Abstract. The aim of this work consisted in applying the Analytic Hierarchy Process (AHP) by considering the generic criteria and sub-criteria to select logistic operator to store and transport frozen products. The outcome of the AHP analysis is a preference priority for each alternative operator describing the expected performance level. Results pointed that the proposed model could be considered as a good alternative to this problem, thus contributing to achieve the goals of the organization.

Keywords: Selection, Logistic Operator, Multicriteria decision, Analytic Hierarchy Process.

1 Introduction

The analytic hierarchy process (AHP) is a structured technique for organizing and analyzing complex decisions. The AHP method was developed during the 70's by Thomas Saaty [1] to solve complex problems that involves multicriteria decisions [2] and has been extensively studied and refined since then. The applications of AHP to complex decision situations have produced extensive results in problems involving planning, resource allocation, priority setting, and selection of logistic operators, among alternatives.

AHP's use for logistic operator selection consists in an important aspect to identify and consider the criteria [3, 4, 5, 6], by knowing the contractor demands in order to achieve the main goal [7, 8], and evaluate alternatives and contract logistic operators that are more efficient [9] adding value to the supply chain [10], by using a evaluation method of analysis before the contractual formalization [11, 12, 13], to verify whether it is worth to outsource or internalize the activities [8].

Usually the focus is on selecting a service provider that has the relational capacity to facilitate the business integration, operation and quality treatment [14], that turns out more feasible to collaboration [15], including establishing common goals to control the performance and the strategic alignment of the partnership [16] to manage the service level [17].

Regarding the quality analysis, it was developed a model based on SERVQUAL (quality dimensions), taking into account the criteria utilized for logistic operator selection [18].

It has been found some works, in which the AHP method was used to select logistic service providers to operate reverse logistic that could be considered a complex decision, once it is a recent operation, that needs reliability [19, 20, 21,22], with contractual renegotiation guaranteed politics [22] and mainly, really contributes with sustainability by reducing waste on transport and storage [15]. Other researchers used the AHP to select logistic operators to act on manufacturing of contractor [23, 24].

In Table 1 it is shown the logistic operator selection generic criteria and sub-criteria developed by action research in logistic services outsourcing processes on Brazil in the last six years. But, with a deep revision in literature it was possible to identify the researches that corroborate with the criteria and sub-criteria established on practice, making it possible to assure that it is made of a 15 criteria and 67 sub-criteria basis consolidated on theoretical research field.

In the literature review it wasn't identified researches that utilize the AHP to select logistic operators that storage and transport frozen refrigerated products and it was noted that it misses a more complete criteria and sub-criteria basis to apply the multicriteria analysis in outsourcing processes. Some researches produced fragmented results [3, 8, 9, 14, 18, 22] that makes it impossible to make decision.

In this context, the aim of this work consists in applying the AHP with support of the generic criteria and sub-criteria basis of logistic operator selection of storage and transport of frozen products.

2 Methodology

At first, the literature revision [25] was performed in the following data bases: Proquest, Ebsco, Science Direct, Emerald, Capes and academic Google, with the following keywords: (i)"Analytic hierarchy process" AND "outsourcing" AND "logistics"; (ii) "Analytic hierarchy process" AND "selection" AND "third party logistics"; (iii) "Analytic hierarchy process" AND "selection" AND "third-party logistics" e (iv) "Analytic hierarchy process" AND "selection" AND "service provider" with the objective of electing the articles that utilized the AHP to select the logistic operators, summarizing 24 researches, that were submitted to content analysis to categorize the data in a spread sheet [26] of the main themes and criteria utilized.

The utilized method was action research, in which the researcher is involved, along with the members of the analyzed organization, to deal with a problem, specifically in the appropriate selection of a logistic operator of storage and transport of frozen load [27], with that, the researcher participates in the process [28, 29, 30].

