9, $p<0.01$), stayed longer in the hospital (6.8±6.2 days vs. 5.2±6.2 days, $p<0.01$), and were discharged with more medications (7.6±4.7 vs. 6.4±4.1, $p<0.01$). They were also more likely to have stayed in the intensive care unit (ICU) during their index admission (OR 1.78, 95 % CI 1.24 to 2.54, $p=0.002$). Patients who were hyponatremic at discharge had a higher risk of the following events within 30-days: readmission or death (RR 1.45, 95 % CI 1.08 to 1.95, $p=0.012$), readmission (RR 1.37, 95 % CI 1.01 to 1.85, $p=0.044$), and death (RR 2.97, 95 % CI 1.15 to 7.66, $p=0.018$).

CONCLUSIONS: Among patients without heart failure or end-stage liver disease, hyponatremia at the time of hospital discharge is associated with an increased risk of 30-day readmission and mortality. However, these patients have higher comorbidity scores, longer hospital stays, more discharge medications, and are more likely to have been in the ICU.

Table 1: Rates of Clinical Outcomes after Hospital Discharge of Patients without Heart Failure or End-Stage Liver Disease

Clinical Outcomes Serum Sodium at Hospital Discharge<135 mEq/L (n=418) Serum Sodium at Hospital Discharge 135–145 mEq/L (n=532) p-value RR 95 % CI

30-DAY READMISSION OR MORTALITY 19.1 % (80) 13.2 % (70) 0.012 1.45 1.08–1.95

30-DAY READMISSION 17.5 % (73) 12.8 % (68) 0.044 1.37 1.01–1.85

30-DAY MORTALITY 3.3 % (14) 1.1 % (6) 0.018 2.97 1.15–7.66

READY TO PROVIDE PREVENTIVE WOMEN'S HEALTH SERVICES?: A SURVEY OF INTERNAL MEDICINE RESIDENTS' TRAINING, ATTITUDES AND CLINICAL PRACTICE

Sara Teasdale[1]; Palav Babaria[2]; Elizabeth Harleman[2]; Alicia Fernandez[2]. [1]UC Davis Medical Center, Sacramento, CA; [2]University of California San Francisco, San Francisco, CA. (Tracking ID #1630436)

BACKGROUND: With expanded coverage for preventive women's health care under the Affordable Care Act and recent Institute of Medicine recommendations, internists will be increasingly expected to address women's health. Prior studies have demonstrated that internal medicine (IM) residency training in women's health is often inadequate. Our goal was to understand the perceived importance for IM residents in providing women's health services, the perceived adequacy of training in these areas, and how residents currently provide these specific services to women.

METHODS: We designed a survey to assess three recommended preventive services for women: well woman exams (pap smears and breast exams), annual contraception counseling, and intimate partner violence (IPV) screening. The 41-question survey was administered to all IM residents enrolled in a three-year training program at an urban, university-based residency program. Descriptive statistics were analyzed using Stata 12. All Likert scale outcomes were dichotomized and logistic regression techniques were used to examine the potential association between each of the 17 outcomes and the primary predictors: gender, categorical vs. primary care track, VA continuity clinic site vs. non-VA site, and post-graduate year (PGY1 vs. PGY 3), in both univariate and multivariate analyses.

RESULTS: Of 175 internal medicine residents, 131 (75 %) completed the survey. Overall, 84 % of residents believe it is important for internists to provide preventive women's health services. However, 45 % of residents feel adequately trained in IPV screening and less than 30 % feel adequately trained in what to do if a woman screens positive for IPV or how to prescribe contraception. Fewer than 40 % feel comfortable prescribing contraception or know what to do if a woman screens positive for IPV. With regards to training, residents at VA clinics feel less adequately trained in how to do a pelvic exam ($p<0.05$, OR 0.40 (CI 0.17–0.94)) and males feel less adequately trained in how to prescribe oral contraception ($p<0.05$, OR 0.39 (CI 0.16–0.95)). PGY3 residents feel more adequately trained ($p<0.05$, OR 2.61(CI 1.10–6.20)) in IPV screening. With regards to comfort,

residents with VA clinic feel less comfortable performing breast exams ($p<0.05$, OR 0.34 (CI 0.14–0.83)), pap smears ($p<0.01$, OR 0.29 (CI 0.12–0.70), IPV screening ($p<0.05$, OR 0.37 (CI 0.15–0.90)) and contraception counseling ($p<0.01$, OR 0.37 (CI 0.15–0.90)). Males feel less comfortable prescribing oral contraceptives ($p<0.01$, OR 0.30 (CI 0.13–0.72)). PGY3 residents are more likely to feel comfortable ($p<0.05$, OR 2.43 (CI 1.01–5.83)) with IPV screening. In multivariate analysis of clinical practice, 29.8 % of residents have performed≥10 PAP smears, with males less likely (OR 0.13(CI 0.04–0.37)) and PGY-3 residents most likely (OR 53.7 (CI 10.1–285.4). 6.8 % of residents have prescribed contraception≥10 times. Male residents are least likely to have written≥10 prescriptions (OR 0.09 (CI 0.01–0.77)). Only 17 % of residents report screening for IPV annually, with no differences between the groups.
CONCLUSIONS: Although internal medicine residents believe it is important for internists to provide preventive health care to women, they do not feel adequately prepared to do so, particularly in contraception counseling or responding to women who screen positive for IPV. Training in preventive women's health may need to improve substantially if internists are to be well prepared to provide universal services.

REASON FOR CONSULTATION AND OUTCOMES OF A NEW PALLIATIVE CARE PROGRAM Aziz Ansari; Elizabeth Schulwolf. Loyola University Medical Center, Maywood, IL. (Tracking ID #1643307)

BACKGROUND: Palliative care (PC) is a specialty focusing on relief of distressing symptoms and facilitating goals of care discussions for people with serious illness. It is well established that PC programs reduce length of stay, improve quality of life and symptom burden along with decreasing utilization of non beneficial resources. We set out to determine the primary reason for consultation and potential impact on change in code status, length of stay (LOS), 90 day readmission rate and discharge disposition for a new PC consult service at an academic institution.
METHODS: Our new PC consultation program began September 1, 2010. As part of efforts to track operational and quality metrics all cases are recorded in a database. We analyzed data from all consults obtained in the first year of the program (September 1, 2010-June 30, 2011) including consulting service, primary reason for consult, change in code status, LOS pre and post consult, and discharge disposition. We then compared change in code status when goals of care was the primary reason for consult vs. symptom management. We also evaluated 90-day readmission rates for patients consulted between September 1, 2010 and March 30, 2011.
RESULTS: There were 282 consults; 254 (90 %) were requested by medicine services and 28 (10 %) were from surgical services. Of these, 226 consults (80 %) were requested primarily for assistance with establishing goals of care and 56 consults (20 %) primarily for assistance with symptom management. Overall, 126 patients (45 %) were full code before a PC consult (100 for goals of care and 26 for symptom management); 61 (48 %) of these patients had a change in code status to DNR following palliative care consultation. More patients had a change in code status when the primary reason for consult was goals of care than when for symptom management (55 % vs. 23 %, $p=0.006$). The 90-day readmission rate for 140 patients consulted between September 1, 2010 and March 30, 2011, dropped by 75 % (201 pre-consult compared to 51 post-consult). Overall, 34 % of patients were discharged to hospice care and 17 % of patients died while receiving inpatient comfort measures. Lastly, the mean post-consult LOS was shorter when compared to mean pre-consult LOS (3.84 vs. 6.84 days).
CONCLUSIONS: The majority of PC consults were requested from medicine services primarily for facilitating goals of care discussions. Following consultation, nearly half of patients who were full code had a change in code status to DNR. Readmission rates and post consult LOS decreased while hospice utilization increased consistent with previous studies. Our data suggest there is a recognized need for assistance with discussions about goals of care and that these conversations help to ensure alignment of treatment plans with patient's wishes as well as to reduce non-beneficial resource utilization.

REASONS FOR HIGH STRESS LEVELS IN AN INNER CITY OUTPATIENT POPULATION Kimberley Lee; Madhav Goyal. Johns Hopkins School of Mediicine, Baltimore, MD. (Tracking ID #1638016)

BACKGROUND: There is limited data examining the factors that contribute to perceived stress for Blacks living in the inner city. The objectives of this study were to measure the perceived stress levels of in an inner city, primarily Black population. We also sought to identify factors associated with higher levels of stress in this population, and identify the proportion of participants interested in a stress-management workshop.
METHODS: This was a cross-sectional anonymous survey of patients in an inner city health center in Baltimore, MD. Consecutive patients who registered at the clinic and who were 18 years of age or older were asked if they would be willing to participate in the study. Participants who consented were given an anonymous survey. Specific stress-related information gathered included the ten-item perceived stress scale (PSS), life events scale (LES), 24-hour and 6-month pain, pain catastrophizing scale (PCS), and mindfulness attention awareness scale (MAAS). Interest in a weekly mind-body workshop for 4 weeks was also assessed. We used linear regression to first identify demographic and other factors associated with perceived stress in a univariate analysis. An initial multivariate model was formed by inclusion of all significant variables ($p<0.05$) from the univariate analysis followed by stepwise deletion. Only variables that were significant in both models were kept. The final multivariate logistic regression model included the following variables: age, PCS score, MAAS score, and change in sleep habits on the LES.
RESULTS: Among all 174 patients surveyed, the mean PSS score was 20.4 (sd 7.2). In a multivariate analysis, higher age and mindfulness scores were associated with lower PSS scores ($p=0.01$). Higher pain catastrophizing scores and number of stressful life events were associated with higher PSS scores ($p<.001$ and $p=.01$ respectively). Of 41 life events, a change in sleep was the only stressful life event associated with higher PSS stress scores ($p=0.007$).
CONCLUSIONS: The perceived stress level of our sample of low-income, inner city outpatients is a standard deviation higher than that of the general population. The majority of this population is black and it has been shown that African Americans have higher perceived stress scores than their Caucasian counterparts. However, our inner city population has higher perceived stress scores than blacks in the general population as well. Higher mindfulness attention awareness scale scores were associated with reduced perceived stress. Thus, training in mind-body programs that develop mindfulness skills may be helpful in reducing stress in this population.

RECOGNITION OF VULNERABILITY IN HOSPITALIZED CARDIOVASCULAR PATIENTS Sunil Kripalani; Susan P. Bell; John F. Schnelle; Samuel K. Nwosu; Courtney Cawthon; Jonathan S. Schildcrout. Vanderbilt University, Nashville, TN. (Tracking ID #1642274)

BACKGROUND: Among elders, low functional health status (vulnerability) is a significant risk factor for poor outcomes, including functional decline and death. Assessment of vulnerability in hospitalized patients may identify at-risk individuals, who could benefit from increased post-acute care services such as home health nursing or rehabilitation. We assessed the prevalence of vulnerability among elders hospitalized with acute cardiovascular conditions, as well as their characteristics, prior health care utilization, and referral for post-acute care services.
METHODS: Individuals over the age of 65 hospitalized with acute coronary syndromes (ACS) or acute decompensated heart failure (ADHF) were enrolled in a prospective cohort study. Participants completed a series of validated measurements to assess demographics, education, cognition, psychosocial factors, and prior health care utilization. Functional health status was measured by the Vulnerable Elders Survey (VES-13), a validated method for identifying vulnerable elders in community settings. With a possible range of 0 to 10, a VES-13 score≥3 represents vulnerability, and scores≥4 represent extreme vulnerability. Disposition and home health services were recorded by chart abstraction.

RESULTS: Among 228 participants, the median VES-13 score was 3 (IQR 1–7), 129 (56 %) met criteria for vulnerability, and 83 (36 %) were classified as extremely vulnerable. Increasing vulnerability was associated with age, female sex, lower education level, lower health literacy (p=0.023), and lower health numeracy (p=0.01). More vulnerable patients were more likely to have moderate or severe depression (p<0.001) and greater difficulty paying bills (p=0.006). ER visits, clinic visits, and hospitalization in the prior 12 months were more frequent in vulnerable adults. However, low utilization of home health and rehabilitation facilities was present, with the majority of patients being discharged home with self-care. Vulnerable elders were no more likely to receive home health (2 %) or transfer to a rehabilitation facility (2 %) than non-vulnerable patients. Only patients classified as extremely vulnerable received higher levels of post-acute care services (33 %).
CONCLUSIONS: Reduced functional health status is highly prevalent in older adults hospitalized with ACS or ADHF. Vulnerability is associated with other risk factors, such as low health literacy and depression, as well as higher levels of health care utilization. Despite this, there is little referral for post-acute care services for adults identified as vulnerable.

RECRUITING AND RETENTION STRATEGIES IN TWO COMMUNITY-BASED RANDOMIZED CONTROL TRIALS OF OLDER BLACK MEN Joseph Ravenell. New York University School of Medicine, New York, NY. (Tracking ID #1640942)

BACKGROUND: Black men are often under-represented in clinical and health services research, decreasing the generalizability of results for many studies. This study aims to describe strategies for recruitment and retention of older black male study participants in two large community-based randomized control trials both with a 6-month intervention period and one 6-month follow-up data collection visit.
METHODS: Research staff in charge of recruiting and retaining study participants in two large community-based trials participated in two nominal group technique (NGT) focus groups where a round-robin facilitated discussion encouraged each participant to give unique responses to the questions: "What strategies have been effective in recruiting participants for the Mister B and FAITH-CRC studies?" and "What strategies have been effective in retaining participants for the Mister B and FAITH-CRC studies?" until all responses had been stated. Participants were then asked to rank responses in terms of importance and rankings were tallied for the entire group.
RESULTS: Recruitment and retention NGT groups had seven and eight participants respectively. Participants represented a variety of study personnel including interventionists, recruiters and administrative staff. Respondents ranked the three most important strategies for recruitment as: 1) incentives, 2) identifying the right neighborhoods and 3) having dynamic, outgoing and personable team members. For retention strategies, respondents identified the most important strategies as: 1) verifying phone numbers at the time of recruitment, 2) calling participants at multiple and varied times for each intervention and follow-up session and 3) developing rapport with interventionists.
CONCLUSIONS: Recruiting and retaining participants, particularly those from hard-to-reach populations, in randomized control trials is essential for the advancement of research and clinical practices focusing on reducing health disparities. This study aims to describe strategies that have been effective for recruiting and retaining older black male study participants recruited from community-based settings.

REDUCTION OF CARDIOVASCULAR RISK FACTORS BY MAGNITUDE OF WEIGHT LOSS IN OBESE AND OVERWEIGHT SUBJECTS WITH ≥2 COMORBIDITIES Lawrence J. Cheskin[1]; Charles H. Bowden[2]. [1]Johns Hopkins Weight Management Center, Baltimore, MD; [2]VIVUS, Inc., Mountain View, CA. (Tracking ID #1609151)

BACKGROUND: Obesity is associated with a significant risk of cardiovascular disease (CVD). Weight loss (WL) increases the odds of improvement in CVD risk factors and these risk factors are further improved with greater WL. Phentermine and topiramate extended-release (PHEN/TPM ER), when used in conjunction with lifestyle modifications, has previously demonstrated significant WL in the 56-week CONQUER study of obese and overweight subjects with ≥2 weight-related comorbidities. This post hoc analysis evaluated CVD risk factors according to degree of WL over 56 weeks.
METHODS: CONQUER was a double-blind, placebo-controlled, Phase 3 trial of 2487 obese and overweight adult subjects (BMI ≥27 to ≤45 kg/m2) with ≥2 weight-related comorbidities randomly assigned to placebo, PHEN 7.5 mg/TPM ER 46 mg (7.5/46), or PHEN 15 mg/TPM ER 92 mg (15/92) plus lifestyle modifications (reduced calorie diet and increased physical activity) for 56 weeks. In this post hoc analysis, lipid parameters and blood pressure (BP) were assessed in subjects achieving <5 %, ≥5 % to <10 %, ≥10 % to <15 %, and ≥15 % WL. Changes in Framingham risk score (which assessed cardiovascular risk over 10 years based on age, gender, total cholesterol, high-density lipoprotein cholesterol [HDL-C], smoking status, systolic BP, and antihypertensive medication use) were also assessed by degree of WL.
RESULTS: Most subjects were female (70 %) and Caucasian (86 %); mean age was 51.1 years, and mean BMI was 36.6 kg/m2. At baseline, 52 % of subjects had hypertension and 36 % had dyslipidemia. At week 56, for the placebo (n=979), 7.5/46 (n=488), and 15/92 (n=981) groups, respectively, least-squares (LS) mean absolute WL was −1.4 kg, −8.1 kg, and −10.2 kg (P<.0001 vs placebo, all comparisons; ITT-LOCF). Significant improvements in CVD risk factors were seen with WL ≥5 % vs <5 %: LS mean change for those achieving WL of <5 %, ≥5 % to <10 %, ≥10 % to <15 %, and ≥15 %, respectively, for systolic BP (mm Hg) were −2.1, −4.9, −7.4, and −9.4 (P<.0001 vs <5 %, all comparisons; ITT-LOCF), and for diastolic BP (mm Hg) were −1.7, −3.8, −5.0, and −5.6 (P <.0001 vs <5 %, all comparisons). LS mean percent change in lipid parameters for each WL category, respectively, was HDL-C (%), −0.2, 1.0, 3.5, and 6.5 (P≤.0078 vs <5 %, all comparisons); non-HDL-C (%), −3.4, −7.2, −8.9, and −13.2 (P<.0001 vs <5 %, all comparisons); triglycerides (%), −2.1, −17.2, −40.5, and −60.0 (P<.0001 vs <5 %, all comparisons). After 56 weeks of treatment, Framingham Risk was decreased, with greater improvements observed with greater WL: −0.2, −0.6, −1.0, and −1.4 for those achieving WL of <5 %, ≥5 % to <10 %, ≥10 % to <15 %, and ≥15 %, respectively (P<.05 vs <5 %, all comparisons; ITT-LOCF); this represents no relative mean reduction with <5 % or ≥5 % to <10 % WL and a 9.8 % and 15.6 % relative mean reduction for ≥10 % to <15 %, and ≥15 %, respectively. Most common adverse events included constipation, dry mouth, and paraesthesia.
CONCLUSIONS: When used in conjunction with lifestyle modification, PHEN/TPM ER led to significant WL in obese and overweight subjects. Framingham risk was improved with increasing degree of WL as were systolic and diastolic BP, HDL-C, non-HDL-C, and triglycerides in those achieving as little as 5 % to <10 % WL. These findings suggest the potential of WL induced by PHEN/TPM ER to significantly reduce CVD risk factors in obese and overweight patients. Dr. Cheskin is a member of the VIVUS, Inc. National Advisory Board and stockholder in the company.

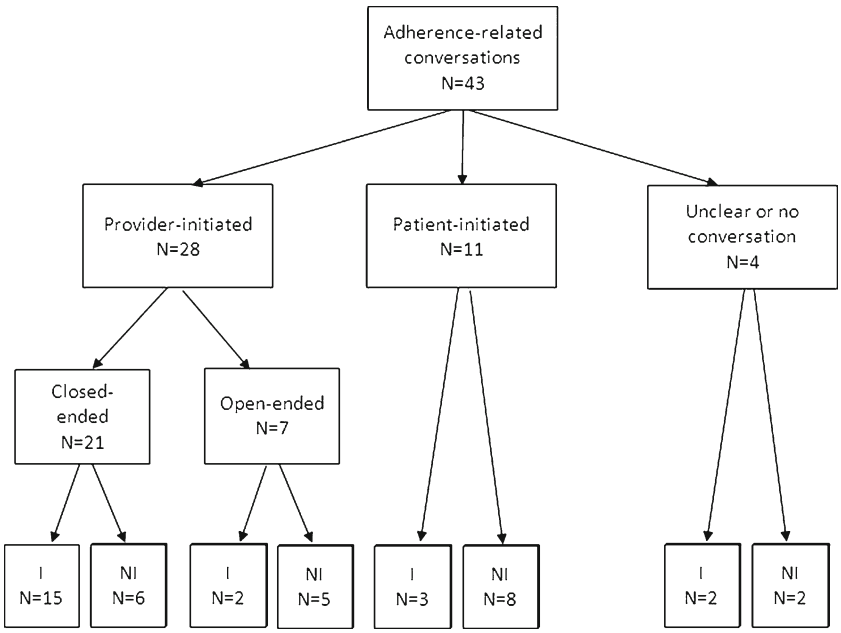
RELATION OF ANTIHYPERTENSIVE TREATMENT INTENSIFICATION TO PATIENT-PROVIDER COMMUNICATION ABOUT ADHERENCE TO MEDICATIONS Varsha Vimalananda[1,2]; Barbara G. Bokhour[1,3]; Jeffrey Solomon[1]. [1]Center for Health Quality, Outcomes and Economic Research (CHQOER), Bedford, MA; [2]Boston University School of Medicine, Boston, MA; [3]Boston University School of Public Health, Boston, MA. (Tracking ID #1639756)

BACKGROUND: In treating patients with uncontrolled blood pressure (BP), providers must distinguish suboptimal adherence to medications from insufficiently intensive therapy. Provider communication strategies are crucial to effective assessment of adherence and thus may influence decisions about whether or not to intensify medical therapy. We explored the relationships between open- or closed-ended questioning, providers' perceptions of adherence and decisions to intensify medications for hypertension (HTN).
METHODS: Data were collected for the CATCH (Culture and Treatment Communication in Hypertension) study. CATCH recruited primary care providers

(PCPs) and their patients from 2 VA medical centers. Eligible patients had a diagnosis of hypertension (HTN) and >=2 BP measurements above goal (>140/90 mmHg or, for diabetes, >130/80 mmHg) in the preceding year. We audiorecorded and transcribed 52 clinical interactions between patients and PCPs. In 43 encounters, PCPs clearly discussed intensification or non-intensification of medications. Among these, we coded segments related to medication-taking according to pre-specified categories based on our analytic goals: patient- or provider-initiated discussion; open- or closed-ended questioning; intensification or non-intensification of medication; and perceived acceptable or unacceptable adherence. For perceived adherence we determined provider assessment based on either explicit statements about adherence or patients' passive agreement with provider's declarative statements.

RESULTS: Of the 43 encounters, 22 resulted in treatment intensification and 21 did not. Forty patients were male. The intensified group was younger (57.5±11.1 vs. 61.3±7.2 years) and had a higher mean BP (166/97±21/11 vs. 155/92±13/8 mmHg). Adherence was addressed in most encounters (39/43) (Figure). Providers initiated the medication-taking discussion more often than did patients (65 % vs. 27 %). Providers used closed-ended more frequently than open-ended questions (75 % vs. 25 %). Intensification was more likely to occur when providers used closed-ended vs. open-ended questions (71 % vs. 40 %). Intensification occurred least frequently (27 %) when patients initiated the conversation. The perception of acceptable adherence was much more likely in cases of closed- than in cases of open-ended questioning (76 % vs. 13 %).

CONCLUSIONS: The methods that providers use to assess adherence in patient encounters influence decisions about treatment intensification for HTN. Use of closed-ended questions is likely to result in incomplete information about adherence, leading to inaccurate judgments of the need to intensify therapy.



RELATIONSHIP BETWEEN SELF-ASSESSED AND TESTED NON-ENGLISH LANGUAGE PROFICIENCY AMONG PRIMARY CARE PROVIDERS Lisa C. Diamond[1,2]; Sukyung Chung[3]; Warren Ferguson[4]; Elizabeth A. Jacobs[5]; Francesca Gany[1,2]. [1]Memorial Sloan-Kettering Cancer Center, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Palo Alto Medical Foundation Research Institute, Palo Alto, CA; [4]University of Massachusetts Medical School, Worcester, MA; [5]University of Wisconsin-Madison, Madison, WI. (Tracking ID #1634474)

BACKGROUND: Individuals with limited English proficiency (LEP) experience poor patient-clinician communication. True language concordance between LEP patients and clinicians can be beneficial but most studies of language concordance have used clinician self-reported non-English language proficiency. Self-assessments are less expensive and less time consuming than oral proficiency tests but may not be as reliable. Our objective was to evaluate the accuracy of self-assessment of non-English language proficiency by clinicians.

METHODS: Primary care providers (PCPs) who spoke one of 6 languages other than English were recruited from a multispecialty group practice in the San Francisco Bay Area of California and from Massachusetts Community Health Centers. PCPs first completed a <5 min self-assessment using a version of the Interagency Language Roundtable (ILR) Scale which was adapted for use in the medical setting. They were then invited to take the Clinician Cultural and Linguistic Assessment (CCLA), a validated oral proficiency interview designed to assess clinician language proficiency in the health care setting. We used non-parametric approaches to assess equality in mean and variance in CCLA scores of each ILR scale and the correlation between CCLA scores and ILR scale by language.

RESULTS: Sixteen PCPs in California and 51 in Massachusetts participated in the study. Spanish was the most common language tested (79 %), followed by Cantonese, Mandarin, French, Portuguese, and Vietnamese. The respondents self-reported their proficiency level as "Excellent" 9 % of the time, 24 % rated "Very Good," 46 % "Good," 18 % "Fair," and 3 % rated "Poor" proficiency. The average CCLA score was 76/100. There was a positive correlation between self-reported ILR scale and CCLA score (rho=0.49, $p<0.001$). Respondents who self-reported "Excellent" on the ILR scored an average of 87 on the CCLA. Respondents who self-reported "Poor" scored an average of 34 and those who self-reported "Fair" scored an average of 64. Scores for participants who self-rated as "Good" or "Very Good" were similar (78 vs. 80). The variance in CCLA scores was wider in the middle categories ("Good" or "Very good") than in the low or high ILR categories ($p=0.003$).

CONCLUSIONS: Self-reporting of non-English language proficiency using the ILR correlates to tested language proficiency, particularly on

the low and high ends of the self-rating scale. Participants who self-report in the middle of the scale may require additional testing. Further research needs to be done to identify the characteristics of PCP whose self-reported non-English proficiency levels are inaccurate and, thus, require proficiency testing.

RELATIONSHIP BETWEEN INCREASED CLOSTRIDIUM DIFFICILE RATES, ANTIBIOTIC UTILIZATION, AND A NEW C. DIFFICILE TESTING ALGORITHM Daniel Caroff[1]; Warren Bilker[3]; David A. Pegues[2]; Keith Hamilton[2]. [1]University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA. (Tracking ID #1634774)

BACKGROUND: At our institution, we have seen a disproportionate increase in rates of positive C. difficile testing on our inpatient oncology units from 2008 to 2011 despite aggressive environmental measures and antimicrobial stewardship. Similarly, utilization of some broad-spectrum antibiotics increased on the same units. In December of 2010, our institution changed C. difficile testing from an enzyme immunoassay (EIA) to an algorithm using glutamate dehydrogenase antigen, EIA, and polymerase chain reaction (PCR) assays. The aim of this study was to examine relationships between positive C. difficile tests, the usage of broad-spectrum antibiotics and a more sensitive assay.
METHODS: We collected data on positive C. difficile tests, number of tests performed, and total defined daily doses of pipericillin-tazobactam, meropenem, levofloxacin, and cefepime used on several oncology, critical care, and general medical units from 2008 to 2011. Data was standardized by patient-days. We designed a mixed-effects Poisson regression model to compare infection rate, unit type, C. difficile assay type, and antibiotic usage trends. All cases of positive C. difficile tests were adjudicated based on National Healthcare Safety Network (NHSN) definitions.
RESULTS: Rates of positive C. difficile testing on oncology units increased by 36 % after introduction of the PCR-based assay ($p<0.001$). There was no relationship between antibiotic usage and rates of C. difficile on any unit. After the implementation of the PCR-based assay, the average rate of colonization (patients with positive C. difficile testing that did not meet NHSN criteria for GI infection) more than doubled from 16 % to 35 % on oncology units compared with no increase (28 % to 27 %) on general medical and critical care units.
CONCLUSIONS: Trends in positive C. difficile results were strongly associated with use of a new assay, but not with trends in antibiotic usage. Specifically, the rate of positive C. difficile testing due to colonization increased significantly on oncology units after implementation of a more sensitive assay. This may be related to a lower threshold for C. difficile testing in oncology patients. In order to minimize the detection of colonization and the subsequent antimicrobial treatment of these patients, we suggest an algorithmic approach to C. difficile testing. Further prospective study is needed to determine whether such an approach is safe and beneficial.

REPATRIATION TO PRIMARY CARE: DO PCPS AND SPECIALISTS AGREE? Nathaniel Gleason; Sara Ackerman; Don Collado; Chanda Ho; Jennifer J. Monacelli; Michael Wang; Ralph Gonzales. UCSF, San Francisco, CA. (Tracking ID #1640636)

BACKGROUND: 'Repatriation'—the return of care management from a specialist to the primary care provider (PCP), accompanied by specialist recommendations—could help optimize the use of specialty care resources. A better understanding of two areas is needed: 1) identification of patients followed by a specialist for a clinical problem that could reasonably be managed by a PCP, and 2) an understanding of barriers to repatriation. Here we report survey results from specialists and PCPs regarding patients under their mutual care; in a companion abstract we report qualitative findings from interviews with PCPs.
METHODS: Specialists (total $n=59$) in 5 medicine subspecialty practices (Cardiology, Endocrinology, Gastroenterology, Pulmonary, and Rheumatology) at a single institution completed a 4-item, self-administered survey following each patient visit ($n=104$–173 surveys per specialty), which asked, "Could this diagnosis be managed exclusively by the PCP?" Response options were "yes", "perhaps," and "no". PCPs (both internal ($n=90$) and external ($n=262$) to the academic medical center) were then identified, and received a similar survey for each patient captured by a specialist survey. Since PCPs were reflecting on their own comfort level with exclusive management, we did not include a "perhaps" response, but rather 'yes' and 'unlikely'. Proportions are presented with 95 % confidence intervals (95 % CI); statistical significance in the difference between specialists and PCPs on the question of repatriation was assessed with McNemar's chi-square test.
RESULTS: Specialists completed surveys for 754 (68 %) of the 1,082 eligible patient visits during the survey period. PCPs were identified for 705 (94 %) of these patients ($n=316$ internal, and 389 external). PCPs completed 383 surveys (response rate=80 % for internal and 37 % for external PCPs). 342 patients had PCP and specialist surveys with no missing data, and served as the final study sample. PCPs identified 46 % of patients appropriate for repatriation, compared with specialists who identified 24 % ($p<0.001$). Among patients whom PCPs deemed appropriate for repatriation ($n=158$), 35 % (95 % CI: 28, 42) of specialists answered "yes," 27 % (95 % CI: 20, 34) answered "perhaps," and 38 % (95 % CI: 30, 45) answered "no." Among patients whom specialists deemed appropriate for repatriation ($n=82$), 67 % (95 % CI: 57, 77) of PCPs answered "yes" and 33 % (95 % CI: 23, 43) answered "unlikely." Overall, 16 % (95 % CI: 13 %, 19 %) of patients had concordant PCPs and specialists, answering "yes" to repatriation. For trends by diagnosis, we limited the analysis to those diagnoses shared by at least 8 patients. The diagnoses with >50 % agreement that repatriation was appropriate were hypertension (6/8 PCP-specialist pairs agree), coronary artery disease (11/21), non-malignant thyroid disease (6/12), and COPD (9/18). Diagnoses with >50 % agreement that repatriation was not appropriate were inflammatory bowel disease (11/13), thyroid cancer (11/13), and rheumatoid arthritis (25/32).
CONCLUSIONS: For patients with continuing care in specialty practices, and an established PCP, PCPs and specialists agreed that return of care management to the PCP is reasonable for a significant proportion. This presents an opportunity to provide less costly, streamlined care for such patients. Conversely, we found a high degree of discordance overall. Several diagnoses emerged as potential targets for empiric interventions to facilitate repatriation where appropriate.

REPRODUCIBILITY OF ASSESSMENTS OF LEARNERS' SKILLS IN QUALITY IMPROVEMENT Robert G. Badgett[1,2]; Edward F. Ellerbeck[3]; Leslie A. Sullivan[3]; Tracie C. Collins[1]. [1]KU School of Medicine-Wichita, Wichita, KS; [2]KU School of Medicine-Wichita, Wichita, KS; [3]KU School of Medicine, Kansas City, KS. (Tracking ID #1635454)

BACKGROUND: The teaching of quality improvement (QI) is an emerging component of curricula for both medical students and resident physicians. In the absence of clear national recommendations, schools are developing independent curricula. The Quality Improvement Knowledge Application Tool (QIKAT) is, to our knowledge, the only existing tool for assessing the knowledge of learners and thus is essential for guiding the assessment of innovations in the teaching of QI. Prior reports of the inter-rater reliability of the QIKAT range from Kappa of 0.2 to 0.8.
METHODS: In a before and after assessment, we administered a modified QIKAT to medical students participating in a required senior course that includes teaching of QI. The QIKAT consists of questions that query learners' confidence in their QI skills and three scenarios in which learners describe the aim and methods of proposed QI projects to address deficits in the quality of care described in the scenarios. Raters assess 4 dimensions of the proposed projects. One dimension is the aim statement of the proposed project. An example of an exemplary aim statement is to "increase the percentage of retinal exams for my patients with diabetes by 50 % in the next 6 months" (Oyler J et al. University of Chicago Medical Center).

During October of 2012, students were randomly given one QI scenario from the QIKAT before the course and a second scenario after the course. Two raters independently and blindly assessed the students' answers to the scenarios. The raters used previously published criteria for scoring the QIKAT. In addition, for the aim statements, all five of Doran's SMART criteria (specific, measurable, attainable, relevant, time-bound) were required for aim statements to be judged as excellent. Inter-rater agreement was measured with Cohen's weighted kappa. For this analysis, we included all tests regardless of whether they were administered before or after the course.

RESULTS: Twenty-nine senior medical students completed tests before and after the course yielding 58 completed tests. For the inter-rater reliability of the assessments of the aim statements component of the QIKAT, kappa was 0.09 (p=0.479). The inter-rater reliability of the other 3 dimensions ranged from 0.25 to 0.31 (p-values ranged from 0.01 to 0.027). For the inter-rated reliability of the overall QIKAT scores, kappa was 0.12 (p=0.122).

CONCLUSIONS: In an independent assessment, we report the QIKAT to be much less reliable than previously reported. We believe the tool is essential in guiding the development of curricula in quality improvement; however, the QIKAT needs more explicit criteria for scoring its subjective components. This is especially true for incorporation of Doran's SMART criteria into the assessment of aim statements for QI projects proposed by the students. A limitation of our study was assessing only two of the three scenarios from the QIKAT.

REPRODUCTIVE CHALLENGES FACING US MILITARY FEMALE SOLDIERS IN A WAR-READY CULTURE April S. Fitzgerald[1]; Rita L. Duboyce[2]; Barbara A. Cooper[2]; Deborah Omori[2]; Joan B. Ritter[2]; Patrick G. O'Malley[2]. [1]Johns Hopkins University, Baltimore, MD; [2]Uniformed Services University of the Health Sciences, Bethesda, MD. (Tracking ID #1641059)

BACKGROUND: Initially capped at 2 % maximum allowable percentage of the military, female soldiers now comprise over 14 % of the U.S. active duty military, numbering over 200,000. The issues of sexuality, family planning, pregnancy, breast feeding, and family care are unique in this population and affect soldier readiness and deployment planning. The goal of our study is to evaluate reproductive and maternity leave policies that affect female soldiers.

METHODS: Systematic review of international and US military policies. We reviewed the US Uniform Code of Military Justice, Department of Defense Instructions, and service specific regulations such as the Air Force Instructions, Army Regulations, and Navy Regulations for barriers to female military service with regards to reproduction. We also compared maternity leave policies applicable to female soldiers among four major countries that have significant numbers of female soldiers serving on active duty: United Kingdom, Canada, Australia, and the United States.

RESULTS: The US provides the shortest length of maternity leave (6 weeks) among four major countries reviewed. In the post-partum time frame, the US Army and Air force defer deployment for 4 months while the Navy defers deployment for 12 months. Only the Air Force and Navy have breastfeeding policies that guarantee time and space for Active Duty mothers to pump breast milk. All military services require a family care plan for dual-military and single parents to ensure adequate care for dependents if the military member is deployed.

CONCLUSIONS: The US military has implemented policies to reduce barriers to the service of female military members, but policymakers could consider further policy changes. Recommendations include increasing education and family planning programs, implementing an optional six-week extension of non-chargeable maternity leave for primipara mothers, and consideration of a temporary 80 % full-time equivalent option for female soldiers during the first 6-months of their newborn's life. These strategies should be studied for impact on female retention, mission effectiveness, unit morale, child well-being, and soldier health.

Maternity Policies in 4 Countries with Female Service Members
Australia </u</b Canada </u</b United Kingdom</u</b United States </u</b

Maternity Pay </b 14 weeks (100 % pay) 38 week (non-paid) Up to 52 week (93 % pay) 6 week(90 % pay) 33 week (lower of 90 % or stnd rate) 6 week (100 % pay)

RESIDENT ATTITUDES, KNOWLEDGE AND BEHAVIORS REGARDING AN ELECTRONIC INCIDENT REPORTING SYSTEM Jessica A. Eng[1,2]; Jonathan Hatoun[3,4]; Constance Liu[3]; Laura Blum-Smith[5]; Sandra Shea[5]; Winnie Suen[3,6]. [1]University of California San Francisco School of Medicine, San Francisco, CA; [2]San Francisco VA Medical Center, San Francisco, CA; [3]Boston Medical Center, Boston, MA; [4]Boston Children's Hospital, Boston, MA; [5]Committee of Interns and Residents, New York, NY; [6]Boston University School of Medicine, Boston, MA. (Tracking ID #1637400)

BACKGROUND: At academic medical centers, resident physicians are frontline providers who can play a key role in improving patient safety and hospital operations. While the use of electronic incident reporting systems to gather data about areas for improvement is increasing, there is little data about the resident perspective on electronic incident reporting systems. In recognition of this issue, Boston Medical Center, a 496-bed urban safety net hospital, collaborated with the Committee of Interns and Residents housestaff union. As the initial step of a hospital-funded project to improve reporting behaviors, we conducted a survey of interns and residents about their attitudes, knowledge, and behaviors regarding the institution's electronic incident reporting system.

METHODS: A resident focus group was used to inform a preliminary survey of graduating house officers in Spring 2012, from which a final survey tool was refined. The voluntary and confidential survey was distributed to the interns and residents of one urban academic medical center at house officer conferences for 8 weeks in Fall 2012. Residents were asked to select the 3 biggest barriers to using the reporting system from a list (knowledge of current electronic incident reporting system, fears related to reporting, perceived effectiveness of current system, and resident work load and priorities). Other survey questions focused on their use of the reporting system, attitudes towards efforts to increase reporting, and attitudes towards learning how to reduce errors. Most survey questions used a 5-point Likert scale ("Strongly Disagree" to "Strongly Agree") categorical response format, and results are reported by combining the "Somewhat Agree" and "Strongly Agree" responses.

RESULTS: Three hundred fifty residents responded (69 % response rate) to the survey. Sixty-three percent reported having been involved in an adverse event, but only 37 % of all residents had submitted an electronic incident report. The most commonly cited barriers to using the electronic reporting system were not knowing which incidents to report (53 %), not knowing how to use the electronic reporting system (45 %), and being too busy with other work to file a report (43 %). Residents were least likely to cite worries about retaliation from other hospital employees (12 %), disciplinary action (7 %), litigation (7 %) as barriers. Respondents indicated that discussion of possible adverse events on a case by case basis with their clinical teams (57 %) and educational conferences about adverse events led by someone from their department (50 %) would increase rates of their reporting. Ninety-one percent agreed that "it is important to learn how to improve systems during residency to reduce errors"; however, only 37 % felt that "reporting adverse events using the electronic incident reporting system is an effective way to help reduce errors and improve patient safety." Only 32 % agreed that their supervisors encourage them to use the reporting system.

CONCLUSIONS: Many adverse events go unreported due to a lack of resident knowledge about how to use the current reporting system and which incidents to report, as well as because of a feeling that the electronic reporting system is not an effective way to improve patient safety. Still, residents believe that it is important to learn how to improve hospital systems during residency. Patient safety efforts at academic medical centers should include education of residents about how adverse event reporting improves patient safety and how to use available reporting systems.

RESIDENT PEER CHART REVIEW: AN EFFECTIVE APPROACH FOR QUALITY IMPROVEMENT AND MEDICAL EDUCATION
Andrew J. Hale; Ryan Nall. Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #1641286)

BACKGROUND: Appropriate follow-up and documentation of outpatient lab results is an ongoing challenge for many healthcare providers. Additionally, teaching resident physicians how to do it correctly is an added difficulty. Peer review among residents is a little explored but potentially valuable intervention to improve safety and education. In this quasi-experimental study, we evaluated the effects of self- and peer-review on laboratory follow-up among internal medicine residents.
METHODS: We examined three groups of residents—those who reviewed their own charts (self-review; $n=69$); those who reviewed other residents' charts (peer-review; $n=59$); and an historical control group of 20 residents. Self- and peer-review occurred in September through October of 2012 and examined the first ten results available from 4/1/12 onwards. Residents assessed the acuity of each lab result, the time to document a discussion with the patient, and undocumented results. We performed a second review after the initial review, using the first 10 results from 11/1/12 forward. We reviewed results from the control group in the same manner, using results from both 4/1/11 and 11/1/11 onwards, to assess the effect of 7 months of additional training. We also surveyed residents about their comfort with the peer review process and its importance.
RESULTS: Before the chart review intervention, from 4/1/12 onwards, the mean time required for documentation was 5.1 (SD 4.7) days based on self-review and 6.2 (SD 7.3) days based on peer-review ($p=0.24$). In self-review, there were 43 (6.2 %) cases of no documentation of lab follow-up, while in peer-review there were 77 (11.2 %) such cases ($p=0.006$). For missed abnormal labs, there were 13 (5.8 %) cases found in self-review and 15 (8.6 %) found in peer-review ($p=0.50$). In self-review, there were 84 (12.2 %) cases of documentation after 7 days, while in peer-review there were 104 (15.1 %) such cases ($p=0.06$). Interim results from the first 10 residents following the intervention, from 11/1/12 onwards, found a mean time to documentation of 2.9 days (SD 1.3). There were 2 (2.0 %) missed labs, 0 of which were abnormal, and 4 (4.0 %) labs documented after 7 days. In interim review of 10 historical control residents, the mean time to documentation was 6.0 (SD 3.0) days initially and 6.1 (SD 3.8) days 7 months later ($p=0.84$). Similarly, initial and subsequent reviews documented 13 % and 16 % of cases with no documentation ($p=0.52$), 11.4 % and 12.2 % undocumented abnormal results ($p=0.57$), and 20 % and 22 % of cases with no documentation within 7 days ($p=0.68$). A total of 78 % of surveyed residents agreed or strongly agreed that peer review was an important part of the quality improvement process, and 85 % felt comfortable or very comfortable reviewing other residents.
CONCLUSIONS: In this innovative application of peer-review to patient safety and resident education, peer-review had a strong effect on improving resident behavior. Peer-review identified more cases of suboptimal laboratory result documentation than did self-review. The process of performing peer review appeared to markedly improve subsequent documentation of laboratory results. The majority of residents felt peer-review was important, and were comfortable with participating in it. Our results support the use of resident peer review in improving the safety of laboratory result follow-up, and suggest it could be used far more broadly in resident quality improvement and education.

RESIDENT-LED INTERVENTION TARGETING HIGH-UTILIZING PATIENTS IN A RESIDENT CONTINUITY CLINIC SHOWS PROMISE IN IMPROVING RESIDENTS' COMPETENCY IN SYSTEMS-BASED PRACTICE
Sean Tackett[1]; Melissa Dattalo[1]; Marc Larochelle[2,1]; Ryan E. Childers[1]; Huy Do[1]; Lauren Graham[1]; Lana R. Elpert[1]; Stephanie Nothelle[1]; Fernanda Porto Carreiro[1]; Justin Elfrey[1]; Laura Hanyok[1]. [1]Johns Hopkins Bayview Medical Center, Baltimore, MD; [2]Harvard Medical School, Boston, MA. (Tracking ID #1638890)

BACKGROUND: Effective systems-based practice has the potential to improve quality and reduce cost for high-utilizing medically and psychosocially complex patients. Residents training in internal medicine continuity clinics provide care for a disproportionate number of such complex patients, making resident clinics an ideal place to develop competency in systems-based practice. In 2011, internal medicine residents at Johns Hopkins Bayview created and implemented a multimodal intervention to improve care for high-utilizing patients in their continuity clinic.
METHODS: We included patients insured by a Medicaid HMO who had 4 or more ED visits or inpatient admissions and 3 or more visits to the continuity clinic in the preceding year. We assigned each intern (PGY-1) starting in July 2011 to a high-utilizing patient whose primary care physician had just graduated from the residency program. The intervention consisted of structured home visits, action plan development, collaboration with an insurer-based nurse case manager (NCM), and monthly multidisciplinary conferences that included problem-solving discussions for selected high-utilizing patients and didactic sessions. Residents (PGY-2 and PGY-3) continued usual care with their established high-utilizing patients and served as a comparison group. We administered surveys to both interns and residents matched with high-utilizing patients at the end of the 2011–2012 academic year. All trainees rated their competency in systems-based practice (4 questions summed, scaled 4–20), ability to work with NCMs (2 questions, each scaled 1–5), and satisfaction with the care they provided (visual analog scale of 0–100), and they completed the Difficult-Doctor Patient Relationship Questionnaire (scores over 30 indicate a difficult relationship). Interns completed an additional series of questions assessing their satisfaction with the intervention.
RESULTS: Fifteen intern-patient dyads (intervention group) and 23 resident-patient dyads (usual care group) were included in the analysis. Most interns felt that the intervention improved their ability to care for their high-utilizing patient (86 %) and for their other patients not involved in the intervention (79 %). Every intern (100 %) agreed that the home visits were personally rewarding, changed their perception of their patient, allowed them to know their patient better as a person, and permitted them to provide better care for their patient. Interns, compared to residents, had a trend toward higher perceived competency in systems-based practice (12.4 (SD 3.2) vs. 10.9 (SD 4.2), $p=0.23$) and felt more strongly that they understood the role of NCMs (3.6 (SD 1.2) vs. 2.4 (SD 1.3), $p=0.01$), and could employ NCM help (3.5 (SD 1.1) vs. 2.3 (SD 1.3), $p=0.01$). Residents, compared to interns, had greater satisfaction with their care of their patients (63.9 (SD 27.2) vs. 55.3 (SD 25.0), $p=0.34$) and did not perceive their patients to be as difficult (28.3 (SD 8.2) vs. 35.6 (SD 11.0), $p=0.04$).
CONCLUSIONS: A resident-led intervention to improve care for high-utilizing patients in resident continuity clinic was well received by interns. The intervention may have led to greater competency in systems-based practice, especially interprofessional collaboration. Further study would be needed to determine why residents reported better relationships with patients. Potential reasons include residents' longer patient relationships and training experience.

RHEUMATOID ARTHRITIS IS ASSOCIATED WITH DISTURBED MACROVASCULAR BUT NOT MICROVASCULAR FUNCTION
Ra'ad Tashman[1]; Ivy Ku[2]; Peter Ganz[2]; Priscilla Hsue[2]; John Imboden[2]; Carl Grunfeld[2]; Jonathan Graf[2]. [1]H Ford Hospital, Detroit, MI; [2]UCSF, San Francisco, CA. (Tracking ID #1642005)

BACKGROUND: Rheumatoid arthritis (RA) patients have macrovascular dysfunction and increased cardiovascular death. Digital pulse amplitude, a measure of microvascular endothelial function, has not been tested in RA. The mechanism of vascular dysfunction in RA is unclear.
METHODS: We conducted a cross-sectional study of 26 RA subjects and 15 matched controls. Macrovascular function was assessed by flow-mediated dilation (FMD) and pulse wave velocity (PWV) and microvascular function by digital pulse amplitude (EndoPAT). Oxidative stress was assessed by asymmetric dimethyl L-arginine (ADMA) and nitrotyrosine (NT) and inflammation by CRP. We used linear regression to evaluate the

association between RA and vascular function, and to assess for potential mediators.
RESULTS: RA was associated with a 2.1 % lower FMD in an age-adjusted model (CI 0.08–4.07, p=0.04). RA was associated with a 1 m/s higher PWV in a model adjusted for age and blood pressure (CI 0.25–1.69, p=0.01). There was no difference in EndoPAT index between RA and controls (Table). ADMA, NT, and CRP were not significant mediators of the association between RA and macrovascular dysfunction. Vascular function measures in RA vs control subjects RA control P value Flow-mediated vasodilation, % 4.44±3.01 6.73±3.11 0.03 Pulse wave velocity, m/s 8.2±1.6 6.9±0.9 0.01 EndoPAT index 2.2±0.6 2.2±0.8 0.77
CONCLUSIONS: RA patients have significantly impaired macrovascular function (by FMD and PWV) while microvascular function is preserved. ADMA, nitrotyrosine or CRP did not mediate the association between RA and macrovascular function. The biological differences in the macrovascular and microvascular beds in RA patients deserve further investigations.

RISK FACTOR PROFILES OF AFRICAN AMERICANS WITH PERIPHERAL ARTERIAL DISEASE Rosalee Zackula[2]; Mojdeh Baniasadi1; Tracie C. Collins[1]. [1]KU School of Medicine-Wichita, Wichita, KS; [2]KU School of Medicine-Wichita, Wichita, KS. (Tracking ID #1642070)

BACKGROUND: African Americans are more than two times as likely as non-Hispanic whites to suffer from peripheral arterial disease (PAD)—atherosclerosis of the abdominal aorta and arteries of lower extremities. Very little is known about risk factors for PAD in African Americans. We explored risk factor profiles of African Ameicans with PAD.
METHODS: A cross-sectional analysis was conducted using data from an NHLBI funded trial to promote walking among community-dwelling African Americans. Exclusion criteria included prior foot or lower leg amputation and an inability to walk for exercise. Participants were evaluated for PAD using the ankle-brachial index (ABI: the ratio of systolic blood pressure in the ankle to that in the arm) and completed a telephone survey that included an assessment of sociodemographics, comorbidities and readiness to engage in exercise. PAD was defined by an ABI<0.995 in either leg. Chi-square and Mann-Whitney U tests were used to compare survey responses by PAD status. Where data were sparse, exact 2-tailed tests were used. Analyses were conducted in IBM SPSS (version 20, Chicago, IL).
RESULTS: Eighty three African Americans were included in the study; 43 (51.8 %) were diagnosed with PAD. Sixty-four (77.1 %) were females of whom 32 screened positive for PAD, 19 (22.9 %) were males of whom 11 screened positive for PAD. However, the median age of females with PAD (66.5 years) versus without (57.0 years) was higher, z=2.71, P=0.006. Results were similar for males; median age for males with PAD was 74.0 years versus 53.0 years without (z=2.74, p=0.004). We found significant differences in number of comorbidities by group (Table 1.); those with PAD reported more comorbidities; z=2.34, p=0.019. The most often reported comorbidities were arthritis and hypertension, PAD=14 (33.3 %) compared with no PAD=7 (17.1 %). No significant differences were found for smoking status or prescriptions for hypertension/cardiovascular disease. Of those diagnosed with PAD, 5 (15.6 %) reported they did not have primary care physicians.
CONCLUSIONS: Results showed higher numbers of comorbidities and advancing age were significantly associated with PAD. However, data were sparse and disproportionately female. Further studies should consider these potential risk factors, the role of diabetes mellitus, and biases when designing research on African Americans with PAD.

RISK FACTORS FOR EMOTIONAL DISTRESS AMONG PHYSICIAN RESIDENTS AND FELLOWS: A DESCRIPTIVE STUDY OF COUNSELING VISITS Anna Golob[1]; Mindy Stern[2]. [1]University of Washington, Seattle, WA; [2]University of Washington, Seattle, WA. (Tracking ID #1635672)

BACKGROUND: A significant proportion of surveyed physician residents report emotional distress, burnout, or poor quality of life. There is evidence that resident distress impacts patient care and can negatively affect medical knowledge as assessed by standardized examinations. Unfortunately, there is a paucity of data regarding causes of resident and fellow distress and effective interventions. Our University Graduate Medical Education Wellness Center offers free and confidential counseling visits to its physician trainees (residents and fellows). The counselors have collected a de-identified database of information about the trainees who receive counseling. The objective of this IRB-approved study is to provide a descriptive analysis of this database with an aim to better characterize risk factors leading to emotional distress among physician trainees.
METHODS: The analysis includes all University Wellness Center physician trainee counseling visits that occurred between 9/1/2009 and 9/30/2012. The database includes age, gender, post graduate year, foreign medical graduate status, amount of medical debt, by whom the trainee was referred, chief complaint, other concerns, history of prior mental health diagnosis/counseling/psychiatric medication use, distress level using a Likert Scale from 1 to 5, whether medication was recommended, and if/where the trainee was referred as a result of the visit.
RESULTS: There were 332 new physician trainee counseling visits during the 3 year study period and 1,312 return counseling visits. The great majority of physician trainees were self referred (80 %) followed by referred by a program director (16 %) or by a partner (2 %). Female physician trainees outnumbered males by nearly two to one (65 % to 35 %). The amount of medical debt ranged from none to $580 K, with an average of $157 K; slightly less than the national average of $162 K for US allopathic graduates. Distress level as assessed by Likert Scale did not vary by amount of medical debt; average distress level at all new visits was 4.0. A chief complaint of mental health disorder was the most common reason for seeking a new counseling visit (46 %) followed by relationship concerns (28 %), career (22 %), physical health (3 %), and chemical dependency (1 %). Depression was the most common mental health condition seen (22 %), followed by anxiety (15 %). As reference, the point prevalence of depression in US adults aged 18–64 is around 4 %. 18 % of trainees were seen for a chief complaint of job stress, burnout, or struggles with work-life balance. Interventions included follow-up counseling visits, utilized by 75 % of trainees, and referrals. Twenty-three percent of trainees seen in new visits were referred to other providers or programs, most commonly to a psychiatrist (54 %), PCP (9 %), or a community counselor (9 %).
CONCLUSIONS: A mental health disorder was the most common reason for seeking counseling in this study. The physician trainees were found to have a higher prevalence of depression than their age matched, non-physician counterparts. They had substantial medical school debt, but this

was not higher than the national average, suggesting amount of debt may not correlate well with emotional distress. As demonstrated in other studies, this population frequently reported stress, burnout, and difficulty with work-life balance. One interesting finding is the large percentage of visits prompted by relationship concerns. This is one potential target for prospective intervention by graduate medical education programs.

RISK FACTORS FOR NON-ADHERENCE WITH ROUTINE SCREENING MAMMOGRAPHY IN HIV-INFECTED WOMEN
Zoe Weinstein[1]; Amy S. Baranoski[2]. [1]Boston Medical Center, Boston, MA; [2]Drexel University College of Medicine, Philadelphia, PA. (Tracking ID #1641730)

BACKGROUND: With advances in antiretroviral treatment over the past two decades, life expectancy has increased significantly for HIV-infected individuals; making it more important than ever to ensure the aging HIV-infected population is obtaining routine cancer screening for non-AIDS-defining malignancies. Screening mammography is especially critical, as breast cancer is the most common malignancy diagnosis for American women. The objective of this study was to identify risk factors for inadequate screening mammography in a diverse cohort of HIV-infected women at a large urban safety-net HIV clinic.
METHODS: This retrospective cohort study reviewed the electronic medical record of HIV-infected women aged 40 and older receiving HIV care between October 1st, 2003 and March 31, 2008, for risk factors associated with inadequate screening mammography, defined as not having a mammogram within 2 years of first HIV clinic visit during the study period. Analyses included Chi square testing and unadjusted and multivariate logistic regression.
RESULTS: One hundred forty-six of 292 (50 %) of women had a mammogram within 2 years of initial HIV clinic visit. In unadjusted analysis, women who were of white race, U.S. born, English-speaking, unemployed, high school or higher education level, or who had an HIV viral load >75 copies/mL or a CD4 T-cell count <200 cells/mm3 had increased odds of not undergoing a mammogram. In multivariate analysis, women who were U.S. born (OR 2.7 CI [1.5–4.6]), completed high school or higher education (OR 1.8 [CI 1.1–3.0]) or had an HIV viral load >75 copies/mL (OR 2.2 CI [1.3–3.9]) had increased odds of not obtaining a mammogram.
CONCLUSIONS: Only half of HIV-infected women aged 40 and older had a mammogram within 2 years of initial HIV clinic visit in this study. U.S. born status, higher education level and detectable HIV viral load were associated with inadequate screening mammography. This study demonstrates an unacceptably low proportion of HIV-infected women undergoing routine screening mammography in a socioeconomically disadvantaged patient population, and further study is needed to identify interventions to improve screening mammography rates in this vulnerable population.

RISK FACTORS FOR POTENTIALLY AVOIDABLE READMISSIONS DUE TO END-OF-LIFE CARE ISSUES
Jacques Donze[1,2]; Stuart R. Lipsitz[1,2]; Jeffrey L. Schnipper[1,2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA. (Tracking ID #1633705)

BACKGROUND: Repeated hospitalizations are frequent towards the end of life, and each admission may be an opportunity to initiate advanced care planning to ensure that care continues to be consistent with patient and caregiver wishes, to address issues such as pain, and to reduce future unnecessary readmissions. Since resources are limited, there is a need to prioritize palliative care services for those most likely to benefit, e.g., those likely to have readmissions due to unresolved end-of-life issues. We aim to identify the risk factors for having a 30-day potentially avoidable readmission due to end-of-life care issues.
METHODS: We included all consecutive discharges from any medical service of an academic tertiary medical center in Boston between July 1, 2009 and June 30, 2010. Potentially avoidable 30-day readmissions to the index hospital or two other hospitals within its network were then identified using a validated computerized algorithm based on administrative data (SQLape®). Finally, a random sample of the 30-day potentially avoidable readmissions was reviewed by 1 of 9 trained physicians to identify the ones due to end of life issues, defined by the following 2 criteria: 1) Patient has a terminal clinical condition, such as metastatic cancer or another condition with a life expectancy of 6 months or less; and 2) The readmission is part of the terminal disease process that was not adequately addressed during the index hospitalization. A nested case-control study was designed, where the potentially avoidable end-of-life readmission cases were compared to the non-readmitted controls. We performed a multivariable logistic regression in which the final model included variables that were found to be significantly associated with the outcome in bivariable testing; age and Elixhauser comorbidity index were forced into the model as important potential confounders.
RESULTS: Our study included 80 cases with potentially avoidable end-of-life readmission and 7,974 controls without any 30-day readmission. In a multivariable analysis, the following risk factors were significantly associated (Table): number of admissions in the previous 12 months, malignant neoplasm, opiate medication use, and Elixhauser comorbidity index. Total number of medications and end-stage renal disease, significant in bivariable testing, were no longer significant in the multivariable model. The C statistic for the final model was 0.85, indicating excellent discrimination.
CONCLUSIONS: In a medical population, the main risk factors associated with 30-day potentially avoidable readmission due to end-of-life care issues are a higher number of admissions in the last year, a diagnosis of cancer, the use of opiates, and a higher comorbidity score. Palliative care prior to discharge could be prioritized to the patients with these risk factors in order to improve end-of-life care and possibly reduce unnecessary hospitalizations.

Multivariable analysis

Variable	Odds Ratio	95 % confidence interval
age, per 10 years	1.04	0.91–1.19
Number of admissions in the previous 12 months	1.10	1.02–1.20*
Total number of medications at discharge	1.04	1.00–1.10
Neoplasm	5.60	2.85–11.0*
End stage renal disease	0.60	0.25–1.42
Opiate medication use	2.29	1.29–4.07*
Elixhauser, per 5 unit increase	1.16	1.10–1.22*

RISK-ADJUSTING HOSPITAL-ACQUIRED PRESSURE ULCER RATES FROM CLAIMS DATA: TEACHING HOSPITALS BEWARE
Jennifer Meddings[1]; Heidi Reichert[1]; Laurence F. McMahon[1,2]. [1]University of Michigan Medical School, Ann Arbor, MI; [2]University of Michigan School of Public Health, Ann Arbor, MI. (Tracking ID #1642519)

BACKGROUND: In October 2014, the Centers for Medicare and Medicaid Services (CMS) will compare hospitals nationwide by their hospital-acquired complication (HAC) rates, and reduce pay for all admissions to the quartile of hospitals with the highest risk-adjusted HAC rates; other payers are expected to adopt similar policies. The risk-adjustment method for HACs has not been determined. Using the example of hospital-acquired pressure ulcers (HAPUs), our objectives were to 1) inform the CMS risk-adjustment methodology by deriving models to predict a patient's risk of developing a HAPU, and 2) assess which types of hospitals benefit from the risk-adjustment procedure. We hypothesized that teaching hospitals would benefit most from risk-adjustment due to traditional wisdom that these hospitals care for more complex and severely ill patients.
METHODS: Based on statistical methods used by CMS to risk-adjust (i.e., risk-standardize) hospital mortality rates, we developed hierarchical models to risk-adjust hospital rates of HAPUs (including all stages). Claims data from the Healthcare Cost and Utilization Project State Inpatient Datasets for California were utilized, consisting of >1.2 million adult discharges

annually (age>=21 years, length-of-stay>=2 days, all payers) from all nonfederal acute care hospitals in 2009 (N=304 hospitals, with 20 teaching hospitals) and 2010 (N=296 hospitals, with 19 teaching hospitals). Independent predictors were chosen by literature review and included only present-on-admission conditions. We studied which hospital types (by teaching status, ownership) benefited by the risk-adjustment procedure.

RESULTS: After adjusting for age and gender, the HAPU risk factors with the largest odds ratios in 2010 (and $p<0.01$ in both years) included respirator dependence (OR 7.5), shock/collapse (2.7), neurologic conditions involving paralysis or spinal cord injury (2.7), feeding disorders/malnutrition (2.5), hip fracture or dislocation (2.3), and pneumonia (2.2). The admission's categorization as elective surgical (OR 2.0), or non-elective surgical (4.0) was also statistically significant, compared to medical admissions without surgery. The residual between-hospital variation in risk was larger in magnitude than many patient-level risk factors as indicated by the median odds ratio being >2.0 in both years. C-statistic was 0.86 in 2009 and 0.87 in 2010. In 2010, 289 (98 %) hospitals changed rank after risk-adjustment; 173 hospitals' ranks improved (i.e., lowered) with 116 hospitals' ranks worsening. Of 74 hospitals in the highest quartile of hospital rates before risk-adjustment, 11 (15 %) were reassigned to better (i.e., lower) quartiles using risk-adjusted rates. Hospitals that benefited from risk-adjustment were largely non-teaching (for-profit and not-for-profit). In 2010, teaching hospitals listed a mean of 9.47 (95 % CI: 9.45,9.49) diagnoses compared to 10.93 (95 % CI: 10.92,10.94) for non-teaching hospitals; both teaching and non-teaching hospitals had a mean Charlson/Deyo comorbidity score of 1.70.

CONCLUSIONS: Unexpectedly, teaching hospitals did not benefit from risk-adjustment of hospital-acquired pressure ulcer rates using models developed from patient-level risk factors available in claims data. It is unclear if the fewer number of diagnoses per discharge and similar Charlson/Deyo comorbidity scores reflect less complex patients or less complete claims data documentation in teaching hospitals compared to non-teaching hospitals.

ROLE MODELING AND MEDICAL ERROR DISCLOSURE: RESULTS OF A NATIONAL SURVEY OF FOURTH-YEAR MEDICAL STUDENTS William Martinez[1,8]; Gerald B. Hickson[2]; Bonnie Miller[2]; David J. Doukas[3]; John D. Buckley[4]; John Song[5]; Niraj Sehgal[6]; Jennifer Deitz[7]; Clarence H. Braddock[7]; Lisa Lehamann[1,8]. [1]Brigham and Women's Hospital, Boston, MA; [2]Vanderbilt University School of Medicine, Nashville, TN; [3]University of Louisville School of Medicine, Louisville, KY; [4]Indiana University School of Medicine, Indianapolis, IN; [5]University of Minnesota Medical School, Minneapolis, MN; [6]University of California San Francisco, San Francisco, CA; [7]Stanford University School of Medicine, Stanford, CA; [8]Harvard Medical School, Boston, MA. (Tracking ID #1642717)

BACKGROUND: Medical students are in a formative stage of their professional development and their attitudes and behaviors regarding error disclosure may be influenced by their learning environment, a phenomena known as the "hidden curriculum". We measured students' exposure to negative and positive role modeling for responding to medical errors and examined the association between exposure to role modeling and students' own attitudes and behaviors regarding error disclosure.

METHODS: We administered an anonymous, electronic questionnaire to 1,187 fourth-year medical students from seven medical schools representing all four regions of the U.S. The questionnaire asked respondents about: (1) personal experience with medical errors; (2) training for responding to errors; (3) nontransparent personal behavior in response to a harmful error (e.g., nondisclosure to supervising physicians or patients/families or evading responsibility); (4) frequency of exposure to role modeling related to disclosure as measured by a 2-item negative role modeling scale (e.g., observe more senior team member evade responsibility for error) (score range: 2–8, Cronbach α=.64) and a 3-item positive role modeling scale (e.g., observe more senior team member openly disclose error) (score range: 3–12, Cronbach α=.91); and (5) attitudes regarding disclosure as measured by a 9-item disclosure attitudes scale (score range: 9–36, Cronbach α=.74). Higher scores on these scales represent more frequent exposure to that type of role modeling and more positive attitudes regarding disclosure, respectively. Factor analysis was used to created summary variables representing scale items. Multivariate regression analysis was used to assess independent predictors of the two primary outcomes: (1) attitudes regarding disclosure and (2) nontransparent behavior in response to a harmful error.

RESULTS: The overall response rate was 53 % (631/1187). More than 80 % of students reported exposure to positive role modeling for responding to errors; while more than 50 % of students reported exposure to negative role modeling. Training for responding to errors had the largest independent, positive effect on attitudes regarding disclosure (standardized effect estimate, 0.32, P<.001); while negative role modeling had the largest independent, negative effect (standardized effect estimate, -0.24, P<.001). Positive role modeling had a similar, positive effect on attitudes (standardized effect estimate, 0.26, P<.001). Of the 11 % (68/631) of students who reported contributing to a harmful error, 44 % (30/68) reported nontransparent behavior in response to such an error. More frequent exposure to negative role modeling was independently associated with an increased likelihood of nontransparent behavior in response to a harmful error (OR 1.46, 95 % CI 1.14–1.86; P<.001). While disclosure training and positive role modeling were associated with attitudes, they were not independently associated with behavior.

CONCLUSIONS: Exposure to role modeling predicts both students' attitudes and behavior regarding the disclosure of harmful medical errors. Negative role models may be a significant impediment to disclosure among students. The findings suggest a "hidden curriculum" regarding error disclosure in which the behavior modeled by more senior team members may have a greater impact on subsequent trainee behavior than the values and expectations espoused by the educational and health care system.

ROLE OF PATIENT-PHYSICIAN LANGUAGE CONCORDANCE IN PREVENTIVE HEALTH SCREENINGS IN CALIFORNIA Jane Jih[1]; Eric Vittinghoff[2]; Alicia Fernandez[1]. [1]University of California San Francisco, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA. (Tracking ID #1624157)

BACKGROUND: Patient-physician language concordance (LC) among limited English proficient (LEP) patients is strongly associated with patient trust and satisfaction and has been found to be important in some clinical settings and for specific outcomes. Whether patient-physician LC contributes to the completion of preventive health screenings is unclear. We examined the relationship between LC and completion of preventive health practices among LEP Latino and Asian Americans in California.

METHODS: Cross-sectional data from the 2007 and 2009 California Health Interview Survey (CHIS) was used. CHIS is a population-based, random-dial telephone survey of non-institutionalized residents of California. Interviews were conducted in English, Spanish, Mandarin, Cantonese, Vietnamese and Korean. Analysis was restricted to non-pregnant adults who a) self-reported as Latino or Chinese, Vietnamese or Korean who were grouped as Asian and b) reported speaking English "not well" or "not at all" and spoke a target non-English language at home. Patient-physician LC was defined by respondents reporting that their main physician spoke their target non-English language. Outcomes were 1) self-reported mammogram in the last 2 years (yrs) and 3) self-reported completion of colorectal cancer screening (defined as fecal hem-occult in last 2 year or colonoscopy in last 10 year or sigmoidoscopy in last 5 year). Analysis of mammogram and colorectal cancer screening was further restricted to women≥40 year old and respondents≥50 year old respectively. We examined the completion rates of the outcomes in the LEP populations compared to their English-speaking counterparts. Following CHIS guidelines, we used weighted logistic models with jackknife standard errors to estimate odds-ratios for the effect of LC, adjusted for age, education, income, percent time in US, health status, insurance and for sex for colorectal cancer screening. Adjusted group completion rates with 95 % confidence intervals were estimated using regression standardization. Stata version 12.1 was used.

