Visceral fat obesity in which lots of fat deposit in adipose tissue on mesenterium is frequently observed in patients with diabetes mellitus or other insulin resistant syndrome. It is unknown which factor contributes to the accumulation of visceral fat. Gastric inhibitory polypeptide (GIP) is known as an incretin. The peptide released from small intestine perfuses mesenterium to portal vein. Besides, it has direct metabolic effects on adipose tissue to incorporate fatty acids. In this study, we investigated relationship GIP secretion and clinical features of insulin resistant syndrome. All subjects were non-obese (BMI<25) men younger than 65 years of age with or without impaired glucose tolerance whose pancreatic beta cell function kept well. The fat distribution was analyzed by measuring visceral fat area / subcutaneous fat area ratio (V/S ratio) on computed tomography pictures of umbilical level. Insulin sensitivity (Si) was assessed by Bergman's minimal model method. Plasma GIP were measured by RIA system specific for human GIP. Fasting plasma insulin or incremental insulin response after 75g glucose ingestion (Σ IRI) had no correlation with V/S ratio or Si. Other metabolic markers; fasting plasma glucose, triglyceride and cholesterol had no significant correlation with those either in this case. The other hand, incremental GIP response after glucose ingestion (Σ GIP) had significant negative correlation with Si ($R=-0.637$, $P=0.046$), and had significant positive correlation with V/S ratio ($R=0.606$, $P=0.0086$). It had no correlation with BMI. These findings demonstrate the relationship between visceral fat accumulation, insulin resistance and hypersecretion of GIP, that is not mediated by insulin. We propose GIP as a promising candidate factor which accumulates visceral fat.

IS LEPTIN RELATED TO ABDOMINAL FAT DISTRIBUTION AND INSULIN RESISTANCE IN NIDDM PATIENTS ?

J.F. GAUTIER*, N. LAHLOU**, A. MOURIER*, E. DE KERVILER*, and G. CATHELINEAU *. * Endocrinology and Radiology Department, Saint-Louis Hospital, 75010 PARIS ; **INSERM 342 , Saint-Vincent de Paul Hospital, 75014 Paris, France.

Leptin is a protein secreted by the adipose tissue. The aim of the present study was to evaluate the relationship of abdominal adipose tissue distribution measured by magnetic resonance imaging and insulin resistance to plasma leptin concentration in NIDDM subjects. Plasma leptin concentrations were measured by radioimmunoassay with a detection limit of 0.1 ng.ml^{-1}. Areas of abdominal fat were calculated from axial magnetic resonance images obtained at the level of umbilicus (L4-L5 vertebrae) in 21 men with NIDDM treated with either hypoglycemic agents (n = 17) or a diet alone (n = 4) : age 46 ± 8 (DS) months, BMI 29.3 ± 4.5 kg.m^2 (range 20.2-36.9), total body fat (skinfold thickness) 26.8 ± 5.4%, waist-to-hip ratio 0.97 ± 0.07, duration of diabetes 59 ± 47 months. The insulin tolerance test (ITT, 0.1 U/kg of intravenous regular insulin) was performed after an overnight fast, at least 48 hours after the withdrawal of metformin. The areas of subcutaneous and of deep abdominal fat were respectively 212 ± 99 cm^2 and 135 ± 55 cm^2 . Plasma leptin levels averaged 8.4 ± 6.8 ng.ml^{-1} (range 1.77 - 32.2) and were positively related to areas of subcutaneous abdominal fat (r = 0.731 , p < 0.001), BMI (r = 0.669 , p < 0.01) and total body fat (r = 0.589 , p < 0.01). In contrast, the areas of visceral adipose tissue, the waist-to-hip ratio and the blood glucose disappearance rate K_{ITT} were not related to plasma leptin concentrations. In conclusion, plasma leptin levels is not associated with deep abdominal fat and insulin resistance in the NIDDM patients of this study.

1022

THE ASSOCIATION OF INSULIN RESISTANCE WITH MUSCLE AND ABDOMINAL FAT IN OBESITY

KI.Ryomoto, T.Imakita, A.Kanazawa, M.Suzuki and Y.Harano. Department of Atherosclerosis, Metabolism and Clinical Nutrition, National Cardiovascular Center, Osaka, Japan

Object: To investigate the association of insulin resistance with muscle and abdominal fat in obesity. **Methods:** 18 male (BMI>26.4: n=9, <26.4: n=9) and 13 female (BMI>26.4: n=8, <26.4: n=5) obese subjects were studied. Insulin resistance was determined with the method of steady-state plasma glucose (SSPG). Visceral fat (V) and subcutaneous abdominal fat (S) were evaluated by a single scan made at the level of the navel. To measure muscle fat, triple 1 cm thickness cross-sectional scan of the mid-thigh was obtained by CT. Thigh fat inside and outside fascia (MF, SF), V and S were electronically measured by using commercially available CT software, with the region of interest window set to attenuation values of -150 to -50 Hounsfield units (HU). The mean attenuation values of thigh tissue except bone tissue inside fascia (mCT) was measured by using the same software. Increased MF correlated with low mCT and the lower mCT correspond to more fat content in muscle. **Results:** When the higher and lower SSPG groups were analyzed, the higher group shared increased V and MF in male, while in female, the more V.

Male	SSPG(mmol/dL)	V(cm)	MF(cm)	Female	SSPG(mmol/L)	V(cm)
n=9	7.7±0.7	156±14	8.4±0.5	n=7	9.8±0.8	111±12
n=9	14.3±0.4*	198±13*	12.0±1.5*	n=6	16.8±1.1*	159±13*

*p<0.05 vs lower SSPG

SSPG was significantly correlated positively with V (r=0.57, p<0.05) and MF (r=0.63, p<0.05), and negatively with mCT (r=-0.52, p<0.05) in male. In female, SSPG was significantly correlated positively with V (r=0.71, p<0.05). **Conclusion:** Insulin resistance was associated with not only visceral fat but also thigh fat inside fascia in male.

1023

THE RELATIONSHIP BETWEEN LEPTIN AND INSULIN SENSITIVITY IN A POPULATION-BASED STUDY IN MAURITIUS.

M. de Courten, P. Zimmet, V. Collins, A. Hodge, G. Collier, G. Dowse, K. Alberti, J. Tuomilehto, F. Hemraj, H. Gareeboo and D. Fareed. International Diabetes Institute, Melbourne, Australia.

It has been shown that fasting serum leptin and insulin concentrations are highly correlated, and in a small clinical study insulin sensitive men had lower leptin levels than insulin resistant men when matched for fat mass. Our aim was to examine the association between insulin resistance (assessed by HOMA model) and leptin after controlling for overall and central adiposity in a population-based cohort. Subjects were participants of a 1987 non-communicable diseases survey conducted in the multiethnic population of Mauritius. 1227 men and 1310 women of Asian Indian, Creole and Chinese ethnicity had normal glucose tolerance and fasting serum leptin measurements. Leptin levels were compared across insulin resistance quartiles within tertiles of body mass index (BMI) by analysis of covariance, and multiple linear regression models were used to assess the relationship between leptin and insulin resistance after adjusting for BMI and waist/hip ratio (WHR). Mean serum leptin concentration increased across insulin resistance quartiles in each BMI group and each sex, after controlling for BMI, WHR and age (p<0.001 for each comparison). Furthermore, insulin resistance was a significant determinant of serum leptin concentration, independent of BMI and WHR, in both men and women. These results suggest that insulin resistance and/or concentration may contribute to the relatively wide variation in leptin seen at similar levels of body mass or alternatively, leptin may play a role in the etiology of insulin resistance. In future work it will be important to determine whether the hyperleptinemia/insulin resistance relationship has a role in the natural history of obesity, NIDDM, and the other metabolic phenomena associated with insulin resistance.

1024

VISCERAL FAT IS ASSOCIATED WITH INCREASED PLASMINOGEN ACTIVATOR INHIBITOR-1 LEVELS IN WOMEN.

B.Janand-Delenne, C.Chagnaud, M.C.Alessi, I.Juhan-Vague and P.Vague. Timone Hospital, Marseille, France.

Increased plasma Plasminogen Activator Inhibitor-1 (PAI-1) levels are a risk factor of myocardial infarction and are considered as one of the parameters of insulin resistance syndrome. The metabolic disorders observed in insulin resistance are associated with android obesity and most particularly with abdominal visceral fat accumulation. To clarify the relationship between PAI-1, insulin-resistance and visceral fat, 40 women (age:18-65 years, BMI:21-49 kg/m^2) have been studied. We have measured visceral and subcutaneous abdominal fat by computed tomography at the level of umbilicus, plasma PAI-1 activity and insulin sensitivity by hyperinsulinemic euglycemic clamp method (1mU/Kg/mn). This results show that PAI-1 levels are positively correlated to fasting insulinemia and negatively to insulin sensitivity index (r=0,48, p<0,01 and r=-0,33, p<0,05). PAI-1 levels are more strongly correlated to visceral fat (r=0,51, p<0,001), whereas no correlation is found with subcutaneous fat (r=0,23, NS). Moreover, visceral fat is positively correlated to fasting insulinemia (r=0,62, p<0,001) and negatively to insulin sensitivity index (r=-0,64, p<0,001). Stepwise multiple regression analysis showed that after adjustement for visceral fat, correlation between PAI-1 activity and fasting insulinemia disappears. These results suggest that visceral fat contributes PAI-1 elevation in insulin resistance syndrome and strengthen other data showing that in animals, PAI-1 is produced by adipose tissue, particularly visceral adipose tissue.

1025

FAT DISTRIBUTION AND SERUM LEPTIN LEVELS IN NON-DIABETIC OFFSPRING OF NIDDM PATIENTS

I.Vauhkonen [1], L. Niskanen[1], S. Kainulainen[2], S. Haffner[3], M. Uusitupa[4] and M. Laakso[1] , Departments of Medicine [1], Radiology[2] and Clinical Nutrition [4], Kuopio University Hospital and University of Kuopio, Finland, University of Texas Health Science Center at San Antonio[3], San Antonio, Texas

Serum leptin levels have been associated with fat mass. Moreover, women have higher leptin levels than men. The impact of fat distribution on leptin levels, however, is a controversial issue. We studied the association of fat distribution on leptin levels in 20 non-diabetic offspring (M/F 5/15; mean age 41.3 yrs) of NIDDM patients with insulin secretion deficient phenotype (IS-group), 18 non-diabetic offspring (M/F 7/11; 40.5 yrs) of NIDDM patients with insulin resistant phenotype (IR-group) and in 14 control subjects (M/F 5/9; 41.1 yrs) without a family history of diabetes. The abdominal fat distribution (subcutaneous fat = SCFAT and intra-abdominal fat = IAFAT) was measured with computed tomography, the total fat mass (TFM) bioelectrical impedance and the whole body glucose uptake (WBGU) with the euglycemic hyperinsulinemic clamp technique.

	Control	IS	IR	ANOVA (adj.forgender[1]+TFM)
BMI, kg/m^2	25.0	24.6	28.8	p<0.05
TFM, kg	19.0	20.5	26.4	p<0.05[1]
WBGU, mg/kg/min	11.1	10.1	7.5	p<0.01
S-leptin, ng/l	12.9	13.4	23.2	p<0.001
SCFAT, cm^2	204	215	310	p =NS
IAFAT, cm^2	72	84	123	p =NS

In control and IS-group, but not in IR-group, serum leptin levels correlated with SCFAT (r=0.81, p<0.01 for controls; r=0.46, p<0.05 for the IS-group; r=0.05, p=NS for the IR-group). The significant correlations persisted after adjustment for age, gender and TFM. No relationship between IAFAT and leptin was observed. In conclusion, SCFAT was a more important determinant of serum leptin levels than IAFAT. This may explain higher leptin levels found in women than in men.

1026

PROSPECTIVE EXERCISE AND WEIGHT LOSS STUDY IN TYPE II DIABETIC SUBJECTS IMPROVED INSULIN RESISTANCE, LIPIDS AND LEPTINS

F.Smith, C. Whitney, E. Friedlander, C. Mullooly, J.Hill, S.- E. Bursell and G.King. Joslin Diabetes Center, Boston, MA, USA

Type II Diabetes Mellitus is characterized by obesity, hyperglycemia, insulin resistance, hyperlipidemia, and increased risk for cardiovascular disease. Risk factors could be reduced by diet and exercise but chronic adherence to a weight loss program or a specialized diet is known to have low success rates. The following study was designed to determine if triglyceride self-monitoring combined with an intensive 16 week exercise, weight loss and diet modification program would improve outcomes. Obese Type II DM males and females over 40 years of age, not treated with insulin or lipid lowering agents were randomized to monitored or non-monitored groups. Weight, glucose, glycohemoglobin A1C, lipids, fasting and stimulated insulin levels, leptin levels, and exercise tolerance (Max O2 levels) were measured at the beginning and end of the program. Statistical analysis was performed using a paired student's t test. Results from all subjects (n=24), showed highly significant decreases in weight (95.7±20.7 kg to 91.0±18.4 kg, p=0.001) which strongly correlated with decreases in leptin levels (r=0.4). Significant improvements were also found in fasting glucose (177.4± 40.5 to 161.3±33.3, p=0.006), triglyceride (235.0±94.6 to 179.2±70.9, p=0.003), and total cholesterol levels (219.7±24.7 to 199.9±28.7, p=0.001). Changes in glycohemoglobin A1c, HDL cholesterol and LDL cholesterol levels were not significant by 16 weeks. Fasting insulin levels were significantly decreased (22.8± 13.2 to 17.0±9.5, p=0.02) but 2 hour sustacal stimulated levels were unchanged. A significant improvement in exercise tolerance was also found by Max O2 testing (26.6±7.4 to 31.1±8.5, p=0.003). The triglyceride meter group had lower average triglycerides, however the variance in the data indicates that more subjects need to be recruited in order to show a significant effect. In summary, an intensive exercise, weight loss and diet program for Type II Diabetic patients significantly improves glucose control, lipids, insulin resistance and increases exercise tolerance, all risk factors for the cardiovascular complications of diabetes.

1027

PLASMA LEPTIN ASSOCIATED WITH BODY MASS INDEX AND INSULIN IN HEALTHY MALE ADOLESCENTS

H. Hirose, I. Saito, K. Nakamura, H. Maruyama, and T. Saruta. Keio University School of Medicine, Tokyo, Japan

Leptin, recently discovered peptide secreted exclusively from adipocytes, regulates appetite and energy expenditure. Plasma leptin level is reported to increase in obese adults. In the present study, we measured plasma leptin, height, weight, blood pressure (SBP and DBP), heart rate, blood cell counts, plasma glucose, insulin, lipid profiles (TC, TG and HDL-C), UA and creatinine in 366 healthy male high school students (aged 16.2±0.4 and BMI 20.8±2.5 (SD)). Plasma leptin and insulin were measured with RIA (Linco and Eiken Co., respectively). Plasma leptin (2.8 ±1.6 ng/ml) was strongly correlated with body weight (r=0.48), BMI (r=0.55) and insulin (r=0.46) (P<0.001 for all). There was also correlation with age (r=0.14), SBP (r=0.21), DBP (r=0.14), heart rate (r=0.19), WBC (r=0.20), RBC (r=0.17), Hct (r=0.17), TC (r=0.16), TG (r=0.20), HDL-C (r=-0.16) and UA (r=0.20) (P<0.01 for all). Stepwise regression analysis revealed significant correlation with BMI (F=108.7), insulin (F=57.2) and WBC (F=5.9) (p<0.05 for all). We conclude that plasma leptin is associated with BMI and insulin also in healthy male adolescents. Relationship with blood cell counts was considered to need further study.

1028

EFFECTS OF LONG-TERM TOTAL FASTING AND INSULIN ON *OB* GENE EXPRESSION IN OBESE PATIENTS

P.H. Andersen[*], K. Kristensen[#], S.B. Pedersen[#], E. Hjøllund[§], O. Schmitz[*] and B. Richelsen[#]. Medical Department M, , Aarhus Kommunehospital[*], Division of Endocrinology and Metabolism, Medical Department C, Aarhus Amtssygehus, Aarhus University Hospitals[#], Aarhus, Division of Internal Medicine, Grenå Centralsygehus, Grenå[§], Denmark.

The aim of the present study was to explore the regulation of *obese (ob)* gene expression in severe obese females during long-term fasting (6 days). Furthermore, the effect of insulin on serum leptin levels was examined before and after fasting. Nine females were included. Age was 34 ± 3 years and BMI 46.4 ± 2.3 kg/m^2. Six days of fasting induced a significant weight loss (126.8 ± 5.3 vs. 120.5 ± 5.1 kg, p < 0.0001). Insulin-stimulated glucose uptake (hyperinsulinemic, euglycemic clamp, insulin infusion rate 1.5 mU/kg/min) was markedly reduced following fasting (M-value 5.96 ± 0.74 vs. 2.79 ± 0.23 mg/kg/min, p < 0.0001). *Ob* mRNA/ß-actin concentration (quantitated by quantitative PCR) in fat biopsies from abdominal subcutaneous adipose tissue was unchanged after 6 days of fasting (1.50 ± 0.40 vs. 1.47 ± 0.36 arb. units, NS), whereas serum leptin levels decreased significantly from 53.8 ± 4.7 ng/ml to 30.7 ± 2.0 ng/ml, p < 0.0001 during the same period. Serum leptin levels were unchanged by hyperinsulinemia for 3 hrs during the clamp prior to the fast, while hyperinsulinemia for 3 hrs after six days of fasting increased serum leptin by 25 %, p < 0.01. In conclusion: Six days of fasting reduced serum leptin by about 40 %. In contrast *ob* mRNA in abdominal subcutaneous adipose tissue was unchanged. The decrease in serum leptin levels after long-term fasting may be due to posttranscriptional events like decreased translation, increased clearance or decreased half-life. Finally, the effect of insulin on serum leptin levels seems to be dependent on the nutritional state.

1029

CIRCULATING LEPTIN CORRELATES TO ISLET FUNCTION IN NON-DIABETIC SUBJECTS

B. Ahrén and H. Larsson, Dept. Medicine, Lund Univ., Malmö, Sweden

It is known that circulating leptin correlates to body fat content and that administration of leptin reduces food intake. Leptin might thus be a humoral signal from fat affecting feeding behaviour, and, consequently, factors influencing the nutritional status might operate through changes in circulating leptin. We have previously shown that circulating leptin correlates to fasting insulin, to maximal insulin secretory response to a glucose + arginine challenge and to the glucose sensitivity of B cell secretion, indicating a relation between leptin and insulin secretion. In this study, we examined whether circulating leptin also correlates to other islet hormones. We therefore injected arginine i.v. (5 g) at fasting glucose and after raising circulating glucose to 14 and 28 mmol/l in 106 postmenopausal women, aged 58 years. We confirmed our previous results that circulating leptin correlates to BMI ($r=0.70$, $p<0.001$), to fasting insulin ($r=0.36$, $p<0.001$), to circulating insulin at 14 mmol/l glucose ($r=0.28$, $p=0.004$) and 28 mmol/l glucose ($r=0.33$, $p<0.001$), as well as to the insulin response to arginine at all three glucose levels ($r>0.29$, $p<0.003$ for all) in a multivariate analysis controlling for the influence of BMI. Furthermore, we demonstrated that leptin, independently of BMI, also correlates to fasting glucagon ($r=0.36$, $p<0.001$), to plasma glucagon at 14 mmol/l glucose ($r=0.20$, $p=0.047$) and to plasma glucagon at 28 mmol/l glucose ($r=0.25$, $p=0.040$) as well as to the glucagon response to arginine at all three glucose levels ($r>0.22$, $p<0.025$ for all). In contrast, circulating leptin did not correlate to plasma levels of pancreatic polypeptide (PP) ($r=0.13$, $p=0.187$). We conclude that circulating leptin correlates to both insulin and glucagon secretion but not to plasma PP in a large group of postmenopausal women. This suggests that islet function is related to circulating leptin in humans.

1030

LEPTIN LEVELS DO NOT PREDICT WEIGHT GAIN: A PROSPECTIVE STUDY

AM Hodge, MP de Courten and PZ Zimmet on behalf of the Mauritian NCD Group. International Diabetes Institute, Melbourne, Australia.

Human obesity is associated with high leptin concentrations, but at any level of body fat leptin varies widely. Relatively low leptin levels may indicate leptin deficiency and risk of weight gain. Alternatively, high leptin could indicate leptin resistance and also increased risk of weight gain. Whether one or both of these mechanisms operate in humans was examined in a longitudinal study of 1988 normoglycaemic Mauritians aged 25 to 45 years who participated in population-based surveys in 1987 and 1992. Changes in BMI, waist/hip ratio (WHR) and waist circumference were compared between leptin 'resistant' 'normal' and 'sensitive' groups. Leptin 'resistance' and 'sensitivity' were defined on the basis of the Studentised residuals (SRESID) from the regression of $\log_{10}$leptin on BMI. If SRESID > 0.9, leptin was considered high or 'resistant'. If SRESID was < -0.9, subjects were considered leptin 'sensitive' or 'deficient'. There were no consistent trends in age or BMI across leptin 'resistant', 'normal' and 'sensitive' men and women. Fasting insulin decreased significantly ($p<0.001$) with increasing leptin sensitivity in men and women. After adjusting for age and BMI by analysis of covariance, there were no significant differences in the changes in BMI (percentage or absolute), waist circumference or WHR between leptin 'resistant' and 'normal' subjects except that in men WHR increased more in the leptin 'resistant' group ($p=0.001$). However, there was a tendency for smaller increases in other measures of obesity among the leptin 'resistant' subjects compared with the 'normal' subjects. Leptin 'sensitive' subjects tended to experience greater increases in the obesity parameters than 'normal', but the differences were not significant. Further adjustment for insulin did not change the results. Redefining leptin 'resistance' and 'sensitivity' as SRESID>1.2 or <-1.2 did not enhance the slight trends observed above. These findings do not support a role for leptin concentration, either high or low, in predicting weight gain. Leptin's main role in humans may be in protecting against the effects of starvation rather than over consumption, consistent with the conditions encountered during most of human evolution.

1031

INSULIN AND LEPTIN ARE RELATED INDEPENDENT FROM BODY MASS INDEX.

R.P. Stolk, J.A.M. Janssen, H.A.P. Pols, P. Inglaro, W.F. Blum, A.M.F. Attanasio, D.E. Grobbee and S.W.J. Lamberts. Department of Epidemiology, Utrecht University & Department of Internal Medicine, Erasmus University Rotterdam, The Netherlands.

We investigated the associations between the components of the insulin resistance syndrome and leptin levels in a sample of participants of the Rotterdam Study: 549 men and 558 women (mean age 66.8 years (SD 5.5). As part of the baseline examination immunoreactive insulin was measured after a non-fasting oral glucose load. At the follow-up examination after 2.1 years a fasting oral glucose tolerance test was performed. Insulin and leptin were measured by highly specific radioimmunoassays.

Serum leptin levels in men and women were 6.14 ng/ml (SD 4.5) and 21.7 ng/ml (15.5), respectively ($p < 0.001$). Leptin levels were associated with all components of the insulin resistance syndrome both assessed at baseline and at follow-up: body mass index, waist/hip ratio, fasting and post-load glucose, fasting and post-load insulin, triglycerides, HDL-cholesterol, and blood pressure, as well as with the presence of diabetes mellitus and hypertension (all associations: $p < 0.001$, adjusted for age and gender). When the analyses were further adjusted for body mass index, leptin remained associated with insulin only: in men an increase of 0.06 ng/ml per mU/l fasting specific insulin (95% confidence interval 0.03; 0.08, $p<0.001$) was found, whereas in women this was 0.50 ng/ml per mU/l (0.39; 0.62, $p<0.001$). The independent associations between insulin and body mass index with leptin were also present in the longitudinal analysis.

The results of this population-based study indicate that insulin levels (but not the other components of the insulin resistance syndrome) are associated with increased leptin levels independently of body mass index. This suggest that hyperinsulinemia plays a key in increased leptin levels.

1032

ARE LEPTIN AND OLEOYL-ESTRONE EQUIVALENT PONDEROSTAT SIGNALS IN LEAN AND OBESE SUBJECTS?

J.M. Fernández-Real, D. Sanchis*, W. Ricart, J. Biarnés, R. Casamitjana**, F. Balada*, M. Fernández-Castañer***, J. Soler***, and M. Alemany*. Department of Endocrinology, Hospital of Girona and ***Bellvitge, Barcelona. *Department of Biochemistry and Molecular Biology, University of Barcelona. **Hormonal Laboratory, Hospital Clínic, Barcelona. SPAIN.

In a recent study, a white adipose tissue component, oleoyl-estrone, induced a dose-dependent loss of weight and decreased food intake in Wistar female rats. We studied plasma concentrations of oleoyl-estrone in 17 lean subjects (8 females), and 25 obese (14 females), matched for age and fasting glucose. Obese female subjects had significantly higher percent body fat, serum leptin ($p<0,01$), and plasma oleoyl-estrone ($p=0.02$) than obese men. Both leptin and oleoyl-estrone strongly correlated with BMI, and with measures of central fat distribution. Serum leptin strongly correlated with percent body fat (PBF, bioelectric impedance) and insulin sensitivity (minimal model analysis; $r=0.72$, $p<0.0001$ and $r=-0.63$, $p=0.003$, in males; $r=0.85$ and -0.86, $p<0.0001$ in females). The same relationships were observed concerning oleoyl-estrone with percent body fat ($r=0.52$ and $r=0.69$, in males and females, respectively) and with insulin sensitivity ($r=-0.72$ and -0.76, in males and females, respectively). The associations between leptin and oleoyl-estrone with insulin sensitivity persisted after controlling for percent body fat ($r=-0.63$, $p=0.003$ in males; and $r=-0.45$, $p=0.04$ in females, for oleoyl estrone; and $r=-0.49$, $p=0.03$ in males, and $r=-0.58$, $p=0.007$ in females, for serum leptin). Fasting serum leptin correlated with plasma oleoyl-estrone ($r=0.64$, $p<0.0001$), which persisted after controlling for insulin sensitivity ($r=0.52$, $p<0.0001$) and fat mass ($r=0.38$, $p=0.01$). In summary, plasma oleoyl-estrone levels are strongly correlated with PBF and insulin sensitivity in humans, in parallel to the same associations described for serum leptin. The relationship between oleoyl-estrone and leptin levels hints at their functional relationship within the framework of body weight control.

1033

SERUM LEPTIN IN ELDERLY PEOPLE

H.A. Koistinen, V.A. Koivisto, S-L. Karonen and R. Tilvis. Helsinki University Central Hospital, Helsinki, Finland.

The recently discovered leptin is a novel hormone, which regulates energy intake and expenditure. Aging is associated with various alterations in food intake and energy metabolism. To investigate whether aging affects serum leptin levels, we measured serum leptin in elderly people with radioimmunoassay. The study population (n=159) included 19–20 men and 20–21 women from each of the four birth cohorts aged 65, 75, 80 and 85 years. The groups were similar with respect to body mass index (BMI), serum total and HDL cholesterol, triglyceride, insulin and blood glucose concentrations. Serum leptin concentration was similar in different age groups, but in each group it was 2–3 fold higher in females (average for all 14.8±16.2 μg/l, mean±SD) than in males (5.9±3.3 μg/l) ($p<0.05$ or less in all groups). In women, who lived longer, serum leptin concentration was 62% higher than in those, who died within 5 yrs after blood sampling (17.6±16.9 vs 10.9±11.2 μg/l, respectively, $p<0.02$). Leptin correlated positively with BMI ($r=0.40$, $p<0.001$) and insulin concentrations ($r=0.31$, $p<0.001$), as previously shown in younger population. In conclusion: 1) Leptin gender difference is present also in the elderly. 2) Aging does not affect serum leptin levels or its correlation with adiposity. 3) Higher leptin concentrations in women living longer may indicate a better nutritional status rather than be a primary factor for survival.

1034

LEPTIN IN NORMAL WEIGHT, OBESE AND OBESE DIABETIC SUBJECTS : EFFECT OF HYPERINSULINEMIC CLAMP AND BODY WEIGHT LOSS

E. Bobbioni-Harsch, F. Assimacopoulos, R. Munger, T. Lehmann and A. Golay. Treatment and Teaching Division for Chronic Diseases. Department of Medical Biochemistry. University Hospital Geneva, Switzerland.

Leptin plasma levels were measured in normal weight (n = 9) and in obese (n = 50) subjects in basal conditions; after two hour euglycemic, hyperinsulinemic clamp (n = 30) or after weight loss (n = 12). In basal conditions, leptin was significantly lower in lean than in obese subjects ($p<0.001$). When obese were subdivided in three groups according to their glucose tolerance (i.e. normal, inpaired glucose tolerance and diabetics), no differences were observed in leptin levels. Obese females showed significantly higher leptin values than males ($p<0.001$). Leptin was significantly ($p<0.0001$) linked to fat body mass (FBM) when expressed both in Kg and as percent of total body weight. No significant relationships were found between plasma leptin and basal Energy Expanditure (EE) nor lipid oxidation, when these values were expressed in function of the lean body mass (LBM). Two hour euglycemic hyperinsulinemic clamp did not modify leptin levels in either lean or obese group, independently of their glucose tolerance. After four weeks hypocaloric diet, a group of obese patients (n = 12) showed a body weight loss of 7.9±1.7 Kg, corresponding to a 12.8±2.3 % decrease of their initial fat mass; at the same time leptin levels were reduced from 77.7±15.0 ng/ml to 55.6±10 ng/ml, i.e. 30.0±7.3% decrease of the initial values. No significant correlation was observed between the amount of fat loss and the reduction in plasma leptin. In conclusion, circulating leptin is, in basal conditions, influenced by sex and fat mass but not by glucose intolerance or diabetes; leptin is not affected by two hour hyperinsulinemia, but is strongly modified by fat loss.

1035

PLASMA LEPTIN LEVELS DO NOT CORRELATE TO PLASMA PROINSULIN LEVELS IN NORMAL ADULTS.

Jeong-Taek Woo, Woo-Sik Kim, Seung-Jae Hong, Sung-Woon Kim, Myung-In Yang, Jin-Woo Kim, Young-Seol Kim, Young-Kil Choi. Kyung-Hee University, Seoul, Korea

It has been demonstrated that plasma leptin levels strongly correlate to body fat content. Increased body fat content , especially intraabdominal fat is accompanied by insulin resistance. We questioned whether plamsa leptin levels is correlate to insulin sensitivity in normal adult individuals. We measured fasting plasma leptin, insulin, proinsulin, C-peptide, glucose and waist/hip ratio in 213 normal subjects(men = 100, women = 113). Their fasting plasma glucose levels were below 6.1 mmol/l and they had no previous medical history and family history of diabetes mellitus. Body fat amount was determined with impedance method. BMIs were 22.4 ± 2.46 in men, 22.4 ± 2.60 in women respectively. Log fasting plasma leptin levels strongly correlate to body fat amount(r = 0.63, P = 0.000). Log fasting plasma proinsulin levels weakly correlate to body fat amount(r = 0.34, P = 0.000) and waist/hip ratio(r = 0.25, P = 0.000). However plasma leptin levels did not correlate to plamsa insulin, proinsulin, c-peptide and waist/hip ratio by partial correlation study controlling body fat amount. Fasting plasma leptin levels were significantly higher in women than men(6.45 ± 4.02 ng/ml, 2.45 ± 1.58 ng/ml, P = 0.000) although body fat amount was not differ between two groups(12.3 ± 4.0 kg in men, 15.7 ± 4.6 kg in women, P = 0.308). In conclusion, plasma leptin reflects body fat amount and may be affected by sex but does not correlate insulin sensitivity independently of body fat amount.

1036

POST-GASTROPLASTY RECOVERY OF IDEAL BODY WEIGHT NORMALIZES SERUM LEPTIN LEVELS OF OBESE WOMEN

M.R. Letiexhe, A.J. Scheen, J.F. Caro and P.J. Lefèbvre. Division of Diabetes, Nutrition & Metabolic Disorders, University of Liège, Belgium and Division of Endocrinology & Metabolism, Thomas Jefferson University, Philadelphia, Pen, USA.

In order to better understand the significance of obesity-associated elevated serum leptin in humans, fasting leptin concentrations were measured in 8 obese women before (BMI = 37.7 ± 0.5 kg/m²) and 14 ± 2 months after successful gastroplasty restoring ideal body weight (BMI = 23.7 ± 0.6 kg/m²). Before gastroplasty, obese women showed markedly higher serum leptin levels (36.8 ± 4.8 *versus* 8.9 ± 1.8 ng/ml, $P < 0.001$) when compared to lean controls (BMI = 23.6 ± 0.7 kg/m²). After gastroplasty, serum leptin concentrations dramatically decreased to 6.4 ± 1.6 ng/ml ($P < 0.0001$) and became similar to those of controls. The minimal model-derived insulin sensitivity index S_I (10^{-5} min^{-1}/pmol.l^{-1}) was lower in obese subjects (4.74 ± 0.74, $P < 0.01$) when compared to that of controls (11.79 ± 1.74), but returned to normal levels after gastroplasty (9.15 ± 0.96). Serum leptin levels were positively related to BMI ($r = 0.882$; $P < 0.0001$; $n = 24$) and to basal plasma insulin levels ($r = 0.516$; $P < 0.01$), and inversely related to the insulin sensitivity index S_I ($r = - 0.379$; $P = 0.068$). However, these two latter correlations disappeared after adjustement for BMI. In conclusion, elevated serum leptin levels return to low normal values in post-obese women, and such normalization might contribute to favour weight regain after dieting in case of central resistance to leptin.