The process of action research involves five stages [28, 29, 30]:

- (i) Action research planning: – in this step, it was identified along with the contractor, the insecurity in selecting a logistic operator to move and transport frozen products, which brought up the following research's question: how to select a logistic operator appropriate to store and transport frozen products.

- (ii) Instruments to collect field data: – active participation in meetings, focal groups and documents analysis. The focal groups or observation groups generate important lessons about the observed phenomenon [30].
- (iii) Action Plans: - the decision making relative to logistic operator selection inevitably includes a consideration and evidence based in multicriteria for the decision making [3, 4, 5, 2, 6]. With that in mind, we adopted 16 criteria and 67 sub-criteria of logistic operator selection [31].

Table 1. Criteria and Sub-criteria of logistic operator selection

Criteria	Sub-criteria	Corroborating Researches
Cost	Transport; Storage and handling; Delay on supplying and Devolutions.	[23, 21, 7, 17, 9, 8]
Financial stability	Investment Capacity; Financial Health and Indebtedness.	[3, 14, 22, 9, 8]
Adaptability	Logistic Operator <i>in lócus</i> with the Contractor; Flexibility in the treatment, Cultural Compatibility and Common Planning.	[17, 8]
Operation Infrastructure	Distribution Centers Location; Facilities Adequacy; Work Security; Loading; Truck Conditions; Equipment required for loading; Receipt in JIT without fault in the Logistic Operator; Equipment required in receipt; Equipment required for Moving; Handling Pallets without fault; Storage and Stacking in the warehouse; Equipment required in the warehouse; Separation to dispatch without fault; Uniting and Own cars; Equipment required to transport and dispatch of the order without fault in JIT.	[18, 3, 22, 16, 17, 8, 20, 6]
Operation Management	Management of: people; loading; receipt; storage; transport; quality and information.	[14, 22, 19]
Flexibility	Treatment capacity; Negotiated nuances and Treatment Service to the Clients.	[23, 3, 21, 15, 9, 19, 8]
Credibility	Business Reputation; Logistic Partnership and amount of Contracts per year.	[3, 14, 22, 6]
Experience	Service efficiency; Product's amount of experience; Amount of time in the market and Clients range.	[14, 7, 20, 6]
Quality	Quality Certification; Physical Integrity Compatibility; Logistic Operator seeks improvement in the process and Traceability.	[23, 14, 21, 22, 9, 8]
Information Technology	Easy Communication (Electronic Data Interchange - EDI); (Enterprise Resource Planning - ERP); (Warehousing Management System-WMS); (Transport Management System TMS) and Routing (Global Positioning System - GPS).	[23, 9, 19, 17, 20]
Human Resources	Employees Qualification; Capacity of Working in Group; Capacitation and practical test, Clothing and neatness of the employees.	[14, 21, 22]
Reliability	Complete Order Dispatching; Classified Information Leaking; Security against load stealing and Fines due to no-treatment.	[18, 8]
Responsibility	Operation in JIT and Dispatch in short term.	[18, 23, 21, 22, 15, 16, 17, 8]
Empathy	After-Sell and Commitment	[18, 14].
Environmental	Certification ISO 14000; Cleaner Production; Reverse Logistic and Training in environmental education	[3, 22, 15, 16, 19, 20]

Source: [31, 32] corroborated with some researches.

In fact the process of decision making is commonly complex. The multicriteria Decision Analysis could support the decision maker to solve problems in which there are many goals to be reached at the same time. Three sets are initially considered in the formulation of multicriteria decision problems: the set of alternatives, the set of criteria and the set of consequences [33]. The process consists of the following stages:

(1) Define the alternatives; (2) Define the relevant criteria to the decision problem; (3) Evaluate the alternatives related to the criteria; (4) Evaluate the relative importance of each criteria and (5) Determine the global evaluation of each alternative.