RESULTS: In the mammography analysis, 68 % of LEP Latinos (n=2184) and 65 % of LEP Asians (n=1069) reported physician LC. LEP women with LC physicians were more likely to report mammogram completion than LEP women with non-LC physicians (Latina LEP LC 79 % vs LEP non-LC 68 %, adjusted odds ratio (AOR) 1.85, 95 % CI 1.36–2.52 and Asian LEP LC 72 % vs LEP non-LC 58 %, AOR 1.99, 95 % CI 1.14–3.47). In the colorectal cancer screening analysis, 62 % of LEP Latinos (n=2151) and 66 % of LEP Asians (n=1407) reported physician LC. There was no clear evidence for differences in the completion of colorectal cancer screening among LEP respondents by physician LC (LEP Latinos AOR 1.24, 95 % CI 0.90–1.69; LEP Asians AOR 1.11, 95 % CI 0.70–1.77). However, the colorectal cancer screening rate was lower among LEP Latinos and Asians than among English-speaking Latinos and Asians (LEP Latinos 50 % vs English-speaking Latinos 70 %; LEP Asians 55 % vs English-speaking Asians 75 %), regardless of physician LC.
CONCLUSIONS: Patient-physician language concordance may be an important contributor to the completion of mammography in LEP Latino and Asian populations in California where many patients report a language concordant physician. Patient-physician language concordance may not be sufficient to overcome barriers to the completion of colorectal cancer screening among LEP Latinos and Asians, and completion rates in the LEP populations are lower than among English-speaking counterparts.

ROLE OF THE PRIMARY CARE PROVIDER (PCP) IN THE CARE OF PATIENTS WITH LOW RISK PROSTATE CANCER: A QUALITATIVE STUDY Zackary Berger[1]; H. B. Carter[2]; Craig E. Pollack[1]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD. (Tracking ID #1640532)

BACKGROUND: Despite unclear evidence regarding the benefits of surgical or radiation treatment for low risk prostate cancer, relatively few men decide on active surveillance as their choice of management. Further, for those men that do enroll in active surveillance, many withdraw to seek surgical or radiation treatment despite lack of disease progression. Though evidence suggests that primary care providers (PCPs) may play an important role in treatment decision-making, their contribution to a patient's choice to remain in active surveillance remains poorly understood. We thus set out to elucidate the roles played by PCPs in active surveillance among men diagnosed with low-risk prostate cancer.
METHODS: Semi-structured interviews with patients who initially enrolled in the active surveillance program at Johns Hopkins. Participants were purposefully sampled to over-represent those who withdrew from active surveillance despite lack of disease progression.
RESULTS: 12 interviews have been conducted to date with recruitment on-going; their average age was 71. A minority (4 out of 12) reported that the PCP played no role in the patient's prostate cancer screening or treatment decisions. Five stated they were referred by their PCP to the urologist, but their PCP did not play any role thereafter in discussing or recommending management options. Two patients said they discussed management options with their PCP, and one patient reported that he discussed side effects of treatment with his PCP. Several main themes emerged regarding the reasons why PCPs did not play a larger role in discussions of treatment: patients' assumptions that PCPs did not have the time to discuss treatment ("they care, but they have so many patients"), and patients understanding of prostate cancer treatment as solely a urological matter. These themes were also relevant to patients' on-going decisions regarding remaining in or withdrawing from active surveillance, with few men reporting that their PCPs were involved in their choice to withdraw from active surveillance. In addition, despite a number of men reporting a years-long relationship with their PCP, they reported that their PCP did not take an interest in their prostate cancer treatment but focused on other issues, e.g., "he's only worried about my blood pressure and my blood sugar"; "he's attentive, but hands me off to the urologist," "I got diabetes, so it's other issues [that he has] to worry about."
CONCLUSIONS: Some patients do not see their PCP as a useful source of recommendations for prostate cancer management, either because they assume the issue is not appropriate to discuss with their PCP, or because they think their PCP is not able or interested. Efforts to encourage men with low risk prostate cancer to enroll and remain in active surveillance may benefit from closer involvement of PCPs.

RURAL MINORITY WILLINGNESS TO PARTICIPATE IN HIV CLINICAL TRIALS Malika Roman Isler; Lloyd Edwards; Alison Halpern; Margaret Miles; Giselle Corbie-Smith. University of North Carolina at Chapel Hill, Chapel Hill, NC. (Tracking ID #1642462)

BACKGROUND: Though African-Americans experience a significant and disparate proportion of HIV/AIDS cases, they remain underrepresented in HIV clinical trials. Due to barriers such as geographic isolation, distance from tertiary medical centers, low provider referral, and pervasive stigma, the challenges to clinical trial participation are magnified for minorities living in rural communities. Structural and social interventions address some barriers; however, participation is predicated on individual willingness. Previous studies indicate varied findings on the willingness of African-Americans to participate in clinical research. This study seeks to characterize the willingness of rural minorities to participate in HIV clinical trials.
METHODS: As part of a multi-level intervention study, we conducted a baseline survey of minorities living with HIV/AIDS (n=196) in 6 contiguous rural counties in NC. Surveys were administered using an audience response system. The outcome of interest was willingness to participate in an HIV clinical trial (yes/no). We fitted a logistic regression model with 14 predictors of willingness: gender, age, race, education, marital status, insurance status, length of diagnosis, history of HIV clinical trial enrollment, knowledge, attitudes, religious belief, current health status, religious attendance, and religious activity participation.
RESULTS: At baseline, 178 (90.8 %) participants indicated willingness to participate in HIV clinical trials. None of the predictor variables reached significance in the bivariate analyses. Race had an unadjusted p-value =.0537. Of the 14 predictors included in the multivariable model, only race was a statistically significant predictor for willingness (p=.0305). Participants self-report of race was: African-American 161 (80.1 %) and non-African-American 40 (19.9 %). Participants who self-identified as African-American were more likely to indicate willingness to participate in HIV clinical trials than those who did not self-identify as Africa-American.
CONCLUSIONS: African-Americans and the field of HIV clinical research stand to benefit from more minority inclusion in HIV clinical trials. Evidence of African-American willingness to participate in HIV clinical trials abates notions of unwillingness and helps to focus intervention efforts on prevailing barriers to minority participation.

SAFETY OF PRECONSULTATION EXCHANGE IN AN ELECTRONIC REFERRAL SYSTEM Erika L. Price; Justin L. Sewell; Alice H. Chen; Urmimala Sarkar. University of California, San Francisco, San Francisco, CA. (Tracking ID #1641626)

BACKGROUND: Preconsultation exchange between primary care and specialty providers via electronic consultation and referral systems can enhance coordination of care by answering clinical questions without specialist appointments and by streamlining the pre-specialty visit workup, particularly within settings with limited specialty access. However, the safety of preconsultation exchange is unknown, and risks may exist for patients not scheduled for specialist visits. To assess this within our safety net healthcare system, we retrospectively reviewed medical records for patients discussed via our established electronic preconsultation and referrals system who were not scheduled for gastroenterology (GI) clinic.
METHODS: We reviewed all electronically submitted GI referrals from hospital-based referring clinics between 11/1/2009 and 6/20/2010 that were not scheduled for appointments. For unscheduled referrals lacking clear resolution through preconsultation exchange, two investigators reviewed the medical record and assessed potential for patient harm from not having a GI appointment scheduled, using a validated scale. When adequate data were present, investigators also assessed actual patient harm. A180-day time horizon was used for all evaluations. Disagreements were resolved via

consensus with a third physician serving as tie-breaker. Referrals through 10/31/2010 will ultimately be reviewed.

RESULTS: 179 of 795 referrals (22 %) were not scheduled for appointments. For 52 (29 %) of these, advice was provided electronically and appointments were not needed. Of the remaining 127 patients referred, only 74 (58 %) had primary care visits within 180 days following referral. Sixty-three of 179 referrals (35 %) were unscheduled because they were from inappropriate sources (including emergency department and inpatient settings) rather than primary care providers, or were made to the wrong clinic (for example, GI rather than liver). Thirty-two (51 %) of these referrals were appropriately redirected. Fifty-four (30 %) were not scheduled because the specialist provider requested additional clinical history that was never provided (n=22) or requested further diagnostic evaluation (n=32) prior to scheduling. Of the 32 referrals for which additional evaluation was requested, testing was ordered in 20 (63 %), and was completed in 13 (41 %), but the referrals system was not updated with results. Of 58 referrals assessed for potential harm from not being scheduled, 41 (71 %) had potential for major harm, and 8 (14 %) had potential for moderate harm. Of 61 referrals assessed for actual harm, 56 (92 %) had no harm, 3 (5 %) had moderate harm, and 2 (3 %) had major harm attributable to not being scheduled for a GI appointment.

CONCLUSIONS: Preconsultation exchange has potential to improve availability, efficiency, and timeliness of specialty care, but its use may pose safety risks. Overall, 23 % of unscheduled referrals in our study had potential for major harm, but only 1 % had major harm to patients, suggesting the relative safety of preconsultation exchange. Much of the harm potential relates to referrals from inappropriate sources, which can be addressed by tailoring the electronic platform, or from referring providers not following up on specialist requests for additional information/workup, which was often attributed to provider discontinuity or patient loss to follow-up. Our results can inform the design and oversight of electronic preconsultation exchange across health systems.

SCREENING AND BRIEF INTERVENTION FOR DRUG USE IN PRIMARY CARE: THE ASPIRE RANDOMIZED TRIAL Richard Saitz[1,2]; Tibor P. Palfai[3]; Debbie M. Cheng[1,4]; Daniel P. Alford[1]; Judith A. Bernstein[5]; Christine A. Lloyd-Travaglini[6]; Seville M. Meli[1]; Christine E. Chaisson[6]; Jeffrey H. Samet[1,5]. [1]Boston University and Boston Medical Center, Boston, MA; [2]Boston University School of Public Health, Boston, MA; [3]Boston University, Boston, MA; [4]Boston University School of Public Health, Boston, MA; [5]Boston University School of Public Health, Boston, MA; [6]Boston University School of Public Health, Boston, MA. (Tracking ID #1632712)

BACKGROUND: The US Federal government has spent several hundred million dollars on training and implementation of alcohol and other drug screening and brief intervention (programs known as Screening, Brief Intervention, Referral and Treatment or SBIRT) in the past decade. However, the efficacy of universal screening and brief intervention (SBI) for drug use among primary care (PC) patients is unknown; consequently it is not recommended by professional organizations such as the US Preventive Services Task Force. This 3-arm randomized trial (the Assessing Screening Plus brief Intervention's Resulting Efficacy to stop drug use (ASPIRE) study) tested the efficacy of two brief interventions (BIs) for drug use—a brief negotiated interview (BNI), and an adaptation of motivational interviewing (AMI)—compared to no BI in PC patients identified by screening.

METHODS: We randomly assigned subjects identified by screening in PC with Alcohol, Smoking and Substance Involvement Screening Test (ASSIST) drug specific scores of ≥4 to BNI, AMI or no BI. BNI was a 10–15 min structured interview conducted by trained paraprofessional health educators. AMI was ≤45 min of MI and an optional booster conducted by trained doctoral psychology students. All subjects received a written list of substance abuse treatment and mutual help resources. Primary outcome was number of days use of the self-identified drug of most concern (DOMC) in the past 30 days as determined by validated calendar method at 6 months. A secondary outcome was number of days heavy use (2 or more times in a day) of the DOMC. Analyses were performed using negative binomial regression adjusted for baseline use, drug dependence, DOMC, and prior outpatient counseling.

RESULTS: Of 876 eligible subjects, 528 (60 %) were randomized. Subjects were 70 % male, 69 % black, with a mean age 41 years. DOMC was: marijuana 63 %, opioid 17 % (prescription opioid 11 %), and cocaine 19 %. ASSIST score was ≥27 (consistent with dependence) for 18 %; 12 % reported injection drug use (past 3 months), mean days DOMC use (of 30 days) was 14.4. At 6 months, 98 % completed follow-up and mean days DOMC use was 14.0 (in the past 30 days). There were no significant effects of BNI or AMI on outcomes. For the primary outcome, mean adjusted days use of the DOMC at 6 months was 11.5 (no BI) vs. 11.2 (BNI) (incidence rate ratio (IRR) 0.97, 95 % CI 0.77–1.22) and 12.1 (AMI)(IRR 1.05, 95 % CI 0.84–1.32) (p=0.81 for both comparisons vs. no BI). There were also no significant effects of BNI or AMI on the secondary outcome, number of days heavy use of the DOMC. There were no significant effects on either outcome in analyses stratified by DOMC or ASSIST score.

CONCLUSIONS: In this trial of brief intervention (BI) among primary care patients identified by screening, BNI and AMI did not have efficacy for decreasing drug use. Future analyses will examine six-week outcomes and additional 6-month outcomes including hair toxicological drug tests. If other trials yield consistent results, widespread implementation of drug screening and BI should be reconsidered, and research should focus on alternative ways to address drug use and consequences in primary care settings. SCREENING FOR SCHISTOSOMIASIS AND STRONGYLOIDES AMONG BRAZILIAN IMMIGRANTS IN THE UNITED STATES Alison B. Rapoport[1,2]; Sarah E. Messmer[1,2]; Pieter Cohen[1,2]. [1]Cambridge Health Alliance, Cambridge, MA; [2]Harvard Medical School, Cambridge, MA. (Tracking ID #1621927)

BACKGROUND: Schistosomiasis and strongyloides are endemic to Brazil, with estimated prevalence rates of active disease of up to 20 % and 5 %, respectively. Clinical manifestations of fulminant disease include pulmonary hypertension and multi-system failure. Even years after initial infection, patients can transition from asymptomatic carrier status to severe illness, making treatment in the asymptomatic stage an important intervention. The Centers for Disease Control (CDC) recommends screening for schistosomiasis serum antibodies in patients from endemic areas and for strongyloides, in patients who are higher risk of infection based on clinical and demographic factors. In clinical practice, immigrants are often tested only if eosinophilia is incidentally noted. Data to support either of these practices among immigrant patients from South America is scant.

METHODS: To identify patients who had a serologic test for either schistosomiasis or strongyloides performed for screening purposes, we conducted a retrospective chart review of all adult Brazilian immigrants who presented for a routine physical exam at one internist's primary care practice in Massachusetts between April 2012 and October 2012. The study was conducted at this site as immigrant patients (mostly from Brazil) were routinely screened beginning in April 2012 for both infections. Our primary outcomes were the presence of a positive serologic tests for schistosomiasis and strongyloides (IgG detected by ELISA). We also assessed whether patient demographic factors or the presence of blood eosinophilia (>7.0 % eosinophils) were associated with sero-positivity using the chi-squared test (p-value of<0.05 considered to be statistically significant).

RESULTS: We identified 125 patients screened for antibodies to both schistosomiasis and strongyloides (no patients were screened for either alone). Twenty-five percent (31/125) had elevated antibodies to schistosomiasis and 6 % (8/125) had elevated antibodies to strongyloides. Those with elevated antibodies to schistosomiasis were more likely to have immigrated from the Southeast region of Brazil (i.e., Minas Gerais, Sao Paulo, Rio de Janeiro, Espirito Santo) vs other areas of Brazil (97 % vs 64 %; p<0.01) and more likely to have lived in the US≥5 years as compared to<5 years (32 % vs 0 %; p=0.01) but were not statistically

more likely to have an elevated eosinophil count (20 % vs 10 %; $p=0.39$). No demographic factor was predictive of strongyloides seropositivity; however, an elevated eosinophil count was associated with strongyloides seropositivity (57 % vs 7 %; $p<0.01$).

CONCLUSIONS: Results of this preliminary study: 1) suggest the possibility that clinicians might be able to selectively screen immigrants who arrive from Southeastern Brazil for schistosomiasis, and 2) provide support for the current practice of selectively screening for strongyloides in patients who have elevated eosinophil counts. Firm guidelines regarding the optimal approach to screening for these conditions will require confirmation of our findings in larger and more representative patient populations as well as additional research regarding factors such as positive predictive value of current serologic tests for active infection, the potential health risks of treating or not treating in the asymptomatic stage, and financial costs of treatment.

SEE ONE, DO MORE THAN ONE, AND ACTUALLY LEARN SOMETHING IN THE PROCESS! THE EFFECTIVENESS OF A RANDOMIZED MUSCULOSKELETAL CURRICULUM IN THE TEACHING AND RETENTION OF KNOWLEDGE AND SKILLS

Cindy Sadikot; Sharon Leung; Darlene LeFrancois. Montefiore Medical Center and Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1642251)

BACKGROUND: Musculoskeletal complaints are some of the most common reasons for primary care visits, yet most Internal Medicine (IM) residents do not feel confident or skilled in their ability to diagnose and treat these complaints. The project aims are to 1) institute and assess the immediate and 6 month effectiveness of a musculoskeletal workshop on IM residents' knowledge and clinical skills and 2) ascertain whether additional specialty clinical exposure is associated with improved performance.

METHODS: The curriculum was taught to second year IM residents during their ambulatory care rotation (ACR) month. The 3 h workshop consisted of a didactic presentation of shoulder and knee anatomy and common pathology, followed by a demonstration of exams and specific maneuvers. Residents then paired and practiced supervised exams until they were able to demonstrate mastery of the skills taught. Before, immediately after, and 6 months after the workshop, residents completed 18 multiple choice questions focused on the evaluation of common knee and shoulder complaints. Examination skills were evaluated with a standardized case based 17 item checklist before the workshop and at 6 months. Scores of 0, 0.5, and 1 signified that the task was not completed, completed partially correctly, or completed correctly respectively. Half of the residents were randomized to attend orthopedics or physical medicine and rehabilitation clinics during ACR and the other half served as a control group.

RESULTS: Of the 39 residents who attended the workshop between January and May 2012, all completed the knowledge questions immediately after the workshop and 34 (87.2 %) completed the 6 month follow-up. Among these 34 residents, a history of personal injury ($n=12$) did not impact how well subjects performed on the observed exam ($p>0.93$). The mean percentages of knowledge questions answered correctly before, immediately following, and 6 months after the workshop were 58.2 %, 80.8 %, and 68.2 % for shoulder questions ($p<0.01$ for all comparisons) and 52.6 %, 76.6 %, and 69.9 % for knee questions (pre vs immediate post, pre vs 6 month $p<0.01$, immediate post vs 6 month $p=0.20$). Of those randomized to attend a specialty clinic, 72 % attended at least 1 session (median 3, IQR 2,6). There was no significant difference between the intervention and control groups in shoulder-related and knee-related knowledge at the pre- and 6 month post-workshop assessments ($p>0.32$). However, the mean scores for the observed knee exam were significantly higher at 6 months compared to control, whereas there was no difference in groups at baseline (0.58 vs 0.46 at 6 month post $p=0.05$ compared to 0.51 vs 0.47 pre intervention, $p=0.49$). There was no significant difference seen between the two groups in the observed shoulder exam pre or post intervention.

CONCLUSIONS: A formal musculoskeletal workshop improved knowledge, both immediately and at 6 months, regardless of randomization to additional specialty clinics. However, those who were randomized to and attended specialty clinics performed significantly better on the observed knee exam at 6 months. This suggests that while a brief workshop with didactics can improve knowledge, additional proficiency in clinical skills requires repetitive clinical exposure. The implication is that iteration of hands-on clinical exposure is required for sustained improvement of musculoskeletal examination skills.

SELF-AUDIT INCREASES CLINICIAN-DRIVEN UNIVERSAL HIV SCREENING AMONG INTERNAL MEDICINE RESIDENTS

Joshua Barocas[1]; Meghan Brennan[1,2]; Christopher Crnich[1]; Timothy Hess[1]; Ajay Sethi[3]; James M. Sosman[1]. [1]University of Wisconsin, Madison, WI; [2]William S Middleton Memorial Veterans Hospital, Madison, WI; [3]University of Wisconsin, Madison, WI. (Tracking ID #1637396)

BACKGROUND: Adoption of universal HIV screening by primary care physicians has been suboptimal, despite CDC recommendations. Less than half of Americans have ever been screened. Internal medicine residents represent the next wave of practicing physicians targeted to integrate HIV screening into their practice. We sought to identify the effect of self-audit on HIV screening rates among internal medicine residents in their out-patient clinics.

METHODS: We used a pre-post intervention design without a control arm where residents received self-audit feedback on their out-patient HIV screening rates. Residents were from a single training program where they participated in a 3-year primary care continuity clinic. In 2010, the intervention was integrated into a longstanding annual chart review where all residents self-audit 20 randomly selected primary care patients on preventive services. Baseline data was collected during the 2010 chart review. 2010 data accurately reflected pre-intervention HIV screening rates because residents were not informed in advance that HIV screening had been added to the chart review form. During the following year, no other intervention occurred, and the formal curriculum was not altered. The annual chart review was repeated in 2011 without modification, providing post-feedback screening rates 1 year after the intervention. A generalized linear mixed approach was used to model the odds ratio of HIV screening between the 2 years, adjusting for resident year of training and gender, clinic site, patient age and gender, and resident-patient gender concordance. Within a single year patient-level data was clustered according to resident, which was treated as a random effect. Odds ratios were constructed similarly for other preventive services included on the chart review to assess whether change between the 2 years was HIV screening-specific. The analysis had >80 % power to establish equivalence for a screening test performed in 80 % of patients with a margin of 5 %.

RESULTS: The study analyzed chart reviews on 2097 individual patients over 2 years. Internal medicine residents increased their out-patient HIV screening rates from 18 to 40 % (adjusted OR 3.16, 95 % CI 1.93–4.39, $p<0.001$) following self-audit feedback. Older patient age was associated with a decreased odds of receiving HIV screening; however no other patient- or resident-level variables were significantly associated with HIV screening. Over the same time period, rates of other preventive services- blood pressure control, diabetes and cholesterol screening, as well as alcohol and tobacco assessment- did not change, suggesting the intervention was HIV screening-specific. Tetanus vaccination increased slightly, however this could be explained by a local pertussis outbreak that likely spurred increased Tdap immunization rates.

CONCLUSIONS: Providing feedback to residents on their HIV screening rates was associated with a significant increase in subsequent out-patient HIV screening. This was achieved with minimal intervention, simply including the topic on an annual chart review. HIV screening continues to be included in the residency program's annual audit, demonstrating its feasibility and sustainability. It should be noted that a screening rate of 40 % is still low. However, we have demonstrated a clear improvement within the residency and general HIV screening rates in the Midwest, which hover around 20 %.

SELF-REFERRAL TO CANCER SPECIALISTS AND QUALITY OF CARE Craig Pollack[1]; Afshin Rastegar[3]; Nancy L. Keating[4]; John Adams[3]; Maria Pisu[5]; Katherine L. Kahn[2,3]. [1]Johns Hopkins School of Mediine, Baltimore, MD; [2]Davide Geffen School of Medicine at UCLA, Los Angeles, CA; [3]RAND Corporation, Santa Monica, CA; [4]Brigham and Women's Hospital, Boston, MA; [5]University of Alabama, Birmingham, AL. (Tracking ID #1642101)

BACKGROUND: Though patients with cancer frequently see multiple different types of physicians for their cancer care, relatively little is known regarding how patients choose their cancer specialists. In general, patients may either follow the referral advice of their physicians or self-refer to a particular specialist. We examine patient correlates of self-referral across multiple types of cancer specialists and test whether self-referral is associated with higher satisfaction and better quality of cancer care.
METHODS: Data were collected as part of the Cancer Care Outcomes Research and Surveillance (CanCORS) Consortium which included detailed survey data on patients diagnosed with lung or colorectal cancer in 2003 to 2005. Patients were eligible if they reported being referred to any of three types of cancer specialists—surgeons, radiation oncologists, and medical oncologists. Patients reported whether they were self or family-referred ('self-referral') or were referred by a provider or clinic to each cancer specialist. We assessed aspects of satisfaction with care using a 13-item scale. Quality indicators included patient-reported overall quality of care and use of appropriate, stage-specific treatment (i.e. adjuvant chemotherapy for stage III colon cancer, adjuvant chemotherapy and radiation therapy for stage II/III rectal cancer, and curative surgery for stage I/II nonsmall cell lung cancer). We used multivariable logistic regression models to assess sociodemographic, clinical, and health-care characteristics that were associated with self-referral. Because each patient may have been referred to more than 1 type of specialist, we adjusted for clustering using robust standard errors. We similarly used multivariable logistic regression analyses to test whether self-referral was associated with satisfaction and quality of care.
RESULTS: The 5,934 patients in our sample—3,052 with lung cancer and 2,882 with colorectal cancer—reported on 11,083 referrals. Overall, 12.1 % of the patients had self-referred to at least one of their cancer specialists: 8.8 % self-referred to their surgeons, 4.5 % to their radiation oncologist, and 8.8 % to their medical oncologist. In adjusted analyses, black patients were significantly less likely to self-refer than white patients (OR 0.48, 95 %CI 0.35–0.65); those with a college degree were significantly less likely to self-refer than those with less than a high school degree (OR 1.58, 95 %CI 1.17–2.12); and those with the highest incomes were more likely to self-referral than those with the lowest incomes (OR 1.54, 95 %CI 1.08–2.21). Compared with colon cancer patients, those with lung cancer (either small cell or non-small cell) were significantly less likely to self-refer. Self-referral was associated with significantly lower physician communication and nursing care scores in multivariable logistic regression analyses. We did not observe significant associations between self-referral and patient-reported quality of care or receipt of recommended care.
CONCLUSIONS: Understanding the pathways that lead patients to receive high quality care is critical. Overall, about 12 % of lung or colorectal cancer patients self-refer to cancer specialists, particularly white patients and those with higher socioeconomic status. However, self-referral is not associated with higher satisfaction or quality of cancer care.

SEX, RACE, AND CONSIDERATION OF WEIGHT LOSS SURGERY BY OBESE PRIMARY CARE PATIENTS Christina C. Wee[1]; Karen W. Huskey[1]; Dragana Bolcic-Jankovic[2]; Mary Ellen Colten[2]; Roger B. Davis[1]; Mary Beth Hamel[1]. [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]University of Massachusetts, Boston, MA. (Tracking ID #1636200)

BACKGROUND: Weight loss surgery (WLS) is one of few obesity treatments to produce substantial and sustained weight loss but only a small proportion of medically-eligible patients (pts) undergo this treatment with disproportionately low use among men and African Americans (AA). Factors underlying these variations in use are unclear.
METHODS: We interviewed 338 moderately to severely obese pts (BMI≥ 35 kg/m2) seen at four diverse primary care practices in Greater-Boston (58 % response rate), oversampling for racial and ethnic minorities. We developed sequential multivariable logistic regression models to describe patients' serious consideration of WLS, potential variation by sex and race, and factors that underlie such variation.
RESULTS: Of 338 pts, the mean age of our sample was 48.7 years, 69 % were women, 36 % were Caucasian, 35 % were AA, and 25 % were Hispanic. 326 pts (96 %) had heard of WLS and 34 % had seriously considered WLS. Men were less likely than women and AAs were less likely than Caucasian pts to have considered WLS after adjustment for age and BMI (Table Model 1). Further adjustment for education (Model 2) and comorbid conditions (Model 3) did not explain differences by race and sex but racial differences largely dissipated after adjustment for quality of life (QOL) (Model 4), which tended to be higher among AA than Caucasian pts. Physician recommendation of WLS was independently associated with serious consideration by pts of this treatment [OR 5.67 (95 % CI 3.35–9.60)], but did not explain gender or racial differences. Nevertheless, 46 % pts reported they would consider WLS if their doctor recommended it; men were as willing and AA and Hispanic patients were more willing to consider WLS than their respective counterparts after adjustment. Only 20 % of pts reported being recommended WLS by their doctor with AAs and men being less likely to receive this recommendation; QOL differences appeared to explain racial variation in recommendations (data not shown). High perceived risk to WLS was the most commonly reported barrier, cited by 39 % of pts; financial and insurance coverage concerns were cited only by 1 %.
CONCLUSIONS: African American and male primary care patients were less likely to have considered weight loss surgery and were less likely to have been recommended these procedures by their doctors. Differences in how obesity affects quality of life appear to account for some of these variations. High perceived risk is a major deterrent for patients whereas financial and insurance coverage concerns were not.
Table. Likelihood (OR and 95 % CI) of Patients' Serious Consideration of WLS by Sex and Race after Sequential Adjustment

SEX-BASED DIFFERENCES IN END-OF-LIFE CARE AMONG HOSPITALIZED ADULTS IN THE US Erica Just[1,2]; David J. Casarett[3]; David A. Asch[3]; Dingwei Dai[1]; Chris Feudtner[1]. [1]Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA. (Tracking ID #1635136)

BACKGROUND: End-of-life care has emerged as a major health care issue over the past two decades. A growing literature has suggested that sex-based disparities affect patients in a variety of settings. Little is known about gender disparities in inpatient care at the end of life. We sought to test whether differences exist in care provided to male and female patients during their final hospitalizations.
METHODS: We reviewed the clinically detailed administrative data of 98,314 patients at least 18 years of age who died while hospitalized in 458 acute care hospitals in the United States during 2011. We modeled sex-based differences in length of stay, code status, intubation, admission to an intensive care unit (ICU), and provision of cardiopulmonary resuscitation (CPR), adjusting for age, race/ethnicity, and medical diagnoses. Multivariable analyses further adjusted for marital status, medical comorbidities, insurance status, and hospital clustering.
RESULTS: Women represented approximately half of the sample (48,509; 49.34 %). They were older than men (73.8 vs. 70.6 years of age, $p<0.0001$)

and less likely to be married (27.7 % vs. 48.3 %, $p<0.001$). The most common diagnostic-related-groups (APR-DRGs) were the same for both sexes. Among all patients, median length of stay was 4 days (IQR 2,10); 11.6 % of subjects were exposed to CPR; 37.6 % had a do-not-resuscitate (DNR) order during the admission; 37.5 % underwent intubation. Women were less likely than men to receive care in an ICU (OR: 0.83; 95 % CI: 0.81, 0.84) and less likely to undergo intubation (OR: 0.80; 95 % CI: 0.78, 0.82). Women were more likely to have a DNR order (OR: 1.16; 95 % CI: 1.29, 1.89). In multivariable multilevel mixed effects analyses, additionally controlling for marital status, payor type, Elixhauser comorbidities, and hospital-level clustering, the odds of DNR status remained greater for women (OR: 1.10; 95 % CI: 1.08, 1.12). Among patients without a DNR order, ICU stay was less common among women (OR: 0.84; 95 % CI: 0.81, 0.86). Among patients with only APR-DRG of pulmonary edema/respiratory failure and without DNR, odds of intubation remained lower among women (OR: 0.78; 95 % CI: 0.68, 0.90). Women were less frequently exposed to CPR (OR: 0.77; 95 % CI: 0.74, 0.80); among patients without a DNR who experienced cardiac arrest, the odds of undergoing CPR remained lower for women (OR: 0.90; 95 % CI: 0. 83, 0.97). Adjustment for age, race, geographic region, and APR-DRG did not alter these findings.

CONCLUSIONS: In this diverse sample of hospitalized patients from across the United States, men received more aggressive care during their terminal hospitalizations than women. This finding was not explained by differences in observable characteristics such as age, race, or marital status. Better understanding of the causes of this sex-based disparity could provide important insights into how to improve hospital-based care at the end of life for all patients.

SEXUAL AND REPRODUCTIVE HEALTH AWARENESS AMONG FEMALE HIGH SCHOOL STUDENTS IN INDIA Chiti Parikh; Erica Phillips; Nicole Sirotin. New York Presbytarian Hospital, New York, NY. (Tracking ID #1643121)

BACKGROUND: Over the last decade there has been a decrease in the rate of new HIV infections worldwide, however this trend is less impressive in India. Over 35 % of all reported AIDS cases in India occur in people aged 15–24 years. Lack of sex education programs in high schools creates a formidable barrier to promotion of HIV awareness and reduction in new infections. Objective of this study is to assess change in sexual and reproductive knowledge among female high school students in India after a sex education seminar.

METHODS: The study was conducted at a high school in Ahmadabad, India. 88 female students ages 15–17 were enrolled in the study after obtaining written and verbal consent from the students and the principal. A 17 question pretest questionnaire (derived from National Family Health Survey-3, administered by Government of India under WHO) was administered to assess their baseline knowledge about contraception, STIs and HIV. After a 30 min seminar the questionnaire was re-administered to assess the impact of the seminar on sexual risk reduction knowledge among participating students.

RESULTS: 88 pretest questionnaires and 84 post-test questionnaires were collected. Average awareness of various methods of contraception increased from 65.2 % to 91.7 %. Awareness of STIs other than HIV increased from 20 % to 91.6 %. 63.9 % of the students knew that condoms can protect against pregnancy and STIs compared to 33.3 % before the seminar. Of note, more than 60 % of the students stated television, magazines and friends as their main source of information pertaining to sexual health and reproduction.

CONCLUSIONS: This study highlights the considerable lack of basic sexual and reproductive knowledge among adolescents in India. This brief educational intervention demonstrated an improvement in knowledge in the area of contraception and HIV awareness. The lack of basic sex education is likely the root cause of the lag in reduction of new HIV infections compared to the vast monies invested in India's current HIV prevention campaigns. This study along with several others highlights the importance of integrating sex education with HIV programs in order to boost the progress India has made in the past decade. Since over a third of new HIV infections occur in the age group of 15–34 years, it is very important to recognize the importance of developing formalized sex education programs at high schools in India.

SEXUAL FUNCTION DOES NOT PREDICT MAINTENANCE OF SEXUAL ACTIVITY IN MIDLIFE WOMEN Holly N. Thomas; Stacey Dillon; Rachel Hess. University of Pittsburgh, Pittsburgh, PA. (Tracking ID #1641052)

BACKGROUND: Frequency of sexual activity as well as sexual function decline as women age, but the reasons for these declines are not well understood. It is not known whether lower sexual function predicts future cessation of sexual activity—in other words, does "poor quality" sex cause women to stop having sex? We hypothesized that sexually active women with worse sexual function would be less likely to engage in partnered sexual activity 4 years later.

METHODS: Do Stage Transitions Result in Detectable Effects (STRIDE) is a longitudinal cohort study of women aged 40–65. Participants completed annual questionnaires regarding demographics, sex, menopause, and medical problems. Sexual activity was defined as any partnered activity, ranging from kissing to intercourse, in the prior 6 months. Body mass index (BMI) and medication use were abstracted from the electronic health record. In study year 4, women completed the Female Sexual Function Index (FSFI), a validated measure of sexual function in women. Characteristics of sexually active and inactive women in study year 4 and 8 were examined and compared using chi2, Fisher's exact, and t-tests as appropriate. For the primary analysis, only women who reported sexual activity at study year 4 were included, and women who answered "no sexual activity in the prior 4 weeks" to one or more of the FSFI questions were excluded. Univariable logistic regression was used to examine the relationship between the predictors at baseline and the primary outcome, sexual activity 4 years later. Variables that were marginally significant ($p<0.2$) were entered into a multivariable model to assess the relationship between FSFI score and future sexual activity while controlling for other factors.

RESULTS: Six hundred two women completed year 4 of the study. Sixty-eight (11.3 %) women did not respond to the questions regarding sex. At study year 4, 354 (66.3 %) women were sexually active. Of these women, 228 (85.4 %) remained sexually active at study year 8, 39 (14.6 %) were not, and 87 had missing data. The mean (sd) FSFI scores among sexually inactive and active women were 21.8 (3.8) and 22.3 (3.8) respectively. In univariable analyses, neither FSFI score nor sexual dysfunction (as defined by an FSFI score <27) were significant predictors of sexual activity at study year 8 ($p=0.653$ and 0.693 respectively). Women who remained sexually active were more likely to be Caucasian, partnered, healthier, earlier in the menopausal transition, and thinner ($p=0.001$, 0.037, 0.006, 0.045, and 0.007 respectively). Women who placed a higher importance on sex were more likely to remain sexually active ($p=0.009$). In the multivariable model, only race and menopausal status remained significant predictors of sexual activity ($p=0.016$ and 0.024 respectively); FSFI score remained a non-significant predictor ($p=0.921$), while importance of sex approached significance ($p=0.079$).

CONCLUSIONS: A majority of women who are sexually active at midlife continue to remain sexually active 4 years later, despite mean FSFI scores that fall into the "dysfunctional" range. Sexual dysfunction, as measured by the FSFI, is not associated with future cessation of sexual activity in midlife women. Reasons that women stop, or continue to have, sex during the midlife transition go beyond the "quality" of sex. Importance of sex may be a significant factor. Further longitudinal exploration of these reasons is necessary to fully understand women's sexual practices in midlife and beyond.

SHARED DECISION MAKING EDUCATION TO IMPLEMENT PRACTICE CHANGE: IMPACT ON PATIENTS' SATISFACTION WITH PHYSICIAN COMMUNICATION AND CONFIDENCE IN DECISION Ade B. Olomu[1]; Venu Gourineni[1]; Steven Pierce[2]; Margaret HolmesRovner[3]. [1]Michigan State University, East Lansing, MI; [2]Michigan State University, East Lansing, MI; [3]Michigan State University, East Lansing, MI. (Tracking ID #1643163)

BACKGROUND: Studies have revealed that a shared decision making (SDM) process accompanied by decision aids (DA) is effective in improving patient knowledge, patient satisfaction and health outcomes. The use of SDM and DAs has been encouraged but is not regularly implemented in low-income

populations. To address this important gap, we conducted a study of our shared decision making program, Office-GAP (Guidelines Applied to Practice) in a Federally Qualified Community Health Center (FQCHC). Objectives were 1) To develop and pilot test an implementation approach that simultaneously taught both physicians' and patients' SDM and use of DA in a FQCHC during office visit, 2) evaluated the impact on patient satisfaction with physician communication and confidence in decision.

METHODS: The study was a process evaluation testing the feasibility of provider training, patient education in a group visit, and use of Guidelines Applied to Practice (GAP) tools during office visits. Two doctors, 1 nurse-practitioner (NP), 8 staff, and patients with a diagnosis of CAD or diabetes mellitus in one FQCHC participated in this pilot study from January 2009 to December 2011. After an initial group visit, patients followed up with 2 physician visits using GAP tools. The Combined Outcome Measure for Risk Communication And treatment Decision making (COMRADE) survey was used with a modified scoring algorithm to measure patient's satisfaction with physician communication (SWC) and confidence in decision (CID) made.

RESULTS: All providers and staff attended the 90-min physician training, while 96 patients who attended 90-min group visits were enrolled in this study. Our results demonstrated the feasibility of an Office-GAP program. The Office-GAP tool was used 98.7 % of the time. Eighty (83.3 %) and 75 (78.1 %) patients completed their first and second Office-GAP provider visits respectively. There were longitudinal increases in both patients' satisfaction (SWC) and confidence in decision (CID) making. Relative to the baseline (M=38.6), SWC increased at visit 2 post-GAP assessment (M=42.9, p=< .001) and at visit 3 (M=44.3, p=< .001). Similarly, CID increased from baseline (M=38.9) to visit 2 (M=43.1, p=< .001) and visit 3 (M=43.8, p=< .001). These results suggest that SDM increased over time among the Office-GAP patients.

CONCLUSIONS: The use SDM and DA in real time is feasible in FQCHC and has the potential to improve satisfaction with physician communication and confidence in decisions among patients with heart disease and diabetes. Further evaluation is needed to establish reach, effectiveness and cost-effectiveness of this approach.

SHARED UNDERSTANDING BETWEEN PATIENTS AND PHYSICIANS ON ASPECTS OF HOSPITAL CARE: IMPLICATION FOR QUALITY OF COMMUNICATION AND POTENTIAL ASSOCIATION WITH PATIENT SATISFACTION Sosena Kebede; Zackary Berger. Johns Hopkins University, Baltimore, MD. (Tracking ID #1642184)

BACKGROUND: The hospital is a complex and intimidating place where sick and anxious patients undergo multiple procedures, and interact with multiple caregivers. Prior studies have documented that patients' understandings of their discharge plans are generally poor but few have looked at patients' understandings of aspects of their in-hospital events. No study that we know of has examined whether the degree of shared understanding influences patients' satisfaction with their physicians. We aim to document the degree of shared understanding between patients and their physicians regarding hospital care,evaluate heterogeneities of the degree of shared understanding among patient subgroups, and assess the association between degree of shared understanding and patient satisfaction.

METHODS: (In 8/11 we completed a pilot study (n=8 patients).) We plan to enroll a total of 200 (currently we are at n=138) adult, medicine patients, with at least 2 chronic medical conditions, have been in the hospital> 2 days and have had at least 2 diagnostic tests/procedures. On the day of discharge we administer a semi-structured questionnaire -questions include reason for admission; medical conditions; tests/procedures done, why they were done and results; and reason for prescribed medications. Physicians' documentations are used to assess the degree of shared understanding between patients and their physicians on the selected items. Three questions adopted from Press Ganey satisfaction survey that focus on physician communication will be used to assess patient satisfaction.

RESULTS: Pilot: 3 out of 8 patients had full concordance with their physicians in regards to their chronic conditions, procedures and indication for medications; 2 of these were black, one was white, one was 56 year old college grad, two were in their 20s and high school graduates, each only had 2 known medical conditions. One 56 year old white female, with a complicated medical history had zero concordance in regards to her medications, and diagnoses and was only able to list 3 out of 6 procedures, and did not know any of the results. The rest had concordance ranging from 50 to 100 % on each of the three domains, 100 % concordance in these patients were seen in the procedure domain where each had only 2 procedures. Satisfaction survey was not collected on the pilot patients but most expressed unsolicited high degree of satisfaction during the interview.

CONCLUSIONS: The pilot study although small indicates important points. Firstly, patients with multiple co-morbidities and multiple procedures/are more likely to have lower shared understanding. Secondly, patients' shared understanding seem to be the lowest in the areas of medications. Finally, based on the unsolicited great review we received from patients their level of satisfaction did not seem to be dampened even when their shared understanding was poor with their physicians. It is possible that patients' satisfaction with their physicians may depend more on their hospitalization outcomes and less with the process (communication), or patients may be fully satisfied with communication efforts by their physicians despite the fact that it may not always be effective. Effective communication is a dimension of quality of care, and these issues ultimately raise the intriguing question-can patients be satisfied without receiving a quality care or vice versa?

SHIFTING UPSTREAM: EFFICACY TRIAL OF A LOW LITERACY, EMR MEDICATION EDUCATION STRATEGY Michael S. Wolf[1]; Laura Curtis[1]; Ashley R. Bergeron[1]; Stacy Bailey[2]; Allison L. Russell[1]; Rebecca Mullen[1]. [1]Northwestern University, Chicago, IL; [2]UNC-Chapel Hill, Chapel Hill, NC. (Tracking ID #1643111)

BACKGROUND: Prior studies have shown that patient-provider communication about new medications is inadequate. Patients often have a limited understanding of medication instructions, warnings, and side-effects. Ineffective communication may be one reason for lack of understanding. We sought to leverage an electronic medical record (EMR, EpiCare, Verona, WI) to support patient education about new prescription medications and encourage patient-provider communication.

METHODS: Patients (N=142) at an academic general internal medicine clinic who received a new prescription were recruited and consented into the study. Physicians were randomized to either usual care or the EMR strategy. Patients seeing a physician in the intervention arm received a low literacy-appropriate, one-page educational 'med sheet' with explicit instructions framed from the physician's voice to the patient regarding proper use and vigilance for any new prescription. Patients were interviewed immediately following their scheduled physician visit; demographic information was collected and patient-provider communication was assessed via CAHPS items. Follow-up telephone interviews were conducted to determine if the patient filled their medication and to assess the patients' functional understanding of their new prescriptions (how to take it, for how long, what it was for, and side-effects). Differences in medication understanding and patient-provider communication by study arm were assessed using the chi-square statistic

RESULTS: A total of 142 patients were recruited (75 usual care, 67 intervention). 76.1 % patients were female, 37.3 % were Black, 44.4 % were White. Patients receiving the EMR strategy were more likely to be White, higher educated, and have adequate literacy. Only 1 % of usual care patients reported receiving written information about their new prescription, compared to 69 % in the intervention arm (p<0.001). Overall, patient-provider communication about indications and directions for use of new prescriptions was very high (98 %), but did not differ by study arm. Information on side effects (47 %) or risks and warnings (21 %) was usually not discussed in either study arm. However, participants receiving the EMR strategy were more able to identify side effects or warnings for their new medication compared to the control arm (39 % vs. 18 %, p=0.01). A non-significant trend suggested participants who received the

intervention were also more able to demonstrate a functional understanding of their new prescriptions (55 % vs. 45 %, p=0.25).

CONCLUSIONS: Our initial pilot trial provides some initial evidence to the value of moving 'upstream' to the point of prescribing to offer easy-to-understand information to patients about new medicines. However, clearly further evaluations are warranted. The rate of counseling and communication was atypically high in our general internal medicine clinic. Future trials should be conducted among more vulnerable populations, such as patients served by community health centers where rates of low health literacy and low socioeconomic status (risk factors to poor understanding and adherence) are greater. Our intervention should also seek to better engage providers to improve spoken counseling during encounters, rather than to solely provide assurances in primary care that plain language, written information and instructions are being provided.

SIGN-OUTS: QUALITY DIFFERENCES BETWEEN PRIMARY AND COVERING RESIDENTS Kevin D. Hauck; Lauren Shapiro. Montefiore Medical Center, Bronx, NY. (Tracking ID #1641712)

BACKGROUND: Failure to give complete sign-outs during clinical handoffs is a potential source of patient harm. New duty hour restrictions have increased the number of handoffs that occur between primary and covering residents, and from one covering resident to another. In this study investigators compared the quality of sign-outs between primary and covering residents on an inpatient medicine service.

METHODS: Eight days of sign-outs between day and night residents on the internal medicine teaching service at Montefiore Medical Center were audiotaped and any written components collected. Primary residents were those day residents principally responsible for a patient's care. Covering residents were residents who covered the primary resident while he or she was in clinic or post-call. During the study period the primary residents were the same but the night and covering resident varied. To assess sign-out quality, investigators adapted a previously evaluated 6-component coding scheme which included a patient's clinical condition, code status, recent or scheduled events, anticipatory guidance, tasks to be completed, the presence of a plan and rationale for any task assigned and a global assessment of the sign-out's quality.

RESULTS: A total of 534 sign-outs were evaluated;16 sign-outs had missing data and could not be coded. 449 sign-outs contained both written and verbal elements and 29 were written only. Of the complete sign-outs, 347 were done by primary residents and 171 by covering residents. The majority of sign-outs by both primary and covering residents were globally adequate but there were significant differences in the components of quality between the two groups. Primary residents were more likely to give an account of recent and scheduled events, provide a synopsis of the patient's clinical condition and provide anticipatory guidance. Primary residents were also more likely to assign tasks to their nightfloats. When covering residents assigned tasks to the night resident, they were less likely to provide a rationale and plan for completing those tasks. These results are summarized in Table 1.

CONCLUSIONS: Our data suggest that sign-outs by covering residents are less complete, and provide less guidance. Failure to provide anticipatory guidance and a plan and rational for tasks assigned may reflect less familiarity with patients and could lead to negative clinical outcomes. The increase in tasks assigned from one covering resident to another likely reflects either lack of ownership or an overwhelming workload among these residents. Given the deficiencies in covering resident signouts we believe that internal medicine residency programs should design their schedules to minimize handoffs by covering residents. Future research should examine sign-outs by covering residents as a target for educational or quality improvement interventions.

Table 1: A comparison of significant differences between sign-outs given by primary and covering residents

Sign-Out Component*	Total Sign-Outs % (N)	Primary Resident % (N)	Covering Resident % (N)
Clinical Condition	90.7 % (470)	95.9 % (329)	80.6 % (141)
Recent/Scheduled Events	96.6 % (495)	97.4 % (334)	92 % (161)
Tasks Assigned	45.9 % (238)	38.8 % (133)	60 % (105)
Plan for Task	62.2 % (150)	69.9 % (95)	52.4 % (55)
Rationale for Task	63.9 % (154)	69.9 % (95)	56.2 % (59)
Anticipatory Guidance	56.4 % (300)	64.3 % (223)	41.6 % (77)
Globally Adequate	92.5 % (478)	94.5 % (324)	88.5 % (154)

All comparisons significant with P<0.05. *Percentages reflect within-group percentages, and thus do not sum to 100 %.

SMOKING BEHAVIOR AND USE OF TOBACCO INDUSTRY SPONSORED WEBSITES AMONG MEDICAL STUDENTS AND RECENT GRADUATES IN ARGENTINA Raul Mejia[1]; Maria Victoria Salgado[1]; Celia P. Kaplan[2]; Eliseo J. Perez-Stable[2]. [1]Universidad de Buenos Aires, Centro de Estudios de Estado y Sociedad,, Buenos Aires, Argentina; [2]UCSF, San Francisco, CA. (Tracking ID #1644107)

BACKGROUND: Internet-based marketing has become an attractive option for promoting tobacco products due to its potential to avoid advertising restrictions. In Argentina, several cigarette brands have designed websites for the local market that promote user participation. This study evaluated the use of tobacco-sponsored websites by medical students and recent graduates.

METHODS: An on-line self-administered survey was conducted among eligible medical students and recent graduates in Buenos Aires, Argentina. Sampling was from lists of email addresses of students enrolled in two required courses. Eligibility criteria were age 18–30 years, a former or current medical student at University of Buenos Aires (UBA), and report on smoking status. Other items asked about demographics, depression, and Internet use, "accessing a tobacco brand website" at least once and using tobacco promotional materials.

RESULTS: There were 1,659 participants (response rate=35.1 %); 73.1 % were women, all ≤30 years; 55.7 % current students, and 43.6 % physicians. Women were more likely to report positive screening for depression (p<0.05). Current smokers constituted 27.3 % of the sample, 73.1 % of them smoked their first cigarette more than 1 h after waking up and 75 % smoked ≤10 cigarettes/day. Among respondents, 19.4 % reported having accessed a tobacco sponsored website at least once in their lifetime and 93.8 % accessed these sites only when it was necessary for participating in a tobacco marketing promotion. Most people logging on for promotions reported entering once a month or less (58.9 %), while 25.5 % reported accessing the tobacco industry Internet sites once a week or more. Only 19 participants responded that they accessed the website for reasons other than participating in a marketing promotion. Men were more likely to report having seen a tobacco advertisement on the Internet, to have received a tobacco promotion personally addressed to them, to have used that promotion and to have accessed a tobacco sponsored website (p<0.05). In adjusted logistic regression models, participants were more likely to have accessed a tobacco website if they reported having seen a tobacco advertisement on the Internet (OR=2.3; 95 % CI 1.7–3.2), received a personalized tobacco promotion (OR=5.8; 95 % CI 4.3–7.8) or used one of these promotions (OR=15.5; 95 % CI 10.2–23.6). Respondents were more likely to be current smokers if they received a tobacco promotion (OR=2.6; 95 % CI 2.0–3.5) or if they used one of these promotions (OR=1.9; 95 % CI 1.3–2.9), and less likely to be current smoker if they have seen a tobacco ad on internet (OR=0.6; 95 % CI 0.5–0.8).

CONCLUSIONS: Medical students and physicians smoke at a similar rate to that found in the general population in Argentina. Our study suggests that tobacco industry websites reach medical students and young physicians in a middle-income country with their marketing promotions. This strategy is one component in maintaining current smoking status among young adults. Current or proposed legislation to ban tobacco advertising needs to include Internet sites and related social media.

SMOKING-ATTRIBUTABLE MORTALITY AMONG HOMELESS ADULTS IN BOSTON Travis P. Baggett[1,2]; Nancy A. Rigotti[1,3]. [1]Massachusetts General Hospital, Boston, MA; [2]Boston Health Care for the Homeless Program, Boston, MA; [3]Harvard Medical School, Boston, MA. (Tracking ID #1642661)

BACKGROUND: Homeless individuals have a 73 % prevalence of cigarette smoking and high rates of premature mortality, but smoking-attributable mortality rates have never been reported in a U.S. homeless population. We used clinical, survey, and vital registry data to estimate smoking-attributable mortality in a cohort of homeless adults in Boston.
METHODS: We cross-linked a cohort of 19,836 adults aged 35–64 years who were seen at Boston Health Care for the Homeless Program in 2003–08 with Massachusetts mortality files spanning the same years to determine the number of deaths due to 19 smoking-related conditions. We calculated smoking-attributable fractions (SAF) for each condition using smoking prevalence estimates from the nationally representative 2003 Health Care for the Homeless User Survey and relative risk estimates from the CDC. For each condition, we multiplied the SAF by the number of deaths to estimate smoking-attributable deaths. We divided this by the person-years of observation to generate smoking-attributable mortality rates, which we compared to rates in the 2004 Massachusetts population using direct standardization to adjust for age and sex differences.
RESULTS: Participants were observed for 62,300 person-years. 71 % were <50 years old at the index observation, 73 % were men, 45 % were white, and 30 % were black. Of 1,053 deaths among 35–64 year old adults, 160 were smoking-attributable, including 136 among men and 24 among women. The age- and sex-standardized smoking-attributable mortality rate in the homeless cohort (250.4 deaths/100,000 person-years) was 3.4-fold higher than in the Massachusetts population (72.6 per 100,000). The leading causes of smoking-attributable death were ischemic heart disease (n=50) and lung cancer (n=50). Other causes of smoking-attributable death included other heart disease (n=14), stroke (n=12), and chronic airways obstruction (n=9).
CONCLUSIONS: Despite their young age, a substantial number of deaths among homeless adults are smoking-attributable. Addressing the high prevalence of cigarette smoking among homeless people has the potential to reduce the burden of premature mortality in this vulnerable population.

SMOKING-ATTRIBUTABLE MORTALITY AMONG STATE PRISONERS IN THE UNITED STATES: 2001–2009 Ingrid A. Binswanger[1,2]; Elizabeth A. Carson[3]; Patrick Krueger[4]; Shane Mueller[1]; William J. Sabol[3]. [1]University of Colorado School of Medicine, Aurora, CO; [2]Bureau of Justice Statistics, Washington, DC; [3]Denver Health, Denver, CO; [4]University of Colorado Denver, Denver, CO. (Tracking ID #1619620)

BACKGROUND: Tobacco use is a significant contributor to preventable death. Prison inmates have a high prevalence of tobacco use and lung cancer has been the leading cause of cancer death in former prison inmates. We determined the smoking-attributable mortality and years of potential life lost due smoking among state prisoners and compared smoking-attributable mortality rates among prisoners with those in the US general population.
METHODS: We analyzed national data on state prisoners from several sources. From the Bureau of Justice Statistics (BJS), we used 1) the Survey of Inmates in State Correctional Facilities, last conducted in 2004, for nationally representative (weighted) self-reported smoking rates; 2) the Deaths in Custody Reporting Program for numbers of deaths by state, gender, age and year and ICD-10 codes for primary cause of death among prisoners 35 and older, 2001–2009; and 3) the National Prisoner Statistics series for year-end prison population by state and gender. We also used the Centers for Disease Control and Prevention Smoking-Attributable Mortality, Morbidity, and Economic Costs (SAMMEC) system, an online application, to calculate the smoking-attributable mortality in 19 cause-of-death categories attributable to smoking (not including secondhand smoke), including cancer, cardiovascular, and pulmonary causes. We used SAMMEC to calculate age-adjusted smoking attributable mortality rates, years of potential life lost (YPLL), and age-adjusted YPLL rates. For comparisons to smoking-attributable mortality rates in the general population, we used 2004 US population estimates in SAMMEC.
RESULTS: Of 1.2 million prisoners at year-end 2004, 76 % had ever smoked, of which 66 % were allowed to smoke at their facility. Among prisoners of all ages, 39 % were current smokers and 37 % were former smokers, whereas 56 % reported daily smokers before their arrest. From 2001 to 2009, there were 5,662 smoking-attributable deaths among state prisoners in the United States. Of these, 172 deaths (3 %) were among women. The largest categories of smoking deaths were tracheal, lung and bronchial cancer (n=1,925), ischemic heart disease (n=1,305), other heart disease (n=1,028), cerebrovascular disease (n=260), chronic airways obstruction (n=238), and pneumonia/Influenza (n=172). The age-adjusted smoking attributable mortality rate among prisoners was 363/100,000 compared with 248/100,000 among the general US population. Smoking was responsible for an estimated 136,960 YPLL. The age-adjusted YPLL among prisoners was 5,241/100,000 compared with 3,501/100,000 in the general population.
CONCLUSIONS: Smoking contributes to substantial mortality in correctional facilities. This study provides the first national estimates of smoking-attributable mortality and years of potential life lost in prisoners. Our results are subject to several limitations related to the measurement of smoking prevalence, reporting of deaths, and releases due to medical parole. These may have resulted in conservative estimates of smoking-attributable mortality. Further efforts to prevent smoking related deaths among prisoners are needed, including enhanced tobacco cessation efforts, quality care for smoking related illness, and relapse prevention.

SOCIAL MEDIA USE AND HIV RISK BEHAVIORS IN YOUNG MEN WHO HAVE SEX WITH MEN OF COLOR IN NEW YORK CITY: IMPLICATIONS FOR OUTREACH AND PREVENTION Viraj V. Patel; Desmond Sutton; Melissa Stein. Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1643201)

BACKGROUND: Men who have sex with men for over 60 % of all new HIV infections, with MSM aged 13–29 (YMSM) accounting for 69 % of new infections among all persons in this age group. While HIV incidence has decreased in most populations, YMSM of color, mostly Black and Latino, is the only group to experience an increasing HIV incidence, with existing prevention interventions failing to reach nearly 75 % of this hard to reach population. Rapid development and implementation of new prevention strategies with a broader reach are urgently needed to stem this epidemic. At the same time, social media access and use by young people is ubiquitous and disparities in use of these sites by racial/ethnic minorities and in low-income groups are minimal. Given the challenges of reaching YMSMC in current HIV prevention activities, social media-based approaches may be particularly efficient in identifying and engaging this population.
METHODS: We conducted a descriptive study using a venue based cross-sectional survey design and used a convenience sample of this hard to reach population. We conducted a venue based survey rather than online to understand the level of social media access and use in this group as an online sample would be biased and less informative in this regard. Survey question items were adapted from the CDC's Youth Behavioral Risk Factor Surveillance Survey and de-novo questions on Internet use, access, use of social and media sites were developed in partnership with a LGBT community center in the Bronx, New York. The survey was pre- and beta-tested with online survey software on iPads, assessed for face validity and comprehension by obtaining qualitative feedback from clients at the center, and then refined as required. To obtain a broad sample, we administered surveys in New York City at 2 LGBT oriented community agencies, a social event organized by LGBT youth ("kiki-ball"), and at 2 bars, all known to be frequented by YMSM of color and provided a $4.50 Metrocard incentive after completion.
RESULTS: RESULTS: 104 individuals out of the 107 approached (97 %) participated, with 91 providing complete responses (88 %). Overall, the sample was young (mean age 23 SD±4.8), mostly Hispanic or Black (>82 %), 81 % male, 11 % Transgender women (male-to-female), relatively poor (20 % homeless, 54 % on Medicaid, 18 % uninsured), with 81 % completing 12th grade or having a GED. Ten percent had HIV (self-report), 15 % were diagnosed with a STI in past 12 months, 86 % had seen a medical doctor in the past year. Twelve percent did not use a condom at last sexual intercourse, 19 % traded sex for money or clothes, 10 % traded sex

for drugs. Eighty-eight percent accessed the internet multiple times/day, 86 % had Internet access through a mobile device, and nearly 60 % used the internet primarily from their mobile devices. Forty-five percent used social media to find sex partners, 11 % to find drugs/alcohol. In bivariate analysis, HIV status was associated with having a STI (OR=8.1, p=0.009), trading sex for money or clothes (OR=5.1, p=0.04), and using social media to find partners (OR=10, p=0.03). Additionally, social media access and use was not associated with homeless status, age, education, or race/ethnicity.

CONCLUSIONS: Our study in high risk and vulnerable YMSM of color population, showed social media access and use by low-income YMSM was ubiquitous, with most having access to social media through their mobile devices and using these sites multiple times/day. Social media may be a feasible way to efficiently reach an otherwise hard to reach population.

SOCIOECONOMIC STATUS AND ACCESS TO CORONARY ANGIOGRAPHY IN THE CONTEXT OF UNIVERSAL HEALTHCARE COVERAGE Gabriel E. Fabreau[1,2]; Alexander A. Leung[4,2]; Danielle Southern[3]; William A. Ghali[3,2]; John Z. Ayanian[1]. [1]Harvard Medical School, Boston, MA; [2]University of Calgary, Calgary, AB, Canada; [3]University of Calgary, Calgary, AB, Canada; [4]Brigham and Women's Hospital, Boston, MA. (Tracking ID #1635712)

BACKGROUND: Socioeconomic status (SES) is closely correlated to health and may affect access to medical care. In Canada, a universal health care system aims to provide care based on need and reduce barriers to access. Previous studies have shown an SES gradient for early access to invasive cardiac procedures after a myocardial infarction, but these studies were based on administrative data that may not capture key confounding variables. We used a provincial multicenter clinical cardiac registry from Alberta, Canada to investigate the relationship of area-level household income to access to coronary angiography and mortality.

METHODS: We performed an analysis of 12,796 patients admitted with an acute coronary syndrome (ACS) to any cardiology service in the southern health zones of Alberta, Canada between April 18, 2004 and Aug 30, 2011 by linking census, vital statistics and clinical registry data. Patient SES was estimated using residential neighbourhood median household income from the 2010 Canadian census. We compared the odds of receiving an invasive cardiac procedure within 1, 7 and 30 days and the odds of dying within 30, 90 and 365 days after admission by income quintile. Using multivariable logistic regression, we controlled for age, sex, urban vs. non-urban residence, cardiac risk factors and comorbidities to estimate the adjusted odds ratio of receiving coronary angiography and of death.

RESULTS: Overall rates of angiography within 1, 7 and 30 days of admission for ACS were 43 %, 75 % and 78 % respectively and mortality at 30 days, 90 days and 1 year were 2.1 %, 2.9 % and 5.4 % respectively. Income was inversely associated with receipt of coronary angiography within 1 day, 7 days and 30 days in unadjusted analyses (Table 1). Similarly, the unadjusted OR of death within 30 days, 90 days and 1 year was increased for the lowest vs. highest income quintile (Table 1). After adjustment for sociodemographic and clinical factors, no significant difference in receipt of coronary angiography was evident between the lowest and highest income quintiles within 1 day or 7 days, but use of angiography was significantly lower for low income patients at 30 days (Table 1). No differences were seen in the adjusted 30-day, 90-day or 1-year mortality between the lowest and highest income quintiles.

CONCLUSIONS: An income gradient exists for receipt of coronary angiography and mortality after an acute coronary syndrome in Canada. However, adjustment for clinical factors and residence outside an urban centre accounts for most of the income disparities relating to both endpoints. These findings underscore the crucial importance of rich clinical registry data for studying socioeconomic disparities in cardiac care. Low income is indeed associated with less use of invasive procedures and poorer survival, but it appears to be factors other than income itself that produce the apparent disparities.

Unadjusted and Adjusted Odds Ratios for Receiving Coronary Angiography and Death Post Acute Coronary Syndrome for Highest vs. Lowest Income Quintiles

Coronary Angiography Within: Odds Ratio of Receiving Cardiac Catheterization

	Unadjusted [CI] P-value	Adjusted [CI] P-value
1d	0.70 [0.63, 0.79]<.001	1.05 [0.92, 1.21] 0.57
7d	0.73 [0.64, 0.83]<.001	0.87 [0.75, 1.01] 0.16
30d	0.76 [0.67, 0.87]<.001	0.84 [0.72, 0.98] 0.045

Death Within: Odds Ratio of Death

30d	2.30 [1.53, 3.44]<.001	1.38 [0.89, 2.13] 0.44
90d	1.99 [1.42, 2.79]<.001	1.23 [0.85, 1.79] 0.51
1 year	1.80 [1.41, 2.29]<.001	1.16 [0.88,1.52] 0.21

SPECIALISTS AS PRIMARY CARE PHYSICIANS: PATIENT CHARACTERISTICS AND QUALITY OF CARE OF VISITS TO GENERALIST AND SPECIALIST PHYSICIANS SELF-IDENTIFIED AS PRIMARY CARE PHYSICIANS. Samuel T. Edwards[1,2]; John N. Mafi[3,2]; Bruce E. Landon[3,4]. [1]Boston VA Healthcare System, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Beth Israel Deaconess Medical Center, Boston, MA; [4]Harvard Medical School, Boston, MA. (Tracking ID #1634943)

BACKGROUND: Adult primary care is typically provided by physicians trained in family practice or general internal medicine, but many patients see medical subspecialists for their primary care.

METHODS: We studied a nationally representative sample of visits for patients ≥18 years identified from the National Ambulatory Medical Care Survey (NAMCS) over the time period 1997–2010 for which the provider indicated that they were the patient's primary care physician. We included visits to generalists (family practice or general internal medicine), cardiologists, and other medical specialists.. We describe patient, provider and visit characteristics and compare visit-based quality of care for several common medical conditions after constructing multivariable models to control for patient demographics, payer type, region, and year. Analyses were performed using SAS 9.3 and SUDAAN for weighted analyses.

RESULTS: Among 81,898 visits to self-identified PCPs, 93.8 % were to generalist physicians, 1.6 % to cardiologists and 4.7 % to other medical specialists. Mean visit time was 18.5, 20.2, and 25.9 min to generalists, cardiologists, and other specialists respectively (p<0.001). The majority of visits to generalists were for new problems (40.5 %), whereas the majority of visits to cardiologists and medical specialists was for chronic disease management (59.4 % and 63.75 % respectively, p<0.001). Mean patient age was 55.5 years for PCPs, 58.5 years for medical specialists, and 67.1 years for cardiologists. Visits to specialist PCPs had a higher prevalence of chronic disease than visits to generalists (2.9 chronic diseases for cardiologists vs. 4.5 for other medical specialists vs. 2.3 for generalists). Quality of care for cardiovascular disease was better for cardiologists than generalists, and better for generalists that for other medical specialists (e.g., beta-blocker for coronary artery disease, 34.5 % for generalists, 41.1 % for cardiology, 22.4 % for other medical specialists, p=0.016). Pulmonary specialists provided more appropriate treatment of asthma than other specialties, but generalists provided better asthma care than other medical specialists and cardiologist (pulmonary 34.8 %, generalist 25.9 %, cardiologist 15.0 %, p=0.0013). Generalists performed better quality of care for depression (treatment of depression 79.3 % for generalists vs. 66.2 % for cardiologists vs. 70.4 % for other medical specialists, p=0.05) and had less misuse of medication in the elderly (9.8 % for generalists vs. 16.4 % in cardiologists). Routine EKGs in low risk patients were more likely ordered by cardiologists than generalists (26.0 % cardiologists, 9.7 % generalists, p=0.0338). All of these differences persisted in adjusted analyses.

CONCLUSIONS: Medical specialists who serve as PCPs tend to take care of older patients with a higher prevalence of chronic disease, and dedicate the majority of their visits to chronic disease management, usually within their specialty. Specialist PCPs demonstrate higher quality of care within their specialty domain, but perform worse outside of their specialty. As we endeavor to transform primary care through innovative practice models such as the Patient-Centered Medical Home, careful consideration is

needed regarding the appropriate integration of specialty care for older more medically complex patients.