1037

SERUM LEPTIN IS INDEPENDENTLY ASSOCIATED WITH INSULIN RESISTANCE IN LEAN AND OBESE SUBJECTS

R. Casamitjana*, W. Ricart, M. Fernández-Castañer#, Joan Soler# and J.M. Fernández-Real. Department of Endocrinology, Hospital de Girona "Dr Josep Trueta", *Hormonal Laboratory, Hospital Clínic, Barcelona.#Department of Endocrinology, Hospital de Bellvitge, Barcelona.

Serum leptin is elevated in most overweight individuals in parallel with increased plasma insulin levels. We evaluated oral glucose tolerance, insulin sensitivity (frequently sampled intravenous glucose tolerance test with minimal model analysis), acute insulin response to glucose (AIRg), 0-10 minutes after the IV glucose bolus, and serum leptin levels in 19 lean [9 males (BMI 22.3, range 20.1-25), and 27 age-matched (mean 34.5 ± 2.1 years) obese (12 males; BMI 32.4 ± 0.6, range 30.1-37.2] subjects. Percent body fat (PBF) was measured using bioelectric impedance. As previously described, log transformed serum leptin was significantly associated with BMI ($r=0.66$, $p<0.0001$), PBF ($r=0.83$, $p<0.0001$) and fasting serum insulin ($r=0.61$, $p<0.01$). A strong linear association between Log_e serum leptin and insulin sensitivity ($r=-0.65$, $p=0.002$ in males; $r=-0.86$, $p<0.0001$ in females) was found. AIRg correlated with leptin levels only in those subjects with normal glucose tolerance. A Multiple Linear Regression Analysis showed that both SI and PBF, independently contributed to 52% (males) and 75% (females) of the variance of serum leptin (for SI, $p=0.02$ in males; $p=0.005$ in females). In summary, differences in leptin levels cause, or are the consequence of, differences in insulin sensitivity.

1038

HYPOLEPTINEMIA IN POST-OBESE WOMEN: A POSSIBLE CAUSE FOR RELAPSE OF BODY WEIGHT.

P.A. Tataranni, G. Mingrone, G. Cizza, A.V. Greco, M. Castagneto and G. Gasbarrini. CDNS-NIDDK-NIH, Phoenix, USA; DEB-NICHD-NIH, Bethesda, USA; Catholic University, Rome, Italy

It has recently been proposed that relatively low plasma concentrations of leptin, a hormone produced by the adipose tissue that decreases food intake and increases energy expenditure in rodents, may predispose humans to obesity. To test this hypothesis, we measured body composition (bioimpedance), energy intake (7-day food diary), energy expenditure (indirect calorimetry) and fasting plasma leptin concentration (RIA) in 6 morbidly obese women (O, 40±1y, 115±17kg, 54±3% body fat, mean±SD), 8 post-obese women 3y after surgical treatment for obesity, i.e. biliopancreatic diversion (PO, 38±9y, 73±9kg, 40±10% body fat), and 8 never-obese women (NO, 35±12y, 57±5kg, 24±7% body fat). After adjusting for metabolic rate, i.e. metabolic body size, energy intake was higher in PO than in both O (excess=2604±284kcal/d; $p<0.01$) and NO (excess=2973±263 kcal/d; $p<0.01$). Plasma leptin concentration was 9.0±4.1 ng/ml in PO, 12.2±6.7 ng/ml in NO and 46.2±14.5 ng/ml in O and correlated positively with % body fat ($n=22$, $r=0.56$; $p<0.01$) and fat mass ($n=22$, $r=0.63$; $p<0.01$). After adjusting for fat mass, mean plasma leptin concentration was 10.0±2.8 ng/ml lower in PO than in NO, and 16.5±7.8 ng/ml lower in PO than in O. Adjusted plasma leptin concentration was negatively correlated with adjusted energy intake ($n=22$, $r=-0.45$; $p=0.03$). In conclusion, our data indicate that post-obese women, who underwent biliopancreatic diversion, have higher energy intake and lower plasma leptin concentration than morbidly obese and normal weight women. These observations suggest that hypoleptinemia may promote body weight gain or relapse (after weight loss) in humans by increasing energy intake.

1039

PLASMA LEPTIN LEVELS IN OBESE SUBJECTS WITH GLUCOSE INTOLERANCE.

R.Kawahara, M.Yoshino, Y.Tasaka, Y.Omori, Diabetes Center, Tokyo Women's Medical College, Tokyo, Japan

The aim of this study was to evaluate the clinical significance of leptin in obese subjects with glucose intolerance. We sutdied 54 obese subjects (37 women, 17 men, body mass index(BMI) 33.3±6.5 kg/m^2, age 40.9±14.1 years, mean±SD) and 18 non-obese control subjects(14 women, 4 men, BMI 19.9 ±2.3, 30.7±14.2 years). Obese subjects were divided into three groups according to WHO criteria for 75g oral glucose tolerance test; with normal glucose tolerance(NGT, n=18), impaired glucose tolerance (IGT, n=16) and diabetes(N=20). Plasma leptin levels were measured using a human leptin RIA kit (Linco Company). Percent body fat was measured by impedance methods. Insulin resistance(IR) and β-cell function (β-CF) were calculated using HOMA model of Matthews et al. Plasma leptin concentration in obese subjects was higher than in control subjects and was higher in women than in men(Women:13.4 ±5.7 ng/ml vs 3.9±1.2 ng/ml,P<0.0001, Men:9.1±7.1ng/ml vs 2.7±0.9ng/ml, P<0.03). Leptin correlated significantly (P<0.0001) with BMI (r=0.57), fat precent (r=0.74) and fat mass (r=0.58), but not with fasting plasma glucose level and HbA1c. Leptin levels in the three obese groups were not significantly different. In the NGT group leptin level correlated significantly (P<0.01) with fasting insulin (r=0.73), IR(r=0.69) and β-CF(r=0.72), but did not in the IGT and DM group. In conclusion, plasma leptin was strongly correlated with body fat accumlation, but not with glucose intolerance.

1040

THE LONGITUDINAL CHANGES OF THE RESTING ENERGY EXPENDITURE IN THE ELDERLY DIABETIC FEMALES.

J.Inoue and H.Ito.Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan.

We examined wheather the resting energy expenditure (REE) in the elderly diabetics changed with age, using the longitudinal study. The REE of 7 diabetic females (age:72+/-9 (mean +/-S.D.) YO; BMI:24.7+/-2.7 kg/m^2), treated by diet or SU agents, were measured before and after 2 to 3 years (mean period: 1034 days). The REE was measured by the indirect calorimetry. The total lean body mass (TLBM) was examined by dual energy X-ray absorptiometry. The total body fat mass per kg body weight decreased from 35+/-5.0 % to 32.6+/-7.1 during the follow-up period. TLBM did not change (31.8+/-4.8 kg vs. 32.3+/-5.1 kg).The REE per kg TLBM did not change also (31+/-5 kcal/kgday vs. 31+/-6 kcal/kgday). However, the respiratory quotient significantly decreased from 0.89+/-0.06 to 0.83+/-0.04 ($p<0.01$). The carbohydrate oxidation rate per REE significantly decreased from 51+/-11 % to 38+/-9 ($p<0.01$). The fat oxidation rate per REE significantly increased from 32+/-15% to 50+/-15 ($p<0.01$). The protein oxidation rate per REE did not change. Therefore the elderly diabetics might decrease their fat mass due to acceleration of their fat oxidation during aging.

1041

INCREASED PLASMA LEPTIN CONCENTRATIONS IN PATIENTS WITH CHRONIC HYPERINSULINEMIA DUE TO INSULINOMA.

P. Sbraccia, M. D'Adamo, M. Mellozzi, A. Paoloni, E. Maroccia§, A. Buongiorno§, and G. Tamburrano. Division of Endocrinology 1, University "La Sapienza", §Clinical Biochemistry Laboratory, Istituto Superiore di Sanità, Rome, Italy.

Leptin is a new hormone secreted by adipocytes which decreases food intake. The role of insulin in the regulation of leptin secretion is poorly understood and is still a matter of debate. Insulin increases leptin mRNA synthesis in rodents whereas in humans the available data are discordant. To investigate the role of chronic hyperinsulinemia in the regulation of circulating leptin concentrations we studied 13 patients with surgically confirmed insulinoma (8F/5M; aged 42.9 yr; range 19-80; BMI 26.7±1.2 kg/m^2; fasting plasma insulin 146.2±27.5 pM; mean±SEM) and 6 healthy subjects (4F/2M; aged 37.8, range 22-54, BMI 25.8±0.8 kg/m^2, fasting plasma insulin 30.7±6.3 pM, mean±SEM). Immunoreactive human leptin plasma levels were measured by radioimmunoassay. Fasting plasma leptin concentrations were significantly higher in insulinoma patients than in controls (16.7±2.7 vs 3.1±0 4 ng/ml respectively; $p<0.01$). In patients with insulinoma fasting plasma leptin concentrations positively correlated with fasting plasma insulin levels ($r=0$ 685; $p<0.01$). In contrast, leptin levels correlated neither with fasting plasma glucose nor, unexpectedly, with BMI. In summary, in patients with insulinoma: 1) plasma leptin levels are elevated; 2) a direct relationship exist between leptin and insulin concentrations. These data, therefore, support a role for insulin in the chronic regulation of leptin secretion.

1042

EFFECT OF WEIGHT LOSS ON RESTING ENERGY EXPENDITURE IN HYPERTENSIVE OBESE WOMEN

W H-H Sheu, H-M L Chin*, H-Y Su* and C-Y Jeng*. Taichung Veterand Gen Hosp, Taichung; Tri-Service Gen Hosp*. Taipei; Taiwan

Hyperinsulinemia and the associated increased sympathetic nervous activity have been proposed to the development of hypertension and obesity. The role of hyperinsulinemia in mediated resting energy expenditure (REE) and the effect of weight loss on REE between hypertensive (HO) and normotensive obese (NO) women are not understood. We measured fasting plasma glucose, insulin (FPI), lipids concentrations, REE and body composition before and after a weight loss program in 9 newly diagnosed HO and 10 NO women. As compared with age-matched lean controls, obese subjects had higher fasting plasma glucose, FPI and REE values. Although REE and FPI concentrations correlated well in simple correlation ($r=0.708$, $p<0.001$), this relationship disappeared after adjusting for values of fat free mass. Weight loss for 10% of initial weight led to significant decreases of blood pressure and FPI concentrations in both obese groups. Fasting plasma cholesterol, LDL cholesterol and triacylglycerol concentrations decreased in HO individuals. Significant fall of REE in HO ($p<0.05$) and NO ($p<0.02$) were observed following weight loss. However, the ratio of REE to FFM decreased significantly only in HO subjects (114.6±9.2 KJ/day. Kg^{-1} to 108.2±4.6 KJ/day. Kg^{-1}, $p<0.05$). In conclusion, 1). HO and NO women had higher FPI concentrations and REE than those of lean controls, 2). No significant relation between FPI and REE could be found, 3).Weight loss produced a significant decrease of REE/FFM only in HO women.

1043

SERUM LEPTIN CONCENTRATION IS HIGHER IN MALE BUT NOT IN FEMALE SUBJECTS WITH CUSHING SYNDROME

A. Widjaja, T. Schürmeyer, A. von zur Mühlen and G. Brabant. Hannover Medical School, Germany.

Corticosteroids and insulin increase leptin expression in vivo and in vitro. To investigate whether increased serum cortisol influence leptin concentrations in humans, we analysed fasting serum leptin (RIA) and insulin (RIA) in 34 females (27 pituitary and 7 adrenal Cushing, 41.6 ± 2.7 yrs, BMI 29.6± 1 2 kg/m^2) and 16 males (16 adrenal, 39.2 ± 3.1 yrs, BMI 26.3 ± 2 3 kg/ m^2) with Cushing syndrome and fasting leptin in controls, matched for BMI and gender (34 females: 38.2 ± 2.4 yrs, 29.6 ± 2.0 kg/ m^2,16 men: 36.8 ± 3.1 yrs, 26.3 ± 1.9 kg/m^2). Cortisol in Cushing subjects was taken in 10 minute intervals over 24 hours and the mean of 144 samples was calculated for each subject. Leptin was higher both in healthy ($p<0,001$) and Cushing ($p<0,01$) females than in males. Leptin concentration was normal in female Cushing subjects (geometric mean (SEM range) 200 (163-245) pmol/l vs controls 209 (170-257) pmol/l, $p=0,51$) but higher in male Cushing subjects (106 (74-150) pmol/l vs 67 (44-101) pmol/l, $p<0,05$). Total testosterone in male Cushing subjects (2,11 ± 0,34 ng/ml) was below the normal range (>3,0 ng/ml). No difference in leptin concentration between female subjects with pituitary and adrenal Cushing was detected. Leptin correlated positively with BMI in healthy females ($r=0,79$, $p<0,01$) and males ($r=0,82$, $p<0,01$). This correlation was weaker in female ($r=0,41$, $p<0,05$) and male ($r=0,51$, $p<0,05$) Cushing subjects. Insulin correlated positively with leptin in female ($r=0,54$, $p<0,05$) and male ($r=0,72$, $p<0,01$) Cushing subjects. No correlation was observed between leptin and cortisol concentrations in subjects with Cushing syndrome. We conclude that chronic hypercortisolnemia does not affect serum leptin concentration and that insulin and adiposity are the major regulators of serum leptin levels in Cushing syndrome. High androgen levels may inhibit leptin secretion in men; this effect could possibly explain the difference in leptin concentration between male Cushing and healthy subjects.

1044

TOTAL ENERGY EXPENDITURE AND PHYSICAL ACTIVITY LEVEL CORRELATE WITH FASTING PLASMA LEPTIN IN CHILDREN.

AD Salbe, M Nicolson and E Ravussin. NIH/NIDDK/CDNS, Phoenix, AZ and AMGEN, Inc., Thousand Oaks, CA, USA

Leptin, the product of the mouse *ob* gene, is a hormone secreted by adipocytes that is known to decrease food intake and increase energy expenditure in rodents. In humans, variants in the *OB* gene have not been detected and very little is known about the action of leptin on energy expenditure and food intake. The purpose of this study was to assess the relationship between fasting plasma leptin concentrations and energy expenditure in 123 5-year old Pima Indian children (67 M/76 F). Total energy expenditure (TEE) and resting metabolic rate (RMR) were measured using doubly-labeled water and indirect calorimetry, respectively. The physical activity level (PAL) was calculated as the ratio of TEE/RMR.

	Mean ± SD	Range
Weight (kg)	23.3 ± 5.8	14.6-42.9
Body Fat (^{18}O dilution, %)	29.7 ± 7.5	17.0-49.8
TEE (kJ/d)	5982 ± 961	4243-9326
PAL (TEE/RMR)	1.34 ± 0.14	1.03-1.75
Leptin (ng/ml)	8.7 ± 10.5	0.5-56.1

Plasma leptin concentrations were positively correlated to percent body fat ($r=0.84$; $p<0.0001$) and were similar in males and females after adjusting for percent body fat. Most importantly, independently of percent body fat, leptin concentrations correlated with TEE (in absolute values [$r=0.37$; $p<0.0001$] or adjusted for body size [$r=0.42$; $p<0.0001$]) and with PAL ($r= 0.26$; $p<0.01$), but not with RMR. These results in young children suggest that, as in animal models, leptin plays a role in energy expenditure and more specifically, with energy expenditure for physical activity.

1045

Serum leptin levels are not affected by neuropeptide Y applications despite supression of cortisol levels and promotion of sleep in man

A. Widjaja, G. Brabant, S. Bohlhalter*, I. Antonijevic*, F. Holsboer*, A. Steiger* Dept. Clin. Endocrinol. Hannover Medical School and Max Planck Institute of Psychiatry, Munich, FRG

In animal studies ICV infusions of neuropeptide Y (NPY) exert important effects on energy consumption and basal metabolic rate. Leptin counteracts these effects, thus a close interconnection of both regulators can be anticipated. No data are available on a potential interaction of NPY on the leptin system in man. To further explore a physiological role of NPY in humans we tested the effect of iv bolus injections of NPY (4 x 50 or 4 x 100 µg) in 11 healthy young men (age 20 to 31 yrs; BMI 22.9 ± 3.6 kg/m^2, mean ± SD). Plasma ACTH and serum levels of cortisol, GH, prolactin and leptin were measured every 20 mins between 22h00 and 07h00 and sleep was polygraphically recorded. Meals were allowed until 19h00. The secretion of ACTH ($p < 0.02$) and cortisol ($p<0.05$) was significantly reduced with the lower dose and with the higher dose of NPY sleep architecture was altered with a shortened sleep onset latency and an increased sleep period time ($p < 0.05$). All other hormones especially serum leptin levels remained largely unchanged during the 9 hrs of follow-up. These data suggest that despite significant effects of NPY on sleep and the ACTH-cortisol axis leptin may not be acutely altered by NPY in man.

1046

TWENTY-FOUR-HOUR RESPIRATORY QUOTIENT IS NEGATIVELY RELATED TO PLASMA LEPTIN CONCENTRATION IN PIMA MALES.

P.A. Tataranni, M. Nicolson, S. Snitker, R.E. Pratley and E. Ravussin. CDNS-NIDDK-NIH, Phoenix, and AMGEN, Thousand Oaks, USA.

A high respiratory quotient (RQ), i.e. a low lipid-to-carbohydrate oxidation ratio, is a predictor of body weight gain in humans. Leptin, a hormone produced by the adipose tissue, is known to be involved in the regulation of body weight, but its impact on energy and substrate metabolism in humans is unknown. We measured fasting plasma leptin concentrations by ELISA and 24-h RQ, 24-h energy expenditure, and spontaneous physical activity in a respiratory chamber in 68 non-diabetic, male Pima Indians (27±6y, 100±22kg, 34±7% body fat). Leptin was positively correlated with %body fat ($r=0.72$; $p<0.01$). There was no correlation between 24-h energy expenditure adjusted for body composition and age and plasma leptin concentration adjusted for %body fat. Similarly, spontaneous physical activity was unrelated to plasma leptin concentration. In contrast, 24-h RQ, in absolute value or adjusted for energy balance, %body fat and age, correlated negatively with adjusted plasma leptin concentration ($r=-0.24$ and $r=-0.28$; $p<0.05$, respectively). The negative correlation between 24-h RQ and plasma leptin concentration was not observed in 29 non-diabetic, female Pima Indians. In conclusion, our results indicate that a high 24-h RQ, i.e. low lipid oxidation rate, is associated with relatively low plasma leptin concentrations in male Pima Indians. This may provide an explanation for the predictive effect of a high RQ on body weight gain.

1047

LEPTIN LEVELS IN CHILDREN WITH DIABETES MELLITUS. W. Kiess, M. Anil, W. Blum, P. Englaro, A. Attanasio, and W. Rascher. Children's Hospital, University of Giessen, Germany, and Lilly Germany, Bad Homburg.

Leptin is produced by adipocytes and is thought to act as an afferent satiety signal regulating appetite and weight. Insulin is a potent regulator of leptin expression. To investigate whether or not leptinconcentrations in children and adolescents with diabetes (IDDM) were related to metabolic status, body weight and insulin treatment, we have measured leptin concentrations in serum from 13 newly diagnosed IDDM patients before the beginning of insulin treatment (8 girls, 5 boys, aged 4.7-17.5 years) and in 134 patients with IDDM during treatment (64 girls, 70 boys, aged 2.6-20.1 years) using a specific radioimmunoassay (RIA). Serum from children with newly diagnosed diabetes had significantly lower levels of leptin (mean 1.28±1.60 ng/ml, range 0.14-6.13 ng/ml) than healthy children (0.1 and 33.3 ug/L, median 2.2 ug/L (N=713) and than insulin treated children and adolescents (mean 5.18±5.48 ng/ml, range 0.26-29.77ng/ml) ($p<0.0001$). Leptin serum levels in patients with IDDM significantly correlated with BMI ($r=0.42$, $p<0.0001$). Multiple regression analysis showed that age and BMI were significantly correlated with leptin levels, while duration of diabetes, mean HbA1c levels, insulin dose and plasma glucose, triglyceride and cholesterol levels were not. Surprisingly and most importantly, leptin levels in young adult (Tanner stage 5) patients were significantly higher than values found in the healthy nondiabetic reference population even when adjusted for age, sex, Tanner stage and BMI. In conclusion, (1) leptin levels in children and adolescents with IDDM are directly related to body adipose tissue and age. (2) Leptin serum concentrations are low at diabetes manifestation. (3) Leptin serum concentrations in young adult patients are higher than in the reference population even when corrected for age, sex, Tanner stage and most importantly for BMI. We hypothesize that the weight gain that is observed during intensified insulin treatment regimens in adolescents and young adults with IDDM is related to high leptin levels.

1048

The Effect of Acarbose on Body Weight Regulation.

A.Lee& J.Morley,St Louis University,Missouri,USA.

Acarbose blocks absorption of carbohydrates(CHO) by inhibiting enzymes needed to digest starch. It decreases insulin responses after CHO loads. One report showed the importance of CHO ingestion for the expression of its antihyperglycemic effect. To test its efficacy in inducing weight loss, 32 obese diet-treated NIDDM women(age:59+3,HbA1c:8.2 +.3%,&BMI:40+2kg/m2) were studied.Subjects were placed on a standard 1400 ADA diet to follow with %CHO↘50%. Subjects were randomized to receive acarbose(AC)100 mg or a placebo(PL)thrice daily in a double-blind fashion for 24 wks. Subjects reported monthly their meals↘6 days of the month for calculations of %CHO,%fat,%protein,&daily calorie intake. There were no significant differ -ences between groups in age,BMI,& HbA1c.Analysis of variance,& Student's t test were used for data analysis. Our data showed 1)AC-treated group continued to lose weight over 24 wks;their mean weight loss(98.7+4.3→91.9+4.5kg)was significantly greater than PL group (96.0+5.6→95.0+5.3kg)(P∠ .03) at 24 wk.2)At the end of treatment,AC group had significantly lower HbA1c than PL group (7.4 +.3 v 8.1+.3%),&3)No significant changes in %CHO & daily calories were detected before & after 24 wks of treatment in both AC & PL groups.

These results indicate the ability of acarbose to produce weight loss in obese NIDDM in whom the % CHO intake is high, and confirm its efficacy as an effective antiobesity agent.

1049

COMPARISON OF PLASMA LEPTIN CONCENTRATIONS IN PATIENTS WITH TYPE I AND TYPE II DIABETES MELLITUS

C. Ludwig, P. Nowotny, C. Fürnsinn, H. Vierhapper, A. Roden, W. Waldhäusl and M. Roden.
Div. Endocrinol. & Metab., Dept. Internal. Med. III, Univ. Vienna, Austria.

Leptin, the gene product of the ob gene, is secreted by adipocytes and its plasma concentrations are correlated with the body mass index (BMI). Mice homozygous for mutations in the ob gene do not produce leptin and develop obesity, hyperglycemia, and hyperinsulinemia. The aim of this study was to compare the plasma leptin concentrations in patients with type I diabetes mellitus (n=42: BMI: 24.8±0.7 kg/m², HbA_{1c}: 7.5±0.4%), with type II diabetes mellitus (n=119: BMI: 29.2±1.0 kg/m², HbA_{1c}: 8.0±0.6%) and in nondiabetic humans (control, n=74: BMI: 28.8±1.5 kg/m², HbA_{1c}: 5.3±0.2%). Obesity was defined by a BMI ≥ 27.8 kg/m² in women and ≥ 27.3 kg/m² in men, respectively. Leptin was determined radioimmunometrically (Linco, St. Charles, MO). Mean leptin levels were 8.7±2.6 ng/ml (obese: 13.6±3.4 ng/ml, lean: 8.0± 1.3 ng/ml) in patients with type I diabetes mellitus, 15.1±2.6 ng/ml (obese: 19.0 ±1.3 ng/ml, lean: 10.1±1.0 ng/ml) type II diabetes mellitus, and 21.5±4.5 (obese: 35.2±4.3 ng/ml, lean: 11.6±2.3 ng/ml) in nondiabetic subjects. In all groups the expected strong correlation between BMI and plasma leptin concentration was found ($p<0.0001$, Wilcoxon test). Even when corrected for BMI, women presented with higher plasma leptin levels than men (type I diabetes mellitus: 12.4 vs 4.2 ng/ml, type II diabetes mellitus: 17.9 vs 11.4 ng/ml, control: 26.1 vs 9.0 ng/ml; $p<0.0003$). Plasma leptin concentrations were also correlated with total serum cholesterol in type II diabetes mellitus ($p=0.015$), and with serum triglyceride in type I diabetes mellitus ($p=0.0032$). Conclusion: In addition to the correlation with BMI and sex, mean plasma leptin concentrations were shown to be lower in obese type I and type II diabetic patients compared with obese nondiabetic humans suggesting a defect in leptin production/secretion by adipose tissue in diabetes mellitus.

THE EFFECT OF GLUCAGON-LIKE PEPTIDE 1 (GLP-1) ON INSULIN SENSITIVITY IN DIABETIC DOGS.

A. Giacca, H. Sandhu, S. Wiesenthal, R.H. McCall, V. Tchipachvili, Z.Q. Shi, M. Vranic and S. Efendic. University of Toronto, Toronto, Canada and Karolinska Hospital, Stockholm Sweden

GLP-1 is a potent incretin. It is also known to have other glucose-lowering effects which might include an increase in insulin sensitivity. To address this issue, we performed hyperinsulinemic glucose clamps with or without GLP-1, in totally depancreatized dogs. These dogs were made moderately hyperglycemic (~10mM) by a basal intraportal insulin infusion (2.04 ± 0.34 $pmol.kg^{-1}.min^{-1}$) which mimicked the residual endogenous insulin secretion in NIDDM. Since GLP also inhibits glucagon secretion, extrapancreatic glucagon was inhibited with somatostatin (0.8 $ug.kg^{-1}.min^{-1}$) and glucagon levels were clamped with intraportal glucagon (0.65 $ng.kg^{-1}.min^{-1}$). At time=0, an additional infusion of insulin (5.4 $pmol.kg^{-1}.min^{-1}$) was infused to determine glucose production and utilization. During the glucose clamp, plasma glucose specific activity was kept constant by the "hot ginf" method. In 12 paired experiments, GLP-1 infusion resulted in higher glucose requirement during the clamp than saline infusion (GLP-1: 60.9 ± 11.0 $umol.kg^{-1}.min^{-1}$ vs saline: 43.6 ± 8.4 $umol.kg^{-1}.min^{-1}$, $p<0.001$). This was due to a significantly greater glucose utilization. (GLP-1: 72.6 ± 11.0 $umol.kg^{-1}.min^{-1}$ vs saline: 56.8 ± 9.7 $umol.kg^{-1}.min^{-1}$, $p<0.001$) whereas the suppression of glucose production was not increased with GLP-1. These data suggest that: 1) GLP-1 increases insulin sensitivity in moderately hyperglycemic depancreatized dogs, independent of the incretin effect. 2) The increase in insulin sensitivity is due to GLP-1's potentiation of insulin's effect on glucose utilization.

PLASMA HUMAN LEPTIN IN OBESE AND DIABETIC SUBJECTS AND IT'S DIURNAL VARIATION

Y. Tasaka, K. Yanagisawa, R. Kawahara, Y. Omori
Tokyo Women's Medical College, Tokyo Japan

In order to clarify the relation between the plasma leptin level (IRL) and obesity or diabetes mellitus and it's diurnal variation, 51 untreated diabetics, 21 subjects with impaired glucose tolerance and 8 normal were studied. Most of them were examined 50g OGTT or breakfast test. Plasma IRL was determined using an immunoassay kit together with plasma glucose and IRI. Plasma IRL levels were correlated significantly with body mass index(BMI,kg/m^2) ($p<0.01$), and the value in female was higher than that in male (reqression line 0.526x-6.76 and 0.458x-7.38, respectively). For the confirmation of sex difference of plasma IRL value, BMI was divided into three grade: less than 25, 25 to 30 and more than 30. The sex difference of plasma leptin was most significant in BMI 25 to 30 ($p<0.002$). The plasma IRL concentration was determined also in 50g OGTT of untreated diabetics. Diabetics were divided according to the fasting plasma glucose: more than 200, 140-200 and less than 140mg/dl. No significant difference of plasma IRL response was found in these groups, however, plasma IRL was decreased slightly during OGTT ($p<0.01$), and this decrease was also found in breakfast test. In the diurnal variation of plasma IRL, the plasma IRL increased during midnight, peaking at am 2 or am 4 and then decreased gradually to the dawn. In conclusion, plasma IRL increased together with the increase of body weight, especially high in female, and had no relation with the severity of diabetes. The plasma IRL decreased during daytime and increased during night, peaking at am 2 or am 4.

1052

GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONIST INDUCE AN INHIBITORY SIGNAL FOR FOOD INTAKE IN OBESE ZUCKER RATS.

F. Rodríguez de Fonseca, M. Navarro, E. Alvarez, I. Roncero, J. Chowen*, O. Maestre and E. Blázquez. Complutense University and * C.S.I.C., Madrid, Spain

Because we and others have reported that GLP-1(7-36) amide reduces both food and drink intake through a central mechanism, this study was designed to determine the possible role of GLP-1 receptor in the feeding behavior of obese diabetic Zucker rats. Accordingly, identification of GLP-1 receptor in brain and the effects of receptor agonist on feeding behavior were studided in Wistar, obese (fa/fa) and lean (fa/+) littermates Zucker rats of 12-16 weeks of age. In situ hybridization showed, specific labeling of the mRNA for GLP-1 receptors in several brain regions from the three group of animals, mainly in hypothalamus. Same tissue distribution of the GLP-1 receptor was obtained after Western blot whith a specific antiserum developed by us. These results indicate that GLP-1 receptors are actually synthesized in Wistar and Zucker rats. For the i.c.v. administration of peptides, stainless steel guide cannulas that were aimed at the lateral ventricle were implanted in the rats. Food and water intake were registered for 4h after the i.c.v. administration of placebo or 5, 25 or 100 ng of GLP-1(7-36) amide or exendin-4. i.c.v. administration of both peptides results in dose-dependent reduction of both food and water intake in Wistar and in Zucker rats. These findings indicate that the synthesis of GLP-1 receptor in the hypothalamus of obese Zucker rats, permit to their agonists modulate both food and water intake through a central mechanism. Therefore, the obesity of Zucker rats may not related to alterations in the effects of GLP-1(7-36) amide in the brain.

1053

PLASMA LEPTIN IS INCREASED PROPORTIONALLY TO ADIPOSITY BY PHYSIOLOGIC INSULINEMIA IN INSULIN-DEPENDENT DIABETES:

P.J. Havel, M.H. Connors, C. L.Acerini, E.C. Crowne, and D.B Dunger. Departments of Pediatrics and Nutrition, University of California, Davis, CA, U.S.A. and University of Oxford, U.K.

High dose insulin infusion increases circulating leptin concentrations within 4-6 hr in nondiabetic, IDDM and NIDDM subjects. The effects of a low dose regular insulin infusion which lowered glucose, but did not produce hypoglycemia, on plasma leptin was examined in 7 subjects with insulin-dependent diabetes (IDDM; 3 Female/4 Male; BMI = 24.9 ± 1.4 kg/m2; Age = 18-25 years). Long-acting insulin was withdrawn for 36 h prior to the insulin infusion which increased plasma free insulin to 187 ± 23 pM for 4 h and decreased plasma glucose from 14.8 ± 1.7 mM to 8.0 ± 1.6 mM. Plasma leptin increased from 7.0 ± 2.0 to 9.8 ± 3.3 ng/ml (%Δ = +32 ± 9, p< 0.01). Subsequently, the insulin infusion rate was decreased; plasma free insulin averaged 78 ± 17 pM and plasma glucose was stabilized at 5.3 ± 0.3 mM from 6-12 h. Plasma leptin increased progressively peaking at 12.7 ± 5.1 ng/ml at 10 h (%Δ = +50 ± 20, p< 0.025). Plasma leptin did not increase during the same time period in 9 other IDDM subjects (7 Female/2 Male; BMI = 23.2 ± 1.0 kg/m2; Age = 12-22 years) infused with somatostatin (Octreotide; 300 ng/kg/hr) plus growth hormone replacement (GH; 9.6 mIU/kg/hr x 1 hr) at 2, 5, and 8 h, however, leptin was significantly increased by 2.7 ± 0.7 ng/ml (%Δ = +39 ± 9, p< 0.005) after 14 h. The addition of rhIGF-1 (40 μg/kg) to this protocol reduced the 14 h leptin response to insulin infusion by 79 ± 36% (p< 0.05). Overall, in 16 subjects the increase of plasma leptin during insulin infusion was positively correlated with BMI (r = 0.65, p< 0.01) or the baseline leptin concentration (r = 0.77, p< 0.0005). We conclude: 1) Low dose insulin infusion producing physiologic levels of insulin and euglycemia increases plasma leptin concentrations in subjects with IDDM. 2) The increase of leptin is proportional to adiposity. 3) Somatostatin plus GH, along with IGF-1, inhibit the leptin response to insulin administration in IDDM. (Supported by the Juvenile Diabetes Foundation, Int.)

