Abstract

This article describes a Java Card programming environment which to a large extent is generated from formal specifications of the syntax and semantics of Java Card, the JCRE (Java Card Runtime Environment), and the Java Card APIs. The resulting environment consists of a set of tightly integrated and somewhat smart tools, such as a Java specific structure editor and a simulator which allows an application to be tested before being downloaded to a card. Furthermore, the simulator analyses the applet in question in order to find out the structure of the accepted commands. This information is then used to automatically adapt the GUI of the simulator.

Keywords: Java Card, programming environment, formal specification, simulation

1. INTRODUCTION

This paper describes a programming environment for Java Card¹ [7] applications which is being developed within the OASIS project² at INRIA Sophia Antipolis.

The Java Card environment is developed within Centaur [2], a generic, interactive programming environment generator. It makes it possible to create programming tools such as structure editors, compilers, interpreters based on formal specifications of the syntax and semantics of

¹Java and Java Card are trademarks of Sun Microsystems Inc. All other trademarks mentioned are proprietary of their respective owners.

²<http://www-sop.inria.fr/oasis>

the language in question. These are then integrated into a graphical programming environment which also can provide viewers for important structures such as stacks, heaps, and objects during interpretation. Centaur thus allows sophisticated tools to be developed quickly at a high level of abstraction. Furthermore, having access to the formal semantics provides the potential for proving interesting properties about applications within the same framework, and since the semantics is executable it can be tested and debugged which is important if it is to be used as the basis for proofs. Proving properties is of key importance in this context since security often is a prime concern in applications involving smart cards. However, this article focuses on the basic aspects of our programming environment, such as editing, testing, and debugging.

The rest of this article is organised as follows. In the next section, we present the architecture of our environment and explain how it is generated from various formal specifications. The following sections each discuss one major part of the Java Card environment in greater detail, illustrating through a running example (see the appendix for the complete source code). Finally, we discuss related work and present conclusions.

2. OVERVIEW

2.1. THE ENVIRONMENT

Our Java Card environment is made up of two parts: a structure editor and a simulator for testing applets. The simulator in turn consists of three parts: the APDU (Application Protocol Data Unit) format extractor, the CAD (Card Access Device) simulator, and the Java Card simulator. Figure 1 shows the architecture and figure 2 the interfaces of the different parts of the environment. Both parts of the environment understand normal text files, so it is easy to import existing code, to replace the editor with some standard editor like Emacs, or to use the structure editor on its own. Compilation to byte code and functionality related to loading applets onto physical cards is outside of the scope of this work, but existing free or proprietary tools could easily be interfaced from the environment.

The editor is Java Card specific. Thus the developer is assured that the written code is free from syntax errors and respects the Java Card subset of Java. Moreover, the editor facilitates development of Java Card code by displaying context-sensitive menus containing all valid syntactic constructs for any selected part of the source code. This feature is useful for people beginning to write Java Card applications, for example smart card developers used to writing assembler code. But it can also be useful

Figure 1 Programming environment architecture.

Figure 2 Windows of the different tools comprising the environment. Top left corner: the structure editor window. Lower half: the window for constructing and sending generic APDUs (New APDU), the menu for selecting applet-specific commands (Extracted Commands), and a window for constructing and sending an APDU for a selected, applet-specific command (Purse PURSE_DEPOSIT). Top right corner: the APDU log and a window showing a failed regression test. The command and APDU log windows all belong to the CAD simulator. Finally, in the centre: the window for setting interpretation parameters belonging to the Java Card simulator.

Figure 3 The relation between specifications and generated tools.

for experienced programmers, who could enter the skeleton of a complete if-statement with a single selection from a menu.

An important aspect of the environment is that it enables the developer to test and debug an applet on a work station. It is not necessary to download it to a real Java Card, or having access to a card reader. This is achieved by providing simulators for the Java Card and the CAD. This should in itself cut down the time for the test-debug-change cycle significantly. In addition, our environment makes it easy to study the communication between the applet and the CAD in terms of sent and received APDUs, as well as the inner workings of the applet itself. The simulation environment also provides a facility to extract APDU formats from applet source code.

2.2. TOOL GENERATION

All the above mentioned tools were created using the Centaur system. Figure 3 illustrates the relationships between the developed specifications on the one hand, and the generated tools on the other.

To obtain the structure editor, we have specified a Java Card parser and a pretty printer or unparsing. The parser specification defines the concrete and abstract syntax of the Java Card language as well as tree building functions. It is written using the Metal formalism which permits the concrete and abstract syntax to be specified simultaneously.