SPECIALISTS' ATTITUDES IN JAPAN TOWARDS THE HOSPITALIST MODEL OF CARE Gautam A. Deshpande[1,2]; Sachiko Ohde[1]; Osamu Takahashi[1]; Tsuguya Fukui[1]. [1]St. Luke's Life Science Institute, Chuoku, Japan; [2]University of Hawaii, Honolulu, HI. (Tracking ID #1626169)

BACKGROUND: Despite the rapid growth of the hospitalist medicine in the U.S., assessments of suitability of this healthcare model to systems overseas are lacking. In Japan, general internal medicine (GIM) has little defined role in the specialty-driven inpatient setting. This pilot study quantitatively explores the attitudes of specialty inpatient physicians towards the model of care provided by inpatient GIM physicians ("hospitalists").
METHODS: This was a prospective, survey-based study at a tertiary-level, community hospital in Tokyo, Japan. After a brief vignette of the hospitalist role, specialists were asked to rate their agreement with 26 statements assessing their attitude towards the hospitalist model of care via standardized surveys. Descriptive statistics were employed for baseline practice characteristics and attitudes. Highly correlated factors were included in exploratory factor analysis to identify latent factors ("components") regarding specialists' attitudes towards hospitalists. Associations between components and practice characteristics were explored via multivariable linear regression analysis.
RESULTS: Of 330 eligible physicians, 38 surveys were received (response rate, 11.5 %; men, 76.3 %). Median (range) time spent in practice was 15 (3–37) years; 89.5 % reported having a subspecialty, with 55.3 % claiming a secondary subspecialty; 89.5 % reported taking care of inpatients and outpatients; 80.6 % reported spending <25 % of time practicing outside their specialty. In 12 months, 42.1 % and 47.4 % of respondents reported sending none or ≤10 % of their inpatients to a hospitalist, respectively, though 59.5 % felt that their patients would appreciate having a hospitalist physician to orchestrate inpatient care; 34.2 % versus 23.7 % agreed that specialists were best able to see their own inpatients and 65.8 % felt responsible for their patients' total care; 57.9 % agreed that using a hospitalist service would be "shirking duty," though only 15.8 % thought that patients would also feel this way. On factor analysis, Scree plot indicated 3 components among 10 highly correlated factors. Component 1, suggesting overwork and priority on outpatients, was associated with more positive responses to hospitalist care. After adjustment, only type of residency program remained statistically significant ($p=0.003$), with those having graduated from university-based programs tending to cluster in Component 1. Component 3 suggested dissatisfaction with time management (work-life schedules), resulting in positive attitudes to hospitalists, though without statistical significance. In contrast, Component 2 suggested a perception of decreased patient and physician satisfaction with hospitalist care. These specialists, tending to be younger with higher call frequencies and inpatient burdens, broadly agreed that, "inpatient generalists will decrease patients' quality of care" ($p=0.032$).
CONCLUSIONS: This preliminary study suggests that overwork, outpatient orientation, and dissatisfaction with time management may favorably influence attitudes towards the hospitalist model of care in Japan, and may be more prevalent among more experienced physicians trained in specialty- and outpatient-oriented settings, such as university-based programs. In contrast, hospitalist care may not be seen as optimal among younger specialty physicians with more active inpatient responsibilities. An understanding of these factors may influence the successful implementation and growth of hospitalist medicine overseas.

STANDARD WORK-HOUR REPORTING INACCURATELY REFLECTS ACTUAL HOURS WORKED DURING 16-h LONG CALL SHIFTS Jed Gonzalo[1,3]; Julius J. Yang[3]; Long Ngo[3]; Alicia Clark[2,3]; Eileen E. Reynolds[3]; Shoshana Herzig[3]. [1]Penn State College of Medicine, Hershey, PA; [2]Duke University School of Medicine, Durham, NC; [3]Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #1635000)

BACKGROUND: The Accreditation Council for Graduate Medical Education (ACGME) duty hour standards were implemented to better balance patient care, resident well-being and education. Numerous studies have evaluated their impact on patient safety, education, and fatigue, resulting in large systematic changes to achieve compliance. These changes are all based upon the results of duty hours surveys, which rely on remote resident retrospective report through the annual ACGME survey, often implemented months after the call shift. No studies have evaluated the accuracy of resident recall of duty hour compliance remotely, in a manner similar to the annual ACGME survey. We examined the accuracy of residents' remote perceptions of shift length compliance and workload characteristics.
METHODS: From July 2011–June 2012, we emailed a survey to medicine ward residents following each 16-h long call shift to determine their compliance with 16-h shift length and workload characteristics, including number of patients on the census, total admissions, and patients accepted after 5 pm. In June 2012, we emailed a second survey to the same residents, assessing perceptions of their 16-h long call shifts during the preceding year. Using matched comparisons, we compared call-shift data to residents' retrospective perceptions of 16-h shift length compliance using general linear models, and call-shift workload characteristics using linear mixed effects models.
RESULTS: Of 648 call-shifts, data were collected from 497 (77 %), with 77 (15 %) including at least one team member having an extended shift beyond 16 h. Eighty-seven of 95 residents completed the end-of-year perceptions survey (92 %). After excluding one resident without call-shift data, 48 (56 %) residents underestimated, 33 (38 %) overestimated, and 5 (6 %) were accurate in their estimation of the percentage of compliant call-shifts. Of residents who overestimated this percentage, they estimated compliance 85 % of the time, compared to 67 % of the time based on actual call-shift data (average overestimation 18 %, 95 % [CI] 13 to 23). Of residents who underestimated this percentage, they estimated compliance 77 % of the time, compared to 95 % of the time based on actual call-shift data (average underestimation 18 %, 95 % CI 13 to 23). Compared to on-call data, residents' recall overestimated the number of patients on a census prior to an admitting day ($p=0.01$), admissions accepted during the call-shift ($p<0.0001$), and admissions accepted after 5 pm (<0.0001).
CONCLUSIONS: Residents' remote recall of 16-h, long call shift compliance and characteristics were not congruent with data obtained from actual shifts. The majority of residents (94 %) either under- or over-reported compliance with shift length while only 6 % were accurate in their recall. Studies investigating the accuracy of resident self-report of duty hours compared to more objective standards have shown mixed results; however, our study most accurately reflects the methods used by the ACGME annual survey. Given the importance of accurate duty hours reporting for targeting changes to admitting structures, measuring the impact of those changes, and maintaining accreditation for residency programs, further work should investigate alternatives to remote recall surveys for duty hour assessment.

STATINS IN WHOSE WATER? MODELING RELATIVE COST-SAVING OF OVER-THE-COUNTER STATIN USE IN SELECTED AMERICAN POPULATIONS INDEPENDENT OF LIPID LEVELS David Heller[1]; Pamela G. Coxson[1]; Mark J. Pletcher[1,2]; Lee Goldman[3]; Kirsten Bibbins-Domingo[1,2]. [1]University of California, San Francisco, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA; [3]Columbia University, New York, NY. (Tracking ID #1641903)

BACKGROUND: Statin medications reduce coronary heart disease risk, but are costly and have multiple toxicities. Current primary care practice guidelines in the United States, such as ATP III, recommend offering statins only to selected patients, based on their low density lipoprotein (LDL) level and other cardiovascular risk factors. Because of lower statin costs and recent data suggesting that statins prevent CHD in broader populations, some argue these medications should be made available without a prescription. We sought to determine in which US populations

statins would prove cost-saving over a 10-year time horizon. We defined these populations by age, gender, BMI, and tobacco use. We explicitly omitted blood pressure, LDL and HDL levels, and any other serologic markers, as such data may be unavailable to statin consumers.
METHODS: We used the Coronary Heart Disease (CHD) Policy Model, a dynamic state transition model of cardiovascular disease in the United States, to estimate the net cost savings associated with 10-year universal statin use (modeled as a 27 % drop in LDL) in 375 sub-populations divided by age, gender, tobacco use, and BMI. We excluded current users of statins, persons with diabetes, and persons with a Framingham risk score of 20 % or more (all based on self-report in the National Health And Nutrition Examination Survey, NHANES), from the analysis. To calculate total cost associated with statin use in each population, we assumed a direct cost of $4 USD per person-month, and also estimated quality of life and toxicity costs. We estimated 97 myopathy events and 110 hepatitis events per 100,000 person-years, with a 1.6 % and 0.45 % risk of rhabdomyolysis and hepatic failure per episode, respectively (and associated with hospitalizations costing $11,745 and $15,729, respectively). We then multiplied these toxicity costs by a factor of 10, presuming statin users not seeing a physician may present later to care. We compared the sum of all of those costs with the sum of all cardiovascular event costs and quality-of-life losses prevented by the medication, calculated based on observational data.
RESULTS: Universal low-dose statin use in all persons in the United States 35 and over is projected to prevent approximately 104,000 total deaths and 1.1 million incident cases of CHD, with a total cost of approximately $11.2 billion USD. Cost savings of approximately $1 billion would be achieved in men overall, offset by a $12.2 billion net loss in women. Universal statin use is estimated to be cost-saving overall in all men from age 45–74. In women 45–74, statin use is estimated to be cost-saving in obese smokers. Statins would not be cost-saving in any strata of women aged under 45 or over 74.
CONCLUSIONS: Universal use of statins in select US populations could avert millions of cardiac events and thousands of deaths at a net cost savings to society, even after accounting for the cost of toxicity. Statin use could be reasonably suggested to all men in the US between age 45–74, and to other high-risk populations who could self-identify based on factors such as obesity or smoking. These data suggest that a policy of over-the-counter statin availability and recommended widespread use could be substantially cost-saving.

STATUS OF ADVANCE DIRECTIVE AND GOALS-OF-CARE DISCUSSIONS IN A UNIVERSITY-AFFILIATED COMMUNITY HOSPITAL Rebecca Eskin[1]; Deepa Shah[1,2]; Beth Barron[1,2]; Zorica Stojanovic[1,2]; Gregory Pappas[1]. [1]Columbia University College of Physicians and Surgeons, New York, NY; [2]New York Presbyterian Hospital, New York, NY. (Tracking ID #1642505)

BACKGROUND: The New York State Palliative Care Information Act, passed in 2011, mandates that physicians offer terminally-ill patients information and counseling on palliative care and end-of-life options. The Allen Hospital of New York Presbyterian serves a population of generally elderly, ethnically diverse patients with multiple comorbidities. many of whom would benefit from discussion about advance directives and goals of care. This study was designed to collect baseline data in preparation for interventions to improve the quality and increase the number of conversations about advance directives and goals of care in this population.
METHODS: All patients over the age of 70 admitted to medical teams at the Allen over a 1-month period in the summer of 2012 were included in a chart review. Data was collected including demographic information, comorbidities, functional status, code status, functional status, and documentation of any discussion about prognosis or goals of care. A survey was distributed to providers about experiences and previous training on advance directive conversations. A sample of patients was interviewed about their experiences discussing code status, goals of care and their wishes for the context and content of these conversations with their providers.
RESULTS: 260 patient charts were reviewed. 24 % had Do Not Resuscitate Orders in the medical record. 21.5 % had documentation of a conversation about prognosis, goals of care, or code status. Higher frequency of DNR orders was seen in patients residing in nursing homes (46 %) and those with a documented diagnosis of dementia (38 %). Goals of care conversations were documented at higher rates in patients with complete functional dependence (39 %) and patients who spent time in the ICU (55 %). Physician surveys revealed that 96 % (23/24) believed it was "very important" or "absolutely necessary" to address advance directives with patients. They identified obstacles including language barriers and time limitation. Patient interviews revealed emphasis on quality of life, misinformation about the definition of a DNR order, and recognition that physicians' time is limited
CONCLUSIONS: This study provided quantitative and qualitative data about the status of advance directives and code status discussions at this community hospital. The data revealed an overall low rate of DNR orders and documented goals of care conversations with variation based on patient characteristics and factors related to the hospitalization. Patient wishes and physician obstacles were further clarified with surveys and interviews. The data will be collected again after physician education and compared to this baseline data to measure the effect of the intervention.

STORIES OF PARTNERSHIP: LAYING THE FOUNDATION FOR A THRIVING MEDICAL-RELIGIOUS PROGRAM TO PROMOTE COMMUNITY ENGAGEMENT Rebeca Rios[1]; Panagis Galiatsatos[1]; William D. Hale[2]; Lisa A. Cooper[1]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #1642162)

BACKGROUND: To meet the health care needs of all community members living with chronic diseases, health care systems must engage community partners and expand circles of care. Partnerships between academic medicine and religious communities offer valuable opportunities to deliver health interventions in ways that are consistent with community and cultural norms. The Healthy Community Partnership (HCP) is a medical-religious partnership between an academically-affiliated medical center and religious congregations in surrounding communities. The aim of this study is to describe the initial process by which individuals from HCP religious and medical communities engaged in the partnership over its first year. By describing key components of the partnering process, we aimed to identify factors influencing partnership engagement that may be compiled and disseminated to those interested in expanding communities of care through medical-religious partnerships.
METHODS: We recruited participants from a group of 20 identified key informants from church congregations and medical staff to participate in in-depth interviews. Trained interviewers covered topics related to reasons for partnering and central aspects of the partnership using a semi-structured interview guide. Using a grounded theory approach to thematic analysis of audiotaped interviews, 2 reviewers identified themes related to the process of partnering.
RESULTS: Among the initial sample, 4 of the respondents were congregation partners, 3 were medical center partners, and 4 out of 7 were male. Several themes related to the initial partnering process emerged. The theme of trust was central, and personal characteristics of trusted individuals, such as integrity, were important. Norms of consistency referred to consistency in responsiveness and communication. Trust was

also borne out of the perception of commitment of leaders at the highest level of partner organizations. A frequent theme concerned the sense of a shared, holistic vision of spiritual/bodily health. Another frequent theme was related to the principle of valuing community partners as experts, exemplified by expressions of the importance of defining partnership goals based on community defined problems and solutions. Good communication, particularly listening, "bridging," and "speaking their language," was often mentioned in relation to facilitators of partnership. Finally, 3 of the respondents described themselves natural liaisons because of their long-term personal relationships with both the medical center and one of the church partners.

CONCLUSIONS: Our results have implications for administrators and practicing physicians interested in enhancing community engagement through partnering with faith communities for health education and outreach. Thematic content suggests the following recommendations for engaging religious communities: 1) Use sound communication skills to listen and learn about how community members and congregation leaders understand community strengths and health problems. 2) Create opportunities to discuss shared values and vision around health and wellness. 3) Seek strong commitment from organizational leaders, and identify staff members who may be natural liaisons due to their involvement with churches. 4) Finally, all partners should demonstrate their commitment through regular communication and following through reliably.

STRATEGIES FOR FACILITATING CARE COORDINATION AMONG UNDERSERVED ADULTS WITH DIABETES Radhika Takiar[1]; Shari Bolen[2]; Adam T. Perzynski[2]; Paulette A. Sage[3]; Kurt Stange[4]. [1]University of Akron, Akron, OH; [2]The MetroHealth System/Case Western Reserve University, Cleveland, OH; [3]Case Western Reserve University, Cleveland, OH; [4]Case Western Reserve University, Cleveland, OH. (Tracking ID #1635218)

BACKGROUND: While several studies have investigated issues of care coordination within primary care, no study has observed and described the range of strategies used to facilitate care coordination at the primary care visit in underserved populations. A better understanding of the depth and range of care coordination activities for underserved populations will help inform investigators, clinicians, administrators, and policymakers about potential strategies to enhance care coordination.

METHODS: We conducted a qualitative study of diabetes visits from a safety net primary care clinic with high quality of care scores for diabetes patients. We recruited adults with type 2 diabetes from the 4 primary care physicians at the clinic until no new themes emerged. We audiotaped, observed, and transcribed the doctor-patient visits. Using a grounded theory approach, one investigator independently coded and analyzed transcripts for all care coordination that arose during the visit and described the strategies used to facilitate care coordination by patients and/or providers. A second investigator independently reviewed 25 % of the visits. Disagreements were resolved by consensus.

RESULTS: Fifteen mainly African American (93 %) middle-aged (mean age 61 years) female (64 %) patients participated. The mean blood sugar, blood pressure, and cholesterol were under fairly good control (HbA1c 7.5 %, BP 134/81 mmHg, and LDL 100 mg/dl). An average of 13 (SD 5) strategies per visit were used to facilitate care coordination including: use of the electronic health record to access notes and lab results, use of the clinic's mailing and phone system to facilitate interprovider and patient-nurse-provider communication, use of ancillary support including on-site nurses and care coordinators, referring patients to nearby specialists, sharing provider knowledge (i.e. regarding useful community resources and access to low cost medications) and sharing patient knowledge (i.e. about finances, insurance coverage, specialist visits). Providers most often initiated strategies of accessing the electronic health record, promoting ancillary support within their own clinic system, and asking patients to share their knowledge about a range of items (i.e. medical history, specialist advice, medications, and social environment support). However, patients most often initiated strategies of sharing their own knowledge (i.e. their medical history, specialist advice, or insurance coverage/finances) and of using clinic resources, like the phone or mail, to facilitate the patient-nurse-provider communication or obtain low cost medications. Together, the patients and providers contribute to care coordination in a complementary manner, following Wagner's Chronic Care Model which focuses on transforming health care from being reactive to proactive.

CONCLUSIONS: Numerous strategies were used for facilitating care coordination by both patients and providers during the primary care office visit in this safety net diabetic population. Patients have important, insider knowledge of their health care that is accessible to them in a manner not always efficiently available to their physicians despite a high functioning EHR. The synthesis of patient and provider strategies can potentially enhance care coordination and subsequent care quality.

STRATEGIES FOR IMPROVING MEDICATION ADHERENCE DISCUSSIONS AT THE PRIMARY CARE VISIT FOR UNDERSERVED ADULTS WITH DIABETES Andrea Grosz[1]; Adam T. Perzynski[2]; Paulette A. Sage[3]; Kurt Stange[3,4]; Shari Bolen[2]. [1]Case Western Reserve University School of Medicine, Cleveland, OH; [2]The MetroHealth System/Case Western Reserve University, Cleveland, OH; [3]Case Western Reserve University School of Medicine, Cleveland, OH; [4]Case Western Reserve University School of Medicine, Cleveland, OH. (Tracking ID #1629942)

BACKGROUND: Although many studies have shown that better medication adherence is associated with improved patient outcomes in adults with diabetes, little is known about the type, number and range of strategies used to facilitate medication adherence during the doctor-patient visit with underserved populations. An increased understanding of strategies to promote medication adherence could inform future translational and quality improvement work.

METHODS: We conducted a qualitative study of diabetes visits from a safety net primary care clinic with high quality of care scores for diabetes patients. We recruited adults with type 2 diabetes from the 4 primary care physicians at the clinic. We audiotaped, observed, and transcribed the doctor-patient visits. Using a grounded theory approach, one investigator coded, analyzed, and timed transcripts for all medication adherence discussions and strategies for facilitating medication adherence. A second independent reviewer coded and analyzed 25 % of the visits. Disagreements were resolved by discussion among the research team.

RESULTS: We enrolled 15 patients, and reached saturation of themes after analyzing 13 subjects. Patients were mainly African American (93 %), middle-aged (mean age 61 years) and female (64 %), and were under fairly good risk factor control (mean HbA1c 7.5 %, mean BP 134/81 mmHg, and mean LDL 100 mg/dl). On average, 7 (SD 3) minutes were spent discussing medications, comprising 28 % (SD 15 %) of the total visit time. The range of potential facilitators of medication adherence included discussions of: side effects, patient knowledge and beliefs, cost, refills, medication importance and purpose, different treatment options, medication instructions, follow-up plans, and reviewing medications. Of note, review of the medication list and inter-provider notes in the electronic medical record often prompted or facilitated these adherence discussions. On average, 13 (SD 5) strategies per visit were used to facilitate medication adherence. Patient strategies (N=52 for all 15 visits) included sharing their knowledge about their current meds and needed refills (42 %), reporting or inquiring about side effects (12 %), reporting reasons for nonadherence and

effective strategies for adherence (8 %), bringing up cost/insurance concerns (8 %), mentioning patient preference for medications (8 %), and bringing in medications (4 %). Provider strategies (N=139 for all 15 visits) included using basic terms to give medication instructions and explain their purpose (13 %), educating about potential side effects (10 %), relating importance of adherence to patient outcomes (9 %), providing low cost medication options (7 %), providing information about how to obtain and determine need for refills (7 %), giving very specific medication instructions (7 %), identifying medications by color/size/nicknames (5 %), inquiring about side effects (3 %), shared decision-making about medication changes (3 %), arranging a follow up plan for potential side effects (3 %), and normalizing medications(1 %).
CONCLUSIONS: Patients and providers initiated numerous strategies for facilitating medication adherence discussions during the primary care visit for adults with diabetes in this safety net population. Clinicians and policymakers should consider how to effectively incorporate and evaluate these strategies in primary care.

STUDENT-RUN CLINICS AS MEDICAL STUDENT SCHOLARLY HOMES FOR GENERAL INTERNAL MEDICINE Scott A. Elman[1]; Linda Wang[2]; Alexandra E. Bachorik[2]; Laura A. Huppert[1]; Nandini C. Palaniappa[2]; Noa Simchoni[2]; Matthew A. Spinelli[2]; David C. Thomas[3]; Rebecca Berman[1,4]; Yasmin S. Meah[3]. [1]Harvard Medical School, Boston, MA; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Massachusetts General Hospital, Boston, MA. (Tracking ID #1640616)

BACKGROUND: As the nation's primary care crisis deepens, concern has grown over how to entice medical students into primary care. Traditional medical school curricula rarely offer students exposure to academic general internal medicine (GIM). Student-run clinics (SRC) are popular activities at over 100 medical schools; many have robust programs with unique exposures to GIM practice, scholarly activities, and mentorship. We aim to 1) highlight innovative scholarly programs at two SRCs that expose students to GIM and 2) propose SRCs as curricular venues with substantial impact on student exposure to GIM that deserve further study. Setting and participants: Harvard Medical School's Crimson Collaborative (CCC) and Icahn School of Medicine at Mount Sinai's East Harlem Health Outreach Partnership (EHHOP) staffed by medical students of all years.
METHODS: CCC and EHHOP have developed programs to train medical students in GIM practice and scholarly research. At the CCC, third-year students may participate in a Primary Care Clerkship, an 8-month longitudinal experience focused on evidence-based, primary care panel management. All students attend post-clinic case review sessions and primary care didactics led by internal medicine residents. Select students are trained in motivational interviewing (MI) to counsel patients on diet, exercise and smoking cessation. The CCC research team, mentored by GIM faculty, tracks patient demographics, health outcomes and patient satisfaction. Through EHHOP's Chronic Care Program, select third-year students follow a panel of complex patients with chronic illness. They are mentored by fourth-year students and generalist physicians to create interdisciplinary care plans and direct patients through all venues of care. Students engage in a primary care curriculum, reflective practice meetings, and case presentations at "EHHOP Grand Rounds". EHHOP's Quality Improvement (QI) Council affords extensive QI training and implementation to improve clinic practice. Through quality-based GIM faculty-mentored research, students investigate preventative practices compared to national standards.
RESULTS: The CCC has trained 473 students; 50 students have been trained in MI. EHHOP has involved 60–90 % of the student body annually since 2004; the Chronic Care Program has trained over 30 third-year and over 60 fourth-year students. Both clinics have made substantial contributions to GIM scholarly research. The CCC has published a paper on increasing student exposure to primary care careers and clinic operations, held two workshops on mental health integration and SRC student education, led 10 national and regional oral presentations on topics like patient satisfaction measurement methods, and has produced 48 posters with 75 different student contributors on topics such as hypertension management and the colocation of psychiatry. EHHOP has led over 20 national and regional workshops and posters in primary care practice innovations, initiated 9 QI projects with over 45 student participants and published four papers discussing SRC student education, depression, diabetes, and hypertension outcomes. EHHOP is also spearheading projects on the quality of diabetes care, ED utilization, and mental health integration.
CONCLUSIONS: We propose the SRC as an emerging venue with robust scholarly opportunities for students to explore the GIM practice, research and mentorship. The educational practices of SRCs deserve study into the impact on medical student careers in primary care and GIM.

SUBOPTIMAL ADHERENCE TO INITIAL PROCESSES OF CARE IN ELDERLY PATIENTS WITH ACUTE VENOUS THROMBOEMBOLISM Anna K. Stuck[1]; Marie Méan[1]; Andreas Limacher[2]; Marc Righini[3]; Kurt A. Jäger[4]; Juerg-Hans Beer[5]; Joseph Osterwalder[6]; Beat Frauchiger[7]; Christian M. Matter[8]; Nils Kucher[9]; Anne Angelillo-Scherrer[10]; Jacques Cornuz[11]; Martin Banyai[12]; Bernhard Lämmle[13]; Marc Husmann[14]; Michael Egloff[5]; Markus Aschwanden[4]; Henri Bounameaux[3]; Nicolas Rodondi[1]; Drahomir Aujesky[1]. [1]Bern University Hospital and University of Bern, Bern, Switzerland; [2]Clinical Trials Unit Bern, University of Bern, Bern, Switzerland; [3]Geneva University Hospital, Geneva, Switzerland; [4]Basel University Hospital, Basel, Switzerland; [5]Cantonal Hospital of Baden, Baden, Switzerland; [6]Cantonal Hospital of St. Gallen, St. Gallen, Switzerland; [7]Cantonal Hospital of Frauenfeld, Frauenfeld, Switzerland; [8]University of Zurich, and Zurich University Hospital, Zurich, Switzerland; [9]Bern University Hospital and University of Bern, Bern, Switzerland; [10]Lausanne University Hospital, Lausanne, Switzerland; [11]University of Lausanne, Lausanne, Switzerland; [12]Cantonal Hospital of Lucerne, Lucerne, Switzerland; [13]Bern University Hospital and University of Bern, Bern, Switzerland; [14]Zurich University Hospital and University of Zurich, Zurich, Switzerland. (Tracking ID #1639290)

BACKGROUND: Although venous thromboembolism (VTE) is common in elderly persons, limited data exist on the quality of care in elderly patients with VTE, and it is unknown whether such patients receive recommended processes of care in the early phase of VTE.
METHODS: We prospectively studied consecutive in- and outpatients aged ≥65 years with acute, symptomatic VTE from all five Swiss university- and four non-university hospitals between September 2009 and March 2011. We systematically assessed whether the following five processes of care, which are recommended by the American College of Chest Physicians, were performed in each patient: (1) duration of parenteral anticoagulation for ≥5 days; (2) start of oral anticoagulation on the first treatment day; (3) continuation of parenteral anticoagulation until the international normalized ratio [INR] is ≥2 for ≥24 h; (4) use of low-molecular-weight heparin monotherapy in patients with cancer; and (5) prescription of compression stockings in patients with symptomatic deep vein thrombosis. We used multivariable logistic models to identify patient and hospital factors independently associated with adherence to recommended processes of care.
RESULTS: Our cohort comprised 950 patients with VTE (median age 75 years). Of these, 86.0 % (645/750) received parenteral anticoagulation for ≥5 days, 46.7 % (350/750) had oral anticoagulation started on the first treatment day, and 36.5 % (274/750) had an INR ≥2 for ≥24 h before parenteral anticoagulation was discontinued. Overall, 34.6 % (53/153) of patients with cancer received low-molecular-weight heparin monotherapy and 71.9 % (304/423) of patients with symptomatic deep vein thrombosis were prescribed compression stockings. In multivariable analysis, obesity (odds ratio [OR] 0.68, 95 % confidence interval [CI] 0.47–0.97), symptomatic pulmonary embolism (OR 0.61, 95 % CI 0.43–0.86), and hospital-acquired VTE (OR 0.32, 95 % CI, 0.19–0.54) were negatively associated with the initiation of oral anticoagulation on the first treatment day.
CONCLUSIONS: The adherence to most recommended processes of care was suboptimal in elderly patients with VTE. Several patient characteristics

were associated with lower rates of initiating oral anticoagulation on the first treatment day. Further efforts are needed to improve quality of care in elderly patients with VTE.

SUBTHRESHOLD PTSD IN MILITARY SERVICE MEMBERS RETURNING FROM IRAQ AND AFGHANISTAN Michael Roy[1,2]; Michelle Costanzo[1,2]; Patricia Taylor[1,2]; Suzanne Leaman[1,2]. [1]Uniformed Services University, Bethesda, MD; [2]Uniformed Services University, Bethesda, MD. (Tracking ID #1643169)

BACKGROUND: Posttraumatic stress disorder (PTSD) has been called a signature injury of the Iraq and Afghanistan wars and has been the subject of considerable attention. However, there is evidence that subthreshold mood anxiety disorders, including PTSD, are associated with functional impairment and are so much more common than the full-blown disorders that they are actually responsible for a greater degree of impairment at the community level. It is therefore important to develop a better understanding of those with subthreshold symptoms and to be able to characterize this population in order to conduct targeted intervention.
METHODS: We conducted a prospective cohort study, enrolling active duty and reserve component U.S. military service members (SMs) at their demobilization station upon their return from Iraq or Afghanistan, and within 2 months of their return we completed a comprehensive 2-day evaluation including multiple psychophysiologic measures, novel brain imaging techniques (functional MRI and diffusion tensor imaging), vestibular and olfactory testing, electroencephalograms, evoked response potentials, and detailed psychological assessment. We identified a cohort of 81 SMs who did not meet criteria for PTSD, depression or postconcussive syndrome (PCS, the aftermath of a traumatic brain injury) upon initial assessment, and we are in the process of conducting 3, 6, and 12 month follow-up assessments for the subsequent development of PTSD, depression or PCS. In this report, we compare the baseline assessments for those with subthreshold PTSD symptoms (PTSD Checklist, or PCL, scoore of 28–49 versus those with no significant PTSD symptoms (PCL<28).
RESULTS: There was no difference in age, gender, branch of service or alcohol use between those with and without subthreshold PTSD symptoms, but those with subthreshold symptoms were more likely to have experienced a significant TBI during deployment (10 % vs. 4 %), and had greater symptoms of depression as measured by the PHQ-9 (mean score 4.3 vs. 1.5) as well as anxiety as measured by the GAD-7 (mean 4.3 vs. 1.6). On the SF-36 assessment of functional status, there was no difference in general health, but differences were evident in social functioning (mean 94 vs. 83) and vitality (76 vs. 67). There were no differences in olfactory or vestibular functioning, and while we are continuing to analyze brain imaging studies we have not yet discerned group differences. However, there are compelling differences in psychophysiologic measures in both phases of a fear acquisition/fear extinction experiment, as those with subthreshold PTSD symptoms tended to have greater responses in heart rate, eye blink, and galvanic skin response to both danger and safety cues in each phase.
CONCLUSIONS: Psychophysiologic measures provide compelling evidence of heightened responses, as well as generalization of fear conditioning, in military service members who have recently returned from combat with subthreshold PTSD symptoms as opposed to their fellow SMs who lack subthreshold symptoms. This provides evidence for the significance of subthreshold symptoms, which are associated with functional impairment and higher rates of progression to full PTSD. Future studies should target interventions at those with subthreshold PTSD.

SUCCESSFUL TREATMENT OF MEDICALLY COMPLEX PATIENTS WITH DEPRESSION USING ALGORITHM BASED CARE IN AN ACADEMIC PRIMARY CARE CLINIC Duncan Vincent; Lauren Metzger; Amy Weil; Diane R. Dolan-Soto; Samuel Cykert. University of North Carolina Hospitals, Chapel Hill, NC. (Tracking ID #1640132)

BACKGROUND: Major depressive disorder (MDD) affects 5–10 % of patients in the primary care setting. The USPSTF recommends screening adults for depression in clinical practices that have systems in place to assure accurate diagnosis, effective treatment and follow-up. The Depression Care Program (DCP) is a multidisciplinary program developed in 2011 that utilizes the Patient Health Questionnaire (PHQ-9) as a screening tool to identify and follow patients that screen positive for depression inside the UNC Internal Medicine clinic. The DCP also conducts follow-up phone calls and offers in-clinic counseling with a licensed clinical social worker for patients with severe depression.
METHODS: In the Internal Medicine clinic at the University of North Carolina Hospitals, 95 patients with MDD have been enrolled to date, though data collection is ongoing. Inclusion criteria are as follows: patients are required to be at least 18 years old, have a PHQ-9 score of 10 or greater, and return for at least one follow-up visit. The medical records of these patients were reviewed by a resident physician to determine the specific intervention from the DCP (i.e. medication change, in-clinic counseling, both, or neither), as well as co-morbid conditions (e.g. diabetes, heart disease, lung disease, or chronic pain syndromes). Descriptive statistics were compiled. Bivariate and regression analyses were performed with significant improvement of the PHQ-9 score, defined as a total score reduction of 5 points or greater, as the primary outcome.
RESULTS: Of the 95 patients enrolled, 38 % are AA, 67 % are women, 80 % had health insurance, and the mean age was 56 years. Sixty-nine percent of patients had long-standing depression and were already on antidepressant medication. Fifty-three percent of patients including those with prolonged depressive illness showed a significant improvement in depression symptoms as measured by an improvement in follow-up PHQ-9 score of five points or greater. Fourteen percent had a medication adjusted only, 9 % had counseling only, 37 % had both medication adjustment and counseling, and 38 % were monitored only without intervention. There was no difference between the intervention groups in PHQ-9 improvement. In bivariate analysis, patients with health insurance did significantly better than those without insurance, 53 % vs. 26 % (p=0.04) and patients with chronic pain trended worse 39 % vs. 59 % (p=0.57). In regression analysis using treatment modality, demographic data, and comorbidities, chronic pain syndrome was the only significant comorbid predictor consistent with significantly less improvement, OR 0.35 (95 % CI 0.14, 0.93). Insurance status trended toward improvement but was no longer statistically significant, OR 3.2 (95 % CI 0.88, 12).
CONCLUSIONS: A standardized depression care program was successful in treating depression in patients with multiple comorbidities in an academic primary care clinic including those who had received standard depression treatment in the past. Lack of health insurance status and the presence of comorbid chronic pain syndromes were associated with treatment-refractory depression. Future directions include creation of a parallel anxiety diagnosis and a treatment algorithm to address confounding components such as prior trauma in those with pain.

SUPPORT FOR HOSPITAL TO HOME FOR ELDERS: A RANDOMIZED CONTROL TRIAL OF AN IN-PATIENT DISCHARGE INTERVENTION AMONG A DIVERSE ELDERLY POPULATION L. E. Goldman[1]; Urmimala Sarkar[1]; Eric R. Kessell[1]; Jeffrey Critchfield[1]; Michelle Schneidermann[1]; Edgar Pierluissi[1]; Barbara Walter[2]; Margot Kushel[1]. [1]University of California, San Francisco, San Francisco, CA; [2]San Francisco General Hospital, San Francisco, CA. (Tracking ID #1642073)

BACKGROUND: Nearly 20 % of hospitalized older adults are readmitted to the hospital within 30 days, costing Medicare more than $17 billion annually. Hospital-based transitional care programs with post-discharge follow-up have reduced readmissions and emergency department (ED) visits among selected populations. It is unclear how a hospital-based nurse-led transitional care intervention affects 30 day acute care use (emergency department (ED) visits and hospitalizations) among ethnically diverse adults age 55 and older hospitalized in a safety-net setting.

METHODS: We conducted a randomized control trial of a hospital-based transitional care intervention versus usual care among English, Spanish, and Chinese (Mandarin and Cantonese)-speaking patients 55 and older admitted to an urban public hospital. Intervention-group participants received supplementary inpatient nurse coaching provided by study nurses regarding medications and follow-up plans, a tailored language-concordant, literacy-appropriate discharge care written plan with medications, follow-up planning, and anticipatory guidance, and received 2 follow-up telephone calls from a nurse practitioner at 1–2 and 7–10 days post-hospitalization. We compared rates of 30-day post-hospitalization ED visits and readmissions to the index hospital using hospital administrative data and 30-day mortality using hospital administrative data and follow-up 30-day telephone calls. Further work to expand the analysis to include results from other area hospitals and linkage to vital statistic data is underway.
RESULTS: We enrolled 700 individuals reflecting an ethnically diverse, low income population with limited educational attainment (mean age=66). Twenty-five percent were African American, 20 % Latino/Hispanic, 19 % White, 25 % Chinese, 6 % Filipino, and 5 % reported other race/ethnicities. Less than 11 % had a household income of greater than $20,000 per year, and 66 % had limited health literacy. At baseline, 85 % of the enrolled population reported a usual source of health care and, 80 % had used the ED and/or had been hospitalized in the past 6 months. Randomization was successful for characteristics including demographics, socioeconomic variables, activities of daily living, and pre-hospitalization health care usage between intervention and control group ($p>0.1$ for all). Of the 700 enrolled, outcomes at 30 days were available in administrative data for 670 (96 %), including 14 (2 %) who died. Thirty days after hospital discharge 45 patients (13.6 %) in the usual care group and 39 (11.9 %) in the intervention group were readmitted to the index hospital ($p=0.51$), and 28 (8.5 %) of the usual care group compared to 28 (8.6 %) of the intervention group visited the ED ($p=1.0$).
CONCLUSIONS: Among a diverse population of adults age 55 and older admitted to an urban public hospital, there was no difference in the 30-day rate of post-hospitalization ED visits and readmissions to the index hospital between an intervention group who received a hospital-based nurse-led transitional care intervention with telephone follow-up and tailored patient education materials and the usual care group. Nurse-led hospital-based discharge interventions for transitional care may not be effective among diverse populations age 55 and older with high pre-admission health care usage and usual source of care. Populations with complex medical and social needs may require transitional-care interventions that partner with outpatient providers and/or include home-based visits.

SURVEY FINDINGS ON MEDICAL HOME IMPLEMENTATION AND TEAM FUNCTIONING IN VHA PRIMARY CARE Emily D. Dolan[2]; Christian Helfrich[1]; Karin M. Nelson[1]; Gordon Schectman[3]; Richard Stark[3]; Stephan D. Fihn[2]. [1]Department for Veterans Affairs, Seattle, WA; [2]Department for Veterans Affairs, Seattle, WA; [3]Department for Veterans Affairs, Washington, DC. (Tracking ID #1633503)

BACKGROUND: In April 2010, the Veteran's Health Administration (VHA) launched the Patient Aligned Cart Team (PACT) initiative to implement a medical home model. It emphasized team-based care to improve continuity; changes to scheduling and alternatives to face-to-face visits to improve access; and use of nurse care managers and additional health promotion support to improve care management and coordination. Reconstituted primary care teams were to include 4 team members: a primary care provider (PCP), nurse care manager, clinical associate (e.g., LPN) and clerical assistants who meet regularly and share responsibility for a defined panel of patients. To support PACT implementation, clinics received funding for the expanded staffing model, and training, including intensive regional learning collaboratives.
METHODS: We developed and fielded a survey in spring 2012 (approximately 2 years into the initiative) to all primary care personnel except for PACT demonstration sites in 2 of the 21 VA networks. The survey included a range of questions on implementation of components of PACT, and a 21-item scale designed to measure team functioning within primary care. Finally respondents reported barriers and facilitators to PACT.
RESULTS: The survey yielded 5,404 respondents (approximately 30 % response rate). When asked if they were assigned to a care team, 90.5 % of PCPs, 94.0 % of nurse care managers, 87.4 % of clinical associates, and 74.1 % of clerical assistants reported being on a team. Respondents reported spending, on average, more than a half-hour each day in team "huddles" (meetings to plan for the work day). Team functioning scores did not differ significantly by team member. When asked how much time was spent each week on work that could be done by someone with less training, 50 % of PCPs, 48 % of nurse care managers, 58 % of clerical assistants, and 64 % of clinical associates reported spending more than 75 % of their time doing work that could be done by someone with less training. PCPs reported delegating tasks to team members, but at lower rates than team members reported being relied upon for those tasks. For example, 45 % of PCPs reported relying on team members to resolve messages from patients, versus 86 % of nurse care managers and 62 % of clinical associates reported being relied upon. When asked what factors were helpful to implementing PACT, the most reported activity was team huddles (41 %) and regular meetings (33 %). Other factors such as information systems, education sessions, and other quality improvement methods were cited less frequently (<21 %). When asked about barriers to implementation, clinical reminder volume (43 %), recruiting and retaining PCPs (42 %), and lack of control over one's schedule (39 %) were reported most frequently. Other factors such as difficulty accessing specialty care (34 %), inadequate time allotted for activities (32 %), and lack of support from leadership (31 %) were reported somewhat less frequently.
CONCLUSIONS: The process of transforming primary care at the VHA into PACT teams is ongoing, and 2 years into the initiative, survey respondents report broad progress on key aspects of PACT. At the same time, adjusting to new team roles so that each member is working to the top of their competency may require more time and support.

SYMPTOM DURATION AND SEVERITY FOLLOWING ACUTE COUGH VISITS IN PRIMARY CARE Patrick P. Dempsey; Lauren E. Whaley; Alexandra C. Businger; Jeffrey A. Linder. Brigham and Women's Hospital, Boston, MA. (Tracking ID #1641202)

BACKGROUND: Acute cough is a common problem in primary care. Patients and physicians are often frustrated by the lack of recommended treatments. Physicians frequently prescribe non-recommended treatments, like antibiotics, when symptoms fail to resolve promptly. We measured the duration and severity of cough and other symptoms following a primary care visit for acute cough.
METHODS: We prospectively screened 138 patients at a primary care practice between March 2011 and September 2012 and enrolled 117 English or Spanish-speaking patients with acute cough. Eligible patients were 18–64 years old, without chronic lung disease, who had not made a clinic visit in the prior month, and who had a cough of less than 21 days duration. Of the 117 recruited patients, 71 (61 %) returned a 21-day questionnaire and answered questions about cough severity. Respondents ranked the severity of symptoms, including cough, shortness of breath, sleep disruption, and feeling unwell on a scale from 0 ("Normal/not affected") to 6 ("As bad as it could be"). We considered the day of the visit "day 1" and considered symptoms resolved when respondents reported no symptom for 2 consecutive days. We used the log rank test to compare cough resolution between respondents who did and did not receive antibiotics.
RESULTS: Respondents had a mean age of 46 years old; 78 % were women, 43 % white, and 24 % black; 69 % had completed at least some undergraduate college; 72 % had private insurance and 26 % had Medicare. The proportion of respondents still coughing on days 7, 14, and 21 was 90 %, 63 %, and 46 %, respectively. The mean duration of cough was 15.0 (95 % confidence interval, 13.6 to 16.3) days. On days 1, 7, 14, and 21, the mean severity of cough was 4.1 ("Bad"), 2.3 ("Slight problem"), 1.6, and 1.1 ("Very little problem"), respectively. On days 1, 7, 14, and 21, the proportion of patients with shortness of breath was 69 %, 49 %, 30 %, and 18 % and the mean severity was 1.8, 1.3, 0.6, and 0.4, respectively; the

proportion of patients with sleep disruption was 90 %, 68 %, 54 %, and 39 % and the mean severity was 3.3, 1.8, 1.4, and 0.9, respectively; and the proportion of patients feeling unwell was 97 %, 77 %, 58 %, and 38 % and the mean severity was 3.8, 1.9, 1.4, and 0.8, respectively. For the 34 (48 %) patients who took any time off work or school the median return was on day 3. A total of 19 (26 %) patients received antibiotics. The average duration of cough was 14.1 days for those who received antibiotics and 15.0 days for those who did not (p=0.71). Within 21 days of the visit, 9 (13 %) patients had at least one cough-related follow up visit to the study practice.
CONCLUSIONS: Roughly half of patients with acute cough were still coughing 21 days after a primary care visit, though the severity was mild. Similarly, on day 21 many patients continued to have mild shortness of breath, mild sleep disruption, and felt a little unwell. Patients who seek primary care for acute cough will miss about 3 days of work or school. Physicians and patients should understand symptom resolution can be prolonged.

SYSTEMATIC REVIEW OF NON-PHARMACOLOGIC INTERVENTIONS TO IMPROVE THE SLEEP OF HOSPITALIZED PATIENTS Ruth Tamrat; Madhav Goyal; Minh-Phuong Huynh-Le. Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #1641906)

BACKGROUND: Adequate levels of sleep are needed in both health and illness. Sleep deprivation is known to have multiple harmful physiological effects, including a decline in immune function and wound healing, along with increased pain perception and mortality. Despite these adverse effects on recovery from illness, a number of studies have shown that sleep deprivation remains an incompletely addressed problem among acutely ill patients admitted to hospitals. While medications can help with inpatient sleep, they may not address the underlying reasons for sleep disturbance in the inpatient setting, and are often accompanied by side effects. We sought to perform a systematic review of the literature to identify non-pharmacologic interventions that have been used to improve the sleep of non-ICU inpatients and their effects on sleep quantity and quality.
METHODS: We searched PubMed, Embase, Web of Science, CINAHL, and Cochrane Library in July 2011. We also performed hand searches from the reference lists. We included any study in which a non-pharmacologic intervention was conducted in a general inpatient setting, and measured nighttime sleep quantity or quality as an outcome. Two reviewers independently performed a title/abstract review followed by a full paper review. We assessed the risk of bias for the various study designs by using an adapted version of the Cochrane's EPOC guide. We assessed the strength of evidence following AHRQ guidelines in the four domains of risk of bias, consistency, directness, and precision. To assess the direction and magnitude of reported effects of the interventions, we calculated the relative difference between groups in how each outcome measure changed from baseline. Given the heterogeneity of trial designs, outcomes, and paucity of studies, we did not conduct meta-analysis. We relied on 50 % or more trials within a category showing a significant result as a precise result for that outcome category.
RESULTS: After a review of 17,322 citations, we included 15 intervention studies with 1,259 participants. These included four RCTs, six nonrandomized controlled trials, and five pre-post studies. The interventions used included relaxation techniques applied prior to sleep, including massage, music, audiotape guided imagery, and a warm drink; sleep hygiene or reduced sleep interruption programs; and daytime bright light therapy. Relaxation techniques improved sleep quality or quantity by −7 % to 29 %, sleep hygiene or reduced sleep interruption programs improved sleep quality or quantity by +1 to+22 %, and daytime bright light therapy improved sleep quantity by +7 to+18 %. The strength of evidence that these interventions improve sleep quality or quantity of inpatients was determined to be as follows: low for relaxation techniques, insufficient for sleep hygiene or reduced sleep interruption programs, and low for daytime bright light therapy.
CONCLUSIONS: Our systematic review found a dearth of trials in this area. There is low strength of evidence that relaxation techniques improve sleep quality of non-critically ill hospitalized patients, and also low strength of evidence that bright light therapy may improve sleep quality. Given the unmet need of adequate sleep in hospitalized patients, future trials should assess non-pharmacologic interventions to improve sleep with randomization and blinded sleep outcome measures. They should also obtain health outcome measures to assess the health effects of improved sleep.

SYSTEMATIC REVIEW OF SURVEYS TO MEASURE INFORMAL CAREGIVER SATISFACTION WITH HOSPICE Anne M. Walling[1,2]; Sangeeta Ahluwalia[2]; Rebecca Anhang-Price[3]; Oluwatobi Oluwatola[2]; Denise Quigley[2]; Karl Lorenz[2]; Roberta Shanman[2]; Joan Teno4. [1]University of California, Los Angeles, Los Angeles, CA; [2]RAND Health, Santa Monica, CA; [3]RAND Health, Washington, DC; [4]Brown University, Providence, RI. (Tracking ID #1642853)

BACKGROUND: Movement towards uniform assessment and public reporting of quality will soon encompass hospice, and there are distinct issues in assessing the experience of hospice, an important one of which is the use of caregivers as the source of information about the experience. To inform the development of a new experience of care survey, we undertook a systematic review of the literature on patients' and caregivers' satisfaction and experience with hospice.
METHODS: We searched PubMed and PsycInfo using specific search criteria for all English-language articles published after 1990 that used survey questions or instruments to measure adult patients' and/or caregiver experiences with hospice and/or palliative care. We also searched PsycTESTS, a database indexing surveys in the fields such as psychology, education, medicine, and social work, and the grey literature (i.e., New York Academy of Medicine Grey Literature Report, Google, and the National Quality Measures Clearinghouse). Additional resources were identified through reference mining and input from experts. We conducted dual review of citations with a consensus procedure to resolve disagreements.
RESULTS: Our search identified 2,094 titles, reduced to 84 articles after title, abstract screening and detailed review. Experts and grey literature contributed an additional 4 articles, 9 surveys and 2 toolkits [Hospice AIM Toolkit (PEACE) and TIME: Toolkit of Instruments to Measure End of Life Care]. The most commonly used surveys include Family Satisfaction with Advanced Cancer Care (FAMCARE) (n=8), Family Evaluation of Hospice Care (FEHC) (n=8), Family Assessment of Treatment at End of Life (FATE) (n=5), After-death bereaved family member interview (n=5), Quality of Dying and Death (QODD) (n=5), and Views of Informal Carers-Evaluation of Services (VOICES) (n=4). The FEHC and the Bereaved Family Survey (derived from FATE) are in national operational use for quality assessment and improvement. Symptom and communication domains were covered by almost all surveys studied, whereas financial and bereavement domains were less commonly represented.
CONCLUSIONS: A number of validated and widely used surveys to measure informal caregiver satisfaction with hospice are available. These instruments vary in their focus for research vs. quality improvement and specific domains covered.

SYSTEMATIC REVIEW: HEALTH-RELATED CHARACTERISTICS OF ELDERLY HOSPITALIZED PATIENTS AND NURSING HOME RESIDENTS ASSOCIATED WITH SHORT-TERM MORTALITY John M. Thomas[1,2]; Leo M. Cooney[3]; Terri Fried[3,4]. [1]VA Connecticut Healthcare System, West Haven, CT; [2]Yale University School of Medicine, New Haven, CT; [3]Yale University School of Medicine, New Haven, CT; [4]VA Connecticut Healthcare System, West Haven, CT. (Tracking ID #1637184)

BACKGROUND: Attempts to aid patients in health care decisions in late life by quantifying life expectancy or mortality risk have met with limited practical success. Prognostic indices, in most cases, have modest overall accuracy, lack validation in diverse populations, and contain factors that may not be readily measured in every clinical setting. Nonetheless, studies have examined numerous risk factors for mortality in older persons, and a systematic review offers the opportunity to organize these factors into broader domains. Our objective was to identify the domains of health-related characteristics of older hospitalized patients and nursing home residents most strongly associated with short-term mortality.
METHODS: We reviewed studies published in English in MEDLINE, Scopus, or Web of Science before August 1, 2010 to find prospective studies consisting of persons 65 years or older that evaluated the association between at least one health-related patient characteristic and mortality within 1 year in multivariable analysis. Once the studies were identified, all health-related characteristics associated with mortality in multivariable analysis were extracted from these studies and categorized into domains. We noted the frequency, across individual studies, with which particular domains were associated with mortality in multivariable analysis.
RESULTS: Thirty-three studies (28 studies involving hospitalized patients and 5 studies involving nursing home residents) reported a large number of characteristics associated with mortality, comprising seven domains: cognitive function, disease diagnosis, laboratory values, nutrition, physical function, pressure sores, and shortness of breath. Measures of physical function and nutrition were the domains most frequently associated with mortality up to 1 year for hospitalized patients and nursing home residents; measures of physical function, cognitive function, and nutrition were the domains most frequently associated with in-hospital mortality for hospitalized patients. Pressure sores and shortness of breath were examined in too few studies to compare with the other domains.
CONCLUSIONS: Among a large number of health-related characteristics of older persons shown to be associated with short-term mortality, measures of nutrition, physical function, and cognitive function were the domains of health most frequently associated with mortality. These domains provide easily measurable factors that may serve as helpful markers to identify patients at increased mortality risk.

TEACHING OSTEOARTHRITIS EVALUATION AND MANAGEMENT IN AN INTERNAL MEDICINE RESIDENCY PROGRAM Ashley Morris; Donald Fox; Amy Thompson; Patty J. Iverson; William P. Moran; Cathryn Caton. Medical University of South Carolina, Charleston, SC. (Tracking ID #1643084)

BACKGROUND: Osteoarthritis affects 50–80 % of people 65 years and older. Osteoarthritis is the most prevalent form of arthritis in the United States and is responsible for half of all disabilities. In older adults it is associated with pain, functional disability and being homebound.
METHODS: A retrospective chart review of history and physical forms was performed to determine the pre-intervention rate of completion of the functional assessment. We utilized a 4 month multilevel, multi-strategy approach to educate 100 residents and prompt them to complete a functional assessment, history, evaluation and management of an elderly patient with osteoarthritis. We combined osteoarthritis lecture and individual resident academic detailing to enhance resident knowledge of functional assessments and osteoarthritis management. Nurses and patient care technicians were utilized to prompt and remind residents to perform functional assessments and manage patients with pain related to osteoarthritis. Improvement in medical knowledge was assessed using a pre and post intervention questionnaire. Skill (i.e. functional assessment) was assessed by calculating the number of completed cue sheets and history and physical forms on the inpatient services.
RESULTS: Fifty-eight percent of attendings participated in resident detailing efforts. Given variable schedules and practice location, only 14 % of residents attended the didactic. Over the 4 month intervention period, 72 % of residents were detailed. Of 750 patients 65 years and older seen in the clinic during this period, 57 % had functional assessments completed. Of the patients admitted to general medicine inpatient services 47 % had functional assessments completed in comparison to 35 % pre-intervention. Response rates for both pre and post tests were> 75 %. Improvement in knowledge was demonstrated on the pre-post test scores (p=0.019).
3**CONCLUSIONS:** Using educational strategies, as well as system changes we improved resident knowledge and skill in functional assessment and management of osteoarthritis in patients 65 years and older.

TEACHING DISCHARGE PLANNING TO SUB-INTERNS: A TRIAL STUDYING THE EFFECT OF MULTI-DISCIPLINARY ROUNDS Ankur Segon; Julie L. Mitchell; Michael Frank; Martin Muntz; Jaren G. Thomas; Kerrie Quirk. Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #1641171)

BACKGROUND: Objectives 1. Determine sub-intern's knowledge and attitudes towards members of the multidisciplinary team 2. Identify areas of deficit in sub-intern's knowledge of the discharge process 3. Evaluate the impact of attendance at daily multidisciplinary rounds on sub-intern's knowledge and attitude towards members of the multidisciplinary team and the discharge process
METHODS: Sub-interns at our institution rotate at 4 different sites. All sub-interns have similar level of prior inpatient medicine experience. Only 1 of 4 sites conducts daily multidisciplinary rounds where senior residents from each medicine team present the team's patients. Over 1 year, we surveyed a total of 105 medicine sub-interns across all 4 sites (response rate 67 %). Students were surveyed both at the beginning and end of their rotation. We compared student responses between sites with and without multidisciplinary rounds to determine impact of these rounds on student's knowledge and attitude.
RESULTS: All responses were scored on a 1–5 Likert-like scale, with 5 being the highest score. Over the course of the sub-internship, there was a statistically significant improvement in student's familiarity with the role of members of the multidisciplinary team and student's appreciation of the importance of various members of the multidisciplinary team in providing comprehensive care to their patients (table). Students also got more comfortable in interacting with members of multidisciplinary team (3.6 to 4.3, p<0.001). There was a marked improvement in student's self-reported ability to manage the discharge process, both in terms of determining discharge disposition (2.8 to 4.3, p<0.001) and execution of the discharge plan (2.6 to 4.1, p<0.001). There was no difference in knowledge and attitude towards members of the multidisciplinary team or comfort with the discharge process between students who attended multidisciplinary rounds and students who did not. Students who attended multidisciplinary rounds reported a decline in perceived clinical and educational utility of these rounds by the end of the sub-internship (table).
CONCLUSIONS: Without any formal or specific curricular intervention, student's knowledge, attitude and comfort level with roles of various members of the healthcare team and the discharge process show a reassuring growth throughout the medicine sub-internship. Attendance at multi-disciplinary rounds does not improve student's experience with members of the multidisciplinary team or the discharge process.

Question 1*			
How familiar are you with the role of each of the following members of the healthcare team?			
	Pre-rotation score	Post rotation score	p-value
Case manager	2.7	3.3	<0.001
Social worker	3.4	3.8	<0.001
Physical therapist	3.7	4.1	<0.001
Respiratory therapist	3.6	4.2	<0.001
Dietitian	3.9	4.1	<0.001
Speech therapist	3.2	4.0	<0.001
Question 2*			
How important is the role of each of the following members of the healthcare team to the overall care of the hospitalized patient?			
	Pre-rotation score	Post rotation score	p-value
Case manager	4.4	3.6	<0.001
Social worker	4.5	4.5	NA
Physical therapist	4.3	4.8	<0.001
Respiratory therapist	4.5	4.6	0.05
Dietitian	4.1	4.5	0.003
Speech therapist	4.0	4.1	0.41
Question 3*			
How important is it to start to the process of discharge planning at the time of admission?			
Pre-rotation score	Post-rotation score	p-value	
4.0	4.3	<0.001	
Question 4*			
What is the utility of multidisciplinary rounds as a learning tool during your sub-internship?			
Pre-rotation score	Post-rotation score	p-value	
3.6	2.8	0.033	
Question 5*			
How useful are multidisciplinary rounds to your overall ability to provide efficient care to your hospitalized patients?			
Pre-rotation score	Post-rotation score	p-value	
3.6	2.8	0.14	

*All questions scored on a 1-5 scale, with 1 being the lowest possible score and 5 being the highest

TEAMWORK ASSESSMENT IN INTERNAL MEDICINE: A SYSTEMATIC REVIEW OF VALIDITY EVIDENCE AND OUTCOMES

Rachel Havyer; Majken T. Wingo; Nneka Comfere; Darlene R. Nelson; Andrew J. Halvorsen; Furman S. McDonald; Darcy Reed. Mayo Clinic, Rochester, MN. (Tracking ID #1642498)

BACKGROUND: Effective teamwork among health professionals improves patient safety and is an essential competency for physicians across the education continuum. Valid teamwork assessment is imperative to determine physician competency and to optimize preparedness to function in teams. Numerous organizations have made teamwork a top priority in their recommendations for improving healthcare, yet there is little consensus on how to measure it. Therefore, we conducted a systematic review of published instruments used to measure teamwork in undergraduate, graduate, and continuing medical education in general internal medicine and all medical subspecialties. We synthesized the validity evidence and outcomes for each unique teamwork assessment tool with the goal of providing a resource for educators, clinicians and other health professionals to identify appropriate assessments to apply to their settings and teams.

METHODS: We searched MEDLINE, MEDLINE In-process, CINAHL and PsycINFO from January 1979 through June 2012, as well as references of included articles and abstracts from 5 professional meetings. Two content experts were queried for additional studies. Included studies described quantitative tools designed for measuring teamwork among medical students, residents, fellows, and practicing physicians on single or multi-professional teams in general internal medicine and all medical subspecialties. Instrument validity and study quality data were abstracted using established frameworks with existing validity evidence. For each tool identified, the literature was again searched for additional validity evidence. Two authors independently abstracted one-third of articles and agreement was calculated.

RESULTS: Of 12,256 citations, 140 articles describing 64 unique teamwork assessment tools met inclusion criteria. Interrater agreement for data abstraction was ICC 0.73 (95 % CI 0.63–0.81). Most (57, 89 %) teamwork assessments involved practicing physicians, 31 (48 %) involved residents/fellows, and 5 (8 %) involved medical students. The majority (58, 91 %) assessed interprofessional teams. Teamwork tools were applied in inpatient (34, 53 %), outpatient (21, 33 %), and classroom settings (8, 13 %). Fifteen teamwork tools used simulation. General internal medicine was the medical specialty with the greatest number of published tools (29, 45 %), followed by critical care medicine (23, 36 %). Of the 64 tools, 17 (27 %) assessed individuals working within teams, 45 (70 %) assessed teams as a whole, and 7 (11 %) assessed both individuals and teams. Validity evidence for teamwork tools included content (50, 78 %), internal structure (47, 73 %), relationships to other variables (25, 39 %), and response process (12, 19 %). Attitudes and opinions were the most frequently assessed outcomes. Relationships between teamwork scores and

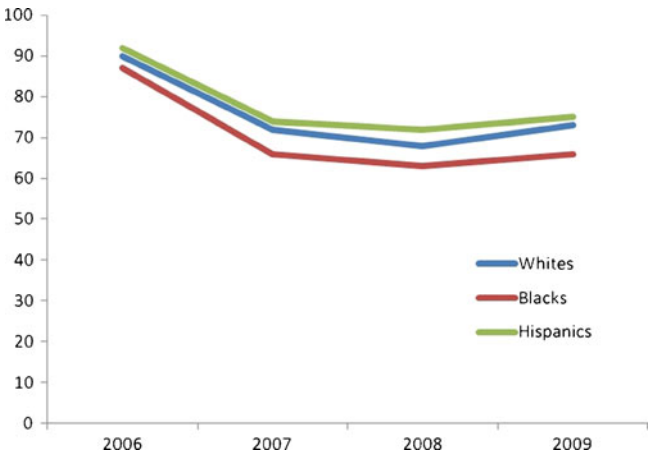
patient outcomes were examined for 12 (19 %) tools. Scores from the Safety Attitudes Questionnaire and Team Climate Inventory have substantial validity evidence and have been associated with improved patient outcomes.
CONCLUSIONS: Numerous tools exist to assess teamwork of physicians and trainees functioning in interprofessional teams across a variety of settings and specialties within internal medicine. There is strong validity evidence for several tools, although few teamwork assessments have been directly linked to patient outcomes. This review may help educators, clinicians, and other health professionals identify appropriate teamwork assessment tools to apply to their own teams.

TECHNOLOGY-ASSISTED WEIGHT LOSS INTERVENTIONS IN PRIMARY CARE: A SYSTEMATIC REVIEW David M. Levine; Joseph Nicholson; Melanie Jay. New York University Medical Center, New York, NY. (Tracking ID #1642413)

BACKGROUND: The obesity epidemic shapes numerous interactions in primary care today, accounting for unprecedented rates of chronic disease. However, there are few available weight loss interventions suitable to primary care (PC). Many are mired by high attrition rates, weight regain, and resource-intensive requirements. Moreover, numerous barriers exist to proper implementation, including deficient training, poor scalability, insufficient time, inadequate reimbursement, and alternate prevention responsibilities. Technology-assisted weight loss interventions may address these barriers through time and cost savings, improved feedback, enhanced self-monitoring, and convenience of use. To date, these programs have employed initial computerized assessment for forthcoming tailoring, web-based and mobile device self-monitoring and counseling, and automated feedback. Many have yet to be pragmatically integrated into PC, where they ultimately need to be deployed. This systematic review examines technology-assisted weight loss interventions specifically provided in a PC setting and highlights pragmatic aspects of the trials. To our knowledge, this is the first such systematic review.
METHODS: We performed a literature search of online databases (MEDLINE, PubMed, Cochrane, Google Scholar) and reference lists of identified studies and reviews between 2000 and 2012. Inclusion criteria included: (1) RCT published in peer-reviewed English-language journal; (2) utilization of the Internet, personal or in-office computer, and/or mobile device; (3) weight-loss as a primary outcome; and (4) intervention facilitated in an ambulatory PC setting. From each study we extracted baseline demographics, recruitment procedures, setting, intensity, mode of customization, motivating theory, tech modality, personnel, and weight loss (kg, percent, and percent achieving greater than 5 % loss). The Delphi and the Cochrane Effective Practice and Organization of Care (EPOC) criteria were used to assess bias. Degree of pragmatism (whether an intervention occurred under realistic versus ideal circumstances) was determined with the Pragmatic Explanatory Continuum Indicator Summary (PRECIS) (0-explanatory, 4-pragmatic).
RESULTS: 14 trials met inclusion criteria. Patients were more often female (61 %), White (67 %), and middle-aged. 13/14 (93 %) trials were of high intensity and employed tailored interventions. 7/14 (50 %) trials employed the Internet and 5/14 (36 %) utilized clinician-guiding software. 10/14 (71 %) involved self-monitoring, 11/14 (79 %) incorporated automated feedback, while 12/14 (86 %) included care-provider feedback. MDs were the most frequently (43 %) utilized personnel, while no personnel were required in 21 % of interventions. Mean attrition ranged from 6 to 80 %. Weight loss in the active treatment arm ranged from 0.08 kg–5.1 kg (0.8 %–5.2 % of initial body weight). Patients losing at least 5 % of baseline weight ranged from 5 %–41.4 %. 13/14 (93 %) and 14/14 studies met more than 4 Delphi and EPOC criteria, respectively. The mean PRECIS score was 2.8/4 (SD 0.42). Given the disparate features of the studies, results were summarized but not pooled quantitatively.
CONCLUSIONS: Compared to usual care, some technology-assisted weight loss interventions in PC demonstrate clinically significant weight loss. However, too few studies of adequate methodology are available to definitively determine impact. Further research particularly employing pragmatic methods is needed to best determine management for obesity in PC.

TEMPORAL TRENDS OF HEALTH DISPARITIES IN DRUG ELUTING STENTS Leonardo Tamariz; Ana M. Palacio; Alexis P. Rodriguez; Hua Li; Mauricio G. Cohen. University of Miami, Miami, FL. (Tracking ID #1639873)

BACKGROUND: Drug Eluting Stents (DES) decrease in stent re-stenosis by approximately 80 % when compared to Bare Metal Stents (BMS). Racial disparities have been reported in the use of cardiovascular procedures. We explore the impact of the 2007 antiplatelet therapy guidelines on racial disparities in the use of DES in the State of Florida.
METHODS: We conducted a cross-sectional analysis of all ambulatory and hospital discharge stent placement procedures between 2006 and 2010. We identified 188,260 percutaneous coronary interventions in which patients received either DES or BMS stents using ICD-9 procedure codes along with the race/ethnicity of each individual. We calculated the yearly usage of stents by race and ethnicity. We used logistic regression to determine the odds ratio (OR) of having a DES by race and ethnicity adjusted for Charlson score, insurance status and year of the procedure. We also conducted a subgroup analysis of diabetics to determine if health disparities existed in this group. To evaluate for temporal trends we used the Cochrane-Armitage trend test.
RESULTS: The majority of stent recipients were White (n=158,039) followed by Hispanics (n=16,087) and Blacks (n=14,037). Blacks had the highest comorbidity scores compared to Whites and Hispanics (p<0.01). The use of DES decreased from 2006 to 2009, and this decrease was seen in all ethnicities. The adjusted OR of having a DES for Blacks was 0.84; 95 % CI 0.81–0.88 (p<0.01) and for Hispanics was 1.24; 95 % CI 1.19–1.29 (p<0.01) when compared to Whites. We identified 62,798 subjects with diabetes and in them the adjusted OR of having a DES for diabetic Blacks was 0.93; 95 % CI 0.88–0.99 (p=0.02) and for Hispanics was 1.34; 95 % CI 1.25–1.43 (p<0.01) when compared to Whites. Figure 1 shows that difference in use of DES increased over time (p<0.01).
CONCLUSIONS: In the state of Florida, during the years of 2006 and 2009, the disparity gap in the use of DES between blacks and Whites increased after the implementation of the new antiplatelet therapy guidelines even among diabetic patients. Hispanics had a higher rate of DES use when compared to non-Hispanic whites. Understanding the reasons for these conflicting disparities may shed light on possible mechanisms to prevent them particularly when instituting practice guidelines that may use subjective measures in the decision making process.
Use of stents by ethnicity

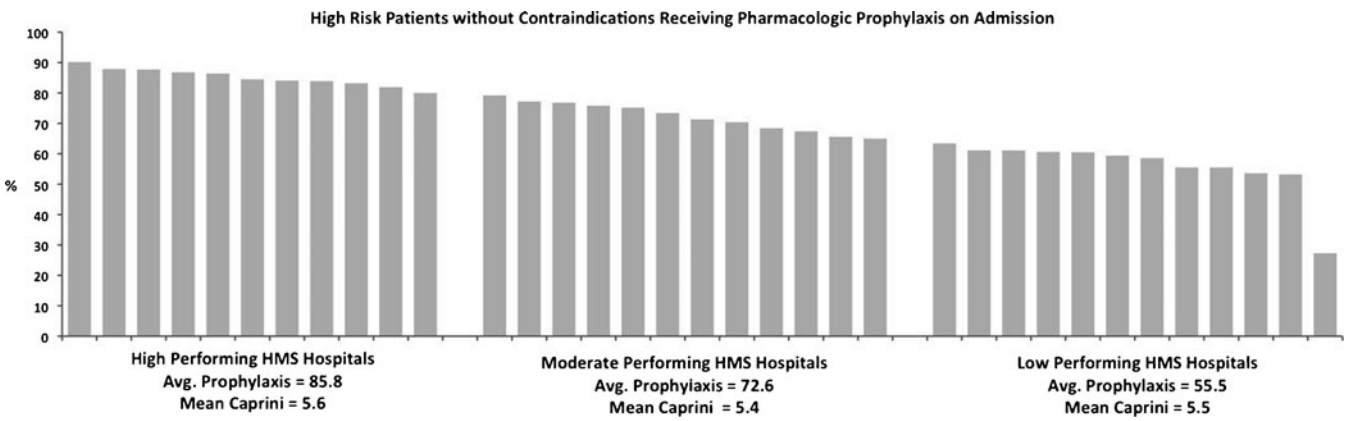


THE ASSOCIATION BETWEEN CARE COORDINATION AND HEALTH OUTCOMES IN EPISODES OF CARE Craig Pollack[1]; Eric Schneider[2]; Julie Lai[2]; Robert Rudin[2]; Steven Fox[2]; Peter S. Hussey[2]. [1]Johns Hopkins School of Mediine, Baltimore, MD; [2]RAND Corporation, Arlington, VA. (Tracking ID #1630687)

BACKGROUND: Better coordinated care is hoped to improve patient outcomes and reduce health spending, but the health and cost consequences associated with the current levels of care coordination have not been quantified. Our goal was to measure the extent to which care coordination was linked with health outcomes and costs of care for Medicare beneficiaries with chronic disease.
METHODS: Using 5 % sample Medicare data from 2008 and 2009, we conducted a retrospective cohort study comparing the health outcomes and costs of care for Medicare beneficiaries experiencing variable continuity of care during a 12 month episode of care for congestive heart failure (CHF, n=53,488), chronic obstructive pulmonary disease (COPD, n=76,520) or diabetes (DM, n=166,654). The Bice-Boxerman Continuity of Care (COC) Index was used to assess care coordination with values ranging from 0 to 1.0. We used multivariable logistic regression models to examine the association between COC and hospitalizations, emergency room visits, and specific types of complications. Two-part models (logistic regression models followed by generalized linear regression models with gamma variance distribution and log link function) were used to test whether COC was associated with costs of care. Sensitivity analyses explored alternative claims-based measures of coordination.
RESULTS: After multivariable adjustment, higher levels of coordination were associated with lower odds of inpatient hospitalization (Odds Ratio [OR] for 0.1 increase in COC Index=0.94 for CHF, 0.95 for COPD, and 0.95 for DM, all p<0.0001), emergency department visits (OR=0.92 for CHF, 0.93 for COPD, and 0.94 for DM, all p<0.0001), and odds of specific types of complications. For every 0.1 increase in the COC index, total episode costs of care were 4.7 % lower for CHF (95 % CI 4.4 % to 5.0 %), 6.3 % lower for COPD (95 % CI 6.0 % to 6.5 %), and 5.1 % lower for DM (95%CI 5.0 % to 5.2 %) in adjusted analyses. Extrapolating the results to all Medicare beneficiaries, the total reduction in Medicare spending associated with improving coordination from its current level to the population median would be approximately $1.5 billion for the three conditions.
CONCLUSIONS: Modest differences in care coordination for Medicare beneficiaries may be associated with sizable cost reductions.