1054

MELANIN CONCENTRATING HORMONE (MCH) CONCENTRATION IS INCREASED IN THE HYPOTHALAMUS OF OBESE ZUCKER RATS

M Rossi, CJ Small, AP Goldstone, MA Ghatei and SR Bloom. Division of Endocrinology, Royal Postgraduate Medical School, Hammersmith Hospital, London, UK

The neuropeptide MCH has recently been implicated in the hypothalamic regulation of body weight. MCH mRNA was found to be overexpressed in *ob/ob* mice and this was further increased by fasting in both obese and normal mice. Central administration of MCH has been shown to stimulate food consumption in rats. The aim of this study was to determine if hypothalamic MCH levels are altered in the obese Zucker (*fa/fa*) rat compared to lean (*fa/+*) control and to assess if an increase occurs on starvation. Adult male obese and lean Zucker rats (n=16-20/group) were caged with free access to water and food. After 7 days, 8-10 animals from each group underwent a 48hr fast. All animals were sacrificed after this period and MCH levels in the hypothalamus, brain stem and cortex were measured by RIA. Hypothalamic MCH levels were significantly increased in the fed obese compared with fed lean rats [(mean±SEM) 70.4±5.0 vs. 43.1±4.5pmol/g wet weight; p<0.001]. Fasting caused MCH levels to increase in the lean rats [60.5±5.3 vs. 43.1±4.5pmol/g; p<0.05] although no further increase was seen in obese animals. There was no difference in MCH levels in the brain stem and cortex of all animals studied [all 6-9pmol/g]. We conclude that there is an increase in MCH concentration in the hypothalamus of obese Zucker rats compared to lean controls which may contribute to their abnormal regulation of energy balance. Furthermore there appears to be dysregulation of MCH release since levels are not altered on fasting.

1055

LEPTIN SECRETION AFTER ORAL GLUCOSE LOAD AND AFTER MIXED MEAL TEST IN YOUNG, HEALTHY SUBJECTS

G.A. Brunner, S. Fleck, A. Wutte, G. Sendlhofer, A. Siebenhofer, and T.R. Pieber. Department of Internal Medicine, Diabetes and Metabolism, Karl-Franzens-University Graz, Austria

AIM: Leptin is a hormone secreted by adipocytes, which may play an important role in human obesity. Aim of this study was to investigate leptin secretion in the postabsorptive state.
METHODS: We measured leptin secretion in 23 young and healthy male subjects. After an overnight fast an oral glucose tolerance test (OGTT; 75 g glucose) and a mixed meal test (MMT) (fat 43%,carbohydrate 51%, protein 6%) over 4 hours were performed in all subjects on 2 different days. Plasma leptin levels were measured at baseline and after 2 and 4 hours using a specific RIA.
RESULTS: Mean age (±SD) in all subjects was 20±2 years. Mean body mass index (BMI) was 23±2.5 kg/m^2. As expected, fasting plasma leptin levels were highly significant correlated with BMI (r=0.774; p<0.0001). After OGTT plasma leptin levels did not change [baseline: 3.9±2.9 ng/ml (range 1.5-11.4); 2 hrs: 4.0±2.9 ng/ml (range 1.5-11.1); 4 hrs: 3.9±2.8 ng/ml (range 1.1-10.6)]. After MMT plasma leptin levels increased in all but 1 subjects [baseline: 3.8±2.9 ng/ml (range 1.3-11.6); 2 hrs: 4.0±3.4 ng/ml (range 1.4-11.8); 4 hrs: 4.6±3.9 ng/ml (range 1.4-14.7); p<0,05 (4 hrs vs. baseline)]. In MMT average increase of plasma leptin levels after 4 hours was 17% when compared to baseline (p<0,001).
CONCLUSION: We could show an acute increase of plasma leptin levels after an oral fat load (mixed meal test) whereas no acute changes in plasma leptin levels were seen after an oral glucose load (OGTT). Lipids or free fatty acids may contribute to this effect.

1056

WEIGHT LOSS AND INSULIN SENSITIVITY: COMPARISON OF DIFFERENT DIETARY PROGRAMMES

J Bryson, S King, S Swaraj, R Donnelly and I Caterson. Dept of Endocrinology, Royal Prince Alfred Hospital, Sydney, NSW, Australia.

Obesity and insulin resistance are associated with dyslipidemia, hypertension and increased risk of cardiovascular disease and so a secondary aim of weight loss programmes is to improve insulin sensitivity. In this study, the effects of 2 dietary programmes were compared. 11 obese non-diabetic subjects (5M/6F) were placed on a very low calorie diet (VLCD) (400kcal/day) for 8w followed by a 4w normalisation period. Another 11 subjects (5M/6F) were placed on a low fat (30g/day) diet (LFD) with no calorie restriction for 12w. Using indirect calorimetry and the hyperinsulinemic, euglycemic clamp (40mU/m^2/min), total (TGD), oxidative (GOX) and non-oxidative (NOX) glucose disposal (mg glucose/ min/g body wt/pM insulin) were determined before and after intervention. Abdominal subcutaneous (sc) and visceral (visc) fat distribution were determined by single cut CT scan.

	VLCD pre	VLCD post	LFD pre	LFD post
Body Wt	106.8 ± 2.7	94.1 ± 3.0*	107.4 ± 3.6	101.0 ± 3.3*
sc (cm^2)	539.3 ± 45.4	427.6 ± 55.4*	550.3 ± 44.8	473.5 ± 45.0*
visc (cm^2)	178.7 ± 24.4	118.3 ± 16.1*	168.2 ± 14.5	141.9 ± 16.3*
TGD	5.60 ± 0.80	8.62 ± 1.35*	4.70 ± 0.68	6.88 ± 0.80*
GOX	2.64 ± 0.20	3.51 ± 0.32*	2.56 ± 0.22	3.06 ± 0.28*
NOX	2.98 ± 0.65	5.10 ± 1.13*	2.14 ± 0.53	3.83 ± 0.62*

*p<0.05, pre vs post. Wt loss was significantly greater on VLCD than LFD, but the differences between VLCD and LFD in the changes to other parameters were not significant. Wt loss was strongly correlated with the decrease in sc (r=0.716, p=0.0002) and visc (r=0.688, p=0.0004) areas, the increase in TGD (r=0.527, p=0.0117) and GOX (r=0.617, p=0.0022), and to a lesser extent the increase in NOX (r=0.397, p=0.0673). These results show that improvements in insulin sensitivity are related to the degree of wt loss regardless of the dietary regime used.

1057

HYPERINSULINEMIA STIMULATES LEPTIN RELEASE INDEPENDENT OF HYPERGLYCEMIA IN NORMAL SUBJECTS

X. Chen, J.W. Kolacyznski and G. Boden. Temple University and Thomas Jefferson University Hospitals, Philadelphia, PA USA

We have previously reported that serum leptin levels increased during 72 h of clamped hyperglycemia (~ 12.6 mM) in normal subjects. It was the objective of this study to determine whether this increase was caused by hyperglycemia or by hyperinsulinemia. To this end, we measured serum leptin (by radioimmunoassay) at 2 h intervals for 72 h during euglycemic clamping (glucose ~ 5 mM, insulin ~ 67 pM, n=4), during hyperinsulinemic clamping (glucose ~5mM, insulin ~880 pM, n=4) and during hyperglycemic clamping (glucose ~ 8.8 mM, insulin ~ 286 pM, n=5) in healthy non-obese young males. During euglycemia (low insulin), serum leptin decreased by 18% over 72 h (from 3.8 to 3.1 ng/ml, $p < 0.05$); during euglycemia (high serum insulin), serum leptin rose by 70% over 72 h (from 3.4 to 5.8 ng/ml, $p < 0.001$); during hyperglycemia (moderate hyperinsulinemia), serum leptin conc. remained unchanged (5.3 to 4.9 ng/ml, NS). These data show that insulin stimulated leptin secretion dose dependently and independent of hyperglycemia. We conclude that insulin stimulated leptin secretion and that this may be a mechanism which could be responsible, at least in part, for the close relationship between serum leptin levels and obesity (which is typically associated with hyperinsulinemia).

1058

CONTINUOUS VERSUS INTERMITTENT VERY LOW CALORIE DIETS IN THE TREATMENT OF OBESE WOMEN.C Filozof,C Gonzalez,S Burastero,P Sanchez,C Murua,P Postel and M Perman,University of Buenos Aires.Argentina

Very low calorie diets (VLCD)are useful in the treatment of severe obesity, as they rapidly provide substantial weight losses, improving metabolic abnormalities .However, the difficulty to maintain them for long periods have limited their use.The *objective* of this study was to compare continuous(C) vs intermittent(I) VLCD in the treatment of severe obese females.Outcomes were: magnitude and composition of weight lost, adverse effects, and metabolic parameters.Group I(n=11, 41.4 ±6.8y, BMI: 40.4 ±6.1Kg/m^2), received for 5 weeks, alternating each week, a formula diet of 408 Kcal , or a low calorie diet LCD of 960 Kcal ;group C (n=11, 40.6±8.6y, BMI: 39.9 ±5.9Kg/m^2) received a formula diet of 550 Kcal for 5 weeks .At day 0 and 35, body composition (bioelectric Impedance, sum of skinfolds,diameters and perimeters , dual X-ray absorptiometry) and fasting plasma concentrations of glucose,triglycerides, cholesterol and fibrinogen were determined. Resting energy expenditure (REE)and respiratory quotient were determined by indirect calorimetry. Adverse effects were assessed by self report on a standardized questionnaire *Results:* Weight lost was similar in both groups(9.2 ±2.5 vs 8 ±2.7 Kg).It was accompanied by a significant reduction in sistolic ($p<.01$) and diastolic blood pressure($p<.001$) in both groups . Significant decreased in s-triglycerides($p<.01$) , total ($p<.001$), LDL($p<.01$) and HDL cholesterol levels($p<.001$) was found both in group C and I .In contrast, we found significant increased($p<.05$) in fibrinogen levels with mean ± SEM increasing from 3.3± 0.4 to 3.7± 0.5g/l in C and 3.1±0.2 to 3.3± 0.4g/l .The composition of weight lost was similar in both groups and there was not difference in the reduction of REE: LBM ratio between groups .Adverse effects and drop out were less frequent in I. *Conclusions:* Intermittent treatment was as effective as continuous VLCD in achieving weight loss and reduction of blood pressure,glucose and lipid levels with lower incidence of side effects. Increment in plasma fibrinogen concentration was found in both groups.

J. W. Kolaczynski and R. V. Considine. LEPTIN AND DEXAMETHASONE IN VIVO; EFFECT OF HYPERINSULINEMIA. Thomas Jefferson University, Philadelphia, Pennsylvania, USA.

Background: Insulin and dexamethasone play a pivotal role in the control of leptin production by human fat *in vitro*. Dexamethasone and insulin acting solo but not together stimulate the Ob gene expression in and leptin production by isolated human adipocytes in the primary culture. The *in vivo* studies on the effect of dexamethasone and insulin on circulating leptin levels in humans are conflicting. Aim: We investigated effect of dexamethasone on circulating leptin levels with and without short-term exposure to supraphysiological exogenous hyperinsulinemia. Method: Four healthy male volunteers participated (age 26.5±1.5 yrs; BMI 27.1±1.4 kg/sq.meter; body fat 17.3±1.1%). Dexamethasone 10 mg in five equal doses was given twice, 8 days apart, beginning 7.00 a.m. on day 1 and ending at 7.00 a.m. on day 2 combined with or without (control) isoglycemic hyperinsulinemic (300 mU/sq. meter BSA/min) clamp commencing at 9.00 a.m. and ending at 1.00 p.m. on day 2. Results: Oral dexamethasone had no acute (up to 5 hours) effect on circulating leptin levels; in contrast, leptin levels doubled and continued to rise 24 hours later ($p<0.05$). In the three participants the elevation of leptin persisted until 8.00 a.m. of the following day (24 hours after the last dose). Short-term isoglycemic hyperinsulinemia had no apparent additional effect on the leptin rise. Summary: 1. 24-hour administration of pharmacological doses of dexamethasone has a marked stimulatory effect on circulting leptin levels; the effect appears to be sustained for the next 24 hours. Short term supraphysiological hyperinsulinemia neither potentiates nor abrogates this effect. Conclusion: The study does not support the existence of interaction of insulin and dexamethasone on leptin production by human fat *in vivo*.

1060

Objective : VERY LOW CALORIE DIET (VLCD) IN WEIGHT REDUCTION OF OBESE DIABETICS

Authors: MW Tsang, KK Chan, S Lo and S Chung, United Christian Hospital, Hong Kong.

Method : Prospective intervention study.Wilcoxon Matched-paired for analysis.

13 consecutive patients with BMI over 30, associated with non-insulin dependent diabetes mellitus, and hypertension were recruited after conventional diet weight reduction therapy for at least 3 months. Parameters monitored were body mass index (BMI), waist hip ratio (WHR), fasting sugar(FBS), insulin sensitivity index (1/insulin), serum cholesterol(Chol), triglyceride(Tri), systolic blood pressure(sbp), diastolic blood pressure(dbp) and subcutaneous fat thickness over; triceps, biceps, subscapular (Sscap), and superior iliac (Siliac) and total body fat(Fat). Changes in these parameters were recorded after two week of VLCD program. Result :one patient stopped prematurely because of intolerance to the liquid diet and one patient was rejected because of poor compliance history. Ten individuals completed the program and followed up for two at least one year. Summary of results were tabulated as followings : four female and 7 male

	BMI	WHR	tricep	bicep	Sscap	Siliac	fat
pre-vlcd	34.36± 5.12	1.03± .06	39.13± 7.11	21.59± 5.06	42.74± 17.83	34.94± 6.83	41.74±3. 35
post-vlcd	32.79± 5.40	.99± .06	32 53± 6.78	18.19± 4.04	38.71± 17.13	32.04± 7.98	39.07± 4 38
P	.0033	.0109	.0117	.03	.1159	0911	.018

	sap	dip	FBAs	I/insulin	Chol	Trio
pre-vlcd	125± 15.81	80.5± 11.17	6.72±2.1	67.33± 55 45	5.57± 74	1 75±. 75
post-vlcd	118 5± 12.92	73.70± 10.81	6.54±2.2	148± 96.89	4.60± .65	2.08± 2.03
p	0587	.1386	7989	.0173	.028	.3525

Conclusion : We concluded that VLCD is safe and effective in grossly obese patients .The decreased in body weight is mainly due to lost of fat and it was associated with improvment in insulin sensitivity as showed clinically by reduction of insulin or oral hypoglycaemic agent requirement and by improvement in insulin sensitivity measured by 1/fasting insulin level.

1061

MARKED AND RAPID DECREASE OF PLASMA LEPTIN IN INSULIN DEFICIENT DIABETES: REVERSAL BY INSULIN.

P.J. Havel, J.Y. Uriu-Hare, K.L. Stanhope, J.S. Stern, and C.K. Keen.
Department of Nutrition, University of California, Davis, CA, U.S.A.

Evidence for regulation of circulating leptin by insulin is conflicting. We examined plasma leptin concentrations before and after the induction of insulin deficient diabetes with streptozotocin (STZ; 40 mg/kg/day x 2 days) in 22 male Sprague-Dawley rats weighing 430 ± 8 g and in 14 saline injected control rats. Within 24 hr after STZ, plasma insulin decreased from 480 ± 30 pM to 130 ± 10 pM (Δ = -73 ± 3%, $p < 0.0001$) and plasma glucose increased from 7.0 ± 0.2 mM to 24.8 mM. Concomitantly, plasma leptin decreased from 3.2 ± 0.2 ng/ml to 1.2 ± 0.1 ng/ml (Δ = -63 ± 3%, $p < 0.0001$) despite a small increase of body weight (+9 ± 1 g). Seven days after STZ, plasma insulin was 80 ± 10 pM, glucose was 25.4 ± 0.8 mM, and leptin was 0.6 ± 0.1 ng/ml (Δ = -77 ± 6%, $p < 0.0001$), while body weight had slightly declined by 7% to 400 g. Plasma leptin remained at this level for the 16 days of the study. Hyperphagia was significant at 4 days and food intake at 7 days was increased by 70% (from 34 ± 1 to 58 ± 2 g/day, $p < 0.0001$). Plasma insulin, glucose, leptin, and food intake were unchanged in control rats (All $p < 0.001$ vs STZ). A subset of STZ diabetic rats (n=8) were treated with subcutaneous lente insulin (12 U/kg twice daily) from days 14-16. Plasma glucose decreased to 11.7 ± 3.9 mM, leptin increased from 0.5 ± 0.1 to 2.9 ± 0.6 ng/ml (Δ = +445 ± 139%, $p < 0.01$), and food intake decreased by 21 ± 3% ($p < 0.0001$). The change of leptin was correlated with the degree of glucose lowering ($r = 0.75$, $p < 0.05$). There was less than a 3% increase of body weight. We conclude that insulin deficient diabetes induced by STZ produces a rapid, marked, and sustained decrease of circulating leptin that does not appear to be related to weight loss. Insulin treatment reverses the hypoleptinemia and the increase of plasma leptin after insulin is proportionate to the reduction of hyperglycemia. We hypothesize that low circulating leptin concentrations in STZ diabetes: 1) are a consequence of hypoinsulinemia; 2) could contribute along with hypoinsulinemia to diabetic hyperphagia. (Supported by the Juvenile Diabetes Association, International).

1062

HYPOCALORIC DIET PLUS GROWTH HORMONE THERAPY INDUCES INSULIN RESISTANCE WITHOUT BENEFIT IN SPARING LEAN BODY MASS. B. Dallagrassa, P.M. Piatti, L.D. Monti, F. Magni, I. Fermo, R. Paroni, M. Galli-Kienle, A.E. Pontiroli, G. Pozza. Istituto Scientifico H. San Raffaele, Milan, Italy.

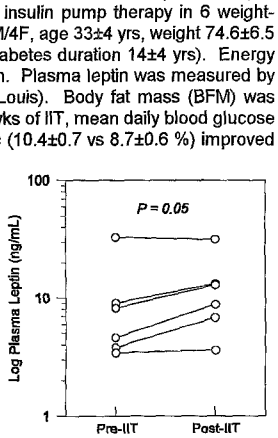
Previous studies have shown that Growth Hormone (GH) administration during hypocaloric diet determines an important decrease in fat mass (FM) sparing fat free mass (FFM). However, little it is known about the effects of chronic GH therapy during hypocaloric diet on glucose metabolism in obese subjects. The aim of the study was to investigate the chronic effects of GH during hypocaloric diet on body weight reduction and composition, insulin sensitivity and proteolysis in 14 normal glucose-tolerant obese women. They were divided in two groups matched for age, BMI, FFM and FM. All subjects underwent a hypocaloric high-protein diet (45% protein, 35% carbohydrate and 20% fat) for 21 days. GH therapy (0.1 mg/Kg IBW s.c., every 48 hours; group 1: 6 subjects) or placebo (group 2: 8 subjects) were also administered. A euglycaemic hyperinsulinaemic (25 mU/Kg/h) clamp (ec) combined with indirect calorimetry and dideuterated glucose infusion was performed before and after the hypocaloric diet in the two groups. Before diet, during ec, M-value (M), Glucose oxidation (GO), Lipid oxidation (LO) and Hepatic Glucose Production (HGP) were similar in the two groups. After diet, body weight, FM and FFM significantly decreased by 5%, 13% ($p<0.001$ vs before diet) and 2.5% (NS vs before diet) in both groups. During ec, M and GO were lower in group 1 than in group 2 (1.6±0.2 vs 2.9±0.2, $p<0.01$ and 0.3±0.3 vs 1.8±0.2 mg/kg.FFM/min, $p<0.01$; respectively) while LO and HGP were higher in group 1 than in group 2 (1.1±0.7 vs 0.5±0.1, $p<0.01$ and 1.6±0.3 vs 0.3±0.3 mg/kg.FFM/min, $p<0.01$; respectively). 3-Methylhistidine excretion, an index of proteolysis, was decreased by 46 and 36% in groups 1 and 2, respectively (NS). In conclusion GH therapy associated to hypocaloric diet induces insulin resistance without further benefit in sparing lean body mass compared with a hypocaloric high-protein diet.

1063

PLASMA LEPTIN CONCENTRATIONS AND INTENSIVE INSULIN THERAPY IN INSULIN-DEPENDENT DIABETES MELLITUS.

M.G.Carlson, W. Snead, and A. Oeser. Vanderbilt University, Nashville, USA.

Intensive insulin therapy (IIT) in IDDM is associated with excessive weight gain and increased adiposity due to reductions in glycosuria, energy expenditure, and daily fat oxidation. In order to determine the effect of IIT on plasma leptin and the role of leptin in the weight gain and increased adiposity in intensively treated IDDM patients, we measured basal plasma leptin concentrations before and after 4 wks of insulin pump therapy in 6 weight-stable, poorly controlled IDDM patients (2M/4F, age 33±4 yrs, weight 74.6±6.5 kg, body mass index [BMI] 24±1 kg/m^2, diabetes duration 14±4 yrs). Energy intake was adjusted to prevent weight gain. Plasma leptin was measured by a specific radioimmunoassay (Linco, St. Louis). Body fat mass (BFM) was assessed by hydrostatic weighing. After 4 wks of IIT, mean daily blood glucose (11.4±0.5 mM vs 8.6±0.8 mM) and HbA1c (10.4±0.7 vs 8.7±0.6 %) improved (both $P < 0.01$) despite no change in daily insulin dose (34±5 vs 34±3 units/day). Body weight, BMI, % body fat, and BFM did not change. Fasting free insulin levels tended to increase with IIT (30 ± 8 pM vs 57±16 pM, $P = 0.1$). Basal plasma leptin levels increased with IIT (10±5 vs 13±4 ng/mL; % change from baseline 46±16%, $P = 0.05$) despite no change in body weight or adiposity. Overall, plasma leptin concentrations were positively correlated with % body fat ($r = 0.59$, $P < 0.05$) and HbA1c ($r = 0.67$, $P < 0.05$). In addition, baseline leptin levels (pre-IIT) were weakly correlated with baseline fasting free insulin ($r=0.72$, $P =0.1$). In summary, plasma leptin increased by over 40% from baseline in this group of intensively treated IDDM patients despite no change in body weight or adiposity. These results suggest that insulinemia and/or glycemia per se may regulate circulating leptin levels in IDDM independently of adiposity.



1064

EFFECTS OF MELATONIN SUPPLEMENTATION ON PLASMA LEPTIN LEVELS.

T.C. Wascher, S. Habersack-Wallner, B. Bahadori, M. Roden*, P. Novotny*, H. Toplak. Dept. Internal Medicine, Univ. of Graz and *III. Dept. Internal Medicine, Univ. of Vienna, Austria

Leptin, as many other hormones, shows a diurnal variation with higher night-time levels. However, the regulation of this cyclic variation is largely unknown. Melatonin, a L-tryptophane derivative that is involved in the regulation of activity and mental disposition, has a similar cyclic regulation as leptin. Since both physical activity and mental disposition are known to influence eating behaviour, the aim of the present study was to investigate whether administration of melatonin affects plasma leptin levels during prolonged fasting. The study was done twice in 6 healthy, normal weight subjects (3 males, 3 females, mean age 26±2 years, BMI 222.8±0.9 kg/m^2) after a 12 hour overnight fast. Subjects remained fasting for additional 6 hours and blood samples were taken every 30 to 60 minutes. At the beginning of the second test 30 mg melatonin were administered orally. In the absence of melatonin, as already shown, plasma leptin concentration declined significantly from 8.6±2.4 ng/ml to 6.9±1.9 ng/ml ($p<0.01$, ANOVA for repeated measures). However, administration of melatonin did not affect the decline of plasma leptin concentration over the 6 hour observation time (from 9.1±2.6 to 7.0±2.1 ng/ml, $p<0.01$ vs. baseline, ns vs. without melatonin). No significant changes of serum glucose and insulin concentrations were observed under both conditions. In conclusion, our results suggest that acute administration of high dose melatonin does not influence plasma leptin concentrations in lean healthy subjects.

1065

INTRAPERITONEAL INSULIN REDUCES PLASMA LEPTIN CONCENTRATION IN DIABETIC PATIENTS ON CAPD.

J.T.Lahtela, A. Pasternack, P. Nevalainen and J. Mustonen. Department of Medicine, University of Tampere, Tampere, Finland.

Leptin, the product of *ob* gene, has been suggested to regulate food intake. High levels associate with obesity, insulin resistance and hyperinsulinaemia. We studied the effect of subcutaneous and intraperitoneal insulin therapy, with clearly different peripheral insulin concentrations, on plasma leptin. A group of 11 type I diabetic patients (6 women) with terminal kidney failure and continuous peritoneal dialysis (CAPD) therapy participated. The mean age was 45.4 ± 2.8 yrs (mean ±SE) and the duration of diabetes 28.3 ± 2.1 yrs. The patients were on CAPD and subcutaneous insulin 3-6 months prior to the studies. The study protocol included a 3-month period alternatively with subcutaneous or intraperitoneal insulin during CAPD. Insulin sensitivity was measured with hyperinsulinaemic (80 mU/m^2/min) euglycaemic clamp and other studies included body weight, HbA_{1c} and serum insulin concentration. During the 3 months with intraperitoneal insulin HbA_{1c} improved (from 9.49 ± 0.40% to 8.13 ± 0.37%, $p<0.01$) and glucose disposal rate enhanced (from 7.13 ± 0.80 mg/kg/min to 8.24 ± 0.82 mg/kg/min, $p< 0.01$) significantly. Fasting insulin concentration declined (from 17.5 ± 2.2 mU/l to 14.5 ± 2.3 mU/l, $p<0.05$). Average plasma leptin level was 20.1 ±6.2 ng/ml during subcutaneous insulin and 13.2 ± 6.4 ng/ml after 3 months with intraperitoneal insulin ($p<0.01$). There was a modest decrease in body weight during intraperitoneal insulin therapy (68.0 ± 3.9 kg to 65.9 ± 4.2 kg, $p<0.05$). Leptin concentration did not correlate to body weight, fasting insulin level, glucose disposal rate or HbA_{1c}. The change in leptin level were related to the change in insulin level and body weight. In conclusion intraperitoneal insulin reduces plasma leptin level possibly via inducing lower peripheral insulin concentration.

1066

BRAIN UPTAKE OF LEPTIN IN RABBIT IS SATURABLE IN VIVO

S-L. Karonen, H.A. Koistinen, P. Nikkinen and V.A. Koivisto, Helsinki University Central Hospital, Helsinki, Finland.

Leptin is a peptide hormone produced by adipocytes, which provides a negative feedback signal to control body fat depot. Leptin is thought to mediate its action on food intake and weight loss by interacting with its hypothalamic receptor. We examined the biodistribution and brain uptake of radioiodinated mouse leptin (^{123}I-leptin) by dynamic gamma imaging in anesthezised New Zealand white rabbits. Leptin uptake was seen in the brain, lungs, liver and in the kidneys. In the brain increased radioactivity as a function of time was seen in the hypothalamic area. Hypothalamic to brain ratio (HT/BR) in radioactivity increased up to approximately 30-55 minutes after which a steady state in HT/BR of approximately 2.5 was achieved. When unlabelled leptin was injected 40 min after the ^{123}I- leptin, HT/BR leptin uptake ratio began to decline and remained at a lower level of approximately 1.2 thereafter. In conclusion: 1) A major proportion of leptin uptake *in vivo* occurs in the hypothalamic region of the brain with minor uptake in the lungs, kidney and the liver. 2) The uptake of leptin in the hypothalamic region is specific and saturable as indicated by the displacement after administration of unlabelled leptin.

1067

SERUM LEPTIN AFTER SHORT AND LONG TERM INSULIN ADMINISTRATION TO SUBJECTS WITH NIDDM.

KI Birkeland, J Falch , S Vaaler , JP Berg . Department of Endocrinology and Hormone Laboratory, Aker Diabetes Research Centre, Aker Hospital, Oslo, Norway.

Aim: To correlate serum leptin levels to body fat and assess the effect of short and long term insulin administration on leptin levels in patients with NIDDM. **Material and methods:** Serum levels of the ob gene product leptin were analysed in 31 men and 22 women with NIDDM treated with diet and sulphonylurea, and related to their body mass indexes and per cent body fat measured by dual X-ray photoabsorptiometry. A subset of the subjects were randomly assigned to treatment with insulin or to continue sulphonylurea for one year. Serum leptin levels were measured in the fasting state and during a euglycaemic, hyperinsulinaemic glucose clamp before and after the treatment period. **Results:** Serum leptin levels at baseline correlated highly significantly to body mass index ($r=0.53$, $p<0.001$) and per cent body fat ($r=0.86$, $p<0.001$). Insulin infusion during euglycaemic, hyperinsulinamic clamp at baseline, produced a slight increase in serum leptin concentration towards the end of the clamp (from 6.1 ±0.8 ng/ml to 6.8 ±1.0 ng/ml ($p=0.0001$) after a mean clamp-duration of 270 min. During one year on insulin therapy, HbA_{1c} were lowered from 8.8 ± 0.4 to 8.0 ± 0.4 ($p<0.05$), body mass index increased by 6% (from 26.7 ± 0.8 to 28.3 ± 0.8 kg/m^2 ,$p<0.001$), and fasting levels of serum leptin nearly doubled (from 7.0 ±1.3 to 13.1 ±2.0 ng/ml, $p<0.0001$). **Conclusion:** In NIDDM patients, serum leptin levels correlate strongly to per cent body fat and BMI. Insulin has only a weak acute effect to increase serum levels of leptin, while long term insulin therapy increases serum leptin more than can be accounted for by the increase in BMI.

1068

THE REGULATION OF LEPTIN RECEPTOR LEVELS IN DIABETES.

A. de Silva, G. Morton, K. Walder, P. Zimmet* and G.R. Collier. School of Nutrition and Public Health, Deakin University, Geelong, Australia, and *International Diabetes Institute, Caulfield, Australia.

The leptin receptor (Ob-R) has several alternatively spliced isoforms which are expressed in a wide variety of tissues. Of these isoforms, Ob-Ra has been shown to be involved in leptin transport, while the Ob-Rb isoform appears to be involved in signal transduction in the hypothalamus. Recently Ob-Ra was found in human liver, and leptin treatment of hepatic cells in vitro was shown to decrease insulin action. These results, together with our own epidemiological evidence, suggests a possible role for leptin in the development of insulin resistance. In the current study we investigated the level of Ob-Ra gene expression in the Israeli Sand Rat, an animal model of obesity and NIDDM, using semi-quantitative RT-PCR. The level of Ob-Ra mRNA was measured in the liver, adipose tissue and hypothalamus of animals with varying degrees of obesity and insulin sensitivity. Correlations between Ob-Ra gene expression and total body fat, insulin and glucose concentrations are shown below.

	Ob-Ra mRNA expression		
n=13	Hypothalamus	Adipose Tissue	Liver
Total body fat	r=0.67*	r=0.59*	r= -0.45; n.s.
Insulin	r=0.37; n.s.	r=0.62*	r= -0.72**
Glucose	r=0.30; n.s.	r=0.11; n.s.	r= -0.55*

*p<0.05; **p<0.01

Both hypothalamic and adipose tissue Ob-Ra receptor levels increased with body fat and insulin levels, suggesting increased transport and uptake of leptin into these tissues. In contrast, Ob-Ra gene expression in the liver decreased as body fat, insulin and glucose increased. The decline in the level of Ob-Ra gene expression in the liver may reduce the impact of hyperleptinaemia on hepatic insulin action. In vivo studies are required to further explore the effect of leptin on insulin action and the regulation of leptin receptors.

1069

IGF-I TREATMENT OF NORMAL RATS SUPPRESSES LEPTIN mRNA IN FAT TISSUE.

M. Böni-Schnetzler, Ch. Hauri, and J. Zapf. University Hospital of Zürich, Div. Endocrinology and Metabolism, Rämistr. 100, 8091 Zürich, Switzerland.

In previous studies we found that hypophysectomised (hypox) rats have low serum insulin and reduced leptin mRNA levels and that rhIGF-I treatment further suppresses leptin mRNA without changing serum insulin levels. The aim of the present study was to examine whether rhIGF-I has similar effects on leptin mRNA expression in rats with normal serum insulin and leptin mRNA levels. Methods: Leptin mRNA was determined by Northern blotting of RNA from epididymal adipose tissue of normal rats infused s.c. for 6 days with rh IGF-I (1mg/d), GH (200 mU/d) or solvent (0.1 M acetic acid) using miniosmotic pumps. In addition, fat pad weight, serum insulin, FFA, IGF-I and food intake/d was determined. Results: In normal rats, leptin mRNA levels were markedly suppressed (38.8 ± 11.7 % of controls) by treatment with rhIGF-I, whereas GH had no significant effect (80 ± 13.1 % of controls). RhIGF-I also suppressed serum insulin levels (1.07 ± 0.51 vs 1.89 ± 0.7 ng/ml in controls) and the fractional fat pad weight (0.52 ±0.13 vs. 0.31 ± 0.03 g/100g of body weight), whereas GH had no effect. Both GH and rhIGF-I treated animals had reduced FFA levels (207 ± 34 and 278 ± 42 vs 561 ± 222 in controls). There was no difference in food consumption and body weight. Conclusions: In both, hypox and normal rats, rhIGF-I treatment resulted in a marked suppression of leptin mRNA. In contrast to hypox rats, IGF-I decreased leptin mRNA together with serum insulin levels in normal rats consistent with the present concept that insulin is a major positive regulator of leptin mRNA expression in rat adipose tissue.