Along the methods developed in the Multicriteria Decisions research, the most well-known is the Analytic Hierarchy Process – AHP, developed by Thomas Saaty [1] to identify the relevant criteria through binary correlation, which allows to associate a priority value above other elements in a numerical scale, merging an hierarchical structure of the problem of decision with support of the mathematical modeling.

As an example, when using the decision matrix A , the AHP method calculates the partial results of the A set inside each criteria $v_i(A_j)$, $j = 1, \dots, n$, called impact value of the j alternative in relation to the i alternative, in which these results represent numerical values of the given data by the decision maker in each alternative comparison. The results are standardized by the expression 1:

$$\sum_{j=1}^n v_i(A_j) = 1, \text{ for } j = 1, \dots, n; \quad (1)$$

where n is the number of alternatives or compared elements. Each part of the sum consists in: $v_i(A_j) = a_{ij} / \sum_{j=1}^n a_{ij}$, for $j = 1, \dots, n$.

This expression relates the priority vector of the alternative i in relation to the C_k criteria be: $v_k(A_i) = \sum_{j=1}^n v_i(A_j) / n$, for $i = 1, \dots, n$

After having the priority vector or the impact value of the alternatives under each C_k criteria, the next step is the criteria levels. In this case, we adopt again the verbal scale to the classification pair-to-pair of the criteria, that are standardized by the expression 2:

$$w_i(C_j) = C_{ij} / \sum_{i=1}^m C_{ij}, \text{ for } j = 1, \dots, m; \quad (2)$$

where m is the number of criteria in the same level. The priority vector is obtained by:

$$w_i(C_i) = \sum_{j=1}^m w(C_j) / m, \text{ for } i = 1, \dots, m; \quad (3)$$

Finally, the final values of the alternatives are obtained through an aggregation process, standardized by the expression 4, in which:

$$f(A_j) = \sum_{i=1}^m w(C_i) * v_i(A_j), \text{ for } j = 1, \dots, n; \quad (4)$$

where n is the number of alternatives

(iv) Implanting Actions – scale selection for decision making to identify the most relevant contractual criteria. The Table 2 shows the scale.

Table 2. Criteria Evaluation Scale

Value	Definiton	Explanation
1	Same Importance	Both criteria contribute in the same way to the objective.
3	Little more Important	The analysis and experience prove that a criteria is a little more important than the other.
5	Much more Important	The analysis and experience prove that a criteria is much more important than the other.
7	A lot more Important	The analysis and experience prove that a criteria is a lot more important than the other.
9	Hugely more Important	Without doubt, a criteria is predominant over the other one.

Source: based on Saaty [1].

- (v) Discuss Results – the final stage implies in learning through reflection among the results of the action of the participants [29] to verify which logistic operator can successfully fulfill the operational capacities (criteria) required as described in the following stage.

3 Results and Discussion

The main focus of the corporation is the product industrialization. Thus, they decided to outsource its storage and frozen product transport processes, taking into account the dispatching capacity of the operators. So, three logistic operators have been chosen to be analysed by AHP method.

Numerical Application

In this section, the multi-criteria group decision model is applied to a procedure for selecting logistic operators. In order to obtain the Multicriteria numerical application it was used the AHP method based on the 16 criteria and 67 sub-criteria, allowing an identification of seven more critical criteria. The main criterion to be observed in the logistic operators' evaluation is the transport responsiveness. However, to make the responsiveness capacity better to the market, it was required criteria of infrastructure (physical resources) to improve the storage capacity, that was missing physical space in the appropriate floor to allocate 134 tons a day – 4 freezing tunnels that allocate 26 docks and infrastructure criteria (physical resources) to improve the transport capacity – strategic localization near the beltway to deliver the products quickly.

This way, the main concern of the contractor was the complementation of storage and transport capacities, variables associated to the responsiveness and infrastructure criteria. It is important to note that the contractor was not only worried about analyzing the physical resources to store and transport, as well, but the managing capacity of the logistic operator within these activities, by considering the efficiency indicators implantation required integrated with fee applications in case of non-effectiveness.