This specification is then used to automatically generate a parser. The parser is responsible for translating Java Card source (text) into an abstract syntax tree which is how Java Card applets are represented inside the environment. The PPML specification is then used to translate an abstract syntax tree back to text, e.g. for display purposes within the editor, or for storing the Java Card program in a file.

The central part of the Java Card simulator is the dynamic semantics of Java Card, specified in Natural Semantics using Typol [6]. Typol is the language used to specify semantics in Centaur. It is a typed, declarative logic language with backtracking, unification and pattern matching mechanisms (see section 5 for an example). The Java Card semantics is specified on the level of the abstract syntax, and thus it too needs to refer to the Java Card abstract syntax specification. For studying the behaviour of an applet during execution, it is possible to view important runtime structures. These structures are represented as trees internally. Thus PPML is used to specify the unparser.

The APDU format extractor also works on the abstract syntax tree of a Java Card applet. In addition, it uses data structures specific to the analysis task, which are again specified using Metal and PPML. The extractor itself is written in Typol.

3. THE JAVA CARD STRUCTURE EDITOR

Firstly the features of the editor are described. Then we explain how to write a Java Card program and we introduce the example used as Ariadne's thread in the next sections.

Our editor is dedicated to the Java Card language. It prevents the developer from making errors w.r.t. the general Java syntax (e.g. a semi-colon or a brace missing), but also from making errors related to the specificities of Java Card (e.g. using the `char`, `long`, `double`, `float` primitive types, multidimensional arrays, or the `synchronized`, `volatile`, `transient` keywords) [4]. These latter errors would otherwise only be discovered when converting class files into CAP (Converted Applet Program) files since standard Java compilers are used to compile Java Card programs. Anyone who uses our editor will only encounter errors related to the static semantics (e.g. undefined variables, type errors) when compiling, and no errors at all during the conversion stage.

Applets are stored as plain Java Card text files. This makes it easy to import existing Java Card applications into our environment, or to use traditional text editors for development should that be desired.

Internally, the applet being edited is represented as an abstract syntax tree. Syntax colouring is made possible by specifying different styles (font,

size, colour) in the unparsing rules. Note that, unlike a conventional text editor like Emacs which does not do a proper parsing, we are sure that the colours will always be correct. Moreover the formatting scheme (i.e. indentations, where the braces are set) is the same for all the Java Card programs ensuring consistency regardless of author.

The editor provides two ways for writing source code: free text editing or syntax-directed editing. In the first mode, the editor behaves like a normal text editor, but the written part is parsed when this mode is exited. Thus, only syntactically correct program fragments can be inserted into the abstract syntax tree. The other mode facilitates the development by displaying all the valid syntactic constructs that can replace the selected part of the code in a context-sensitive menu. When any of these constructs is selected, its structure replaces the selected part and only the placeholders need to be filled in by the developer (a placeholder starts with a dollar sign). If the placeholder is for an identifier, the completion mechanism can be used to avoid writing the full name of an identifier which occurs somewhere else in the program.

When starting writing a Java Card program from scratch, a menu allows either an applet pattern or a class pattern to be inserted into the empty editor window; see figure 4. If the developer chooses the applet pattern in the menu, the skeleton of an applet is displayed. This skeleton contains the structures of the applet constructor and the main methods i.e. process, install, select, deselect and getShareableInterfaceObject. The install method already contains the creation of the applet object and the registration call to the JCRE. Thus, the developer has only to fill in the placeholders.

Figure 5 shows a menu of the available block statements and the result of selecting and inserting the if-pattern into an applet being developed. This is a simple purse applet, which we are using as a running example in the rest of the article. The complete program can be found in the appendix. The services provided by this applet are deposits, withdrawals, and balance checkings. See Chen [3] for an introduction to how to write Java Card applets. Finally, also note that comments are handled. They are seen as decorations in the abstract syntax tree and correctly handled by the pretty printer (in green on lavender background).

4. THE CAD SIMULATOR

The CAD simulator gives the user the possibility to interactively test applets. It provides a graphical user interface which allows both generic an application-specific APDUs to be constructed and sent to the Java Card simulator. It also allows the returned response APDUs to be in-

Figure 4 Menu displayed when starting writing a new Java Card program and the syntax-coloured applet skeleton which results when the developer chooses Applet from the menu.

Figure 5 Menu showing the various block statements and the result of selecting and inserting the if-then-pattern during development of the Purse applet.

Figure 6 The general layout of APDUs.

spected. An APDU log records all sent and received APDUs, a session. The CAD simulator allows sessions to be stored and later re-used in order to undertake regression testing.