THE ASSOCIATION BETWEEN HOSPITAL PERFORMANCE FOR PHARMACOLOGIC VENOUS THROMBOEMBOLISM PROPHYLAXIS AND RATES OF VENOUS THROMBOEMBOLISM
Scott Flanders[1]; M. Todd Greene[1]; Paul Grant[1]; Scott Kaatz[2]; David Paje[3]; Bobby Lee[4]; James Barron[5]; Steven J. Bernstein[1,6]. [1]University of Michgian, Ann Arbor, MI; [2]Hurley Medical Center, Flint, MI; [3]Henry Ford Health System, Detroit, MI; [4]Oakwood Healthcare System, Dearborn, MI; [5]Spectrum Health, Grand Rapids, MI; 6VA Ann Arbor Healthcare System, Ann Arbor, MI. (Tracking ID #1637138)

BACKGROUND: Hospital-associated venous thromboembolism (VTE) affects up to 15 % of hospitalized medical patients and is felt to be one of the most common preventable causes of death in the hospital. Pharmacologic prophylaxis has been shown to reduce rates of hospital-associated VTE, yet is underutilized in U.S. hospitals. Although improving VTE prophylaxis rates in hospitals has been the focus of recent quality improvement efforts, the effect of improving prophylaxis rates on VTE outcomes in hospitalized patients admitted to the general medical ward has not previously been described.
METHODS: The Michigan Hospital Medicine Safety Consortium is a quality collaborative of 35 hospitals with a goal of preventing adverse events in hospitalized medical patients. Using web-based data entry, an abstractor at each hospital collects detailed demographic and clinical data, including all known risk factors for VTE and use of pharmacologic prophylaxis for 800 patients per year. For this analysis, patients<18 years of age, obstetric or surgical patients, patients with contraindications to prophylaxis, and patients admitted directly to the ICU were excluded. VTE outcomes during hospitalization and at 90 days after discharge were determined by medical record review and follow-up phone calls. High risk was defined as a Caprini score≥2. Performance categories based on pharmacologic prophylaxis rates were defined as follows: high≥80 %; moderate<80 %–≥65 %; low <65 %.
RESULTS: Among 20,796 high-risk patients, the mean age was 66 years, mean Caprini score was 5.6 and mean length of stay was 4.4 days. Hospital rates of pharmacologic prophylaxis varied between 27 % and 90 % with an overall average of 70 %. A total of 11 hospitals were classified as high performers on prophylaxis. There were 12 hospitals in each of the moderate and low performance categories. Average rates of prophylaxis differed significantly by performance level (figure). The rate of VTE at 90 days in the high, moderate, and low performing hospitals was 1.09 %, 1.30 %, and 0.99 % respectively, and did not differ significantly. Relative to high performing hospitals, moderate and low performing hospitals did not have significantly higher rates of risk-adjusted VTE. Caprini score was associated with in-hospital (OR=1.21, 95%CI 1.09–1.35) and 90-day (OR=1.13, 95 % CI 1.08–1.18) rates of VTE.
CONCLUSIONS: Hospital level of performance for pharmacologic VTE prophylaxis does not appear to be associated with in-hospital or 90 day rates of VTE. The impact of increasing rates of pharmacologic prophylaxis to prevent hospital associated VTE in general medical patients imay be minimal.
Hospital Rate of Pharmacologic Prophylaxis on Admission for High Risk Patients with No Contraindications



THE ASSOCIATION BETWEEN MEDICAL STUDENT CAREER INTERESTS AND ATTITUDES TOWARD PRIMARY CARE, FACULTY MENTORSHIP, AND INSTITUTIONAL SUPPORT
Charlotte E. Ward; Susan Edgman-Levitan; Marya J. Cohen; Rebecca Berman. Massachusetts General Hospital, Boston, MA. (Tracking ID #1640366)

BACKGROUND: It is becoming increasingly difficult for patients to find primary care physicians (PCPs) in the United States. By expanding Medicaid and providing federal subsidies to help lower-income individuals purchase private insurance, the Affordable Care Act will extend insurance coverage to 30 million new patients, many

of whom will likely need a PCP. It is important therefore, to attract a greater number of medical students to the field of primary care and to better understand factors that contribute to student career interests. The Crimson Care Collaborative (CCC), a series of 5 student-faculty collaborative practices, aims to give students hands-on practical experience in primary care practices across the Harvard Medical School network, with the hope that these students will be more inclined to pursue a career in primary care after they graduate. We surveyed medical students prior to participating in CCC. Our goal was to examine the relationship between student career interest and faculty mentorship, institutional support and attitudes toward primary care.

METHODS: All Harvard Medical School (HMS) students who joined the Crimson Care Collaborative as student-volunteers were administered a survey prior to volunteering which asked questions about their career interests, attitudes toward and knowledge about primary care, and presence of faculty mentoring. Survey responses were compared with Chi-square tests.

RESULTS: The study population included 129 HMS students who filled out a survey prior to participating in CCC. Among students who reported having a faculty mentor at HMS within the field of general medicine, reported interest was higher in general medicine than specialty medicine (60 %, vs. 8 %, $p<0.0001$). Students interested in general medicine were more likely to report having met a HMS faculty member whose general medicine career is one they would like to emulate (59 % vs. 15 %, $p<0.001$) and to report having disagreed with negative comments that they heard about primary care from either faculty, residents, or their peers (86 % vs. 45 %, $p<0.001$) compared to students interested in specialty medicine. Students interested in general medicine were less likely to report that there was institutional support for future primary care careers than students not interested in general medicine (38 % vs. 69 %, $p=0.002$). There were no significant differences in student-reported importance of income, ability to pay back loans, or amount of student debt between students interested in general medicine versus specialty medicine.

CONCLUSIONS: Harvard Medical School students interested in general medicine were more likely to report having faculty mentors and members that they emulate in the fields of general medicine, more likely to disagree with negative comments that they had heard in regard to primary care, but were less likely to report the presence of institutional support. The ability to pay back loans, student debt and importance of income were not associated with career interest, in contrast to previous studies. Our study finds that there are other factors that may be important, aside from student debt and income, that play a role in primary care career interest. Further research into what institutions as a whole can do to improve student perceptions regarding institutional support for general medicine and primary care is needed.

THE ASSOCIATION BETWEEN OUTPATIENT EXPERIENCE OF CARE AND SUBSEQUENT RESOURCE UTILIZATION IN A PRIMARY CARE NETWORK Charlotte E. Ward; Jeffrey M. Ashburner; Wei He; Steven J. Atlas. Massachusetts General Hospital, Boston, MA. (Tracking ID #1641674)

BACKGROUND: Assessing patient experience, using surveys such as the Consumer Assessment of Healthcare Providers and Systems (CAHPS), is increasingly part of performance measurement efforts. The relationship between patient reported access to care and subsequent resource utilization has not been extensively studied. Our goal was to examine the relationship between patient reported access to care, using the Clinician and Group (CG) CAHPS survey, and measures of resource utilization within a large, academic primary care network.

METHODS: Subjects included adult patients seen in any of 13 primary care practices affiliated with Massachusetts General Hospital who completed a CG-CAHPS survey after an outpatient visit between January, 2009 and December, 2010. CG-CAHPS individual item measures were assessed within the access domain (5 items) by taking the percentage of respondents reporting the most positive response ('Always') for the question item, commonly referred to as the 'Top Box' score. Resource utilization measures were assessed through December 2011 and included high cost imaging tests (computed tomography, magnetic resonance imaging, and nuclear cardiology), emergency department (ED) visits, and inpatient admissions or readmissions. We examined the association among CG-CAHPS items and subsequent resource utilization outcome measures using generalized linear models. We assessed adjusted outcomes controlling for age, gender, race, insurance status, language spoken and Charlson score.

RESULTS: The study population included 13,945 adult patients who completed a CG-CAHPS survey and had data available for at least one utilization measure. Among these patients, 1,375 (9.9 %) had a high cost imaging test, 1,312 (9.4 %) had a visit to the ED, 1,095 (7.9 %) had an inpatient admission, and 196 (1.4 %) had a readmission within 30 days. After adjusting for patient characteristics, three items within the access composite were significantly associated with resource utilization outcome measures. Patients who reported getting an urgent care appointment as soon as they needed it were less likely to have had a high cost imaging test completed (RR, 0.82; 95 % CI, 0.71–0.94; $P=.006$) and were less likely to have an ED visit (RR, 0.87; 95 % CI, 0.75–1.00; $P=.06$). Patients who reported getting a routine care appointment as soon as they needed it were less likely to have had a readmission (RR, 0.65; 95 % CI, 0.47–0.91; $P=0.01$). Patients who reported getting an answer to their medical question after regular office hours were less likely to have had a high cost imaging test completed (RR, 0.68; 95 % CI, 0.49–0.92; $P=0.01$).

CONCLUSIONS: Within a large, academic primary care network, higher patient-reported access to care after outpatient visits was associated with decreased subsequent high cost imaging tests, ED visits and hospital readmissions. Whether improved access to outpatient primary care services decreases overall health care utilization and costs requires further study.

THE ASSOCIATION BETWEEN PATIENT EXPERIENCE OF CARE AND SUBSEQUENT CANCER PREVENTION AND CHRONIC DISEASE OUTCOMES Charlotte E. Ward; Jeffrey M. Ashburner; Wei He; Steven J. Atlas. Massachusetts General Hospital, Boston, MA. (Tracking ID #1636341)

BACKGROUND: Assessing patient experience, using surveys such as the Consumer Assessment of Healthcare Providers and Systems (CAHPS), is increasingly part of performance measurement efforts. While evidence suggests CAHPS is positively associated with improved outcomes in the hospital setting, it is less clear whether this is also true in outpatient primary care settings. Our goal was to examine the relationship between patient experience of care, using the Clinician and Group (CG) CAHPS survey and measures of quality of care within a large, academic primary care network.

METHODS: Subjects included adult patients seen in any of 13 practices affiliated with Massachusetts General Hospital who completed a CG-CAHPS survey after an outpatient visit between August, 2008 and December, 2010 and were eligible for preventive cancer screening or chronic disease management (diabetes and coronary artery disease [CAD]). CG-CAHPS individual item measures were assessed within access (5 items) and communication (6 items) domains by taking the percentage of respondents reporting the most positive response ('Always') for the question item, commonly referred to as the 'Top Box' score. Quality of care measures assessed through December 2011 included outpatient Healthcare Effectiveness Data and Information Set (HEDIS) items for cancer screening completion (breast, cervical and colorectal), and screening and goal attainment measures for diabetes (LDL and HbA1c) and CAD (LDL). We examined the association among CG-CAHPS items and subsequent HEDIS outcome measures using generalized linear models. We assessed adjusted outcomes controlling for age, gender, race, insurance status, language and Charlson score.
RESULTS: The study population included 4,949 women aged 42–74 who were eligible for breast cancer screening, 4,012 women aged of 21–64 who were eligible for cervical cancer screening, 7,067 patients aged 52–75 who were eligible for colorectal cancer screening, and 2,385 diabetic and 1,576 CAD patients who completed a CG-CAHPS survey and had HEDIS outcome measures. A total of 99 models were assessed (9 CG-CAHPS items and 11 HEDIS measures). After adjusting for patient characteristics, only 3 patient experience measures were significantly associated with HEDIS outcome measures. Diabetic patients who reported getting an answer to their medical question during office hours were more likely to have a HbA1c<9 % (RR, 1.07; 95 % CI, 1.01–1.12; P=.02). Patients who reported that the physician knew important information about their medical history were more likely to receive a colonoscopy (RR, 1.05; 95 % CI, 1.02–1.09; P=0.003). Patients who reported seeing the physician within 15 min of their appointment time were less likely to receive a mammogram (RR, 0.98; 95 % CI, 0.95–1.00; P =0.04), and less likely to receive a colonoscopy (RR, 0.97; 95 % CI, 0.95–1.00; P=0.02).
CONCLUSIONS: Within a large, academic primary care network, most patient-reported physician communication and access to care questions after outpatient visits were not associated with subsequent preventive cancer screening and chronic disease management outcomes. Among significant associations, CG-CAHPS items were both positively and negatively predictive of HEDIS outcomes. These results support assessing patient experience as a unique domain of quality of care in addition to HEDIS measures.

THE ASSOCIATION OF ELECTRONIC HEALTH RECORD MEANINGFUL USE WITH CHRONIC DISEASE QUALITY MEASURES Lipika Samal[1,2]; Adam Wright[1,2]; Jeffrey A. Linder[1,2]; David W. Bates[1,2]. [1]Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA. (Tracking ID #1642581)

BACKGROUND: Electronic health records (EHRs) may improve quality of care when used in a meaningful way. The Department of Health and Human Services has defined stage 1 of meaningful use as a minimum level of performance on 15 core objectives including computerized order entry, electronic prescribing, clinical decision support, providing health information to patients, and data exchange, among others; additionally federal policy defines a set of clinical quality measures. We evaluated the association of meaningful use with quality.
METHODS: We compared physicians at our hospital and affiliated practices who met meaningful use criteria with those physicians who did not meet the criteria and excluded physicians with fewer than 10 patients in the denominator of any of the meaningful use core objectives. We examined data from September to November 2012 and determined quality measures for hypertension (HTN), diabetes (DM), coronary artery disease (CAD), asthma, and depression. We used Student's t-test to assess the relationship between meaningful use (as a dichotomous variable) with seven quality measures (as a proportion of patients meeting each quality measure). We excluded physicians with zero patients in the denominator of each quality measure.
RESULTS: We analyzed data on 1,213 physicians, 754 (62 %) of whom were meaningful users. For one quality measure (blood pressure control <140/90 mmHg in HTN patients) meaningful use was marginally associated with better quality (n=962; 47 % vs. 44 %; p=0.05). For five quality measures, meaningful use was not associated with better quality: 1) hemoglobin A1C control <9.0 % in DM patients (n=174; 70 % vs. 61 %; p=0.07); 2) urine protein screening in DM patients (n=642; 77 % vs. 79 %; p=0.28); 3) LDL control <100 mg/dL in DM patients (n=673; 81 % vs. 80 %; p=0.62); 4) beta blocker therapy in CAD patients (n=187; 96 % vs. 96 %; p=0.90); and 5) asthma medication (n=739; 59 % vs. 62 %; p=0.13). For one quality measure, continuous depression treatment for 12 weeks after diagnosis, meaningful use was associated with worse quality (n=139; 48 % vs. 69 %; p=0.001).
CONCLUSIONS: In this sample of physicians using the same EHR, we found no difference in quality between meaningful users and non-meaningful users.

THE ASSOCIATION OF HEALTH LITERACY WITH ILLNESS AND MEDICATION BELIEFS AMONG OLDER ADULTS WITH ASTHMA Alex Federman[1]; Michael S. Wolf[2]; Anastasia Sofianou[1]; Melissa Martynenko[1]; Ethan Halm[3]; Howard Leventhal[4]; Juan P. Wisnivesky[1]. [1]Mount Sinai School of Medicine, New York, NY; [2]Northwestern University, Chicago, IL; [3]UT Southwestern Medical Center, Dallas, TX; [4]Rutgers, The State University of New Jersey, New Brunswick, NJ. (Tracking ID #1636522)

BACKGROUND: Older adults with asthma have disproportionately poor asthma outcomes, yet remain a relatively understudied group. Suboptimal health literacy (HL) and asthma beliefs are associated with poor asthma self-management and outcomes. We tested the hypothesis that low HL is associated with inaccurate beliefs about asthma among older asthmatics.
METHODS: Asthmatics ages ≥60 years were recruited from hospital and community practices in New York, NY and Chicago, IL (n=420). HL was measured with the Short Test of Functional Health Literacy in Adults; validated instruments derived from the Self Regulation Model were used to assess beliefs. The association of beliefs with HL was evaluated with multivariate models.
RESULTS: Thirty-six percent of patients had low HL; 54 % believed they only have asthma with symptoms, 29 % believed they will not always have asthma and 20 % believed that their doctor can cure asthma. Low HL was associated with the 'not always have' and 'doctor can cure' asthma beliefs (OR: 1.84, 95 % CI: 1.2 to 2.82; OR: 2.22, 95 % CI: 1.29 to 3.82, respectively). Patients with low HL were also more likely to be concerned about medication use (β=0.92, p=.05), despite recognizing their necessity (β=−1.36, p=.01).
CONCLUSIONS: Older asthmatics with low HL endorse inaccurate asthma beliefs. Practitioners should use HL appropriate strategies to counter misconceptions about asthma among older adults to improve asthma self-management.

THE BORDER OF REPRODUCTIVE CONTROL: UNDOCUMENTED IMMIGRATION AS A RISK FACTOR FOR UNINTENDED PREGNANCY IN SWITZERLAND Alejandra Casillas[1,4]; Patrick Bodenmann[4]; Manuella Epiney[3]; Laurent Gétaz[2]; Olivier Irion[3]; Hans Wolff[2]. [1]Geneva University Hospital, Genève, Switzerland; [2]Geneva University Hospital, Genève, Switzerland; [3]Geneva University Hospital, Genève, Switzerland; [4]Lausanne University Hospital, Lausanne, Switzerland. (Tracking ID #1620117)

BACKGROUND: Unintended pregnancy reflects the unmet public health need for family planning, as prioritized in Healthy People 2020. An issue of disparities, it is linked to factors that disproportionately impact vulnerable populations. In Switzerland, where access to care is frequently lauded, undocumented immigrants are nevertheless limited. Swiss studies have demonstrated undocumented women's lack of insurance, low rates of preventive primary care, and poor knowledge of birth control. Using the only database to inquire about unintended pregnancy in Switzerland, this study examined the relationship between immigrant documentation and unintended pregnancy.
METHODS: This cross-sectional analysis used data from pregnant women presenting to the university public hospital in Geneva from February 2005–October 2006. Information was collected by midwives in face-to-face interviews during the initial pregnancy consultation and/or follow-up for a general study on pregnant women's health. As part of the questionnaire, women were asked if their current pregnancy was intended. Using Chi-square exact tests, we compared the proportion of unintended pregnancies between documented and undocumented women. We used logistic regression to examine whether undocumented status was associated with unintended pregnancy after adjusting for socio-demographics (age, marriage, employment, living quarters), family interaction (relationship with partner, presence of family, children), health-services utilization (Pap smear, medication use, contraception), reproductive history (abortion, knowledge of emergency contraception), drug use (tobacco, other substances), violence exposure, and psychological trauma. We present odds ratios with 95 % confidence intervals of the adjusted analyses, significant at the $p \leq 0.05$ level.
RESULTS: Four hundred nine women were invited to participate and 394 accepted (96 %). 161 were undocumented immigrants (41 %), of which nearly all were Latina (84 %) and all uninsured. More undocumented women were younger, employed, lived in a single-quarters apartment, used contraception (including "insecure" methods: condom-only, calendar, retraction) when she became pregnant and never had a Pap smear. Less were married, had a stable relationship with the baby's father, had family or children in Geneva, had knowledge of emergency contraception, used medications, and ever used tobacco or any other substance. Undocumented women had a higher proportion of unintended pregnancies (75 % vs. 21 %, $p<0.001$). Undocumented status was associated with unintended pregnancy even after adjustment (OR 6.2, 1.8–21.2), as was a history of psychological problems (OR 4.1, 1.3–12.7). Stable relationship with baby's father (OR 0.10, 0.02–0.60), history of abortion (OR 0.35, 0.12–0.997), and current psychiatric treatment (OR 0.03, 0.004–0.04) decreased odds. Contraception non-use was notably associated with lower odds of unintended pregnancy (OR 0.013, 0.004–0.04).
CONCLUSIONS: Undocumented status increased the odds of unintended pregnancy, calling provider attention to a lack of effective family planning among this population in Switzerland. Factors linked to domestic stability and health treatment were protective. Contraception non-use decreased odds of unintended pregnancy—likely reflecting a plan for pregnancy in this group. However, this also distributes some focus to the need for teaching of effective and correctly-utilized methods, among all women, given the use of insecure contraception observed in the study.

THE CORRELATION BETWEEN PATIENT PROPENSITY FOR ACTIVE PARTICIPATION IN DECISION-MAKING AND ACTUAL SHARED DECISION MAKING BEHAVIORS DURING CHRONIC CARE ENCOUNTERS Gretchen Rickards[1,2]; Dorothy Becher[2]; Jeffrey L. Jackson[2,3]; Janice L. Hanson[2,4]; Patrick G. O'Malley[2,1]. [1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Uniformed Services University, Bethesda, MD; [3]Medical College of Wisconsin, Milwaukee, WI; [4]University of Colorado, Aurora, CO. (Tracking ID #1637701)

BACKGROUND: Optimal shared decision making requires patients to be actively engaged in agenda setting, information exchange, valuation of outcomes, and decisions. While there are tools to measure one's propensity for activation, it is not clear if this corresponds with actual activation during an encounter. We sought to assess the relationship between patient propensity for activation and actual activation behavior during encounter decision making.
METHODS: Prospective study using dual, blinded rating of transcribed audiotapes of a consecutive sample of 98 consenting participants aged 40–80 years old with 3 or more chronic conditions seeing their internist (N=11) for a routine appointment. Prior to each encounter, patients completed a survey to measure their propensity for participation in shared decision making based on their knowledge (health literacy), skills (medication adherence), and confidence (locus of control). Each domain was scaled to 10 and summed, yielding a total "patient activation propensity" score. Using transcriptions, actual patient activation was rated on a scale of 1–10 (based on relationship symmetry, control of session, quality of questions, directness of decision making, specificity of responses, and focus). Each encounter was also rated by level of decision-making complexity (low, medium, high) and shared decision making (0–10 scale; with additional categorization of each encounter as doctor- or patient-dominated). All encounter measures were dual-rated by 3 authors (GR, DB, PO), with disagreements reconciled through consensus.
RESULTS: Patients were 53 % female, 33 % Caucasian, mean age was 66, 88 % were on five or more medications, and 30 % had very good or excellent functional status. Doctors were 55 % female, mean age 48yo, and had a mean of 19 year since graduation. The level of decision making was: 61 % Low, 39 % Medium/High. Patient propensity for activation was moderate to high (mean: 19.8, on scale of 0–30) while actual patient activation during the encounters was low (mean: 4.0; SD 1.6, on a scale of 0–10). There were higher patient activation scores with increasing levels of decision making (means: 3.75 for low complexity vs 4.39 moderate to high complexity; p=0.05). Encounters were overwhelmingly doctor-dominated (88/98), with low levels of sharing in decision making (mean score: 4.4, range 0–10). There was no correlation between patient propensity for activation and actual activation (r=0.14; p=0.24), though there was a trend toward correlation with actual shared decision making (r=0.27, p=0.07). However, observed patient activation was strongly correlated with the observed degree of shared decision making (r=0.65, $p<0.001$).
CONCLUSIONS: Patient propensity for activation in encounters does not correlate with actual patient activation, and may be suppressed by doctor domination and other structural components of the interaction. Further work is needed to improve the interactional facilitation of patients' participation in shared decision making.

THE DESIGN OF THE HCNI, A COMMUNITY PARTNERED APPROACH TO CVD RISK FACTOR REDUCTION IN SOUTH LOS ANGELES. Arleen Brown[1]; D'Ann M. Morris[3,4]; Katherine L. Kahn[1]; Roberto Vargas[1]; Aziza L. Wright[4,2]; Felica U. Jones[2]; Nell Forge[4]; Keith C. Norris[4]; Astrea Flowers[3]; Ibrahima Sankare[1]; Keyonna M. King[1]; Lujia Zhang[1]; Sigrid K. Madrigal[2]; Dennishia Banner[2]; Rachelle Bross[5]; Orwilda L. Pitts[4]; Loretta Jones[2,4]. [1]UCLA, Los Angeles, CA; [2]Healthy African American Families, Los Angeles, CA; [3]Los Angeles Urban League, Los Angeles, CA; [4]Charles Drew University, Los Angeles, CA; [5]Los Angeles Biomed, Los Angeles, CA. (Tracking ID #1641978)

BACKGROUND: Widespread behavioral, clinical, and public health efforts to improve awareness and management of cardiovascular disease (CVD) and its risk factors have had limited success in reducing disparities. Community-partnered participatory research (CPPR) may be an effective strategy for designing and implementing more effective community-level risk reduction efforts. The Healthy Community Neighborhood Initiative (HCNI) is a multifaceted community partnered study that aims to improve health and health care in a predominantly African American and Latino community in South Los Angeles. The HCNI partners have developed strategies to understand and mitigate chronic disease disparities in this community through CPPR, including weekly meetings of

the partners (the Los Angeles Urban League, Healthy African American Families, Charles Drew University, and University of California in Los Angeles), participation in community and academic events, and invited sessions with "guest" community and academic experts. Throughout this process, 6 students, 5 community health workers and community partners new to research have been mentored in CPPR.

METHODS: The HCNI designed a baseline assessment consisting of a household survey (interviews and clinical exams); neighborhood observations; and community asset mapping to examine clinical and social determinants of health. The study protocol, data collection instruments, and participant feedback forms were reviewed and revised by community residents and subsequently approved by the CDU and UCLA Human Subjects Protection Committees. The protocols for all components of the initiative were designed and pilot tested collaboratively by the partners.

RESULTS: Over a 5 month period, the recruitment team contacted 90 community residents and enrolled 79 into the study. Seventy-five enrollees completed the household survey, which includes an interview, a physical examination and laboratory studies to collect biomarkers (A1c, c-Reactive Peptide, lipids, and hemoglobin). Thirty-six functional status tests (grip strength and chair stands) were also administered to participants ages 50 and older. Consistent with efforts to disseminate community-partnered research findings and build a sustainable community-academic partnership that enhances community capacity, the HCNI held 3 community research training sessions on medical research informed consent, survey and clinical exam administration, and depression assessment. The HCNI also provided each study participant with a community resource guide and distributed the guide at a free clinic event attended by 5,000 community residents.

CONCLUSIONS: The HCNI and community residents have developed effective strategies for designing and conducting a community assessment to understand CVD disparities and building community and academic capacity to engage in CPPR. These findings will be linked to data from neighborhood observations and community asset mapping to inform future strategies for collaboration with community residents to develop community based interventions.

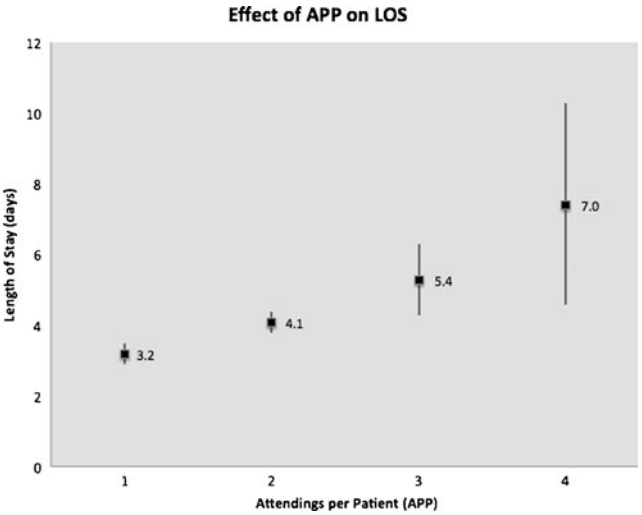
THE EFFECT OF ATTENDING DISCONTINUITY ON QUALITY OF CARE AT A UNIVERSITY-BASED INTERNAL MEDICINE PROGRAM Charlie M. Wray[1]; Adarsh Sai[1]; Waheed Baqai[2]; David H. Kim[1]; Lawrence Loo[1]. [1]Loma Linda School of Medicine, Loma Linda, CA; [2]Loma Linda University Medical Center, Loma Linda, CA. (Tracking ID #1608493)

BACKGROUND: Studies examining the importance of continuity of care with a single physician have demonstrated improved patient outcomes. Unfortunately, most of these studies were performed in the outpatient, rather than the inpatient setting. With over 18 million inpatients admitted to teaching hospitals in 2010, the impact of the attending physician continuity of care on quality outcomes has not been explored. We hypothesized that attending physician discontinuity at a large university-based internal medicine program may adversely affect the quality of care given to hospitalized patients.

METHODS: We performed a six-month retrospective analysis of administrative data from November 2011 to April 2012. We included all adult patients ≥18 years old admitted to/discharged from the internal medicine teaching service. Attendings per Patient (APP) reflect a count of each internal medicine attending physician who oversaw the care of a patient. The primary outcome was hospital Length of Stay (LOS), with a secondary outcome of ICU (Intensive Care Unit) transfer rate. Multivariate regression analysis was performed for LOS with patient race, gender, Charles Combined-Age Comorbidity Index (CCI; to adjust for severity of illness), and APP as the independent variables.

RESULTS: Our study sample included 1,012 patients with mean ± SD age of 56.3±20.5 years, 59 % were females, the majority Caucasian (55 %), and mean CCI 2.0±2.3. Mean ± SD LOS was 5.4±6.2 days, and 81 (8 %) patients were transferred to ICU during hospitalization. The mean LOS for 1, 2, 3, 4-APP was 3.2, 4.1, 5.4, and 7.0 days (±95 % CI), respectively—see Figure displaying the mean ±95 % CI for each LOS. CCI and APP were significantly associated with LOS after adjustment for confounders (F=29.2, p<0.01 for CCI and F=12.4, p<0.01 for APP). CCI and APP were also significantly associated with ICU transfer (F=6.2, p<0.01 for CCI and F=1.0, p<0.01).

CONCLUSIONS: To our knowledge, this is the first study to examine how the number of attending physicians per patient in a University hospital teaching service is associated with an adverse effect on the overall inpatient LOS and subsequent transfer to the ICU. Future prospective studies should examine the optimal duration of attending faculty rotations who oversee a ward team to optimize the balance of teaching, quality and costs of patient care.



THE EFFECT OF INFORMATION PRESENTATION ON THE DECISION TO UNDERGO ELECTIVE PERCUTANEOUS CORONARY INTERVENTION MIchael B. Rothberg[1]; Laura Scherer[3]; Mohammed Amin Kashef[5]; Henry Ting[4]; Megan Coylewright[4]; Brian Zikmund-Fisher[2]. [1]Cleveland Clinic, Cleveland, OH; [2]University of Michigan, Ann Arbor, MI; [3]University of Missouri, Columbia, MO; [4]Mayo Clinic, Rochester, MN; [5]Baystate Medical Center, Springfield, MA. (Tracking ID #1643063)

BACKGROUND: Clinical trials of percutaneous coronary intervention (PCI) for stable coronary artery disease (CAD) demonstrate that the benefits of PCI are limited to symptom relief. However, most patients believe that PCI also prevents myocardial infarction (MI). We explored subjects' beliefs and willingness to accept hypothetical PCI depending on how information was presented.

METHODS: Individuals aged ≥50 years who had never had PCI were recruited for a web-based survey. Participants were randomized to read 1 of 4 hypothetical scenarios and complete a questionnaire. Participants were asked to imagine visiting a cardiologist after experiencing stable chest pain and a positive stress test. In 3 scenarios the cardiologist described CAD as artery blockage and provided either no information about the effects of PCI on MI risk (NO INFO), specifically told the patient that PCI does not reduce MI risk (SPECIFIC INFO), or explained why PCI does not reduce MI risk (EXPLANATORY INFO). In a 4th scenario, CAD was described simply as inflammation (INFLAMMATION). Identical information about PCI complications, the role of PCI in reducing angina, and the benefits of optimal medical therapy (OMT) were provided in all scenarios. Subjects were asked if they would opt for PCI and for OMT, and how effective PCI was for preventing MI.

RESULTS: The final sample consisted of 1678 participants (total completion rate=89 %). Mean age was 60, 51 % were female and 79 % were white. Overall, 52 % of respondents chose PCI. Compared to the other groups, the NO INFO respondents were most likely to choose PCI (69 % vs. 46 %, p<0.001), and to believe that PCI prevents MI (71 % vs. 36 %, p<0.001). Those receiving EXPLANATORY INFO were least likely

to think PCI would prevent MI (31 %, $p<.05$ vs. other information states). Participants receiving NO INFO were least likely (83 %) and those receiving EXPLANATORY INFO most likely (92 %) to agree to take medications (83 % vs. 92 %, $p<0.001$). Subjects given NO INFO thought PCI was more effective than medication; the rest thought the opposite. When asked to recall what the doctor told them, 52 % of the NO INFO participants falsely remembered that the doctor had told them that PCI prevented MI vs. 19 % of other participants ($p<0.001$). Across the entire sample, belief that PCI would prevent MI was strongly correlated with the decision to have PCI (OR 9.05; 95 % CI 7.37, 11.62). Other predictors of PCI were an action bias ($p<0.001$), being more worried ($p<0.001$), and having symptoms that were judged to be bothersome or limit activity ($p<0.001$). Age, sex, and race were not associated with the PCI decision (all $p>.40$).

CONCLUSIONS: In the absence of information to the contrary, most patients assume that PCI prevents MI in stable angina and are likely to choose it. Explicit information can partially overcome that bias and influence decision-making. Explaining why PCI does not prevent MI was the most effective means of overcoming this bias.

THE EFFECT OF LANGUAGE CONGRUENCY ON THE OUT-OF-HOSPITAL (OOH) MANAGEMENT OF CHEST PAIN Madeline Sterling[2,1]; Sandra Echeverria[2]; Mark Merlin[2]. [1]UMDNJ-School of Public Health, Piscataway, NJ; [2]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ. (Tracking ID #1620664)

BACKGROUND: Although language barriers are associated with disparities and delays in cardiovascular care in the hospital, little is known about how they affect care in the prehospital setting. The out-of hospital (OOH) management of chest pain is protocol driven, however language barriers likely affect the care provided by Advanced Life Support (ALS) paramedics aboard Emergency Medical Services (EMS) units.

METHODS: This is a 4-year retrospective cohort study of New Jersey patients who called 911 for chest pain from April 2008 to January 2011. Using an electronic medical record system, we examined the association between language barriers and total On-Scene-Time (OST) spent by ALS paramedics from one of the state's largest EMS systems. A series of linear regression models were built to examine this association and we adjusted for confounding by demographic and clinical variables.

RESULTS: 11, 249 patients cared for by a NJ-EMS system for the treatment of chest pain were included in our study. Of these, 222 had a perceived language barrier (1.98 %). Contrary to expectations, language barriers were associated with less OST (β=0-.85400, $p<.0028$). After adjusting for demographic and clinical variables, a language barrier between patient and paramedic persisted as a significant independent predictor of less OST (β=−.7149, $p<.0146$). Paramedics spent less OST with Hispanics (β=− .3717, $p<.0228$), Asian/Others (β=−.5647, $p<.0101$) and patients with abnormal heart rates (β=−.007, $p<.0001$). Additionally, we found that the association between language barriers and OST varied significantly among racial/ethnic groups in adjusted models.

CONCLUSIONS: Among patients with chest pain, language barriers between patients and paramedics are associated with decreased total On-Scene-Time. Adjusted models indicate that paramedics spend less OST with Hispanics and Asian/Others (compared to whites) and those with abnormal heart rates, independent of the presence of a language barrier. Our study suggests that for those with chest pain, disparities and delays in cardiovascular care do not occur in the prehospital setting. Further research ought to concentrate on the quality of cardiac care rendered in formal medical setting in order to improve existing disparities.

Study Population By Language Barrier

Characteristics	Overall	No Language Barrier (Yes)	Language Barrier	p value
Gender				
Male	5,507 (48.96 %)	5,403 (98.1 %)	104 (1.9 %)	<.5256
Female	5,742 (51.04 %)	5,624 (97.9 %)	118 (2.06 %)	
Age (years) mean, (SD)	63.08 (16.79)	63.04 (16.8)	65.25 (16.2)	
18–45	1,761 (15.65 %)	1,736 (98.5 %)	25 (1.42 %)	<.1403
46–75	6,308 (56.08 %)	6,172 (97.8 %)	136 (2.16 %)	
76–105	3,180 (28.27 %)	3,119 (98.1 %)	61 (1.91 %)	
Race/Ethnicity				
White, Non-Hispanic	7,890 (70.14 %)	7,798 (98.8 %)	92 (1.2 %)	<.0001
Hispanic	765 (6.80 %)	689 (90.0 %)	76 (10.0 %)	
Black, Non-Hispanic	2,220 (19.56 %)	2,176 (98.0 %)	24 (1.08 %)	
Asian/Other	394 (3.50 %)	364 (92.4 %)	30 (7.6 %)	
Heart Rate (BPM) mean, (SD)	87.82 (21.9)	87.76 (4.23)	88.27 (20.50)	
Normal (60–100 BPM)	8,245 (73.3 %)	8,093 (98.1 %)	152 (1.8 %)	<1.006
Abnormal (<60 BPM or>100 BPM)	3,000 (26.7 %)	2,930 (97.6 %)	70 (2.3 %)	
On-Scene-Time (minutes) mean, (SD)	9.769 (4.22)	9.78 (4.23)	8.93 (3.4)	<.0001

THE EFFECT OF A YOGA INTERVENTION ON ALCOHOL AND DRUG ABUSE RISK IN VETERAN AND CIVILIAN WOMEN WITH PTSD. Shivani M. Reddy[1,2]; Megan R. Gerber[1,2]; Karen S. Mitchell[3,4]. [1]Boston University School of Medicine, Boston, MA; [2]VA Boston Healthcare System, Boston, MA; [3]VA Boston Healthcare System, Boston, MA; [4]Boston University School of Medicine, Boston, MA. (Tracking ID #1630672)

BACKGROUND: Post-traumatic Stress Disorder (PTSD) is of particular importance to the Veteran population. Many patients with PTSD have co-morbidities, including alcohol and substance abuse, which may impede diagnosis and treatment of PTSD. There is growing interest among Veterans and civilians in complementary and alternative medicine (CAM), though evidence for the efficacy of CAM in PTSD is sparse. In this study, we investigated the impact of a yoga intervention on alcohol and drug abuse risk in women with PTSD.

METHODS: We conducted a pilot study of a randomized controlled trial at a VA medical center comparing a 12-session weekly yoga intervention with control. Veteran and civilian women ages 18–65 with PTSD or sub-threshold PTSD were included. Participants were excluded if they attended a yoga class in the last 6 months or reported substance abuse in the previous 3 months. The intervention consisted of a hatha yoga class taught according to trauma-sensitive yoga guidelines, and the control group completed weekly assessments. All participants completed self-reported measures at baseline, post-intervention, and at 1-month follow-up, including Alcohol Use Disorder Identification Test (AUDIT) and Drug Use Disorder Identification Test (DUDIT). Mean AUDIT and DUDIT scores were calculated at each time point and compared using Wilcoxon Rank Sum tests. AUDIT and DUDIT scores were dichotomized into high or low risk of harmful use and compared with Fisher's exact tests.

RESULTS: Thirty-eight women were randomized to the yoga intervention (n=20) and assessment-only control (n=18). Participant mean age was 43.3; 24 % were Veterans. The majority of participants (76 %) completed the study. There was no difference in baseline AUDIT and DUDIT scores of participants lost to follow-up. By dichotomizing AUDIT and DUDIT score, we observed at baseline, 8 % and 21 % of participants had high risk drinking and drug use behaviors, respectively. At post-intervention and follow-up, there were no higher risk alcohol or drug users in the yoga group compared to 2–3 higher risk users in the control group. This difference was not statistically significant. Mean AUDIT scores decreased over the study period in the yoga group, declining from 1.95 (SD=2.35, 95 % CI: 0.85–3.05) at baseline to 1.29 (SD=1.20, 95 % CI: 0.59–1.98) post intervention, and 1.00 (SD=1.35, 95 % CI: 0.18–1.92) at follow-up. The mean difference between intervention and control groups approached significance over time. (Post-intervention p=0.247, Follow-up p=0.052) Post-intervention, mean DUDIT scores were lower in the yoga group (0.07, SD=1.92, 95 % CI: −0.08–0.23) than the control group (1.09 SD=1.79, 95 % CI: −0.20–2.38); this difference approached significance (p=0.081), although it disappeared at follow-up (p=0.209).

CONCLUSIONS: A pilot study of a yoga intervention for women with PTSD resulted in lower alcohol use and drug use risk scores compared to controls, with results approaching statistical significance. Findings suggest that yoga may be a feasible adjunctive treatment for patients with PTSD and substance abuse disorders. Further studies into the efficacy of CAM in the treatment of PTSD are warranted.

THE EFFECTIVENESS OF MOBILE ELECTRONIC DEVICES IN WEIGHT LOSS AMONG OVERWEIGHT AND OBESE POPULATIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS
Bushra Khokhar; Jessica Jones; Paul Ronksley; Jeff Caird; Doreen Rabi. University of Calgary, Calgary, AB, Canada. (Tracking ID #1638887)

BACKGROUND: Mobile electronic devices, such as mobile phones and personal digital assistants (PDAs), have emerged as useful tools in the facilitation and maintenance of weight loss. However, while randomized controlled studies have demonstrated a positive impact of mobile interventions, the extent to which mobile electronic devices are more effective than usual care methods is still being debated.
METHODS: Electronic databases were systematically searched for randomized controlled trails (RCT) evaluating the effectiveness of mobile electronic device interventions among overweight and obese populations. Weighted mean difference (WMD) for change in body weight (kg) was the primary outcome.
RESULTS: The search strategy yielded 457 citations and of the 46 potentially relevant studies, five met the criteria and four were included in the meta-analysis. A total of 461 participants were included in the four studies reporting a mean change in body weight. There were 232 participants who used some form of a mobile electronic device and 229 control comparator participants. Using a random-effects model, the WMD for the effect of using mobile electronic devices on reduction in body weight was −0.40 kg (95 % CI −2.44, 1.65). Mobile electronic device interventions were associated with a greater reduction in body weight (kg) compared to control groups during short duration interventions (</= 6 months) (−1.65 kg (95 % CI −2.50, −0.80)).
CONCLUSIONS: There was no reduction in body weight among the intervention and control groups during long duration interventions (> 6 months) (1.19 kg (95 % CI 0.77, 1.60)). Mobile electronic devices appear to enhance weight loss in the short term but currently there is insufficient literature on this topic to make a definitive recommendation. The literature on the efficacy of mobile devices in improving health is rapidly evolving and their use in health care is quickly expanding. While mobile devices hold great promise in health care, critical evaluations of effectiveness are required to ensure optimal benefit to potential users. Keywords: Mobile electronic device, weight loss, obesity, overweight.

THE EFFECTIVENESS OF A MANDATE FOR INFLUENZA VACCINATION IN HEALTH CARE PROVIDERS: A SYSTEMATIC REVIEW
Samantha I. Pitts[1]; Kathryn R. Millar[2]; Jodi B. Segal[1]. [1]Johns Hopkins University, School of Medicine, Baltimore, MD; [2]Johns Hopkins University, School of Public Health, Baltimore, MD. (Tracking ID #1637404)

BACKGROUND: Despite recommendations for influenza vaccination of health care providers (HCPs), vaccination rates in the US remain low, with an estimated 67 % of HCPs vaccinated. Consequently, several key professional societies have endorsed mandatory influenza vaccination policies. Objective: To systematically examine the published evidence of the effectiveness of an institutional mandate for influenza vaccination in HCPs.
METHODS: We searched MEDLINE, Embase, the Cochrane Library, CINAHL, and Web of Science until 12/14/2012 using controlled vocabulary and key word searches to identify studies that evaluated a mandate. We defined "mandate" as required influenza vaccination for continued employment or clinical practice, with limited exemptions for medical or religious reasons. Two reviewers independently screened all articles by title/abstract and then by full text based on specified eligibility criteria. Two reviewers sequentially abstracted study design and outcome data from each article, including HCP attitudes, vaccination rates, absenteeism, and clinical outcomes. We assessed the risk of bias due to the known limitations of observational studies.
RESULTS: Our search strategy yielded 693 unique records. We included 11 published studies; 8 examined mandates at single institutions or health systems, and 3 assessed mandates across multiple institutions. Six studies are pending full text screening. Ten included studies involved hospitals or health systems including hospitals, and one involved pharmacists. All were within the United States. All 11 studies examined vaccination rates. Five single institution studies reported pre- and post-mandate rates in comparable populations, with increases in vaccination rates of 27 % (in 3 studies), 44 % (in 1) and 44–68 % (in 1, depending on the comparison season). All 5 studies implemented at least one additional strategy with the mandate (e.g., an educational campaign). An additional pre/post study which expanded the population requiring vaccination with the mandate reported a 7 % increase; this institution had a comprehensive influenza vaccination strategy and high vaccination rate prior to the mandate (92 %). A multi-institution study reported an average increase across sites of 24 %, and one performance improvement initiative reported that hospitals with a mandate had a 9 % higher vaccination rate in the final year of the program ($P<0.001$). The remaining 3 studies had incomplete reporting and vaccination rate changes were indeterminable. No study reported on clinical outcomes in patients. Two single institution studies reported on absenteeism among health care providers; one reported a reduction, while the second found no significant difference. Six of the 11 studies reported on terminations and "voluntary resignations," which combined ranged from 0.02–0.15 %.
CONCLUSIONS: A mandate for influenza vaccination among HCPs is associated with substantial increases in vaccination rates in observational studies. The 2 studies with the least improvement had institutions with a high pre-mandate vaccination rate or that were already participating in a multifaceted performance improvement project. The mandate was frequently implemented with other strategies to increase vaccination. There were insufficient studies to draw conclusions about clinical outcomes among HCPs or patients. Knowledge of clinical outcomes will require systematic surveillance for health care associated influenza.

THE EFFECTS OF A DECADE OF PROGRESSIVE DUTY HOUR LIMITATIONS AT A MULTI-HOSPITAL INTERNAL MEDICINE RESIDENCY PROGRAM
Michael F. Krug[1]; Heather L. Davidson[2,1]; P. L. Wander[1]; Joyce E. Wipf[2,1]. [1]University of Washington, Seattle, WA; [2]VA Puget Sound HCS, Seattle, WA. (Tracking ID #1642238)

BACKGROUND: In July of 2003, the Accreditation Council for Graduate Medical Education (ACGME) mandated that resident duty hour limitations be implemented (including a maximum shift length of 24+6 h and 80 h of work per week). Eight years later, the ACGME required more restrictive measures, limiting interns to no more than 16 h of continuous duty. The effects of changes in work hours on resident well-being, patient care, and education remain unclear. The purpose of our IRB-approved study was: 1) to look for measurable changes in resident well-being and burnout prevalence over the last decade and 2) to investigate residents' perception of the impact of July 2011 changes.
METHODS: In spring of 2012 we sent all current internal medicine residents at a large university-based, multi-hospital residency program an anonymous mailed survey consisting of: 1) a validated depression screening questionnaire 2) the Maslach Burnout Inventory, and 3) a previously described questionnaire on career satisfaction. All three of these instruments were used in prior resident surveys at our institution in 2001 and 2004. The results from each time point were compared using pairwise comparisons for Z-tests of proportion and the p value was set at<.004 after Bonferroni correction for multiple comparisons. Additionally, in the current survey we queried residents about the impact of the latest work hour restrictions on resident well-being, patient care, and education.
RESULTS: Overall,112 out of 170 residents returned the survey (66 %). Table 1 compares 2012 resident data with results from 2004 and 2001. Significantly fewer residents had a positive screening result for depression in 2011 compared with 2004. Career satisfaction remains high after improvement seen from 2001 to 2004. There was a non-significant trend toward reduction in burnout. 58 % of 2012 survey respondents favored returning to the pre-July 2011 work hour limitations (ie interns able to work 24+6 h continuously) rather than keeping the current system (16 %) or

limiting both interns and senior residents to 16 h (26 %). Senior residents were more likely than R1s to favor reversion to the previous system (69 % vs. 40 %). Most residents (62 %) felt that the 2011 duty hour limitations negatively impacted their education. Table 1. Resident Well-Being in 2011 Survey Compared to Historical Results No. (%) of respondents: 2011 (n=112) 2004 (n=118) 2001 (n=115) Burnout: Met burnout criteria 2011 68(61) 2004 75(68) p value 0.267 2001 87(76) p value 0.015 Career satisfaction: Happy with career choice 2011 89(79) 2004 94(80) p-value 0.851 2001 76(66) p-value 0.029 Depression: Positive result on screen 2011 35(32) 2004 65(56) p-value 0.0003 2001 52(45) p-value 0.045

CONCLUSIONS: Indicators of resident well-being at our institution have changed over time from 2001 to 2011 as duty hour limitations have evolved. Fewer residents screened positive for depression in 2011 compared with 2004, which we hypothesize may be related to reduced sleep deprivation. Career satisfaction improved after the 2003 duty hour limitations and has remained high. Burnout rates continue to be high despite dramatic alterations in duty hour regulations. Residents believe that the latest duty hour limitations negatively affected their education, and most prefer to work under pre-July 2011 conditions. This study contributes to the ongoing national conversation about duty hour limitations.

THE FEASIBILITY OF COMPUTER ASSISTED INSTRUCTION FOR LOW LITERACY PATIENTS David P. Miller[2]; Vanessa Duren-Winfield[1]; James L. Wofford[2]; Michael Pignone[3]; Larry D. Case[4]. [1]Winston-Salem State University School of Health Sciences, Winston-Salem, NC; [2]Wake Forest School of Medicine, Winston-Salem, NC; [3]University of North Carolina School of Medicine, Chapel Hill, NC; [4]Wake Forest School of Medicine, Winston-Salem, NC. (Tracking ID #1637327)

BACKGROUND: One-third of Americans have low health literacy. Patients with low health literacy have difficulty understanding their doctors, ask fewer questions in medical encounters, and cannot comprehend the majority of printed patient education materials currently in use. New educational strategies are needed to reach low literacy patients. Computer-assisted instruction (CAI) offers the potential to overcome literacy barriers by incorporating multimedia elements and allowing users to proceed at their own pace. We investigated the feasibility of using CAI to educate patients of varying literacy levels by examining patients' preferences for learning and their assessment of computer-based patient education programs.

METHODS: We analyzed patient preference and usability data from a trial which randomly assigned participants to interact with a touch screen computer program focusing on either colorectal cancer screening or prescription drug safety. Both programs were developed for a mixed literacy audience with prominent use of audio narration, graphics, pictures, and animations or video. Participants were English-speaking patients aged 50–74 years old who were scheduled for a routine medical visit and were overdue for colorectal cancer screening. A verbally administered baseline questionnaire assessed health literacy level, participants' usual sources of health information, and prior computer experience. Following the computer programs, each participant completed a verbally administered program evaluation survey. A research assistant recorded the number of times each participant asked for assistance using the program.

RESULTS: A total of 264 participants enrolled in the study and completed the assigned computer program. Most participants were female (67 %), African-American (74 %), had annual household incomes of<$20,000 (76 %), and had limited health literacy (56 %). Compared to those with adequate literacy, limited literacy patients were less likely to have prior computer experience (58 % vs. 80 %, p<0.001) or use the internet to get health information (18 % vs. 34 %, p<0.01). Overall, doctors were the most common source of medical information, used by 85 % of both limited and adequate literacy patients. Regardless of literacy level, over 98 % of participants stated the computer programs were easy, were preferred to reading a brochure, and would be personally recommended to others. Over 90 % of all patients reported they learned something important from the programs, but limited literacy patients were more likely to state they learned more from the programs than they would have from a brochure (97 % limited literacy vs. 88 % adequate literacy, p=0.02). Over three-quarters of all participants were able to complete the programs without any assistance (74 % limited literacy vs. 85 % for adequate literacy, p=0.03), and even 84 % of limited literacy patients required no more than one episode of assistance.

CONCLUSIONS: Although patients with limited health literacy have less prior computer experience, the overwhelming majority completed the programs with minimal assistance and stated they learned more from the computer programs than they would have from a brochure. Future research should investigate ways CAI can be incorporated in medical care to enhance patient understanding, particularly for low literacy patients.

THE FREQUENCY AND CHARACTERISTICS OF OLDER HOSPITALIZED ADULTS WHO REQUIRE A SURROGATE DECISION MAKER Alexia Torke[2,3]; Greg A. Sachs[1,2]; Paul R. Helft[1,3]; Kianna Montz[2]; Siu Hui[2]; James E. Slaven[4]; Christopher M. Callahan[1,2]. [1]Indiana University, Indianapolis, IN; [2]Regenstrief Institute, Indianapolis, IN; [3]Indiana University Health, Indianapolis, IN; [4]Indiana University, Indianapolis, IN. (Tracking ID #1635119)

BACKGROUND: Although many hospitalized older adults lose the ability to make medical decisions, little is known about the frequency that surrogates make medical decisions, the characteristics of the patients who require a surrogate, or the nature of decisions.

METHODS: We conducted a prospective, observational study of hospitalized adults 65 and older at two Midwest hospitals: a tertiary referral center; and a public urban hospital. Patients were identified at admission from the medical record. We conducted a physician screen between hospital days 2–4 to identify patients who required major decisions related to life sustaining care (including code status), procedures and surgeries, and discharge placement. Physicians identified patients who required a surrogate to make all decisions or participate with patients in decision making. Data on patient characteristics were obtained from electronic medical records.

RESULTS: We enrolled 597 of 1084 eligible patients (55 % enrollment) with mean age 76.1 (SD 8.18), Patients were 51 % white and 48 % African American. Of these, 41 % had surrogate involvement in decision making (17 % required a surrogate for all decisions, 24 % had both surrogate and patient involvement). In the ICU, surrogate decision making was even more common with surrogate involvement in 59 % (38 % of patients entirely required a surrogate and 29 % both). Surrogates were most commonly daughters (59 %), sons (25 %), or spouses (21 %). In multivariable analyses, patients with surrogate involvement were more likely to have an admission diagnosis of altered mental status, odds ratio (OR) 6.35 (95 % Confidence Interval (CI) 3.35, 12.1), to have lower SES as indicated by Medicaid insurance, OR 6.68 (CI 1.66, 26.93), to be admitted to the ICU (OR 4.12, CI 2.29, 7.41), to be older compared to the baseline group of those ages 65–69, (ages 70–74, OR 2.08 (CI 1.13, 3.84); ages 75–84, OR 4.13 (CI 2.41, 7.08), and 85+, OR 8.02 (CI 4.17, 15.39), and to be admitted from a nursing home, OR 1.91 (CI 1.02, 3.56). Patients with a surrogate were more seriously ill as indicated by higher scores on the Cumulative Illness Severity Scale (mean 21.45 for patients who made decisions, 22.78 both, 23.97 surrogate, p<0.0001) and more likely to die in the hospital (0 % patient, 2.8 % both, 9.9 % surrogate, p<0.0001). Overall, only 7 % of patients had a living will and 25 % had chosen a health care representative. These numbers did not differ by surrogate status. Patients with surrogate involvement were more likely to face decisions about life sustaining care (44 % patient, 51 % both, 66 % surrogate, p=0.0003) and discharge placement (33 % patient, 46 % both, 49 % surrogate, p=0.0026) within even the first 4 days of admission.

CONCLUSIONS: Decisions for older adults involve surrogates 40 % of the time for all hospitalized patients and almost 2/3 of the time in the ICU. In many cases, decisions are shared with patients who are partially or temporarily incapacitated. Given this data, approaches to shared decision making in the hospital must include surrogates nearly as much as patients. Clinicians should be highly attuned to the need for a surrogate when a patient is admitted with altered mental status, but also when patients are

older, in the ICU, from a nursing home, or on Medicaid. Most patients requiring a surrogate will face at least one decision about life sustaining care, and decisions will be commonly made by daughters without the help of living wills or previously appointed health care power of attorney forms.

THE GENERAL PUBLIC'S COMFORT WITH DECEASED ORGAN DONATION DISCUSSION IN PRIMARY CARE SETTINGS: OPPORTUNITIES FOR INTERVENTION Tanjala S. Purnell[1]; Neil R. Powe[2]; Misty U. Troll[1]; Nae-Yuh Wang[1]; Marshala R. Lee[3]; Sydney M. Dy[1]; Lisa A. Cooper[1]; L. Ebony Boulware[1]. [1]Johns Hopkins University, Baltimore, MD; [2]University of California San Francisco, San Francisco, CA; [3]University of Maryland, Baltimore, MD. (Tracking ID #1642715)

BACKGROUND: Discussion about deceased organ donation preferences is increasingly promoted as an important aspect of end of life decision-making to be addressed by primary care physicians (PCPs). However, little is known about comfort levels regarding discussing organ donation preferences with primary care doctors among adults in the US general public.
METHODS: We conducted a national household telephone survey using random digit selection of telephone numbers to assess comfort with and frequency of discussions with primary care physicians about deceased organ donation among US adults in the general public. In multivariable logistic regression models, we assessed the independent association of demographic, socioeconomic, and attitudinal factors with comfort and having a discussion with a PCP about donation.
RESULTS: Among 845 total participants (from 85 % of eligible households), mean age was 45 years with 12 % African Americans and 16 % Hispanics. Among the 683 participants who reported having a PCP, 631 (92 %) stated they were very or moderately comfortable discussing organ donation with their PCP, but only 129 (19 %) had previously discussed organ donation with their PCP. After multivariable adjustment, minority race (OR: 0.47, 95 % CI: 0.23–0.99), lack of interest in deceased donation (OR: 0.19, 95 % CI: 0.09–0.40), and less trust in physicians (OR: 0.39, 95 % CI: 0.18–0.83) were independently associated with less comfort discussing deceased donation with a PCP, while participants with lack of interest in deceased donation (OR: 0.27, 95 % CI: 0.09–0.78) were less likely to report prior discussion about donation with a PCP. We found no significant differences in comfort with or prior discussion about donation by participant age, gender, education, marital status, insurance status, or US census region.
CONCLUSIONS: Despite high levels of comfort with discussing deceased organ donation with PCPs among the US general public, few participants had previously engaged in discussions. Strategies to engage patients in discussions about organ donation during end of life planning in primary care settings may improve both donation rates and the quality of end of life decision-making. Efforts to address concerns regarding medical mistrust and to engage minorities may be particularly effective.

THE HUDDLE: TRAINEE EXPERIENCES IN TEAM-BASED PRIMARY CARE IN AN INNOVATIVE INTERPROFESSIONAL EDUCATION PROGRAM Kelli Copeland; Rebecca L. Shunk; Susan L. Janson; Bridget O'Brien. University of California San Francisco, San Francisco, CA. (Tracking ID #1640109)

BACKGROUND: Team-based primary care delivery is a central component of the patient-centered medical home model. Brief team meetings, or "huddles," have been identified as an important component of safe, effective team-based care. Inclusion of trainees in huddles can provide valuable interprofessional learning opportunities, particularly for development of skills in communication and coordination of care. This qualitative study examines trainee perceptions of the role of huddles in team-based primary care, key elements of huddles, and their impact on provider and patient experience.
METHODS: In 2011, the San Francisco VA and the University of California San Francisco established the Education in Patient Aligned Care Teams (EdPACT) Program to prepare Internal Medicine residents (R2s) and Adult Nurse Practitioner students (NP2s) to work in teams with staff to care for a panel of primary care patients. EdPACT encourages regular huddles before clinic to formalize interprofessional communication. Semi-structured interviews were conducted with EdPACT trainees about their experiences with huddles. Two authors reviewed interview transcripts for alignment with a framework for interprofessional collaboration that includes relational, process, and organizational factors. The authors developed a coding scheme based on this framework, independently coded the transcripts and reconciled to consensus, then analyzed coded passages for themes.
RESULTS: 19 of 23 trainees participated in interviews. Nearly all trainees identified huddles as valuable to their clinic experience; all described the role of relational factors in their huddle and 18 out of 19 described process factors. The most common relational factors were 1) team dynamic (i.e., getting to know members, establishing a team identity), 2) consistent participation in huddles, and 3) defined roles and role clarity. Trainees highlighted team dynamic as particularly important for effective huddles and noted improvements over the year. The two process factors most commonly referenced were 1) communication related to clinical tasks, and 2) having established routines. Many trainees described pre-huddle review of patient charts and ordering tests/procedures, i.e. "scrubbing," as an important routine that improved the efficiency of huddles and clinic. The VA-supported team structure (PACT) was the primary organizational factor mentioned by trainees. PACT was a new concept that some trainees found challenging in the beginning of the year but was appreciated more as the year progressed and relational and process factors improved. Trainees characterized the huddle as the primary event for interprofessional collaboration. Some suggested that huddles improved the primary care experience for both providers and patients. Several trainees said regular communication about tasks and scheduling before clinic increased team efficiency. Others stated that multiple team members knowing the patients and providing different services contributed to better care for patients.
CONCLUSIONS: Trainees valued huddles for building interprofessional relationships and as key for delivering team-based primary care. Some trainees believed that huddles contributed to efficiency in clinic and better patient outcomes through improved relationships, communication, and coordination between team members. Several of the relational and process factors highlighted by trainees suggest areas in need of focused training and feedback to maximize huddle effectiveness.

THE IMPACT OF ANTI-INFLAMMATORY AGENTS ON CD4 RECOVERY IN HIV INFECTED INDIVIDUALS. IS THERE A CLINICAL DIFFERENCE? Raji Shameem; Vanya Grover; Pooja Kumar; Ladan Ahmadi. Lenox Hill Hospital, New York, NY. (Tracking ID #1639172)

BACKGROUND: One topic of interest that has emerged is the use of anti-inflammatory medications for the treatment of HIV. This includes statins, aspirin, and other NSAIDS. The aim of this study was to see if chronic use of anti-inflammatory agents leads to a clinically significant increase in CD4 recovery.
METHODS: The study population comprised of HIV patients in an urban ambulatory site. Chart review was performed to detect patients treated with aspirin, statins, and NSAIDS. CD4 counts were analyzed through a retrospective chart analysis. CD4 recovery was calculated as the most recent CD4 count divided by the CD4 nadir (most recent CD4 count/CD4 count nadir). For inclusion, patients must have received anti-retroviral therapy for at least 6 months and an undetectable viral load for 6 months. A viral load less than 200 via PCR testing was defined to be undetectable. The study arm was HIV patients treated with statins, aspirin, or other NSAIDS for at least 6 months. The control arm was HIV patients who were not receiving anti-inflammatory therapy. Patients with malignancy, chronic kidney disease, receiving chemotherapy or corticosteroids were excluded.

RESULTS: A total of 526 charts were analyzed in an urban ambulatory setting. A total of 71 patients receiving anti-inflammatory treatment for at least 6 months met the inclusion criteria. These patients comprised the study group. Ninety-nine patients who met the inclusion criteria and did not receive anti-inflammatory treatment comprised the control group. A large number of patients were excluded from the study due to a lack of undetectable viral loads for at least 6 months and/or viral load values greater than 200 at any point in a 6 month period. (n=260). Other patients were not included due to other exclusion criteria (n=96). In the study group CD4 recovery median was 2.69. For the control group the CD4 recovery median was 2.42. Median values were used as opposed to mean values due to the skewed distribution of the data. The distribution of the CD4 recovery ratio was shown to be the same across both groups with the Mann-Whitney U test. The p value was determined to be 0.87, signifying that there was no clinically significant difference between both groups in our study.
CONCLUSIONS: In vitro studies have shown a potential benefit of anti-inflammatory medications for the treatment of HIV. However, there was no statistically significant difference in CD4 recovery in HIV patients receiving anti-inflammatory treatment as opposed to HIV patients not on anti-inflammatory treatment. Future randomized prospective studies with larger study sample sizes are necessary to evaluate if there is a role of anti-inflammatory agents in HIV treatment.

THE IMPACT OF DUTY HOUR RESTRICTIONS ON JOB BURNOUT IN INTERNAL MEDICINE RESIDENTS Jonathan Ripp[1]; Robert Fallar[1]; Joel T. Katz[2]; Hasan Bazari[3]; Lisa Bellini[4]; Deborah Korenstein[1]. [1]Mount Sinai School of Medicine, New York, NY; [2]Brigham and Women's Hospital, Boston, MA; [3]Massachusetts General Hospital, Boston, MA; [4]University of Pennsylvania School of Medicine, Philadelphia, PA. (Tracking ID #1642287)

BACKGROUND: Internal medicine (IM) residents commonly develop job burnout, potentially leading to poor academic performance, depression and errors. Prolonged work hours are believed to be a risk factor for burnout, but the extent to which work hour limitations (WHL) can mitigate job burnout remains uncertain. We hypothesized that the July 2011 WHL would lead to a decrease in burnout incidence in IM residents.
METHODS: We administered a survey to first-year IM residents at 4 institutions twice between June 2011 and July 2012, linking individual pre- and post- responses. The survey measured job burnout, sleepiness and other characteristics, and has been previously used by our group. In order to estimate the impact of the 2011 WHL, data gathered from this cohort were compared to findings collected in 2008–9 from a cohort of first-year IM residents at the same 4 institutions. With SAS statistical software, we analyzed our data using dichotomous chi-square tests to compare variables in both cohorts.
RESULTS: Of 265 first-year residents eligible to participate in our study, 237 (89 %) completed the initial survey and 146 (55 %) completed both surveys. Year-end burnout prevalence (106/146 v. 105/127; 73 % v. 83 %; P=0.05) and burnout incidence (68/105 v. 67/82; 65 % v. 82 %; P=0.01) were both significantly lower in the 2011–12 cohort as compared with the 2008–9 cohort. Among residents who developed burnout during internship, when comparing 2011–12 and 2008–9 cohorts, there were no significant differences in excessive Epworth sleepiness (47/67 v. 48/67; 70 % v. 67 %; P=0.85), high depersonalization (56/68 v 59/67; 82 % v. 88 %; P=0.35) or high emotional exhaustion (53/68 v 54/67; 78 % v. 81 %; P=0.70) scores. There was no difference in year-end prevalence of excessive Epworth sleepiness (86/145 v. 85/127; 59 % v.67 %; P=0.19) between the two cohorts; however, residents who developed burnout in the 2011–12 cohort were more likely to report working >70 h when compared with residents who remained burnout free. (57/68 v. 24/37; 84 % v. 65 %; P=0.02)
CONCLUSIONS: Job burnout in IM resident physicians decreased modestly after implementation of the 2011 WHL. This benefit seems unrelated to excessive sleepiness though may be correlated with hours worked. Despite these findings, resident burnout remains unacceptably high and further interventions to address the issue need to be explored.