1070

AN INCREASED ENERGY EXPENDITURE PREDICTS INCREASE IN BODY FAT IN GIRLS.

D. Harsha, and G.A. Bray. Pennington Biomedical Research Center, Baton Rouge, Louisiana 70808

Studies in Pima Indiana and in infants have suggested that high energy expenditure predicts increases in body fat. This study was designed to test this hypothesis in girls as they entered puberty. A group of 69 girls in 4th and 5th grade were recruited to include equal numbers of black and white girls with a range of body composition. Body composition was measured with dual energy x-ray absorptiometry. Total daily energy expenditure (TDEE) was measured by doubly-labeled water and resting metabolic rate (RMR) was measured with a metabolic cart. Change in % body fat over two years was the primary end-point. Since it was determined that there was no main effect of race, ethnic groups were combined for the remaining analyses. A high TDEE and a high RMR predicted fat gain in these girls. When analyzed by body fat grouping, this relationship was only apparent in the obese girls. Since it was a higher energy expenditure that predicted increased body fat gain, this suggests that these girls ate proportionately more calories than the other girls.

SEASONAL WEIGHT VARIATION IN PEOPLE WITH DIABETES - FACT OR FICTION?

K. R. Paterson, S. A. Bremner, J. Davidson, E. McKenzie and G. C. Gettinby, Diabetes Centre, Royal Infirmary, Glasgow, Scotland and Department of Statistics and Modelling Science, University of Strathclyde, Glasgow, Scotland.

To assess the contention of many people with diabetes that they gain weight in winter and lose weight in summer we have investigated 10836 weights recorded during all the routine clinic visits of 3119 patients (age 18-93 years, 51.7% male, 31.2% diet controlled, 32.8% on oral hypoglycaemic agents, 36.0% on insulin) between February 1992 and July 1995. Efforts to fit a sine-waveform to the weight data (raw and log transformed) plotted against time of the year were unsuccessful and a smoothed mean weight plotted over time closely matched the overall mean. Linear modelling was applied to data from each clinic visit relating log transformed weight to age, gender, diabetes therapy, random plasma glucose and the interactions of these terms. The best fitting model accounted for 23.3% of the observed variability with gender, diabetes therapy, age, age squared and interactions between these as the key factors; interpatient variation accounted for over 95% of the residual variance from the model. Addition of time of year as a continuous variable or as 12 discrete factors (= months) did not improve the fit of the model. We conclude that there is no general tendency to seasonal weight variation in people with diabetes.

INSULIN SENSITIVITY AND SODIUM HANDLING IN OFFSPRING OF HYPERTENSIVE PARENTS

D. Kopf, I. Mühlen, G. Kröning*, I. Sendzik, B. Nestler, and H. Lehnert. Department of Endocrinology and Metabolism, *Department of Clinical Chemistry, Otto von Guericke University, Magdeburg, Germany

Insulin mediated sodium retention has been proposed to be one link between insulin resistance and hypertension. We examined the influence of insulin sensitivity and acute hyperinsulinemia on renal sodium excretion and pressor hormones in normotensive subjects who are at risk of hypertension. **Design:** 22 fasting healthy offspring (Off) of at least one hypertensive parent and 16 controls (Con) were examined. After initial rapid infusion of 1000 mL isotonic saline, fractional sodium excretion, urinary catecholamine excretion, plasma renin, aldosterone and immuno reactive insulin concentrations were measured in 60 min intervals. During the second and third hour after sodium loading, a euglycemic, hyperinsulinemic clamp with a constant insulin infusion rate (1 mU/min/kgBW) was performed. All results are given as means $\pm$ SEM. **Results:** Both groups were closely matched for all possibly confounding variables, such as age (Con 24.2$\pm$2.3; Off 23.6$\pm$2.4 y), blood pressure (Con 112.5$\pm$2.6 / 73.3$\pm$2.3 mmHg; Off 113.2$\pm$3.2 / 68.8$\pm$2.1 mmHg), BMI (Con 22.9$\pm$2.3; Off 22,5$\pm$2.5 kg/m^2), fasting glucose and lipid parameters (all parameters not significantly different at $p<0.05$). Parameters of insulin sensitivity, i e. steady state glucose infusion rate and sensitivity index, correlated well with baseline lipid parameters ($p < 0,01$), WHR and fasting insulin ($p<0.05$), but did not differ between both groups (Con 51.6 $\pm$3.9; Off 51.5$\pm$3.1µmol/min/kgBW). Urinary sodium excretion and fractional sodium excretion were independent of family history, insulin sensitivity and steady state insulin concentration. Pressor hormones did not change significantly in response to hyperinsulinemia. **Conclusions:** In young, normotensive offspring of hypertensive patients, who are at increased genetic risk, but have not yet developped clinical or laboratory features of the metabolic syndrome, we could not find decreased insulin sensitivity. In this very early state, insulin mediated sodium retention obviously does not reach functional significance.

1073

INSULIN RESISTANCE IN METABOLIC CLUSTERS OF FAMILIAL HYPERURICAEMIA

A.Paetzold, J. Graessler, H.-E. Schroeder, G. Siegert and S. Bergmann. Technical University of Dresden, Med. Faculty, Med. Clinic III, Dresden, Germany

Metabolic clusters in 20 families (204 individuals) with hyperuricaemia and gout have been established by multivariat analysis of age- and sex-adjusted clinical and metabolic data using factor analysis, cluster analysis and analysis of variance (MANOVA). Regarding the degree of impairment of uric acid excretion and hyperlipoproteinaemia (HLP) six clusters could be differentiated. Highest prevalence of arteriosclerotic signs (by duplex sonography of Aa.carotes and femorales) have been found in clusters 3 (17/35 $\approx$ 49%) and 5 (10/24 $\approx$ 42%). Whereas individuals in cluster 3 were characterised by pronounced combined HLP, individuals in cluster 5 had minor deteriorations in lipid metabolism but, in contrast, the highest values for body mass index (BMI) and fasting insulin. Dividing investigated population in low (LI; <0,11 mmol/l) and high (HI; $\geq$ 0,11mmol/l) fasting insulin groups, prevalence of HI varied from 10-14% in clusters 1,2,4 to 40% in clusters 5 and 6. High fasting insulin was accompanied by significant higher BMI, waist-to-hip ratio, uric acid, systolic and diastolic blood pressures, triglycerides, ApoB, glucose and lower HDL-cholesterol. Furthermore, clusters 5 and 6 were characterised by highest values for area under the curve for glucose and insulin in oral glucose tolerance test. Insulin resistance in clusters 5 and 6 was accompanied by significant lower activity of t-plasminogen activator as well as significant higher values for α_2-antiplasmin and antigen of plasminogen activator inhibitor. These data indicate, that insulin resistance could be proved for 2 of 6 metabolic clusters found in families with hyperuricaemia and is accompanied with metabolic and hemostatic deteriorations that are known to be involved in arteriosclerosis.

1074

EFFECTS OF ENDOTHELIN-1 INFUSION ON INSULIN SENSITIVITY AND INSULIN SECRETION IN NORMOTENSIVE LEAN SUBJECTS

A.U. Teuscher, M. Lerch, S. Shaw, and P. Weidmann. University of Bern, Bern, Switzerland.

Elevated plasma endothelin (ET)-1 levels have been described in different insulin resistant states such as syndrome X, obesity, non-insulin-dependent diabetes mellitus (NIDDM), and essential hypertension. To investigate whether physiological to pathophysiological increases in circulating ET-1 can modulate insulin levels and/or insulin sensitivity in humans, we assessed these variables during low, non-pressor dose ET-1 as compared to placebo infusion in lean normotensive healthy subjects. Ten healthy, caucasian males, age 20-30 years and with a body mass index (BMI) of 20-26 kg/m^2 were included in the study. Insulin sensitivity was assessed dynamically by the Minimal Model Approach with use of the modified frequent sampling intravenous glucose tolerance test (FSIGT). In a randomized, single blind cross-over fashion the subjects then received either an intravenous infusion of ET-1 dissolved in polygeline, or a control infusion of polygeline only (=placebo). The acute insulin response (AIR) was calculated as the average of the three peak values between 2 and 5 min after injection of glucose from which the basal insulin levels were substracted. The index of insulin sensitivity (S_I) measured during ET-1 infusion was 11.1$\pm$1.9$\times10^{-4}$ /min/mU/l versus 10.8$\pm$2.1$\times10^{-4}$/min/mU/l during placebo infusion (p=NS). ET-1 infusion markedly reduced plasma insulin levels during the FSIGT compared to placebo (ANOVA $p < 0.0001$). The acute insulin response (AIR) to glucose during ET-1 infusion was 34.8$\pm$4.3 versus 49.3$\pm$6.9 µU/ml during placebo (p=0.017). In conclusion, we have demonstrated that short term moderatly increased ET-1 levels do not impair insulin sensitivity. However, ET-1 markedly diminished the acute insulin secretion. Our data suggest that ET-1 decreases pancreatic β cell function.

1075

RELATIONSHIP BETWEEN HYPERURICEMIA AND INSULIN RESISTANCE

M. Iwatani[1], T. Wasada[2], K. Katsumori[2] and A. Sato[2]. Institute of Rheumatology[1] and Diabetes Center[2]. Tokyo Women's Medical College, Tokyo, Japan.

Hyperuricemia is often associated with obesity, hypertension and dyslipidemia, and is considered to be a risk factor for cardiovascular disease, thus being similar to the insulin resistance syndrome. A low, but significant correlation was found between serum uric acid concentration and the degree of insulin resistance (GIR) estimated by the euglycemic hyperinsulinemic clamp method in 67 subjects with combined normal glucose tolerance and impaired glucose tolerance (IGT, $r=-0.278$, $p<0.05$). In a separate group of 30 non-obese subjects including 7 with IGT, UA was correlated with GIR($r=-0.518$, $p<0.01$). Plasma HDL-C and triglyceride (TG) levels were also correlated with uric acid levels. One hundred and sixty non-insulin dependent diabetes mellitus (NIDDM) patients who had undergone the clamp study were classified into 5 groups according to serum uric acid level. In the top quintile (UA:7.8$\pm$0.8), body mass index (BMI), male prevalence, plasma TG, HDL-C, fasting IRI and total IRI response (0+60+120) during the meal tolerance test were significantly higher, while age and GIR were lower than those in the bottom quintile (UA:3.4$\pm$0.5), but the differences were not significant. These findings indicate that elevated serum uric acid is a feature of the insulin resistance syndrome.

1076

EARLY PROTEIN RESTRICTION AND SUBSEQUENT OBESITY ARE INDEPENDENT RISK FACTORS FOR HYPERTENSION

C.J. Petry, S.E. Ozanne, C.L. Wang and C.N. Hales. Clinical Biochemistry Dept., University Of Cambridge, Cambridge, England.

Recent epidemiological studies have revealed a link between fetal and early post-natal growth retardation and the development of hypertension and glucose intolerance in later life. The aim of this study was to assess whether growth retardation, caused by early protein restriction, is a risk factor for the subsequent development of hypertension that is independent from any risk associated with obesity. Pregnant Sprague Dawley rats were given either a 20% protein ('control') diet or an isocaloric 8% protein ('LP') diet throughout pregnancy and lactation. The female pups were weaned onto the diets that their mothers had been given and remained on these diets until 70 days of age. Then some of the rats were given a standard laboratory chow ('pellet') diet whilst other rats were fed a cafeteria-style high calorie ('cafeteria') diet. The rats remained on these diets throughout the remainder of the study. At one year of age the rats underwent an intra-peritoneal glucose tolerance test and had their blood pressures measured using a tail cuff technique. The body weights at this age (g) were as follows (mean (SD)): control-pellet 421.7 (31.5) (n=7), control-cafeteria 799.9 (131.3) (n=6), LP-pellet 333.7 (23.6) (n=9), LP-cafeteria 594.1 (127.1) (n=9) (early diet $p<0.001$, adult diet $p<0.001$, interaction $p=0.110$; 2-way ANOVA). Neither early ($p=0.829$) nor adult ($p=0.221$) diets were associated with alterations in glucose tolerance at this age (2-way ANOVA). Systolic blood pressures (mmHg) (mean (SD)) were: control-pellet 128 (25), control-cafeteria 157 (29), LP-pellet 158 (28), LP-cafeteria 182 (40) (early diet $p=0.025$. adult diet $p=0.026$, interaction $p=0.815$; 2-way ANOVA). The data suggest that both early protein restriction and subsequent diet-induced obesity are independent risk factors for the development of hypertension, which can present without an associated worsening of glucose tolerance at one year of age.

1077

PHYSIOLOGICAL LEVELS OF RAT C-PEPTIDE IMPROVES GLUCOSE UTILIZATION IN DIABETIC RATS

Y. Sato, Y. Oshida, L. Li, J. Sato, N. Yanaihara*, B-L Johansson** and J. Wahren**, Nagoya University, Nagoya, *Yanaihara Institute, Shizuoka, Japan, **Karolinska Hospital, Stockholm, Sweden

Recent study suggests that supraphysiological amounts of human C-peptide (20-40nmol/l) augments glucose utilization in STZ induced diabetic(STZ-D) rats. The present study was undertaken to determine the influence of physiological conc. of rat C-peptide on in vivo glucose utilization in STZ-D (60mg/kg) rats by using an euglycemic clamp technique. Two different insulin infusion rates, 3.0(low-dose) and 30.0(high-dose) mU/kg•min, were used. Rat C-peptide I or II was infused at a rate of 0.05 nmol/kg•min, which increased plasma levels from 0.15±0.03 to 0.37±0.03 nmol /l, from 0.13±0.03 to 0.40±0.06nmol/l, respectively. (fasting levels in controls were 0.53±0.06 nmol/l). Plasma insulin levels during the low- and high-dose insulin infusion were 40 and 400 μU/ml, respectively, and blood glucose was clamped at 7.5mmol/l by periodic adjustment of the *i.v.* glucose infusion rate. Glucose metabolic clearance rate (MCR) was 160% greater ($P<0.05$) in STZ-D rats recieving C-peptide I during the low-dose insulin period(17.9±4.0 ml/kg•min, n=6) than in STZ-D control rats(7.2 ±0.8ml/kg•min, n=6). Likewise, MCR in STZ-D rats given C-peptide II(13.6±3.3ml/kg•min) tended to be greater than in STZ-D control rats ($0.05<p<0.1$). MCR of STZ-D rats infused with either C-peptide I or II was similar to the MCR found in the non-diabetic control rats (15.1±2.0 ml/kg•min). C-peptide I and II did not significantly influence MCR during the high-dose insulin period. It is concluded that phyiological amounts of rat C-peptide I and II improves glucose utilization in STZ-D rats.

1078

INSULIN RESISTANCE IN ESSENTIAL HYPERTENSION AND ITS ASSOCIATION TO ASYMPTOMATIC ATHEROSCLEROSIS

M. Suzuki, A. Kanazawa, D. Zhao, M. Tsushima, and Y. Harano. National Cardiovascular Center, Suita, Japan

Insulin sensitivity was determined in subjects with essential hypertension, and effects of antihypertensive drugs on insulin sensitivities were evaluated. Furthermore, the relation between carotid atherosclerosis and insulin resistance was studied. Using SSPG method, insulin sensitivity was measured in non-obese and non-diabetic subjects with essential hypertension. SSPG was significantly ($p<0.05$) higher in subjects with borderline HT (n=86) and HT (n=90) compared with normal (n=24) subjects. SSPG was significantly ($p<0.01$) correlated with systolic (r=0.37) and diastolic (r=0.31) blood pressures in hypertensive subjects. In essential hypertension, with normal glucose tolerance, insulin resistance was noted in 75%. Intra-platelet Ca^{2+} after collagen stimulation was higher in subjects with HT. Intra-platelet Ca^{2+} after collagen stimulation decreased during insulin infusion, and basal Ca^{2+} correlated with SSPG. SSPG reduced significantly by α1 blocker, bunazosin (-26%), ACE inhibitor, cilazapril (-26%), β-blocker (K-channel opener), tilisolol (-18%), and long acting Ca antagonist, amlodipine (-20%) & benidipine (-20%). The relation between early asymptomatic carotid atherosclerosis and these risk factors was examined in 72 non-diabetic subjects with essential hypertension aged 50-59 years. Intima-media thickness of carotid artery was assessed by B-mode ultrasonography. By multiple regression analysis, steady state plasma glucose was the strongest risk, followed by lower high density lipoprotein and systolic blood pressure. In hypertension, insulin resistance which is presumed to be derived from intracellular Ca^{2+} derangement, further elevates blood pressure and aggravates atherosclerosis. The above antihypertensive drugs help to correct the vicious cycle.

1079

HYPERINSULINEMIA IN MICROVASCULAR ANGINA IS COMBINED WITH HIGH Na+/Li+ COUNTERTRANSPORT.

G.DeMattia,*A.Gaspardone,*F.Crea, C.Ferri, L. De Siati, O.Laurenti, C.Bravi, *F.Tomai, *M.Iamele,A. Santucci and P.A. Gioffre'. I Clinica Medica & *Cardiosurgery Dept. Universities "La Sapienza" and "Tor Vergata", Rome, Italy.

Stimulated hyperinsulinemia during OGTT has been demonstrated in patients with microvascular angina (MA). Insulin resistance is frequently associated with overactivity of red blood cell Na+/Li+ countertransport (Na+/Li+ CTT), a specific marker of in vivo Na+/H+ antiport activity. The present study was aimed to assess this system in 12 females (mean age 57+6 years) with MA and in 10 sex and age-matched controls. Na+/Li+ CTT was evaluated as Li+ efflux from Li+ loaded erythrocytes. Insulin levels were evaluated by RIA. Results:

TESTS	CONTROLS	MA	p
Na+/Li+ CTT (umol/L/h)	320±49	642±220	0.0001
Glucose (mg/%)			
Fasting	76±15	85±7	0.2455
90 min.	95±43	129±47	0.1444
180 mi	74±20	102±39	0.0855
Insulin (uU/ml)			
Fasting	10±2	22±23	0.0443
90 min.	41±20	102±73	0.0006
180 min.	16±8	62±46	0.0159

As is shown, hyperinsulinemia is combined with an accelerated Na+/Li+ CTT. This overactivity may cause microvascular dysfunction through intracellular alcalosis which may decrease insulin sensitivity and increase vascular response to constrictor stimuli.

BLOOD PRESSURE CIRCADIAN RHYTHM IN "NORMOTENSIVE" INSULIN DEPENDENT DIABETIC PATIENTS.

G.Burlando,A.García,S.Vasta,J.Alvariñas and C.González,Servicio de Nutrición,Hospital Tornú and Dept of Pharmacology,University of Buenos Aires,Argentina

Objective: To assess the strength of the association between the alterations of blood pressure circadian rhythm and the presence of microalbuminuria(M) in "normotensive"(according manometric JNC V criteria) IDDM patients. As a secondary goal, to assess the correlation between hypertension (determined by ambulatory blood pressure monitoring [ABPM]) and several clinical and biochemical covariates.**Methods**: We studied 84 IDDM patients, normotensive in manometric tests (JNC V criteria), 42 male, aged 36.8±13.0 yr.; in them we performed a 24 hours ABPM study. The level of metabolic control was established through HbA1c determinations.M was determined by RIA (cut-off point: 15 micrograms/minute).Statistical analysis: 1)univariate methods (t-test,Mann-Whitney,Pearson and non-parametric correlations);2) Factor Analysis (varimax rotation);3) multiple logistic regression (Quasi-Newton;Maximum likelihood).Soft: CSS/Statistica,StatSoft,Tulsa,1993.**Results**:58.4% of the sample showed alterations of circadian rhythm (non-deeper status); positive M was observed in 30.9%.In factor analysis, a consistent link was found among systo-diastolic (SD) alteration of circadian rhythm , positive M, retinopathy, diabetes duration and LDL levels. SD alteration was positively and significantly associated with the presence of M both in the univariate correlation model (R=0.25;p=0.02) and in the logistic regression (OR=2.94;95%CI=1.13-7.69;p=0.03).Isolated diastolic rhythm alterations correlated significantly with diabetes duration in the logistic model (p=0.01).Hypertension determined by ABPM according mean blood pressure (JNC V criteria),was associated (logistic regression) with age, first degree relatives positive antecedents and HbA1c level.**Conclusions**:1) SD alterations of circadian rhythm were significantly associated to positive M. 2) High blood pressure values by ABPM correlated with age, family history of hypertension and HbA1c levels. 3)ABPM may be an useful method for precocious detection of blood pressure alterations. Further studies should demonstrate the real potential of this method in this field.

1081

EFFECTS OF TWO PHARMACOLOGICAL THERAPIES FOR ISCHAEMIC HEART DISEASE ON INSULIN SENSITIVITY.

G Piédrola, A Becerra, E Novo, O González, ML De Teresa, R García Robles. Hospital Virgen de las Nieves, Granada. Hospital Ramón y Cajal, Madrid. Spain.

Aims: To evaluate insulin sensitivity (IS) in patients with ischaemic heart disease (IHD) and to study its evolution with two conventional pharmacological therapies. **Patients and Methods**: We have studied 20 patients with IHD demonstrated by treadmill exercise test (ST depression >0.1 mV) and/or coronary angiography. Patients with history of glucose intolerance, body mass index (BMI) >30 Kg/m2, fasting plasma glucose (FPG) >140 mg/dl or under any medication with potential effects on IS were excluded. Fifteen healthy volunteers, matched for sex, age and BMI were considered as controls. To assess IS, an insulin suppression test (IST) was performed both in controls and patients. IHD patients were then randomly treated with either acetylsalicilic acid (ASA)(200 mg/d)+atenolol (50 mg/d) [Group BETA; n=10] or ASA (200 mg/d)+isosorbide mononitrate (40 mg/d)+captopril (25 mg/d) [Group ACEI; n=10]. After 6 months, they underwent a second IST. Steady-state plasma glucose (SSPG), insulin sensitivity index (ISI=1000xglucose infusion rate/SSPG) FPG and fasting plasma insulin (FPI) were considered as a measure of IS. **Results**: As a group, IHD patients (n=20) showed higher SSPG (237,90±36,04 vs 123,36±24,43 mg/dl; p<0,001) and lower ISI (25,81±4,35 vs 50,33±9,37 dl/kg•min; P<0,001) values than Control Group. After 6 months, 8 patients from the ACEI Group and 7 patients from the BETA Group could be reevaluated. Data are summarized below (*p<0,001 vs Before Treatment):

	SSPG		ISI	
	Before Treatment	After Treatment	Before Treatment	After Treatment
BETA	235,75±43,23	245,75±30,34	26,30±5,49	24,75±2,83
ACEI	240,05±28,66	162,90±74,64*	25,33±3,22	46,79±26,03*

There were no differences among groups in age, sex, BMI, FPG, FPI. **Conclusions**: Preliminary results of this study show that IHD patients have a decrease in IS. Six months treatment with isosorbide mononitrate and captopril, but not atenolol, improve IS. Finally, SSPG and ISI obtained from IST are more powerful markers of IS than FPG and FPI.

1082

RELATIONSHIP BETWEEN 24-h AMBULATORY BLOOD PRESSURE AND URINARY ALBUMIN EXCRETION IN PATIENTS WITH IMPAIRED GLUCOSE TOLERANCE

Pan Changyu, Li Chunlin, Lu Jumin, et al. Department of Endocrinology, Chinese PLA general hosipital, Beijing, China

In order to investigate the relationship between UAE and change of ABPM in IGT patients, ABPM was performed in 18 subjects with high UAE (UAE>10ug/min) and in 26 subjects with normal UAE (UAE <10ug/min). The occasional blood pressure, biochemical index and UAE were measured, and heart autonomic nerve function was evaluated.

The results showed that the occasional DBP and MBP were significantly higher in the IGT with elevated UAE than that of IGT with normal UAE (DBP 88±2.3mmHg vs 80±2.1mmHg, MBP: 103±2.7mmHg vs 95±2.6mmHg, P<0.05) . The peak value of SBP (173±6 vs 153±4mmHg), DBP (134±7 vs 108± 4mmHg) and abnormal SBP load (29. 6±5.85 vs 14.3±3.19%) were higher in high UAE group than that of normal UAE group in ABPM examination. 24-h DBP(87±3 vs 81± 2mmHg) and nighttime DBP(80 ± 3 vs 71 ± 2mmHg) were increased. Nocturnal blood pressure fall of SBP (5.73±2.12 vs 11.5±1.82 mmHg) and MBP (7.22±2.18 vs 13.2±1.73mmHg) were decreased in high UAE group. The reduction of nocturnal blood pressure was decreased (P< 0.05) and the profile of 24-h blood pressure was smoother compared with normal UAE group. A significant positive correlation was found between the UAE and nighttime DBP, blood pressure load of SBP and DBP, 24hDBP and 24hSBP, r=0.4860~0.3070, P< 0.05; and there was a negative correlation between the UAE and the decrease rate in nighttime blood pressure (SBP, DBP and MBP), r=-0.3977~0.4670, p<0.01. No correlation was found between UAE and occasional blood pressure, autonomic nerve score, BMI, Ch, Tg, blood glucose or insulin level.

Conclusion: Our data suggests that the change of ABPM in high UAE group was similar to diabetic nephropathy and the UAE level was correlated with most index of ABPM.

1083

PARTICULARITIES OF INSULIN ACTION ON MYOCARDIAL FUNCTION AND METABOLISM IN DIABETIC DOGS

A.P. Nescheret, I.V. Gonchar, N.V. Okhrimenko and A.I. Khomazjuk. Institute of Endocrinology and Metabolism, Vyshgorodska 69, Kiev, Ukraine, 254114.

The aim of this investigation was to evaluate the action of insulin (I) on myocardial metabolism and function in diabetes (D). Experiments were performed on 18 control dogs and 12 dogs with alloxane induced D. Catheterization and extracorporal autoperfusion of coronary artery, catheterization and continuous drainage of coronary sinus (CS) were used without opening the chest under anaesthesia. The heart reactions to I were estimated by changes of heart contractility (HC), coronary artery resistance (CAR), coronary arterio-venous difference (CAVD) by pO_2, pCO_2, pH, glucose (G) and FFA. In control dogs I injection (1.0 IU/kg, i.v.) initially on 5-10 min of reaction induced slight and unstable increase of CAR and HC (+4.8±0.3% and +9.2±1.2%, rsp.) which later were followed by more pronounced their decrease (-12.0±0.9% and -13.5±2.5%, rsp.). The latter changes were accompanied by the increase of CAVD by G (from 0.4±0.06 to 0.7±0.07 mmol/l), reduction of CAVD by FFA (from 0.18±0.05 to 0.07±0.02 mmol/l) and elevation of CS blood O_2 saturation (+15.5±4.28%). The heart reaction changes in mild and moderate D were similar to those in control dogs but their magnitude was accentuated. On the contrary in dogs with severe D (G - 14.6±0.38 mmol/l) during the first hour after I injection only slight decrease of CAR (- 2.0±0.4%) and increase of HC (+5.2±0.5%) took place while CAVD by G and FFA as well as CS blood O_2 saturation remained practically unchanged. These data indicate that secondary insulin resistance in severe D includes also attenuation of I action on myocardial function and metabolism.

1084

ANGIOTENSIN-CONVERTING ENZYME GENOTYPING, INSULIN RESISTANCE IN HYPERTENSIVE YOUNG MEN.

E.Fomicheva, V.Popov, Y.Kovalev and E. Schwartz. St. Petersburg Institute of Nuclear Physics, RAS, St. Petersburg, Russia.

Recent studies have reported that angiotensin-converting enzyme gene (ACE) polymorphism to be connected with altered sensitivity of tissues to insulin. We studied the insertion/deletion (I/D) polymorphism of ACE gene among 131 young males with borderline hypertension (BHT) and 87 normotensive (NT) young males as a control group using polymerase chain reaction (PCR). The frequencies of insertion and deletion ACE alleles for NT and BHT groups were 0.448 and 0.552 , 0.443 and 0.557, respectively. These differences were not significant. OGTT was performed among 47 BHT patients and 40 NT persons. BHT patients with II genotype had higher average glucose concentration in two hours after glucose loading compared to ID and DD genotypes patients (statistical significant difference was between II genotype and ID genotype). There was some increase in glucose concentration of 40 NT patients with II genotype (point 30, 60 and 120 min) compared to other genotypes, but not statistical significant. There was the most increment of glycemia during OGTT in two hours in NT persons with II genotype to other genotypes (II vs ID, $p<0.01$). Levels of insulinemia obtained during OGTT (point 0, 60, 120 min) were not significant difference among persons with various genotypes in both groups. We have concluded that BHT patients with II genotype and NT persons with II genotype have less insulin sensitivity compared to persons with DD and ID genotypes.

1085

INSULIN SENSITIVITY STUDIES IN OFFSPRING OF PATIENTS WITH CORONARY HEART DISEASE.

D Tripathy, P Shah, AC Ammini, and KS Reddy*. Departments of Endocrinology and *Cardiology, All India Inst Med Sci, New Delhi, India.

Background: Insulin resistance is proposed to be a risk factor for development of coronary heart disease. Cross sectional studies demonstrating correlation between fasting insulin levels and presence of coronary heart disease fail to look at the temporal relation required to demonstrate causation.

Aim: to determine whether significant insulin resistance predates clinical manifestation of CHD (offspring of CHD taken as surrogates for pre-CHD) \

Design: Case control; *cases:* 7 offspring of coronary heart disease patients; *controls:* 6 controls without any family history of CHD; *matching:* group, for age and gender. *Outcome measure:* M value on hyperinsulinaemic euglycaemic clamps at insulin infusion rate of 40mU/m^2 (insulin concentration: 89mU/L and 100mU/L).

Results: There was no significant difference between cases and controls as regards anthropometry [BMI: 21.5+1.45 vs. 20.3+1.69, p=0.6; waist to hip ratio: 0.877+0.51 vs. 0.873+0.50, p=0.90]; glucose area under curve after oral glucose load (11407+26.7 vs. 12045+25.0 mg.min.dL^{-1}, p=0.184); and M value [(mg/kg/min) 5.2+1.7 vs. 6.9+1.9, p=0.167. There was no significant difference between cholesterol, HDL and triglyceride levels.

Conclusions: The offsprings of patients with CHD did not have different glucose disposal rates on hyperinsulinaemic euglycaemic clamp studies than controls. The cause effect relation between insulin resistance and coronary heart disease remains to be proven.

1086

CIRCARDIAN BLOOD PRESSURE, CORTISOL AND PROLACTIN IN DIABETIC AUTONOMIC NEUROPATHY

N. Kostić,M.Kocijančić,D.Simić,Z.Čaparević,S.Jelić and G.Bojković, Department of Endocrinology KBC"Dr Dragiša Mišović"-University of Belgrade

The aim of the study was to investigated the relationship between circardian rhythm of blood pressure (BP) and autonomic neuropathy in noninsulin dependent diabetes mellitus. Ambulatory blood pressure (ABP) was measured every 15 min for 24 h in 50 diabetics without hypertension and in 40 healthy controls. The autonomic control in diabetics was evaluated by R.R interval measurements during deep breathing and uprising. The diurnal cycle of BP was assessed by the difference of BP between daytime and nighttime, the night/day ratio of BP and the percent decrease in nighttime BP. We investigated diurnal rhythms of cortisol and prolactin determined by RIA method. The results of our study showed significantly smaller diurnal noctural differences in diabetics than in nondiabetic controls. A subgroup of diabetics with autonomic neuropathy showed significantly smaller diurnal noctural differences of BP, lower ratio between day/night in diastolic BP (0,98 v.s 0,86; p 0,001) and significantly lower parcent (10%) decrease in diastolic BP compared to the group without autonomic neuropathy. A significant decrease of the daily levels of cortisol and increase of prolactin were present in investigated diabetics. It seems that vagal dysfunction may be the main cause of the higher nighttime BP in autonomic neuropathy. ABP monitoring may be useful in evaluating diabetic autonomic neropathy.

1087

RELATIONSHIP BETWEEN INSULIN SENSITIVITY AND DEHYDROEPIANDROSTERONE-SULFATE IN PATIENTS WITH ISCHAEMIC HEART DISEASE.

A Becerra, G Piédrola, E Novo, O González, ML De Teresa and R García Robles . Hospital Ramón y Cajal, Hospital Virgen de las Nieves, Granada. Madrid. Spain.

