Erratum

The handling of five amines by the extraneuronal deaminating system of the rat heart

M. Grohmann and U. Trendelenburg

Naunyn-Schmiedeberg's Arch Pharmacol (1988) 337:159–163

Due to an unfortunate error of the authors, the IC_{50} -values presented in Table 1 were corrected in an *upward* direction, to yield HSOC-values (half-saturating outside concentrations) that were *higher* than the IC_{50} -values. The correction should have been made in a *downward* direction. Hence, Table 1 should have shown the following HSOC-values (in $\mu\text{mol/l}$, with 95% confidence limits in parentheses):

(–)-Adrenaline	6.14	(1.58; 11.9)
Tyramine	10.1	(3.26; 20.5)
(–)-Noradrenaline	16.4	(5.87; 37.0)
5-HT	19.3	(8.51; 47.8)
Dopamine	16.4	(6.22; 35.9)

It should be noted that this re-calculation of the HSOC-values does not alter the main conclusion, namely that higher outside concentrations of catecholamine are needed for saturation of the intracellular monoamine oxidase than for that of the intracellular catechol-O-methyl transferase, in the extraneuronal system of the rat heart.