The results pointed that the qualitative analysis should precede the AHP application with the objective of knowing the demands of the contractor regarding the capacities. In most published works, decision makers applied the multicriteria analysis [3, 4, 5, 6, 8, 9, 10, 11, 12, 13, 21, and 32], neglecting the qualitative evaluation. Many authors pointed out the need of relational capacity without a deeper analysis of the other required capacities [14, 15, 17, and 28]. The relational capacity and the quality capacity can be considered generic, because this is a common necessity in any outsourcing process, being required a deeper analysis on the operational routine of the contractor to identify specific capacities, as shown in the results.

Table 3 shows the consequence matrix with critic criteria obtained after the model application. The numbers were normalized to obtain the relative importance (pair-wise comparison).

Table 3. Consequence Matrix

Criteria	Operation Infrastructure	Operation Management	Quality	Tech-nology	Human Resources	Relia-bility	Respon-siveness
Operation Infrastructure	1,000	1,000	0,111	0,111	0,111	0,111	0,111
Operation Management	1,000	1,000	0,111	0,111	0,111	0,111	0,111
Quality	3,000	1,000	3,000	0,333	0,333	0,333	0,333
Technology	3,000	1,000	0,600	0,333	0,333	0,333	0,333
Human Resources	3,000	1,000	0,600	0,333	0,333	0,333	0,333
Reliability	3,000	1,000	0,600	0,333	0,333	0,333	0,333
Responsiveness	9,000	1,000	1,800	1,000	1,000	1,000	1,000

Based on the seven critical criteria, the three logistic operators were analyzed. Table 4 presented the decision matrix and the results obtained for each alternative.

Table 4. Decision Matrix

Alter-native	Operation Infrastructure	Operation Management	Quality	Tech-nology	Human Resources	Relia-bility	Respon-siveness
LO 1	0,195	0,210	0,397	0,162	0,302	0,250	0,203
LO 2	0,520	0,519	0,503	0,543	0,397	0,491	0,593
LO 3	0,284	0,271	0,101	0,295	0,302	0,259	0,203

Once obtained the decision matrix, it was possible to evaluate the score and classify the logistic operators, indicating which of them was considered more able to store and transport frozen products.

The logistic operator 2 (score 0.41) was considered more able to improve the dispatch responsiveness of the contractor in the metropolitan region of São Paulo, because it is in a strategic localization near the beltway, allowing better product outflowing, among having better consolidated infrastructure concerning equipment, as for an example, term kings to control the temperature, and freezing tunnels in the warehouse.

The second-best (score 0.23) was the logistic operator 1 that presented low capacity of infrastructure that could prejudice the dispatching responsiveness.

Finally, the logistic operator 3 (score 0.21), that presented lack of control in the efficiency of the provided services, making it impossible to analyze the punctuality indicators of dispatch.

Both logistic operators 1 and 3 were not localized near a beltway, which was considered, by the contractor, a crucial aspect.

This results corroborate with the researches of [19, 20] related to the development of a ranking to avoid the opportunist behavior of logistic operator regarding the possibility of offering sets of generic services that do not meet the contractor demands and could lead to the outsourcing failure.

4 Conclusions

In this work, the AHP technique was used in the selection of logistic operators to store and transport frozen products. The AHP is a structured technique for organizing and analyzing complex decisions, and could be useful, especially in complex decision processes, once it enables people to make decisions involving many kinds of concerns including planning, setting priorities, selecting the best among a number of alternatives, and allocating resources. Complex problems or issues involving value or subjective judgments are suitable applications of the AHP method. Its approach of division in hierarchical criteria and alternative correlation with criteria, allows an easy comprehension and better evaluation of the problem. Taking into account that many strategic decisions, such as logistic operator selection, are many times, made without any methodical support, the proposed model can be considered as a good alternative to the investigated problem, since it can support the decision process, which can contribute to increase efficiency of the supply chain of the organization.