THE IMPACT OF LIMITED TEAM CONTINUITY ON MEDICAL STUDENTS: A SURVEY-BASED EVALUATION OF TEAM FRAGMENTATION'S EFFECTS ON THIRD-YEAR MEDICAL STUDENTS DURING THEIR INPATIENT INTERNAL MEDICINE CLERKSHIP David A. Williams; Traci E. Yamashita; Eva M. Aagaard. University of Colorado, Aurora, CO. (Tracking ID #1611146)

BACKGROUND: As programs adapt to new resident duty hour changes implemented in July 2011, internal medicine resident work schedules have progressively transitioned toward shift-based systems, often resulting in increased team fragmentation. We hypothesized that exposure to shift-based schedules that result in such team fragmentation would have a negative effect on medical student experiences during their required third-year internal medicine clerkship.
METHODS: As part of a larger national study on the impact of duty hour reform on medical students, 67 of 150 eligible third-year medical students completed surveys about career choice, teaching and supervision, assessment, patient care, well-being, and attractiveness of an internal medicine career after completing their internal medicine clerkship. Non-demographic variables used a 5-point Likert scale from strongly disagree to strongly agree. We assessed the impact of exposure to shift-based schedules on student perceptions of these variables. Chi-squared and Fisher's exact tests were used to assess relationships between exposure to shift-based schedules and student responses. Questions with univariate p<0.1 were included in multivariable logistic regression models.
RESULTS: Of the 67 students, 37 (54 %), were exposed to shift-based schedules. Overall satisfaction with the clerkship was high (>90 %) as was expressed interest in a career in internal medicine or a combined specialty with internal medicine (66 %) and these variables did not vary by exposure. Exposed students were less likely to agree or strongly agree that their attendings were committed to teaching (88 % vs. 100 %, OR 0.35, 95 % CI 0.13–0.90). There was no difference between groups in perceived time to teach by attendings, residents or interns, nor did perceived commitment to teaching vary for residents or interns. However, exposed students were more likely to agree or strongly agree that interns were able to observe them at the bedside (79.4 % vs. 58.1 %, OR 1.89, 95 % CI 1.08–3.13) and had sufficient exposure to assess their performance (97.1 % vs. 80.7 %, OR 3.00, 95 % CI 1.01–8.86), whereas they were less likely to strongly agree or agree that residents had sufficient exposure to assess their performance (88.3 % vs. 90.3 % OR 0.29, 95 % CI 0.09–0.91). Finally, although not statistically significant, there was a trend towards students feeling less team support in the exposed group (OR 0.51, 95 % CI 0.24–1.11).
CONCLUSIONS: Medical student exposure to shift-based schedules with rotating residents had little effect on their perceptions of residents as teachers or their overall satisfaction with their rotation, and seemed to increase the importance of interns in student assessment. However, such exposure appears to adversely affect the relationship between medical students and attending physicians by significantly decreasing attendings' perceived commitment to teaching. It also impacted perceived ability of residents to be able to assess student performance. Moreover, there was a trend toward reduced feeling of team support. These findings suggest that team continuity may have important broader implications for the teaching environment and should be an important consideration when implementing shift-based schedules. The larger study may help further inform these results.

THE IMPACT OF A NOVEL POPULATION MANAGEMENT SYSTEM ON DECREASING EDUCATIONAL DISPARITIES IN COLORECTAL CANCER SCREENING Seth A. Berkowitz; Jeffrey M. Ashburner; Yuchiao Chang; Adrian Zai; Sanja Percac-Lima; Steven J. Atlas. MGH, Boston, MA. (Tracking ID #1624592)

BACKGROUND: Compared to patients with greater than HS (>HS) educational attainment, patients with a high school diploma or less (≤HS) have lower colorectal cancer (CRC) screening rates and 50 % greater risk of CRC mortality. Population management strategies, facilitated by advanced health information technology, are increasingly used to improve

screening rates, but often do not specifically target health inequities. We evaluated whether such a system might still decrease educational disparities in CRC screening.

METHODS: From June 15, 2011 to June 14, 2012 we utilized TopCare (Technology for Optimizing Population Care in a Resource-limited Environment) to identify and manage all patients eligible for CRC screening (men and women age 52–75 without prior total colectomy) within an 18-practice academic primary care network. Practices were randomized to one of two versions of TopCare. Patients overdue for screening received interventions to promote completion including notification of primary care providers, reminder letters, and listing with practice delegates who could schedule tests and visits. Because the two versions of TopCare did not have a differential effect on outcomes (test for interaction was non-significant), we report pooled results. Our primary outcome was CRC screening completion, stratified by patient educational attainment (≤HS vs. >HS), a correlate of low socioeconomic status. We performed descriptive statistics and unadjusted comparisons using chi-square and McNemar's tests. A logistic regression model was used to compare CRC screening completion among patients with complete follow-up. A Cox regression model was used to evaluate time-to-screening completion among all patients overdue for screening at any time during the study period.

RESULTS: Among 40,454 patients in 18 practice sites eligible for CRC screening for the entire study period, 75 % had > HS educational attainment. ≤HS patients were more likely to be non-white, non-English speaking, and have Medicare, Medicaid, or no insurance ($p<.001$ for all comparisons). Prior to TopCare implementation, 73.0 % of ≤ HS patients had completed CRC screening, compared to 80.6 % of > HS ($p<.001$). At the end of the study period, screening completion increased for both groups (+3.2 % for ≤ HS, $p<.001$; + 2.5 % for > HS, $p<.001$). However, a significant disparity in screening completion between ≤ HS and > HS remained (76.2 % vs. 83.1 %, $p<.001$). In a logistic regression model accounting for physician/practice clustering and adjusting for age, gender, race/ethnicity, language, insurance, and TopCare version, ≤HS was significantly associated with lower CRC screening completion (adjusted completion rate 76.8 % in ≤ HS vs. 79.0 % in > HS, $p<.001$). In a multivariable Cox regression analysis among the 11,976 patients overdue for screening during the study period, ≤HS was associated with prolonged time to screening completion (HR 0.89, 95 % CI 0.81–0.98, adjusted for same covariates as above).

CONCLUSIONS: Despite the promise of population management systems to increase the overall use of preventive services, CRC screening disparities did not decrease over a 1-year follow-up period among patients with low educational attainment. Population management approaches that do not specifically address disparities may not improve them, and if less effective in low SES patients may actually widen disparities over time. Future strategies should specifically address causes of CRC screening disparities in order to improve health equity.

THE IMPACT OF THE DIABETES HEALTH PLAN ON CARDIOVASCULAR RISK FACTORS AMONG PATIENTS WITH DIABETES O. Kenrik Duru; Susan Ettner; Norman Turk; Jinnan Li; Ekaterina Vaisberg; Lindsay Kimbro; Carol Mangione. UCLA, Los Angeles, CA. (Tracking ID #1642762)

BACKGROUND: A key objective of the Diabetes Health Plan (DHP), a new disease-specific health plan, is the avoidance of complications among diabetic patients through early identification and increased adherence to preventive care and treatments for cardiovascular risk factors. We conducted analyses to determine whether participation in the DHP is associated with better control of cardiovascular risk factors. We hypothesized that among persons with diabetes, those offered the DHP would have better glycemic (A1c) and lipid (LDL) control relative to those only offered the standard benefit.

METHODS: The DHP includes several enhancements to a standard plan: 1) financial incentives with reduced/eliminated co-pays for medications to lower blood glucose and cholesterol as well as for office visits to the PCP and selected specialists; 2) enhanced access to care management and individualized telephonic coaching; 3) enhanced communication with beneficiaries via online data and adherence tracking; and 4) a compliance design that requires members to comply with evidence-based guidelines to receive enhanced benefits, or potentially be terminated from the plan. For these analyses, we used a longitudinal study design with a before/after comparison group. Patients with diabetes were defined as having any of the following: 1) at least one 250.xx inpatient, outpatient, or ED claim, 2) an A1c value > 6.5 %, or 3) use of insulin or an oral hypoglycemic medication other than metformin. We compared eligible diabetic patients within employer groups that offered the DHP with eligible diabetic patients in employer groups that did not have access to the DHP (controls). We applied propensity score matching to select 5 control employers for each DHP employer, using matching variables including mean salary, member count, % female, and % with a chronic condition. We used a 2 year study window to measure A1c and LDL, with a 1-year "pre" period and 1-year "post" period for both the DHP and control samples, but only included patients who had at least 9 months between their "pre" and "post" lab values in the analyses. We constructed multivariate linear regressions to estimate study outcomes, controlling for individual-level income, race, education, age and gender, and compared change in the last recorded laboratory value within each period using difference-in-difference analyses. Results were expressed as predicted probabilities.

RESULTS: Our analytic sample included 500 patients within DHP employer groups and 751 patients in control employer groups. At baseline, the mean A1c value was 7.17 % in the DHP groups and 7.26 % in the control groups. In difference-in-difference analyses, the change in A1c for DHP patients relative to control patients was −0.27 % ($p=0.002$). At baseline, the mean LDL value was 97.6 mg/dl in the DHP groups and 94.5 mg/dl in the control groups. In difference-in-difference analyses, the change in LDL for DHP patients relative to control patients was −2.7 mg/dl ($p=0.25$).

CONCLUSIONS: We found that the Diabetes Health Plan was associated with a significant decrease in A1c values, but not in LDL values, among patients in DHP employer groups compared with similar patients in control employer groups. These preliminary results provide support for this "real-world" implementation of a disease-specific health plan in terms of improving glycemic control, but additional studies over a longer follow-up period and examining a wider range of outcomes are needed for a complete evaluation.

THE IMPACT OF THE ECONOMIC RECESSION IN LATE 2000S ON ACUTE MYOCARDIAL INFARCTION OCCURRENCE IN DIFFERENT SOCIOECONOMIC AREAS OF NEW JERSEY RARITAN BAY REGION Yulong Li; Iris Rukshin; Fangfang Pan; Shuvendu Sen; Mohammed Islam; Abdalla Yousif; Vladimir Rukshin. Raritan Bay Medical Center, Perth Amboy, NJ. (Tracking ID #1614818)

BACKGROUND: The financial crisis in 2008 started the late 2000s economic recession. During this recession, the Dow Jones Industry Average (Dow Average) decreased over 50 % and the US unemployment rate reached a historical high of 10 %. Previous researches have demonstrated that the incidences of acute myocardial infarction and stroke increased during economic recessions. We hypothesize that socioeconomic inequality in neighborhood of residence can worsen the negative impact of economic recession on AMI incidence. This retrospective case-control study was designed to assess the impact of the economic recession from 12/2007 to 07/2009 on occurrence of acute myocardial infarction (AMI) in different socioeconomic areas of Raritan Bay region, New Jersey (NJ).

METHODS: We analyzed a retrospective cohort of AMI patients that were treated at two main MI centers in Raritan Bay region from 01/2006 to 06/2012. All cases were identified by having AMI as the primary diagnosis at discharge. These cases were divided into two groups based on whether the adjusted annual income (abbreviated as income) of the zip code area they resided in was above or below the NJ state average. Student-*t* test was used to compare the age difference between these two groups. The differences in

gender and presence of co-morbidities (hypertension, diabetes mellitus, and hyperlipidemia) were examined using Chi-square test. Spearman Rank Correlation test was used to examine correlation between monthly AMI occurrence in each group and NJ unemployment rate/Dow Jones Industrial Average in the corresponding month.
RESULTS: A total of 1,467 cases of AMI with residence in Raritan Bay region were treated from 01/2006 to 06/2012. There were 990 AMI patients living in the areas (average income: $44,515; total population: 187,328) with income less than the state average ($52,118), and 477 in the areas (average income: $64,138; total population: 90,013) with income greater than the state average. Between these two groups (lower-income group vs. higher-income group), the differences in age (69.5 vs. 70.1, P=0.50), gender (female/male ratio: 0.857 vs. 0.807, P=0.58), hypertension (46 % vs. 41 %, P=0.07), diabetes (37 % vs. 32 %, P=0.09) and hyperlipidemia (38 % vs. 34 %, P=0.10) were not statistically significant. In the lower-income group, monthly incidence of AMI trended up after onset of the recession and this increase was correlated with the rise of unemployment rate in NJ (coefficient=0.231, P=0.042). In contrast, in the higher income group, monthly occurrence of AMI remained stable and was not correlated with the unemployment rate (coefficient=−0.02, P=0.887). No significant correlation was found between the monthly Dow averages and the AMI incidences in both groups.
CONCLUSIONS: The findings of this study suggest that the residents in low socioeconomic areas have a higher risk for AMI during economic recessions and that unemployment is a contributing factor. This could be caused by several factors, which may include a higher stress level and/or a decreased compliance to treatment of comorbid conditions because of economic strain. Policy makers and social program planners should be aware of such an increased risk for AMI among the residents living in low socioeconomic neighborhoods, and design programmatic interventions to lessen the adverse impact of economic recession on cardiovascular diseases.

THE J-CURVE IN THE CLINIC: IS REAL-WORLD BLOOD PRESSURE AS MEASURED IN OUR CLINICS A MAJOR CARDIAC RISK FACTOR? Jeremy Sussman[1,2]; Wyndy Wiitala[1]; Edward H. Kennedy[1]; Rodney A. Hayward[1,2]. [1]VA Ann Arbor Healthcare System, Ann Arbor, MI; [2]University of MIchigan, Ann Arbor, MI. (Tracking ID #1641896)

BACKGROUND: While systolic blood pressure (BP) has been a strong, consistent predictor of cardiovascular disease (CVD) in risk prediction tools, the BP assessments in most of those studies used rigorous research protocols and consistent measurement techniques. However, the BPs taken in routine clinic practice are known to be much less reliable. Further, few risk prediction tools have accounted for the long-noted "J-shape" of the BP risk curve or examined how the rise of more aggressive BP treatment could alter the association with measured BP and CVD events. In this study we used a large clinical database to see how real-world clinic blood pressure measures are associated with heart disease mortality risk.
METHODS: We conducted a retrospective cohort study of all patients at 12 Veterans' Health Affairs facilities without a documented history of a CVD event or congestive heart failure. The outcome variable was CVD death over 5 years of follow-up starting in 2003, as obtained from the National Death Index. We examined 3 categories of risk predictor variables: traditional risk factors, BP medications used, and comorbidities. We developed risk prediction scores using logistic regression with multivariable regression splines for continuous variables, including scores with and without SBP and DBP as predictors. We used five-fold cross-validation to estimate over-fitting. We assessed each prediction score's predictive performance with the area under the receiver operating characteristic (AUROC) curve and net reclassification improvement (NRI), using cut-points of low risk (<2.5 %), medium risk (2.5 %–10 %), and high risk (>10 %). The NRI assessed how many patients' estimated risk would be reclassified above and below those cut-points when BP was added to the model, and what percentage of those changes would improve the predictive accuracy of the model.
RESULTS: 4880 of 100,354 Veterans (4.8 %) died of CVD during the 5 year follow-up. The full model, excluding the BP variables, had an AUROC of 78.9. Including systolic BP in the model increased the AUROC by 0.1 (to 79.0) whereas including diastolic BP increased the AUROC by 0.3 (to 79.2). In comparison, removing age reduced the AUROC by almost 6.5 (to 72.5). Similarly, the NRI was quite small, at 0.9 % for SBP and 1.1 % for DBP. The relationship between systolic BP and CVD events was clearly J-shaped, with the lowest risk SBP found at 138 mmHg. The weakness of the association between BP and CVD mortality and the existence of a J-shaped curve held regardless of the number of BP-lowering medications a patient was on and was similar for diastolic BP. The relationship between blood pressure and CVD mortality did not become stronger when using a single blood pressure measurement or an average of three measurements. Five-fold cross-validation showed no major over-fitting for any model.
CONCLUSIONS: These results show that in routine clinical practice BP has a very weak association with CVD mortality, but that the slight J-shaped association still holds. This suggests that estimates from most widely used risk calculators will be inaccurate in routine clinical practice unless steps are taken to improve clinic BP measures or until risk calculators based on data from regular clinical use are developed.

THE JOHNS HOPKINS LEARNING ENVIRONMENT SURVEY (JHLES): DEVELOPMENT OF AN EFFICIENT TOOL TO ASSESS STUDENT PERCEPTIONS OF THE MEDICAL SCHOOL LEARNING ENVIRONMENT. Robert Shochet; Jorie Colbert-Getz; Scott Wright. Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #1642672)

BACKGROUND: The medical school learning environment (LE) encompasses the physical, social and psychological context in which students are immersed, and holds significant influence on how students form professional identities, express humanistic behaviors and achieve academic success. Traditional LE assessments provide aggregated institutional or cohort data, and miss the opportunity to consider how individual students might interact differently with the multi-dimensional LE. The objective of this study was to construct a reliable measure of student perceptions of their interface with the social, relational, and academic aspects of the medical school learning environment, and provide a window to potential differences in patterns of engagement.
METHODS: Study subjects were actively enrolled JHUSOM students across 4 classes during the 2011–2012 academic year. We developed a 65-item LE questionnaire created by literature review, iteratively revised, then pilot tested to actively enrolled students in April–July, 2011. We then revised the survey and re-administered with 32-items in the spring of 2012. To assess the internal structure of item scores, EFA was performed on the correlation matrix using principle axis factoring with varimax rotation. Composite JHLES scores were analyzed by gender, race/ethnicity, medical school year, and to overall LE perception with one-way ANOVAs.
RESULTS: In 2012, 377 of the 465 students responded to the survey (response rate=81 %); 49 % of responders were female, 49 % Caucasian, 33 % Asian, 7 % African American, and 4 % Hispanic. Responses by class year: Y-1- 112 (30 %), Y-2-96 (25 %), Y-3- 81 (22 %), Y-4- 88 (23 %). The final factor structure of 28 items grouped into 7 domains, named: community of peers, faculty relationships, academic climate, growth promoting, mentoring, sense of safety, and physical space. These 7 factors accounted for 57 % of the overall variance. Composite LE scores ranged from 51 to 139 with a mean of 107 (SD=15). JHLES scores did not differ significantly by age, gender or race/ethnicity. When comparing ratings of overall perception of the LE to JHLES scores, those perceiving the LE as exceptional (n=64) scored higher than those perceiving the LE as good (n=225), p<0.001, or fair (n=63), p<0.001, or poor/terrible (n=25), p<0.001.
CONCLUSIONS: Relative to published LE studies, the 7 factor, 28-item JHLES accounted for a higher percentage of variance despite its shorter length. JHLES scores correlated linearly with their overall LE perceptions, potentially shedding light on the unique and varying ways students interact with and acclimate to the school's academic climate and socio-relational qualities. Thus, the JHLES might be used as a tool to measure how well

students are navigating the LE to enhance their professional growth and in identifying at-risk students. Limitations include single institution study, recall bias, and students surveyed at one point in time. The JHLES should be studied across institutions to confirm its value as an efficient LE measure, as well as a means to study medical student patterns of interactivity with the LE.

THE NEW FRONTIER OF MEDICATION RECONCILIATION: USE OF AN ELECTRONIC MEDICATION REFILL HISTORY IN PRIMARY CARE Daniel J. Elliott[1]; Elizabeth Mearns[2]; Dominique Comer[2]; Lindsey Olivere[3]; Joseph Couto[2]. [1]Christiana Care Health System, Newark, DE; [2]Thomas Jefferson University, Philadelphia, PA; [3]Duke Univerity, Durham, NC. (Tracking ID #1640231)

BACKGROUND: Medication Reconciliation including assessing adherence is a core responsibility of primary care providers. Providers historically rely upon patients to subjectively report medication usage, but electronic-prescribing networks have made multi-payer pharmacy fill history information increasingly available to clinicians. This data may facilitate medication reconciliation and adherence assessment. The objective of this study is to understand the adoption, utilization, and impact of pharmacy refill data in primary care practice.
METHODS: We conducted a survey of primary care providers in a large community practice network one year after an electronic Medication Refill History became available within the shared electronic health record (EHR). The function allowed providers to retrieve prescription fill data through SureScripts (Arlington, VA). We developed a 14-item survey to assess knowledge of the medication history function within the EHR, previous experience with the system, and identification of barriers to using the function. We also asked providers to identify the potential value of prescription fill data. Surveys were distributed to providers at practice meetings and electronically through SurveyMonkey (Palo Alto, CA). Responses are summarized as proportions.
RESULTS: We received surveys from 55 of 72 providers (76.4 % response rate). Of these, 47 (86 %) were aware of the function within the EHR, and 36 (77 %) had used it previously. Of these 36, 19 (53 %) reported that it was extremely helpful, and 16 (44 %) said it was somewhat helpful to clinical care. Eighty percent (29/36) used the function for 30 % or less of their patients in the previous 3 months. The most common situations that providers reported using the medication history were at the time they are considering prescribing a narcotic (92 %), when seeing a new patient (79 %), and when they have a concern about non-adherence (79 %). Providers were least likely to use it when prescribing a medication for acute illness (36 %). In terms of Medication Reconciliation, providers indicated that when used in the past, the refill history enabled them to confirm adherence to currently prescribed medications (54 %), identify medications that were not on their current medication list (69 %), and identify a potentially significant medication discrepancy (49 %). Barriers to use included delays in access (57 %), concern for inconsistent or incomplete data (15 %), and the time pressures of clinical practice (37 %). All providers reported that a complete, reliable, and accessible medication refill history would be extremely (74 %) or somewhat (26 %) helpful to clinical practice, particularly in the setting of pain management (96 %) and transitions of care (89 %).
CONCLUSIONS: Improvements in information technology infrastructure have increasingly made a patient's multi-payer Medication Refill History available to practicing physicians. Our results suggest that practicing primary care providers may access this data in a variable and selective manner, with emphasis on high-risk situations such as pain management and transitions of care. When used, primary care providers indicate that the data is valuable, including identifying medication discrepancies. If this data is to provide maximum benefit to inform clinical care, implementation should focus on making this data complete and readily-accessible to providers in routine clinical practice.

THE OLDER ADULT SYMPTOM INVENTORY SCALE (OASIS): DEVELOPMENT, RELIABILITY, AND VALIDITY OF A NEW GERIATRIC SYMPTOM BURDEN SCALE Hilary Mosher[1,2]; Skyler Johnson[1]; Peter Kaboli[1,2]. [1]Iowa City VA Healthcare System, Iowa City, IA; [2]University of Iowa Carver College of Medicine, Iowa City, IA. (Tracking ID #1619647)

BACKGROUND: Symptoms are a major driver for health care use, especially in older adults. Assessing presence and burden of symptoms can be challenging in both clinical and research settings. Having a more efficient and effective inventory of symptom presence and burden may facilitate improvements in patient health and satisfaction. The study objective was to develop and test the reliability and concurrent validity of the Older Adult Symptom Inventory Scale (OASIS), a new instrument measuring symptom presence and burden in an elderly population.
METHODS: This prospective cohort study within the Veterans Administration (VA) healthcare system included cognitively intact outpatients aged 65 years and older, including 17 subjects during the development phase and 532 during the testing phase. The 47-item OASIS contains a Count scale and a Bother scale. Both scales were tested for internal consistency, test-retest reliability, and associations with widely used scales to determine concurrent validity.
RESULTS: In reliability testing, the 46-item OASIS symptom Count and Bother scales had excellent internal consistency (alphas>0.9) and excellent test-retest reliability (r=0.77 for Count scale; r=0.86 for Bother scale). Both scales highly correlated (P<0.001) with the SF-36 scale and subscales, the Modified OARS Instrumental Activities of Daily Living, the Geriatric Depression Scale, a single item indicator of well-being, and medication use. The test group found the OASIS practical and useful, with 75 % stating it would provide useful information to health care providers. The most prevalent symptom reported was fatigue (71.6 %), followed by joint pain/ache/stiffness (70.6 %) and drowsiness (61.2 %). All other symptoms, except for hallucinations, were reported by over 12 % of respondents. The most bothersome symptoms, when endorsed were problems having or enjoying sexual intercourse (mean 3.78, mode 5), back pain (mean 3.16, mode 3) and joint pain/ache/stiffness (mean 3.11, mode 2).
CONCLUSIONS: The OASIS Count and Bother scales are practical, reliable and valid instruments to measure symptom burden in an elderly population. Development and use of the OASIS may improve identification of untreated conditions and symptomatic adverse drug events, and permit better longitudinal management in complex medically ill elders.

THE OPTIMAL INTERVAL OF DIABETES MELLITUS SCREENING IN HEALTHY ADULTS: A COMPETING RISK ANALYSIS Osamu Takahashi[1,2]; Gautam A. Deshpande[1]; Sachiko Ohde[1]; Tsuguya Fukui[1,2]. [1]St. Luke's Life Science Institute, Tokyo, Japan; [2]St. Luke's International Hospital, Tokyo, Japan. (Tracking ID #1643149)

BACKGROUND: To identify adults at risk for cardiovascular disease, diabetes mellitus (DM) screening using hemoglobin A1c (HbA1c) is important, but there are few studies regarding the appropriate monitoring interval for re-screening. We aimed to determine the optimal interval for rechecking HbA1c levels below the diagnostic threshold of 6.5 % for healthy adults in Japan.
METHODS: This was a population-based cohort study from 2005 to 2008 in Tokyo, Japan. In healthy adults with HbA1c of <6.5 %, no prior cardiovascular diseases (CVD), and taking no diabetes medication at baseline, we measured the serum HbA1c annually for 4 years. We estimated the optimal interval of screening when the cumulative incidence of HbA1c ≥6.5 % or fasting plasma glucose (FPG) ≥126 mg/dl surpassed 10 %. We used a competing risk analysis adjusting for CVD and anti-diabetic medication as competing risks.
RESULTS: At baseline, 12,440 people (52 % male) with a mean age of 50 years old (SD: 12 years, range: 21–92), had a mean FPG of 98.3 mg/dl (SD: 10.2 mg/dl) and mean HbA1c of 5.3 % (SD: 0.4 %). For those with baseline HbA1c of <5.5 %, 5.5–5.9 %, and 6.0–6.4 %, the cumulative incidences of DM were 0.1 %, 1.6 %, and 17 % at 1 year and 0.2 %, 3 %, and 33 % at 3 years, respectively. Competing risk regression indicated that

hazard ratio (HR) for the cumulative incidence of DM were 6.3 (95 % CI: 4.5–8.8) for baseline HbA1c of 5.5–5.9 % and 51.6 (95 % CI: 36.3–73.3) for baseline HbA1c of 6.0–6.4 %, when using HbA1c <5.0 % as reference. Increased body mass index (HR: 1.1, 95%CI: 1.1–1.7) and male gender (HR: 1.5, 95 % CI: 1.1–2.0) were also associated with an increased cumulative incidence of DM.

CONCLUSIONS: The optimal interval for re-screening healthy adults should be more than 3 years for those with baseline HbA1c of <6.0 % and 1 year for those with baseline HbA1c of 6.0–6.4 %.

THE PHQ-2 DEPRESSION SCREEN PREDICTS ALL-CAUSE MORTALITY FOR UP TO 2 YEARS FOLLOWING HOSPITALIZATION WITH HEART FAILURE Tatiana Deveney[1,2]; Bea Herbeck Belnap[2]; Fanyin He[3]; Sati Mazumdar[3]; Bruce L. Rollman[2]. [1]University of Rochester School of Medicine, Rochester, NY; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]University of Pittsburgh, Pittsburgh, PA. (Tracking ID #1634679)

BACKGROUND: The American Heart Association (AHA) Science Advisory recommends routine screening of cardiac patients for depression with the 2-item Patient Health Questionnaire-2 (PHQ-2). The PHQ-2 assesses for depression and anhedonia, the two cardinal DSM-IV symptoms of depression, and is considered positive if one or both items are endorsed. Reports suggest a positive PHQ-2 is associated with mortality at 1-year following hospitalization with heart failure (HF), but its longer term predictive effect is unknown. (Rollman BL et al., J Cardiac Failure, 2012) The objective of this report is to determine the long-term durability of the association between a positive PHQ-2 screen and all-cause mortality following hospitalization with HF.

METHODS: 471 hospitalized HF patients with an ejection fraction (EF) <40 %, NYHA functional class II-IV symptoms, who were suspected of depression were screened with the PHQ-2 prior to discharge from 4 Pittsburgh-area hospitals (12/07 to 6/09). Sociodemographic, health-related quality of life (SF-12), and clinical information were collected at baseline. We used Kaplan-Meier analyses to calculate the annual incidence of all-cause mortality by PHQ-2 status with log-rank tests for statistical significance. Multivariate Cox models were used to generate hazard ratios (HR) by PHQ-2 status adjusting for differences in baseline covariates and known predictors of heart failure morbidity and mortality.

RESULTS: At baseline, PHQ-2 positive patients (PHQ-2 (+); n=371), compared with PHQ-2 negative patients (PHQ-2 (−); n=100) were younger (age 65 vs. 70) and more likely to report lower levels of function (NYHA Class: 67 % III-IV vs. 61 % II) and health-related quality of life (mean SF-12 MCS: 44 vs. 59) (all p<0.005). We confirmed vital status on 99 % (467/471) of our study cohort as of 6/30/12 (mean follow up: 34.9 months ±17.6 months) and identified 198 deaths (42 %). At both 1- and 2-years follow-up, significantly more PHQ-2 (+) vs. PHQ-2 (−) patients had died (Table), and the mortality risk associated with a positive PHQ-2 persisted even after adjustment for age, gender, EF, and other established predictors of HF mortality (1-year: HR: 3.19 (95 % CI: 1.50–6.80); p=0.003; 2-year: HR: 2.01 (1.19–3.37); p=0.009). However, this difference in mortality risk by PHQ-2 status disappeared by 3 years follow-up (3-year: HR: 1.36 (0.90–2.06); p=0.14; 4-year: HR: 1.44 (0.98–2.12); p=0.07).

CONCLUSIONS: A positive PHQ-2 depression screen is associated with significantly elevated mortality risk for up to 2 years following hospital discharge, even after adjustment for a variety of established predictors of HF mortality. While our findings support the AHA recommendation to screen cardiac patients for depression and confirm the negative impact of depression in patients with heart failure, well designed clinical trials remain necessary to determine whether depression treatment can reduce all-cause HF mortality.

Cumulative Mortality Incidence by PHQ-2 Status

Year	PHQ-2 (+) % (n)	PHQ-2 (−) % (n)	p Value
1st Year	20 (76)	8 (8)	0.005
2nd Year	31 (116)	19 (19)	0.02
3rd Year	37 (138)	33 (33)	0.28
4th Year	43 (161)	37 (37)	0.26

THE PREVALENCE AND CAUSES OF PRESCRIBING AND MONITORING ERRORS IN U.K. PRIMARY CARE Sarah P. Slight[1,2]; Rachel Howard[3]; Maisoon Ghaleb[5]; Nick Barber[5]; Bryony D. Franklin[5,6]; Anthony J. Avery[2]. [1]Brigham and Women's Hospital, Boston, MA; [2]University of Nottingham, Nottingham, United Kingdom; [3]University of Reading, Reading, United Kingdom; [4]The University of Hertfordshire, Hatfield, United Kingdom; [5]University College London, London, United Kingdom; [6]Imperial College Healthcare NHS Trust, London, United Kingdom. (Tracking ID #1628834)

BACKGROUND: Prescribing is an essential task for any doctor. Errors can and do occur when prescribing, the majority of which are preventable. Relatively little is known about the prevalence and underlying causes of prescribing and monitoring errors in primary care. We conducted a large-scale, mixed methods study in a broad range of English family practices to address this knowledge gap, and provide recommendations for how these errors may be overcome.

METHODS: Fifteen family practices were purposively selected within three Primary Care Trusts (PCTs) with differing characteristics (inner-city London, urban and suburban/rural) to participate. Four trained pharmacists undertook a retrospective review of unique medication items, prescribed over a 12-month period, to a 2 % random sample of patients. The severity of each error identified was assessed on a reliable, validated, ten-point scale. The primary outcome measure was binary, indicating the presence of one or more prescribing or monitoring errors, and modelled using logistic regression. The significance of the variables in the models was assessed using the Wald chi-squared test and determination of odds ratio (OR) with associated 95 % confidence intervals (CI). All statistical analyses were performed using STATA (version 11.2, Stata Corp LP). A wide range of different types of the more serious errors was also discussed with members of practice staff (n=80) to explore the underlying reasons why these errors occurred. Interviews were audio-recorded with permission and transcribed verbatim. A list of main- and sub-themes was applied systematically to the whole data set with the aid of qualitative analysis software QSR N-Vivo version 8.0.

RESULTS: Prescribing and/or monitoring errors were detected in 4.9 % (296/6048) of all prescription items (95 % CI 4.4–5.5 %). Modelling suggested that the factors associated with an increased risk of error in patients were: age less than 15 years (OR 1.81, 1.15 to 2.85, p=0.010) or greater than 64 (OR 1.67, 1.03 to 2.71, p=0.037), and higher numbers of unique medication items prescribed (OR 1.16, 1.12 to 1.19, p<0.001). The vast majority of errors were of mild to moderate severity, with 0.2 % (11/6048) of items having a severe error. Seven categories of high-level error-producing conditions were identified: the prescriber, the patient, the team, the task, the working environment, the practice computer system, and the primary/secondary care interface. Further subcategories were identified within each of these. The prescriber's therapeutic training, drug knowledge and experience, knowledge of the patient, perception of risk, and their physical and emotional health, were all identified as possible causes. The working environment with its high workload, time pressures, and interruptions, and computer related issues, were all highlighted as possible causes and often interconnected.

CONCLUSIONS: Prescribing and monitoring errors, while mainly of minor significance, are common in English family practice. Several factors were found to increase the risk of error. These findings suggest that substantial improvements could be made to the safety of prescribing in family practices.

THE PREVALENCE, PREDICTORS, AND COST OF FUTILE TREATMENT IN THE INTENSIVE CARE UNIT Neil Wenger; Thanh N. Huynh; Eric Kleerup. UCLA, Los Angeles, CA. (Tracking ID #1631453)

BACKGROUND: Medicine is now able to keep patients alive for long periods of time in conditions such as permanent unconsciousness and permanent dependence on ICU-level treatment, conditions that nearly all people would not want. When a patient's chance of survival is very low or the quality of life is markedly diminished, intensive care interventions that

prolong life without achieving the goals of medicine are often considered "futile" by health care providers. We aimed to quantify the prevalence, cost, and predictors of futile treatment at one academic health system.
METHODS: A focus group of clinicians who provide care for critically ill patients was convened to develop a common definition of futile critical care treatment. On a daily basis for 3 months, we surveyed critical care specialists in five ICUs at an academic health care system to identify patients that clinicians felt were receiving futile treatment. Using a multivariate model, we identified patient and clinician characteristics associated with patients receiving futile treatment. We calculated the cost of futile treatment by summing daily hospital charges after a patient was assessed to be receiving futile treatment.
RESULTS: The 6,916 assessments by 36 critical care specialists on 1,136 patients over 3 months found that 904 (80 %) patients never received futile treatment, 98 (8.6 %) patients received probably futile treatment, and 123 (11 %) patients received futile treatment. These 123 patients received 464 days of futile treatment in critical care (ranging from 1 to 58 days), accounting for 6.7 % of all assessed patient days in the five ICUs. Eighty-four of the 123 futile patients died before hospital discharge and 20 patients died within 6 months of ICU care (6-month mortality was 85 %) with survivors remaining in severely compromised health states. Patients who were older, male, African American, admitted from a nursing home or long term acute care facility, cared for in the medical ICU, and had longer hospital stays were more likely to be assessed as receiving futile treatment. The proportion of variation in futile treatment assessment accounted for by patient factors was 10 times the size of that accounted for by physician characteristics. The cost of futile treatment in critical care was estimated to be $5.3 million for this 3 month period at one academic health system.
CONCLUSIONS: At the studied center, futile treatment in critical care is common, affecting more than 1 out of every 10 critical care patients. Futile treatment in critical care can be identified prospectively and its cost is not insignificant, exceeding an estimated $20 million annually at one medical center. Efforts are needed to identify patients receiving futile treatment and to explore methods to re-orient treatments to better serve patients.

THE RELATION BETWEEN SUBJECTIVE SOCIOECONOMIC STATUS, DEPRESSION AND SELF-RATED HEALTH IN A POPULATION OF AFRICAN AMERICANS, HISPANICS AND NON-HISPANIC WHITES WITH DIABETES Jose A. Delgado[1]; Elizabeth A. Jacobs[2]; Nancy E. Adler[3]; Keegan Korthauer[5]; Alicia Fernandez[5]. [1]Georgetown University Hospital, Washington, DC; [2]University of Wisconsin School of Medicine and Public Health, Madison, WI; [3]University of California, San Francisco, San Francisco, CA; [4]University of Wisconsin School of Medicine and Public Health, Madison, WI; [5]University of California, San Francisco, San Francisco, CA. (Tracking ID #1643166)

BACKGROUND: The prevalence of chronic medical conditions is increasing among minority populations compared to non-Hispanic whites. Studies of the factors contributing to these disparities have focused on objective measures of socioeconomic status (OSS) rather than minority individuals' perception of their subjective social status (SSS). Our objective was to examine the relationship between subjective social status, depression and self-rated health to explore whether or not the relationship between SSS and these conditions differed across African Americans, Mexican Americans, and non-Hispanic whites with diabetes.
METHODS: We conducted a survey and abstracted data from the medical records from 711 diverse patients seeking care for diabetes in safety net institutions in Chicago and the Bay Area. SSS was measured using the McArthur scale. Depression symptoms were determined by using the Patient Health Questionnaire (PHQ-9). Participants were asked about their general health during the 4 weeks prior to the survey using a standard single-item indicator of self-reported general health from the SF-8 Health Survey. Kruskal-Wallis and Wilcoxon rank sum tests were used to test for racial differences in SSS. Logistic regression models were used to evaluate the effect of SSS on depression and self-rated health.
RESULTS: There were significant differences in SSS among the three racial groups when ranking themselves in their communities ($p<0.0001$) and within the US overall ($p=0.0306$). For SSS in the community, African Americans had significantly higher average rankings than both Mexican Americans ($p<0.0001$) and non-Hispanic Whites ($p=0.0035$). The difference between Mexican Americans and non-Hispanic Whites was not significant after adjusting for multiple comparisons ($p=0.0375$, significance level of multiple comparisons requires $p<0.017$). We found a significant relationship between SSS and both depression and self-rated health ($p<0.01$). This effect was observed in both the US and the community ladders. Higher SSS was inversely related to depression, while higher SSS was found to be associated with higher overall health status
CONCLUSIONS: Subjective and objective social status are two important factors involved in the presence of common chronic conditions. Characterizing the effect of SES on depression and self-rated health could lead to better targeted interventions in different ethnic communities.

THE RISK OF THIAZIDE-INDUCED ADVERSE EFFECTS IN OLDER ADULTS Anil N. Makam[1]; W. John Boscardin[1,2]; Yinghui Miao[1,2]; Michael Steinman[1,2]. [1]University of California, San Francisco, San Francisco, CA; [2]San Francisco VA Medical Center, San Francisco, CA. (Tracking ID #1631749)

BACKGROUND: While thiazide diuretics have been shown to be safe in older adults within the context of randomized controlled trials, relatively little is known about the risk of thiazide-induced adverse effects (AEs) among older adults with hypertension in real-world settings. We sought to evaluate the magnitude of the risk of thiazide-induced metabolic AEs in older adults with hypertension and to examine whether age and comorbid burden increase this risk.
METHODS: This is an observational cohort study using national data from the Department of Veterans Affairs. Veterans aged 65 years or older with hypertension who were newly prescribed a thiazide diuretic ($N=1,163$) or were non-users of first-line anti-hypertensive medications ($N=21,666$) between July and December 2007 were followed for up to 15 months. We performed a propensity score analysis accounting for clustering within medical centers to compare new thiazide users ($N=1,041$) to nearest matched non-users ($N=1,041$) on the primary composite outcome of mild AEs and secondary outcomes of severe AEs, emergency department (ED) visits for AEs, and hospitalizations for AEs. Mild AEs were defined as sodium <135 meq/L, potassium <3.5 meq/L, or a decrease in estimated GFR by more than 25 % from baseline. Severe AEs were sodium <130 meq/L, potassium <3.0 meq/L, or a decrease in estimated GFR by more than 50 %. We used multivariable logistic regression to analyze age and comorbidity count as predictors of developing AEs among thiazide users.
RESULTS: Among thiazide users, only 49 % had follow-up laboratory testing within 3 months after the index date. Compared to matched non-users, new users of thiazide diuretics had an absolute risk increase of 7.1 % for at least one mild AE (3.5 % for hyponatremia, 3.0 % for hypokalemia, and 1.6 % were at risk for kidney injury; NNH=15, $p<.001$), 1.2 % for at least one severe AE (NNH=87, $p=.03$), and 1.7 % for an ED visit or hospitalization for AEs (NNH=58, $p=.04$). Among thiazide users, having 5 or greater comorbidities compared to 1 comorbidity (hypertension) was associated with 2.9 times the odds of developing a mild AE (95 % CI, 1.4–5.8). There was no relationship between advancing age and the composite outcome of any mild AE (OR 1.2, 95 % CI, 0.9–1.7); however, each 10 years increase in age was associated with 1.5 times the odds of developing mild hyponatremia (95 % CI, 1.0–2.2).
CONCLUSIONS: Although 1 in 15 elderly patients with hypertension prescribed a thiazide diuretic develop a mild metabolic adverse effect and 1 in 87 patients a severe adverse effect, less than half of the patients have follow-up laboratory monitoring within 3-months. Closer monitoring is warranted after initiation of thiazide diuretics, especially among older adults with multiple chronic conditions.

THE ROLE OF COGNITIVE PERFORMANCE ON THE RELATIONSHIP BETWEEN PAIN AND PHYSICAL FUNCTION IN OLDER ADULTS WITH KNEE OSTEOARTHRITIS Natalia Morone[2,1]; Kaleab Abebe[1]; Lisa Morrow[1]; Debra K. Weiner[2,1]. [1]University of PIttsburgh, Pittsburgh, PA; [2]Veterans Affairs Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1634860)

BACKGROUND: There is evidence of an association between physical functional decline and cognitive decline prior to the onset of dementia. In patients with chronic non-malignant pain, diminished cognitive function has also been associated with pain severity. Given this early evidence of an association between early cognitive decline, chronic pain, and decreased physical function, our objective was to corroborate and extend these findings to older adults with knee osteoarthritis (OA)-associated chronic pain. We hypothesized that higher levels of self-reported chronic knee OA pain would be associated with decreased executive cognitive function and decreased physical function among cognitively intact older adults with advanced knee OA.
METHODS: We performed a cross-sectional secondary data analysis on 79 Veterans who had participated in a Veteran's Affairs clinical trial of periosteal stimulation for advanced knee OA. Participants had to be ≥60 years, have pain of at least moderate intensity (pain occurring most days of the week and of at least 3 months duration), and meet clinical criteria for painful knee OA. Measures included executive function tests of cognitive performance (Computer-Based Assessment of Mild Cognitive Impairment), pain (McGill Pain Questionnaire-Short Form) and physical function measures (gait speed and stair climbing). Descriptive statistics for the sample as a whole were generated. Linear regression models were run on the variables of interest. We carried out exploratory analyses to see if cognitive performance affected the relationship between pain and physical function, which could suggest a potential mediating relationship. This was done using the template of Baron & Kenny.
RESULTS: The sample was predominantly male, 76/79 (96 %), white 57/79 (72 %), and overweight (mean body mass index=31). Pain had a significant relationship with gait speed and stair climbing so that as pain scores worsened gait speed and stair climbing worsened (P=0.007, 0.035, respectively). Higher performance on the executive function tests was also significantly associated with improved gait speed and stair climbing (P=0.002, P=0.014 respectively). We did not find a significant relationship between pain and cognitive performance. We explored the relationship between pain and physical function adjusted for cognitive performance and found that pain was no longer associated with gait speed (P=0.06), suggesting cognitive function mediated this relationship.
CONCLUSIONS: Deterioration in physical function was associated with deterioration in cognition in cognitively intact older adults with chronic painful knee OA. This suggests slower gait speed in patients could be an indication to clinicians to monitor their patient's cognitive function. Executive function in particular affected the relationship between gait speed and pain suggesting a possible mediating relationship.

THE ROLE OF INTERNS AS TEACHERS: INTERNS' AND MEDICAL STUDENTS' PERCEPTIONS David R. Linz; Carla Spagnoletti. University of Pittsburgh School of Medicine, Pittsburgh, PA. (Tracking ID #1638727)

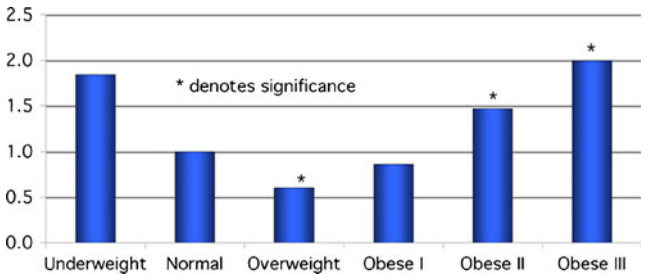
BACKGROUND: Teaching is a vital skill of physicians and one that typically develops in residency. While published studies report that residents-as-teachers curricula improve teaching skills, none have described the unique role or needs of interns as teachers. The objective of this study was to explore the knowledge, attitudes, and reported teaching behaviors of interns who work with medical students and to assess medical students' perceptions of their interns' teaching behaviors in an environment where no formal interns-as-teacher curriculum exists.
METHODS: In November 2012, the prior class (2011–2012) of categorical, medicine/pediatrics, preliminary and transitional interns at a university-based (N=66) and a community-based (N=18) internal medicine training program in Pittsburgh were surveyed electronically. Prior teaching experience and education, perceived comfort with and barriers to teaching, and reported teaching quality and frequency were assessed. Concurrently, a sample of 2011–2012 third-year medical students (MS3's) who worked with these interns during their inpatient medicine clerkship (N=20) were surveyed to assess their perceptions of intern teaching quality and frequency, and perceived facilitators and barriers to teaching. Both surveys were anonymous. Descriptive statistics were performed for demographic items. Percentage correct was calculated for multiple choice knowledge-based items. Frequencies, means and standard deviations were calculated for attitudinal and skill items.
RESULTS: Of those surveyed, 69 % of former interns responded. Among them, 31 % reported prior teaching experience and 29 % prior training in teaching. The average percentage correct for knowledge items was 72 %. A total of 74 % felt interns play an important role in the education of MS3's, but only 24 % had confidence in their teaching ability, 22 % were aware of their expectations as a teacher, and 21 % felt well prepared to teach during their internship. Among the 80 % of former MS3's who responded, 81 % felt interns play an important role in the education of third year medical students. Former MS3's estimated that they spent an average of 25 h per week interacting with interns during their medicine clerkship and that one-third of the clinical knowledge learned on that clerkship was taught by interns. The mean rating for teaching quality in 15 teaching scenarios was 3.1 (SD 0.8) by former interns and 3.1 (SD 0.7) by former MS3's (5-point Likert-type scale where 1 = poor, 3 = average, and 5 = excellent). The mean rating for teaching frequency of 22 teaching tasks ranged from 0.5 to 2.9 by former interns and 0.6 to 3.3 by former MS3's (5-point scale where 0 = never, 1 = rarely/0–1 time(s) per week, 2 = occasionally/2-6 times per week, 3 = usually/once per day, and 4 = all the time/more than once per day). Both former interns and medical students agreed on the following as the three greatest barriers to intern teaching: heavy workload, distractions, and stress.
CONCLUSIONS: Though former interns and MS3's felt that interns play an important role in the education of medical students, most interns did not feel well-prepared to teach, lacked confidence in their teaching skills, and were unaware of their expectations as teachers. Therefore, curricula targeted specifically at developing the teaching skills of interns are needed.

THE ROLE OF OBESITY AND DIABETES IN PERSISTENT NEUTROPHILIA Margarita Kushnir; Hillel W. Cohen; Henny H. Billett. Montefiore Medical Center and the Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1642147)

BACKGROUND: Chronic neutrophilia is a relatively common problem in primary care clinics that often leads to an expensive and invasive work-up. Prior studies have linked obesity with leukocytosis and other markers of inflammation. We examined this association further to determine the degree of obesity at which the risk of neutrophilia increases. We also investigated whether the frequently coexisting diabetes may be a confounder in this relationship.
METHODS: Data from Montefiore Medical Center primary care clinics were obtained from electronic medical records. All patients (age ≥21 year) that had 3 outpatient complete blood cell counts checked, 2–24 months apart, over a period of 6 years, were included. Patients with hematologic disorders or those on medications that may cause leukocytosis were excluded from the study. Patients were stratified according to WHO-defined BMI criteria into six groups: Underweight (BMI <18.5), Normal (BMI 18.5–24.9), Overweight (BMI 25–29.9), Obese Class I (BMI 30–34.9), Obese Class II (BMI 35–39.9), and Obese Class III (BMI≥40). Persistent neutrophilia was defined as an absolute neutrophil count (ANC) of ≥7.8 x109/L on at least three occasions. Neutrophilia rates were compared by chi-square analysis. Odds ratios (OR) were estimated with multivariate logistic regression models. A two-tailed alpha of 0.05 was used to denote significance.

RESULTS: Data on 34,508 Bronx patients were collected; 12,993 (37.7 %) were diabetic and 6,698 (19.4 %) were smokers. A total of 563 patients (1.6 %) had persistent neutrophilia. For simplicity, the following results are from our non-smoker cohort but our overall population had a very similar trend. When comparing odds ratios of neutrophilia by BMI group a parabolic trend emerged, as depicted in Figure 1. While Obesity Class I was not associated with a statistically significant increase in risk, there was a strong association with neutrophilia in Obese Class II and III patients (Obese II: OR 1.47, 95%CI: 1.04, 2.08, p=0.03; Obese III: OR 2.00, 95%CI: 1.41, 2.83, p<0.001). The risk of persistent neutrophilia was actually decreased in Overweight patients (OR 0.60, 95%CI: 0.43, 0.84, p=0.003) compared to patients in the Normal BMI group. In the overall population, smokers had an increased risk of neutrophilia (OR 2.00, 95%CI: 1.67, 2.40, p<0.001). Diabetes was also independently and strongly associated with persistent neutrophilia (OR 1.82 95%CI: 1.52, 2.19, p<0.001).

CONCLUSIONS: Overall, there was a significant association of persistent neutrophilia with obesity only with BMI≥40 (with smokers excluded, BMI≥35 was significant). We conclude that persistent neutrophilia is associated with obesity but only in the very obese and has a signficant association with diabetes.



THE ROLE OF PROVIDER CONTINUITY IN RACIAL DISPARITIES IN CHRONIC CARE OUTCOMES Rose M. Kakoza[1]; Thomas D. Sequist[1,2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA. (Tracking ID #1642722)

BACKGROUND: Racial and ethnic minorities achieve worse health outcomes for chronic illnesses; and these groups may also receive more fragmented primary care. We analyzed the contribution of primary care continuity to racial disparities in quality of care for hypertension and diabetes.

METHODS: We used electronic health record data to identify 14,413 adults with diabetes and 36,882 adults with hypertension cared for by 225 primary care physicians across 15 health centers in a multispecialty group practice. Eligible patients were white, black, or Hispanic and had an assigned primary care physician with at least one primary care visit between 2009 and 2012. We measured primary care continuity during 2009–2011 and assessed quality of care in 2012. Continuity was measured using the Usual Provider Continuity (UPC) index, defined as the ratio of visits made to the assigned primary care physician to the total number of primary care visits including those to nurse practitioners, physician assistants, and covering physicians. The index ranges from 0 (low continuity) to 1 (high continuity). For diabetics, we assessed rates of control of HbA1c (<7.0 %), LDL cholesterol (<100 mg/dL), and blood pressure (<130/80 mmHg). For patients with hypertension, we assessed rates of blood pressure control (<140/90 mmHg). We fit multivariable logistic regression models adjusting for age, gender, and insurance status to analyze 1) the association between each chronic care outcome and primary care continuity (UPC); 2) the association between each chronic care outcome and patient race/ethnicity and 3) the impact of primary care continuity on racial/ethnic disparities in each chronic care outcome.

RESULTS: The majority of the study cohort was male (51 %) and commercially insured (66 %), with a mean age of 58 years. The majority of patients were white (74 %), with the remainder black (21 %) and Hispanic (4 %). The mean UPC index was 0.54 for patients with diabetes and 0.57 for patients with hypertension, and did not vary according to patient race/ethnicity. Among all diabetics, UPC index was significantly associated with achieving control of HbA1c (OR 1.19; 95 % CI 1.06–1.34), LDL cholesterol (OR 1.14; 95 % CI 1.00,1.30) and blood pressure (OR 1.28; 95 % CI 1.13–1.44). Among all patients with hypertension, UPC index was significantly associated with achieving blood pressure control (OR 1.28; 95 % CI 1.05–1.57). Among patients with diabetes, blacks (OR 0.90; 95 % CI 0.83–0.98) and Hispanics (OR 0.74; 95 % CI 0.62–0.89) were less likely than whites to achieve HbA1c control; and blacks were less likely than whites to achieve control of LDL cholesterol (OR 0.79; 95 % CI 0.68–0.90) and blood pressure (OR 0.74; 95 % CI 0.63–0.87). Among patients with hypertension, blacks were less likely than whites to achieve blood pressure control (OR 0.86; 95 % CI 0.75–0.98). These significant racial disparities in diabetes and hypertension outcomes were not significantly changed after adjusting for primary care continuity.

CONCLUSIONS: We identified relatively high rates of primary care continuity, which were associated with improved outcomes for patients with diabetes and hypertension. Significant racial disparities in chronic care outcomes were not related to the degree of primary care continuity. Programs including patient-centered medical homes may need to focus on more than pairing patients and physicians to impact existing racial disparities in quality of chronic care.

THE ROLE OF SOCIAL SUPPORT IN DRUG AND ALCOHOL USE AMONG FORMER PRISON INMATES **SUSAN CALCATERRA MD, MPH, BRENDA BEATY MPH, INGRID A. BINSWANGER MD, MPH, MS** Susan L. Calcaterra[1,2]; Ingrid A. Binswanger[2,1]; Brenda Beaty[3,4]. [1]Denver Health Hospital, Denver, CO; [2]University of Colorado, Aurora, CO; [3]University of Colorado, Aurora, CO; [4]Children's Hospital Colorado, Aurora, CO. (Tracking ID #1638479)

BACKGROUND: Prison inmates are at an increased risk of death upon prison release. Prior work suggests that overdose due to drugs and alcohol is a leading cause of death among recently released inmates. Among the non-incarcerated population, factors such as perceived social support, in the form of marriage and healthy relationships with family and friends, have been shown to be protective in maintaining abstinence. Factors which predict drug or alcohol use in prison inmates have not been examined. We aimed to identify factors associated with drug use and hazardous alcohol use in a population of recently released prison inmates.

METHODS: This study involved in-person, structured interviews with 200 former prison inmates recruited within 3 weeks of prison release as part of a prospective cohort study. Interviews were conducted using computer assisted survey software for sensitive questions. Sociodemographic characteristics were obtained during the baseline interview. Follow-up interviews were conducted after 3 months with 155 participants (76 % retention). Associations between perceived social support and drug use and/or hazardous drinking behaviors were determined using data obtained during the 3 month post release interview. Hazardous drinking behaviors were determined by using questions taken from the Alcohol Use Disorders Identification Test-Consumption (AUDIT-C) questionnaire, a 3-item alcohol screen that reliably identifies hazardous drinking behaviors. Drug use and alcohol use responses were not mutually exclusive. Social support was characterized as1) perceived conflict among family or friends, 2) employment status, 3) marital status, and 4) housing status. Associations between past 30 days drug use and/or hazardous drinking behaviors were examined using Fisher's exact tests and Wilcoxon tests. Multivariable logistic regression was used to assess the independent association of perceived social support with past 30 day substance use and/or hazardous drinking behaviors.

RESULTS: Of the 155 respondents, 73.6 % (n=114) were male. In the past 30 days, 17.5 % (n=27) had used drugs and 20.7 % (n=32) had exhibited hazardous drinking behaviors. Among those who used drugs, 63.0 % (N=17) were male, 40.7 % (n=11) were non Hispanic black, and the mean age was 43.4 years old (SD 8.9). Among those who exhibited

hazardous drinking behaviors, 75 % (n=24, p=NS) were male and had a mean age of 39.5 years old (SD 7.8; p=0.03). Among non Hispanic whites (NHWs), the majority reported hazardous drinking behaviors (46.9 %, n= 15 vs. 29.3, n=36, respectively; p=0.01). After adjusting for the effects of drug use on major social obligations, being bothered by family problems was associated with drug use (adjusted odds ratio [AOR] 3.27, 95 % CI 1.30–8.19). After adjusting for race/ethnicity, being bothered by family problems was also associated with hazardous drinking (AOR 2.28, 95 % CI 1.05–6.87). Being homeless was not found to be associated with drug use or hazardous drinking behaviors in the adjusted models.
CONCLUSIONS: Former inmates with perceived family problems had increased odds of past 30 day drug use and hazardous drinking behaviors. Future studies need to confirm a protective effect of family support and post-release substance use. These findings support a future study which would examine the effect of improving family relationships on post-release substance use.

THE ROLE OF THE PCP IN PREVENTIVE CANCER SCREENING USING A NOVEL POPULATION MANAGEMENT SYSTEM
Steven J. Atlas[1]; Jeffrey M. Ashburner[1]; Adrian Zai[2]; Yuchiao Chang[1]; Sanja Percac-Lima[1]; Douglas Levy[1]; Richard W. Grant1. [1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA. (Tracking ID #1633208)

BACKGROUND: Preventive cancer testing rates remain suboptimal despite known benefits of screening and use of visit-based reminders. Advances in health information technology (HIT) now permit population-based screening, but the best methods remain uncertain. We implemented a novel visit-independent, population management system within a large primary care (PC) network and compared two versions: one that involved PC providers (PCPs) in patient screening and one that did not. We hypothesized that involving PCPs would lead to more effective and efficient cancer screening.
METHODS: We randomized 18 PC sites within an academic network to intervention (n=9) or augmented usual care control (n=9) groups. Patients eligible for breast, cervical and colorectal cancer screening were included. All practices employed a novel HIT system that identified patients overdue for screening, mailed reminder letters, and tracked scheduling and completion of screening; used scheduling delegates to assist patients; and had access to patient navigators for those at high risk for non-adherence. In intervention practices, physicians (for their patients) and population managers (for other practice patients) personally screened real-time rosters of patients overdue for screening, and could choose an individualized method of patient contact (reminder letter, referral to scheduling delegate, referral to patient navigator) or defer screening. In control practices, all overdue patients were initially sent a reminder letter without provider review and then transferred to a delegate list. Intervention patients without provider action within 8 weeks defaulted to the automated control version. We examined average cancer screening test completion over 1-year of follow-up for each eligible patient and all eligible cancers using a mixed effects model accounting for clustering by PCP or practice and adjusting for age, race, insurance, language, and time since last visit.
RESULTS: Among 104,074 eligible patients, baseline screening rates were similar in intervention and control patients for breast (79.4 % vs. 79.8 %), cervical (80.9 % vs. 82.0 %), and colorectal (77.6 % vs. 76.4 %) cancer. Small but statistically significant differences in patient characteristics for age, gender, ethnicity, language spoken, insurance status and time since last visit were seen among intervention (n=51,166) and control (n= 52,908) patients (all p<0.001). Most intervention providers used the tool (88 of 98, 90 %) and reviewed 8,115 patients overdue for at least 1 cancer screening (6,017 selected to receive a reminder letter, 407 referred directly to a scheduling delegate, 48 referred to a patient navigator, and 1,744 were deferred from screening). An additional 6,159 letters were sent to intervention patients not reviewed by a provider (total 12,176 letters). In control practices, 17,237 patient letters were mailed. Adjusted average cancer screening rates did not differ among intervention and control practices for all cancers combined (79.6 % vs. 79.6 %, p=0.87), or breast (79.7 % vs. 79.7 %, p=0.98), cervical (80.6 % vs. 81.3 %, p=0.58), or colorectal cancer (78.0 % vs. 77.5 %, p=0.78).
CONCLUSIONS: Involving providers in a visit-independent, population management HIT system for breast, cervical or colorectal cancer screening did not increase screening rates compared to an automated reminder system. However, similar screening rates were achieved with fewer patient contacts in intervention practices.

THE SILO NEXT DOOR: PRIMARY CARE LEADERS' PERSPECTIVES ON COLLABORATING WITH HOSPITALS DURING HOSPITAL-TO-CLINIC CARE TRANSITIONS IN THE SAFETY NET
Oanh K. Nguyen[1]; Jenna Kruger[1]; S. Ryan R. Greysen[1]; Audrey Lyndon[2]; L. E. Goldman1. [1]University of California San Francisco, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA. (Tracking ID #1642926)

BACKGROUND: Poorly coordinated care between hospital and outpatient settings, and delayed access to primary care contributes to hospital readmissions. Given financial penalties for readmissions, hospitals are investing in interventions to improve care transitions following discharge. In parallel, Medicaid managed care organizations are providing incentives to primary care clinics to improve care coordination. Despite this, there is little collaboration between hospitals and primary care practices in efforts to improve care coordination following discharge. We sought to understand what primary care leaders perceived as barriers and facilitators to working with hospitals to improve patient transitions from acute inpatient hospital settings to outpatient care.
METHODS: We conducted semi-structured telephone interviews with primary care leaders in California, focusing on 'safety net' clinics serving Medicaid and uninsured patients, who are at higher risk of readmission. We purposely sampled clinics to maximize variation in geography, urban vs. rural, and types of county health systems. Participants included medical directors, CEOs, and clinic champions for transitional care, care coordination or quality improvement. Questions focused on barriers and facilitators to collaboration with hospitals, including clinic priorities and quality improvement efforts, past or on-going collaboration with hospitals, and existing infrastructure. We systematically coded transcripts to identify emergent, recurring policy-relevant themes using thematic analysis and an inductive framework strategy.
RESULTS: We interviewed 21 primary care leaders (45 % response) at safety net clinics in 10 urban and rural counties. We identified the following themes around working with hospitals on transitions: Barriers: 1) current reimbursement does not provide incentives for care coordination; 2) competing priorities for resources (spending on physical infrastructure, expanding clinic capacity, core clinic functions, and measurement of policy-mandated quality measures) limits opportunities to focus on transitions and hospital collaboration; 3) lack of a shared communication infrastructure connecting settings/institutions. Facilitators: 1) external funding support for dedicated personnel and program development; 2) existing personal relationships with hospital leaders; 3) having a large number of shared patients with a hospital; 4) alignment of clinic and hospital missions.
CONCLUSIONS: Primary care leaders perceived reimbursement, competing priorities and lack of a shared communication infrastructure as major barriers to hospital collaboration, while facilitators included external funding, relationships with hospital leadership, a shared patient population and alignment of organizational priorities. Stakeholders interested in improving care coordination after discharge should consider revising reimbursement policies to align hospital and primary care incentives, providing resources for dedicated personnel and program development and facilitating information technology interoperability.
Table: Themes with Representative Quotes
Theme Representative Quote
Barriers Current reimbursement structure does not provide incentives for care coordination \"Fix the reimbursement system. That is the single biggest issue and that is what causes silos; it is the biggest impediment for hospitals and safety net providers to work together.\"
Competing priorities: spending on core clinic functions \"I think we're all financially strapped enough. You know, it looks like we're getting all these

big, big bucks but it's amazing how fast those…bucks go when you're providing medications, labs, and…other things for your patients. So I think that intentionally puts a strain on a relationship.\"
Competing priorities: clinic expansion \"Well, our biggest priority lately has been finding enough space to see the volume of patients.\"
Competing priorities: policy-mandated quality measures \"Now the focus is more towards the number of clinic visits that we have to make in order to qualify for certain government funding. [This] could be standing in the way of how to really best deliver care.\"
Lack of shared communication infrastructure across settings \"It's a lot of effort to get medical records back. It is often not timely…When patients do go to the ER and get admitted, we may or may not find out about it. So, the chances are that the very high risk, high cost, high frequency patients that are going to cycle in and out of more costly acute care is greater because we don't know that its happening. So, communication between facilities is one of the most challenging issues.\"
Facilitators Existing personal relationships with hospital leaders \"Our CEO…has had very deep and ongoing relationships with the [hospital] management and their leadership. So this has been a longstanding, well-developed relationship.\"
Alignment of clinic and hospital missions \"The local hospital…a lot of our missions are actually very intertwined, and so…they have actually sought us out to be more involved in hospital administrative work for their discharging.\"

THE SYMPTOMS OF GASTROESOPHAGEAL REFLUX DISEASE, GERD, ARE CORRELATED WITH BODY MASS INDEX, AST/ALT RATIO AND INSULIN RESISTANCE IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE IN JAPAN Motoshi Fujiwara[1]; Yuichiro Eguchi[2]; Hidetoshi Aihara[1]; Naoko E. Furukawa[1,2]; Hitoshi Eguchi[1]; Masaki Tago[1]; Motosuke Tomonaga[1]; Tsuneaki Yoshioka[1]; Masaki Hyakutake[1]; Yuta Sakanishi[3]; Itaru Kyoraku[1]; Takashi Sugioka[3]; Kazuma Fujimoto[5]; Shu-ichi Yamashita[1]. [1]Saga Medical School, Saga, Japan; [2]Saga Medical School, Saga, Japan; [3]Saga Medical School, Saga, Japan; [4]Saga Medical School, Saga, Japan. (Tracking ID #1635977)

BACKGROUND: In western countries, there is a significant relationship between the prevalence of gastroesophageal reflux disease (GERD) and metabolic syndrome consisting of visceral obesity, insulin resistance, et al. However, the relationship between the severity of upper gastrointestinal symptoms and metabolic risk factors is still controversial in Japan. The aim of this study is to clarify the relationship between the seriousness of the upper gastrointestinal symptoms defined by the frequency scale for the symptoms of gastroesophageal reflux disease (FSSG) and metabolic risk factors (in apparently normal individuals who received medical checkups and in patients with non-alcoholic fatty liver disease (NAFLD)).
METHODS: Two hundred twenty-eight individuals who lived in Saga, Japan and received medical checkups and underwent gastrointestinal endoscopy in 2009 (Group A) and 50 patients with NAFLD (Group B) were enrolled in this study. FSSG, biochemical examination of blood, waist circumference, amount of visceral fat measured by body-composition analyzer (BCA), and visceral fat area measured by abdominal computed tomography (CT) were evaluated.
RESULTS: There were no significant difference between group A (51.0± 9.5 years) and group B (51.4±12.3 years) in mean age. Mean body mass index (BMI) of Group B was higher than that of Group A (Group A: 23.1± 3.4, Group B: 27.2±4.2, respectively, $p<0.05$). In Group A, there were no correlation between FSSG score, and BMI, waist circumference, and visceral fat area, respectively. Furthermore, when Group A was divided into three subgroups by BMI (BMI<25, 25<and >28, >28, respectively), there was no significant difference in FSSG score among each subgroup. In contrast, there were significant correlations between FSSG score and BMI, AST/ALT ratio, and insulin resistance calculated by QUICKI ($r=0.34$, $R=-0.31$, $r=-0.29$, $p<0.05$, respectively) in Group B. Insulin resistance also showed significant relationship especially with the degree of esophageal dysmotility which could be discriminated from complaints about acid excretion by the type of FSSG questions. BMI was higher in Group B with GER symptoms (FSSG score >8) than Group B without GER symptoms or Group A both with and without GER symptoms (post hoc, $p<0.05$).
CONCLUSIONS: Presumably normal patients who undergo medical checkups show no correlation between the severity of the upper gastrointestinal symptoms and metabolic risk factors. However, in patients with NAFLD, increased BMI, AST/ALT ratio and insulin resistance are associated with an increased risk of developing GER symptoms. This study suggests that the treatment of obesity may improve GER symptoms in NAFLD patients in Japan.