While the basic APDU layout and some commands are standardised (figure 6), any particular application necessitates the definition of application specific commands. Since an APDU is just a byte sequence, it would in principle be enough if the CAD simulator simply allowed arbitrary byte sequences to be assembled and sent. But that would clearly be rather inconvenient for the user under normal circumstances. It is far easier to just specify the contents of an APDU and let the simulation environment take care of the packing (and unpacking) details.

However, this means that the CAD simulator needs to be told about the details of application specific APDUs, such as what command names there are, the command number for each one, the names and types of any arguments (in the data field), etc. To make it possible to use the CAD simulator without first having to provide a separate specification of the application specific APDU formats, we have developed a tool, the APDU format extractor, which extracts this information from an applet by static analysis. The extraction scheme works reasonably well since a Java Card applet usually is written in a very stylized way (there is always

Figure 7 The structure of an applet description. Square brackets indicate a list.

a method process which does the initial command decoding, the basic layout of the APDUs is standardised, etc.). Thus a developer typically just has to write the applet code, or indeed, get code from somewhere else, and the CAD interface will automatically adapt itself to the applet (or applets) in question. The results from an analysis can be saved to avoid having to re-analyse known applets.

Figure 7 shows a somewhat simplified structure of the applet descriptions returned by the format extractor. For the purpose of the CAD simulator, an applet is described by its name and AID (applet ID, for selecting the applet), and descriptions of the accepted commands and their associated formats. The format extractor works by symbolically executing the applet code, keeping track of data dependences and constant and variable names in the process. When the extractor encounters a conditional statement where the CLA and INS part of an APDU is compared to some (symbolic) constant, this establishes the existence of a command whose name is given by the name of the constant in question. The code in the corresponding branch of the conditional is then executed symbolically in order to figure out the format for that particular command. For example, when an instruction reading from the data part of the APDU buffer is encountered, the name of the variable in which this value is stored is used to provide a name for the corresponding APDU argument, whose length and position are also inferred from the instruction in question. Response APDUs are analysed in a similar way. Figure 8 gives an example which schematically illustrates the principle behind the extraction process. See Henrio [5] for further details.

Figure 8 Illustration of the extraction process.

Figure 9 The CAD simulator command selection window.

It could happen that the analysis carried out by the format extractor fails due to an applet not being sufficiently stylized. In that case the user can create the applet description manually by using an editor.

The CAD simulator also allows standard applet installation and selection APDUs to be sent, as well as arbitrary APDUs assembled from scratch. The latter is useful for sending non-conforming APDUs in order to test that an applet handles invalid commands correctly, for instance. Furthermore, there is an option to simulate card withdrawal, which optionally can be combined with saving the state of the running card. The card simulator can be initialized from such a saved state.

When applied to the Purse example, the extractor determines that the name of the applet is Purse, and that this applet accepts three commands: PURSE_DEPOSIT, PURSE_WITHDRAW, and PURSE_BALANCE_CHECK with instruction numbers 1, 2, and 3 respectively. PURSE_DEPOSIT is found to have one short (2-byte) argument amountOfDeposit at position 5, and PURSE_WITHDRAW is similarly found to have one short argument amountOfWithdraw at position 5. Finally, the extractor determines that all commands return a short result purseTotal, i.e. the resulting balance.

The result of the analysis is sent to the CAD simulator which opens a window which allows one of the three identified commands to be sent to the applet; see figure 9. Once one of these commands has been selected (by clicking on it), a second window pops up which allows any parameters to be filled in prior to sending the complete APDU to the applet. The window also shows the full details of the sent command APDU and, eventually, the received response APDU in the form of byte strings. Figure 10 shows the result once a deposit of 101 Euros has been made to an empty purse. Note that the resulting balance is 101 (0x0065) Euros. The figure also shows the APDU log which keeps track of all sent and received APDUs and allows them to be examined.

5. THE JAVA CARD SIMULATOR

The central part of the Java Card simulator is an executable specification of the dynamic semantics of the Java Card language [7]. It is

Figure 10 The CAD simulator command send window and the APDU log. The former allows a selected application-specific commands to be constructed and sent. Its appearance is similar to the window for sending generic APDUs, but many of the APDU fields are fixed since they are given by the selected command, and there is one field for each argument rather than a single, generic, data field. The APDU log shows all sent and received APDUs with explaining comments. The log window also allows sessions to be saved and re-used for regression testing.

expressed in Natural Semantics, small-step style, using Typol. Thus the semantic rules express the stepwise transformation of the abstract syntax tree of an applet into the final result. The semantic specification is derived from a Java specification also developed within our group [1]. Almost the entire Java semantics has been re-used without changes to make it easy to profit from further developments of it (or vice versa). Java Card specificities are handled by a few extra modules. Furthermore, executable specifications of Java Card APIs (i.e. specifications of Java Card classes such as AID, APDU, APDUException, Applet, JCSysyem) as well as of the JCRE (Java Card Runtime Environment, i.e. the ‘operating system’) have been added [4].