Decreased insulin sensitivity (IS) has been related with the pathogenesis of ischaemic heart disease (IHD). Dehydropiandrosterone-sulfate (DHEA-S) has been suggested as the possible link between these two entities. **Aims**: To clarify the relationship between IS and DHEA-S in patients with IHD and without known metabolic disorders. **Patients and Methods**: We have studied 32 male patients with typical coronary angina and IHD demonstrated by treadmill exercise test (ST depression >0.1 mV) and/or coronary angiography. Patients with history of glucose intolerance, body mass index (BMI) >30 Kg/m2, fasting plasma glucose >140 mg/dl or under any medication with potential effects on IS were excluded. Eleven healthy male volunteers, matched for age and BMI were considered as controls. Insulin sensitivity was assessed by an insulin suppression test, and DHEA-S levels were measured before the test (basal) and at the end of it (during hyperinsulinemia). Steady-state plasma glucose (SSPG) and insulin sensitivity index (ISI=1000xglucose infusion rate/SSPG) were considered as a measure of IS. **Results**: Insulin resistance, defined by an ISI below the mean-2SD of the control group, was present in 78% of IHD patients. As a group, they displayed lower ISI (30,62±12,11 vs 49,82±9,62 dl/kg•min; P<0,0001) and higher SSPG (217,74±59,76 vs 124,67±24,98 mg/dl; p<0,0001) than controls. DHEA-S values were lower in IHD than in controls, both basal (1224±796 vs 1935±1260 ng/ml; P<0,05) and during hyperinsulinemia (1083±761 vs 1683±1051 ng/ml; P<0,05). DHEA-S levels decreased with hyperinsulinemia, both in patients (1224±796 vs 1083±761 ng/ml; P<0,0005) and controls (1935±1260 vs 1683±1051 ng/ml; P<0,0005). The magnitude of that decrease was the same in both groups. No correlation between ISI or SSPG and DHEA-S was found. **Conclusions**: IS is decreased in patients with IHD, even when metabolic abnormalities associated with reduced IS are excluded. These patients also show decreased DHEA-S levels, which are even more reduced when acute induced hyperinsulinemia is achieved although, as the decline was similar to that of controls, there does not seem to be resistance to that particular action of insulin.

1088

ALTERATIONS IN CARBOHYDRATE METABOLISM IN A SAMPLE OF THE ARGENTINE HYPERTENSIVE POPULATION. A.García, G.Burlando,E.López González,L.de Loredo, C.D.González and Committee of Hypertension, Argentine Society of Diabetes, Argentina.

Objective: to evaluate the distribution of the alterations in carbohydrate metabolism (determined through oral glucose tolerance test [GTT]) in a sample of hypertensive subjects, determining also the strength of the association between the presence of an abnormal test result and several clinical and biochemical independent covariates. **Methods**: We studied 292 hypertensive patients (according JNC V criteria),105 women (age:55.2±11.7) and 187 men (age: 54.4±10.0) without a previously known alteration in carbohydrate metabolism. GTT was performed according WHO criteria.Statistical analysis: 1) univariate methods (t-test, Mann-Whitney, Pearson and non-parametric correlations) and, 2) multiple logistic regression [MLR] (Quasi-Newton; Maximum Likelihood).Soft:CSS/Statistica , StatSoft,Tulsa,1993. **Results**:29.8% of the total sample showed glucose intolerance (Fleiss quadratic 95% confidence interval: 24.7-35.4%). Both in uni and in multivariate analysis, this intolerance was significantly associated to: age (adjusted [MLR] OR=1.03 per yr;95%CI=1.01-1.05;p=0.01), BMI (adjusted OR= 1.99 per Kg/m^2; 95%CI=1.12-3.51; p=0.01) and first degree relatives antecedents of diabetes (adjusted OR=2.61; 95%CI=1.50-4.52, p=0.0006). Male sex correlated significantly only in the univariate analysis (rS=0.11,p<0.05).**Conclusions**:1) Approx.30% of studied patients showed impairment of glucose tolerance. 2) In this sample, this intolerance was positively associated with age, BMI and first degree relatives history. 3)May be of great importance to evaluate glucose tolerance in hypertensive patients, specially in obese over 50 yrs with a positive family history.

1089

FREQUENCY OF HYPERTENSION IN DIABETIC PATIENTS IN CONGO

Service maladies Métabolique et Endocriniennes
C.H.U. BP 2725 BRAZZAVILLE
H. MBADINGA-MUPANGU ; H. MONABEKA ; P. KIBEKE

The objective is to study the frequency of hypertension in diabetic patients of Congo. It is a retrospective study of diabetic patients admetted in our Service between July 1991 and June 1996..

The hypertension criteri are the the ones World Health Organisation 160/95. (W.H.O.)

This studey conmed 1297 patients, 874 men, 423 wonen divided into two groups : group I : diabetc patients with hypertension, groupe II : diabetc without hypertension.

Hypertension was diagnosed in 152 (11,71 %) of 1297 diabetic patients . There are 73 men (39,91 %) and 79 women (60,09 %).

The patients' age in comprised between 30 and 70 years old.

Among those suffring of hypertension, 2,5 % have an increase in diastolic blood pressure only, 6% that of systolic and 91,5% that of both (diastolic and systolic). In 25% hypertension precedes the discovery of diabetes and in 75 % its discovery coincide with that of diabetes. Twenty seven (1,17,76 %) are requirin insulin, 125 (82,23 %) not requiring insulin, 4(2,6%) of thise requiring insulin are related to malnutrition and 9 five (3,6%) fibrocalculous.

In conclusion; the frequency pf hypertension in low in the diabetic patients followed in our Service. The weakness can be explained by existence of a carodiology service which also takes care of some diabetic patients with hypertension.

1090

INCIDENCE OF INSULIN RESISTANCE SYNDROME IN CHILDREN AGED 7-16 FROM FAMILIES WITH HYPERTENSION AND OBESITY.

G. Mardarowicz, J. Łopatyński, W. Szydlowski - Medical Academy of Lublin, Poland.

During the examination of villagers from Eastern Poland 105 school age children coming from 30 families were examined where both parents had hypertension and/or obesity. The aim of the study was to search for family aggregation of insulin resistance syndrome elements. Body weight, height, waist to hip ratio measurements and oral glucose tolerance, blood lipids, fasting serum insulin and microalbuminuria estimations were performed. Diabetes Mellitus (DM) was recognised in 8,8 %, impaired glucose tolerance (IGT) in 15,5% of parents. None of the examined children did not have DM, IGT or hypertension. 36% of the examined had obesity. 45% proved to have low HDL cholesterol level below 1mM/L. In 39% fasting insulin level was above 10 mIU/ml and in 10% - above 20 mIU/ml. In 18% of the offspring we found coexistence of low HDL level and hyperinsulinemia. 7,3% of the had microalbuminuria > 50 µg/ml. Every fifth child from the families with hypertension and obesity in parents showed the symptoms which can be connected with the presence of insulin resistance syndrome. Children from such families should be subject to an early diabetes prevention.

1091

USEFULLNESS OF A MODIFIED LOW DOSE INSULIN TOLERANCE TEST FOR EVALUATION OF INSULIN SENSITIVITY IN NIDDM.

L. Millot*, P. Margaillan*, H. Gin**, N. Vergely*, V. Brulport*, A. Caillot* and B. Estour*, *Bellevue Hosp., Saint Etienne; **Haut Leveque Hosp., Bordeaux, France

Background: The assessment of insulin sensitivity by glucose clamp technique is the reference method, but is unusefullness in clinical practice. The conventional insulin tolerance test (ITT) using an insulin dose of 0.1 unit/kg is a simple and rapid method and correlate with glucose clamp, but may result in hypoglycaemia in patients without insulinresistance. In order to avoid this problem, we describe an ITT technique using a lower dose of insulin on a 3h continuous IV infusion (O.O4 U/kg/h). Since a direct negative feed-back of insulin on βcells was described, T1/2PCP (time necessary to decrease initial plasma C peptide by half) is considered to correlate with insulin resistance (IR). Design and methods: 1) Eleven healthy normal weight control subjects underwent an ITT. 2) Six subjects (three healthy volunteers and three NIDDM patients) were studied with an ITT and a euglycaemic hyperinsulinaemic clamp. With that technique, insulin sensitivity was derived from the average amount of glucose infused at the steady state. 3) ITT was carried out in 88 NIDDM patients. Three tertiles were defined according to the T1/2 PCP: A (<110 mn; n=28), B (110 to 150 mn; n=31) and C (>150 mn; n=29). Clinical and metabolic data were compared in A and C subgroups. Results: 1) Mean T1/2PCP in controls range from 25 to 72 mn. 2) There was a good negative correlation (r=0.88; p<0.05) between insulin resistance derived from the T1/2 PCP and that obtained from the clamp study (glucose disposal rate). 3) In the subgroups A and C of NIDDM patients, there was no difference in age, known duration of diabetes, fasting insulin concentration, urinary C peptide and cholesterol. Body mass index, blood pressure at rest, average glycaemia (based on a 8 points monitoring during 2-3 days), HbA1c, PCP before and 10 mn after 1mg glucagon IV infusion and fasting triglycerides were significantly higher in subgroup C, but there was a consistent overlap of individual values between the two subgroups. Conclusion: 1) The decrease of plasma C peptide during a short insulin tolerance test employing 0.4 units/kg/h insulin correlate with euglycaemic hyperinsulinaemic clamp results in controls and NIDDM patients. 2) T1/2 PCP results are concordant with clinical and biological parameters of insulin resistance in NIDDM patients. This test seems to be a simple and reliable method for assessment of insulin sensitivity in NIDDM.

1092

DERMAL GLUCOCORTICOID SENSITIVITY IS ASSOCIATED WITH INSULIN RESISTANCE AND RELATED CARDIOVASCULAR RISK FACTORS

DIW Phillips[a], BR Walker[b] and JR Seckl[b]. [a]MRC Metabolic Programming Group, University of Southampton, Southampton, UK and [b]University of Edinburgh, Edinburgh, UK.

The cluster of cardiovascular risk factors comprising the metabolic syndrome (hypertension, glucose intolerance and dyslipidaemia) resemble the effects of Cushing's syndrome or glucocorticoid administration but cannot be explained by increased circulating levels of glucocorticoids. Recent evidence, however, suggests that in hypertension tissue sensitivity to glucocorticoids may be increased, as judged by more intense dermal vasoconstriction following topical application of glucocorticoids. To determine whether increased glucocorticoid sensitivity might be associated with other components of the metabolic syndrome, we studied 32 men (aged 50-57 years) of whom 8 had impaired glucose tolerance (IGT). Forearm dermal blanching was measured on a visual analogue scale after overnight application of beclomethasone dipropionate. (13μl/cm^2, 0.1-10μg/ml) Increased dermal glucocorticoid sensitivity correlated with higher systolic BP (r=0.34, p=0.05), higher 120min plasma glucose after 75g oral glucose (r=0.54, $p<0.001$), greater insulin resistance as measured by a short insulin tolerance test (r=0.43, p=0.016), increased fasting triglyceride (r=0.36, p=0.04) but not BMI or waist/hip ratio. In regression analyses the associations between glucocorticoid sensitivity and glucose intolerance/insulin resistance were independent of obesity and persisted after exclusion of the subjects with IGT. As dermal vasoconstrictor sensitivity reflects tissue sensitivity to glucocorticoids, thus the present data suggest an increase in tissue sensitivity to glucocorticoids mediates the association between cardiovascular risk factors and insulin resistance.

1093

Measurement of Insulin Resistance in a Group of Obese Versus Non Obese Costaricans, Usein Harano's Method of Steady State Plasma Glucose

Arguedas C., Manley D. Department of Internal Medicien, Mexico Hospital, Costa Rica.

Background: Insulin resistance (IR) is a phenomenon of great interest, to the point of having the World Health Organisation recommend its study, specifically as to the need of "conducting large population studies to determine the real prevalence of the syndrome by age and sex". In Costa Rica no large estudies of IR have been conducted, since classic methods for its measurement are expensive and time consuming. In this study we applied a simple method of steady state plasma glucose (SSPG) to evaluate IR in a population of obese and non obese patients, both to prove the applicability of the method in our country and to evaluate the effects of obesity on insulin resistance.

Method: The SSPG method of Harano was used, with personal modifications to simplify equipment requirements. After a 12 hour fasting, a solution of ocreotide acetate (Sandostatin$^{(R)}$) (50ug bolus, infusion at 75 ug/h), insulin (7.5 mU/kg bolus, infusion at 0.77 mU/kg/min), glucose (6 mg/kg/min), potassium (0.5 mmol/kg/min), water and blood (25 cc) was infused for two hours, with measurement of blood glucose at 0 and 120 minutes. Glucose level at 120 minutes correlate directly with the degree of IR. The method was applied to 13 patients, 7 with body mass index (BMI)$>$25 (obese), and 6 non obese (BMI$<$25).

Results: No significant difference in initial glucose level was found between the obese and non obese groups (94.929 mg% versus 80.5 mg%, p$>$0.1 respectively), but at 2 hours the difference was clear (244.429 mg% versus 129.5 mg%, p$<$0.0004, respectively).

Conclusions:

1) Obese Costarican subjects have significantly higher levels of insulin resistance than non obese subjects.
2) Harano's SSPG method can be applied with existing equipment in Costarican national hospitals to measure insulin sensivity.

1094

IMPROVEMENT IN INSULIN SENSITIVITY BUT NOT IN GLUCOSE EFFECTIVENESS FOLLOWING CHANGES IN BODY COMPOSITION.

AM Rosenfalck, H Hendel, M Højby, T Almdal, J Hilsted and S Madsbad. Department of Internal Medicine and Endocrinology, Hvidovre University Hospital, Copenhagen, Denmark.

In normal subjects insulin sensitivity is related to the body composition with a positively correlation to the relative muscle mass and a negative correlation to the relative fat mass. The purpose of the present study was to evaluate the relation between changes in insulin sensitivity and noninsulin mediated glucose disposal (glucose effectiveness, S_G) and the changes in body composition following weight reduction. 12 obese subjects (11♀, 1♂), age 45.8 $\pm$ 10.5 years, body weight (BW) 99.7 $\pm$ 13.3 kg, BMI 35.3 $\pm$ 2.8 kg/m^2 were examined before and one year after treatment with Orlistat (pancreaslipase inhibitor) for 12 month. At inclusion and two years later an oral glucose tolerance test, a frequently sampled intravenous glucose tolerance test (FSIVGTT) and a DXA whole body scanning was performed. The included subjects obtained quite different changes in weight ranging from a loss of 18.9 kg to a gain of 6.2 kg. Corresponding ranges for changes in lean body mass (LBM) were -4.6 to 0.9 kg, in fat mass (FM) -17.9 to 8.7 kg, relative FM -12.2 to 5.5% , insulin sensitivity (SI) from -2.6 to 2.1 10^{-4}min^{-1}uU^{-1}ml^{-1} and S_G 0 - 0.027 min^{-1}. No significant changes in S_E was observed. A stepwise multiple regression analysis revealed that the strongest predictor for change in SI was delta FM (r=0.81, p$<$0.003), explaining 67% of the variation in SI.

Conclusion: There is a strong correlation between change in insulin sensitivity and change in body weight. Change in total body fat mass is the strongest predictor for change in insulin sensitivity. S_G seems to be independent of changes in body composition.

1095

THE BREATH TEST USING PURE [1-^{13}C] GLUCOSE : A NEW SIMPLE METHOD FOR EVALUATING THE GLUCOSE OXIDATION CAPACITY.

M.Hirai[1,2], T.Shimosegawa[1], A.Hirai[1,2], K.Satoh[1], A.Takasu[1], A.Masamune[1], H.Akai[2], K.Iida[3], K.Takatori[3], M.Kajiwara[3] and T.Toyota[1]. Tohoku University School of Medicine[1], Sendai Kosei Hospital[2], Sendai, Meiji College of Pharmacy[3], Tokyo, Japan

Stable isotope of carbon, ^{13}C has been widely used as a tracer of metabolic analyses, and breath tests using the isotope have become valuable clinical tests, in which ^{13}C-labeled compounds are administered and the the ^{13}C/^{12}C ratio(δ^{13}C) of the expired CO_2 is measured. The aim of this study was to examine the glucose oxidation capacity in non insulin dependent diabetes mellitus (NIDDM) patients using [1-^{13}C] glucose. After an overnight fast, aqueous solution of 75g of usual glucose and 1g of pure [1-^{13}C] glucose was administered orally and the δ^{13}C was measured in the NIDDM patients and the controls at 1, 2, 3, 4, and 5 hrs using gaschromatography-mass spectrometer. The glucose oxidation capacity was impaired in the NIDDM group compared with the control group. The delta over the baseline (Δ^{13}C) of δ^{13}C in the expired CO_2 at 3hrs after the load was significantly lower in the NIDDM group (37.21±8.13, n=9) than the control group(50.73±7.76, n=4) (p=0.017). The glucose oxidation capacity was also measured under the insulin-nonstimulating condition, wherein only 1g of [1-^{13}C] glucose dissolved in saline was ingested, and the δ^{13}C in the breath CO_2 was determined in the 2 groups. The Δ^{13}C at 2hrs was 51.53±16.17 in the NIDDM patients(n=11) and 76.54±16.58 in the controls(n=4) (p=0.02), suggesting that the glucose oxidation capacity at the basal state was also impaired in the NIDDM compared with the controls. We also examined the glucose oxidation in the NIDDM patients before and after treatments using 1g of [1-^{13}C] glucose. The Δ^{13}C in the breath CO_2 at 2hrs was 46.97±13.99 before treatments(n=9) and 58.59±9.83 after treatments(n=6). In conclusion, the breath test using [1-^{13}C] glucose is a simple and useful method for evaluating the glucose oxidation capacity. The present results suggest that the glucose oxidation capacity is impaired in NIDDM under both endogenous insulin-stimulating and nonstimulating conditions. The impairment of glucose oxidation at basal state may be partly reversible by treatments of hyperglycemia.

1096

NO EVIDENCE OF SEASONAL VARIATION IN INSULIN SENSITIVITY IN YOUNG ADULTS

C.H. Gravholt[1], P. Holck[1], B. Nyholm[1], E. Christiansen[2] and O. Schmitz[1]. [1]Medical Department M, Aarhus University Hospital, Aarhus; [2]Medical Department A, Rigshospitalet, Copenhagen, Denmark.

Insulin resistance is of pathogenetic importance for the development of NIDDM and essential hypertension. Not much is known of the variation in insulin sensitivity in the individual over longer periods. We measured insulin sensitivity (Si) and glucose effectiveness (Sg) in healthy male adults (24.2±1.8 y, mean±SD) (N=10) five times over a period of 15 months. Data from a FSIVGTT (minimal model), indirect calorimetry, BMI, maximal aerobic capacity (V_{O_2}-max), 24-hour blood pressure and fat free mass (FFM) was measured. ANOVA was used to detect differences between examinations and linear regression analysis to examine the slope of individual Si and Sg for every patient. Slopes were compared by T-test. Regression coefficients for Si and Sg for every single person did not differ from zero (Si: p=0.7; Sg: p=0.3). The coefficient of variation (CV) for Si was 24.0% and the fractional SD was 3.7% (SD: 2.51), whereas the CV for Sg was 26.0% and the fractional SD was 16.0% (SD: 6.4). The seasonal pattern in presentation of NIDDM can be described as following a sinus curve. Applying a very flexible multiple linear regression model to explain any kind of seasonal variation in S_I and S_G did not reveal any trends in variation. The model, expected to follow a sinus curve, was without restrictions as to when the insulin sensitivity might be highest or lowest and allowed for different levels of insulin sensitivity (or glucose effectiveness) between individuals and different phases, e.g. individuals could have high and low insulin sensitivity at different times of the year. The model also allowed us to test the impact of covariates, e.g. the additional variables measured in the study. Si (p=0.38), Sg (p=0.71), fasting insulin (p=0.98), maximal aerobic capacity (p=0.13), BMI (p=0.64), energy expenditure (p=0.19), 24-hour blood pressure (systolic: p=0.37 and diastolic: p=0.48) and fat free mass (p=0.92) were constant over time. In conclusion we observed no significant seasonal variation in insulin sensitivity and glucose effectiveness in healthy sedentary young men. Therefore indices of these two variables obtained at different times of the year, appear to be comparable.

1097

COMPARISON OF EUGLYCAEMIC CLAMP AND LOW-DOSE INSULIN INFUSION IN ASSESSING INSULIN SENSITIVITY IN NIDDM PATIENTS.

J. Webber, D. Whitelaw, J. Smith and M. Nattrass. Selly Oak Hospital, Birmingham, UK.

The hyperinsulinaemic euglycaemic clamp is widely used as the gold standard in the assessment of insulin sensitivity. However, although it provides a good index of insulin-mediated glucose-uptake, lipolysis is completed inhibited at much lower concentrations of insulin than are commonly obtained during the clamp. The low-dose insulin infusion, which achieves physiological insulinaemia, allows more detailed assessment of NEFA metabolism. The aim of this study was to compare clamp measures of insulin sensitivity (M values) with those obtained during low-dose insulin infusion. 13 men with NIDDM (age 56.2 ± 2.4 (mean ± SEM); BMI 28.7 ± 0.8 kg m^{-2}), treated with diet alone were studied. During the clamp insulin was infused at 2 mU kg^{-1} min^{-1} for 180 min, whilst during the low-dose protocol insulin was infused sequentially at 0.005, 0.01 and 0.05 U kg^{-1} min^{-1} for 60 min at each dose. Insulin concentrations during the clamps were 183 ± 9 mU L^{-1}, whilst during low-dose infusion they were 15.9 ± 2.0, 22.1 ± 2.7 and 62.8 ± 4.5 mU L^{-1} respectively. Blood glucose and plasma NEFA during the low-dose insulin infusion were plotted against log plasma insulin, and the glucose and NEFA concentrations at an insulin level of 30 mU L^{-1} were calculated and used as measures of insulin sensitivity (I_{30}). Mean M value was 33.4 ± 2.2 μmol kg BW^{-1} min^{-1}. The correlation between clamp M values and insulin infusion I_{30} values for glucose was 0.64 ($p < 0.05$). There was no correlation between either of these indices of glucose metabolism and the I_{30} values for NEFA. The low-dose insulin infusion demonstrates that insulin sensitivity, as assessed by measures of glucose metabolism, may not equate with other actions of insulin such as inhibition of lipolysis.

1098

CHRONIC CIGARETTE SMOKING AND INSULIN RESISTANCE IN PATIENTS WITH NIDDM.

G. Targher, M. Alberiche, M.B. Zenere, R.C. Bonadonna, M. Muggeo and E. Bonora. Division of Endocrinology and Metabolic Diseases, University of Verona, Verona, Italy.

Aim of this study was to evaluate the effects of chronic cigarette smoking on insulin sensitivity in patients with NIDDM. We examined 28 smokers and 12 nonsmokers with NIDDM. The two groups were comparable for sex, age, body mass index, waist/hip ratio, alcohol consumption, degree of physical activity, glycometabolic control as well as diabetes duration and treatment. Plasma glucose, insulin and C-peptide concentrations following an oral glucose load were measured. Total, non-oxidative and oxidative rates of insulin-mediated glucose disposal were assessed by using a 4 hour euglycemic hyperinsulinemic clamp (20 mU/min·m^2 body surface area) in combination with [^{3}H]-3-D-glucose infusion and indirect calorimetry. Insulin and C-peptide responses to oral glucose load were significantly higher in smokers than in nonsmokers, while glucose levels were not substantially different. During insulin clamp total glucose disposal was markedly reduced in smokers than in nonsmokers (19±1.2 vs 33±5 μmol/min·kg fat free mass; p<0.001), in a dose-dependent manner (F=6.8, p<0.001 by ANOVA when subjects were categorized for number of cigarettes smoked per day). Oxidative (9±1 vs 14±2 μmol/min·kg fat free mass; p<0.01) and non-oxidative (10±1 vs 19±4 μmol/min·kg fat free mass; p<0.01) pathways of insulin-mediated intracellular glucose metabolism were similarly reduced in smokers vs nonsmokers. Plasma free fatty acid levels (240±33 vs 130±23 μEq/L; p<0.05) and lipid oxidation rate (1.39±0.1 vs 0.95±0.2 μmol/min·kg fat free mass; p<0.05) were less suppressed by hyperinsulinemia in smokers than nonsmokers. In conclusion, chronic cigarette smoking seems to markedly aggravate insulin resistance in patients with NIDDM. Smoking cessation might favourably affect cardiovascular risk and long-term glycometabolic control through an improvement of insulin sensitivity in NIDDM.

1099

Insulin Sensitivity in NIDDM: Insulin Modified Intravenous Glucose Tolerance vs Isoglycemic Hyperinsulinemic Clamp

G. Mehring[1], PA Coates[2], PC. Brunel[3], SD. Luzio[2], P. Beck[2] and DR. Owens[2]. [1]Biometrics and [3]Medicine and Clinical Research Dept, Ciba-Geigy, Basel, Switzerland; [2]Diabetes Research Unit, Llandough Hospital, Penarth, U.K

This study compares estimates of insulin sensitivity derived from minimal modelling (MINMOD) of a 4-h insulin-modified frequent sampled intravenous glucose tolerance test (FSIVGTT) with the isoglycemic glucose 'clamp' in subjects with NIDDM, also assessing the reproducibility of the FSIVGTT Twelve men aged 59 ±2.6 years, time from diagnosis 6.3±0.6 years, BMI 28 1±1 0 kg/m^2 (mean±SE) after a 12-hour overnight fast, underwent a FSIVGTT (300 mg/kg glucose at 0 min; 0.05 U/kg insulin at 20 min) and an isoglycemic hyperinsulinemic clamp (40 mU.$min^{-1}m^{-2}$) in random order 2-4 weeks apart. Reproducibility of the FSIVGTT was tested in four patients carried out on three separate occasions. FSIVGTT data were assessed by means of standard MINMOD and both univariate and multivariate techniques. The sensitivity index for the FSIVGTT ranged from 0.162 to 3.292 (mean 1.378) $*10^{-4}$*mL/(min*μU) for the standard approach and from 0.163 to 2.727 (mean 1.180) $*10^{-4}$*mL/(min*μU)] for the multivariate analysis. For SI_{clamp}, the minimal value was 3.06, the maximum 10.86 and the mean 6.19 $*10^{-4}$ $*L^{-2}$/(min *pmol). The correlation of the insulin sensitivity indices between the clamp and the FSIVGTT was 0.51 (p=0.056, n.s.) for the univariate and 0.67 (p=0.017) for the multivariate analyses. Repeated FSIVGTTs showed a lower variability for the multivariate than for the standard approach.

SMOKING AND MUSCLE BLOOD FLOW AND GLUCOSE UPTAKE ASSESSED BY POSITRON EMISSION TOMOGRAPHY

E.M. Rönnemaa, T. Rönnemaa, M. Raitakari, H. Laine, T. Utriainen, O.-P. Pitkänen and P. Nuutila. Department of Medicine, University of Turku, Turku, Finland

Previous studies have suggested that smoking is associated with decreased insulin sensitivity. We hypothetized that this might be caused by decreased muscle blood flow. We studied 22 healthy non-diabetic men, eight smokers and 16 non-smokers. Mean age was 37 years and BMI 24.8 kg/m^2 in both groups, VO_2 max was 35±9 mL/kg/min in smokers and 42±8 mL/kg/min in non-smokers (p=0.11). Basal and insulin-stimulated femoral muscle blood flow was measured using [^{15}O]-water and glucose uptake using [^{18}F]-fluorodeoxyglucose with positron emission tomography. Whole body glucose uptake was assessed using the hyperinsulinemic (5 mU/kg/min) euglycemic clamp technique. Fasting plasma insulin was 9.4±3.4 mU/L in smokers and 6.3±2.4 mU/L in non-smokers (p=0.016). In the basal state, muscle blood flow was 50% lower in smokers (18±4 mL/kg/min) than in non-smokers (36±20 mL/kg/min; p=0.006). Respective insulin-stimulated values were 30±10 and 53±36 mL/kg/min (p=0.038). There was no difference between smokers and non-smokers in whole body glucose uptake (49±13 vs 48±10 μmol/kg/min) or in femoral glucose uptake (116±32 vs 106±39 μmol/kg/min). We conclude that differences in skeletal muscle blood flow between smokers and non-smokers are not reflected in differences in insulin sensitivity. Our finding does not support the idea that muscle blood flow is a major determinant of insulin sensitivity.

1101

ASSESSING GLUCOSE EFFECTIVENESS WITH THE MINIMAL MODEL: INSIGHTS FROM AN IVGTT AT BASAL INSULIN

A. Caumo, G. Meregalli, R. Ghelardi, S. Scotto, R. Mangili, A.E. Pontiroli, and (*) C. Cobelli. Istituto Scientifico San Raffaele, Milano, and (*) Dipartimento di Elettronica ed Informatica, Universita' di Padova, Padova, Italy.

The minimal model estimate of glucose effectiveness (S_G) is affected by an error that is related with the monocompartmental approximation of the model and is dependent on the insulin profile during the IVGTT. It is commonly believed that S_G can be accurately estimated by maintaining insulin at the basal level during the test. However, a recent theoretical analysis by our group, showing that glucose decay at basal insulin is two-exponential (and not monoexponential as predicted by the minimal model), casts doubts on S_G validity even under such optimized conditions. In this study we assessed the validity of S_G estimated from an IVGTT at basal insulin against a model-independent measure of glucose effectiveness. For this purpose we analyzed IVGTT studies in 12 NIDDM subjects who showed no incremental insulin response to the glucose bolus. We found that glucose decay was two-exponential (with fast and slow time constants equal to 0.2 and 0.01 min^{-1}, respectively) and that the model well-described the glucose data only from 20 min onwards, i.e. when the contribution of the fast time constant became negligible. When the model was identified ignoring the glucose data collected in the first 20 min of the test, S_G resulted similar to the slow time constant of the two-exponential decay in each subject. S_G validity was tested against a model-independent measure of glucose effectiveness (GE). GE was derived from the area under the glycaemic excursion and was mathematically shown to be equivalent to the clamp measure of glucose effectiveness. To allow a comparison with GE (ml/kg min), S_G (min^{-1}) was multiplied by the minimal model volume (V, ml/kg). S_GV and GE resulted similar (3.5±0.6 vs 3.4±0.6 ml/kg min) and highly correlated (r=0.98). In conclusion, although the minimal model suffers from the monocompartmental approximation, S_GV estimated from an IVGTT at basal insulin is equivalent to a model-independent measure of glucose effectiveness directly derived from the glucose curve.

1102

PARADOXICAL ASSOCIATIONS BETWEEN SMOKING AND GLUCOSE METABOLISM

J.B. Ruige, J.M. Dekker, S J.L. Bakker, J.M. Mooy, L.M. Bouter and R.J. Heine. Institute for Research in Extramural Medicine, Vrije Universiteit, Amsterdam, The Netherlands.

We studied the relationship between smoking and glucose metabolism in non-diabetic subjects. Glucose tolerance was assessed in a general population sample of 2,484 subjects, aged 50-74, with an oral glucose tolerance test. Subjects with diabetes (n=200, WHO-criteria) were excluded. Multiple linear regression analyses were performed using fasting- (FPG) and post-load plasma glucose (2h-PG) levels and HbA_{1c} as dependent variables. Smoking and ex-smoking were used as independent variables and adjusted for age, gender, BMI, waist to hip ratio, triglycerides, HDL-cholesterol, hypertension, alcohol consumption, fasting specific insulin and plasma glucose levels. After adjustment, there was no association between smoking and fasting plasma glucose. Smokers, as well as ex-smokers, had a lower post-load plasma glucose and smokers had a higher HbA_{1c}. Thus, while smokers had a similar fasting plasma glucose and a lower post-load glucose, they had a higher HbA_{1c}. Increased glycosylation caused by smoking seems to be the most logical explanation. Apparently, smoking dissociates glucose levels and levels of glycosylation. The underlying mechanism remains to be established.

Table — Glucose and HbA_{1c} according to smoking category.

	non-smokers n = 756	ex-smokers n = 770	smokers n = 730
FPG (mmol/l)	5.4 (0 5)	5.5 (0 6)*	5.5 (0.6) *
2h-PG (mmol/l)	5.8 (1.6)	5.6 (1.7)*	5.3 (1.6) *
β		-0.2 (-0.3 – 0.0)*	-0.5 (-0.6 – -0.3)*
HbA_{1c} (%)	5.3 (0.5)	5.3 (0.5)	5.5 (0.5) *
β		0.0 (0.0 – 0.1)	0.2 (0.2 – 0.3)*

Data are non-adjusted mean values (SD), and adjusted regression coefficients β (95% Confidence Interval)

*) $p < 0.05$ vs non-smokers.

1103

ESTIMATING INSULIN SENSITIVITY FROM ORAL GLUCOSE TOLERANCE TEST

M.A. Boroujerdi, S.B. Bowes, A.M. Umpleby, D. L. Russell-Jones, R.H. Jones, C. Lowy, P.H. Sonksen. United Medical and Dental Schools of Guy's and St Thomas' Hospitals, London, United Kingdom.