THE USE OF INDIVIDUALIZED DASHBOARDS AND PAY-FOR-PERFORMANCE TO IMPROVE VENOUS THROMBOEMBOLISM PROPHYLAXIS COMPLIANCE BY HOSPITALISTS Henry J. Michtalik[1,2]; Howard T. Carolan[1]; Michael B. Streiff[1]; Elliott R. Haut[1,2]; Joseph Finkelstein[1]; Nowella Durkin[1]; Murali A. Padmanaban[1]; Brandyn D. Lau[1]; Daniel Brotman1. [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Armstrong Institute for Patient Safety and Quality, Baltimore, MD. (Tracking ID #1638740)

BACKGROUND: Venous thromboembolism (VTE) accounts for over 100,000 deaths per year and costs the healthcare system approximately $15,000 per event. Methods to increase appropriate prophylaxis have included computerized physician order entry (CPOE) with decision support, dashboards, and pay-for-performance (P4P) programs. In this study, we sequentially examined CPOE-based decision support alone, group and individualized feedback using a dashboard plus decision support, and a P4P program in conjunction with dashboards and decision support to improve VTE prophylaxis.
METHODS: CPOE with decision support for appropriate VTE prophylaxis based on American College of Chest Physicians (ACCP) guidelines was incorporated into the admission order-sets for all adults admitted to our tertiary care academic medical center in 2008. Appropriate prophylaxis was audited through the CPOE system 24 h from admission. To further improve VTE prophylaxis, a web-based dashboard specific to the hospitalist group was launched in January 2011, providing both hospitalist group and individualized hospitalist compliance rates. Benchmarks were determined using this dashboard. After 6 months of feedback only, a P4P program was initiated with hospital funding. No payment was made to individual hospitalists with ACCP-compliant VTE prophylaxis rates of <80 %. Graduated payouts were made for compliance rates of 80–100 % to a maximum of $0.50 per work RVU. Using time series analysis, the percent compliance for the hospitalist group was compared during all three periods: CPOE alone, CPOE with dashboard, and CPOE with dashboard tied to P4P. The analysis was restricted to the non-teaching unit of the hospital where individual housestaff practice would be unlikely to confound the results. A sensitivity analysis explored the potential impact from physician turnover.
RESULTS: We examined 4,119 inpatient admissions by 38 hospitalists from 2008 to 2012. The 5 most frequent primary diagnoses were heart failure, acute kidney failure, syncope, pneumonia, and chest pain. Patients had a median age of 57 years [IQR: 44, 69], APR-DRG severity of illness score of 2 [IQR: 2, 3] and length of stay of 3 days [IQR: 2, 6]. VTE prophylaxis group compliance rates were 84 % (95 % CI: 83, 85), 90 % (95 %: 88, 93), and 94 % (95 %: 93, 96) for CPOE alone, CPOE with dashboard, and CPOE with dashboard tied to P4P respectively. Compliance significantly improved with both the use of the dashboard ($p<0.001$) and the addition of the P4P program ($p=0.01$). Annual individual physician VTE P4P payments ranged from $80 to $1,429 (mean $654; SD ±364). The total annual cost of the P4P program of $12,422 was distributed to 19 providers. Sensitivity analysis accounting for physician turnover did not significantly impact the comparisons.
CONCLUSIONS: Although CPOE with decision support assists with appropriate VTE prophylaxis, direct feedback using dashboards significantly improved compliance. This effect was further augmented by incorporating an individual physician pay-for-performance program. The total P4P payments for an entire year were less than the cost of a single VTE event, suggesting an actual cost-savings. Real-time dashboards and physician-level incentives may assist hospitals in reducing preventable harm and achieving quality and safety benchmarks.

THE ASSOCIATION BETWEEN PRIMARY CARE CONTINUITY, ACCESS, AND CARE COORDINATION WITH HEALTH OUTCOMES AMONG A NATIONAL COHORT OF VETERANS Karin M. Nelson[1]; Haili Sun[1]; Nancy Sharp[1]; Emily D. Dolan[1]; Charles Maynard[1]; Gordon Schectman[2]; Stephan D. Fihn3. [1]Department of Veterans Affairs, Seattle, WA; [2]Department of Veterans Affairs, Seattle, WA; [3]Department of Veterans Affairs, Seattle, WA. (Tracking ID #1633498)

BACKGROUND: The Veterans Health Administration (VHA), the largest integrated health system in the US, has been implementing a patient-centered medical home model, called the Patient Aligned Care Team (PACT), that is intended to improve coordination of health services, increase non-face-to-face access, and improve continuity with assigned providers in primary care. We sought to determine if these factors were associated with the likelihood of hospitalization among veterans receiving primary care within VHA.
METHODS: We analyzed national data on over 4.3 million Veterans enrolled in the VHA from 4/2009 to 4/2010. We constructed logistic models to assess the relationship between attributes of PACT and VHA hospitalization during the subsequent year (4/2010–4/2011) among Veterans with 2 or more primary care visits, adjusting for demographic characteristics, medical and psychiatric co-morbidity and accounting for clustering by facility. Continuity was defined using the proportion of visits to the Veteran's assigned primary care provider. Access to care outside of clinic visits was assessed by the use of primary care telephone clinics and by primary care group visits. We also examined indicators of team-based care, such as visits with a clinic nurse. Results were stratified by age greater or less than 65 years.
RESULTS: Of Veterans enrolled in primary care, 372,170 (8.5 %) were admitted to a VHA hospital during the subsequent year and 145,142 (3.3 %) died. Among veterans over age 65, increasing age and presence of medical or psychiatric conditions were associated with a greater likelihood of admission to a VA hospital. Veterans with an increasing proportion of primary care visits with their assigned primary care provider (OR 0.76, 95 % CI 0.72, 0.80 for all visits with the same PCP compared with less than 50 % of visits with PCP) and a visit with the clinic RN (0.92, 95 % CI 0.87, 0.98) had a lower likelihood of hospitalization. Similar to the older age group, lower risk for admission was associated with an increasing proportion of primary care visits with their assigned primary care provider (OR 0.88, 95 % CI 0.86, 0.89 for all visits with the same PCP compared with less than 50 % of visits with PCP). Primary care phone visits and group visits were not associated with subsequent hospitalizations.
CONCLUSIONS: Among a national cohort of veterans, key components of the patient-centered medical home within VHA, notably continuity with a primary care provider, were associated with a lower likelihood of hospitalization.

THE ASSOCIATION OF PRIOR CULTURAL COMPETENCE TRAINING AND PERCEPTIONS OF THE DEPARTMENTAL ENVIRONMENT WITH SELF-REPORTED CROSS-CULTURAL BEHAVIORS IN PRACTICE Rebeca Rios[1]; Tanjala S. Purnell[1]; Jessie K. Kimbrough-Sugick[1]; Letitia Wright[1]; Stephen Sisson[1]; Brian K. Gibbs[2]; Leonard S. Feldman[1]; Rosalyn W. Stewart[1]; Lisa A. Cooper1. [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #1641143)

BACKGROUND: Training in cultural competence for health professionals is increasingly recognized as an important target for improving quality of care and reducing ethno-racial health care disparities. Learning and practice environments have an important influence on patient-centered and cross-cultural (CC) behaviors, which strengthen the patient-physician relationship. Yet, little is known about the influence of cultural competence training and environmental characteristics on performing CC behaviors in clinical practice. The objective of this study was to examine whether prior cultural competence training and perceptions of the departmental environment were independently associated with self-reported frequencies of key CC behaviors within a university teaching setting.
METHODS: We surveyed faculty, fellows, and residents within 10 clinical departments of an urban academic medical institution. Outcome measures were self-reported frequencies of 3 specific CC behaviors: 1) asking patients/families about their explanations of illness; 2) asking patients/families about their expectations of care; and 3) finding ways to adapt clinical services to patient/family cultural preferences. One item measured prior CC training ("none or very little" vs. "some or a lot"). Departmental environment measures were perceived commitment of departmental leaders to cultural competence (agree vs. disagree), and interactional diversity, consisting of self-rated exposure to diverse perspectives and positive interracial interactions (satisfied vs. dissatisfied). Differences in frequencies of CC behaviors (dichotomized into ≤75 % versus >75 % of the time) by prior CC training and departmental environment measures were assessed using the chi-square statistic and multivariable logistic regression.
RESULTS: The sample consisted of 1,220 (47 % response rate) respondents; 52 % were male, and mean age was 39.8 years (SD=10.7). Sixty-two percent were Caucasian, 21 % Asian, 10 % African American, and 4 % reported Hispanic ethnicity. 66 % of were born in the U.S. Two thirds of the study sample reported having at least some CC training; 60 % endorsed interactional diversity, and 71 % of the sample believed that departmental leaders were committed to cultural competence. Overall, 32 % of respondents reported that they elicit explanations of health and illness, 36 % ask about expectations for care, and 44 % adapt services to cultural preferences >75 % of the time. Compared with participants who received little or no prior CC training, those who received prior CC training were more likely to report they frequently elicit explanations (OR: 1.5; 95 % CI: 1.1–2.0), ask about expectations, (OR: 1.9; 95 % CI: 1.4–2.6), and adapt care to cultural preferences (OR: 1.7; 95 % CI: 1.2–2.2). Similarly, those who endorsed that their departments had a climate of interactional diversity were more likely than their counterparts to perform 2 of the CC behaviors (elicit explanations, OR: 1.8; 95 % CI: 1.2–2.5; asking about expectations, OR: 1.7; 95 % CI: 1.2–2.4).
CONCLUSIONS: The application of prior training to clinical practice represents the deepest level of educational success. Prior CC training and perceived interactional diversity in one's department were associated with cross-cultural behaviors in practice. Results highlight the importance of departmental support of both cultural competence training and diverse environments. Future work is warranted to identify specific aspects of medical institutional environments that shape cross-cultural training and care.

THE CYCLE OF SUBSTANCE ABUSE, PROSTITUTION AND PSYCHOLOGICAL DISTRESS AND ITS EFFECT ON HEALTH SEEKING BEHAVIOR AMONG HIV POSITIVE BLACK WOMEN. Jennifer L. Grant[2,1]; Loida Bonney[1]; Judith C. Barker[3]. [1]Emory University School of Medicine, Atlanta, GA; [2]Rollins School of Public Health, Atlanta, GA; [3]University of CA, San Francisco, San Francisco, CA. (Tracking ID #1637292)

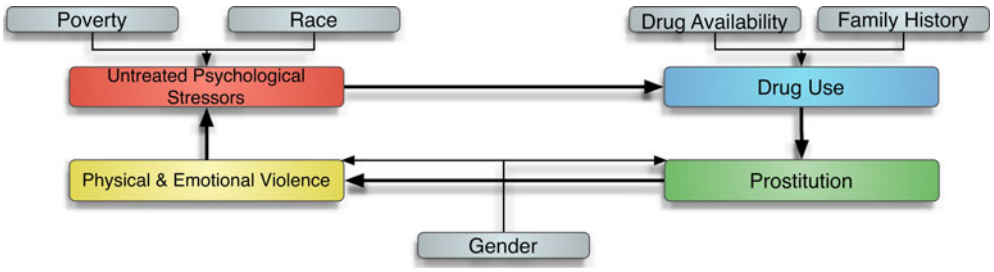
BACKGROUND: Black women in the South have increasing rates of HIV infection and disproportionately high rates of adverse HIV-related outcomes. To explain these findings, several studies have reported the association of substance abuse, and gender related violence with increased risk for HIV infection. However, fewer have looked at how and why drug use interferes with engagement in HIV care following diagnosis. The objective of this analysis was to examine how the vulnerabilities of poverty, race, and gender influence drug abuse, prostitution and psychological distress, and their effects on health seeking behavior among HIV positive black women through the narratives of Black women.
METHODS: Individual semi-structured in-depth interviews were conducted with 20 HIV-positive Black women residing in Atlanta, GA

using a phenomenological approach. Participants were identified from an electronic medical record review of an HIV primary care clinic and recruited by telephone call or formal letter. Inclusion criteria specified that women identify as Black, had been aware of their HIV serostatus for at least 2 years, and had been linked to HIV care. Participants were asked about their racial, gender, and socioeconomic identities and how these affected treatment of their HIV. In addition, questions were directed to include experiences with substance abuse, criminal activity, and romantic relationships. Finally, participants were invited to disclose their experiences with the HIV health care system. Interviews were digitally recorded, transcribed and analyzed thematically.

RESULTS: One hundred eleven black women were screened for eligibility during the initial chart review. Seventy-eight women were contacted. There was a high rate of non-response. Almost all 20 participants reported annual incomes below the federal poverty level. Ten participants admitted to prior substance abuse. Of the 10, 8 spoke of engaging in sex work to finance their addiction and an additional 2 entered into ongoing relationships with men in exchange for housing, money, or drugs. All 10 of these women stated their sex work or relationships lead to considerable amounts of violence and sexual exploitation, which lead to psychological distress and further drug abuse. All women reporting history of substance abuse stated that this cycle of addiction, specifically their preoccupation with obtaining drugs, low self worth and/or lack of desire to live, was their primary reason for not seeking HIV healthcare.

CONCLUSIONS: We conclude that there are low-income Black women with HIV-infection in the South who are trapped in a self-reinforcing cycle of drug abuse, prostitution, and psychological distress. Increasing mental health resources and harm reduction and empowerment programs may facilitate engagement in care for this highly vulnerable population. Intervention at multiple points in the cycle can lead to improved outcomes.

Race and poverty promote lack of access to mental health care following trauma. Family history of substance abuse and widespread availability of illegal drugs in Black communities promote to drug use. Gender dynamics in the streets influences entry into prostitution as well as occurrences of physical and emotional violence.



THE ECONOMIC CONSEQUENCES OF CONTEMPORARY PATTERNS OF ANTIDEPRESSANT PRESCRIBING Niteesh K. Choudhry; Daniel A. Lieberman; Jerry Avorn; Joan Landon. Brigham and Women's Hospital, Harvard Medical School, Boston, MA. (Tracking ID #1643949)

BACKGROUND: Serotonin norepinephrine reuptake inhibitors (SNRIs) are frequently prescribed as initial antidepressant therapy, although selective-serotonin reuptake inhibitors (SSRIs) are equally or more effective as well as being less expensive. We sought to evaluate recent patterns of antidepressant prescribing and their economic consequences.

METHODS: We examined a national cohort of privately insured patients with an open formulary and tiered copayments. We identified patients ≥18 years of age with at least 2 years of prior continuous enrollment who initiated a SSRI, SNRI or atypical antidepressant (bupropion, mirtazapine) between January 2008 and June 2011. Patients were excluded if they previously received any antidepressant or had diabetic neuropathy, chronic pain, fibromyalgia, bipolar disorder, or psychotic disorders. For each month, we calculated the percent of patients receiving each medication class and the percent receiving branded drugs. We assessed the use of each class over time using bivariate linear regression models. We used multivariate linear regression models to identify predictors of being initiated on each class, including age, sex, geographical region, copayment, clinical comorbidities, and month. We next identified patients with at least 6 months of continuous enrollment after filling their original prescription and calculated patient, insurer, and total costs for antidepressants during those 6 months for these patients. Finally, we estimated projected savings if patients prescribed SNRIs had received the generic SSRI sertraline.

RESULTS: Our cohort consisted of 248,550 patients who initiated antidepressants during the study period (62.5 % female, average age 42.8). SSRIs accounted for 76.9 % of the initial prescriptions, SNRIs for 9.6 %, and atypicals for 13.5 %. The percent of patients initiating therapy with SSRIs did not significantly change over time ($P>0.10$). In contrast, SNRI use decreased by an average of 0.12 % per month ($P<0.001$) and atypical use increased by an average of 0.11 % per month ($P<0.001$). Brand drug use decreased from 38.1 % to 26.7 %, a 0.49 % monthly decrease ($P<0.001$). Characteristics associated with a higher probability of receiving SNRIs, as compared to other antidepressants, were: female sex (odds ratio [OR] 1.25, $P<0.001$) older age (OR 1.01 per year, $P<0.001$), and higher Charlson comorbidity score (OR 1.07 per point, $P<0.001$). Combined patient and insurer spending for patients who initiated therapy with SSRIs was $358.32 (patient costs: $57.55; insurer costs: $300.78) over the subsequent 6 months. In contrast, SNRI and atypical treated patients had average costs of $673.30 (patient costs: $118.26; insurer costs: $555.03) and $454.92 (patient costs: $53.2[1]; insurer costs: $401.71), respectively. If patients receiving SNRIs had instead been prescribed sertraline, this would result in annual savings of more than $700 per patient.

CONCLUSIONS: Despite higher costs and equal or inferior clinical effectiveness, a considerable proportion of privately insured patients received initial antidepressant therapy with SNRIs. Though the proportion of patients receiving SNRIs and branded antidepressants decreased over the study period, savings would be considerable if patients starting SNRIs had instead been prescribed SSRIs.

THE EFFECT OF MEDICAID STATUS ON WEIGHT LOSS OUTCOMES AFTER GASTRIC BYPASS SURGERY Elsbeth Jensen-Otsu[1]; Emily Ward[2]; Breana Mitchell[3]; Jonathan A. Schoen[3]; Kevin Rothchild[3]; Gregory L. Austin[2]. [1]University of Colorado Denver, Aurora, CO; [2]University of Colorado Denver, Aurora, CO; [3]University of Colorado Denver, Aurora, CO. (Tracking ID #1642234)

BACKGROUND: Severe obesity (BMI>40 kg/m2 or >35 kg/m2 with one or more co-morbid conditions) disproportionately affects

individuals in the lowest socioeconomic status group, and these individuals are more likely to be enrolled in state Medicaid programs. Bariatric surgery, including Roux-en-Y gastric bypass (RYGB), achieves the greatest long-term weight loss for severe obesity and is increasingly utilized. Patients with severe obesity enrolled in Medicaid are less likely to undergo bariatric surgery, and not all state Medicaid programs provide coverage for bariatric surgery. The purpose of this study was to compare weight loss outcomes after RYGB surgery between patients with Medicaid and other insurance.

METHODS: This was a retrospective cohort study of 318 consecutive patients (n=113 for Medicaid; n=130 for other government insurance; n=75 for commercial insurance) who underwent RYGB surgery at a single academic center between 2004 and 2011 and who had at least 6 months of follow-up after RYGB. Data on age, race, gender, pre-surgery weight/BMI, comorbidities, and insurance provider were collected. Percent weight loss (PWL) and absolute weight loss (AWL, in kg) were recorded at 6 months. Linear regression analysis was used to compare PWL and AWL at 6 months between patients with Medicaid, other government insurance, and commercial insurance.

RESULTS: Patients with other government insurance were less heavy and had a lower BMI compared to both the Medicaid and commercial insurance patients (both $p<0.001$) prior to RYBG. Medicaid patients (mean age 35.8 y) were substantially younger (overall $p<0.0001$) compared to other government (mean age 44.4 y) and commercial insurance patients (mean age 42.9 y). The proportion of female patients was higher ($p=0.012$) in the Medicaid group (94.7 %) compared to other government insurance (84.6 %) and commercial insurance patients (81.3 %). There was no difference in the racial distribution. In unadjusted analyses, Medicaid patients had significantly greater PWL by 1.91 percentage points ($p=0.03$) compared to commercial insurance patients. Patients with other government insurance had a borderline significant ($p=0.061$) increase in PWL of 1.61 percentage points compared to commercial insurance patients. There was no significant difference in absolute weight loss between the 3 groups. However, increasing age was associated with decreased PWL ($p=0.002$) and AWL ($p<0.001$) across all patients and was a confounder of the relationship between PWL and insurance provider. In regression analysis adjusted for age, Medicaid patients had a non-significant increase in PWL ($p=0.163$) compared to patients with commercial insurance. Interestingly, PWL for those with other government insurance was now significantly increased compared to the commercial insurance patients ($p=0.039$). When adjusted for age, there were no differences in AWL. Hospital length of stay was similar between the three groups.

CONCLUSIONS: Our data support more recent data that Medicaid patients have at least equal weight loss following RYGB for severe obesity. Although patients with Medicaid are less likely to undergo RYGB surgery, it is the most effective treatment for severe obesity. Given the younger cohort of patients in a Medicaid population, these patients may derive even greater long-term benefit than other patients. This should be considered as many states expand Medicaid and make policy decisions regarding obesity treatment.

THE EFFECT OF PATIENT-CENTERED MEDICAL HOME TRANSFORMATION COUPLED WITH PAYMENT REFORM: PATIENT EXPERIENCE OUTCOMES Leonie Heyworth[1,2]; Asaf Bitton[2]; Stuart R. Lipsitz[2]; Thad Schilling[3]; Gordon D. Schiff[2]; David W. Bates[2]; Steven R. Simon[1,2]. [1]VA Boston Healthcare System, Boston, MA; 2Brigham and Women's Hospital, Boston, MA; [3]Atrius Health, Boston, MA. (Tracking ID #1642620)

BACKGROUND: The patient-centered medical home (PCMH) has emerged as a patient-focused, quality-driven, cost-effective model to revive primary care. Linking practice transformation to payment reform may incent more rapid adoption of the PCMH model. Existing literature has examined short-term patient satisfaction outcomes, but results have been mixed. We undertook a 3-year quasi-experimental study to evaluate patient experience following a pilot PCMH transformation with payment reform at an intervention and control clinic site.

METHODS: Study setting was 2 internal medicine clinics of a large multi-specialty group of 14 practices in greater Boston. The pilot PCMH transformation started in April 2009 and consisted of team restructuring, process improvements and replacing fee-for-service physician reimbursement with a salary scheme. To understand patient experiences with care "pre" and "post" the PCMH transformation, we analyzed 4,124 responses to the Press-Ganey patient experience survey in both intervention and control sites from 2008 to 2010. Our primary outcome was overall visit satisfaction. Secondary outcomes reflected the core principles of the PCMH: enhanced access to care, visit coordination and care, physician communication, and whole-person orientation of care. Each outcome was rated on a 1–5 Likert-type scale from "very good" to "very poor". Individual survey responses were linked to each patient's medical record, providing demographic information, healthcare utilization, certain medical conditions and provider characteristics. Propensity score weighting adjusted for case-mix differences between patients in the control and intervention groups in the pre and post periods. Multivariable logistic regression models assessed the adjusted differences between patients' experiences before and after the PCMH transformation at intervention and control sites.

RESULTS: Between 2008 and 2010, 4,124 patients at the intervention and control sites responded to the Press-Ganey patient experience survey. Pre-PCMH intervention (January 2008–March 2009), 1,224 patients had received care at the intervention site and 803 received care at the control site. Post-intervention (October 2009–December 2010), 1,278 patients at the intervention site and 819 patients at the control site completed a post-transformation survey. After propensity weighting on all available demographic and clinical status variables, intervention and control sites were similar with respect to all baseline variables. Pre-intervention, 62 % of intervention participants were very satisfied compared with 68 % post-intervention ($p=0.004$). At the control site, 63 % of patients felt satisfied pre-intervention versus 64 % post-intervention ($p=0.58$). Using a difference-of-differences approach, a trend towards improved overall satisfaction emerged at the intervention site ($p=0.10$). In analysis of secondary outcomes, intervention participants were more likely to report faster speed of registration ($p=0.04$), and provide superior ratings to the four questions in the personal physician and communication domain (all $p\leq0.05$).

CONCLUSIONS: While earlier PCMH pilot studies showed no improvement in patient satisfaction, using a quasi-experimental design to evaluate patient experience following PCMH practice transformation coupled with payment reform, we found meaningful improvements in key areas. Future studies are needed to determine if physicians, over time, will thrive under salary-based reimbursement.

THE EFFECTIVENESS AND COSTS OF TWO POPULATION-BASED CANCER SCREENING PROGRAMS: THE VALUE OF PCP INPUT Douglas Levy[1]; Vidit Munshi[2]; Jeffrey M. Ashburner[3]; Adrian Zai[5]; Richard W. Grant[3]; Steven J. Atlas[3]. [1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Massachusetts General Hospital, Boston, MA; [4]Massachusetts General Hospital, Boston, MA. (Tracking ID #1639629)

BACKGROUND: Rates of guideline-recommended preventive cancer screening remain suboptimal despite proven health benefits. Our primary care (PC) network recently completed a practice-randomized trial comparing two versions of a health information technology (HIT) population management system to increase preventive cancer screening in eligible patients. We assessed the relative effectiveness and costs of these two population management programs.

METHODS: The HIT system included a patient registry which continuously identified PC network patients overdue for breast, cervical, or colorectal cancer screening; permitted targeted outreach; and tracked tests scheduled and completed. The control program used an automated outreach process where overdue patients were first sent letters asking them to call and schedule an appointment. If there was no response, delegates in the provider's office would call the patient. If there was still no response, patients at high risk for non-adherence were assigned to navigators who would work closely with patients to complete screening. The intervention program leveraged providers' personal knowledge to update patients' screening status or designate them for personalized letter, phone, or navigator outreach. If a provider did not act within 8 weeks, the patient defaulted to the automated outreach used in the control arm. Nine practice sites were randomized to each study arm. Effectiveness was measured as the proportion of time eligible patients were up to date on all screening (up to 3 tests). We used micro-costing techniques to estimate the costs of the HIT tool, HIT training, mailing materials, and clinical staff time over 1 year. Monte Carlo methods were used to aggregate costs taking into account uncertainty in individual parameter values.
RESULTS: Over the 1-year study period, there were 104,074 eligible patients. Adjusting for practice-level clustering, patient age, race, insurance, language, and time since last visit, patients in intervention and control groups spent equal amounts of time with all pertinent screenings completed (79.9 % vs. 79.6 %, $p=0.87$). We estimated the cost for the control arm was $167,170 while the cost for the intervention arm was $215,377 (95 % CI for difference $1,717–$126,321). One-time costs (software, training) were lower for control ($125,144) than intervention ($175,780; 95 %CI for difference $6,265–$128,211), driven almost entirely by the additional complexity of the intervention software design. However, ongoing costs (mailing, personnel) were somewhat higher for the control arm ($42,026) than intervention ($39,596; 95 % CI for difference −$8,709–$15,248). Physicians estimated they spent less time managing patients' cancer screening in the intervention arm than in the control arm, though this difference was only statistically significant for Pap tests (24.5 min/day intervention, 30.0 min/day control, $p=0.04$). Sensitivity analyses suggest that software costs, and therefore overall program costs, could be increased 4 to 5 times if the program were introduced in a setting where there was substantial incompatibility across existing information systems.
CONCLUSIONS: An automated program of patient outreach achieved identical screening success at lower cost compared to one designed to take advantage of providers' personal knowledge of their patients. Standardized software design could reduce one-time costs and make the intervention approach more cost-effective compared to the control.

THE IMPACT OF AN HIV ADHERENCE INFORMATICS INTERVENTION ON PATIENT-PROVIDER COMMUNICATION ABOUT ART ADHERENCE Barbara G. Bokhour[1,2]; Jeffrey Solomon[1]; Michael B. Laws[5]; Allen L. Gifford[1,2]; Matthew B. Goetz[3]. [1]ENRM Veterans Affairs Medical Center, Bedford, MA; [2]Boston University School of Public Health, Boston, MA; [3]VA Greater Los Angeles Health Care System, Los Angeles, CA; [4]Brown University, Providence, RI. (Tracking ID #1641720)

BACKGROUND: Successfully managing HIV infection depends upon patients' strict adherence to antiretroviral (ART) medication regimens. Communication in patient-provider encounters is a critical component of fostering adherence, and informatics-based interventions offer a promising means of improving communication. MedCHEC uses a tablet-computer pre-visit clinical assessment, plus tailored adherence support, to improve HIV medication adherence. One mechanism through which such interventions may have an effect on outcomes is through its effect on the patient-provider clinical encounter. The goals of this study were to evaluate the impact of the MedCHEC tablet-computer pre-visit clinical assessment on the actual communication between patients and providers in HIV-related clinical encounters.
METHODS: We audio-recorded and analyzed a sample of 42 patient-provider clinical visits with 12 providers in the MedCHEC study at two Veterans Affairs HIV clinics. Of these, 21 patients had received the MedChec intervention, while 21 were in the control group and received usual care. Audio-recorded visits were transcribed verbatim and uploaded into NVivo 10, a coding software program. We coded interactions for specific reference to the output of the MedChec tablet intervention, different types of adherence talk and the speech acts (ways of talking) for the adherence talk that was present. We then compared the proportion of types of talk for patients in the intervention vs. control groups. In the intervention group, we also compared adherence noted in the tablet reports with the discussion of adherence in the interactions.We qualitatively examined discussions of nonadherence to HIV medications, to identify who initiated such discussions and the extent to which physicians inquired about the reasons for nonadherence and/or engaged in problem-solving with patients about nonadherence.
RESULTS: Fourteen of the 21 tablet reports indicated ART adherence problems. However, physicians made reference to tablet reports in only 3 of these interactions. Physicians in the intervention group more frequently engaged in any type of "adherence talk", including inquiring about adherence, nonadherence problem-solving, and medication side effects. In both intervention and control interactions, when engaged in adherence talk, physicians most frequently use closed questions (questions with "yes" or "no" answers) and the expression of factual information (for example, explaining the importance of ART adherence). In 12 interactions, equally distributed across groups, providers did not explore reasons for nonadherence or engage in nonadherence problem-solving, despite indications by patients that they were nonadherent.
CONCLUSIONS: Although physicians explicitly referenced the tablet report in only three interactions, physicians in the intervention group exhibited more adherence talk, which might be due to having been exposed to tablet reports. However, because physicians used language forms not conducive to encouraging patients to elaborate on nonadherence, and because some physicians did not explore nonadherence with patients who raised the topic, our findings suggest that doctors could benefit from interventions geared toward how to engage in discussions about and find solutions to improve patient adherence to ART.

THE IMPACT OF ELIMINATING MEDICATION COPAYMENTS ON DISPARITIES IN CARDIOVASCULAR CARE Niteesh K. Choudhry[1]; Katsiaryna Bykov[1]; William Shrank[1]; Michele A. Toscano[2]; Wayne Rawlins[2]; Jessica Myers[1]. [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [2]Aetna, Hartford, CT. (Tracking ID #1640327)

BACKGROUND: Racial and ethnic disparities in cardiovascular care have been widely documented. Reducing copayments for highly effective medications, such as those prescribed after myocardial infarction (MI), has been shown to improve medication adherence and reduce rates of major vascular events; however, the impact of such programs on health disparities is unknown. We used data from the Post-Myocardial Infarction Free Rx Event and Economic Evaluation (MI FREEE) trial to evaluate whether pharmacy benefit design changes had differential effects based on race/ethnicity. In addition, we assessed the accuracy of indirect methods of race/ethnicity identification by comparing results obtained using RAND's geocoding and surname techniques with those based upon self-reported race/ethnicity information.
METHODS: The effect of full prescription coverage as compared to usual prescription coverage for all statins, beta-blockers, angiotensin converting enzyme inhibitors and angiotensin receptor blockers prescribed after MI was examined in 2,387 patients enrolled in the

MI FREEE trial for whom both self-reported and indirect race/ethnicity information was available. Cox proportional hazards models and generalized estimating equations with interaction testing were used to examine the trial's impact on the trial's primary outcome (time to first major vascular event or revascularization) and total health spending for white and non-white subjects. We classified patients as being white using indirect methods if their predicted probability of white race was ≥55 %. We also used each patient's predicted probability of white race to create 100 imputed race variables and then compared the intervention's impact for white and non-white patients.

RESULTS: Providing full drug coverage significantly reduced rates of the primary outcome among patients who self-identified as being non-white (hazard ratio [HR] 0.62, 95 % confidence interval [CI] 0.41–0.94, $p=0.03$) but not for those of white race/ethnicity (HR 0.96, 95 % CI 0.77–1.20, $p=0.74$; p-value for interaction=0.05). Similarly, using self-identified race/ethnicity, the intervention reduced total health care spending among non-whites (relative spending 0.28, 95 % CI 0.14–0.56, $p<0.05$) but not among white subjects (relative spending 1.26, 95 % CI 0.57–2.79, $p=0.56$; interaction p-value <0.001). In contrast, when race/ethnicity was assessed using indirect methods, the impact of full coverage did not differ for white and non-white patients (interaction p-value 0.85–0.93).

CONCLUSIONS: Eliminating copayments for post-MI secondary prevention drugs was significantly more effective at reducing rates of major vascular events or revascularization, as well as total health care spending, among patients who self-identified that they were not white. These results suggest that eliminating cost-sharing for evidence-based post-MI medications may help reduce cardiovascular disparities. In addition, we obtained quantitatively and qualitatively different results using indirect race/ethnicity identification methods, suggesting that these techniques may not accurately capture race and ethnicity.

THE IMPACT OF PRICE TRANSPARENCY ON MEDICAL DECISIONS AND PRACTICE: A SYSTEMATIC REVIEW OF THE LITERATURE Celine Goetz[1]; Stephen R. Rotman[1]; Helen-Ann B. Epstein[2]; Tara F. Bishop[3,4]. [1]New York-Presbyterian Hospital-Weill Cornell Medical Center, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Weill Cornell Medical College, New York, NY; [4]Weill Cornell Medical College, New York, NY. (Tracking ID #1638105)

BACKGROUND: Given rising health care costs, policymakers and the medical community have called for more price transparency to allow physicians and patients to make cost-conscious decisions about medical care. The purpose of this study was to systematically review studies that have examined the impact of price transparency on physicians' use of services, on cost of care, or on changes in physician decisions.

METHODS: We performed a systematic review using PubMed, Web of Knowledge, ABI/Inform, Academic Search Premiere for studies published in English between 1982 and 2012. We included articles that studied the effect of price transparency interventions (including educational interventions) on the use of services, cost of care, or changes in physician decisions. We included studies that had a concurrent comparison group and those that used a pre-post design with no concurrent comparison group. We only included studies that provided quantitative results. We did not include studies where the outcome was change in attitudes, but did include studies where the outcome was changes in case-based decisions. One reviewer assessed titles and abstracts. Two reviewers independently reviewed full-text articles. When the reviewers disagreed, an additional reviewer resolved the discrepancy. The following data were extracted from the articles: study design, setting, type of intervention, type of participants, number of participants, outcome measures, and results. The quality of each article was rated using the GRADE criteria.

RESULTS: We identified 16 articles that met our inclusion and exclusion criteria. Nine (56.3 %) studies used a pre-post design; 7 (43.8 %) were prospective with a concurrent control group. Only one study randomized subjects. Five (31.3 %) studies used hypothetical cases and looked for differences in physician decision-making. The other 11 (68.8 %) studies looked at changes in clinical practice and used outcomes of either cost or use of specific tests, drugs, or procedures. The types of interventions varied from educational interventions to labeling supplies and medications to alerts using electronic systems. Eleven (68.8 %) studies demonstrated lower costs or use after the intervention or for the intervention group. Three (18.8 %) had mixed effects and 2 (12.5 %) had no effect.

CONCLUSIONS: Few studies have rigorously assessed the impact of price transparency on use of services, cost of care, or changes in physician decisions. The types of interventions and study designs that have been used have been very heterogeneous. The majority of studies, however, showed lower cost or use with these interventions.

THE IMPACT OF PROFESSIONAL INTERPRETATION ON LENGTH OF STAY IN AN OBSERVATION UNIT Christopher Moreland[1]; Letitica Z. Bresnahan[1]; Wayne Fischer[2]. [1]The University of Texas HSC-San Antonio, San Antonio, TX; [2]The University of Texas Medical Branch, Galveston, TX. (Tracking ID #1645335)

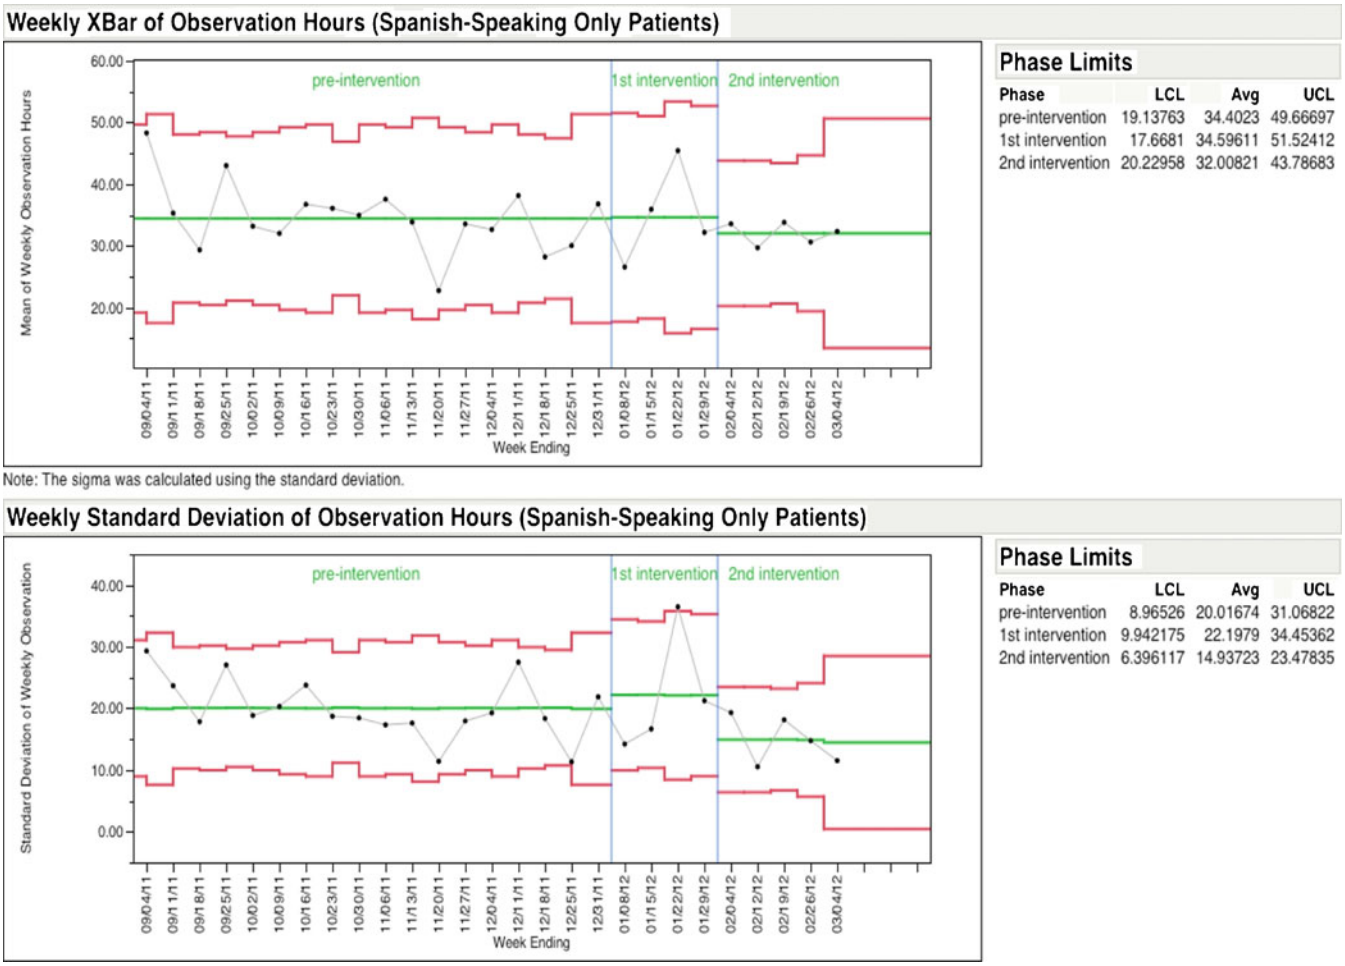
BACKGROUND: Language barriers contribute to poor access to healthcare. According to the U.S. Census 2007 American Community Survey, about 34.5 million Americans spoke Spanish. The Joint Commission requires that hospitals provide interpretation services for limited-English proficient (LEP) people. Professional interpretation can decrease hospital length of stay (LOS) by days. No study to our knowledge has evaluated the impact of interpretation services on LOS in hospital observation units, where LOS is measured in hours.

METHODS: We aimed to measure the impact of Spanish interpretation on LEP patients' LOS in an observation unit. On admission, nurses identified and documented Spanish language use. A Pre-Intervention phase ran September-December 2012, followed by two interpretation phases: telephone and in-person. In January 2012 (Intervention 1), a dual-handset telephone was placed in each room. Providers received education on telephone availability and encouragement to use them with LEP patients. In February 2012 (Intervention 2), a community-based interpretation vendor provided a professional, on-site interpreter for the observation unit during weekdays. The primary measure was observation unit LOS in hours.

RESULTS: Pre-Intervention, there were 319 admissions of Spanish speakers with a mean LOS of 34.4 h (SD 20.5). During Intervention 1, there were 60 admissions with a mean LOS of 34.6 h (SD 23.3). During Intervention 2, there were 65 admissions with a mean LOS of 32.0 (SD 15.4). When comparing Pre-Intervention and Intervention 1 phases, the variances (by F test) were not statistically significantly different, nor were the mean LOS. However, the variances were statistically significantly different between Pre-intervention (420.36) and Intervention 2 (237.44) phases ($p=0.007$); Levene's test recalculation (to avoid normal distribution assumptions) showed $p=0.079$. The upper half of Figure 1 displays the weekly average of observation hours (green) with upper and lower limits (red), while the lower half shows the weekly standard deviation. From the Pre-Intervention to Intervention 2 phases, the number of outliers and the data variation visibly drop.

CONCLUSIONS: For Spanish-speaking patients in an academic county hospital observation unit, telephone interpretation did not seem to impact LOS. In-person interpretation resulted in an absolute reduction in LOS with reduction in variation, suggesting that provider behavior with interpretation services may lead to more predictable patient management patterns in the observation unit; the lack of statistically significant difference may be due to a low N for Intervention 2. Such a LOS reduction in an observation unit, where rapid turnaround is key, should be further evaluated with extended in-person interpretation.

Figure 1



THE RELATIONSHIP BETWEEN PCP PANEL SIZE AND CONTINUITY OF VA PRIMARY CARE David A. Katz[1,2]; Kimberly McCoy[1]; Mary Vaugha Sarrazin[1]. [1]University of Iowa, Iowa City, IA; [2]University of Iowa Carver College of Medicine, Iowa City, IA. (Tracking ID #1640510)

BACKGROUND: The Veterans Health Administration (VHA) faces the dilemma of maintaining continuity of care in the face of increasing demand for services and expanded panel sizes. A key strategy for managing this dilemma is the Patient Aligned Care Team (PACT) model, which aims to distribute the responsibilities of patient care among an interdisciplinary mix of primary care team members, allowing clinicians to provide improved access and care coordination to a large but manageable panel size. The objective of this study is to determine the association between primary care panel size and continuity of care (COC) during the PACT initiative.

METHODS: We conducted a cross-sectional analysis of 180,808 VA outpatients in Region 23 who had at least one primary care visit during each of 3 years (FY2009-11). We used data from the Patient Care Management Module (PCMM) to compute the discrepancy between actual panel size and maximum panel size for each PCP, standardized for a full time equivalent (FTE) position. Maximum PCP panel size at each facility was adjusted for primary care intensity score, support staff to PCP ratio, and clinic space. Patients (pts) of resident providers and VA providers with <1 year of service were excluded. To measure longitudinal COC, data from the 2011 PCMM were linked to VA outpatient datasets; clinic stop codes were used to identify primary care visits. Usual Provider Continuity (UPC) and Modified Continuity Index (MMCI) were calculated for each patient on a scale of 0–1 (where 1 is perfect continuity) and were dichotomized based on the national PACT benchmark (>=0.75). To measure relational continuity, the Survey of Healthcare Experiences of Patients (SHEP) was administered in FY2011 to a subset of 6,196 pts in the analysis sample. SHEP includes items pertaining to interpersonal communication (4 items) and shared decision making (SDM, 2 items). To identify excellent care, we used an "all-or-none" scoring strategy: when all items within a subscale were rated "always," the subscale was assigned a value of 1 (otherwise 0). Multivariable random effects logistic regression models were used to predict superior longitudinal COC, excellent communication, and excellent SDM, after controlling for demographics, disability status, 22 chronic medical and psychiatric conditions [Romano, 1993; Abrams, 2009], number of primary care clinic visits, primary care FTE, PCP participation in a PACT Learning Collaborative, and usual site of care (modeled as a random effect).

RESULTS: Median panel size for a full-time PCP was 1,178 (IQR 982–1295); 59 % of pts were seen by PCPs with panel sizes above capacity. Mean UPC and MMCI scores were higher (0.75 and 0.83) for pts of "above capacity" PCPs, compared to pts of "submaximal capacity" PCPs (0.55 and 0.75), respectively. In multivariable models, there was no association between panel size discrepancy and either COC measure (adj OR=1.000, 95 % CI=0.997, 1.002 for UPC model). Panel size discrepancy showed a weakly positive association with excellent communication (adj OR=1.007, 95 % CI=1.005, 1.009 for each 10 pt increase in panel size); no association was observed for SDM.

CONCLUSIONS: During implementation of the VA medical home model, deviations from the maximum PCP panel size were modest and were not associated with worsened longitudinal or relational COC. Further analyses are warranted to identify panel size thresholds beyond which measures of continuity and access show clinically meaningful decrements.

THE RELATIONSHIP BETWEEN USMLE STEP 1 SCORES, ANNUAL MEDICINE INSERVICE EXAMINATIONS, ATTENDING RATINGS AND PERFORMANCE ON THE ABIM CERTIFYING EXAMINATION Cynthia Kay[2]; Michael Frank[2]; Jeffrey L. Jackson[1,2]. [1]Zablocki VAMC, Milwaukee, WI; [2]Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #1641464)

BACKGROUND: Passing the American Board of Internal Medicine certifying examination is an important goal of medicine residents. Program directors currently use USMLE Step 1 scores to select medicine residents for training and then annual in-service training examinations and attending evaluations to identify medicine residents at risk for failing these boards. Our study's purpose was to explore the relationship between USMLE Step 1 scores, attending evaluations, the yearly inservice examinations and the ABIM board score.

METHODS: We included internal medicine residents at the Medical College of Wisconsin between 2004 and 2012. Attending evaluations assessed residents using the ACGME 6-domain questionnaire. Additional variables included the USMLE Step1 scores from the 2nd year of medical school, resident performance on the annual inservice examination for each year of training and the medicine board score.

RESULTS: There were 232 residents, who participated in 730 annual inservice examinations and had 6,603 evaluations completed by 334 attending physicians. Among the questions completed by attendings, ratings of the resident's medical knowledge (r=0.11) and overall performance (r=0.09) correlated weakly with the ABIM exams, though explained only 2 % of the variance. There was moderate correlation between Step1 USMLE scores, inservice scores and ABIM exam scores (Table 1). Beginning with internship, being in the bottom quartile on the inservice examination markedly increased the risk of failing the certifying boards (PGY1 RR: 7.4, 95 % CI: 2.12–26.05; PGY2: RR: 5.94, 95 % CI: 2.19–16.07, PGY 3: RR 10.5, 95 % CI: 3.12–35.09). Being in the bottom quartile on the USMLE Step 1 test also increased the risk of failing the ABIM exams (RR: 3.65, 95 % CI: 1.2–10.8).

CONCLUSIONS: Monthly attending evaluations were a poor predictor of performance on the ABIM examination. Performance on the Step 1 scores during medical school had a modest correlation with performance on the boards after finishing residency. Beginning with the intern year, inservice examination scores during each year of training had slightly stronger correlation with board performance. Being in the bottom quartile on the USMLE step 1 scores tripled the risk of failing the medicine boards, suggesting that USMLE scores are one reasonable criterion for selecting medicine residents. During residency, and beginning with the intern year, scoring in the bottom quartile increased the risk of failing the boards 7–10 fold, providing program directors the opportunity to intervene. What interventions, if any, would be effective is a question deserving of further research.

Correlation between USMLE, ITE and ABIM-CE scores

	USMLE	ITE
ITE	0.55	
ABIM	0.59	0.68

THE RELATIONSHIP BETWEEN PHYSICIAN UNCERTAINTY AND CRC SCREENING RECOMMENDATIONS IN ELDERLY PATIENTS Carmen L. Lewis. [1]University of North Carolina, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC. (Tracking ID #1641576)

BACKGROUND: To determine whether or not colorectal cancer (CRC) screening could benefit elderly patients with multi-morbidity, physicians estimate individuals' life expectancies and the potential risks and benefits of screening. Physicians' perceptions of the accuracy of these clinical assessments could influence whether physicians seek patient input before making recommendations. The purpose of this study was to examine the relationship between physicians' confidence about their life expectancy estimates, certainty of risk/benefit assessment, and patient centered recommendations for colon cancer screening in elderly patients.

METHODS: We surveyed a random sample of 650 US primary care physicians by mail. Physicians responded to questions about three clinical vignettes involving 80 year old female patients in good, fair, and poor health. We determined physicians' life expectancy estimates for each vignette, as well as their confidence in these estimates for each vignette. Physicians also reported risk/benefit assessments and their perceptions about the certainty of these assessments. We then used logistic regression to determine whether physicians' confidence in their life expectancy estimates or their perceptions of certainty about their risk/benefit assessment was related to patient centered recommendations for CRC screening. A patient centered recommendation was defined as seeking patient input before making a recommendation about screening.

RESULTS: 276 eligible physicians responded (52 % corrected response rate). The proportion of physicians who were extremely or very confident in their estimates of life expectancy varied by vignette (46 %, 38 %, 58 % for good, fair, and poor health). The proportion of physicians who felt that the benefits outweighed the risks of screening ranged from 77 % (good health) to 28 % (fair health) to 6 % (poor health). The proportion of physicians who felt extremely or very certain of the risk/benefit assessment was 67 %, 52 %, and 63 % for the good, fair, and poor health vignettes respectively. The proportion of patient centered recommendations also varied by vignette (45 %, 49 %, and 26 % for good, fair, and poor health; p<.001). Regression analysis for all three vignettes combined demonstrates that as physician confidence decreases, the odds of a patient centered recommendation increase. Compared to extremely confident, the odds increased from 2.8 for very confident, to 3.8 for neutral; to 5.9 for not very confident to 11.5 for not at all confident. Using physicians perceptions that benefits clearly outweigh the risks of screening as the reference category, the odds of a patient centered recommendation are 13.98 when the risks and benefits were perceived as equal and 0.51 when the downsides were perceived as clearly outweighing the benefits. When the physician reports being neither certain nor uncertain about the risk/benefit assessment, they are more than twice as likely to make a patient centered recommendation (OR 2.28), compared to when they are extremely or very certain.

CONCLUSIONS: Physicians' perceived confidence in their life expectancy estimates was inversely related to patient centered recommendations for colon cancer screening in the elderly. Physicians' uncertainty about their risk/benefit assessment also increased the likelihood of a patient centered recommendation. Physicians' perceptions of their clinical assessments may be an important driver of patient centered care.

THE ROLE AND IMPACT OF MEDICATION INTENSIFICATION IN SELF-MANAGEMENT INTERVENTIONS FOR ADULTS WITH TYPE 2 DIABETES: A SYSTEMATIC REVIEW AND METAREGRESSION Sophia Bellin Warren[1]; Shari Bolen[3,5]; Adam T. Perzynski[3,7]; Corinna Falck-Ytter[3]; Donna Windish[5]; Apoorva K. Chandar[6]; Paulette A. Sage[7]; Steve A. Lewis[3]; Carl V. Tyler[2]. [1]Columbia University, New York, NY; [2]The Cleveland Clinic, Cleveland, OH; [3]The MetroHealth System, Cleveland, OH; [4]Case Western Reserve University, Cleveland, OH; [5]Yale University, New Haven, CT; [6]Case Western Reserve University, Cleveland, OH; [7]Case Western Reserve University, Cleveland, OH. (Tracking ID #1638370)

BACKGROUND: Although medication intensification has been associated with improvements in glycemic control for adults with type 2 diabetes (DM), less is known about the role and additional impact of medication intensification (defined as increasing or starting a new diabetes medication) within self management interventions. Therefore, we conducted a systematic review to assess the role and impact of medication intensification in self-management interventions for adults with DM.

METHODS: We searched the MEDLINE, EMBASE, CINAHL and Cochrane Central Register of Controlled Trials databases from inception for original English-language articles. Our search strategy combined terms for Type 2 DM, randomized controlled trials, and self-management interventions. We selected original studies of adults with DM that assessed

the impact of patient activating interventions on A1c. Reviewers extracted data for each article using standardized protocols. We identified which studies reported diabetes medication intensification as part of the intervention. We then conducted unadjusted stratified meta-analyses using a random effects model to account for between study heterogeneity, followed by metaregression to determine the additional impact of medication intensification on A1c.

RESULTS: Out of 10,219 citations, 124 studies compared a self-management intervention to usual care or a minimal control group (i.e. handout) for adults with DM and also measured change in A1c. Of these, 13 studies reported using medication intensification as part of the intervention. Of these 13, nine reported sufficient data on A1c to combine in a meta-analysis. Unadjusted stratified meta-analyses of A1c showed a weighted mean difference (WMD) and 95 % confidence intervals (CI) between intervention and control/usual care arms of −0.64 % (CI −0.93 to −0.34 %; *N*=9 studies) and −0.34 % (CI −0.43 to −0.25 %; *N*=102 studies) respectively for the studies with and without medication intensification reported as part of the intervention. In a metaregression (*N*=111 studies) which adjusted for baseline A1c, study duration and study quality, medication intensification showed no significant difference in A1c between groups when compared to studies which did not report using medication intensification as part of their strategy (Beta coefficient −0.24, 95 % CI −0.59 to 0.11).

CONCLUSIONS: Medication intensification is rarely reported as an additive component to a diabetes self-management intervention, but is more commonly reported as an outcome. Given the suggestion of a larger impact on A1c in studies which combined medication intensification with self-management, we should further investigate methods that promote greater synergism between self-management and medication intensification strategies.

THE ROLE OF PHLEBOTOMY IN IMPROVING THE PATIENT EXPERIENCE OF CARE Neil N. Shah[1,2]; Carol T. DiMeo[1]; Herve Jean-Baptiste[1]; Rebecca Osgood[1]; Nicolas Nguyen[1]; David Elvin[1]. [1]Cambridge Health Alliance, Cambridge, MA; [2]Harvard Medical School, Boston, MA. (Tracking ID #1642605)

BACKGROUND: The inpatient floors of Cambridge Health Alliance (CHA) implemented computerized provider order entry (CPOE) in 2012. Laboratory utilization data demonstrated a rise in the frequency of phlebotomy since CPOE implementation. Possible explanations include an eliminated opportunity to batch labs together while processing hand-written orders and an increased ease in ordering labs multiple times per day. Improving the patient experience of care is one of the core foundations of the Institute for Healthcare Improvement's "Triple Aim," and has been embraced as an institutional priority at CHA. The authors identified frequent phlebotomy as a potential target for improving patient experience and proposed an intervention to reduce the frequency of phlebotomy on the inpatient teaching service.

METHODS: The intervention consisted of an educational campaign (presenting a 30 min lecture at the residents' weekly didactic conference and displaying posters on the inpatient floor with the message: "Patients, Not Pincushions") and an alteration in the CPOE system (an easy-to-use "3 PM" lab option) with the rationale that most afternoon labs could be batched to a single time and patients may avoid multiple blood draws. The effect of the intervention was measured by recording the number of blood draws per patient per day for 4 weeks prior to the intervention and 4 weeks after its implementation. Surveys were administered to all admitted patients on the day prior to the intervention regarding their phlebotomy experience and re-administered to all admitted patients 4 weeks later.

RESULTS: During the 4 weeks preceding the intervention, the average frequency of phlebotomy per patient per day was 1.714 with 40 % and 21 % getting drawn more than once or twice respectively. During the 4 weeks after the intervention began, the average frequency was 1.716 with 43 % and 16 % getting drawn more than once or twice respectively. Before the intervention, the patients rated their phlebotomy experience at 57 % and the courtesy of their phlebotomists at 85 % versus 71 % and 94 % respectively after the intervention. The average patient perceived his/her blood was drawn approximately 3 times per day prior to the intervention versus 2 times afterwards. The average patient rated his/her willingness to recommend the hospital to others at 84 % prior to the intervention versus 92 % afterwards.

CONCLUSIONS: The frequency of phlebotomy remained stable 4 weeks after the intervention began although there was a shift from patients getting drawn three or more times to two times. It's possible that reductions in phlebotomy were limited by an increase in patients who required monitoring of serial troponin or PTT levels (who are often the most phlebotomized patients.) The surveys suggest that patients noted improvements in their experience of phlebotomy, the courtesy of phlebotomists, and their willingness to recommend the hospital to others. Surprisingly, even though the actual frequencies stayed relatively constant, patients perceived they were phlebotomized less often after the intervention. The reasons for these changes are unclear but may reflect a change in the attitude of the staff since the intervention was implemented.

THE ROLE OF RELIGION AT THE END OF LIFE: A MEDICAL SCHOOL CURRICULUM NEEDS ASSESSMENT Zahava N. Brodt; Robert Sidlow. Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1640171)

BACKGROUND: Studies have shown that patients want physicians to attend to their spiritual concerns, and that such attention influences health care decision making. The desire for spiritual support is particularly acute in the context of end of life (EOL) care. Nevertheless, studies show that physicians are poorly prepared to deal with spirituality in the patient encounter. We sought to describe the degree of self-described religious/spiritual competency in EOL care among students at the Albert Einstein College of Medicine (AECOM.) In addition, students were asked about their educational experiences and needs regarding religion and EOL care.

METHODS: An anonymous, online survey was designed by the authors, was pilot tested, and was posted on surveymonkey.com. In September 2012, the entire AECOM student body was solicited via email to participate; requests to participate in the study were repeated for four subsequent weeks. The study was approved by the AECOM IRB.

RESULTS: Two hundred seventeen medical students participated in this study. Seven percent felt "knowledgeable" about the EOL beliefs and practices of Buddhism, 3 % about Confucianism, 7 % about Hinduism, 5 % about Islam, 39 % about Judaism, 21 % about Protestantism, and 23 % about Roman Catholicism. Seventy-four percent of respondents had interacted with a dying patient. Thirty-two percent of this subset reported that spirituality was discussed at some point during their care of the dying patient; 23 % felt "competent" providing religious or spiritual support in this context. A majority of respondents felt they needed more education regarding specific religious beliefs and rituals at the end of life in order to provide meaningful support for the dying patient.

CONCLUSIONS: This study suggests that a majority of students at one medical school were not familiar with the variety of EOL religious beliefs commonly encountered among their diverse patient population. While students often interacted with dying patients, they seldom addressed issues of spirituality with those patients, nor did they feel competent doing so. A majority of student respondents desired more education on the role of specific religions in the care of the dying patient. How to effectively incorporate this topic into a medical school curriculum is unclear at this time.

THEMES FROM FOCUS GROUPS OF VETERANS WITH CHRONIC NON-CANCER PAIN ON HIGH DOSE OPIOID ANALGESICS: LOVE/HATE OF OPIOIDS AND CHALLENGES WITH ALTERNATIVE PAIN CARE STRATEGIES Barbara J. Turner[1,3]; Erin Finley[2,3]; Diandrea R. Garza[1,3]; Shruthi Vale[1,3]; Maureen J. Simmonds[4,3]; Mary Jo Pugh[2,3]. [1]University of Texas Health Science Center San Antonio, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX; [3]University of Texas Health Science Center at San Antonio, San Antonio, TX; [4]University of Texas Health Science Center at San Antonio, San Antonio, TX. (Tracking ID #1640133)

BACKGROUND: Thousands of veterans with chronic pain are treated with long-term, high dose opioid analgesics (OAs) but little is known about their experiences/challenges with OAs and acceptance/barriers to alternative pain care strategies. We examined these topics in preparation for a small trial of peer support to improve coping and functional skills.
METHODS: We conducted 3 focus groups with 25 veterans (7–9 in each) prescribed OAs at>=50 mg morphine equivalent daily dose (MED). Focus groups were held in fall 2012 and lasted 1.5 h. A facilitator followed a guide and asked about experiences with OAs, alternatives for pain care, quality of life, problems with medical care, and receptiveness to peer support. Discussions were audio-recorded, transcribed verbatim, de-identified, and reviewed by 3 readers independently for themes based on a predetermined set of topics. Each reader proposed additional themes that were discussed by the research team. Revisions to the coding schema
RESULTS: The 25 participants' mean age was 52 (range 39–70), 32 % women, and 24 % minority. Sixty percent were taking OAs at very high doses (>=100 MED). The vast majority of statements about experiences with OAs addressed problems including: inadequate pain relief, insufficient dosing, needing to try many drugs, fear of not receiving drugs, fear of dependence, and side effects (e.g. "brain messed"). Regarding benefits, some veterans endorsed the value of high doses, methadone, multiple options of drugs, and rotating drugs. A few veterans acknowledged ease of obtaining illegal prescriptions and desirability of a "buzz". Most participants reported using alternatives to manage pain such as: stretching, relaxation, prayer, dogs, steroid injections, physical therapy, massage, chiropractors, water exercises, stimulators, other supplementary pain drugs, assistance devices, chiropractors, and humor. Yet many complained about poor access to and short duration of using these alternatives, especially physical therapy. Most veterans were unhappy, even angry, about many aspects of their medical care including: restricted resources, poor staff support, limited physician education, accusations of drug seeking, discontinuity of care, and scant information about community resources. In regard to mental health issues, several mentioned death as preferable, suicide (denying plans), poor quality of life, severe functional limitations, and social isolation. In response to the idea of peer support, most participants were leery, wanting more professional support and peers with similar pain problems who had done military service while avoiding a "pity party". Positive comments about a peer support program included: having someone to talk to, sharing strategies, value of other types of support groups, and camaraderie with other veterans.
CONCLUSIONS: This qualitative study of veterans on high dose OAs reveals enormous dissatisfaction with OA therapy. Yet participants still wanted to continue these drugs even at higher doses because they are ineffective at the current dose. Many alternatives for pain care are described but few veterans used them long term. Quality of life was poor with severe functional limitations, mood disorders, anger, and frustration with many aspects of care. We received limited support for a peer support program that offers substantial professional oversight/education and careful matching of peers.

THROUGH A GENDER LENS: A VIEW OF GENDER AND LEADERSHIP POSITIONS IN THE DEPARTMENT OF MEDICINE AT AN ACADEMIC MEDICAL CENTER Anne Monroe[1]; Rachel Levine[1]; Jeanne M. Clark[1]; Janet Bickel[2]; Linda Smith Resar[1]. [1]Johns Hopkins University, Baltimore, MD; [2]George Washington University School of Medicine, Washington, DC. (Tracking ID #1642662)

BACKGROUND: Despite increasing numbers in academic medicine, women remain underrepresented in top leadership positions. To better understand women's leadership roles, we compared the numbers and types of leadership positions held by women faculty to those held by men in the Department of Medicine (DOM) at a single academic medical center.
METHODS: We queried Division Directors and Administrators in the DOM at The Johns Hopkins University SOM in 2012. Survey information included financial compensation attached to each leadership position (% FTE and/or salary supplement) and leadership position selection process. The DOM Chair provided rank, gender, and age information for each faculty member. We assigned leadership positions to one of three tiers (Upper, Middle, or Lower) based on perceived contribution to career advancement (visibility) and salary support. Upper-tier positions were highly visible (Chair, Division Director, Associate Dean) and compensated. Middle-tier positions were less visible and compensated (e.g., Fellowship Director). Lower-tier positions were less visible and not compensated (e.g., Clinical Director). We generated summary statistics (means, proportions) for the demographic characteristics of faculty and characteristics of the leadership positions. Chi-square testing was used to compare proportions.
RESULTS: In May 2012, there were 435 DOM faculty: 160 (36.8 %) women and 275 (63.2 %) men. The percentage of women at the Asst. and Assoc. ranks was similar to men (45.4 % v 54.6 % and 39 % v 61 %, respectively). Among Full Professors, women were underrepresented compared to men (18.2 % v 81.8 %). Women were more likely to be at the Assoc. and Full Professor ranks for fewer years compared to men (4.2 y v 7.9 y and 7.4 y v 11.6 y, respectively, $p<0.05$ for both). 208 faculty members held 272 leadership positions. Women were as likely to hold a leadership position as men (46.3 % and 48.7 %, $p=0.62$). Asst. Professor women were more likely to hold a leadership position compared with Asst. Professor men (38.3 % v. 24.8 %, $p=0.04$). 25 positions were Upper-Tier, of which only 5 (20 %) were held by women compared to 20 (80 %) held by men ($p<0.0001$). About one-third of Middle-Tier (36.1 %) and Lower-Tier (35.6 %) positions were held by women. Most women (82.5 %) who held a leadership position held only one position, with fewer men (74.3 %) holding only one position ($p=0.18$). Most positions received either salary support or a salary supplement (83.6 %). There was no difference in compensated positions (Upper- and Middle-Tier v. Lower-Tier) by gender overall ($p=0.88$). However, when examined by rank, Assoc. Professor women were more likely to have a Lower-Tier position compared with Assoc. Professor men (26.7 % v. 11.8 %, $p=0.07$). Median salary support (% FTE) was 17 % (IQR 5 %, 25 %) and did not differ by gender. Chair or chief appointment accounted for the majority of leadership position selection (84 %).
CONCLUSIONS: Despite women holding leadership positions proportionate to their representation in the DOM, they were less likely to hold Upper- Tier positions that traditionally lead to the highest leadership roles such as department chair or medical school dean. Overrepresentation in noncompensated roles at the lower ranks may actually be detrimental to women, in particular as these roles may take away from other activities that contribute to advancement. More research needs to be done on the exact types of "leadership roles" women accept.

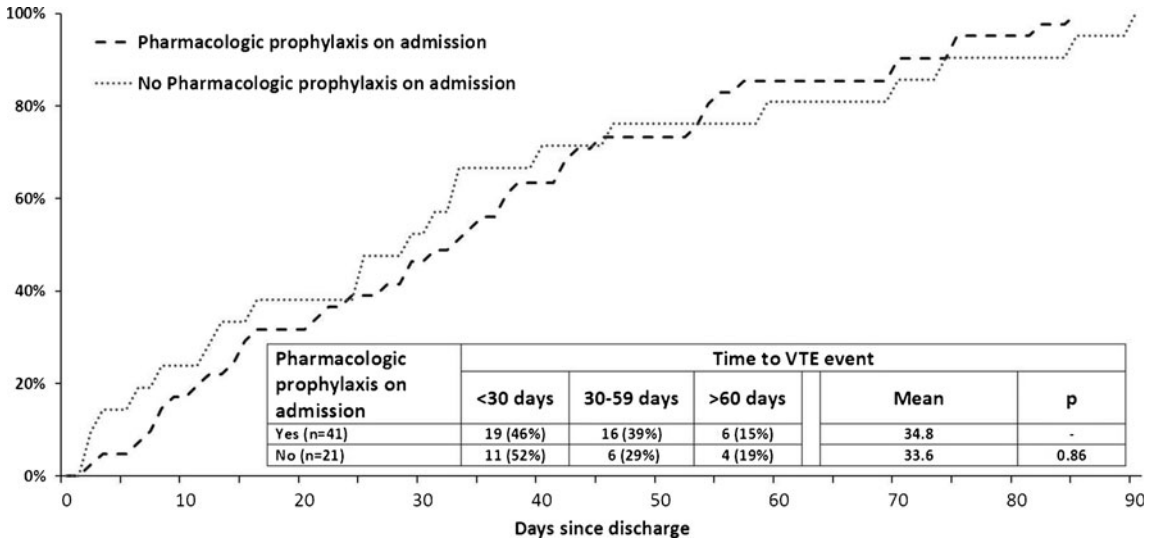
TIMING OF POST-DISCHARGE VENOUS THROMBOEMBOLIC EVENTS AND EFFECT OF PROPHYLAXIS IN HOSPITALIZED MEDICINE PATIENTS Paul Grant[1]; M. Todd Greene[1]; Steven J. Bernstein[1,2]; Julie N. Wietzke[1]; Kristen Cowan[1]; Elizabeth McLaughlin[1]; Scott Kaatz[3]; David Paje[5]; Bobby Lee[5]; James Barron[6]; Scott Flanders[1]. [1]University of Michgian, Ann Arbor, MI; [2]VA Ann Arbor Healthcare System, Ann Arbor, MI; [3]Hurley Medical Center, Flint, MI; [4]Henry Ford Health System, Detroit, MI; [5]Oakwood Healthcare System, Dearborn, MI; [6]Spectrum Health, Grand Rapids, MI. (Tracking ID #1637303)

BACKGROUND: Hospitalized patients are known to be at increased risk for venous thromboembolism (VTE). The timing of post-discharge VTE events and the effect of pharmacologic prophylaxis exposure during hospitalization on such events are not well understood. The Michigan Hospital Medicine Safety Consortium, a statewide collaborative designed to prevent adverse events in hospitalized medical patients, assessed VTE events post-discharge.
METHODS: Using web-based data entry, a nurse abstractor at each participating hospital ($n=35$) collected detailed demographic and clinical data, including all known risk factors for VTE and use of pharmacologic prophylaxis. The occurrence and date of VTE events during a 90-day post-discharge follow-up period among patients who had not experienced a VTE during hospitalization and who were discharged to home or an assisted

living facility were determined by medical record review and follow-up phone calls. Time to 90-day VTE event was stratified by receipt of pharmacologic prophylaxis on admission. Patients were excluded if they were: <18 years of age; admitted for VTE, surgery, or comfort care; had an elevated INR or exposure to systemic anticoagulation on admission; transferred to the intensive care unit during the hospitalization; or had a subsequent inpatient stay prior to a 90-day follow-up VTE event.

RESULTS: Of 25,423 patients included, 247 (0.97 %) had a post-discharge VTE event during 90-day follow-up. Patients who received pharmacologic prophylaxis on the day of admission or the following day (60 %) were older (66.9 vs. 62.3 years, $p<0.001$) and had a higher Caprini score (5.8 vs. 5.1, $p<0.001$), but had the same length of hospital stay (4.4 days, $p=0.99$), compared to those with no prophylaxis. Of the 247 patients with VTE, 132 (53 %) were discharged to home or an assisted living facility and had a VTE date identified. Of these patients, 58 (44 %) had another inpatient stay prior to their VTE event. The subsequent inpatient stay status was not known for 12 (9 %) patients. Among the 62 patients (47 %) who did not have a subsequent inpatient stay, the mean time to post-discharge VTE event did not differ by receipt of pharmacologic prophylaxis on admission (figure).

