from which one has, taking into account eq. (9),

$$(11) \quad M > \frac{2\pi^2}{3} N.$$

So there is surely condensation when (11) is not satisfied. It is therefore proved that in the ground state of a lattice gas there is surely a Bose-Einstein condensation at a low density of the particles.

It follows from eq. (11) that in the ground state of a system of particles having very small radius ($\varepsilon \rightarrow 0$, $N \rightarrow \infty$) there is a Bose-Einstein condensation even when the density of the particles is great.

* * *

It is a pleasure to thank our friend F. MIGLIETTA for useful discussions.

Rotational Levels of Odd-Odd Light Deformed Nuclei.

In the legend to Fig. 3 the value of V should read -39 MeV and in that to Fig. 6 it should read -40 MeV. In this last figure the two-body force employed is that of ref. (9) and not that of ref. (8).