A kinetic model of glucose distribution and metabolism was used to explore whether the plasma glucose and insulin measurements following a 75 g oral glucose tolerance test (OGTT) can provide a useful measure of insulin sensitivity. The glucose kinetic model is non-linear incorporating glucose transporters as a mechanism for glucose uptake such that glucose disappearance rate becomes saturable. The glucose entry to the model assumes that 50% of the ingested glucose will appear in the systemic circulation within two hours as an output flux of a cascade of three compartments. During the OGTT the increment in plasma insulin concentration above basal acting from a remote compartment controls the number of available glucose transporters and the rate of glucose uptake while reducing hepatic glucose production rate from its basal steady state value. Mean values of plasma glucose and insulin concentrations were taken from published OGTTs in three groups of subjects. A controls group, a group with impaired glucose tolerance (IGT) and a group with NIDDM. Simulation of these results indicates an increase in glucose production rate in NIDDM (14.43 μmol/min/kg) compared to the value in controls (9.06 μmol/min/kg) and (10.12 μmol/min/kg) in IGT. During the OGTT only the controls and IGT groups increased the number of functioning glucose transporters and the rate of glucose uptake by (60% and 60%) and (30% and 30%) respectively. Basal glucose production rate was reduced by 80% in the controls and by 60% and 40% in IGT and NIDDM groups. The insulin sensitivity defined as the ratio of the change in glucose utilisation rate (maximum value minus basal) to the increase in plasma insulin concentration from basal value were 0.37, 0.16 and 0.16 in the controls, NIDDM and IGT groups respectively.

1104

SMOKING IS ASSOCIATED WITH HIGHER INSULIN LEVELS AND LOWER SEX HORMONE BINDING GLOBULIN IN NIDDM MALE PATIENTS
A.Vrionidou,A.Garidou,V.Loi,S.Papavergis,T. Koursouba and C.Phenekos
Department of Endocrinology,Red Cross Hospital,Athens,Greece.

Both insulin resistance and normal insulin action have been reported in smokers.In view of the great importance of insulin resistance in the pathogenesis of NIDDM,we investigated the concentrations of fasting plasma insulin (IRI) and sex hormone binding globulin (SHBG),both indices of insulin action,in 95 male NIDDM patients (mean age 62.06,range 30-75 years),on treatment either with diet or/and oral hypoglycemic agents.In the study group 68 patients neither smoked nor had been smokers in the past 10 years whereas 27 consumed at the time of the investigation up to 20 cigarettes/day (range 8-20) for more than 5 years.We applied multiple analysis of variance to detect differences between means and the LSD test for post-hoc comparisons.The groups did not differ significantly in the degree of glycaemic control,as assessed by fasting glucose and HbA1c levels nor in the body mass index.The latter,as well age and duration of the disease,were entered as covariates in the statistical model.It was found that IRI (Mean±SEM) was higher in the smokers group (109.56±11.2 versus 86.8±8.06 pmol/L),p=0.05,whereas SHBG was significantly lower(33.6±5.06 versus 41.8±6.84 nmol/L),p=0.03.No difference was detected in total,HDL cholesterol and triglycerides levels.It is concluded that chronic cigarette smoking may exacerbate the inherent insulin resistance characteristic of the diabetic syndrome as shown by the increased fasting insulin and low SHBG concentrations detected in our study group.

1105

VALIDATED MEASURE OF GLUCOSE EFFECTIVENESS AND ITS METABOLIC COMPONENTS FROM I.V. GLUCOSE INJECTION.
M. Ader, T.-C. Ni, and R.N. Bergman. University of Southern California, Los Angeles, CA, USA.

Glucose effectiveness (GE) is a major determinant of glucose tolerance, and is particularly important to the determination of tolerance in the prediabetic state. To quantify GE, and its components of glucose-mediated stimulation of glucose uptake ($GE_{(uptake)}$) and suppression of hepatic glucose output ($GE_{(HGO)}$), we injected cold glucose (0.3 g/kg), into which 3-^{3}H-glucose (1.2 μCi/kg) was added (n=8 dogs). The dynamic insulin response was prevented by somatostatin, and basal hormones were replaced. After rising with injection, glucose fell towards basal, with a $t_{½}$ of 28±4 min (K_G = 0.88 min^{-1}); tracer decline was more rapid ($t_{½}$ = 20±1 min; p=0.047). Cold and hot data were analyzed with a validated 2-compartment model of glucose kinetics: compartment 1 reflects the plasma pool, from which R_d is considered independent of insulin; compartment 2 is the remote, interstitial space, the primary site of insulin-stimulated R_d. Total GE, expressed as a fraction of the plasma glucose pool, averaged 0.0298±0.0022 min^{-1} (range: 0.0202 to 0.0409). Glucose's action on R_d ($GE_{(uptake)}$) dominated overall GE, averaging 0.0206±0.0014 min^{-1} (71.6±6.1% of total); $GE_{(HGO)}$ was 0.0092±0.0024 min^{-1} (28.4±6.1% of total). Model-based GE estimates were confirmed by independent measures in the same dogs obtained from hyperglycemic clamps at basal insulin (p>0.38 by paired t-test, after all measures converted to similar units of dl/min). These data indicate that glucose-stimulated R_d, not suppression of HGO, dominates glucose effectiveness. Also, similar values are found from dynamic and steady-state protocols. Glucose effectiveness is a major component of glucose tolerance which can be accurately measured. Its overall role in the pathogenesis of NIDDM remains to be elucidated.

1106

INSULIN RESISTANCE IN FAMILIAL COMBINED HYPERLIPIDEMIA.
J.F. Ascaso, A. Merchante, S. Lorente, J. Real, M. Tolosa, A. Priego, J. Martinez-Valls, FJ Ampudia and R. Carmena. University of Valencia. Valencia. Spain.

Goals. To study the insulin sensitivity index (Si), using the Minimal model method, and its relationship with central obesity in 31 non-smokers, normotensive Familial Combined Hyperlipidemia (FCH) male subjects. *Subjects*: 31 FCH males, mean age 48.2±9.6 y., with central obesity (WHR ≥0.95; n=23) were compared with 20 control subjects of similar age, gender and body weight. Secondary hyperlipidemia was ruled out and plasma TC, TG, HDL-C, Apo B, FFA, glucose and insulin at baseline and during OGTT (75 g glucose) were measured. Intravenous glucose tolerance test (Minimal model method) modified with insulin was performed. *Results:* The Si index was 1.65±0.96 $x10^{-4}$ min^{-1} mU/l in FCH subjects and 2.86±1.22 $x10^{-4}$ min^{-1} mU/l in controls (p<0.01). In the 8 FCH subjects with WHR <0.95 Si was 2.66±0.96 $x10^{-4}$ min^{-1} mU/l and AUC glucose 858±99 pmol/l/min, significantly different (p<0.01) from FCH with WHR ≥0.95 and Si 1.30±0.68 $x10^{-4}$ min^{-1} mU/l and AUC glucose 1203±201 pmol/l/min. In this group, fasting and 120 min plasma glucose, triglycerides and 120 min plasma insulin were significantly higher (p<0.01) than in FCH with WHR <0.95. In all FCH subjects the Si index correlated negatively with the BMI, WHR, FFA and triglyceride concentrations. *Conclusions:* Insulin resistance (expressed as low Si values) is a frequent finding in patients with FCH, with or without abnormal glucose tolerance. Central obesity exacerbates the hyperglycemia, hyperinsulinemia, and hypertriglyceridemia. These abnormalities could predispose to the elevated cardiovascular risk present in FCH subjects.

1107

COMPARISON OF INSULIN TOLERANCE TEST WITH VARIOUS SIMPLE AND SAFE METHODS IN THE PREDICTION OF INSULIN SENSITIVITY.
Y.Altuntaş[1],Ü.Korugan[2],N.Hekim[3]
[1]Haseki State Hospital, [2]University of Istanbul, Cerrahpaşa Medical Faculty, Department of Endocrinology and Metabolism, [3]Pakize Tarzi Laboratuary, Istanbul-TURKEY

In the measurement of insulin sensitivity, intravenous insulin tolerance test (IVITT) has been shown to have a high correlation with the euglycemic hyperinsulinemic clamp method. We compared IVITT with levels of plasma Insulin/Glucose ratio (IGR), levels of plasma insulin/C-peptid ratio (ICR), fasting and 1-h postload insulin levels in 58 nondiabetic obese subjects (Mean BMI :28.9±3.4 kg/m2, Age: 42.8±8.5 yrs). The glucose levels were determined at 3 min intervals for 15 min after insulin injection. Insulin sensitivity was estimated with blood glucose disappearance rate (KITT). KITT 3.52±2.38%.min-1; fasting IGR 35.2±25.8 pM/mM;1-h postload IGR 138.5±74 pM/mM; fasting ICR 0.14±0.13 pM; 1-h postload ICR 0.25±0.15 pM, fasting and 1-h post load insulin levels were 124.2±48, 882±364 pM, respectively. KITT correlated only with fasting insulin level (r=0.52, p<0.05) and fasting IGR (r=-0.47, p<0.05). Fasting insulin level correlated with 1-h postload insulin level (r=0.58, p<0.05) Fasting IGR correlated with 1-h postload IGR (r=0.55, p<0.05) and fasting ICR (r=0.65, p=0.003) Fasting ICR correlated with 1-h postload ICR (r=0.67,p<0.001). As a conclusion, fasting IGR, in terms of having a good correlation with IVITT, is shown to be a simple and safe method in the measurement of insulin resistance in obesity in epidemiological studies.

LONG-TERM AMYLOPECTIN FEEDING CAUSES TISSUE-SPECIFIC CHANGES IN INSULIN RESPONSIVENESS

J. Higgins, J. Brand Miller and G. Denyer. University of Sydney, Australia.

Dietary starch consists of a mixture of amylose (AMOSE) and amylopectin (AMPEC). AMOSE is more slowly digested and absorbed than AMPEC. We have previously shown that long-term AMPEC feeding causes whole body insulin resistance with respect to AMOSE feeding. The present study was conducted in order to define the tissue-specific effects of long-term AMOSE- or AMPEC-feeding and thereby identify the primary lesion responsible for the onset of insulin resistance in the AMPEC-fed rat. Male Wistar rats were maintained on AMOSE or AMPEC diets for a period of 26 weeks, at which time hyperinsulinemic-euglycemic clamps were performed at either basal (50 μU/ml) or mid-physiological (150 μU/ml) plasma insulin concentrations. Immediately following sacrifice, the liver, soleus muscle and adipose tissues were excised and frozen until assayed for the rate of glucose uptake, glycogenesis and lipogenesis. At physiological plasma insulin concentrations, glucose metabolic flux was significantly greater in AMOSE-fed than AMPEC-fed animals in all tissues but brown adipose tissue (BAT). In particular, glycogenesis was impaired in AMPEC animals relative to AMOSE animals. For example, the rate of glycogenesis in liver from AMOSE-fed animals (117 ± 10 nmol glucose incorporated/min/g) was double that observed in AMPEC-fed rats (54 ± 8 nmol glucose incorporated/min/g; $p < 0.01$). Despite this extensive decrease in tissue-specific insulin responsiveness, AMPEC-fed animals displayed no impairment in whole body glucose disposal due to compensatory glucose flux through lipogenesis in BAT. The rate of lipogenesis in BAT from AMPEC-fed rats (443 ± 77 nmol glucose incorporated/min/g) was more than double that from AMOSE-fed animals (203 ± 34 nmol glucose incorporated/min/g; $p < 0.05$). These tissue-specific changes in glucose metabolic flux may be indicative of a 'pre-insulin resistant' state similar to that which occurs during the onset of obesity.

1109

CONSEQUENCES OF UNDERMODELING ON GLUCOSE EFFECTIVENESS AND INSULIN SENSITIVITY FROM THE MINIMAL MODELS ASSESSED BY MONTE CARLO SIMULATION.

Paolo Vicini[1], Andrea Caumo[2] and Claudio Cobelli[1]. [1]Department of Electronics and Informatics, University of Padova, Italy, and [2]Scientific Institute San Raffaele, Milano, Italy.

The cold (CMM) and hot (HMM) minimal models of the IVGTT are a powerful tool to investigate glucose metabolism in vivo. They allow to estimate, from glucose, tracer glucose and insulin data, metabolic indices of the glucose-insulin system, namely glucose effectiveness (GE) and insulin sensitivity (IS) (of peripheral uptake & endogenous production those of the CMM, S_G and S_I, of peripheral uptake only those of the HMM, S_G^* and S_I^*). Recently, the MM single compartment approximation of glucose kinetics has been questioned on a theoretical basis. Here, its consequences are investigated via Monte Carlo (MC) simulation, by using a physiologically based two compartment model of the glucose-insulin system as a reference model (RM). The RM allows to generate a high number of noisy synthetic data sets of glucose, tracer glucose and insulin plasma concentrations during an IVGTT, which are then analyzed with the CMM and the HMM. The CMM and HMM indices are then compared with the "true" ones from MC simulation. Results (mean of 400 runs) show that: A) correlation of S_G=1.99 10^{-2} min^{-1} with the RM GE=1.33 10^{-2} min^{-1} is weak (r=0.54), B) S_I=2.39 10^{-4} min^{-1} per μU ml^{-1} is well correlated with the RM IS=6.46 10^{-4} min^{-1} per μU ml^{-1} (r=0.92), but severely underestimates it, C) S_G^*=1.01 10^{-2} min^{-1} is correlated (r=0.68) with the RM clearance rate FCR=1.59 10^{-2} min^{-1}, but not with the RM GE GE^*=0.89 10^{-2} min^{-1} (r=0.34), D) HMM insulin sensitivity S_I^*=3.66 10^{-4} min^{-1} per μU ml^{-1} is well correlated (r=0.91) with the RM index IS^*=5.02 10^{-4} min^{-1} per μU ml^{-1}. Correlations and comparison of means improve, for the HMM indexes only, if a volume of distribution is used. These results show that S_G is the parameter most affected by the single compartment approximation and that the indices of HMM are much more robust than those of the CMM.

Insulin Resistance in Diabetes, Pathogenesis of NIDDM

1110

TIME-DEPENDENT REGULATION OF INSULIN RECEPTORS, GLUT4, HEXOKINASE II, AND GLYCOGEN SYNTHASE BY INSULIN IN RAT MUSCLES

A. Handberg, L. Koranyi, L. Groop, J. Vinten and S.J. Koopmans. University of Copenhagen, Denmark, Wallenberg Institute, Malmoe, Sweden and University Hospital Leiden, The Netherlands

Our aim was to study the time-course of insulin-dependent regulation and expression of the insulin receptor (IR), insulin dependent glucose transporter (GLUT4), hexokinase II (HK II), and glycogen synthase (GS) in skeletal muscle of rats. Conscious rats were exposed to euglycemic (6 mM) hyperinsulinemia (100 mU/l) for 0, 0.5, 2, 4, 8, or 12 hours, and subsequently soleus, gastrocnemius, and rectus muscles were freeze clamped and studied in vitro. Insulin receptor number and affinity for insulin was unaffected by in vivo insulin exposure, and receptor number correlated with basal glucose uptake ($r=0.9$, $p<0.025$). IR tyrosine kinase activity (IRTK), however, was increased almost twofold ($p<0.01$) after in vivo insulin stimulation (0.5–12 h), and correlated with insulin levels during the clamp ($r=0.4$, $p<0.01$). A transient, muscle-type dependent reduction (4 and 8 h, $p<0.05$) of GLUT4 and no change in GS protein levels were found. GS activity in both soleus and gastrocnemius muscles showed a transient increase (0.5 h, $p<0.01$) in fractional velocity with no change in Vmax. This was accompanied by a transient increase of GLUT4, GS, and HK II mRNA (0.5 h, $p<0.1$) after in vivo insulin exposure. Insulin levels during the clamp correlated with GLUT4 protein in gastrocnemius muscles ($r=0.4$, $p<0.05$) and with GLUT4 mRNA in soleus muscles ($r=0.67$, $p<0.005$). These data indicate that primary insulin receptor signalling is unaffected by prolonged in vivo insulin stimulation in muscle, whereas the insulin response can be modified at the post-receptor level by transient effects of insulin on mRNA or protein levels and enzyme activities in certain effector systems.

1111

AGGRAVATING EFFECT OF FATTY MUSCLE AND FATTY LIVER ON HYPERINSULINEMIA IN PATIENTS WITH NIDDM

S. Katoh[1], Y. Mori[1], J. Yokoyama[1], N. Tajima[1], Y. Ikeda[1] and K. Ikeda[2]. [1] Jikei Univ. Sch. of Med., Tokyo, [2] Kawaguchi Municipal Medical Center, Saitama, Japan

Recently, triglyceride deposition in skeletal muscle has been reported to be associated with insulin resistance in obese patients. In the present study, we examined the effect of triglyceride deposition in muscle and liver, which is the major target organ of insulin, on plasma insulin level in patients with NIDDM. For 37 NIDDM patients (BMI 24.28±11.13kg/m^2, 21 men, 16 women), the abdominal CT was performed to evaluate mean hounsfield unit of psoas muscle (PmCT) of the umbilical region, liver (LmCT) and spleen (SmCT). We evaluated fatty muscle and fatty liver by the ratio of PmCT/SmCT and LmCT/SmCT respectively. Visceral fat area (V), subcutaneous fat area (S) and V/S ratio were measured by the abdominal CT of the umbilical region. Furthermore, we evaluated insulin response by the oral glucose tolerance test. Fasting plasma insulin level (FIRI) inversely correlated significantly with PmCT/SmCT ratio and LmCT/SmCT ratio ($r=-0.59$; $r=-0.66$, $p<0.05$, respectively). There were no significant relationship between V/S ratio and FIRI. In 16 female cases, FIRI inversely correlated significantly with PmCT/SmCT ratio and LmCT/SmCT ratio ($r=-0.75$; $r=-0.83$, $p<0.05$, respectively). In conclusion, not only fatty muscle but also fatty liver may contribute to fasting hyperinsulinemia in patients with NIDDM.

1112

GLUT 4 EXPRESSION IS MUSCLE GROUP SPECIFIC IN TYPE II DIABETES MELLITUS. D.S. Hardin and J. Karczewski. University of Texas, Houston,TX USA.

Significance: We have previously described muscle group specificity of GLUT 4 expression in rats and in human controls and athletes. However, to date, muscle group specificity of GLUT 4 expression in human diabetics has not been evaluated. Such specificity could have ramifications for the interpretation of data regarding the relationship of GLUT 4 and insulin sensitivity in humans. We hypothesized that expression of GLUT 4 is muscle-group specific in human diabetics. Methods: In order to test our hypothesis, 9 non-insulin dependent diabetes mellitus subjects, "NIDDM" (ages:39-53;HbA1c=5.9-11.4;BMI=21-52) underwent percutaneous biopsies of 3 separate muscle groups: vastus lateralis (V), gastrocnemius (G) and biceps (B). Each muscle sample was snap-frozen in liquid nitrogen for future quantification of GLUT 4 content. GLUT 4 was isolated by SDS-PAGE and immunoblot analysis and was quantified with I^{125}-labelled anti-rat GLUT 4 antibody and radionucleotide counting. Results: Muscle-group specific expression of GLUT 4 was determined by calculating a percentile for each muscle group (% of total gamma counts relative to the total counts in all three muscle groups) in each individual subject. Results for all patients reveal significant and consistent differences between expression of GLUT 4 in the leg muscles (G=40±9%, V=33±7%, and B=34±6%; $p<0.05$ between V and the other two muscle groups). Also noted was a positive correlation between BMI and GLUT 4 content in all muscle groups (G:r=0.64,V:r=0.71,B:r=0.75). A negative correlation was noted for HbA1c with biceps (r=-.65) and vastus (r= -.61); however this relationship was not observed in gastrocnemius (r=-.29). Summary: 1) Muscle-group specific expression of GLUT 4 was observed in these NIDDM subjects; 2) GLUT 4 expression was significantly lower in V than in G or B; 3) Positive correlation was observed between GLUT 4 and body mass index in all muscle groups; 4) negative correlation was observed between GLUT 4 content and HbA1c in V and B. Speculation: In humans, V is the most commonly sampled muscle group for determining the role of GLUT 4 in mediating insulin resistance. Perhaps additional muscle groups should be studied before dismissing down-regulation of GLUT 4 expression as a mechanism of human insulin resistance.

1113

EFFECT OF MATERNAL DIABETES ON BETA CELL FUNCTION AND INSULIN SENSITIVITY IN NON DIABETIC OFFSPRINGS.

J. Biarnés, I. Camps*, JM. Fernández-Real, J. Soler** and M. Fernández-Castañer**. Endocrinology Unit, Hospital Josep Trueta de Girona, * Endocrinology Unit, Hospital Arnau de Vilanova de LLeida, ** Endocrinology Department, CSU Bellvitge, Barcelona, Spain.

The aim of our study was to analyze the effect of paternal and maternal antecedents of NIDDM on beta cell function and insulin resistance parameters in non-diabetic offsprings of NIDDM. Ninety-nine non-diabetic first-degree offsprings: 31 with a NIDDM father (Group A) and 68 with a NIDDM mother (Group B) were studied. We measured total and HDL-cholesterol, triglycerides, fasting serum glucose, insulin and C-peptide. We performed a 5 mg/kg ideal weight continous infusion of glucose (CIGMA) to evaluate beta cell function and insulin sensitivity from achieved values of glucose, C-peptide and insulin respectively. The groups were matched by age, sex and BMI. Group B have higher waist/hip ratio (0.93 ± 0.08 vs 0.87 ± 0.08, p = 0.007), higher fasting (96.1 ± 54.9 vs 77.6 ± 20.5 pmol/l, p = 0.01) and achieved (243.0 ± 142.1 vs 195.6 ± 77.5 pmol/l, p= 0.03) insulin levels than Group A. Blood pressure, triglycerides, cholesterol, fasting and achieved serum glucose, C-peptide, beta cell function and insulin sensitivity were not different. We concluded that offsprings of NIDDM mothers exhibit higher waist/hip ratio and hyperinsulinemia, factors that are linked to an increase risk for NIDDM.

1114

EVIDENCE OF AN INCREASED NUMBER OF TYPE IIb MUSCLE FIBRES IN INSULIN RESISTANT RELATIVES OF NIDDM PATIENTS.

B.Nyholm[1], Z.Qu[2], A.Kaal[1], S.B.Pedersen[1], C.H.Gravholt[1] J.L.Andersen[2], B.Saltin[2] and O.Schmitz[1].[1] Dept. of Medicine M, Aarhus Kommunehospital, Aarhus and [2]Copenhagen Muscle Research Centre, Rigshospitalet, Copenhagen, Denmark.

Insulin resistance is a common feature in healthy first-degree relatives of NIDDM patients. To explore the mechanism(s) behind this condition in more detail, a percutaneous muscle biopsy (vastus lateralis) was performed in 25 first-degree relatives of NIDDM patients (R) and 21 matched controls (C) to examine muscle fibre composition and capillary density. Insulin-stimulated glucose uptake (Rd) was measured employing a hyperinsulinaemic (insulin infusion rate 0.6 mU/kg/min) euglycaemic clamp and maximal aerobic work capacity (VO_2max) was determined using a bicycle ergometer test. All had a normal OGTT. Rd (5.76±0.35 vs 8.06±0.36 mg/kg LBW/min, $p<0.001$) and VO_2max (49.3±2.8 vs 57.2±3.5 ml/kg LBW/min, $0.05<p<0.10$) were decreased in R vs C. An increased number of type IIb fibres (29.5±2.5 vs 21.0±2.8 %, $p<0.05$) was observed in R compared to C, whereas no significant differences were found in the other muscle fibre types or the capillary density between the two groups. Correlations were observed between number of type I fibres (positive), number of type IIb fibres (negative) and capillary density (positive) vs Rd (Type I fibres: $r=0.39$, $p<0.01$; type IIb fibres: $r= - 0.51$, $p<0.001$; capillaries/ type 1 fibre: $r=0.44$, $p<0.01$; capillaries/IIb fibre: $r=0.35$, $p<0.05$) as well as VO_2max (Type I fibres: $r=0.47$, $p<0.01$; type IIb fibres: $r= - 0.42$, $p<0.01$; capillaries/type 1 fibre: $r=0.39$, $p<0.05$; capillaries/IIb fibre: $r=0.45$, $p<0.01$). In a multiple linear regression analysis with Rd as the dependent variable, VO_2max ($p<0.001$), family history of NIDDM and number of type IIb fibres ($p<0.05$) significantly determined the level of Rd ($r^2=0.64$), whereas capillary density did not. In conclusion, insulin resistant first-degree relatives of NIDDM patients are characterized by an increased number of type IIb muscle fibres. Wether this finding reflects a reduced physical activity level and fitness in R or is of primary genetic origin remains to be determined.

1115

FACTORS WHICH DETERMINE THE WORSENING OF INTRAVENOUS GLUCOSE TOLERANCE IN THE OFFSPRING OF PATIENTS WITH NIDDM

D. Araújo, D A. García-Estévez and J. Cabezas-Cerrato. S. de Endocrinología. C.H.U S Santiago de Compostela University. Santiago de Compostela. Spain.

Objective. In order to evaluate the factors which determine the worsening of intravenous glucose tolerance in subjetcs at high risk for developing NIDDM 15 glucose-tolerant offspring of NIDDM patients and 21 control subjects were studied. **Research design and methods**. Each subject underwent a frequently sampled intravenous glucose tolerance [FSIGT] test. K_G index was calculated between 10 and 40 min of an FSIGT test. Insulin sensitivity [S_I], glucose effectiveness at zero insulin [GEZI] and first and second phases of insulin responsiveness [Φ_1 and Φ_2] were estimated using glucose and insulin kinetics minimal models. The acute insulin response to glucose [AIRg] was calculated as the area under the insulin curve above basal betwen 0 and 10 min., and the suprabasal insulin effect was determined by the product of S_I times AIRg. **Results.** Offspring showed a lower S_I [14.1 ± 7 5 vs 9.25 ± 4.20 $\times 10^{-5}$ $min^{-1}(pmol \cdot l^{-1})^{-1}$, $p<0.01$] and a similar AIRg [3284 ± 2280 vs 3105 ± 1499 $pmol \cdot l^{-1}$, NS] than controls. Sample division according to median of K_G showed that control subjects with low tolerance had a lower AIRg [4417 ± 2531 vs 2043 ± 1068 $pmol \cdot l^{-1}$, $p<0.05$] and lower suprabasal insulin effect [0.057 ± 0.03 vs 0.023 ± 0.009 min^{-1}, $p<0.05$] than controls with high tolerance. Offspring with low tolerance had a lower AIRg [2574 ± 1197 vs 3707 ± 1656 $pmol \cdot l^{-1}$, $p<0.05$] and a lower GEZI [0.101 ± 0.05 vs 0.212 ± 0.08 $\times 10^{-1}$ min^{-1}, $p<0.05$] than offspring with high tolerance. Offspring with high and low tolerance showed lower Φ_1 [375 ± 155 vs 272 ± 181 vs 698 ± 336 $(pmol \cdot l^{-1})min(mmol \cdot l^{-1})$, NS] than controls with high tolerance. **Conclusions**. Our data suggest that a decrease in GEZI and in AIRg are the main factors responsible for the worsening of intravenous glucose tolerance in offspring of NIDDM patients.

1116

ACUTE AND TISSUE SPECIFIC REGULATION OF GLUTAMINE: FRUCTOSE-6-PHOSPHATE AMIDOTRANSFERASE BY INSULIN IN VIVO

***E. Rissanen, *A. Virkamäki, *S. Hämäläinen and H. Yki-Järvinen. *Minerva Foundation for Medical Research and Department of Medicine, University of Helsinki, Helsinki, FINLAND**

Previous studies have shown that chronic changes (4 days) in glycemia and insulinemia can regulate glutamine:fructose-6-phosphate amidotransferase (GFA) in human and rat skeletal muscle. We examined whether GFA regulation by insulin exhibits tissue specificity and whether it responds to acute hyperinsulinemia induced by a 2-hour insulin clamp (insulin infusion rate 18 mU/kg'min) in nondiabetic (glucose 6.6±0.5 mmol/l, n=16) and STZ-diabetic (20.1±1.4 mmol/l, n=16) rats. In the nondiabetic rats, 2 hours of hyperinsulinemia increased liver GFA activity by 21 % from 244±16 to 295±14 pmol/mg'min ($p<0.02$). In the diabetic rats, both basal (182±17, $p<0.01$) and insulin-stimulated (241±10, $p<0.01$) GFA activities were significantly lower than in the nondiabetic rats. The insulin induced 32 % increase in GFA was significant also in the STZ rats within the 2 hour period ($p<0.01$). In hindlimb muscle, GFA activities were 50-54 % lower in the diabetic vs nondiabetic rats both basally (18.9±5.5 vs 34.9±4.3, $p<0.02$) and during hyperinsulinemia (21.1±2.3 vs 31.7±4.4, $p<0.05$) but insulin didn't change GFA acutely in either group. In the brain, GFA activities were comparable both basally (80±13 vs 93±6) and during hyperinsulinemia (84±7 vs 83±4, diabetic vs control rats). These data demonstrate that GFA is chronically downregulated by the combination of hyperglycemia and hypoinsulinemia in insulin sensitive tissues such as liver and in skeletal muscle but remains unaltered in the brain, which is insulin insensitive. In the liver, GFA activity is acutely increased by insulin implying that the time course for insulin regulation of GFA is shorter than has been previously thought.

1117

CAFETERIA DIET CAUSES FEATURES OF INSULIN RESISTANCE IN MATERNAL PROTEIN-RESTRICTED RAT OFFSPRING

M.Desai, CD.Byrne, K.Meeran*, ND.Martenz, SR.Bloom* and CN. Hales. University of Cambridge, Cambridge, UK; *Hammersmith Hospital, London, UK.

The aim of the present study was to investigate whether the interaction of early maternal protein restriction combined with a subsequent cafeteria diet would affect the glucose and lipid metabolism in the offspring. Rats were exposed to either a maternal 20% (C) or an isocaloric 8% (LP) protein diet during fetal and postnatal life. All offspring were weaned on to a normal laboratory chow until 6 weeks, at which time they continued on either the same diet or were fed a cafeteria diet. After 48hrs starvationt, at 12 weeks of age, significantly increased plasma insulin concentrations were seen in LP rats on a cafeteria diet compared to male C rats on the same diet [606 (479-766) vs 462 (392-542) pmol/l, geometric mean (95% CI) of n=10 per group; p=0.03]. This was despite a 16% reduction in body weight in LP rats compared to C rats ($p<0.001$). Nevertheless, in both C and LP rats fed cafetria diet, the blood glucose (6.0 ± 0.1 vs 5.9 ± 0.1 mmol/l, mean ± SEM, respectively), plasma triglyceride [1.82 (1.64-2.23) vs 1.27 (1.00-3.36) mmol/l] and non-esterified fatty acid concentrations [1.28 (1.12-1.46) vs 1.36 (0.97-1.90) mmol/l] were comparable. Furthermore, cafeteria diet did not result in a significant increase in insulin concentrations in the female LP rats compared to C rats, suggesting that some factor(s) associated with gender protected these rats [174 (111-274) vs 221 (180-273) pmol/l, respectively]. Thus, male rats exposed to maternal protein-restricted diet during early development and fed a high fat-high calorie diet in later life were becoming insulin resistant at only 12 weeks of age although this was not sufficient to affect their blood glucose levels or lipid profile.

1118

GLUCOSE TOLERANCE IS RELATED TO LIVER PROTEIN KINASE A ACTIVITY IN NORMAL AND DIABETIC MONKEYS.

N.L. Bodkin and H.K. Ortmeyer. University of Maryland at Baltimore, Baltimore, MD USA

It is well known that impaired glucose tolerance is a hallmark of insulin resistant states, including older age and type 2 diabetes mellitus. We have previously shown that the basal activity of liver protein kinase A (PKA), a serine/threonine kinase, was strongly inversely related to age in a group of monkeys (age between 13 to 29 years) with a wide range of insulin sensitivity. In these same monkeys (4 were normal, 5 were hyperinsulinemic, and 7 had type 2 diabetes) we now report that the basal activity of liver PKA (1.8 to 39.1%) is positively related to glucose tolerance (glucose disappearance rate from 0.6 to 4.3 %/min) as measured during an intravenous glucose tolerance test ($r=0.54$, $p<0.05$). In order to determine whether PKA activity was related to glucose tolerance without age as a confounding variable, basal fasting PKA activity was measured in liver samples from 10 young adult (7 yr old) monkeys. The monkeys ranged in body weight from 7 to 12 kg, in body fat from 4 to 19 %, in fasting plasma glucose from 2.6 to 3.6 mmol/l, in fasting plasma insulin from 162 to 462 pmol/l, in glucose disappearance rate from 2.2 to 5.3 %/min, and in acute (0-10 min) insulin response to intravenous glucose (AIR) from 510 to 1704 pmol/l/min. Basal PKA activities ranged between 2.2 to 21.8 %. PKA activity was strongly positively related to glucose disappearance rate in these young adult monkeys ($r=0.78$, $p<0.005$). We conclude that the impaired glucose tolerance associated with aging may be due in part to a decrease in basal liver PKA activity, and that basal liver PKA activity may determine glucose disappearance rates in lean young adult rhesus monkeys.

1119

INSULIN SENSITIVITY IN FIRST DEGREE RELATIVES OF NIDDM PATIENTS.

Ali Abbassy, Gamal El-Bassiouny, Ahmed Gamal, Aida Saleh, Soheir Said, Mona Abou El-Soud.

This Study was designed to predict whom of the first degree relatives of type II Diabetes is Vulnerable to become diabetic.