CONCLUSIONS: Post-discharge VTE among medical patients is uncommon and almost half of patients had a subsequent inpatient stay prior to the 90-day follow-up VTE event. A majority of VTE events in patients without a subsequent inpatient stay occurred within the first 35 days post-discharge. The trajectories of time to VTE events do not appear to be associated with receipt of pharmacologic prophylaxis during hospitalization.



Pharmacologic prophylaxis on admission	Time to VTE event				
	<30 days	30-59 days	>60 days	Mean	p
Yes (n=41)	19 (46%)	16 (39%)	6 (15%)	34.8	-
No (n=21)	11 (52%)	6 (29%)	4 (19%)	33.6	0.86

TO SAVE MONEY ON PRESCRIPTION DRUGS, ARE PATIENTS WILLING TO TRADE OFF CONVENIENCE, SIDE EFFECTS, AND EFFICACY? Margaret Lowenstein[1]; Carolyn C. Cannuscio[2,3]; Madeleine P. Tardif[5]; David Grande[5,3]. [1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]Leonard Davis Institute of Health Economics, University of Pennsylvania, Philadelphia, PA; [4]University of Pennsylvania, Philadelphia, PA; [5]University of Pennsylvania, Philadelphia, PA. (Tracking ID #1640103)

BACKGROUND: Individuals with chronic illnesses face substantial, and often unaffordable, out-of-pocket health care costs, leading many patients to forego needed medical therapy. Cost-related non-adherence has significant negative health ramifications. Strategies are needed to help patients and physicians navigate cost concerns, in order to achieve care plans that optimize affordability and patient outcomes. Prior research has shown that patients want to have conversations with their doctors about cost and believe their doctors can lower their cost burden. However, little is known about patients' willingness to endure tradeoffs like inconvenience, reduced efficacy, and side effects, in order to save money.

METHODS: We conducted a mail survey, with an embedded randomized experiment, in a sample of 1,400 adults nationwide who applied for financial support from a patient assistance program (HealthWell Foundation). A total of 842 responded (107 incorrect addresses, 6 deceased; response rate: 65 %). Participants were randomized to one of two groups that could, theoretically, save either $50 or $150 per month in out of pockets costs by changing their prescription drugs and enduring 10 different tradeoffs across three domains (convenience, efficacy, and side effects). Using a 5-point Likert scale, participants rated their willingness to make each specified tradeoff. A rating from 1 to 2 on any item indicated that a patient was "unwilling" to accept the specified tradeoff in order to save $50 or $150 per month.

RESULTS: Among respondents, 86 % wanted their doctor to consider medication cost when prescribing and 78 % believed that their doctor had the ability to lower out-of-pocket costs. Patients were generally willing to endure inconvenience to save money; only 31 % were unwilling to accept the inconvenience (e.g., more frequent dosing) associated with a cheaper prescription drug. There was no difference between the $50 versus $150 cost savings experimental groups (31 % vs 30 %, $p=0.61$). Patients were generally unwilling to endure reduced efficacy or increased side effects in order to save money. Regardless of the hypothetical monthly cost savings ($50 vs $150), the majority of patients were unwilling to tolerate a higher risk of hospitalization (69 % vs 64 %, $p=0.21$), heart attack (75 % vs 70 %, $p=0.10$), or functional limitations (73 % vs 68 %, $p=0.13$). Similarly, the majority were unwilling to accept greater side effects for cost savings, but there were small but significant differences by experimental group ($50 vs. $150) for headache (81 % vs. 73 %, $p=0.006$), sexual dysfunction (68 % vs. 59 %, $p=0.007$), fatigue (77 % vs. 69 %, $p=0.008$), muscle aches (79 % vs. 71 %, $p=0.014$), and upset stomach (80 % vs 74 %, $p=0.041$) but not urinary frequency (60 % vs. 55 %, $p=0.170$).

CONCLUSIONS: In our study, the majority of patients were open to enduring inconvenience in order to save money on prescription drug costs. Patients were generally opposed to enduring increased side effects, although there were modest increases in willingness when the cost savings were greater ($150/month vs. $50 per month). Regardless of potential cost savings, patients were generally opposed to sacrificing efficacy in order to reduce out-of-pocket costs. Physicians can consider these potential tradeoffs in discussions with patients regarding how to optimize both cost savings and patient outcomes.

TRANSITIONS OF CARE: INTERNAL MEDICINE PGY1 AMBULATORY EDUCATION Rachel K. Miller; Christina R. Whitehouse; Jerry Johnson; Jennifer Lapin; Karen B. Hirschman. University of Pennsylvania, Philadelphia, PA. (Tracking ID #1643097)

BACKGROUND: Transitions of care pose significant risks for complex medical patients. In July 2007, the American College of Physicians, Society of Hospital Medicine, and Society of General Internal Medicine came together to address quality issues and to develop consensus standards for transitions of care between inpatient and outpatient settings. In parallel, the Accreditation Council of Graduate Medical Education (ACMGE) has identified systems-based practice as a core competency or all residents. Still, there are scarce educational interventions for trainees to learn principles of safe transitions. Most also do not actively engage the learners. Our hypothesis was that an internal medicine transitions of care curriculum that spanned the hospital to home through small, interactive group didactics and a post-hospitalization discharge home visit would increase residents' confidence and knowledge in implementing safer discharges.
METHODS: Two cohorts of Internal Medicine interns (PGY1) at a large academic medical center participated in this study between 7/2010 and 12/2011 in the 4 week ambulatory block. A 1 h small group session focused on: identifying vulnerable patients, the interprofessional team, home services and skilled nursing facilities, medication reconciliation, discharge summaries/instructions, and patient communication. The interns went on a post-hospitalization discharge home visit with a visiting nurse led by the University of Pennsylvania Transitions of Care Nursing Team or selected Penn Care at Home nurses. In a debriefing session, each pair of interns described the patient they had seen in the home and key transitions issues that they encountered.
RESULTS: Interns' knowledge and attitudes about transitions of care were captured using pre/post test questions with a 5-point Likert scale. The assessment tool contained questions of knowledge and self-assessment of confidence and attitudes about transitions of care themes. The pre-post analysis on 107 pretest and 90 post-test was conducted using independent *t*-test analysis. The first six items of the knowledge tool were scored and a pre-post analysis using independent sample t-tests on unmatched data found a statistically significant increase in knowledge ($t=-7.268$, $p=.000$). Overall, the interns showed an increased degree of confidence in: identifying potential threats to a well executed transition between sites of care ($p<0.001$); managing the discharge process of complex patients with chronic illness ($p<0.001$); performing medication reconciliation at the time of hospital discharge ($p<0.001$); and knowledge of the home health care services available to patients with chronic illness ($p<0.001$). In addition, they showed increased knowledge in the roles of physical therapists ($p<0.001$), occupational therapists ($p<0.001$), nursing ($p<0.010$), and social work ($p<0.046$). Open ended comments included themes of greater awareness of interprofessional roles and services available in the discharge process, importance of medication reconciliation and discharge documentation.
CONCLUSIONS: This transitions of care education initiative for internal medicine interns showed increased confidence in high risk discharge issues and increased knowledge of community resources and the role of multidisciplinary team members in safe transitions of care. Future directions include narrative analysis of the interns' reflections of the curriculum and further evaluation of the long term impact of a transitions of care education program.

TRANSITIONS OF CARE AT A COMMUNITY HOSPITAL: A SERIES OF QUALITATIVE INTERVIEWS Manik Chhabra; Janet J. Ho; Krisda Chaiyachati; Jing Luo; Trishul Siddharthan; Theodore Long; Donna Windish. Yale University School of Medicine, New Haven, CT. (Tracking ID #1640075)

BACKGROUND: As the Patient Protection and Affordable Care Act measures quality through hospital readmission rates and enforces it financially, research evaluating alterable risk factors has expanded. Most studies on the readmissions challenge have explored the healthcare providers' viewpoint, while few assess the patient's perspective. Because little is known about the patient's experience when transitioning from hospital discharge to home, we have conducted a qualitative study of our readmitted patients to lay the foundation for a patient-centered intervention to improve readmission rates.
METHODS: We completed semi-structured qualitative interviews of patients readmitted to a medicine service within 30 days of discharge at Waterbury Hospital—a 357-bed, private, community teaching hospital in Waterbury, Connecticut using a sample of convenience. Exclusion criteria included the inability to pass a Mini-Cog screen, speaking a language other than English or Spanish, and chart evidence of advanced cognitive impairment. All interviews were conducted while patients were readmitted to the hospital and were audiotaped and transcribed by an independent company. Three investigators independently generated codes from the primary data and developed a final code list using the constant comparative method, and themes were then identified.
RESULTS: Six patients were interviewed: three women, three Caucasian, with a mean age of 49.3 years. All had only high school education, and five received Supplemental Security Income. All patients had insurance; four had Medicaid and one had Medicare. Five patients' admission diagnoses were identical to their prior discharge diagnoses. The average age-adjusted Charlson Comorbidity score was 4.2. Overall, patients stated positive experiences with the hospital discharge process, including medication reconciliation, discharge instructions, and follow-up appointments with primary care providers (PCP). Despite reporting good PCP relationships, when patients experienced changes in health status or unanticipated medication side effects, several reported making the decision to visit the emergency department without PCP input. At home, patients felt capable enacting their care plans, but reported difficulty accessing healthy food and had limited assistance from family members who also faced health and economic barriers.
CONCLUSIONS: Previous literature suggests correlations between increased readmission risks and low socioeconomic status (SES), with subsequent discharge interventions targeted at medication reconciliation and education. We found, however, that despite a low SES, our patients infrequently reported financial obstacles to obtaining medications, access to a PCP, receipt of in-home services (e.g. visiting nurses), or stated confusion about medication instructions. Instead, emergency department visits and readmissions were commonly the result of patients making their own triage decisions that bypassed potential intervention from a PCP. As we continue to interview our readmitted patients, we hope to reveal more patient-driven themes, which will guide potential interventions for reducing Waterbury's readmission rate.

TREATING COMPLEX PATIENTS IN PRIMARY CARE: PHYSICIAN OFFER A NEW VIEW OF COMPETING DEMANDS Danielle F. Loeb[1]; Elizabeth A. Bayliss[2,3]; Carey Candrian[1]; Frank V. deGruy[3]; Ingrid A. Binswanger[1]. [1]University of Colorado School of Medicine, Aurora, CO; [2]Kaiser Permanente, Denver, CO; [3]University of Colorado School of Medicine, DenverAurora, CO. (Tracking ID #1629676)

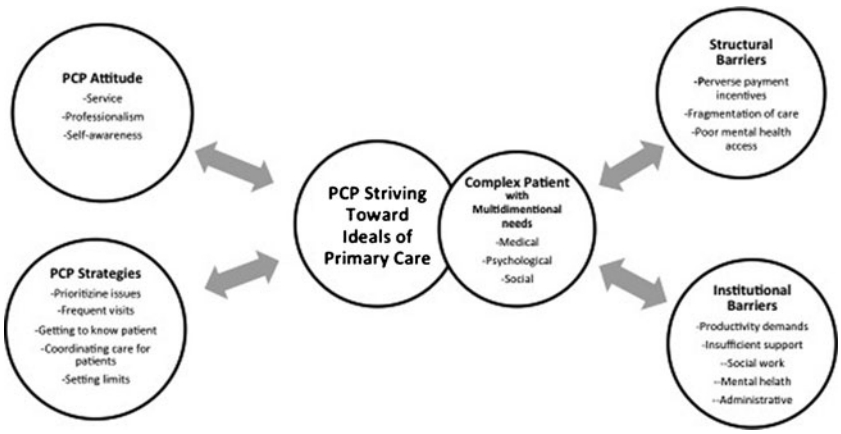
BACKGROUND: Complex patients with multiple chronic conditions present unique management challenges for primary care physicians (PCPs). Polypharmacy, multiple consultants, and conflicting guidelines for their different conditions complicate the care of these patients. We sought to understand PCPs' experiences in managing complex patients, the system barriers and facilitators in their management, and the changes PCPs feel would improve their ability to effectively treat these patients.
METHODS: This study was a part of a qualitative investigation of physician experiences with complex patients. We recruited 15 internal medicine PCPs from 2 university clinics and 3 community health clinics using email notices sent to all physicians in the practices. We used systematic non-probabilistic sampling to achieve an even distribution of participants with respect to gender, years in practice, and practice site. Providers received a working definition of complexity in advance of the interviews and were asked to bring de-identified notes from three patient encounters with patients they considered complex. We conducted open-

ended in-depth interviews. Transcripts were coded and analyzed utilizing a team-based participatory general inductive approach.

RESULTS: PCPs described daily struggles and successes in caring for patients with complicated medical, psychological, and social needs. From these descriptions four primary domains emerged: 1) healthcare system barriers, 2) institutional barriers, 3) the importance of PCP attitudes, and 4) PCPs' personal strategies for managing these patients. Physicians experienced competing demands in their efforts to overcome institutional and structural barriers while trying to live up to their own ideals. (Figure 1) They attributed many of their struggles to inadequate time and resources. In particular, they expressed frustration over the lack of support in addressing patients' social and mental health needs. They defined their successes as times when they were effectively able to fulfill what they saw as their true role as a PCP: managing medical issues to help patients avoid hospitalizations, using their knowledge and trusting relationships with patients to help patients make difficult medical decisions, and coordinating the care of multiple specialists. PCPs felt that systematic changes such as decreasing productivity demands on providers caring for complex patients and improving support services for complex patients would allow them to use their expertise to effectively manage the overall care of these patients.

CONCLUSIONS: In this study, we identified core struggles in the daily practice of PCPs managing complex patients. New models of care such as the patient centered medical home may address some of these struggles. However, whether these models of care alone can meet the time and personnel resource needs of complex patients still needs further investigation.

A New View of Competing Demands



TREATMENT DECISIONS AMONG MEN WITH LOW-RISK PROSTATE CANCER Richard Hoffman[1]; Stephen K. Van Den Eeden[3]; Amethyst Leimpeter[3]; Catherine Tomko[2]; Kimberly Davis[2]; Jun Shan[3]; Kathryn Taylor[2]. [1]Albuquerque VA Medical Center, Albuquerque, NM; [2]Georgetown University, Washington, DC; [3]Kaiser Permanente Northern California, Oakland, CA. (Tracking ID #1638750)

BACKGROUND: Prostate cancer screening can lead to overdiagnosing and overtreating low-risk prostate cancer (PCa). Active surveillance (AS) is an intensive monitoring strategy involving periodic PSA tests, digital rectal examinations, and prostate biopsies that offers active treatment (AT), either surgery or radiotherapy, only for evidence of cancer progression (or for patient request). Although AS mitigates the harms of prostate cancer screening without apparently compromising cancer control, it is not widely utilized. We assessed clinical and decision-making factors associated with selecting AS vs. AT.

METHODS: In the first phase of a longitudinal cohort study, we conducted baseline telephone interviews with 116 (77 % response rate) Kaiser Permanente Northern California men with newly diagnosed (median 23 days), low-risk PCa (PSA<10, Gleason <7). Enrollment is ongoing with a target of 1,470 subjects. Survey domains included socio-demographics, family history, decision-making processes and preferences, and general and disease-specific quality of life measures.

RESULTS: Men were 61.7 (SD=6.7) years old, 84 % were white, 75 % were married, 52 % had completed college, and 57 % were employed. By the time of the baseline assessment, 64 % (N=74) had already made a treatment decision, including 28 % selecting AS, 58 % selecting AT (56 % of whom selected surgery), and 14 % selecting watchful waiting (no intention of undergoing curative treatment). Although the AS and AT groups had similar PSA (mean [SD] 5.7 [1.6] ng/mL vs. 6.0 ng/mL [1.6]) and Gleason scores (both 6), AT patients were younger (60.9 [5.2] vs. 63.5 [7.7], p<0.08), had better physical function (p<0.05), and were more likely to have relatives who died from PCa (26 % vs. 3 %, p<0.05). Treatment groups did not differ on education, PCa knowledge, prostate-related symptoms, anxiety, or depression. AT recipients were more likely to have assumed primary responsibility for making the treatment decision (86 % vs. 63 %), to feel completely sure of their decision (79 % vs. 42 %), and to consider that actively treating the cancer was very important (72 % vs. 52 %), all p values<0.05. Men selecting AS were more likely to engage in shared decision-making (29 % vs. 12 %, p<0.05). Men selecting AT (65 %) were far more likely than AS men (10 %) to receive recommendations for AT, p<0.05. Only 8 (19 %) of the men selecting AT discussed AS.

CONCLUSIONS: Most men with low-risk PCa made treatment decisions within 30 days of diagnosis, usually selecting AT. Men selecting AT were more likely than those selecting AS to highly value active cancer treatment and to be quite certain of their decision. However, men selecting AT were less likely to engage in shared decision-making. Reducing unnecessary treatment for low-risk PCa will likely require providing balanced decision-support information very soon after—or even before—diagnosis.

TREATMENT SEEKING CHARACTERISTICS OF WOMEN PARTICIPATING IN A YOGA INTERVENTION FOR PTSD Shivani M. Reddy[1,2]; Alexandra M. Dick[3]; Megan R. Gerber[1,2]; Karen S. Mitchell[3,4]. [1]Boston University School of Medicine, Boston, MA; [2]VA Boston Healthcare System, Boston, MA; [3]VA Boston Healthcare System, Boston, MA; [4]Boston University School of Medicine, Boston, MA. (Tracking ID #1630738)

BACKGROUND: Veterans and civilians with mental health disorders have a growing interest in complementary and alternative medicine (CAM), though evidence for efficacy is sparse. Patients who seek CAM range in their traditional mental healthcare utilization, from minimal to extensive, and they may face several barriers in accessing mental health services. We describe treatment seeking (TS) characteristics of women with PTSD who participated in a yoga intervention, as well as subsequent perception of PTSD symptoms and symptom management.

METHODS: We conducted a pilot study of a randomized controlled trial at a VA medical center comparing a 12-session weekly yoga intervention with control. Veteran and civilian women ages 18–65 with PTSD or sub-threshold PTSD were included. The intervention consisted of trauma-sensitive yoga; controls completed weekly assessments. Demographic data included age, ethnicity, education, and veteran status. Self-reported measures of TS at baseline included treatment history, characteristics of providers accessed, and reasons for not seeking treatment. We then assessed subsequent treatment uptake among those without prior mental healthcare at post intervention and 1-month follow-up. We also examined interest in treatment, perception of PTSD symptoms, and self-efficacy around symptom management. We used Fisher exact tests to compare yoga and control groups.
RESULTS: Thirty-eight women were randomized to the yoga intervention (n=20) and assessment-only control (n=18). Mean age was 43.3. 53 % were Caucasian, 37 % Black, and 11 % Asian or other. Over 90 % had education beyond high school. The majority of participants (76 %) completed the study. At baseline, the majority of participants reported accessing mental health care in several settings including the VA, community health clinics, and private practices. Forty-one percent of participants had specifically engaged in PTSD treatment prior to the study. Participants reported visits to psychologists and social workers (53 %), primary care physicians (25 %), and psychiatrists (9 %). Over 50 % had seen more than one provider. Of patients without prior treatment, only 1 in 12 participants post intervention and 1 in 10 at follow-up had met with a professional to discuss a mental health problem. However, the majority of patients in both groups expressed interest in PTSD treatment (post-intervention 72 %, follow-up 56 %). 71 % of yoga group participants, compared to 25 % of controls, noticed reduced PTSD symptoms post intervention (p=0.19); this trend was similar at follow-up (69 % yoga vs. 18 % control, p=0.05). Yoga group participants also reported improved ability to self-manage symptoms (Post intervention: 78 % yoga vs. 50 % control, p=0.15. Follow-up: 92 % yoga vs. 9 % control, p<0.001).
CONCLUSIONS: Many women with PTSD participating in a yoga intervention had accessed mental health services, often from multiple providers. During the study, there was limited uptake of traditional therapy, though many treatment-naïve participants expressed interest in PTSD treatment. Additionally, yoga group participants reported improved perception of PTSD symptoms and self-efficacy compared to the controls. Further study is warranted into the role of CAM in conventional mental healthcare utilization.

TREATMENT TRIALS IN INTENSIVE CARE Yael Schenker[1]; Greer A. Tiver[1]; Seo Yeon Hong[2]; Douglas B. White[3]. [1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh, Pittsburgh, PA. (Tracking ID #1634829)

BACKGROUND: Family members of critically-ill patients in the ICU face complex choices about whether to continue life-sustaining therapies or transition to comfort care. Offering limited trials of intensive care for patients with an uncertain but relatively poor prognosis has been recommended as a way to frame treatment options that accords with many patients' preferences. However, to date it is not know the extent to which treatment trials are discussed or how they are presented in actual practice. We sought to characterize whether and how the option of a treatment trial is discussed with families during decision making about life-sustaining treatment.
METHODS: We conducted a mixed-methods cohort study of audio-recorded family conferences in 5 ICUs at two hospitals in San Francisco, California. We identified conferences about life-sustaining treatment decisions by asking physicians beforehand if they anticipated discussion of withholding or withdrawing treatment or bad news. We used the analytic technique of qualitative description with constant comparative techniques to inductively develop a framework categorizing: 1) types of trials and 2) discussion of advantages or disadvantages of trials. Based on prior work, we also assessed whether and how three key elements of a trial were discussed: clinical milestones to evaluate outcomes of the trial, a suggested timeframe for re-evaluation, and a description of potential actions at the end of the trial. Kappa statistics for our main results ranged from 0.85 to 1.0, indicating excellent inter-rater reliability.
RESULTS: A total of 169 family members and 54 physicians participated in 72 family conferences for patients at high risk of death or severe functional impairment. Audio-recorded conferences took place an average of 10 days after ICU admission. The inpatient mortality rate was 72 %. Trials were offered in 15 % (11 of 72) conferences and consisted of two types: 1) time-limited trials, defined as continuing life-sustaining treatment with a plan to reassess after a defined period of time using clinical milestones and 2) symptom-limited trials, defined as discontinuing life-sustaining treatments but continuing basic medical care aimed at survival—rather than transitioning to a purely palliative approach—with a plan to reassess based on the patient's symptoms. Discussion of advantages and disadvantages of a treatment trial focused on whether a trial would be in accordance with the patient's wishes; whether the patient may be more comfortable, live longer or recover; and whether a trial might provide benefit to the family. Clinicians frequently did not fully address key elements of a trial, such as specific criteria by which its effectiveness would be evaluated and possible next steps based on the results of the trial.
CONCLUSIONS: In this cohort of patients with advanced critical illness, trials were infrequently and incompletely discussed. We present an empirically-derived framework describing two types of treatment trials in intensive care. Additional work is needed to improve communication about treatment trials and evaluate their impact on patient and family outcomes.

TREATMENT WITH DALTEPARIN IS ASSOCIATED WITH LOWER RISK OF BLEEDING COMPARED TO TREATMENT WITH UNFRACTIONATED HEPARIN, IN PATIENTS WITH CHRONIC KIDNEY DISEASE Doyun Park; Margarita Kushnir; Manuela Calvo; Clemencia Solorzano; Mark Sinnet; Henny H. Billett; William Southern. Montefiore Medical Center-Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1642363)

BACKGROUND: Subcutaneously administered low-molecular-weight heparins (LMWH) have emerged as the drugs of choice for hospitalized patients requiring anticoagulation because of their favorable safety profile and ease of use. However, because LMWHs are excreted by the kidneys, and accumulate in patients with chronic kidney disease (CKD), intravenous infusion of unfractionated heparin (UFH) is often used in patients with CKD. We sought to examine the safety of using Dalteparin, a LMWH that has shown minimal tendency to accumulate, in patients with CKD. We hypothesized that any risk associated with accumulation of Dalteparin would be offset by the risks of intravenous infusion of UFH, which requires more frequent monitoring and adjustment of dosing. We therefore compared the risks of bleeding in patients with CKD who are treated with Dalteparin vs. UFH.
METHODS: In this retrospective cohort study we examined all patients with CKD (GFR <60), admitted to the medical service of an urban academic medical center from January 1, 2006 to June 30, 2010 who were treated with treatment doses of Dalteparin or UFH. Treatment doses were defined as >10,000 units of daily for a minimun of 3 days for Dalteparin and intravenous infusion for a minimun of 3 days with at least one activated partial thromboplatin time >50 s for UFH. Smaller doses were thought likely to be used for prophylaxis, and were excluded. Demographic characteristics, laboratory values, ICD-9 code diagnoses, and inpatient medications were extracted for each admission from the electronic medical record. The primary outcome was bleeding, defined as an ICD-9 code for any bleeding event within 60 days of the initiation of anticoagulant therapy. Patients treated with dalteparin vs. UFH were compared with respect to demographic characteristics, length of stay, admitting diagnosis, co-morbidities, history of bleeding, treatment with warfarin, laboratory values (creatinine, liver function tests, hemoglobin, platelet count, INR, aPTT) and bleeding rates using t-tests and chi-squared tests, as appropriate. We constructed logistic regression models to examine the independent association between choice of anticoagulant (Dalteparin vs. UFH) and

bleeding rates, after adjustment for demographic and clinical characteristics of patients. A systematic chart review to confirm bleeding events identified by ICD-9 codes is underway but not complete.
RESULTS: Of 3,546 patients with CKD treated with anticoagulants, 2,045 (58 %) received Dalteparin and 1,501 (42 %) received UFH. Patients treated with dalteparin were older, and had fewer co-morbidities. A total of 355 bleeding events were identified. The incidence of bleeding was 7.6 % in the dalterparin group vs. 11.7 % in the UFH group ($p<0.001$). After adjustment for demographic and clinical characteristics, treatment with dalteparin was associated with significantly smaller risk of bleeding (OR 0.69, 95 % CI: 0.55–0.88) when compared with treatment with UFH. A preliminary analysis of the chart review suggests that 54.0 % of ICD-9 coded bleeding events were confirmed.
CONCLUSIONS: The use of dalteparin in patients with renal insufficiency was associated with a lower rate of ICD-9 coded bleeding events compared to the use of UFH in a group of patients with similar characteristics. Dalteparin appears to be safe to use in patients with CKD. An assessment of the full chart review to confirm the bleeding events is ongoing.

TRENDS AND CORRELATES OF OPIOID ANALGESIC RECEIPT AMONG VETERANS WITH AND WITHOUT HIV: 1999–2010 William Becker[2,1]; E. J. Edelman[1]; Kirsha S. Gordon[2]; Robert Kerns[2,1]; Stephen Crystal[5]; Lynn E. Fiellin[1]; Adam Gordon[3]; Joseph L. Goulet[2,1]; Amy C. Justice[1,2]; David A. Fiellin[1]. [1]Yale University School of Medicine, New Haven, CT; [2]VA Connecticut Healthcare System, West Haven, CT; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]Rutgers, State University of New Jersey, New Brunswich, NJ. (Tracking ID #1642150)

BACKGROUND: Recent observational studies have demonstrated increased risk of adverse effects of opioid analgesics among those with serious mental illness (SMI) and substance use disorders, conditions that are disproportionately prevalent among Veterans and patients with HIV. In order to characterize change in opioid exposure over time, we sought to examine trends and correlates of opioid receipt in a large, national sample of Veterans with HIV (HIV+) and without HIV (HIV-).
METHODS: Using the Veterans Aging Cohort Study-Virtual Cohort consisting of 41,924 HIV + and 85,470 demographically-matched HIV- patients from 1999 to 2010, our sample included Veterans lacking a cancer diagnosis with ≥1 outpatient or inpatient encounter. Using the 12-year time frame as a single period, we performed descriptive statistics to characterize patients receiving opioids and their receipt patterns—any, high dose (>120 mg/day) and long-term (>90 days) receipt—using equianalgesic conversions to standardize dose. We then constructed multivariable models to assess the relationship between demographic and clinical characteristics and receipt of any, high dose, and long-term opioids, using generalized estimating equations to account for repeated measures. Finally, using each of the 12 years as a serial cross section, we examined trends in the proportion of the sample with any, high dose and long-term receipt as well as total yearly opioid dose, days supplied and median daily dose.
RESULTS: Among 127,394 patients, 67 % received ≥1 opioid prescription during the study period. Among patients receiving opioids, 11 % received high dose and 38 % received long-term therapy. In multivariable analyses, HIV, having an acute pain-related diagnosis, having a chronic pain-related diagnosis, number of pain-related diagnoses, Hepatitis C, diabetes, and smoking (current or former) were positively associated with opioid receipt whereas black race, Hispanic ethnicity, other race/ethnicity, SMI, alcohol use disorder, and drug use disorder were negatively associated with receipt. Among those receiving opioids, HIV, number of pain-related diagnoses, Hepatitis C, SMI, and smoking (current or former) were positively associated, and black race, Hispanic ethnicity, other race/ethnicity, alcohol use disorder and drug use disorder negatively associated with high dose opioid receipt. Also, older age, having a chronic pain-related diagnosis, number of pain-related diagnoses, Hepatitis C, diabetes, SMI, and smoking (current or former), were positively associated, and black race, Hispanic ethnicity, other race/ethnicity, having an acute pain-related diagnosis and drug use disorder negatively associated with long-term opioid receipt. In yearly trends analysis, the proportion of HIV + patients receiving opioids significantly increased from 21 % in 1999 to 40 % in 2010, and from 25 % to 37 % for HIV- patients. The proportion of patients with high dose receipt increased significantly, as did total yearly opioid dose and days supplied. Median daily dose remained stable. Trends were similar in patients with and without HIV.
CONCLUSIONS: We observed an increase in opioid receipt among HIV + and HIV- Veterans, increased odds of any, high dose and long-term opioid receipt among subpopulations at higher risk of adverse effects and decreased odds of receipt among non-white patients. These findings suggest ongoing need for development of risk mitigation and clinical standardization interventions.

TRENDS IN ADVANCE DIRECTIVE USE AND HOSPITALIZATION AMONG ELDERLY AMERICANS, 2000–2010 Maria J. Silveira; John D. Piette. Ann Arbor VAMC HSRD, Ann Arbor, MI. (Tracking ID #1643048)

BACKGROUND: Background: Elderly patients are advised to complete advance directives (i.e. living wills and durable powers of attorney for healthcare) to guide decision-making about the aggressiveness of treatment in the event that they lose decision-making capacity. Studies show that most elderly prefer to limit aggressive care at the end of life, avoid hospitalization, and die at home. We chose to describe population trends in advance directive completion, hospitalization, and place of death for 2000–2010.
METHODS: Methods: We used data from the Health and Retirement Study (HRS), a biennial longitudinal survey of a nationally representative cohort of elderly adults regarding their medical, social, and financial situation. The sample included 6,122 HRS participants who died between 2000 and 2010 and were 60 or older at the time of death. Data were drawn from proxy interviews regarding the decedent's circumstances at death. We used descriptive statistics to examine variation in prevalence of living wills (LWs), durable powers of attorney for healthcare (DPAHC), hospitalization rates in the last year of life, and rates of hospital death by year of death. We used multivariable logistic regression to explore the association between these outcomes and subjects' sociodemographic and clinical characteristics. We accounted for the complex sampling design of the HRS in all analyses.
RESULTS: RESULTS: Most subjects had an advance directive prior to death (63.2 %). The proportion of decedents who had a LW and/or DPAHC at the time of death increased from 47 % in 2000 to 72 % in 2010 ($p=0.000$). DPAHCs were more popular than LW for 10 out of 10 years and rates of DPAHC completion increased more rapidly over time. During the same period of time, the rates of hospitalization in the year prior to death significantly increased, while the rates of hospital death significantly decreased.
CONCLUSIONS: Conclusions: There has been a significant increase in rates of advance directive completion over the last decade, with durable powers of attorney for healthcare being preferred over living wills. During the same time period, however, there was a significant increase in hospitalization rates but a decrease in hospital death, suggesting that advance directives may not protect patients from hospitalization, but instead increase the likelihood that they are discharged prior to death.

TRENDS IN AND CORRELATES OF AWARENESS OF A PREDIABETES DIAGNOSIS AMONG US ADULTS Jeffrey T. Kullgren[1]; HwaJung Choi[2]; Michele Heisler[1]. [1]Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI. (Tracking ID #1642610)

BACKGROUND: An estimated 1 in 3 US adults have prediabetes, an asymptomatic condition associated with an elevated risk for developing type 2 diabetes. This risk can be significantly reduced through lifestyle modification or pharmacotherapy. An important first step in engaging these high-risk patients in programs shown to be effective such as the Diabetes

Prevention Program (DPP) is to ensure that they are aware of their prediabetes diagnosis. Although the main DPP results were published in 2002 and have been widely disseminated, we lack information on current rates of awareness of a prediabetes diagnosis, and correlates of such an awareness. The objective of this study was to describe recent trends in and factors associated with awareness of a prediabetes diagnosis among US adults.

METHODS: We conducted repeated and pooled cross-sectional analyses of data from the nationally-representative 2005–2006, 2007–2008, and 2009–2010 continuous National Health and Nutritional Examination Survey (NHANES). The analytic sample (n=2,178) was comprised of adults without diabetes who met the American Diabetes Association (ADA) criteria for prediabetes used from 2005 to 2010: a fasting plasma glucose of 100 to 125 mg/dL or a 75 g oral glucose tolerance test 2-h glucose of 140 to 199 mg/dL. In the repeated cross-sectional analysis we estimated a univariate logistic regression model to examine the relationship between NHANES cycle and awareness of a prediabetes diagnosis. In the pooled cross-sectional analysis, we used multivariable logistic regression to estimate associations between individual, insurance, and access characteristics and awareness of a prediabetes diagnosis.

RESULTS: Among US adults with prediabetes from 2005 to 2010, only 5.0 % (95 % CI, 4.2 to 6.0) were aware of a prediabetes diagnosis. There was a slightly higher prevalence of awareness in 2009–2010 (6.5 %, 95 % CI, 4.7 to 8.3) compared to 2007–2008 (4.1 %, 95 % CI, 2.7 to 5.5; P= 0.04). In multivariable logistic regression, adults who met one or more ADA criteria for screening for diabetes did not have greater awareness than those who did not meet any ADA criteria [adjusted odds ratio (AOR) 1.99, 95 % CI, 0.36 to 11.13; P=0.42]. However, adults with at least 2 chronic conditions that are not ADA criteria for diabetes screening (e.g., asthma or arthritis) had greater awareness than those without a chronic condition outside of the ADA diabetes screening criteria (AOR 2.51, 95 % CI, 1.17 to 5.40; P=0.02). Additionally, adults with at least 2 outpatient health care visits in the last year had greater awareness than those without any outpatient utilization in the last year (AOR 2.84, 95 % CI, 1.17 to 6.92; P=0.02).

CONCLUSIONS: Despite a slight recent increase, fewer than 1 in 10 US adults with prediabetes are even aware that they have this condition, meaning that an estimated 58 million Americans do not know that they have prediabetes. Individuals with few chronic conditions or little outpatient utilization are even less likely to be aware of a prediabetes diagnosis. This lack of awareness means that millions of Americans who could benefit from strategies proven to reduce rates of progression to diabetes may lack the knowledge and motivation to engage in evidence-based programs.

TRENDS IN THE QUALITY OF CARE AND RACIAL/ETHNIC DISPARITIES IN US HOSPITALS, 2005–2010 Amal N. Trivedi[1,2]; Wato Nsa[3]; Leslie R. Hausmann[5]; Jonathan S. Lee[5]; Allen Ma[3]; Dale W. Bratzler[3]; Kate Goodrich[5]; Fiona M. Larbi[5]; Michael J. Fine[4]. [1]Providence VA Medical Center, Providence, RI; [2]Alpert Medical School of Brown University, Providence, RI; [3]Oklahoma Foundation for Medical Quality, Oklahoma City, OK; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA; [5]Centers for Medicare and Medicaid Services, Baltimore, MD. (Tracking ID #1641183)

BACKGROUND: In 2004, the Centers for Medicare and Medicaid Services (CMS) initiated public reporting on the quality of care in US hospitals for 3 common conditions: acute myocardial infarction (AMI), congestive heart failure (CHF), and community-acquired pneumonia (CAP). Hospitals report performance without stratifying results for vulnerable subgroups; therefore, it is unclear whether potential secular changes in performance are accompanied by corresponding changes in racial and ethnic differences. We examined trends in the quality of care for white, black, and Hispanic patients during the 6 years following the public reporting initiative.

METHODS: We used 2005–2010 data from the Quality Improvement Organization Clinical Data Warehouse, a CMS-maintained all-payer patient-level repository to which approximately 95 % of US hospitals report. We included patients age 18 and older sampled for at least 1 quality indicator. The outcomes were adherence to 18 quality indicators for AMI, CHF and CAP. The primary independent variable was race/ethnicity (non-Hispanic white, black, Hispanic). Covariates included age, sex, comorbidities and the following hospital characteristics: volume, bed size, teaching status, and rural location. We employed hierarchical regression to model within-hospital disparities (quality gaps between whites and minority patients at the same hospital) and between-hospital disparities (quality gaps arising from disproportionate concentration of black or Hispanic patients in low-quality hospitals). We examined change over time in all measures and change in racial/ethnic disparities for measures that had at least a 3 point white-black or white-Hispanic difference in 2005.

RESULTS: The sample included 13,297,043 hospitalizations in 5,013 acute care hospitals. From 2005 to 2010, performance rates improved on all 18 measures, ranging from 3.2 % for receipt of aspirin at discharge (from 95.4 % to 98.6 %; p<0.001) to 49.1 % for receipt of PCI within 90 min (from 42.0 % to 91.1 %; p<0.001). The white-black difference (higher quality for whites) exceeded 3 % for 8 measures in 2005. The white-black gap significantly narrowed over time for 7, ranging from a 2 % decrease in disparity in blood culture prior to antibiotic administration to an 11.9 % decrease in disparities for influenza vaccination (p<0.001 for each change). The white-Hispanic disparity exceeded 3 % for 12 measures in 2005. We observed significant narrowing of this disparity over time for all of these measures. The reductions ranged from a 1.4 % decrease in disparity for guideline-consistent antibiotic selection to a 12.9 % decrease in disparity for pneumococcal vaccination (p<0.001 for each change). In analyses of the 3 measures with the largest racial-ethnic gaps in 2005, changes in within-hospital disparity accounted for 51 %–55 % of the decline in white-black disparity and 23 %–48 % of the decline in white-Hispanic disparity. Changes in between-hospital disparity accounted for 49 %–55 % of the decline in white-black disparity and 52 %–77 % of the decline in white-Hispanic disparity.

CONCLUSIONS: From 2005 to 2010, we observed overall improvements and significantly narrowed racial and ethnic disparities in the quality of hospital care for AMI, CHF, and CAP. Reductions in racial/ethnic disparities were driven both by more equal care for whites and minorities receiving care in the same hospital and improved quality of care among hospitals serving disproportionately higher proportions of minority patients.

TRENDS IN THE AMBULATORY DIAGNOSIS AND TREATMENT OF NON-MALIGNANT PAIN IN THE UNITED STATES, 2000–2010 G. Caleb Alexander[3,5]; Daubresse Matthew[1]; Hsien-Yen Chang[2]; Yuping Yu[1]; Shilpa Viswanathan[1]; Nilay Shah[6]; Randall S. Stafford[5]; Stefan P. Kruszewski[7]. [1]Johns Hopkins School of Public Health, Baltimore, MD; [2]Johns Hopkins School of Public Health, Baltimore, MD; [3]Johns Hopkins School of Public Health, Baltimore, MD; [4]Johns Hopkins Medicine, Baltimore, MD; [5]University of Illinois at Chicago School of Pharmacy, Chicago, IL; [6]Mayo Clinic, Rochester, MN; [7]Stefan P. Kruszewski, M.D. & Associates, Harrisburg, PA. (Tracking ID #1633140)

BACKGROUND: The United States accounts for 5 % of the world's population yet 80 % of prescription opioid consumption. However, escalating rates of prescription opioid use and abuse have occurred in the context of efforts to improve the identification, treatment and management of non-malignant pain. This is important, since chronic pain affects approximately 100 million adults in the United States and pain is the most common reason patients seek health care. We sought to characterize the diagnosis and pharmacologic management of non-malignant pain in ambulatory, office-based settings between 2000 and 2010.

METHODS: We conducted a serial cross-sectional analysis of the National Ambulatory Medical Care Survey (NAMCS), a nationally representative audit of office-based physician visits. Analyses were limited to adults without a diagnosis of malignancy. Our main outcomes included the annual volume of visits with a primary symptom or diagnosis of pain and reported prescription opioid or non-opioid pharmacologic therapy in visits limited to new musculoskeletal pain.

RESULTS: The prevalence of reported pain as a primary symptom or diagnosis consistently represented one-fourth of visits, varying less than 1 % from 2000 through 2010. Patient-reported pain as a primary symptom comprised 21 % to 22 % of visits, whereas provider diagnoses of pain increased nearly 50 % from 2000 (5.7 % of visits with pain as a primary diagnosis) to 2010 (8.5 %). Among all pain visits, opioid prescriptions nearly doubled from 10.1 % to 18.6 %, whereas acetaminophen use increased modestly (2.80 % to 3.41 %) and NSAID use remained unchanged (23.0 %–23.5 % of visits). From two-fifths to one-half (42 %–50 %) of new musculoskeletal pain visits were associated with a pain medication. Rates of opioid utilization increased 62 % from 15 % of visits (2000) to 24 % of visits (2010) and rates of non-opioid pharmacotherapies, such as NSAIDs, decreased from 32 % of visits (2000) to 23 % of visits (2010). Multiple sensitivity analyses supported the robustness of our results and their substantive interpretation.
CONCLUSIONS: Concern among clinicians and policy-makers regarding prescription drug abuse has often been countered by calls to improve the identification and treatment of chronic non-malignant pain. We examine whether the dramatic escalation of prescription opioid sales has been accompanied by similar increases in non-opioid analgesics and changes in pain prevalence. Our findings indicate that the prevalence of reported pain in ambulatory practice has not changed during the past decade. However, patients' symptoms are increasingly diagnosed by clinicians and treated with prescription opioids. Trends in opioid prescriptions have not been paralleled by similar increases in the use of non-opioid therapies, representing an important opportunity to reduce a growing epidemic of prescription opioid abuse.

UNDERSTANDING AFRICAN-AMERICAN PATIENTS' REFUSAL OF PNEUMOCOCCAL VACCINATION Tiffany Brown; Francisco Acosta; Ariane M. Garrett; Ji Young Lee; Stephen D. Persell; David W. Baker; Shira N. Goldman; Kenzie A. Cameron. Northwestern University Feinberg School of Medicine, Chicago, IL. (Tracking ID #1624562)

BACKGROUND: The Advisory Committee on Immunization Practices recommends that adults 65 and older get vaccinated against invasive pneumococcal disease. In 2008, approximately 60 % of older adults reported receiving pneumococcal vaccination (PnVx). However, racial disparities in rates of PnVx exist; only 46 % of African Americans have been vaccinated compared to two-thirds of whites. In one urban academic practice, we found that only 2.9 % of white patients directly refused PnVx after their doctor recommended it, whereas 11.4 % of African Americans refused vaccination. We sought to better understand the reasons African-American patients refused the vaccine.
METHODS: We conducted a mixed method telephone survey of patients in a general internal medicine clinic. African Americans age 65 or older with a documented refusal of PnVx in the electronic health record system were eligible. We assessed a range of beliefs including: (a) perceptions of susceptibility to pneumonia; (b) perceived severity of pneumonia; (c) beliefs about the side effects of PnVx; (d) normative influences; and (e) comparative perceptions of the safety and importance of childhood vs. adult vaccinations. Participants responded to a series of knowledge and belief items on a Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree), and responded to open-ended questions. Participants' medical records were queried to identify adherence to other recommended preventive services (e.g. cancer screenings).
RESULTS: Participants' (N=40) mean age was 73 years, 95 % were female, 72 % had at least some college education, and 35 % self-reported receiving other adult vaccinations. Electronic queries of the participants' medical records indicated that 81 % of the sample had documentation of at least one recommended cancer screening. Participants reported low levels of personal susceptibility to pneumonia (M=2.75, sd=1.43), but recognized that pneumonia could be deadly (M=4.32, sd=0.97). Participants worried about the side effects of PnVx (M=4.13, sd=1.34). Regarding normative influences, participants reported disagreement with the statement "My relatives and/or close friends think that I should get the pneumonia shot" (M=2.30, sd=1.27). Participants felt childhood vaccines were safer (M=4.24, sd=1.22) than adult vaccines (M=3.41, sd=1.40; $p<0.01$). Similarly, participants believed in the importance of childhood vaccinations (M=4.23, sd=1.33), yet were neutral about the importance of booster vaccinations for adults (M=3.16, sd=1.48). Participant responses to open-ended questions provided additional context for their reported perceptions of low susceptibility (e.g., "Well, I really feel that if you take all precautions that brings on pneumonia you shouldn't have it") and high severity (e.g., "[It's] serious, very serious. It's life threatening if it goes untreated").
CONCLUSIONS: Results from our sample of primarily female African-American patients suggest that those who refuse PnVx do understand the severity of pneumonia, yet may not perceive themselves to be susceptible to the disease. Strategies to improve vaccination rates among African Americans may need to include a strong focus on personal susceptibility. Additionally, given the large discrepancies in how this sample perceives childhood vs. adulthood vaccinations, the use of consistency theory in persuasive messages regarding adult vaccination should be explored, focusing on the importance of vaccination across the lifespan.

UNDERSTANDING RESIDENT LEARNING PREFERENCES WITHIN THE NOON CONFERENCE LECTURE SERIES: A QUALITATIVE STUDY Adam Sawatsky[1]; Susan Zickmund[1]; Kathryn Berlacher[2]; Dan Lesky[3]; Rosanne Granieri1. [1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA. (Tracking ID #1615062)

BACKGROUND: The Accreditation Council for Graduate Medical Education (ACGME) mandates that U.S. residency programs provide regular didactic sessions. The noon conference lecture remains a central means for meeting this mandate. Studies have demonstrated conflicting evidence for long-term knowledge gains and improvement in scores on national standardized exams using this approach. This has led to attempts at innovation in how we teach residents. We conducted a qualitative study to explore the attitudes of residents toward the lecture format to describe their learning preferences and to plan educational interventions.
METHODS: We conducted focus groups with internal medicine, internal medicine-pediatric and preliminary residents at the University of Pittsburgh to discuss their attitudes about noon conference, a lecture series that is designed to teach core medical knowledge to residents. Using standard methods for conducting focus groups, we developed a focus group guide through an iterative process involving core residency faculty. This guide was pilot-tested before the final version was established. A study team member who is trained as a focus group moderator and is independent from the training program moderated the discussions and transcribed them verbatim. The principal investigator reviewed each transcript and developed a codebook; two coders independently applied codes to the transcripts. We used Cohen's κ statistic to calculate inter-coder reliability; the total mean kappa value for the assignment of codes was 0.80. We used qualitative content analysis to summarize the content and identify themes derived from the data.
RESULTS: Of the 144 total internal medicine, medicine-pediatrics and preliminary residents at our institution, 41 (28 %) participated in 7 focus groups. Of the 41 participants, there were 17 (41 %) first-year residents and 24 (59 %) second- and third-year residents, and 22 (54 %) were men. Four main categories emerged from the qualitative analysis: motivations for attendance, content of sessions, teaching methods, and engagement. The main motivations for attendance were learning, eating lunch, and having a break in the day; the main deterrent from attending was a heavy workload. Regarding the content of sessions, residents preferred content that was clinically relevant, common, practical, readily applicable and likely to change their management of patients. In discussion about teaching methods, many residents believed that the most effective lectures had a limited number (approximately 3–5) of clearly-stated learning points and used a framework of clinical cases and questions to illustrate concepts. Residents desired active engagement in a safe environment that encouraged participation without fear of judgment.

CONCLUSIONS: The results of this qualitative analysis provide essential information to medical educators about the motivations and learning preferences of residents. Residents' stated learning preferences in this study are consistent with principles of adult learning, yet these principles are not routinely implemented in the standard lecture format. The lecture format for teaching residents is also not congruent with the ACGME learning objective of application of knowledge to clinical care. This study has begun to evaluate and understand the learning preferences of residents and, in conjunction with principles of adult learning, can guide how we restructure residency education.

UNDERSTANDING THE STRUCTURE AND FUNCTION OF PHYSICIAN-PATIENT INTERACTIONS IN TERMS OF CONTINGENT BEHAVIORS Harry B. Burke; Dorothy Becher; Patrick G. O'Malley. Uniformed Services University of the Health Sciences, Bethesda, MD. (Tracking ID #1640479)

BACKGROUND: The physician-patient interaction is central to medicine. The predominant approach to understanding these interactions has been based on Roter's system of coding participants' direct utterances (the purpose of the utterance and its literal meaning are the same) into one of 37 mutually exclusive and exhaustive categories, summing up the instances of each utterance type, and inferring the characteristics of the interaction. There are two problems with this approach. The first problem is that many times the participants will say something that is indirect and there are more than 37 types of indirect utterances. The second problem is that an interaction, by its very nature, is conditional—the actions of one person are conditional on the actions of the other person. This means that the unit of analysis must be dyadic rather than individual; contingent rather than unilateral; it must include both participants and the meaning of an utterance is known in the context of what the other participant said before and after the utterance.
METHODS: For outpatient physician-patient interactions, we created new a functional unit system composed of 8 types of interactional units. These units are: (1A) discussing a new clinical problem, (1B) discussing an existing clinical problem, (2) reviewing what has happened to the patient since the last visit, (3) discussing treatments and tests, (4A) filing out forms, (4B) ordering screening and prevention tests, (5) medical conversations not directly related to the patient, and (6) social conversation including greetings and closings. Each functional unit includes all the utterances by both physician and patient that are related to that unit. The functional units have high inter-rater agreement. We audio-recorded, transcribed, and coded 10 outpatient physician-patient interactions.
RESULTS: There were 272 occurrences of all the interactional units across the 10 interactions. Discussions of new or existing problems comprised 16 % of the interactional units, reviewing what had happened to the patient since the last visit comprised 28 % of the units, discussing tests and treatments comprised 23 % of the units, filling out forms and screening comprised 17 % of the units, non-patient related medical conversations comprised 5 % of the units, and social conversations comprised 11 % of the units. These interactional units can be used to model the structure of the interaction. One type of structure is how the units are related to each other. We examined the structure of the interaction by determining the probability of occurrence of adjacent units. When the interaction transitions from interactional unit 1A, 33 % of the time it goes to unit 2; and when the interaction is in interactional unit 2, it was preceded by unit 1A 13 % of the time. The most common transition was from unit 2 to unit 3, which occurred 29 times. The chance of transitioning from unit 2 to unit 3 was 38 %, and unit 3 is preceded by unit 2 46 % of the time.
CONCLUSIONS: We suggest that interactions cannot be understood as unilateral activity because they are inherently social; they must be understood in terms of contingent behaviors. We created a new functional unit system, where the units include the contingent behaviors of both participants, and we examined the transitions between units. The units and transitions between units can be used to model physician-patient interactions.

UNDERSTANDING TIME SPENT ABOVE AND BELOW THE TARGET RANGE AMONG PATIENTS RECEIVING WARFARIN Zayd A. Razouki; Adam Rose. Bedford VA Medical Center, Bedford, MA. (Tracking ID #1628372)

BACKGROUND: Poor anticoagulation control, which can be represented by low percent time in therapeutic range (TTR), is a known predictor for morbidity among patients receiving warfarin. While a considerable amount is known about patient characteristics predicting low TTR, little is known about what predicts whether patients will spend time specifically below or above the target range. It is usually assumed that poor control is the same as erratic control, in which a patient spends time both above and below the target range, but this has not been examined. Our goal was to differentiate between patient characteristics associated with a low TTR that has a unidirectional tendency (INR consistently above or consistently below) as opposed to those that are associated with an erratic pattern.
METHODS: We studied 103,897 patients who received warfarin for more than 6 months, with a target INR of 2–3 from 100 Veterans Health Administration (VA) sites between 10/06–9/08. Our primary outcomes of interest were percent time spent above an INR of 3 and percent time spent below an INR of 2. Independent variables included patient demographics, physical and mental illness, number of non warfarin medications, number of hospitalizations during the study period, in addition to anticoagulation indication. All results given below are fully-adjusted for the other variables in our final multivariate model.
RESULTS: Nonwhite race was found to predict more time spent below the target range (unidirectional low TTR). For example, Black and Hispanic patients spent 3.3 % and 1.5 % time more below range, compared to Whites ($p<0.001$), while spending 0.5 %. 0.9 % less time above target ($p<0.001$). Similarly, patients living in high poverty areas spent more time below range (2.1 %) and less time above range (1.5 %) compared to those living in low-poverty areas. Cancer, non-alcohol drug abuse, dementia, and bipolar disorder were also strongly associated more time below the target range (3.1 %, 2.7 %, 2.1 % and 1.9 %, respectively, $p<0.001$) and less time above target. On the other hand, other characteristics were associated with erratic low TTR (more time spent both above and below the target range). For example, patients with alcohol abuse spent 3.6 % more time below target, and 2.5 % more time above target, compared to patients who did not abuse alcohol (both $p<0.001$). Patients hospitalized 4 or more times during the study period spent 7.9 % more time above and 2.1 % more time below target range (both $p<0.001$), compared to patient not hospitalized at all. Similarly, patients who were taking more than 16 medications spent 4.5 % more time below range and 1.6 % more time above range, compared to patients taking 0–7 medications. There were no factors that consistently predicted a unidirectional tendency to spend time above the target range.
CONCLUSIONS: We identified two patterns of poor anticoagulation control, namely poor control with an erratic pattern and poor control with a unidirectional tendency towards low INR. Specific patient-level characteristics predicted one or the other pattern. The most likely explanation for a unidirectional tendency toward low INR is that providers intentionally choose to target a low (guideline-discordant) target range for certain groups of patients. Our results suggest that poor anticoagulation control is not a monolithic phenomenon, but rather a common final pathway for at least two separate phenomena, each of which may need to be addressed on its own terms.

UNEXPLAINED GEOGRAPHIC VARIATION IN OPIOID UTILIZATION IN HOSPITALIZED US MEDICAL PATIENTS Shoshana J. Herzig[1]; MIchael B. Rothberg[2]; Michael Cheung[1]; Long Ngo[1]; Edward R. Marcantonio[1]. [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Cleveland Clinic, Cleveland, OH. (Tracking ID #1641125)

BACKGROUND: Recent literature has drawn attention to the high and increasing rates of opioid prescribing and overdose-related deaths in the United States. These studies have focused on community-based and emergency department prescribing, leaving prescribing practices in the inpatient setting unexamined. Considerable variation in use, unrelated to patient characteristics,

could be a marker of inappropriate prescribing practices and poor quality of care.

METHODS: We studied a large cohort of adult admissions to the internal medicine service from July 2009 through June, 2010 using Premier's Perspective database—the nation's largest inpatient drug utilization database, containing administrative data from over 600 hospitals similar in composition to acute care hospitals nationwide. We defined opioid exposure as presence of at least one charge for an opioid medication during the admission. We used a generalized estimating equation with a log link to investigate the association between opioid use and patient characteristics, hospital characteristics, and US census region, controlling for repeated patient admissions with an autoregressive correlation structure.

RESULTS: Our cohort included 1.14 million medicine admissions, spanning 288 hospitals (median age=64 years; 46 % men). Opioids were used in 49 % of admissions. Morphine was the most commonly used opioid medication (20 %), followed by hydrocodone (14 %) and hydromorphone (13 %). Opioids were administered in 39 %, 50 %, 53 %, and 55 % of admissions to hospitals in the Northeast, Midwest, South, and West, respectively. After adjustment for patient demographics, comorbidities, and hospital characteristics, opioid use was more common in patients who were female, aged 25–64 (compared to those older and younger), of Caucasian race, with non-private insurance. The strongest predictor of receipt of opioid medication was US census region; compared to patients in the Northeast, the relative risk of opioid receipt for patients in the Midwest, South, and West were 1.26 (1.26–1.27), 1.35 (1.35–1.36), and 1.41 (1.40–1.42), respectively.

CONCLUSIONS: In this large pharmacoepidemiologic cohort, we found that opioids were used in almost half of hospitalized medical patients. Considerable geographic variation in opioid use was evident even after controlling for patient and hospital characteristics. Increased attention should be paid to the role that inpatient opioid prescribing plays in the increased rates of chronic opioid use and overdose related deaths in the US.

UNMET NEEDS, SERVICE USE AND PATIENT ACTIVATION: IMPLICATIONS FOR PANEL MANAGEMENT TO PROMOTE SELF-MANAGEMENT OF CHRONIC ILLNESS Ashley E. Jensen[1,2]; Katelyn Bennett[1,2]; Rachel Blitzer[1,2]; Scott Sherman[2,1]; Mark D. Schwartz[1,2]. [1]NYU School of Medicine, New York, NY; [2]Veterans Affairs New York Harbor Healthcare System, New York, NY. (Tracking ID #1640260)

BACKGROUND: As primary care shifts to patient centered medical home (PCMH) models, we need to clarify patients' preferences for health care services and support for self-management of chronic illnesses. Need and strategies for support may depend on the level of patient activation, a measure of skills, knowledge, and confidence in managing one's health. To address these questions, we assessed patient activation, unmet care needs, and service use.

METHODS: We surveyed a randomly selected sample of 965 patients at baseline of the Program for Research on the Outcomes of VA Education (PROVE), a controlled trial of the impact of panel management on hypertension and smoking outcomes through the addition of a non-clinical panel management assistant (PMA) and clinical microsystem education to randomly assigned primary care teams at two campuses of the VA New York Harbor Health Care System (NYHHS). Eligible patients were smokers or hypertensive veterans whose last blood pressure reading was uncontrolled (systolic greater than 140 or diastolic greater than 90). We used the Patient Activation Measure (PAM), a reliable and valid, unidimensional, 13-item scale, that scores activation from 0 to 100. PAM scores are divided into 4 stages of activation: Stage 1 individuals may not believe the patient role is important (PAM<=47.0), Stage 2 patients may lack knowledge or skill to take action (47.1–55.1), Stage 3 patients are beginning to take action (55.2–67.0), and Stage 4 patients have taken action but may have difficulty maintaining behaviors over time (>67.0). Other survey items included measures of health care service use and unmet needs, and interest in outreach by telephone from PMAs.

RESULTS: Overall survey response rate was 50 % (481/965). Mean PAM score was 63.3 with a 95 % CI [61.7, 65.0]. Of the 175 hypertensive patients, 72 % were in the highest stage of activation (Stage 4) compared with 35 % of the 266 smoking patients, and 21 % of the 40 patients with both conditions ($p<0.01$). The most common services patients were not currently using but would like to (Unmet Need) were: help to build motivation to improve health (40 %); groups to improve health (36 %); telephone support to monitor and managing health (34 %); and materials to help understand health conditions (32 %). Patients reporting unmet needs had lower PAM scores than those already using or not interested in the service (Table 1). Overall 85 % of patients would not mind being contacted by telephone by PMAs to help them manage their health conditions between visits.

CONCLUSIONS: Our findings indicate gaps in patient support that may be addressed through proactive outreach by PMAs. Patient activation may be a helpful marker of engagement and self-management behaviors to track as we test strategies of population level outreach. Further research is warranted to determine how panel management outreach impacts patient activation, service use, and clinical outcomes.

Table 1: Mean PAM Score by Service Needs and Use

Service	Mean PAM Score		ANOVA p value
Unmet need for service	Used Service	Would not use service	
Help to build motivation to improve health	61.8	64.4	62.3 0.075
Groups to improve health	60.2	62.4	65.3 0.071
Telephone support	59.3	65.7	62.6 0.041
Materials to understand health conditions	60.1	66.5	61.3 0.0040

UNMET HEALTH NEEDS AMONG HOMELESS AND VULNERABLY HOUSED ADULTS IN THREE CANADIAN CITIES Niran Argintaru[1,2]; Catharine Chambers[1]; Evie Gogosis[1]; Susan Farrell[3]; Anita Palepu[5]; Fran Klodawsky[5]; Stephen Hwang[1]. [1]Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada; [2]University Of Western Ontario, Toronto, ON, Canada; [3]University of Ottawa, Ottawa, ON, Canada; [4]University of British Columbia, Vancouver, BC, Canada; [5]Carlton University, Ottawa, ON, Canada. (Tracking ID #1641955)

BACKGROUND: Approximately 150,000 Canadians and up to 3.5 million Americans experience homelessness each year. Homeless individuals experience a high burden of health problems, yet face significant barriers in accessing health care. Less is known about unmet needs for care among vulnerably housed persons—those living in poor-quality or temporary housing, and at high risk of becoming homeless. The objectives of the study presented here were to examine the factors associated with unmet needs for health care in a community-based sample of homeless and vulnerably housed individuals within a universal health insurance system.

METHODS: 1,191 single adults were recruited at shelters, meal programs, community health centers, drop-in centers, rooming houses, and single room occupancy hotels in Vancouver, Toronto, and Ottawa, Canada, throughout 2009. Baseline interviews elicited demographic characteristics, physical and mental health statuses, chronic health conditions, health-related quality of life, health care providers and utilization, perceived barriers to health care, and unmet needs for health care. Multivariate logistic regression was used to identify factors associated with self-reported unmet needs for health care during the past 12 months.

RESULTS: Of the 1,181 participants included in the analysis, 445 (37 %) reported unmet needs for health care. There were no significant differences between homeless and vulnerably housed participants, therefore the two groups were analyzed together. In adjusted multivariate analyses, factors associated with a greater likelihood of reporting unmet needs were employment in the past 12 months (AOR=1.40, 95 % CI=1.03–1.91) and having ≥3 chronic health conditions (AOR=2.17, 95 % CI=1.24–3.79). Having higher health-related quality of life (AOR=0.21, 95 % CI=0.09–0.53), improved mental (AOR=0.97, 95 % CI=0.96–0.98) or physical health (AOR=0.98, 95 % CI=0.96–0.99), and having a primary care provider (AOR=0.63, 95 % CI=0.46–0.85) decreased the likelihood of reporting unmet needs. An analysis of participants reporting one

or more previous mental health diagnoses identifies significantly increased likelihood of unmet need for health care in participants with mood disorders (OR=1.73 95 % CI=1.36, 2.20) and anxiety disorders (OR=1.96 95 % CI=1.48, 2.57).
CONCLUSIONS: Homeless and vulnerably housed adults have a similar likelihood of experiencing unmet health care needs, highlighting that the provision of insecure, poor-quality housing does not improve unmet needs for health care. Despite Canada's universal health insurance system, these populations face sizeable barriers to meeting health care needs and are burdened by a high prevalence of unmet needs for care. Participants with multiple chronic health conditions, worse health status, or no primary care provider were more likely to report unmet needs for health care. It is therefore critical to develop policies and programs that are easily accessible and appropriate for vulnerable individuals in order to meet their unique health care needs. Future studies should identify the types of health care that are lacking and explore effective strategies to reduce barriers to accessing care.

UNMET NEEDS OF CAREGIVERS OF PATIENTS REFERRED TO A DEMENTIA CARE PROGRAM Lee A. Jennings[1]; David B. Reuben[2]; Leslie C. Evertson[2]; Katherine S. Serrano[2]; Linda Ercoli[3]; Zaldy Tan[2]; Neil Wenger[1]. [1]University of California, Los Angeles, Los Angeles, CA; [2]University of California, Los Angeles, Los Angeles, CA; [3]University of California, Los Angeles, Los Angeles, CA. (Tracking ID #1642624)

BACKGROUND: Research has demonstrated that in practice settings, primary care physicians (PCP) do not provide high quality care for patients with dementia. As part of the baseline evaluation of a new comprehensive dementia care management program, we evaluated caregiver reports of dementia care and self-efficacy as well as mental health and burnout.
METHODS: We developed a 9-item pre-visit caregiver survey to assess caregiver perception of the PCP's recognition of the patient's cognitive impairment and its impact on health conditions, the caregiver's experience with advice on dementia-related topics, and the caregiver's self-efficacy for caring for the patient with dementia and for accessing help. Response options were on a five-point rating scale with 1 = strongly agree and 5 = strongly disagree. Caregivers completed the survey as a supplement to the patient pre-visit assessment prior to the program intake visit, and during the intake visit, caregivers completed the PHQ-9 survey about themselves and also completed the 13-item Modified Caregiver Strain Index (CSI). Survey data were analyzed using simple univariate statistics.
RESULTS: To date, 125 patients and 159 caregivers have been evaluated as part of the dementia care program. 99 caregivers of 72 patients have been administered the caregiver pre-visit survey supplement. 51 caregivers (51.5 %) completed the pre-visit supplement survey. Although 44 % of responding caregivers agreed that they have received advice, only 30 % were aware of services available to help them provide care and only 16 % knew how to get community services that will help them provide care. Moreover, only 16 % agreed that they feel confident handling problems like the patient's memory loss, wandering, or behavioral problems, and only 20 % agreed that they feel confident that they can deal with the frustrations of caregiving. Although the majority of respondents (78 %) agreed that the patient's regular doctor understands how memory or behavior problems complicate other health conditions, only 28 % agreed that they have a healthcare professional who helps them work through dementia care problems. One hundred fifty-one caregivers (98.1 %) completed the PHQ-9 with mean score of 4.26 (+/−4.41). 138 caregivers (89.6 %) completed the Modified CSI with a mean score of 11.49 (+/−6.93).
CONCLUSIONS: These initial data from caregivers of patients with dementia referred to a dementia care program demonstrate that although PCPs were perceived as understanding how dementia affects other conditions, most caregivers felt they did not have a healthcare professional to help them with dementia problems, had considerable unmet need, and had low confidence in their ability to manage caregiving. On average, caregivers reported low levels of depression and moderate caregiver strain.

UNPACKING RESIDENT-LED CODE STATUS DISCUSSIONS: RESULTS FROM A MIXED METHODS STUDY Rashmi K. Sharma; Nelia Jain; Eytan Szmuilowicz; Diane Wayne; Kenzie A. Cameron. Northwestern University, Chicago, IL. (Tracking ID #1640547)

BACKGROUND: We previously showed that a multimodality communication skills intervention improved internal medicine residents' ability to perform a code status discussion (CSD) with a standardized patient (SP). However, the impact of education on CSD content and outcomes is unknown. We compared CSDs between intervention and control residents to identify key drivers of code status determination.
METHODS: Fifty-one internal medicine PGY1 residents were randomized to either intervention (n=23) or control (n=28). Intervention group residents received a multimodality CSD skills training program including lectures, deliberate practice of CSD skills, and maintenance of a CSD log. Six months later all residents completed a 15 min videotaped CSD with a single SP portraying a 47-year-old man hospitalized with metastatic colon cancer. Digital recordings were transcribed verbatim, de-identifed, independently reviewed, and coded by two of three coders using an open coding approach. Coders assessed the final CSD determination based on resident statements as: a) full code, b) do-not-resuscitate (DNR), or c) could not be determined. Discrepancies were discussed and resolved by consensus. Chi-square tests were used to evaluate the association between study group (intervention vs. control) and the key themes identified through qualitative analysis.
RESULTS: Inter-rater reliability for code status determination was high (Cohen's kappa=0.89). Three intervention and one control resident (8 %) did not complete code status determination within the allotted time. Final code status determination for the remaining discussions was full code for 12/20 (60 %) in the intervention group and 22/27 (81 %) in the control group (p=0.10). Themes associated with determination of full code included focusing on the mechanics of resuscitation and not providing clinical context, framing the decision as one that only the patient can make, and equating the patient's description of himself as a fighter with a desire to be resuscitated. Themes associated with determination of DNR included: discussion of outcomes of resuscitation and quality of life, discussing resuscitation in the context of patient values/goals, and physician recommendation regarding code status. Compared to controls, intervention residents were more likely to explore patient values/goals (75 % vs. 33 %; p=0.005), provide clinical context when discussing resuscitation (80 % vs. 19 %, p=0.000), and make a recommendation regarding code status (40 % vs. 0 %; p=0.000). They were less likely than controls to equate the patient's use of the term "fighter" with preference for full code (20 % vs. 52 %, p=0.03) and frame the decision as one solely for the patient (25 % vs. 59 %, p=0.02). There were no significant differences between intervention and control residents for discussion of outcomes or quality of life; topics which both groups did infrequently.
CONCLUSIONS: CSD determination was driven primarily by how residents framed discussion of code status, and whether they incorporated patient values and goals and/or made a recommendation regarding code status. Limited by a small sample size, we found a trend toward intervention residents being more likely than controls to conclude the SP desired DNR status. Additional research is needed to evaluate the effect of education on CSD determination in actual patient encounters.