Figure 11 shows some Typol rules from our Java Card semantics. They are concerned with giving the semantics of an if-statement. The first rule says that an if-statement where the condition is not yet in normal form, is to be rewritten to an if-statement where the condition has been evaluated one step further by the rule `evaluateExpression`. The two following rules state that an if-statement where the condition is in normal form (i.e. true or false), should be replaced by either the then-branch or the else-branch depending on the condition.

It should be pointed out that the current semantics is incomplete in some respects. For example, it is a dynamic semantics which currently

```

If _EvaluateExpression:
  evaluateExpression(ObjL1, CVarL1, Env1, OThId, ObjId1, Mode
    |- Expr1 ->
      ObjL1_1, CVarL1_1, Env1_1, Expr1_1, InstL2,
      ThStatus) &
  appendtree(InstL2, insts[if(Expr1_1, Stat1, Stat2).InstL1], InstL3)
  -----
  ObjL1, CVarL1, OThId
  |- clr(ObjId1, Mode, MethName, Env1,
    insts[if(Expr1, Stat1, Stat2).InstL1])
  -> ObjL1_1,
    CVarL1_1,
    clr(ObjId1, Mode, MethName, Env1_1, InstL3),
    ThStatus ;
  provided diff(Expr1, true()) & diff(Expr1, false());

If _False:
  ObjL, CVarL, _
  |- clr(ObjId, Mode, MethName, Env,
    insts[if(false(), _, ElseStatement).InstL])
  -> ObjL,
    CVarL,
    clr(ObjId, Mode, MethName, Env, insts[ElseStatement.InstL]),
    executing() ;

If _True:
  ObjL, CVarL, _
  |- clr(ObjId, Mode, MethName, Env,
    insts[if(true(), ThenStatement, _).InstL])
  -> ObjL,
    CVarL,
    clr(ObjId, Mode, MethName, Env, insts[ThenStatement.InstL]),
    executing() ;

```

Figure 11 Excerpts from the Java Card dynamic semantics specification.

does not perform static type checking. As a consequence, overloading resolution is not handled completely accurately. Another point is that the modelling of control-flow is incomplete in some cases. However, since Java Card applets tend to be small and fairly simple, the current limitations have as yet not caused any major problems.

The formalisation of the JCRE covers the basic aspects of the runtime system such as loading and registration of applets, selection and deselection of applets, and the primitives necessary for communication with the environment, i.e. the CAD simulator in our case. There is also support for saving and loading the state of a running card. This is used to simulate card insertion and withdrawal, but it is also useful for debugging or if one simply would like to take a pause and continue from where one left off at some later point.

When it comes to the APIs, there are two basic approaches. One possibility is to describe them in Java, somehow making use of built-in primitives where necessary. The API classes would then be loaded into the simulation environment prior to the loading of any applets. The other approach is to describe the semantics of the API classes and their methods directly in Typol. Basically, this means that there is a set of hard-coded rules for each method which describes what happens when the method in question is invoked. We have chosen the latter approach for three reasons:

- It is much more efficient.
- Having the semantics of important methods directly available as Typol rules hopefully makes it easier to prove properties about the specification as well as individual applets.
- It is natural and simple to let the API methods be the built-in primitives. Otherwise, it would be necessary to provide access to primitives by some other means, in which case many of the API methods would not do more than invoke such a primitive anyway.

The specification of the Java Card APIs is not as yet complete. For example, the mechanisms for atomic transactions and object sharing, as well as the related API methods, are currently not in place.

During simulation, the developer can follow the execution in detail at a selectable speed through a graphical user interface. It is also possible to stop (interactively or by setting breakpoints), single step, and continue. The breakpoint and single stepping facilities currently work at the level of the semantic rules, not at the level of the Java Card source code. This is suitable for debugging the Java Card specification, or for a user who would like to learn about the semantics of Java card, but it is not ideal

Figure 12 The Java Card simulator during execution of the Purse applet.

for debugging applications. Improved debugging support in this respect is something which we plan to look into.

Other features include textual browsers for inspection of variables and objects. Our Java environment [1] provides a dynamic, graphical view of the created object structures which would be useful also for the Java Card environment. This functionality could easily be carried over.