The Study was conducted on 15 obese (groupI) and 15 non obese (group II) obese first degree relatives of type II diabetics compared with 10 healthy control Subjects of matched age and sex with no family history of diabetes or other endocrinopathies.

Intravenous glucose tolerance test, C peptide levels after intravenous glucagon, glucose decay constant, incremental areas under glucose and insulin curves were determined. Also, first and second phase insulin secretion were estimated and insulin sensitivity (S_I), glucose effectivenes (S_G) were calculated using MINMOOD computer program. Our results revelead only a significant change in insulin senstivity between group I & II (Reduction 40.91, $P< 0.028$) while there was no significant change on comparing between group I & controls & group II & controls.

These results indicate that the obese first degree relatives of NIDDM patients are more suceptible to diabetes than non obese relatives.

1120

IN VIVO INSULIN INCREASES THE ACTIVITY OF SKELETAL MUSCLE PROTEIN KINASE A IN PREDIABETIC MONKEYS.

H.K. Ortmeyer, N.L. Bodkin and B.C. Hansen. University of Maryland at Baltimore, Baltimore, MD USA.

Insulin activation of skeletal muscle glycogen synthase and glucose disposal is defective in both prediabetic and diabetic primates. The reduced activation of glycogen synthase by insulin could be the cause of lower glucose disposal rates, and could be the result of the failure of insulin to inhibit cAMP-dependent protein kinase activity, a.k.a. protein kinase A (PKA). To examine this proposed mechanism, PKA activity was measured in skeletal muscle (vastus lateralis) samples freeze-clamped *in situ* before (basal fasting) and during a euglycemic hyperinsulinemic clamp in 27 rhesus monkeys. Nine of the monkeys were normal (normal fasting glucose and insulin), 8 were prediabetic (normal fasting glucose and hyperinsulinemia) and 10 had spontaneous type 2 diabetes (hyperglycemia). Insulin lowered PKA activity in normal monkeys (basal vs insulin-stimulated, 14.4 ± 3.2 vs $8.1 \pm 1.8\%$, $p<0.05$), but raised PKA activity in prediabetic monkeys (5.4 ± 1.4 vs 10.5 ± 2.6, $p<0.05$). PKA activity was unaffected by insulin in the diabetic monkeys (6.7 ± 1.8 vs $7.5 \pm 1.4\%$). Basal PKA activity was higher in normal monkeys compared to prediabetic ($p<0.05$) and diabetic monkeys ($p<0.05$). Basal PKA activity was inversely related to the insulin-stimulated minus basal change in PKA activity ($r=-0.72$, $p<0.001$). We conclude that in vivo insulin during a euglycemic hyperinsulinemic clamp decreases skeletal muscle PKA activity in normal monkeys but is unable to decrease the activity of PKA in insulin resistant (prediabetic and diabetic) monkeys. Also, the insulin resistant state is characterized by low basal fasting skeletal muscle PKA activity.

1121

THE INFLUENCE OF FAMILY HISTORY ON INSULIN SECRETION AND SENSITIVITY IN NORMAL GLUCOSE TOLERANT OFFSPRING OF NIDDM PROBANDS

F.J. Pirie, M.A.K. Omar, A.A. Motala, A. Amod, G.M.B. Berger and E. Gouws. University of Natal, Durban, South Africa.

Normal glucose tolerant first degree relatives of non-insulin dependent diabetic probands have been shown to have metabolic abnormalities including impaired first phase insulin secretion, insulin resistance and hyper-proinsulinaemia. The current study aimed to evaluate insulin levels at fasting and 2 hours after 75g oral glucose in relation to the family history of NIDDM

Patients and methods:

109 subjects, normal glucose tolerant by the WHO criteria were drawn from an incidence study cohort. 38 had maternal inheritance, 24 paternal, 16 bi-parental and 31 nil inheritance of NIDDM on history. Basic demographic data was collected and all subjects underwent a standard 75g oral glucose tolerant test. Homeostasis model assessment and the insulinogenic index at 120 minutes were used to estimate ß-cell function and insulin sensitivity.

Results:

The groups were matched with respect to age, gender, systolic and diastolic blood pressure. Body mass index was marginally different between groups ($p=0.062$). There was a significant difference between groups for waist-hip ratio ($p=0.021$). No significant differences were found between the groups for fasting insulin ($p=8601$), insulin at 120 minutes ($p=0.587$), insulin-glucose ratio at 0 and 120 minutes ($p=0.1589$ and $p=0.8478$), the insulinogenic index at 120 minutes ($p=0.9748$), % ß-cell function or insulin sensitivity as assessed by the HOMA model ($p=0.6989$ and $p=0.1994$).

Conclusion:

The presence of a single or bi-parental family history of NIDDM does not confer a special risk for the disorder in terms of ß-cell function or insulin resistance as computed by the HOMA model in the Durban Indian population.

INCREASED ACTIVITY OF MEMBRANE GLYCOPROTEIN PC-1 IN JAPANESE NIDDM PATIENTS WITH INSULIN RESISTANCE

S. Teno, Y. Iwamoto, H. Kanno, S. Kumakura, A. Yokokouji, R. Kanamuro, A. Sato and Y. Omori. Tokyo Women's Medical College, Tokyo, JAPAN.

Insulin resistance is one of the characteristic features of non-insulin-dependent diabetes mellitus (NIDDM). Recent studies revealed that the membrane glycoprotein PC-1 inhibited insulin receptor tyrosine kinase and played a role at least in part in the insulin resistance of NIDDM. In order to know whether PC-1 activity of fibroblasts is also elevated in Japanese NIDDM patients, we measured the PC-1 activity of cultured fibroblasts obtained from 12 NIDDM patients (BMI; 27.5 ± 7.8, mean $\pm$SD) including 7 insulin resistant patients with reduced glucose infusion rate (GIR; 1.45 ± 0.26 mg/kg/min) during euglycemic clamp study and 7 nondiabetic controls (BMI; 23.8 ± 2.6). A diabetic patient with Werner's syndrome (WS; 29yr, male; GIR 1.21 mg/kg/min) was also a subject of this study. Dermal fibroblasts taken from these subjects by forearm skin biopsy were cultured in DMEM with 10% FCS, and the PC-1 activity of the fibroblasts were measured using [^{35}S] 3'-phosphoadenosine, 5'-phosphosulphate as a substrate. Levels of PC-1 activity of 12 NIDDM patients and 7 insulin resistant patients were 98.3 ± 31.8 and 107.9 ± 26.3 nmol/mg/min, and were higher than controls (42.6 ± 13.8 nmol/mg/min, $p<0.01$). PC-1 activity of the patient with WS was also elevated (99.0 nmol/mg/min). The results suggest that the insulin resistance is correlated with PC-1 activity of skin fibroblasts in Japanese NIDDM patients and a patient with WS.

1123

EARLY INSULIN SECRETORY DEFECT RATHER THAN INSULIN RESISTANCE AS A METABOLIC DEFECT IN OFFSPRING OF NIDDM

Y-S. Chung, K-W. Lee and H-M. Kim. Department of Endocrinology and Metabolism, Ajou University, Suwon, Korea

Pathogenesis of non-insulin-dependent diabetes mellitus(NIDDM) is heterogeneous; both insulin secretory defect and peripheral insulin resistance contribute to the development of NIDDM. The purpose of this study was to clarify the mechanism of early metabolic defect causing NIDDM in the offspring of Korean NIDDM patients. Eight control subjects(age 25.5±1.6; BMI 22.8±0.9) and six healthy offspring of NIDDM patients(age 25.4±2.7; BMI 22.9±1.7)participated in this study. 75g oral glucose tolerance test(GTT) with C-peptide and insulin response, euglycemic hyperinsulinemic clamp test, and hyperglycemic clamp test were performed. First and second phases of insulin secretion were defined as the mean of 0-10min and 10-120min. insulin secretion during hyperglycemic clamp test, respectively. Oral GTT revealed that all of the study subjects had normal glucose tolerance levels. The offspring of NIDDM and control subjects showed similar insulin secretory capacity in oral GTT(insulin area under the curve; control 75.4±14.6 vs. offspring 72.6±21.1μU/ml x hr). There was no significant difference in peripheral insulin sensitivity between control and offspring groups(control 8.13±1.42 vs. offspring 8.34±1.01mg/kg/min). Two out of the six offspring of NIDDM had decreases in first and second phases of insulin secretion in hyperglycemic clamp test compared to normal control subjects, and the mean values were slightly lower in offspring group (first 27.7±7.1, second 46.4±10.4μU/ml) compared to control group (first 37.7±5.8, second 71.9±19.9μU/ml). In conclusion, early metabolic defects of Korean offspring of NIDDM maybe related to insulin secretory defect rather than peripheral insulin resistance.

1124

SKELETAL MUSCLE TRIGLYCERIDES IN IMPAIRED GLUCOSE TOLERANCE AND NIDDM.

K-F. Eriksson[1], E. Laurila[1], B. Kiens[2] and L. Groop[1]. Dept of Endocrinology, Lund University, Malmö, Sweden[1] and August Krogh Institute, Copenhagen University, Denmark[2].

Increased triglyceride content is believed to be an important factor for insulin resistance in skeletal muscles. In the Malmö study 125 65-year old men, originally identified in a health screening project, were subjected to a hyperinsulinaemic euglycaemic 2-h clamp combined with indirect calorimetry and a needle biopsy of the vastus lateralis muscle at the end of the clamp. Muscle triglycerides were analysed with a fluorometric assay and expressed in mmol/kg dry muscle weight. At the preceding OGTT 56 men had NIDDM, 34 impaired glucose tolerance (IGT) and 35 normal glucose tolerance (NGT) (WHO criteria). All groups were well matched for BMI (27.6, 27.8 and 27.1), for percent body fat (25.1, 24.0 and 22.5) and fat distribution (wast to hip ratio 0.99, 0.98 and 0.97) whereas maximal oxygen uptake was lower in the NIDDM and IGT groups (2.1, 2.3 and 2.4 l/min, p=0.004). Mean fasting glucose was 8.6, 4.8 and 4.6 mmol/l and serum triglycerides 2.2, 1.5 and 1.4 (p=0.003). Total glucose disposal was lower in the NIDDM and IGT groups (3.2, 4.2 and 5.7 mg/min/kg, p=0.0001), affecting both non-oxidative (1.6, 2.4 and 3.6 mg/min/kg, p=0.0001) and oxidative (1.6, 1.8 and 2.1 mg/min/kg, p=0.0001) glucose metabolism, but lipid oxidation was increased in the NIDDM group (0.6, 0.4 and 0.5 mg/min/kg, p=0.0008). The muscle triglyceride concentration was similar in all groups (63.4, 76.2 and 65.1 mmol/kg) but higher in normalweight (BMI 22.9) IGT subjects (62.2, n=6) than in both normalweight NGT (37.1, n=8) and NIDDM subjects (30.5, n=12) (p=0.02 and p=0.04). Considering all subjects muscle triglycerides correlated with BMI (r=0.42, p=0.0001), waist to hip ratio (r=0.24, p=0.02), total glucose disposal (r=-0.18, p=0.04), non-oxidative glucose metabolism (r=-0.19, p=0.03) but not with serum triglcyerides. In a general linear model muscle triglycerides were dependent upon BMI (p=0.0001) and inversely upon lipidoxidation (p=0.03) but not upon the glucose metabolism. In conclusion muscle triglycerides are not increased in NIDDM when taking body weight into account but may be increased in IGT.

1125

INCREASED SPLANCHNIC GLUCOSE OUTPUT AFTER ORAL GLUCOSE IN NIDDM WAS BASED ON THE SECONDARY INSULIN RESISTANCE

T. Ishida, S. Horikawa, H. Daikuhara, H. Hosokawa, Y. Sayou and J. Takahara. Kagawa Medical University, Kagawa, Japan.

The both pre and postprandial hyperglycemia in NIDDM are based on both impaired peripheral glucose clearance (PGC) and increased splanchnic glucose output (SGO). The different tissue of insulin (Ins) resistance (IR) was studied with either hyper-insulinemic euglycemic clamp combined with oral glucose (OG) (0.2-0.75g/kg) or hyperglycemic clamp with OG (0.1-0.5g/kg) with or without basal Ins replacement. The rate of SGO after OG (%SGO) was analysed. Attitude of Ins release was analysed by the delta increment of Ins after OG (75g). These studied were performed before and after glycemic control. Before glycemic control, most of non-obese NIDDM (N=66) have IR on both peripheral and hepatic tissue. Hepatic IR was well negatively correlated with the delta increment of Ins in non obese NIDDM. NIDDM with subcutaneous fat syndrome (N=12) have marked decrease of PGC and mild increase of %SGO (85-90%) (control value of 60-70%), while NIDDM with visceral fat syndrome (N=14) have marked increase of %SGO (95-100%) and mild decrease of PGC. Mitochondrial abnormal DM (N=4) had markedly increased SGO (90-96%) and mild decreased PGC. After acute replacement of basal Ins, half of increased SGO was normalized. After reaching excellent glycemic control, the DM whose delta increment of Ins was over 30 μU/ml obtained the improvement of SGO. We founded that the increased SGO was normalized by both replacement of basal Ins and improvement the daily profile of blood glucose, though the attitude of Ins secretion after OG was not normalized despite the excellent daily glucose profile.

1126

INOSITOL GLYCAN IN INSULIN ACTION AND RESISTANCE.

J. Larner, G. Allan, M. Sleevi and L.C. Huang, Insmed Pharm., Richmond, Va. and University of Virginia, Charlottesville, Va., U.S.A.

Insulin interacts with its receptor and provokes a series of multiple intracellular events. Defects in these signaling pathways can lead to insulin resistance. The formation of low molecular weight substances termed insulin mediators is one of the products of the signaling events. We have purified and characterized one of these insulin mediators as an inositol glycan (IG). This mediator has been idenitified as 3-O-methyl-D-chiroinositol-galactosamine (IG). This pseudo disaccharide acts as potent stimulator of phosphoprotein phosphatases which control key enzymes in glucose metabolism. Several lines of evidence have demonstrated that a defect in its generation contributes to insulin resistance. IG isolated from hemodialysate, urine, and autopsy muscle is deficient in Type II diabetics when compared to control subjects. Similar data have been obtained in both rodent and primate models. Infusion of IG to streptozotocin-diabetic rats restored euglycemia without hypoglycemia. Chemically synthesized IG can mimic insulin action in vivo and in human ovarian cells. In conclusion, we have demonstrated that a IG isolated from bovine liver or synthesized chemically has insulin-like action in vivo and in vitro.

1127

ENHANCEMENT OF GLUCOSE TURNOVER AND OF SUPPRESSION OF HEPATIC GLUCOSE PRODUCTION WITH PORTAL INSULIN DELIVERY IN RATS WITH RENAL SUBCAPSULAR ISLET GRAFTS

J. Guan, M.T. Behme, P.F. Zucker, R. Zhong, P. Atkison, and J. Dupré. University of Western Ontario, London, Canada.

We have demonstrated decreased metabolic clearance of insulin, and insulin resistance, in rats with syngeneic renal subcapsular islet grafts (REN), that reversed streptozotocin diabetes. These abnormalities were absent with portal delivery of insulin after renal-mesenteric-vein anastomosis (RMA). In the present study, glucose turnover (GTR) was determined by ^{3}H-glucose infusion during euglycemic hyperinsulinemic clamps, with matching steady state insulin levels in similar rats with REN with or without RMA. Two months after transplantation, GTR was assessed in 4 REN and 4 RMA conscious fasted rats. After priming of 4 μCi ^{3}H-glucose, ^{3}H-glucose (0.4 μCi/min) was infused for 240 minutes and insulin (REN: 10, and RMA: 20 pmol/kg/min) was infused from 60 to 240 min with 25% dextrose infusion adjusted to maintain euglycemia. Mean values over 45 to 60 min were used for basal state; and over 180 to 240 min for insulin-stimulated steady state (INS-SS). Basal plasma glucose levels were similar (REN: 5.9±0.3, RMA: 6.2±0.1 mM); however insulin levels were higher in REN (132±18 pM) than in RMA rats (70±3), p<.005. During INS-SS, plasma glucose (REN: 4.4; RMA: 4.5 mM) and insulin levels (571±46; RMA: 574±25 pM) were similar. GTR, hepatic glucose production (HGP), and glucose infusion rate (GIR) are tabulated.

		REN	RMA	p
Basal	GTR=HGP, mg/kg/min	6.9 ± 1.2	8.7 ± 1.0	NS
INS-SS	GTR, mg/kg/min	6.5 ± 0.8	11.6 ± 1.0	0.006
	GIR, mg/kg/min	4.1 ± 1.0	15.8 ± 0.9	0.0001
	HGP, mg/kg/min	2.4 ± 0.5	-4.2 ± 0.7	0.0002

Thus we conclude that chronic systemic delivery of insulin from islet grafts results in insulin resistance with impairment of both suppression of HGP and stimulation of GTR. These abnormalities are prevented by portal delivery of insulin.

1128

A TYROSINE PHOSPHATASE AND PKC CONTRIBUTE TO INSULIN RECEPTOR KINASE INHIBITION BY HYPERGLYCAEMIA

A.K. Busch, L.L. Hansen, G.S. Olsen and L. Mosthaf. Hagedorn Research Institute, Gentofte, Denmark.

Cells incubated in high glucose develop an impaired insulin receptor kinase (IRK) activity. Several studies suggested that the activation of serine/threonine kinases might be involved in this effect. It has been speculated that an analogous mechanism is responsible for the reduced IRK activity in NIDDM. We therefore designed a study with a range of specific pharmacological inhibitors of different serine/threonine kinases to identify the crucial proteins involved in IRK modulation. As reported earlier, a relatively unspecific PKC inhibitor (H7), which also inhibits PKA, prevented the negative effect of glucose on IR autophosphorylation. We have now used three specific PKC inhibitors with inhibitory activity to different PKC isotypes: RO318220 (PKC $\alpha,\beta1,\gamma,\varepsilon$), Bisindolylmaleimide (PKC $\alpha,\beta1,\varepsilon,\gamma$) and Gö6976 (PKC δ,ε,ζ). IR tyrosine phosphorylation was reduced to about 51% in cells incubated in 25mM 2-Deoxyglucose. Pre-treatment with RO318220 (100nM) and Bisindolylmalemide (250nM) abolished or reduced this inhibition (110% and 81% of insulin stimulated (100%), whereas Gö6976 had no effect. This most likely indicates that additional PKC isotypes are inhibited by RO318220. After downregulation of PKC with TPA for 16 hrs the IRK inhibition was retained, suggesting that a TPA insensitive isoform can mediate the effect. We could not detect a reversal of the glucose effect with the PI3-kinase inhibitor Wortmannin, the PKA inhibitor H89, the Cam-kinase inhibitor KT5926 or the serine/threonine phosphatase inhibitor ocadaic acid. Treatment of the cells with the tyrosine phosphatase inhibitor vanadate (100µM) abolished the glucose induced inhibition. We also used an antibody that recognises the active form of the stress kinase p38, however, since p38 was not activated a role of this pathway can be excluded. In summary, we can demonstrate that the glucose induced IRK inhibition is regulated by at least two different mechanisms, a PKC isoform that is resistant to downregulation by TPA and a tyrosine phosphatase. We speculate that changes in the expression level or function of these proteins could contribute to the insulin resistant state in obesity and NIDDM.

1129

INSULIN SENSITIVITY AND PANCREATIC β-CELL RESPONSIVENESS IN NEWLY DIAGNOSED NON INSULIN DEPENDENT DIABETICS

L. Chassin, S.D. Luzio, R. Hovorka, D.R. Owens, University of Cardiff College of Medicine, Cardiff, City University, London, UK

We have evaluated insulin sensitivity and pancreatic β-cell responsiveness in newly diagnosed non-insulin dependent diabetics (NIDDMs) and made comparison with BMI-matched normals. A frequently sampled insulin-modified IVGTT (0.3g glucose, 0.05 or 0.03 insulin per kg body weight) with minimal model (MINMOD) assessment of insulin sensitivity (S_I and S_G) was performed in 20 NIDDMs (age: 54±9 yrs, BMI: 28.5±3.6 kg/m^2, FPG: 12.6±3.5 mmol/L; mean±SD) and 20 normals (age: 47±11 yrs, BMI: 28.5±3.7 kg/m^2, FPG: 5.0±0.5 mmol/L). A standardised meal tolerance test (MTT, 75g CHO, 500 kcal) was performed in 16 NIDDMs (age: 50±9 yrs, BMI: 29.3±3.7 kg/m^2, FPG: 12.6±3.2 mmol/L) and 16 normals (age: 50±10 yrs, BMI: 29.2±3.6 kg/m^2, FPG: 5.1±0.5 mmol/L). Pancreatic sensitivity M_I (increase in C-peptide secretion per unit increase in plasma glucose concentration) and basal pancreatic sensitivity M_0 (fasting C-peptide secretion per unit fasting glucose concentration) were calculated employing a novel model of pancreatic responsiveness during MTT. In comparison with normals, insulin sensitivity S_I and pancreatic sensitivity M_I in NIDDMs were reduced by ~80% (S_I: 0.8±0.5 vs 3.8±1.8x10^{-4}/min per mU/L, p<0.001; M_I: 17.7±11.4 vs 90.0±43.3x10^{-9}/min, p<0.001; NIDDMs vs normal), glucose effectiveness S_G by ~25% (1.6±1.0 vs 2.2±0.6x10^{-2} /min, p<0.05), and basal pancreatic sensitivity M_0 by ~50% (5.4±2.2 vs 10.3±4.9x10^{-9}/min, p < 0.005). We conclude that in newly presenting NIDDM there is a 4 to 5 fold reduction in *both* insulin and pancreatic sensitivity.

1130

MUSCLE GLYCOGEN SYNTHASE AND PHOSPHORYLASE IN OBESE SUBJECTS WITH AND WITHOUT DIABETES

R. Munger, A. Golay, F. Assimacopoulos, E. Bobbioni, E. Jéquier, J.P. Felber. University Hospital Geneva and Institute of Physiology Lausanne, Switzerland.

The purpose of the present study was to verify in muscle biopsies, in obese subjects ± NIDDM, previous observations in normal subjects where a rise of plasma FFA by means of a neutral fat infusion was inducing during a glucose-insulin clamp a negative correlation between glycogen concentration [gly] and glycogen synthase activity (GS) and a positive correlation between [gly] and glycogen phosphorylase activity (GP). A euglycemic hyperinsulinemic clamp, associated with indirect calorimetry, was performed in 18 non-diabetic obese, 6 obese diabetic and 9 lean subjects taken as a control. Muscle biopsies were performed in vastus lateralis for measurements of GS, GP and [gly]. Results showed a negative correlation between [gly] and GS (p=0.007) and a positive correlation between [gly] and GP (p<0.001), both in the obese group but not in the control group (NS). The positive correlation between the rise in GS (ΔGS) and [gly] (Δ[gly]) during the clamp in the control group (p=0.05), which might correspond to stimulation of glycogen synthesis by GS, was absent in the obese groups (NS). Plasma FFA were higher (186 ± 24 vs 60 ± 9 µmol/L, p=0.004) in the obese compared to the control group, total glucose disposal (M) lower (3.67 ± 0.42 vs 7.24 ± 0.68 mg/kglbm.min, p=0.0002) and glucose storage lower (1.15 ± 0.42 vs 3.70 ± 0.64 mg/kglbm.min, p=0.004). This study suggests that the negative correlation of [gly] to GS might correspond to inhibition of GS in obese subjects (retrograde regulation of GS) while the positive correlation of ΔGS to Δ[gly], which normally correspond to the stimulation of glycogen synthesis by GS (anterograde regulation), was blunted. The resultant of these two opposite forces in obese subjects and even more pronounced in obese diabetic patients would lead to a lower rise in GS and lower glucose storage in response to the glucose-insulin infusion. The positive correlation of [gly] to GP classically represents stimulation of GP by glycogen concentration. It might possibly oppose inhibition of GP by increase in G-6-P resulting from decreased glucose oxidation. These results present a mechanism which might participate to the decrease in glucose disposal (lower M) and lead to insulin resistance in obesity and type II diabetes.

1131

INSULIN RESISTANCE, HYPERINSULINEMIA AND SALT SENSITIVITY IN NORMOTENSIVE, OBESE TYPE 2 DIABETICS AND NONDIABETICS.

L. Majkowska,W. Wieliczko, E. Andrysiak, B. Krzyżanowska, J. Goździk, R. Bohatyrewicz, and S. Czekalski. Dept. of Endocrinology and Metabolic Diseases, University School of Medicine.

The aim of the study was an evaluation of the relationship between insulin resistance, hyperinsulinaemia, and blood pressure response to salt intake (salt sensitivity) in normotensive, obese (BMI>25,0) patients with and without type II diabetes. Material: 10 newly diagnosed, obese, normotensive type II diabetic patients (DM), aged 18-41 ys (x=35,7±7,2 ys) and 21 obese normotensive subjects (OB), aged 19-43 ys (x=33,1±8,1 ys) without diabetes. BMI and basal 24-h blood pressure measurements were similar in both groups. Plasma insulin levels were measured on fast and during oral glucose tolerance test (OGTT). Insulin sensitivity was estimated by steady-state plasma glucose concentrations (SSPG) achived during infusion of somatostatin, insulin, and glucose. Salt sensitivity was defined as an increase of mean arterial blood pressure > 5% after 7 days of a high vs. 7 days of low dietary Na intake. Insulin resistance was significantly higher in DM than in OB group (SSPG: 11,70±1,2 mmol/L vs. 7,9± 2,4 mmol/L, respectively, p<0,05). Fasting insulin levels were 32,8±12,0 mU/L and 19,1±11,1 mU/L, respecitvely, p<0,01; while insulin secretion measured as area under the curve (AUC) during OGGT wes similar in DM and OB groups (62,9±18,3 mU/L/min and 58,2±17,2 mU/L/min, respectively). Salt sensitivity was found in 6 of DM patients and in 10 of OB patients. SSPG levels in DM group were similar in SS and SR group (11,8±0,6 mmol/L and 11,6 ±1,9 mmol/L, respectively). Fasting insulin levels in DM were higher in SS than in SR group (38,0±8,9 mU/L vs. 25,1±8,2 mU/L, respectively, p<0,05) . In DM patients AUC of insulin during OGTT was also higher in SS than in SR group (71,3±12,1 mU/L/min and 50,2±16,0 mU/L/min, respectively, p<0,05), In OB subjects insulin resistance was higher in SS than SR group (SSPG levels 9,54±1,2 mmol/L vs. 6,82±2,4 mmol/L respectively, p<0,01) while insulin levels and insulin secretion were similar in both SS and SR groups. Conclusion: Salt sensitivity of blood pressure seems to be related to hyperinsulinaemia in normotensive, obese, type II diabetics and to insulin resistance in normotensive, non-diabetic obese subjects.

1132

SKIN FIBROBLAST PC-1 mRNA CONTENT AND INSULIN SENSITIVITY IN KOREAN NIDDM PATIENTS

H-M Kim, D-B Park, Y-S Chung, and K-W Lee. Department of Endocrinology and Metabolism, Ajou University, Suwon, Korea

The pathogenesis of non-insulin dependent diabetes mellitus(NIDDM) consisted of decreased insulin secretion and insulin resistance. The cellular mechanism causing insulin resistance is not fully understood. Recently, It is reported that overexpression of PC-1 is related with insulin resistance in NIDDM patients. The present study was undertaken to determine whether skin fibroblast PC-1 is related with insulin resistance in Korean NIDDM patients. We have measured insulin sensitivity by euglycemic hyperinsulinemic clamp test and PC-1 mRNA content(arbitrary densitometric unit, ADU) of skin fibroblast in 13 Korean NIDDM patients(Age, 31.9±5.0 yr; BMI, 24.7 ±2.5 kg/m') and 8 healthy control subjects (Age, 29.4±5.2 yr; BMI, 22.4±2.2 kg/m'). Insulin sensitivity in NIDDM patients was slightly lower than that of control subjects(5.4±2.6 vs. 7.8±4.2 mg/kg/min, p>0.05). 2. PC-1 mRNA content in the NIDDM patients was slightly higher than that of control subjects(2.4±1.6 vs. 1.9±0.8 ADU, p>0.05). 3. There were significant positive correlation between BMI and PC-1 mRNA content(r=0.51, p<0.05), and negative correlation between BMI and insulin sensitivity(r=0.49, p<0.05). However, there was no significant correlation between insulin sensitivity and PC-1 mRNA content. This data suggest that skin fibroblast PC-1 is not related with insulin resistance in Korean NIDDM patients.

1133

INSULIN SENSITIVITY AND BODY FAT DISTRIBUTION IN A GROUP OF VARYING GLUCOSE TOLERANCE SUBJECTS.

R. Lichiardopol and C. Dumitrescu , Clinic of Diabetes "N. Malaxa" Hospital Bucharest, Romania

The body fat accumulation is associated to insulin resistance. The aim of our study was to evaluate the influence of body mass index (BMI) and of visceral fat accumulation on the insulin resistance and some associated cardiovascular risk factors. After an overnight fast an insulin tolerance test (0.1U.Kg^{-1}), in 28 subjects with varying glucose tolerance, was performed. The mean (± SD) value of the blood glucose disappearance rate (K_{ITT}) was significantly reduced in non-insulin-dependent diabetes mellitus (NIDDM: 1.53 ± 0.4 ;n=13) as compared to normal glucose tolerance (NGT: 3.68 ±1.9 n = 6; p<0.02) impaired glucose tolerance (IGT: 2.72 ± 0.9; n=5 ; p<0.02) and insulin dependent diabetes mellitus (IDDM: 3.65 ± 0.5; n = 4; p<0.001) subjects.
The visceral fat accumulation (waist to hip ratio :W/H) was greater in NIDDM (1.00 ± 0.07) versus IDDM (0.88 ± 0.07; p<0.01) and NGT (0.87 ± 0.09; p<0.01) subjects. It was no significant difference in BMI between NIDDM (28.7 ± 5.6) IGT (31.6 ± 2.1) and NGT (30.5 ± 4.2) subjects. IDDM subjects had lower BMI (21.8 ± 2.6; p<0.01) as compared to NIDDM, IGT and NGT groups. W/H was correlated to K_{ITT} (r = -0.70; n=28;p<0.001), basal insulin levels (r=0.69 ; n=13 ; p<0.05), Total cholesterol/HDL cholesterol ratio (r=0.61;n=23;p<0.01) systolic and diastolic arterial blood pressure (r=0.44; n=28; p<0.05).Between BMI and K_{ITT}, W/H, arterial pressure and lipid parameters it was no significant correlation.
Our data suggest that visceral fat accumulation is associated to insulin resistance and some vascular risk factors, independent of BMI variation.

1134

INSULIN RESISTANCE IN NIGERIAN SUBJECTS WTH NIDDM.

O.A. FASANMADE, A.E. OHWOVORIOLE, T.O. JOHNSON DEPARTMENT OF MEDICINE, LAGOS UNIVERSITY TEACHING HOSPITAL, LAGOS , NIGERIA.

Insulin resistance is now well documented to be closely related to the onset and course of NIDDM. Nigerians are generally thought to be very sensitive to insulin. No previous studies have looked into the insulin sensisitivity status of Nigerians. A study was thus carried out to measure insulin sensitivity (IS) in uncomplicated NIDDM subjects.. The glucose disposal rates (GDR) of the study subjects was compared with a control group. Forty-three (22 males, and 21 females) people with NIDDM were recruited. The two groups of subjects had their IS determined by short insulin tolerance tests. The mean (SEM) of the GDR (the index of insulin sensitivity). for the control subjects was 3.20 (1.06) and 3.17 (1.07) in males and females respectively; in the non diabetics GDR correlated negatively with age, BMI and WHR. The mean (SEM) values for GDR in the NIDDM subject was 1.73 (1.04) and 1.80%(1.06) in males and females respectively. The GDR in NIDDM subjects was significantly lower (p<0.05) than in the control subjects. 70% of NIDDM subjects had insulin resistance by comparison with the controls. We conclude that in Nigerians insulin resistance is commoner than generally thought among people with NIDDM.

1135

BASAL C-PEPTIDE IN ORALLY-TREATED, FAIRLY CONTROLLED NIDDM.

F. Losada, F. Relimpio, A. Pumar, D. Acosta, F. Morales and R. Astorga. Servicio de Endocrinología. Hospital Universitario Virgen del Rocío (Seville, Spain).