UNSTABLE HOUSING AS A RISK FACTOR FOR POOR DIABETES AND HYPERTENSION CONTROL Michael S. Wolf[1]; Elizabeth A. Bojarski[1]; Laura Curtis[1]; Stacy Bailey[2]; Hilary K. Seligman[3]. [1]Northwestern University, Chicago, IL; [2]UNC-Chapel Hill, Chapel Hill, NC; [3]UCSF, San Francisco, CA. (Tracking ID #1643090)

BACKGROUND: Root causes of known disparities in chronic disease outcomes, including diabetes, are not entirely known. One less-studied, psychosocial risk factor may be unstable housing, which could present enormous challenges for diabetes self-management. The objective of this

study was to examine the association between housing status and glycemic and blood pressure control among low-income patients from primary care clinics in Missouri.
METHODS: A secondary, observational analysis was conducted using baseline data from a clinical trial evaluating a diabetes self-management intervention in patients with type II diabetes. In-person interviews were conducted with 667 patients receiving care in ten federally qualified health centers at three sites in 2008 and 2009. Living situation, socioeconomic and other personal characteristics were collected. Self-reported living situation was defined as stable or unstable housing; the former renting or owning a house or apartment and the latter was defined as temporary arrangements including living with a friend or relative without paying rent, or other. The most recent hemoglobin A1c (HbA1c) value and three blood pressure values recorded prior to the baseline interview were obtained from medical charts, when available (n=631, 95 %). Chi-square and t-tests were used to examine the bivariate associations between demographic variables and tight glycemic and blood pressure control. Separate multivariable logistic regression models, clustered by site, were run for each clinical outcome with housing status as the main independent variable of interest.
RESULTS: Out of 631 diabetic participants with available medical record data; mean age was 54.8 years old (SD=11.1), 63 % were female, and 31 % identified as African-American. 13 % were classified as having unstable housing. In terms of self-care, 72 % had not achieved tight glycemic control (HbA1c≥7.0), and similarly 72 % had also uncontrolled blood pressure (average SBP≥130 or DBP≥80). In bivariated analyses, trends indicated associations between unstable housing and both poorer glycemic control (80 % vs. 71 %, p=0.09) and blood pressure control (81 % vs. 70 %, p=−.04). In multivariable logistic regression models, housing status was significantly associated with both outcomes, adjusting for age, sex, race, educational attainment, income level, and employment status. Those who had unstable housing were more likely to have not achieved tight glycemic control(OR, 1.37; 95 % CI, 1.15 to 1.62; p<0.001) or have controlled blood pressure (OR, 2.65; 95 % CI, 1.06 to 6.60; p=0.04) than those who did not possess stable housing.
CONCLUSIONS: Findings suggest that housing status is strongly related to glycemic and blood pressure control. However, this may go undetected by physicians. Steps should be taken to ensure clinicians routinely assess their patients' psychosocial circumstances and consider these factors in treatment.

USABILITY OF A FAMILY HEALTH HISTORY AND CLINICAL DECISION SUPPORT TOOL FOR PATIENTS AND PRIMARY CARE PROVIDERS Rebekah R. Wu[1,2]; Tiffany Himmel[3]; Karen Powell[5]; Elizabeth Hauser[5,6]; Astrid B. Agbaje[7]; Vincent Henrich[5]; Geoffrey S. Ginsburg[2,3]; Lori A. Orlando[2,8]. [1]VA Healthcare System, Durham, NC; 2Duke University Health System, Durham, NC; [3]Duke University, Durham, NC; [4]UNC Greensboro, Greensboro, NC; [5]Duke University, Durham, NC; [6]VA Healthcare System, Durham, NC; [7]Cone Health System, Greensboro, NC; [8]Duke University Health System, Durham, NC. (Tracking ID #1637191)

BACKGROUND: Family health history (FHH) is the single strongest predictor of disease risk and yet is significantly underutilized in primary care. We developed a patient facing FHH collection tool, MeTree©, with embedded education for patients and providers on the collection (particularly how to collect from relatives) and importance of FHH, as well as decision support for breast cancer, colon cancer, ovarian cancer, hereditary cancer syndromes, and thrombosis. To evaluate the impact of the tool on patients, providers, clinic workflow, and patient care we integrated it into real world clinics and for this abstract we report on the usability of MeTree© for patients and providers.
METHODS: All non-adopted adult English speaking patients with an upcoming routine appointment with their provider at 2 primary care clinics with 14 physicians in the Cone Health System were invited to participate by completing MeTree some time prior to their appointment. Patients and physicians completed surveys on their experience, patients after their appointment and at 3 and 12 months post-visit, physicians after 3 months of integration.
RESULTS: Total patient enrollment was 1,184. Average time to complete MeTree was 27 min. Patients found MeTree: easy to use (93 %), easy to understand (97 %), useful (98 %), raised their awareness of disease risk (81 %), and changed how they think about their health (82 %). Of the 26 % (n=311) asking for assistance to complete MeTree, age (mean 65 sd 9.4 vs. 57 sd 11.7, p-value<0.00) and large pedigree size (24.5 sd 9.81 vs. 22.3 sd 8.41, p-value<0.00) were the only significant factors. 77 % (239) of those requiring assistance were over the age of 60. Patients learned: more relatives had diseases than they realized (20 %), relatives' diseases were more severe (11 %), relatives had diseases they did not know about (39 %), they were mistaken about what diseases some relatives had (18 %), and learned how old relatives were when they got a disease (39 %). Providers (n=14) found MeTree: improved their practice (87 %), improved their understanding of FHH (63 %), made practice easier (75 %), and worthy of recommending to their peers (93 %).
CONCLUSIONS: Our study shows that FHH collection can be a positive experience for patients and providers and can be implemented without disruption to workflow.

USE AND SAFETY OF BUPRENORPHINE IN HIV-INFECTED AND UNINFECTED OPIOID DEPENDENT PATIENTS Jeanette M. Tetrault[1]; Janet P. Tate[2]; Jennifer Edelman[1]; Adam Gordon[3]; Vincent Lo Re[5]; Lynn E. Fiellin[1]; Kendall Bryant[5]; Amy C. Justice[2,1]; David A. Fiellin[1]. [1]Yale University School of Medicine, New Haven, CT; [2]VA Connecticut Healthcare System, West Haven, CT; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]University of Pennsylvania School of Medicine, Philadelphia, PA; [5]National Institute of Alcohol Abuse and Alcoholism, Rockville, MD. (Tracking ID #1640823)

BACKGROUND: Reports suggest that combined buprenorphine/naloxone (BUP) may cause transaminitis, especially in patients with chronic hepatitis C virus (HCV) infection. This is concerning for HIV-infected (HIV+) patients who may have co-occurring HCV infection and/or unhealthy alcohol use. Additionally, HIV + patients commonly take medications with potential hepatotoxicity. Because BUP is metabolized by the cytochrome P450 3A4 system, medication interactions requiring dose changes are of concern, especially in HIV + patients on atazanavir (ATZ), a cytochrome P450 3A4 inhibitor. We compared the use of BUP in HIV + and HIV-uninfected (HIV-) patients and explored the impact of BUP on liver enzymes. Among HIV + patients we also conducted surveillance for BUP dose decreases with the ATZ.
METHODS: We conducted a retrospective cohort study among HIV + and HIV- patients in the Veterans Aging Cohort Study-Virtual Cohort (between 2003 and 2009). We compared changes in AST, ALT, and total bilirubin (TB) for up to a 365 day exposure period between HIV + and HIV- patients who received a BUP prescription of at least 7 days duration and who had relevant laboratory data. Using a nested case-series analysis, we identified cases of 1) liver enzyme elevation [LEE;defined as an increase of greater than 5 times baseline in ALT or AST or greater than 3.5 times baseline, if baseline was greater than 40 IU/L (normal range for ALT 9–60, normal range for AST 10–40)] and 2)TB elevation [defined as 2X upper limit of normal (normal range 0.2–1.2 mg/dL) among patients with normal TB at baseline] during the exposure period. To assess for evidence of a pharmacodynamic interaction, among HIV + patients we assessed median BUP dose in those patients receiving both BUP and ATZ.
RESULTS: Of the 394 patients with a BUP prescription meeting the inclusion criteria, 39 % were HIV+, 98 % were male, 33 % were white and 76 % were HCV-antibody positive (HCV-Ab +). The median age of the sample was 52 years (interquartile range (IQR) 48–55). The median duration of exposure to BUP was 120 days (IQR 39–346) among HIV + and 143 days (IQR 36–353) among HIV- patients, (p=0.88). The median dose of BUP was 12 mg (IQR 8–16) among HIV + and 16 mg (IQR 8–24) among HIV- patients, (p=0.10). Median ALT decreased 1.0 IU/L (IQR −10.4–9.1) in HIV + and increased 1.0 IU/L (IQR −6.3–7.5) in HIV-patients (p= 0.25); median AST decreased 0.7 IU/L (IQR −6.0–5.4) in HIV + and decreased 1.0 IU/L (IQR −10.7–7.9) in HIV-patients (p=0.5); median TB decreased 0.09 mg/dL (IQR −0.2–0.10) in HIV + and increased

0.02 mg/dL (IQR −0.19–0.19) in HIV-patients (p=0.16). Of 348 patients with available labs, 15 (4.3 %) had LEE; 8 (5.6 %) in HIV + and 7 (3.4 %) in HIV-patients (p=.34). Of 146 patients with normal TB at baseline, 3 had TB elevation, 2 (1.4 %) in HIV + and 1 (0.5 %) in the HIV-patients (p=.95). All cases of LEE and TB elevation occurred in patients who were HCV Ab+. Among HIV + patients, median BUP dose in those receiving both BUP and ATZ (N= 20) was 12 mg (IQR 8–18 mg), compared with 12 mg (IQR 8–16 mg) among those not on ATZ (p=0.51).

CONCLUSIONS: Exposure to BUP is associated with minimal changes in liver enzymes. However, in the setting of HCV infection, cases of LEE and TB elevation did occur in HIV + and HIV-patients, with no differences between the two groups. There was no evidence of a dose adjustment in patients receiving BUP and ATZ. Baseline and periodic liver enzyme tests should be monitored in HCV-infected patients prescribed BUP, regardless of HIV status.

USE OF THE EMR AND ITS EFFECTS ON PATIENT-CENTERED COMMUNICATION AND PATIENTS' EVALUATIONS OF CARE

Neil J. Farber[1]; Richard L. Street[2,3]; Yunan Chen[5]; Alan Calvitti[4,1]; Danielle Zuest[5]; Lin Liu[1]; Kristin Bell[4,1]; Barbara Gray[5]; Mark Gabuzda[5]; Zia Agha[4,1]. [1]University of California, San Diego, La Jolla, CA; [2]Texas A & M University, College Station, TX; [3]Baylor College of Medicine, Houston, TX; [4]San Diego VAMC, La Jolla, CA; [5]University of California, Irvine, Irvine, CA. (Tracking ID #1642520)

BACKGROUND: The electronic medical record (EMR) with its embodiment in the computer should be considered an additional 'interactant' in the medical consultation. Clinicians must engage patient and computer simultaneously or in alternation in an effort to provide medical care. While the evidence is mixed regarding whether physician use of the EMR during the consultation affects patient evaluations of care, few studies have examined the degree to which use of the computer affects the extent to which physicians display patient-centered communication (PCC). In this investigation of physician-patient encounters at a VA clinic, we hypothesized that physicians who spend more time engaging the computer when interacting with the patient will have lower ratings of PCC.

METHODS: General internal medicine physicians (n=21) were recruited from VAMC clinics located in a West Coast city. Five to six patients (follow-up or acute visit) for each physician were recruited to participate in a study of physician-patient communication. Physician use of the computer and the patient-physician interaction in the exam room were captured in real time via videotape of the interaction, videotape of the computer screen, and through the use of the Morae system that records physician clicks and scrolls on the computer. After the visit, patients completed survey of their satisfaction with the visit. Trained coders, blinds to the study's hypothesis, viewed videorecordings of the interactions and rated the physicians' communication along three domains of patient-centeredness—informative, supportive, and partnership-building—which, when summed, created the PCC score. Based on their average proportion of time they used and/or looked at the computer during the visit, physicians were divided into two groups—heavy EMR users (> 50 % of the time looking at/working with the computer) (n=12) and moderate EMR users (< 50 % of time looking at/working with the computer). Multivariable regressions analyses, which controlled for patients' demographics and nesting of patients within physicians, were used to test the study's hypotheses.

RESULTS: The final sample consisted of 121 consultations. Although patients expressed marginally greater satisfaction (p<.09) with physicians who were moderate users of the EMR compared with heavy EMR users, coders of the recorded interactions rated the communication of heavy EMR users as significantly less patient-centered than that of the moderate EMR users (P<.0009). Moreover, in regression analyses controlling for other variables, coders' ratings of the physicians' PCC strongly predicted patients' satisfaction with care (p<.0001).

CONCLUSIONS: In this study of VA general internists' use of the EMR, heavy users of the EMR received lower ratings of PCC which in turn predicted less patient satisfaction. Because patient satisfaction was only marginally related to whether physicians were heavy or moderate EMR users, it would appear some physicians are quite skilled at multitasking and are able to perform necessary EMR tasks as well as communicate in a more patient-centered way. The findings have important implications for clinical training, particularly with respect to use of the EMR in ways that do not interfere with efforts to be patient-centered.

USING ELECTRONIC HEALTH RECORD CLINICAL DECISION SUPPORT IMPROVES QUALITY OF CARE

Rebecca G. Mishuris[1,2]; David W. Bates[1,2]; Asaf Bitton[1,3]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; 3Harvard Medical School, Boston, MA. (Tracking ID #1640999)

BACKGROUND: Electronic health records (EHRs) have been adopted by about 72 % of US physicians. The Medicare and Medicaid EHR Incentive Program, or "meaningful use", incents physicians to adopt EHRs by 2015 or face penalties. When a practice purchases an EHR they can choose which suite of clinical decision support (CDS) functions they want to install. Given this, we sought to examine whether actively turning off any CDS functions had an impact on quality of care.

METHODS: Using cross-sectional surveys, the National Ambulatory and National Hospital Ambulatory Medical Care Surveys, from 2006 to 2009, we analyzed adult outpatient visits to clinics with and without certain CDS for a variety of outcome measures: blood pressure control, cancer screening, health education, receipt of the influenza vaccine, and whether the visit was related to an adverse drug event. We evaluated the following EHR functions, deemed essential by meaningful use: problem lists, preventive care reminders, lab results, lab range notifications, and drug-drug interaction warnings. We used logistic regression, controlling for patient and practice characteristics, with the outcome measures as the dependent variables. Visits were categorized into two groups: any of the CDS functions turned on or off.

RESULTS: There were an estimated 900 million visits to US ambulatory clinics with EHRs from 2006 to 2009; 98 % had some form of CDS. The absence of certain CDS functions reduced the provision of some health outcome measures. Not having preventive care reminders was associated with increased odds of not receiving preventive care (OR 1.1; 95 %CI 1.01,1.26), not receiving health education (OR 1.1; 95 %CI 1.0,1.2), not ordering age-appropriate cancer screening (OR 1.4; 95 %CI 1.1,1.7), and of having uncontrolled blood pressure (OR 1.6; 95 %CI 1.4,1.8). Lacking electronic problem lists increased the odds of not receiving health education (OR 1.1; 95 %CI 1.0,1.3) and of having uncontrolled blood pressure (OR 2.5; 95 %CI 2.2,2.7). The odds of not receiving cancer screening were increased if the provider did not have electronic lab results (OR 1.3; 95 %CI 1.1,1.5) or out of range lab notification (OR 1.2; 95 %CI 1.1,1.5). There were decreased odds of avoiding an adverse drug event visit if the provider did not have drug-drug interaction warnings (OR 0.5; 95 %CI 0.4,0.6), electronic lab results (OR 0.32; 95 %CI 0.27,0.4), or out of range lab notification (OR 0.37; 95 %CI 0.32,0.43). Most of these associations were no longer apparent when examining just those providers who actively turned off the EHR function versus those that had the function turned on. Only 1.8 % of visits to practices with EHRs were to practices with any CDS turned off. There remained increased odds of not providing health education if the provider had actively turned off the electronic problem list (OR 1.3; 95 %CI 1.04,1.6) versus maintaining the function. When examining all of the CDS functions together, there was no significant difference in the odds of attaining any outcome measures based on having any of the functions turned off versus on.

CONCLUSIONS: We found significant associations between the use of certain CDS functions and improved quality of care. Actively choosing to turn off any of the CDS functions was infrequent; turning off the functions eliminated most of these associations. These findings are encouraging that the meaningful use standards will have a significant impact on national quality of care and health outcomes once fully implemented.

USING NATURAL LANGUAGE PROCESSING TO EXTRACT ABNORMAL RESULTS FROM MAMMOGRAPHY REPORTS
Carlton R. Moore[1]; Ashraf Farrag[1]; Evan Ashkin[2]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC. (Tracking ID #1639922)

BACKGROUND: Timely follow-up of abnormal test results is increasingly recognized as a key component of healthcare quality. However, numerous studies show that follow-up of abnormal mammography results is frequently inadequate and 28 % of women requiring immediate or short-term follow-up for abnormal mammograms do not receive recommended care. Automated alerts generated when patients' test results are abnormal have been shown to improve test follow-up. However, many test results, such as mammography reports, are stored as free-text and require manual review to identify abnormal results. Natural language processing (NLP) software can be used to automatically extract results from free-text reports and generate alerts for abnormal results. The purpose of the current study is to evaluate the performance of NLP software for extracting results from free-text mammography reports.
METHODS: A random sample of 421 free-text mammography reports completed between January 2003 and January 2012 was manually reviewed by a general internist (CM) and the Breast Imaging Reporting and Data System (BI-RADS) results determined for each. We developed and tested the performance of an NLP model to extract the BI-RADS results from the same set of reports. The two assessments ('gold' standard vs. NLP) were compared to determine the precision, recall and accuracy of NLP for extracting mammography results. Precision, recall and accuracy were calculated as follows: Precision = TP/(TP + FP), Recall = TP/(TP + FN), and Accuracy = (TP + TN)/Total; where TP = true-positive, FP = false-positive, TN = true-negative, and FN = false-negative.
RESULTS: Manual review ('gold' standard) of the 421 mammography reports determined that 3.6 %, 13.5 %, 58.2 %, 12.1 %, 8.6 %, 1.2 %, and 2.9 % of results were BI-RADS 0 thru 6; respectively. When we compared NLP against the 'gold' standard manual review, the results were as follows: Precision=98 % (96–99 %), Recall=100 % (98–100 %) and Accuracy=98 % (96–99 %). The only inaccuracies in the NLP model occurred with mammography reports that had initial BI-RADS results of zero (0) with later addendums documenting result changes (example; changing BI-RADS 0 to BI-RADS 2) based on radiologists' reviews of previous mammography results. In these situations, the NLP model identified the BI-RADS 0 as the final result and did not detect results in the addenda. This occurred in a total of 10 (2.4 %) of the 421 reports and we have since modified the NLP model so that it now identifies results in report addenda.
CONCLUSIONS: We have developed and tested an NLP model that accurately extracts BI-RADS results from mammography reports. Future plans include using the NLP model to generate real-time alerts and reports for providers to help facilitate timely follow-up of abnormal mammography results.

USING OSCE CASES TO ASSESS RESIDENT PHYSICIANS' COMPETENCE IN INTER-PROFESSIONAL COLLABORATIVE PRACTICE
Colleen Gillespie; Barbara Porter; Margaret Horlick; Kathleen Hanley; Jennifer Adams; Jaclyn Fox; Angela Burgess; Sondra Zabar. NYU School of Medicine, New York, NY. (Tracking ID #1639871)

BACKGROUND: Inter-professional collaboration (IPC) is essential to effective and safe practice, especially within new models of team-based, patient-centered care. An understanding of resident physicians' current levels of competence in this area is a critical first step to designing targeted curricula and workplace learning experiences. This study sought to assess internal medicine residents' competence through the use of OSCE cases designed to require IPC. In addition, we examined whether skills in IPC were distinct from other core clinical skills.
METHODS: Widely accepted conceptual frameworks for IPC were used to create checklist items that included clarifying roles; inter-professional communication (using SBAR strategies, eliciting full information from team members); respect (valuing team member information and assessments); and teamwork (in developing a plan, delegation). Response options were not done, partly done and well done, each with descriptive behavioral anchors to enhance accuracy. These skills were assessed in two clinical cases designed to assess IPC with a "Standardized Nurse" - an outpatient case that called for the physician to collaborate with an RN to assess the patient, identify an error, and develop a treatment plan (annual OSCE for Primary Care IM Residents, PGY1-3, n=21) and an emergency department case in which the resident needed to collaborate effectively with an ED RN to evaluate and respond to a patient's chest pain (annual OSCE for PGY 2 Categorical IM residents, n=35). Checklists were completed by the "Standardized Nurse" and included, in addition to IPC, competence in communication, history gathering and physical exam skills. Summary scores were computed as % of items rated well done (Cronbach's alpha >.75 for both cases). Analyses include frequencies for specific items and examination of summary scores.
RESULTS: Our OSCE cases documented deficits in IPC skills. Only 43 % of residents introduced themselves and clarified their role. Less than half of residents (n=26/56) fully explored the RN's knowledge of the situation and even fewer (n=22/56) fully explored the RN's assessment of the situation. More residents demonstrated respect for the RN's contributions (60 % for the information the RN was scripted to provide and 67 % for the RN's suggestions)—however, a third did not. Finally, 38 % of Primary Care residents failed to even discuss the follow-up plan with the RN in the outpatient case. Residents, on average, received an overall inter-professional collaboration score of 53 % (items rated well done) (SD 25 %). Inter-professional collaboration was not significantly correlated with any of the other core clinical skills assessed in the OSCE (e.g., correlation with communication skills=.04, p=.88).
CONCLUSIONS: Findings document the need among our residents for education and training in inter-professional collaboration. Our data also suggest that this is a distinct domain of competence, largely unrelated to other core clinical skills, including communication. While data are not from actual practice and are based on one sample of performance, the fact that many residents were unable to effectively collaborate with the RNs in an "examination" context reinforces that residents may simply lack the necessary knowledge and abilities. Further research should expand beyond collaboration with nurses, however findings are likely to be generalizable to other members of inter-professional care teams.

UTILIZATION AND SOCIODEMOGRAPHIC CHARACTERISTICS OF IRAQ AND AFGHANISTAN WOMEN VETERANS WHO USE AND DO NOT USE VHA PRIMARY CARE
Susan M. Frayne[1]; Andrea Finlay[1]; Vidhya Balasubramanian[1]; Fay Saechao[1]; Ciaran S. Phibbs[1,2]; Patricia M. Hayes[3]; Sally G. Haskell[3,5]; Samina Iqbal[5]; Eric Berg[1]. [1]VA Palo Alto Health Care System, Menlo Park, CA; [2]VA Palo Alto Health Care System, Menlo Park, CA; [3]VA Central Office, Washington, D.C., DC; [4]VA Connecticut Health Care System, West Haven, CT; [5]VA Palo Alto Health Care System, Palo Alto, CA. (Tracking ID #1641034)

BACKGROUND: Women are the fastest growing subpopulation of Veterans Health Administration (VHA) users, nearly doubling in the last 10 years. Despite multiple initiatives of the VHA to meet the unique needs of women Veterans, there are women VHA patients who do not use VHA primary care services. Our objectives were to compare sociodemographic characteristics and mental health (MH)/emergency department (ED) utilization of women Veterans recently returned from military service who do not versus do use VHA primary care (PC) services.
METHODS: Utilizing VHA electronic health records and Iraq/Afghanistan Veteran Roster data, we selected all women Veterans who finished their last deployment during 2009 and used any outpatient VHA service during 2010 (N=5,915). Measures of age, education, race/ethnicity, rank, branch of service, and multiple deployments were drawn from the Roster. Use of PC services, service-connected disability rating, rurality, and annual counts of MH and ED care were collected from VHA health records. PC use differences were tested using an ANOVA for age and chi-square tests

for all other sociodemographic variables. The percentage who had at least 1 visit to each clinic type (MH or ED) and the mean of the number of MH or ED visits as a percent of all outpatient visits were calculated for non-PC and PC users.

RESULTS: Non-PC users (n=885) accounted for 15 % of women in our sample. Non-PC users were less likely to have a service-connected disability rating (18 % vs 42 %; p<.001), more likely to be deployed multiple times (60 % vs. 55 %; p<.01), and were marginally older (29.5 vs. 29.2; p<.001) than PC users, but were similar across other sociodemographic measures. 35 % of non-PC users compared to 54 % of PC users received MH care (p<.001). Rates were more similar for ED care: 16 % for non-PC users versus 17 % PC users (p<.001). MH and ED care comprised a larger proportion of non-PC users' total outpatient visits. Specifically, among non-PC users, visits to MH care accounted for a mean of 28 % of all outpatient visits vs. a mean of 20 % for PC users (p<.001). For ED visits the proportion of total outpatient visits were also different for both groups: among non-PC users, visits to the ED accounted for a mean of 10 % of all visits, vs. a mean of 3 % for PC users (p<.001).

CONCLUSIONS: While VHA has successfully engaged most recently-deployed new women patients in primary care, women without a service-connected disability rating and women with multiple deployments may represent subgroups for whom primary care outreach efforts may be of particular importance. Given that women non-PC users disproportionately visit ED and MH clinics, these settings may be venues appropriate for such engagement efforts.

VALIDATING ALCOHOL SCREENING SCORES AS PATIENT-REPORTED OUTCOME MEASURES - RESULTS OF THE MONITOR STUDY

Katharine Bradley[1,2]; Anna D. Rubinsky[1]; David Au[1,4]; Christopher L. Bryson[1,4]; Carol Achtmeyer[1]; Emily Williams[1,3]; Gwendolyn Lapham[1]; Laura Chavez[1]; Daniel Kivlahan[5]. [1]VA Puget Sound, Seattle, WA; [2]Group Health Cooperative, Seattle, WA; [3]University of Washington, Seattle, WA; [4]University of Washington, Seattle, WA; [5]Veterans Health Administration, Seattle, WA. (Tracking ID #1643959)

BACKGROUND: The Institute of Medicine has called for identification and validation of screening questionnaires that can be used to monitor patient outcomes. The AUDIT-C (scored 0–12) is a validated alcohol screen as well as a scaled marker of alcohol consumption, alcohol-related symptoms, and adverse consequences of drinking, and has been proposed as an alcohol misuse vital sign. However, the validity of the AUDIT-C as a measure of changes in alcohol use is unknown. This study evaluated whether VA outpatients whose AUDIT-C results decreased, stayed the same, or increased at repeat annual screening had the expected parallel differences in 3 objective outcomes associated with alcohol use in the year after their second screen —HDL cholesterol, trauma and hospitalizations for alcohol-related GI conditions.

METHODS: This retrospective cohort study used secondary data from VA and Medicare datasets. Eligible patients received care at 24 VA facilities and were screened with the AUDIT-C on 2 occasions at least 12 months apart 2004–2007. Patients' 1st and 2nd AUDIT-C scores were each categorized into one of 5 drinking groups: two negative-screen groups—no alcohol use (AUDIT-C score 0 points) and drinkers with negative screens (AUDIT-C 1–2 women; 1–3 men)—and 3 positive-screen groups with mild (3–4 women; 4 men); moderate (5–8) or severe (9–12) alcohol misuse. Three outcomes were assessed in the year after the 2nd AUDIT-C: 1) mean HDL cholesterol, a known biomarker of alcohol use; 2) "trauma" defined as a primary inpatient trauma or fracture diagnosis or any outpatient fracture diagnosis in VA or Medicare, and 3) "GI hospitalization" defined as a primary inpatient diagnosis of liver disease, pancreatitis or upper GI bleeding in VA or Medicare. Analyses evaluated each outcome across 25 groups based on patients' 1st and 2nd AUDIT-C scores (5×5 groups), adjusting for age, gender, race, marital status, VA eligibility, days between screens, and facility, and accounting for correlation within facilities. Linear regression was used to estimate mean HDL, and logistic regression was used to estimate the risk of trauma and GI hospitalizations, across the 25 groups.

RESULTS: Of 486,115 VA outpatients with 2 AUDIT-Cs, 61 % (294,662) had their HDL tested in the year after each AUDIT-C. As expected, patients who increased from negative to positive alcohol screen groups had higher HDLs at follow-up (e.g. 51.6 mg/dl; 95 %CI 50.0–53.1) than those who remained negative on their 2nd AUDIT-C (e.g. HDL 41.6; 41.5–41.7), and vice versa. Further, patients who increased from a negative-screen group to a moderate-severe positive-screen group were at higher risk of trauma (e.g. 2.3 %; 1.6–2.9) and GI hospitalizations (e.g. 1.2 %; 0.6–1.8) in the year after their 2nd AUDIT-C than those who remained in a negative-screen group (e.g. 0.4 %; 0.3–0.4 and 0.9 %; 0.5–1.3, respectively). However, those who decreased from a moderate-severe positive-screen group to a negative-screen group were at lower risk of GI hospitalizations but not trauma, compared to those who remained in a moderate-severe positive-screen group. When trauma was restricted to incident trauma, findings were as expected: those who decreased to a negative-screen group were at lower risk.

CONCLUSIONS: Overall findings indicate that changes in AUDIT-C scores have predictive validity. This suggests that AUDIT-C scores at follow-up could be used to evaluate and compare the effectiveness of different approaches to implementing alcohol interventions.

VALIDATION OF A NOVEL SELF-REPORT INSTRUMENT FOR MEASURING PANEL MANAGEMENT IN PRIMARY CARE

Elizabeth Rogers[1,2]; Danielle Hessler[3]; Rachel Willard-Grace[3]; Kate Dube[3]; Reena Gupta[1]; Thomas Bodenheimer[3]; Kevin Grumbach[3]. [1]University of California San Francisco, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA; [3]University of California San Francisco, San Francisco, CA. (Tracking ID #1619055)

BACKGROUND: To meet demands for evidence-based chronic and preventive services and improve performance, primary care practices are turning toward team-based strategies such as panel management (PM). In PM, non-clinician staff such as medical assistants are given increased responsibility for routine preventive and chronic care, using patient registries to identify care gaps and standing orders to close these gaps. No validated instruments have been published for measuring the degree to which a practice has implemented PM. We developed and tested a self-report Panel Management Questionnaire (PMQ) for primary care clinicians and staff to assess implementation of PM.

METHODS: Our conceptual model of PM included 4 domains: 1. Proper care gap identification by PM staff, 2. confidence in use of standing orders, 3. ability of PM staff to counsel patients regarding needed services, and 4. overall buy-in into the PM model. The 12-item PMQ includes one item to represent each of these domains, with each item applied to three representative service areas: immunizations, cancer screening, and diabetes care. Language on items was tailored into a clinician PMQ and staff PMQ to represent each perspective. A 1–10 Likert scale was used for each item. We calculated a PMQ subscale score for each service type (e.g. immunizations) by averaging scores for the 4 domains, and an overall PMQ score as the mean of all 12 items, with a score of 10 representing the greatest degree of PM implementation. We administered the PMQ to clinicians and staff in 10 county-operated and 5 university-based primary care clinics in San Francisco, CA in various phases of PM implementation using a self-administered questionnaire between February-May 2012. We tested PMQ internal consistency using Cronbach's alpha. We tested external validity at the clinic level, using Pearson's correlation to measure within-clinic agreement between clinician and staff PMQ scores, and the association between PMQ scores and a composite measure of clinic quality of care for the three service areas included in the PMQ (percent of eligible patients with up-to-date Tdap vaccination, breast cancer screening, and hemoglobin A1c and LDL testing for diabetics).

RESULTS: Respondents included 208 clinicians and 136 staff respondents. The response rate was 55 % for clinicians and 65 % for staff. Mean score for the overall 12-item PMQ was 6.0 (SD+1.7, range 2–10) for clinicians and 7.2 (SD+2.3, range 1–10) for staff. Clinician and staff mean scores for each subscale were 6.4 and 7.8 for immunizations, 5.9 and 7.4 for cancer screening, and 5.6 and 6.2 for diabetes care. The scale

demonstrated good internal consistency. Cronbach's alpha for the total 12-item PMQ was 0.84 and 0.92 for clinicians and staff, respectively. Subscale score alphas ranged from 0.59 to 0.62 for clinicians and 0.62–0.91 for staff. Clinician and staff total PMQ scores within each clinic were highly correlated (r=0.77, p< .001), indicating a high convergence between clinician and staff perspectives. We found support for external validity with higher clinician and staff PMQ scores at the clinic level associated with better clinic quality of preventive and chronic care (r=0.35 and r= 0.71, respectively, for clinician and staff).

CONCLUSIONS: The PMQ is a valid tool to measure the degree of implementation of PM by primary care practices. The PMQ holds promise both for use in research on emerging models of primary care and for pragmatic assessment of PM implementation and quality improvement.

VARIABILITY IN RESPONSE: PATTERNS IN PRESCRIBING ANTIPLATELET THERAPY AFTER CYP2C19 GENOTYPING AMONG PATIENTS WITH ACS AND PCI Nihar Desai[1,2]; William Canestaro[3,1]; Donald Chaplin[5]; Lori Martell[5]; Olga S. Matlin[5]; Pavlo Kyrychenko[5]; Troyen A. Brennan[5]; Niteesh K. Choudhry[1,2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]University of Washington, Seattle, WA; [4]CVS CareMark, Woonsocket, RI; [5]Generation Health, Waltham, MA. (Tracking ID #1636420)

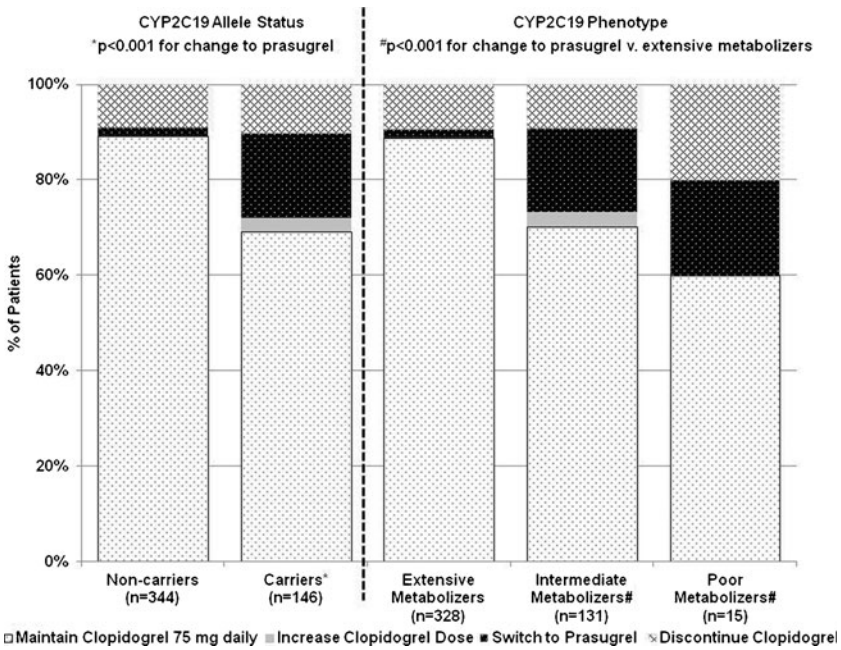
BACKGROUND: Patients treated with clopidogrel who have a loss of function allele for CYP2C19 have an increased risk for major adverse cardiovascular events. In 2010, the US Food and Drug Administration (FDA) issued a boxed warning cautioning use of clopidogrel in patients with such a genotype. Little is known about whether providing genotypic information to physicians and patients changes antiplatelet prescribing patterns.

METHODS: Patients prescribed clopidogrel and their treating physicians were contacted and offered CYP2C19 testing. Genotype and phenotype information was communicated back to consenting patients and their physicians. No specific treatment recommendations were provided. Patients were categorized based on their genotype (carriers v. noncarriers) and phenotype (extensive, intermediate, and poor metabolizers) based upon the presence of 0, 1, or 2 reduced function alleles respectively. Changes in antiplatelet therapy were captured for 90 days after the return of test results.

RESULTS: Between July 2010 - August 2011, 6,032 patients were identified and 499 (8.3 %) underwent genotyping. These patients had a median age of 61 years, 71 % male, 80 % had > 5 co-prescribed medications and 146 patients (30 %) were found to have at least 1 reduced function allele, including 15 (3 %) with 2 reduced function alleles. Although reduced function allele carriers were significantly more likely than non-carriers to have a change in their antiplatelet therapy, only 20 % of poor metabolizers had an escalation in their antiplatelet therapy. In contrast, a small proportion (2 %) of extensive and ultra-rapid metabolizers were changed to more intensive therapy.

CONCLUSIONS: While providers were significantly more likely to alter the antiplatelet regimen in CYP2C19 allele carriers, only 20 % of those at highest risk were switched to prasugrel and a small proportion of extensive metabolizers had their therapy change without a clinically-obvious reason. These prescribing patterns likely reflect the unclear impact and rapidly evolving evidence for clopidogrel pharmacogenomics and have broader implications for the use of genetic testing to guide cardiovascular therapeutics.

Provider Response to CYP2C19 Testing Results By Allele Carrier Status and Phenotype



VARIATION IN DIAGNOSTIC CODING OF PATIENTS WITH PNEUMONIA AND ITS ASSOCIATION WITH HOSPITAL RISK-STANDARDIZED MORTALITY RATES MIchael B. Rothberg[1]; Penelope S. Pekow[2]; Aruna Priya[2]; Peter K. Lindenauer[2]. [1]Cleveland Clinic, Cleveland, OH; [2]Baystate Medical Center, Springfield, MA. (Tracking ID #1641932)

BACKGROUND: Thirty day risk standardized pneumonia mortality rates are now publicly reported for most US hospitals. These rates are based on the outcomes of patients with the principal diagnosis of pneumonia and do not include those with a secondary diagnosis of pneumonia when the principal diagnosis is respiratory failure or sepsis. Our objective was to examine the impact of alternative approaches to identifying patients with pneumonia on hospital risk standardized mortality rates.

METHODS: We conducted a cross-sectional study of pneumonia patients admitted to US hospitals in Premier's Perspective database. We included patients with either a principal diagnosis of pneumonia or a secondary

diagnosis of pneumonia paired with a principal diagnosis of sepsis or respiratory failure between July 2007 and June 2010. We developed multivariable hierarchical generalized linear models with a random effect for hospital to predict each patient's probability of mortality based on age and comorbidities. For each hospital, we calculated risk-standardized mortality rates first excluding, and then including, patients with a principal diagnosis of respiratory failure or sepsis. For each hospital we calculated a predicted rate of sepsis/respiratory failure coding based on patient demographics and co-morbidities, admission to intensive care, and initiation of mechanical ventilation or vasopressor medications in the first 48 h of hospitalization.
RESULTS: After excluding 18 hospitals that had fewer than 100 cases per hospital, our final dataset contained 329 hospitals and 250,016 admissions. The median proportion of pneumonia cases who received a principal diagnosis of sepsis or respiratory failure was 26 % (IQR 18 % to 34 %). When the definition of pneumonia was limited to patients with the principal diagnosis of pneumonia, 2.7 % of hospitals had a risk-standardized mortality rate that was significantly better and 8.8 % significantly worse than the mean. When the definition was broadened to include patients with a principal diagnosis of sepsis or respiratory failure, 12.8 % of hospitals were significantly better and 21.9 % were significantly worse than the mean. This was associated with a change in the outlier status of 29 % of hospitals (43 hospitals' outlier status improved, and 53 hospitals worsened). Hospitals whose outlier status worsened under the broader definition coded a higher than expected proportion of patients with a principal diagnosis of sepsis or respiratory failure (34.3 % vs. 29.7 %, $p=0.01$). Conversely, those whose outlier status improved used the sepsis and respiratory failure codes in the principal position in fewer than expected cases (22.1 % vs. 24.9 %, $p=0.28$)
CONCLUSIONS: Variation in the tendency to use the principal diagnosis of sepsis or respiratory failure may bias current efforts to compare the performance of US hospitals with regard to the outcomes of patients with pneumonia.

VARIATION IN TIME TO PALLIATIVE CARE CONSULTATION BY SERVICE Aziz Ansari; Elizabeth Schulwolf. Loyola University Medical Center, Maywood, IL. (Tracking ID #1643290)

BACKGROUND: Palliative Care consultation services are increasingly available in hospitals across the country. It is well established that length of stay and use of non-beneficial resources drops significantly following palliative care consultation compared with patients of similar illness who do not receive consultation. By reducing time to initial consultation, palliative care services may be better able to meet the needs of patients and families while reducing non-beneficial resource utilization. We sought to determine variation in time to first consult by service line and type of attending physician (hospitalist vs non-hospitalist) as a way of focusing future quality improvement efforts.
METHODS: Our new palliative care consultation program began September 1, 2010. As part of efforts to track operational and quality metrics all cases are recorded in a database. We analyzed data from all consults obtained in the first year of the program (September 1, 2010-June 30, 2011). We determined time to first consult in days for the following services: General Medicine (total, teaching, and non-teaching /hospitalist), all ICU's, MICU, Hematology-Oncology and other services. We further analyzed time to first consult on the general medicine teaching service based on type of attending (hospitalist vs non-hospitalist). Time to consult was compared using the Student's t-test.
RESULTS: There were a total of 282 unique consults: 159 from General Medicine, 65 from any ICU (38 from MICU), 34 from Hematology-Oncology, and 24 from other services. Ninety-five patients on the general medical service were on a teaching service and 56 of those had a hospitalist attending. The number of days to first consult for patients in the ICU was significantly longer than for patients admitted to any other service (10.91 vs 5.59 days, $p<0.001$) including general medicine (10.86 vs 5.13 days, $p<0.001$). This was also true for MICU patients (9.63 vs 5.59 days, $p=0.002$) when compared to all other services. While shorter, there was no significant difference in time to consult when comparing general medicine teaching to non-teaching service (5.85 vs 4.05 days, $p=0.12$). There was also no significant difference when a hospitalist was attending on the teaching service as compared with a non-hospitalist (5.11 vs. 6.92, $p=0.26$). Lastly, there was no difference in time to consult for patients admitted to General Medicine vs Hematology-Oncology (5.13 vs 5.82 days, $p=0.58$).
CONCLUSIONS: Time to palliative care consultation was similar between hospitalists and non-hospitalists for general medical patients. Palliative care consults were called much later in the hospital course when patients were hospitalized in the ICU and may have been beneficial earlier in the patient's clinical course. Future quality improvement efforts aimed at reducing time to initial palliative care consultation should focus on intensive care units.

VARIATIONS IN 30-DAY HOSPITAL READMISSION RATES ACROSS PRIMARY CARE CLINIC SPECIALTIES Ning Tang; Judith H. Maselli; Ralph Gonzales. UCSF, San Francisco, CA. (Tracking ID #1634573)

BACKGROUND: Reducing hospital readmissions is a national health care priority. In October 2012, the Centers for Medicare and Medicaid Services (CMS) enacted financial penalties on hospitals with higher than average risk-adjusted readmissions. Although CMS calculates readmission rates at the hospital level, understanding these rates at the clinic level is critical for developing strategies for improvement. Furthermore, variations in readmission rates across unique primary care practices are not well understood. We set out to develop a methodology for calculating all-cause 30-day hospital readmission rates at the level of individual primary care practices and to identify factors associated with variations in these rates.
METHODS: We analyzed hospital discharge claims from July 1, 2009 to June 30, 2012 for all adults ≥18 years with a primary care provider (PCP) at UCSF. We adapted CMS' methodology for calculating readmission rates by including all discharge diagnoses and grouping patients within their primary care clinic (General Internal Medicine, GIM; Family Practice, FP; Women's Health, WH; Geriatrics, Geri; Combined IM/FP, IM/FP; HIV primary care, HIV; and Concierge IM, C-IM). We built a model to predict readmissions using the demographic and clinical variables with Chi-square $p<0.20$ in an initial bivariate analysis, and then removed, with backward selection, the least significant variables until only those with $p\leq0.05$ remained. Age, log-LOS, and ICU stay were forced in the model, and results were expressed as adjusted odds ratios (OR) with 95 % confidence intervals (CI).
RESULTS: During the study period, there were 12,564 discharges for patients belonging to the 7 clinics. Of these, 8,685 were the first index discharges for each patient and 1,032 had a readmission within 30 days. Readmission rates varied across practices, with HIV being the highest at 18.9 %, followed by Geri at 16.3 %, GIM at 15.3 %, C-IM at 11.6 %, FP at 9.7 %, IM/FP at 9.5 % and WH at 8.4 %. In multivariable analyses, factors associated with variation in readmission rates included: being a patient in the GIM clinic (OR 1.31, CI 1.04, 1.64; ref = FP), male gender (OR 1.32, CI 1.15, 1.52), Medicare (OR 1.44, CI 1.19, 1.75; ref = private), unknown primary language (OR 0.06, CI 0.01, 0.24; ref = English), and the following comorbidities: pulmonary circulatory disease, peripheral vascular disease, renal failure, lymphoma, fluid and electrolyte disorders, and anemia. Having a resident PCP was not significant at the $p=0.05$ level (OR 1.17, CI 0.96, 1.42; Ref = Attending PCP). However, patients with a graduated resident PCP or departed faculty PCP awaiting transfer assignment to a new PCP had OR 1.63 (CI 1.19, 2.23) compared with having a current faculty PCP. The c-statistic for this model was 0.64.
CONCLUSIONS: Primary care practices are important partners in improving care transitions and reducing hospital readmissions, and this study introduces a new way to view readmission rates. Men, people with Medicare, and patients in our GIM clinic were independent risk factors for hospital readmission after controlling for clinic, provider and patient factors. In addition, it appears that PCP turnover is a significant contributor to higher readmission rates. This finding

underscores the importance of continuity of care in the optimal management of patients following hospital discharge. Further exploration of high readmission rates in the GIM practice after controlling for case-mix and hospitalization factors is warranted.

VIRTUAL MEDICATION RECONCILIATION: A PILOT STUDY OF INTERACTIVE MEDICATION RECONCILIATION BY SECURE MESSAGING Leonie Heyworth; Allison M. Paquin; Justice Clark; Victor J. Orlov; Max D. Stewart; Tracey L. Martin; Steven R. Simon. VA Boston Healthcare System, Boston, MA. (Tracking ID #1642568)

BACKGROUND: Adverse drug events (ADE) are the most common of all healthcare associated adverse events. Transitions between inpatient and ambulatory care can lead to ADE and avoidable healthcare utilization affecting up to 20 % of patients. Insufficient monitoring has been identified as a particularly common cause of preventable and ameliorable ADE. We examined the impact of secure messaging for medication reconciliation among a group of patients discharged home following hospitalization.
METHODS: Patients admitted to a Veterans Affairs Medical Center in Boston, MA from June to December 2012 were screened for pilot study participation. Inclusion criteria were age 18 and over, capacity to make medical decisions, primary care recipient at a VA facility and planned disposition home. Patients were excluded from study participation if they (or a caregiver) did not have computer access. Eligible patients were instructed on the use of secure messaging and given a $50 cash incentive for participation. An interactive medication reconciliation template, modeled after AHRQ resources, was developed by the research team. Medication reconciliation of discharge medication lists were facilitated by the study pharmacist and sent to the patient via secure message within 72 h of discharge. Patients replied by checking "yes" or "no" to the listed medication and free-texting comments. Information about the frequency and severity of clinically important medication errors and potential ADE was collected. We conducted bivariate analysis to determine individual characteristics associated with medication errors and potential ADE.
RESULTS: We enrolled 51 Veterans, of whom 48 (94 %) were male. Average age was 61 years and 94 % had health insurance. A total of 51 medication lists were sent, and 33 replies were received (response rate of 65 %). All pilot participants had at least one chronic condition, defined as diabetes, hypertension, prior MI/stroke, hyperlipidemia or heart disease. Overall, we observed a total of 127 clinically important medication errors, 108 of which were found in 51 patient discharges and 19 of which were observed in participant responses. The median number of medication errors per patient was 2 at discharge. In bivariate analysis, clinically important medication errors were significantly more likely to be observed among patients taking greater than 5 medications ($p<0.001$) and those with a hospital length of stay longer than the median of 4 days ($p<0.001$). A total of 23 potential ADE were identified among 15 participants. Potential ADE were significantly more common among patients with greater than 5 medications ($p=0.03$) and in those with a longer length of hospitalization ($p=0.02$) in bivariate analysis.
CONCLUSIONS: Our pilot study demonstrated that the use of secure messaging for medication reconciliation among patients post-discharge is feasible and may be a valuable tool to improve ambulatory medication safety. We found that clinically important medication errors and potential ADE were common. Medication errors and potential ADE occurred more frequently in patients taking more medications and in those with a longer hospital stay. Further research is needed to assess whether our findings are replicable among a larger group of patients post-discharge and among those receiving ambulatory care.

VISIT BASED EHR REMINDERS IMPROVE THE QUALITY OF OUTPATIENT CARE Jason Fish[1]; Deepa Bhat[1]; Brett Moran[1]; Temple S. Howell-Stampley[1]; Lynne Kirk[1]; Michael E. Bowen[1]; Kim Batchelor[1]; David Leonard[1]; Stephen D. Persell[2]; David W. Baker[2]; Ethan Halm[1]. [1]UT Southwestern, Dallas, TX; [2]Northwestern University, Chicago, IL. (Tracking ID #1638946)

BACKGROUND: Current electronic health records (EHRs) are efficient in collecting and storing enormous amounts of patient data; yet, standard build EHRs often provide little or no intelligent decision support to facilitate evidence-based care. We developed and implemented a suite of just-in-time, visit-based, EHR-enabled Best Practice Alerts (BPAs) with exception reporting for 3 chronic diseases and 5 preventative services in 3 academic general medicine practices using the Epic EHR. We assessed the impact of the EHR-based decision support and exception reporting intervention on national quality indicators.
METHODS: We assessed pre-post performance differences on 13 quality indicators for diabetes (DM), heart disease (HD), and heart failure (HF) and 5 preventative services in the 12 months before and after implementation of the BPAs. Time series linear regression was used to adjust for autoregressive errors and secular trends. Rates of change (% per year) in performance in the pre- and post-intervention periods are reported.. Quality measures were satisfied if the recommended care occurred or if an appropriate exception was documented using the BPAs: did not have the disease (e.g. h/o gestational diabetes, not diabetes), not done for medical (contraindications) or patient (refusal) reasons, or done outside of our health system with results not automatically available. Our study sample included all established patients with at least 1 office visit in the past 12 months. The study period included a baseline data period from June 2010 to June 2011 and a post-BPA intervention period from July 2011 to June 2012.
RESULTS: Eligible patients completed 23,437 visits in the pre- and 25,615 visits in the post-intervention period, triggering 33,194 BPAs in the post-intervention period. For the 18 quality indicators, we saw statistically significant improvements in rates per year for 13 indicators ($p<0.05$) and a trend towards improvement in another 2 ($p<0.06$) after adjusting for secular trends. All 5 preventative services had significant improvements: mammography rates improved 9.9 %, colorectal cancer screening 4.5 %, cervical cancer screening 7.2 %, osteoporosis screening 7.3 %, and pneumonia vaccination 7.4 %. For chronic disease metrics, we found significant improvements in lab monitoring (DM LDL: 5.7 %, HD LDL: 4.1 %), medication use (HD beta blocker: 11.4 %, HD ACEI/ARBs: 2 %, HF anticoagulants: 5.3 %, HF ACEI/ARB 2.5 %, HF beta blocker: 6.2 %), and outcomes (DM A1C <8 %: 3.2 %, DM LDL <100: 2.7 %, HD LDL <100: 2.6 %). No improvements were seen for DM A1C monitoring or nephropathy screening. As a comparison, we did not create BPAs for BP monitoring or control for DM or HD. We found no change in BP measurement in either DM or HD; BP control worsened significantly (−4.3 %, $p<0.05$) for DM and improved significantly (3.5 %, $p<0.05$) for HD which had 2 reminder BPAs for beta blocker and ACEI/ARB medication usage. Exception reporting had the biggest impact for preventive services that were done outside of our health system.
CONCLUSIONS: Our suite of visit-based, EHR-enabled BPAs with exception reporting achieved significant but modest improvements in delivery of all of the preventive service and most of the chronic disease metrics we targeted even after adjusting for secular trends. Further improvements in outpatient quality will likely require more intensive case- and population management, audit and feedback, and/or other incentives.

VITAMIN D AND RACIAL DIFFERENCES IN PROSTATE CANCER INCIDENCE AND MORTALITY Glen Taksler[1]; David M. Cutler[2,3]; Edward Giovannucci[5]; Matthew R. Smith[5,6]; Nancy L. Keating[7,8]. [1]New York University School of Medicine, New York, NY; [2]Harvard University, Cambridge, MA; [3]National Bureau of Economic Research, Cambridge, MA; [4]Harvard School of Public Health, Boston, MA; [5]Massachusetts General Hospital Cancer Center, Boston, MA; [6]Harvard Medical School, Boston, MA; [7]Brigham and Women's Hospital, Boston, MA; 8Harvard Medical School, Boston, MA. (Tracking ID #1637882)

BACKGROUND: Prior studies suggest that low vitamin D levels may be associated with higher prostate cancer incidence for white men, but darker skin reduces the body's ability to generate vitamin D from sunshine. The

impact of sunshine on racial disparities in prostate cancer incidence and mortality is unknown.
METHODS: Using the Surveillance, Epidemiology, and End Results (SEER) database, we calculated age-adjusted incidence of prostate cancer among black and white males aged ≥45 years and living in SEER regions, for each race and county during 2000–2009 (N=906,381). Similarly, we calculated county-level rates of prostate cancer deaths among men in the US aged ≥45 years using 2000–2009 data from Vital Statistics (N= 288,874). We linked these data with the average January ultraviolet (UV) index for each county, calculated from NASA satellites, and county- or state-level data on health, wellness, and demographics from the US Census Bureau and Centers for Disease Control and Prevention. We used multivariable regression models to assess whether the UV index moderated the association of black race with incidence and mortality, adjusting for health, wellness, and demographics. Key independent variables of interest were the UV index and an interaction term between black race and the UV index. The interaction term measured the marginal association of black race to the relationship between prostate cancer and the UV index. To reflect each county's relative importance in national data, observations were weighted by the at-risk population of each county and race.
RESULTS: Relative to prostate cancer incidence rates in counties in the lowest decile of the UV index, incidence rates in counties in the 2nd-4th deciles of the UV index were 9–10 % lower for whites (all P≤0.01), 13–16 % lower in the 5th-6th deciles (both P<0.001), and 19–23 % lower in the 7th–10th (highest) deciles (all P<0.001). We observed a similar pattern for blacks, with prostate cancer incidence rates 10–12 % lower in the 2nd–3rd deciles of the UV index (both P≤0.03), 20–23 % lower in the 4th–5th deciles (both P<0.001), 10–22 % lower in the 6th–9th deciles (all P≤0.05), and 34 % lower in the 10th (highest) decile (P<0.001). The racial disparity in incidence rates was 9 % lower for counties in the 4th–5th deciles of the UV index (both P for interaction≤0.02) and 10 % lower for counties in the 10th decile, although this did not reach statistical significance (P for interaction=0.057). Mortality rates were 5–6 % lower for whites residing in the 4th–5th deciles of the UV index (both P≤0.003) and 8–16 % lower in the 6th–10th deciles (all P≤0.001). However, we observed an unexplained increase in prostate cancer mortality rates for black men, and racial differences in mortality rates, with the UV index. Mortality rates for black men were 18–37 % higher, and the racial difference in mortality rates 24–48 % higher, for counties in the 3rd–4th, and 6th–10th deciles (all P≤0.02). This result may be influenced by lack of county-level data in rural areas, primarily located in the 6th, 7th, and 9th deciles of the UV index.
CONCLUSIONS: Prostate cancer incidence for black and white men, the racial difference in incidence, and prostate cancer mortality for white males appear to be inversely associated with ultraviolet radiation from sunshine. Additional research is needed to confirm our findings and assess if optimizing vitamin D levels among men with darker skin can lessen prostate cancer disparities.

WARFARIN ANTICOAGULATION THERAPY AND MORTALITY FOLLOWING GASTROINTESTINAL HEMORRHAGE IN PATIENTS WITH ATRIAL FIBRILLATION IN CLINICAL CARE: THE ATRIA AND ATRIA-CVRN COHORTS Jeffrey M. Ashburner[1,5]; Alan S. Go[2]; Kristi Reynolds[3]; Yuchiao Chang[1]; Margaret Fang[5]; Lisa Fredman[5]; Daniel E. Singer[1]. [1]Massachusetts General Hospital, Boston, MA; [2]Kaiser Permanente Northern California, Oakland, CA; [3]Kaiser Permanente Southern California, Pasadena, CA; [4]University of California, San Francicso, San Francisco, CA; [5]Boston University School of Public Health, Boston, MA. (Tracking ID #1637565)

BACKGROUND: Warfarin therapy reduces the risk of ischemic stroke in patients with atrial fibrillation (AF), but also increases the risk of hemorrhage. Fear of causing hemorrhage in AF patients may result in underuse of warfarin. We examined short and long-term mortality outcomes of gastrointestinal (GI) hemorrhage, the most common site of bleeding, in AF patients on and off warfarin in contemporary clinical care.
METHODS: We evaluated this association by combining two prospective cohort studies from Kaiser Permanente (KP) Northern and Southern California (CA). The AnTicoagulation and Risk Factors In AF (ATRIA) sample includes 13,559 adult AF patients from KP Northern CA, followed from July 1996-September 2003. The ATRIA-CVRN (Cardiovascular Research Network) sample includes 33,247 adult patients with incident AF from KP Northern and Southern CA, followed from January 2006-June 2009. GI hemorrhages were identified by searching hospital databases for primary discharge diagnoses and validated by chart review. Major GI hemorrhages required transfusion of ≥2 units of packed red blood cells. GI hemorrhages were considered exposed to warfarin if the admission record indicated the patient was taking warfarin on or within 7 days before the event. Deaths were determined through medical records and the CA state death registry. Generalized linear modeling was used to estimate the risk ratio (RR) for the association between warfarin status at the time of GI hemorrhage and 30-day mortality. Cox proportional hazards regression was used to estimate the mortality rate ratio (mRR) over the follow-up period. Models were adjusted for cohort, age, aspirin use at the time of hemorrhage, and history of GI hemorrhage and dementia.
RESULTS: The sample included 1520 GI hemorrhages, with 779 (51 %) exposed to warfarin and 741 (49 %) unexposed to warfarin. Median follow-up after GI hemorrhage was 1.4 years (interquartile range [IQR]: 0.4–3.2 years) in ATRIA and 0.7 years (IQR: 0.3–1.4 years) in ATRIA-CVRN. Patients exposed to warfarin at the time of hemorrhage were younger (75.8 vs. 78.8 years), less likely to be male, and to have a history of falls, a prior GI hemorrhage, dementia, and chronic liver disease, and also less likely to be taking aspirin. Among those taking warfarin, 36 % had an international normalized ratio (INR) ≥3.5 at presentation. By 30-days, 6.2 % of patients on warfarin had died, compared to 10.8 % of those not on non-warfarin. After 30 days, an additional 33.8 % of the sample died. Patients on warfarin had a significantly lower risk of 30-day mortality following any GI hemorrhage than those not on warfarin (adjusted RR=0.60, 95 % CI= 0.41–0.88). Similar results were observed in the 918 patients who had a major GI hemorrhage (adjusted RR=0.70, 95 % CI=0.45–1.07). However, there was no association between warfarin use and long-term mortality after the 30-days following any GI hemorrhage (adjusted mRR=1.03, 95 % CI=0.84–1.27) or major GI hemorrhage (adjusted mRR=0.96, 95 % CI=0.74–1.24).
CONCLUSIONS: Warfarin use at the time of GI hemorrhage was associated with a reduced risk of short term mortality. However, this effect was limited to the first 30-days after the event. Warfarin may increase the rate of GI hemorrhage, but short-term outcomes are milder, likely because the hemorrhagic effect of warfarin is either actively or passively reversed or due to residual confounding.

WAS A DECISION MADE? AN ASSESSMENT OF DISCORDANCE AMONG PATIENTS AND PHYSICIANS IN A MEDICAL ONCOLOGY ENCOUNTER. Aaron L. Leppin[1]; Katherine M. James[1]; Cara A. Fernandez[2]; Ashok Kumbamu[1]; Kathleen J. Yost[3]; Victor M. Montori[2]; Jon C. Tilburt[1,2]. [1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN; [3]Mayo Clinic, Rochester, MN. (Tracking ID #1619182)

BACKGROUND: Assessing decisional quality presupposes stakeholders agree a decision was made. Scant literature assesses concordance among patients' and providers' ability to recognize when a medical decision has occurred in an oncology encounter. The aim of this analysis was to determine the degree of agreement or lack thereof among medical oncology patients and providers in their ratings of whether a specific medical decision had been made in an outpatient encounter. A secondary aim was to assess for the presence of attitudes or demographic factors that might contribute to any discordance.
METHODS: The first 130 patients and 14 providers enrolled in an observational study assessing cancer communication were considered eligible for this analysis. Patients were at various stages of treatment and were being treated for a variety of cancers at a single center. Patients and providers each completed a survey immediately following a clinical encounter. The surveys contained a common item that asked whether "a specific decision" about cancer care had been made during the encounter; responses were manually and independently double-entered into an electronic database (REDcap Version

3.1.1) and discrepancies were resolved by an independent adjudicator. SAS version 9.2 (Cary, NC) software was used to identify concordant and discordant pairs; pairs in which one response was missing were not included in subsequent analyses (n=8). Bivariate tests of association were used to determine whether patient demographics, ratings of clinicians, and interaction attitude factors, as well as provider assessment of rapport and interaction satisfaction were associated with concordance or discordance. Data were evaluated with the Fisher exact test; significance was established as $p<0.05$.

RESULTS: Patients were 69 % female and 98 % were white. Of 122 encounters considered eligible for analysis, 30 % (n=36) revealed patient-provider pairs with discordant ratings of whether a "specific decision about cancer care" had occurred. About half of the instances of discordance occurred where the provider felt a decision was made and the patient did not (n=19), and the other half where the patient felt a decision was made and the provider did not (n=17). In bivariate analyses, neither patient or provider attitudes toward the encounter, overall satisfaction, nor evaluation of encounter quality predicted whether or not a response pair was concordant or discordant. Patient demographic data also failed to explain the discordance and no distinguishing characteristics of providers with instances of discordance in over half of their clinical encounters (n=2/14) could be found.

CONCLUSIONS: Discordance between patient and clinician perceptions of whether a decision was made in a clinical encounter is common and is not readily explained by demographics or attitudes toward communication quality. Further study may be needed to assess for the presence of marked differences in how patients and providers define "decisions." Surveys may also be inadequate tools for assessing true beliefs and understanding about whether decisions occurred and more qualitative assessments in these regards will be helpful. More concrete and accepted definitions of what constitutes a medical decision may need to be established and confirmed with patients prior to the utilization of shared decision-making tools or communication quality assessments so as not to threaten their validity.

WEIGHT LOSS WITH PHENTERMINE AND TOPIRAMATE EXTENDED-RELEASE IN OBESE AND OVERWEIGHT SUBJECTS OVER 56 WEEKS Robert F. Kushner[1]; Santosh T. Varghese[2]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]VIVUS, Inc., Mountain View, CA. (Tracking ID #1624371)

BACKGROUND: Obesity is associated with multiple comorbidities, and modest weight loss (5–7 %) has been shown to improve cardiometabolic parameters, thereby delaying or preventing comorbidities. The combination of phentermine and topiramate extended-release (PHEN/TPM ER) was studied as an adjunct to lifestyle modifications (including a reduced-calorie diet and increased physical activity) for chronic weight management at an initial dose of PHEN 3.75 mg/TPM ER 23 mg (3.75/23) daily for 14 days, which is then increased to PHEN 7.5 mg/TPM ER 46 mg (7.5/46) daily, and may include doses up to PHEN 15 mg/TPM ER 92 mg (15/92). The CONQUER trial was designed to evaluate the safety and efficacy of 2 dosages of PHEN/TPM ER in the treatment of obese and overweight adults with ≥2 weight-related comorbidities.

METHODS: The CONQUER trial was a double-blind, placebo-controlled, Phase 3 trial of 2487 obese and overweight subjects (body mass index [BMI] ≥27 and ≤45 kg/m2) with ≥2 weight-related comorbidities randomly assigned to placebo, 7.5/46, or 15/92 plus lifestyle modification for 56 weeks. The primary variables were percent weight loss and the percentage of subjects with ≥5 % weight loss at week 56. Secondary variables included absolute weight loss and the percentage of subjects with ≥10 %, ≥15 %, and ≥20 % weight loss at week 56. Subjects in the 7.5/46 group received 3.75/23 for 1 week prior to increasing the dosage to 7.5/46 in week 2. For subjects in the 15/92 group, dosage was further increased from 7.5/46 to 11.25/69 in week 3 and then to 15/92 in week 4. Thus, at week 56, subjects in the 7.5/46 group had received 7.5/46 for 55 weeks, and subjects in the 15/92 group had received 15/92 for 53 weeks.

RESULTS: Most subjects were female (70 %) and Caucasian (86 %); mean age was 51.1 years, and mean BMI was 36.6 kg/m2. At baseline, 52 % of subjects had hypertension and 16 % had diabetes; 17 % had a history of depression and 16 % were taking antidepressant medication. At week 56, PHEN/TPM ER led to significantly greater weight loss vs placebo (P<.0001, all comparisons), and more subjects achieved weight loss of ≥5 %, ≥10 %, ≥15 %, and ≥20 % when compared with placebo (P<.0001, all comparisons; Table). Of the 2487 randomized subjects, a higher proportion of subjects in the PHEN/TPM ER groups completed the study than in the placebo group (placebo, 62.0 %; 7.5/46, 75.1 %; and 15/92, 73.7 %). The most common reasons for discontinuation were withdrawal of consent (11.0 %), loss to follow-up (10.2 %), and adverse event (4.9 %). Common treatment-emergent adverse events were constipation, dry mouth, and paraesthesia; these effects were dose related and occurred most frequently during titration. There was 1 death of a placebo-treated subject in the CONQUER trial.

CONCLUSIONS: PHEN/TPM ER, when used in combination with lifestyle modifications, is associated with significant and clinically meaningful weight loss in obese and overweight subjects. PHEN/TPM ER was generally well tolerated. The titration schedule was aimed at maintaining clinical benefit by improving tolerability.

Table. Effects on weight loss from baseline to week 56 (ITT-LOCF).

	Placebo (n=979)	PHEN/TPM ER 7.5/46 (n=488)	PHEN/TPM ER 15/92 (n=981)
LS mean percent weight loss, %	-1.2	-7.8*	-9.8*
LS mean absolute weight loss, kg	-1.4	-8.1*	-10.2*
Percentage of subjects with:			
≥5% weight loss	20.8%	62.1%*	70%*
≥10% weight loss	7.4%	37.3%*	47.6%*
≥15% weight loss	2.9%	19.3%*	28.8%*
≥20% weight loss	1.1%	7.6%*	14.4%*

*P<.0001 vs placebo

WHAT ACTUALLY HAPPENS OVERNIGHT? A STUDY DESCRIBING HANDOFFS AT A LARGE ACADEMIC INSTITUTION. Joshua T. Hanson[1,2]; Sahand Rahnama[1]; Tareq Nassar[1]; Luci Leykum[1]. [1]UT Heath Sciences Center, San Antonio, San Antonio, TX; [2]South Texas Veteran's Healthcare System, San Antonio, TX. (Tracking ID #1642604)

BACKGROUND: Changes in duty hour regulations have required more handoffs. These changes have led to increased interest in handoff performance and cross-coverage outcomes. The current handoff literature describes the philosophy behind good or idealized handoffs. However, there is no data on "real-world" handoff performance or the information actually needed for medical decision making. Our institution implemented a night-float coverage system prior to the institution of the 2011 ACGME Common Program Requirements. Our goals were to understand the types of cross-coverage calls received overnight, the data required for medical decision making, and the type of communication to the primary team.

METHODS: Six interns collected data regarding overnight calls. A structured data collection tool was used that included information on the

caller, the reason for the call, where the intern obtained the information needed to respond, and whether physician documentation occurred.

RESULTS: Data on 299 separate encounters over 18 nights were collected. Most calls were initiated by the nursing staff. Eighty (26.8 %) encounters required the use of the hand-off instrument for medical decision making while 165 (55.2 %) encounters required the use of the electronic medical record (EMR). One hundred twelve encounters (37.5 %) resulted in a new medicine being ordered, but only six encounters (2.0 %) resulted in a note being written. Ten (3.3 %) encounters resulted in discussion with the senior resident. Every request for pain medicine resulted in one being prescribed.