Figure 12 shows the Java Card simulator executing the Purse applet just after having received an APDU requesting the deposit of 100 Euro. The large window is the main Typol debug window which shows the current rule. It is equipped with buttons for controlling the execution. The small window shows the value of the variable `commandAPDU` which has been selected in the main window. The shown value is the received command APDU: note the value `0x0064 = 100` in the APDU's data field.

6. RELATED WORK

Sun has developed free tools around Java Card: a converter (available since November 1999) and a simulator. The latter allows Java Card applet code to be simulated, but unfortunately it has no debugging facilities such as breakpoints, step by step execution, or variable value inspection. Thus it works as a black box taking a file of command APDUs as input (byte sequences in textual format) and giving back a file of response APDUs as output. Moreover, all the tests cannot be performed since it is not possible to simulate card withdrawal or power failure.

There are also commercial Java Card development kits, for instance Odyssey labTM from Bull, CyberflexTM from Schlumberger, GemXpresso RADTM from Gemplus, Sm@rtCafé ProfessionalTM from Gieseke & Devrient, GalatICTM from Oberthur Card Systems. These kits contain a

card reader, cards, and software tools (a converter, a loader, a tool to test applets on the card, and sometimes a simulator).

Our aim is obviously not to compete with these smart card manufacturers, but to propose new methods for creating development environments with innovative functionality. Furthermore, we are not currently in a position to make a fair comparison between these tools and ours since we have only seen commercial demonstrations and hand-outs. However, as far as we know, the commercial environments are not Java Card specific since they are meant to be integrated into development environments for ordinary Java such as J++TM or Symantec CaféTM. Thus it would seem that a developer using any of these available tools would not know for sure whether the application being developed conforms to the Java Card subset until an attempt is made to convert the compiled code into a CAP file. In contrast, our editor makes it impossible³ to write code which does not conform to the Java Card subset.

In our environment, we have put a lot of effort into making it easy to simulate and test the behaviour of Java cards at the APDU level. While communication at the APDU level and the associated code to interpret APDU commands and dispatch on them is the current standard for writing Java Card applets, and will continue to be the standard for the foreseeable future in legacy contexts, it has been proposed that higher-level protocols would be more appropriate for new developments. For example, Vandewalle and Vétillard [8] propose a design framework where a card application is viewed as a remote object. Its methods are invoked through a proxy object executing on the CAD. Behind the scenes, a special protocol called DMI (Direct Method Invocation), built on top of the APDU standard, handles the communication. (This is all similar to how Java's RMI works.) This framework has been implemented in the GemXpresso RAD environment by Gemplus.

Since DMI is still based on APDUs, this and similar protocols could be incorporated directly on top of what we have. This might have advantages since the simulation would be sufficiently detailed to make it possible to simulate events such as card withdrawal or power failure. On the other hand, since the aim of such protocols is to hide the low-level communication details, it might make more sense to simulate such protocols directly. It would not be difficult to adapt our environment in this way, but one should probably still keep the simulation capability at the APDU level as well for those who needs or prefers this.

³There is currently one minor exception. The developer can invoke a command from a menu to check for that case.

7. CONCLUSIONS AND FUTURE WORK

This article described a Java Card programming environment which to a large extent has been generated from formal specifications of the syntax and semantics of Java Card. Through this approach, we were able to develop a set of tightly integrated tools with useful and novel functionality, such as the APDU format extraction, at a high level of abstraction. The main features of the environment from a user perspective are:

- Java Card-specific structure editor.
- CAD simulator which makes it easy to send and receive APDUs.
- Automatic extraction of the APDU formats from applet source code and automatic adaptation of the user interface of the CAD simulator accordingly.
- Semantics-based Java Card simulator with facilities for monitoring the execution and important data structures.

This makes the environment useful for applet developers, applet testers, and people wanting to learn about the Java Card semantics.

Furthermore, the fact that a formal, dynamic Java Card semantics is the basis of the simulator, means that it has been possible to test and debug this formalisation. This is important since a correct formalisation of the language semantics is a prerequisite for proving properties about programs and analyses concerning dynamic properties of programs, something we believe is particularly important in the context of typical smart card applications. For example, in the framework of Java cards with several applications, we are starting some work on static analysis of object sharing between applications. One outcome of this research could be a facility for statically detecting sharing violations or the absence of such violations. Since a violation will cause an exception, it would clearly be reassuring to know that this cannot happen.

The current semantics is still missing a few features. This should be addressed. We would also like to further improve the debugging support, for instance by making it possible to set breakpoints, single step, etc. at the Java Card source level. We also aim to integrate capability for graphical object structure browsing along the lines found in Attali et al. [1]. Finally, it is planned to move towards a SmartTools⁴-based solution, SmartTools being the 100 % Java successor to Centaur.