We aim at elucidating the relationships of C-peptide and the C-peptide/glycaemia ratio with known surrogate markers for insulin resistance in NIDDM patients in good to fair control obtained without the use of exogenous insulin. To achieve such a purpose, 130 orally-treated patients with a HbA_{1c} level<7.5% have been studied. Non-stimulated C-peptide levels (RIA) and the C-peptide/glycaemia have been determined, and their relationships with the blood pressure status, blood pressure figures, estimates of adiposity, age, known duration of diabetes, current therapies, plasma lipids, glycaemic control, urinary albumin excretion rate, uric acid and creatinine have been ascertained. C-peptide levels were significantly (p<0.05) correlated with systolic (r=0.21) and diastolic blood pressure (r=0.19), BMI (r=0.21), HDL (r=-0.22) and non-HDL-cholesterol (r=0.23), apolipoprotein B (r=0.29), log of triglycerides (r=0.39) and uric acid (r=0.35); and almost significantly (p<0.1) with waist-to-hip ratio (r=0.18) and total cholesterol (r=0.17). The C-peptide/glycaemia ratio had significant correlations with known duration of diabetes (r= -0.23), diastolic blood pressure (r=0.21), BMI (r=0.22), log of triglycerides (r=0.23) and uric acid (r=0.36). Hypertensives had significantly higher C-peptide levels than normotensives (1.04±0.04 vs. 0.88±0.04 nmol/ml, respectively (mean±SE), p<0.05), and this difference remained significant after adjustment for age and known duration of diabetes, and almost significant after adjustment for the previous variables and BMI. The C-peptide/glycaemia ratio was almost significantly greater in hypertensives only after adjustment for age and known duration of diabetes. In conclusion, in well-controlled NIDDM patients not receiving exogenous insulin, both C-peptide levels and the C-peptide/glycaemia ratio have significant relationships with surrogate markers for insulin resistance.

1136

CLINICAL CHARACTERISTICS OF HIGH SERUM CPR LEVELS IN PATIENTS WITH NON-INSULIN DEPENDENT DIABETES MELLITUS.

T.Inukai, Y.Fujiwara, K.Tayama, Y.Aso, K.Ogino and Y.Takemura. Koshigaya Hospital, Dokkyo University School of Medicine, Koshigaya, Japan

Syndrome X is defined as a concept including hyperinsulinemia, impaired glucose tolerance, lipid metabolism disorder and hypertension, and it advances atherosclerosis and then leads to ischemic heart disease. We designed that some of patients with non-insulin dependent diabetes mellitus (NIDDM) might reveal the pathogenesis similar to syndrome X. We therefore analysed clinical characteristics of NIDDM patients showing high serum CPR levels. Studies were conducted in 116 NIDDM patients (male:62, female:54, mean age:54.3 ± 2.4 y-o) therapied by diet alone or oral hypoglycemic agents (OHA). Serum CPR were measured at fasting in the morning by RIA method and then we divided into two groups as follows: one is a high CPR group with values more than 2.3 ng/ml (group A) and another is a normal or low CPR group with those less than 2.3 ng/ml (group B). All patients were measured body weight, blood pressure, and serum lipids. Twenty eight percent of all patients showed high serum CPR levels (Diet:15%, OHA:31%). There was the tendency of a positive correlation between CPR levels and the mean blood pressure. Prevalence of the complication with hypertension in group A was 38%, whereas that in group B was 23%, and therefore a significant discrepancy was observed between both groups. Body mass index in group A was obviously high compared with that in group B, and prevalence of the complication with obesity in group A was significantly higher than that in group B. In lipid, serum triglyceride levels in group A was significantly high compared with that in group B ($p<0.05$).
Conclusions: Diabetic patients with high serum CPR levels were frequently complicated with hypertension, obesity and hypertriglyceridemia, and therefore they might possess a critical risk to provoke the atherosclerosis.

1137

INSULIN RESISTANCE MEASURED WITH SPECIFIC INSULIN ASSAY AND MINIMAL MODELLING IN SUBJECTS WITH NIDDM

C.Kong, V.N. Anyaoku, S. Batty, P. Chong, D G. Goulis, D.G. Johnston, R S. Elkeles and S. Robinson. *Unit of Metabolic Medicine, Imperial College School of Medicine at St Mary's, London, UK.*

NIDDM patients have impaired insulin sensitivity (Si) and glucose effectiveness (Sg) when estimated by minimal modelling. However insulin measurements in previous studies were performed using radioimmunoassay, therefore including biologically less active substances eg. split-32,33 proinsulin. We measured insulin action and secretion in 20 NIDDM and 10 normal subjects using a specific insulin assay measured by ELISA (BMI 24.9 (IQR 24.1-26.5) vs 24.0 (20.7-28.8) $kg \cdot m^{-2}$. Fasting glucose, insulin and lipid concentrations were measured while Si and Sg were derived from Bergman's minimal model applied to an insulin-modified frequently-sampled intravenous glucose tolerance test. NIDDM had significantly higher fasting glucose 9.7 (8.4-10.8) vs 4.9 (4.7-5.3) $mmol \cdot l^{-1}$, $p<0.001$; as well as fasting total cholesterol 5.6 (4.8-6.2) vs 4.7(4.1-5 4) $mmol\ l^{-1}$, $p<0.05$, and triglyceride levels 1.63 (0.90-2 59)] vs 0.64 (0.57-0.68) $mmol \cdot l^{-1}$, $p<0.005$. HDL-C was significantly lower 1.03 (0.90-1.21) vs 1.49 (1.27-1.66) $mmol \cdot l^{-1}$, $p<0.05$ Glucose tolerance as well as first phase insulin response were significantly impaired in NIDDM, 0.60 (0.46-0.77) vs 2.33 (1.57-2 68) $mmol \cdot min^{-1}$, $p<0.001$; 24 (12-146) vs 107 (94-599) $pmol \cdot l^{-1}$, $p<0.05$ but there was no significant difference in fasting insulin levels, 1.8 (1.0-11.8) vs 5.0 (1.4-6.7) $pmol \cdot l^{-1}$. NIDDM also had reduced Si and Sg compared to normals, 3.08 (0.98-6.52) vs 18.26 (5.93-26.90) $10^{-4} \cdot min^{-1}$ per $pmol \cdot l^{-1}$, $p<0.005$; 1.2 (0.9-1.4) vs 2.5 (2.0-2.9) $10^{-2} \cdot min^{-1}$, $p<0.001$. Impaired insulin sensitivity and glucose effectiveness have therefore been demonstrated in NIDDM using our assay for specific insulin which is more logical for modelling purposes

1138

INSULIN RESISTANCE, HIPERINSULINEMIA, OBESITY, HYPERTENSION, AND DYSLIPIDEMIA IN NIDDM SUBJECT IN INDONESIA, S.Ndraha, M. Oemardi, I.Subekti, P.Soewondo, S.Sugondo, S. Waspadji, A.B.Ranakusuma, S. Suyono, Metabolism and Endocrinology Division, Department of Internal Medicine, Faculty of Medicine, University of Indonesia Jakarta, Indonesia

Non Insulin Dependent Diabetes Mellitus (NIDDM) is recognized to be associated with obesity, hypertension, dyslipidemia, hyperinsulinemia and insulin resistance. This cluster of metabolic-cardiovascular disorders is known as the Insulin Resistance Syndrome. However, insulin resistance in NIDDM subjects in Indonesia has not evaluated. A cross sectional study was conducted to find it. The correlation between insulin resistance and obesity, fasting insulin level, hypertension and dyslipidemia were also evaluated.
A body mass index, blood pressure and lipid profile studies as well as euglycemic clamp technique were performed in 20 NIDDM subjects (8 women and 12 men, mean [±SD] age, 46,1 ± 3,5yrs, mean [±SD] BMI, 25,1±4,3 kg/m^2). The mean [±SD] fasting insulin level, insulin sensitivity (M) and sensitivity index (M/I) were 14 ± 6 mU/L, 6,4±2 mg/kg/min and 5,6±2, respectively. BMI had significant inverse correlation with insulin sensitivity. There was a significant correlation between M value and fasting insulin level. However, no significant correlation between systolic, diastolic blood pressure, serum triglyceride, cholesterol HDL and total cholesterol.
The result suggest that (1) fasting insulin level was lower than non diabetic Asian subjects, (2) insulin sensitivity was higher, (3) obesity was associated with insulin sensitivity (4) insulin sensitivity was related to fasting insulin level, but not related to blood pressure, triglyceride, HDL cholesterol and total cholesterol level. As conclusion, insulin sensitivity in NIDDM subjects in Indonesia was higher compared to the previous studies, and no significant correlation between insulin sensitivity and blood pressure, plasma triglyseride, HDL cholesterol and total cholesterol. However, insulin sensitivity was associated with hyperinsulinemia and obesity.

1139

CLINICAL REMISSION IN TYPE I DIABETIC PATIENTS RESULTS FROM ENHANCEMENT OF INSULIN SENSITIVITY

K.Karşıdağ, İ.Arslanoğlu, Y.Altıntaş, İ.Satman, N.Dinççağ, A.R.Odabaş, F.Salman, M.Sargın, A.M.Şengül, Ş.Karadeniz and M.T.Yılmaz. Division of Diabetes, Istanbul Faculty of Medicine, and Insitute for Experimental Medicine, Diabetes Research Unit, Istanbul University, Istanbul-Turkey

In this study, we aimed to investigate peripheral insulin resistance (PIR) and beta cell functions in 8 Type I diabetic patients with clinical complete remission (F/M; 1/7, mean age; 23.8 ± 8.9 year BMI; 22.3 ±3.1 $kg.m^{-2}$, and Hb A_{1c}; 5.82±1.1 %). Remission was induced by multiple subcutaneous insulin injections (MSCII) and defined by no insulin requirement in spite of daytime normoglycaemic for at least 15 days. Results were compared with data of 4 healty control subjects (F/M; 3/1, mean age 21.2±6.5 year, BMI; 19.8±2.2 $kg.m^{-2}$, and HbA_{1C}; 5.6±1.2 %). PIR was assessed with hyperinsulinemic euglycaemic clamp technique and beta cell functions with first phase insulin release (FPIR) to IVGTT and C-peptide stimulation test (after 1 mg Glucagon i.v. injection). No difference was observed in glucose disposal rate (M value) between remission and control subjects (6.76±1. and 7.11±1.1 $mg.kg^{-1}. min^{-1}$). On the contrary, FPIR [(1'+3' min. insulin)-2x basal insulin] was almost completely lost in remission patients (6.01 ± 6.5 $mU.ml^{-1}$, compared to 98.19 ± 23.2 $mU.ml^{-1}$ in control group). Moreover, both basal (BCP) and stimulated C-peptide (SCP) levels in the remission group were found to be significantly lower than in the control group (BCP; 0.6 ± 1.9 and 1.9±0.5 ng/ml, $p<0.005$, and SCP; 1.9±0.7 and 3.4±0.5 ng/ml, $p<0.01$ in remission and control groups respectively). No correlation was noticed between M value and FPIR. As a conclusion, our study suggested that improvement in peripheral glucose utilization induced by removal of glucose toxicity with MSCII rather than relieved endogen insulin secretion capacity might have impact on appearance of clinical remission in Type I diabetes.

1140

IMPAIRED PROTEIN-INDUCED CATECHOLAMINE (CA) EXCRETION IN DIABETIC RATS.

B.N. Mankovsky*, J.B. Young, and B.E. Metzger**. *Institute of Endocrinology and Metabolism, Kiev, Ukraine; **Northwestern University, Chicago, USA**

It was shown earlier that protein supplementation to diet results in an increase of CA excretion in normal humans and animals. However, there is no data regarding the influence of protein on CA secretion in diabetes mellitus. We investigated urine excretion of epinephrine (E), norepinephrine (NE), and dopamine (D) in 18 streptozotocin-induced diabetic (1 month duration of disease) and 18 control rats fed with chow and protein diets. CA were measured by HPLC in urine collected for 24 hours 4 days before and during protein (casein) supplementation. Results were analyzed using ANOVA-test. Basal CA levels were significantly increased in diabetic rats compared to controls. The supplementation of protein led to an increase of CA excretion in control animals with the most pronounced elevation of D excretion. However, in diabetic rats protein induced significant rise of NE excretion only. Urine D levels rose from 27026±2399 to 54275±5130 pmol/ml (mean±SEM), $p<0.01$ in controls, and from 56740±7309 to 70715±12025 pmol/ml, $p>0.05$ in diabetic rats. NE excretion changed from 4014±152 to 4598±222, $p<0.05$ in controls, and from 7404±317 to 9276±990 pmol/ml, $p<0.05$ in diabetics. E excretion did not change significantly in diabetics while it increased in controls by 29.5%. Thus, short-term diabetes mellitus is associated with diminished response of D and E excretion to protein supplementation to diet and these changes may reflect impairment of CA secretion in diabetic rats.

INSULIN RESISTANCE IN CHRONIC LIVER DISEASE WITH IMPAIRED GLICOREGULATION

M.Motocu, D.Sâmpelean, M.Sâmpelean, University of Medicine and Pharmacy Cluj-Napoca, Romania

The aim of this study was to investigate the action of exogenous insulin on glucose metabolism in a group of patients with liver cirrhosis (LC) and chronic hepatitis (CH) in correlation with the altered glucose tolerance (DGT/DM) and the degree of liver damage (LC/CH). **Material and method.** The study was carried out in a group of 36 patients with LC and CH with or without DM or DGT. 11 patients with LC (Child class B and C) also had DM, 4 patients with LC presented DGT after OGTT with 75g powder glucose. The 17 patients with CH, of the same etiology, presented normal oral glucose tolerance. All the patients were submitted to insulin tolerance test (ITT) with i.v. 0,1 IU insulin/Kg body weight, determining the rate of serum glucose disappearance (K-ITT) and the insulin sensitivity index (Delta Glucose/Glucose=DG/G). The area under the curve was also calculated (AUC-TAI method). The results were statistically interpreted using the ANOVA test and the Student t test, comparing the 3 groups. **Results.** 1. A significant decrease of the mean K-ITT in LC with DM was found, compared to CH without DM (2,21 vs. 3,53, $p<0,05$) and a slow rate of serum glucose disappearance. 2. Significantly modified AUC in chronic liver disease with DM, compared to that without DM or DGT (table). 3. Insulin sensitivity index (DG/G) was correlated with the degree of glucose tolerance impairment and liver damage (DG/G=0,24 in CH without DM, versus 0,40 in LC with DM, $p<0,05$). **Conclusions.** 1. Patients with LC and DM present a more marked insulin sensivity. 2. The degree of insulin resistance is correlated with level of glucose tolerance and liver function.

LC with DGT (4 patients)	2371 mg/dl/30'
LC with DM (11 patients)	4024 mg/dl/30'
CH without DM/DGT (17 patients)	2180 mg/dl/30'

SEVERE INSULIN RESISTANCE IN A MODEL OF CRITICAL ILLNESS AND PARENTERAL NUTRITION

Tim Heise, Lutz Heinemann, Achim A.R. Starke, Clinic of nutrition and metabolic diseases, Heinrich-Heine-University Düsseldorf, Germany

During parenteral nutrition critically ill nondiabetic patients often show elevated blood glucose levels despite high doses of insulin. This is most likely due to insulin resistance caused by high concentrations of insulin-counteracting hormones. As studies in such patients are difficult to perform we tried to simulate hormonal and carbohydrate metabolism of critically ill patients and quantified insulin resistance in this model. 6 healthy volunteers received an i.v. infusion of 4 insulin-counteracting hormones (epinephrine 100 ng/kg/min, glucagon 16 ng/kg/min, cortisone 5 µg/kg/min, growth hormone releasing hormone 8 ng/kg/min) for 4h together with glucose (260 ng/kg/min) as simulation of parenteral nutrition. In a control experiment only glucose was infused. In a second study insulin sensitivity was estimated by means of a two-step hyperinsulinaemic euglycaemic glucose clamp (blood glucose 5.0 mmol/l, insulin infusion rates 2.5 and 5.0 mU/kg/min with hormone infusion; 1.0 and 2.5 mU/kg/min in the control experiment without hormone infusion). This model established a metabolic situation comparable to that seen in critical ill patients as indicated by highly elevated concentrations of the infused hormones (epinephrine 1085±89 pg/ml (mean±SEM), glucagon 1100±114 pg/ml, cortisol 1004±32 ng/ml, growth hormone 21±6 pg/ml), blood glucose concentrations (20.2±2.1 mmol/l), insulin concentrations (90±32 µU/ml), FFA (1073±159 µmol/l), lactate (5.7±0.4 mmol/l), pyruvate (188±20 µmol/l) and ß-hydroxybutyrate (143±1 µmol/l). In the control experiment blood glucose and insulin concentrations increased slightly (blood glucose 6.9±0.8 mmol/l, insulin 18±7 µU/ml, $p<0.001$ vs. hormone infusion), wheras the metabolites remained stable (pyruvate, lactate) or decreased slightly (FFA, ß-hydroxybutyrate), $p<0.05$ vs. hormone infusion, resp.). Infusion of insulin-counteracting hormones led to a app. 90% decrease of the insulin sensitivity index (0.6±0.4 vs. 4.5±1.3 ml/min x m^2 / µU/ml, $p<0.001$). This model is able to establish a metabolic situation as observed in critical illness under parenteral nutrition. The 90% decrease in insulin sensitivity explains the hyperglycaemia seen in nondiabetic critically ill patients.

1143

TYPE 2 DIABETES MELLITUS AND HCV-Ab+ CHRONIC ACTIVE HEPATITIS: EFFECT OF RECOMBINANT α-2b-IFN TREATMENT

S. Gentile, A. De Bellis, S. Turco*, T. Salvatore, M. Persico, S. Conte, A. Panariello, M. De Seta, L. Gesue', A. Bizzarro and R. Torella. 1ST* and 2nd University of Naples, Naples, Italy.

It has reported that the Interferon (IFN) treatment (tr) of Chronic hepatitis (CAH) in patients with diabetes mellitus could interfere with insulin action/secretion. **AIM**: to evaluate in NIDDM pts with biopsy-proven HCV+ CAH the effect of recombinant IFN-α-2b (*INTRON-A®, Schering-Plough*) on: 1) glycemic control, 2) autoimmune responses of islet cell antibodies (ICA), **PATIENTS**: 15 ICA- NIDDM pts (12F/3M) with mean age 58±4y, diabetes duration 9±4y. All had had serum ALT persistently > twice the upper normal limit for at least 6 months (**mo.**), ad had fasting glycemia 142±65 mg/dl, mean daily glycemia (MDG; on 7 values) 158±71, HbA1c 7.6±1% . **METHODS**: All subjects received 3 MU IFN thrice weekly (tw) for 2 mo., then 5 MU tw for 10 mo. MDG, HbA1c (Bio-Rad, n.v.<6.6), body weight (BW), ICA (indirect IF on human pancreas according to the 3rd Int. Workshop Stand. of ICA), were measured before, 6 and 12 mo. after IFN starting. IFN efficacy was assessed on persistent ALT normalization for at least other 6 mo. **RESULTS**: compared to baseline, IFN Tr produced no impairment of glycemic control (this being improved in 10 pts and unchanges in 5), MDG was -9.5±3% (141±9 vs 156±7, p n.s.), HbA1c -6.3±0.6% (7.1±0.6 vs 7.6±1, p n.s.), body weight -5±2.5% (74±7 vs 79±9, p n.s.). Apon IFN withdrawal, 4 pts were sustained responders (26.7%), 6 early rsponders with relaps (40%), and 5 non-responders (33.3%). All had no significant changes of ICA titres. **CONCLUSION**: the effect of recombinant IFN-α-2b Tr that we observed in ICA- NIDDM pts: 1) is similar to that already reported by other, 2) does not affect the glycemic control, and 3) does not induce ICA+, therefore it may be safely used in NIDDM pts with HCV+ ICA- CAH.

1144

INSULIN SENSITIVITY AFTER CHRONIC PREDNISONE TREATMENT

BRUNO A., FORNENGO P., DE SALVIA A., PACINI* G., CAVALLO-PERIN P., PAGANO G.
INTERNAL MEDICINE DEPARTMENT - UNIVERSITY OF TURIN - * LADSEB-CNR - UNIVERSITY OF PADUA - ITALY

Glucocorticosteroid treatment produces glucose intolerance combined with higher insulin levels. Peripheral hyperinsulinemia can be due to an enhanced beta-cell secretion, to a reduced hepatic extraction or to a combination of both. The simple observation of the peripheral values of the hormone does not provide further information on the level at which the impairment occurs. Aim of the study is to evaluate the beta-cell insulin production and his hepatic clearance, in normal glucose tolerance subjects treated with a long term prednisone (PN) therapy. We studied 6 subjects (2 males, 4 females; BMI 26.9±2.6 kg/m^2; 49.3±9.0 yrs), with normal oGTT, without family evidence of diabetes mellitus, not in therapy with any drugs in the last 6 weeks, with normal renal and liver function, affering to the Pneumology ward for sarcoidosys or chronic obstuctive pulmonary disease and needing for prolonged prednisone treatment (50 mg orally for 30 days). They received a Frequent Sampling Intra-venous Glucose Test (FSIGT: 0.33 g glucose/kg) the day before the beginning (BT) ant after thirty days of treatment (AT), minimal model is used. Fasting plasma glucose, insulin, C-peptide levels, glucose effectivness (SG) and basal insulin delivery rate (BDR) during FSIGT were not modified by PN treatment. whereas insulin sensitivity (SI = BT: 44.2±25.9 vs AT: 35.9±22.4 min^{-2} /(pmol/L) MEAN±DS; $p < 0.05$ Student's t test for paired data) and sensitivity of the first-phase C-peptide secretion (ΦIC = BT:106±52 vs AT: 193±62 pmol min^{-1} mg^{-1}dl; $p<0.003$) were significantly modified. These results suggest that chronic prednisone treatment induces a reduction of insulin sensitivity with higher insulin secretion and normal hepatic extraction without hyperglicaemia.

1145

DIABETES MELLITUS AND LIVER TRANSPLANTATION IN MALNOURISHED HCV-Ab+ CIRRHOTIC PATIENTS

S. Gentile, S. Turco*, T. Salvatore, F. Sasso, M. Persico and R. Torella. Liver Unit, 1st * and 2nd University of Naples, Italy.

The asociation between non insulin dependent diabetes mellitus (NIDDM) and liver cirrhosis (C) has been frequently described. In addition, transient diabetes mellitus has been reported after orthotopic liver transplantation (OLT) in C as a consequence of prednisone treatment (PT). NIDDM is more frequent in decompensated than in compensated C. In turn, a close relationship is reported between liver function (LF) and nutritional status (NS), the prevalence of malnutrition (Ma) increasing as liver function deteriorates. ***AIM***: evaluate a possible relationship between changes of NS and glycometabolic equilibrium (GE) in 5 malnourished HCV+ C pts (Child C) with NIDDM before and during 24 months after OLT. Mean age pre-OLT was 57±6, and b wt 62±5 (BMI 23±3 even though with acites), diabetes duration 8±3y and cirrhosis known by 5±2y. ***METHODS***: lean body mass (cm, MAMC: mid-arm muscle circumference), triceps skinfold thickness (mm, TSF: fat deposit), muscle arm area (cm2, MAA, extrapolated) were measured and insulin dosage (IU) (U/kg b wt) was recorded. ***RESULTS***: compared with pre-OLT values, a significant increase of MAMC (23±7 vs 28±4, p<0.01), TSF (7.5± vs 10.2±4, p<0.05), and 43±8.9 vs 51.4±9.4, p<0.05) and a significant decrease of ID (0.9±0.5 vs 0.2±0.2, p<0.05) were observed in parallel with prednisone reduction; 2 out of 5 pts withdrown insulin. The correlation coefficient between the reduction of ID and MAMC was -0.738, p<0.01. ***CONCLUSION***: a significant increase in lean body mass is associated with a reduction of insulin need in C pts with NIDDM, probably due, in addition to prednisone reduction, to an improvement of insulin-resistance of malnourished and decompensated cirrhotic patients.

1146

INSULIN ACTION IN PRIMARY HYPERALDOSTERONISM

J. Škrha, G. Šindelka, J. Widimský and J. Hilgertová. Dept. of Internal Medicine 3, Faculty of Medicine 1, Charles University, Prague, Czech Republic

The impaired insulin sensitivity has been repeatedly described in patients with essential hypertension. The aim of this study was to evaluate insulin action at receptor and postreceptor levels in hypertensive patients with primary hyperaldosteronism (PH). This diagnosis was confirmed in six patients (mean age 50 yrs, range 38-61 yrs, body mass index 28.2±2.8 kg/m^2) by clinical and laboratory test. Their blood pressure was monitored during 24 hrs by Spacelab tonometer (SBP 159±13 mm Hg, DBP 98±8 mm Hg), plasma aldosterone concentration in supine position was 344±168 pg/ml (normal value below 150 pg/ml) and serum potassium concentration 3.0±0.3 mmol/l. All patients had normal fasting plasma glucose (4.6±0.4 mmol/l) and fasting serum insulin concentration (15.5±4.3 mU/l). Isoglycaemic hyperinsulinemic clamp on Biostator (insulin infusion rate 1.0 mU/kg/min) and insulin receptors on erythrocytes were evaluated in all of them. Plasma potassium concentration was maintained within the normal limits during the clamp. Control group consisted of 7 healthy persons of appropriate age and body mass index. A decreased glucose disposal rate (21.0±6.6 vs 34.9±10.2 μmol/kg/min, p<0.01), metabolic clearance rate of glucose (4.6±1.6 vs 7.6±1.9 ml/kg/min, p<0.01) and insulin sensitivity index (23.8±9.8 vs 39.4±13.7 μmol/kg/min per mU/lx100, p<0.02) were found in patients with PH as compared to healthy persons. No changes in the insulin receptor binding characteristics were present in these patients. An inverse relationship between plasma aldosterone concentration and insulin sensitivity index (r=-0.36, p=0.05) was observed in PH patients. We conclude that primary hyperaldosteronism is accompanied by insulin insensitivity at postreceptor level. Further research will be necessary to discover possible underlying pathogenetic mechanism.

1147

POST TRANSPLANT DIABETES MELLITUS IN LIVE RELATED RENAL TRANSPLANT RECIPIENTS

F. Jawad, R. Shaikh, A. Naqvi and A. Rizvi, Sindh Institute of Urology and Transplantation (SIUT), Dow Medical College, Karachi-Pakistan

Post Transplant diabetes mellitus (PTDM) is a major sequelae secondary to glucocorticosteroid therapy in renal transplant recipients. The aim of this study was to determine the prevalence of PTDM in the early post transplant period in two groups of patients, in relation to dosage of steroids. Group I on a high dose (0.6 mg/kg/day) and Group II on low dose (0.3 mg/kg/day). Each group comprised of 62 patients with a renal allograft from a live related donor. The follow-up period was one year. Cyclosporin was given to both groups in the dose of 10 mg/kg/day. Each recipient was subjected to a fastmg and 2 hours post prandial blood glucose on every follow-up visit. The WHO criteria of fasting blood glucose $\geq$ 7.8 mmol/l and 2 hours post prandial blood glucose $\geq$ 11.1 mmol/l (venous plasma) was diagnostic for diabetes mellitus. Patients with doubtful values were subjected to a formal Oral Glucose Tolerance Test as recommended by WHO. Body mass index (BMI) of all cases was calculated by the formula : wt in kg / ht in m^2. Family history of diabetes was inquired and HLA-DR antigens noted. The male to female ratio (4.6 : 1 vs 4.2 : 1) and the mean age (30.2 yrs vs 29.25 yrs) was similar in both groups. Thirteen patients from Group I and 4 from Group II developed PTDM. The mean time period between transplantation and appearance of PTDM was 79 days in Group I and 108 days in Group II. The mean dose of methylprednisolone taken by PTDM subjects of Group I (36.5 mg/day) was significantly higher than those with a normal glucose tolerance (28.1 mg/day) $p < 0.001$. In Group II the mean dose in PTDM subjects was 16mg and in non PTDM 14mg daily. BMI was significantly higher in the PTDM subjects of both groups compared with non PTDM (Group I : 21.8 vs 18.4, $p < 0.01$ and Group II : 21.02 vs 17.9, $p < 0.01$). Other factors as HLA antigens, family history of diabetes and gender did not influence the development of PTDM. Satatistical analysis included Chi Square Test and Student t Test. The study concluded that steroid dose was directly related to the development of PTDM in the early post transplant period and obesity (raise BMI) was also an associated risk factor.

1148

CARDIOVASCULAR RISK FACTORS IN ADULT TURNER SYNDROME AND THE INFLUENCE OF SEX HORMONE SUBSTITUTION

C.H. Gravholt[1], R.W. Naeraa[2], B. Nyholm[1], U. Gerdes[3], E. Chistiansen[4], O. Schmitz[1] and J.S. Christiansen[1]. [1]Medical Department M, [2]Paediatrics and [3]Clinical Chemistry, Aarhus University Hospital, Aarhus Kommunehospital, Aarhus; [4]Medical Department A, Rigshospitalet, Copenhagen, Denmark.

Turner syndrome is associated with abnormalities of glucose metabolism and epidemiological data show increased frequency of NIDDM, ischaemic heart disease and osteoporosis. Since most women with Turner syndrome are treated with sex hormone substitution we examined the impact of this treatment on cardiovascular risk factors. We performed OGGT and FSIVGTT (minimal model), as well as 24 hour ambulatory blood pressure and measurement of circulating lipids. The patients (N=26, 33.1±7.9 y (mean±SD)), were examined twice before (TB) and after (TA) sex hormone treatment, while controls (N=24, 32.7±7.8 y) were examined once. Women with Turner syndrome received either oral (O) or transdermal (T) 17-β-estradiol (17-β-E) and oral norethisterone (O-17-β-E: N=14; T-17-β-E: N=12) for 6 month after 4 month washout. AUC_{glc}(TB) from OGTT was significantly higher than in controls (7.7±2.3 vs 4.9±2.0 mmol/L*3 h, $p < 0.0005$), and increased after treatment ($p < 0.02$). AUC_{ins}(TB) from OGTT was also significantly higher than in controls (622±380 vs 441±152 pM*3 h, $p = 0.05$), while there was no difference before and after treatment. S_I(TB) was similar to controls, and unchanged after treatment. First phase insulin secretion was deficient compared with controls ($p = 0.03$) and did not increase with treatment. No change in S_G and circulating levels of cholesterol, HDL-cholesterol and triglycerides was seen. 24-hour systolic, diastolic BP and diastolic night/day (N/D) ratio were all significantly elevated in Turner syndrome before treatment compared with controls, and 24 hour diastolic BP decreased, while diastolic N/D ratio increased significantly with treatment, as did LBM ($p = 0.0005$). No differences could be attributed to route of administration. Glucose intolerance and deficient insulin secretion are prominent characteristics in Turner syndrome. Elevated blood pressure, partly normalized by sex hormones, and increased diastolic N/D ratio, suggesting that Turners are non-dippers, and a normal lipid metabolism was seen. In conclusion, women with Turner syndrome have several of the characteristics seen in the metabolic syndrome.

1149

DISTURBANCES IN CARBOHYDRATE METABOLISM AMONG PATIENTS WITH SHEEHAN'S SYNDROME

F.Bayram, K.Ünlühızarcı and F.Keleştimur. Erciyes University, Kayseri, Turkey.

Sheehan's syndrome is a clinical picture due to postpartum necrosis of anterior pituitary gland with various degree of pituitary insufficiency. Tendency to hypoglycemia is an expected situation because of counter-regulatory hormone deficiencies such as growth hormone (GH) and cortisol. Although fasting blood glucose levels and insulin values were reported as normal, impaired glucose tolerance and reduced stimulatory effect of glucose on insulin secretion were also reported in GH deficient states. In order to determine the prevalence of glucose intolerance, an oral glucose tolerance test (OGTT) was caried out and blood glucose, insulin and C peptide values were determined at 0, 30, 60, 90, 120, 150, 180, 240, 300 minutes in six incomplete (three of them have normal ACTH reserve) and 13 complete ; total 19 patients with Sheehan's syndrome. All cases were GH deficient. Average age (year) and body mass index (BMI= kg/m^2) for control group was 45.6± 9.1 and 31± 2.2 and for the patients with Sheehan's syndrome was 45.9± 7.7 and 28.1± 6.6 respectively. All patients had normal fasting blood glucose levels , however, three (15.8%) of them showed diabetic curve after OGTT. Thirty minutes blood glucose values (188.7± 16.6 ; 155.4± 33.3 mmol/l) and 150 and 180 minutes insulin values (6.0± 2.4 / 19.8± 14.4 ; 3.6± 1.8 / 22.2±28.8 nmol/l) were significantly ($p<0.05$) different in control and patient groups respectively, as determined by area under curve (AUC) at 30 minute intervals and results are expressed as means± SD. In conclusion; like GH excess, GH deficiencies, meanwhile Sheehan syndrome, may cause glucose intolerance although the underlying mechanism is not completely clear.

1150

ANDROGEN STEROID PATTERN IN NORMAL WEIGHT MEN WITH INSULIN DEPENDENT DIABETES MELLITUS. EWCM van Dam, EWGM Lentjes and HMJ Krans. University of Leiden, Leiden, The Netherlands.

Androgens, insulin resistance and hyperinsulinemia are supposed to be factors involved in the pathogenesis of atherosclerosis. Current literature suggests that insulin resistance and hyperinsulinemia are accompanied by decreased serum concentrations of Testosterone (T), Sex Hormone Binding Globulin (SHBG) and Dehydroepiandrosterone Sulphate (DHEAS). Persons with IDDM have increased (peripheral) insulin levels and develop insulin resistance. Therefore we compared fourty-seven men with IDDM of 2 to 15 years duration, in the age of 30 to 45 years, without complications or other diseases, with 44 sex-, age- and weight-matched controls, who have no relatives (up to third degree) with Diabetes Mellitus. The following results were obtained (t-test for independent samples):

	control (n)	IDDM (n)	p-value
$Insulin_{day}$ (U/day)	-	58.1±1.9(47)	-
$glucose_{fasting}$ (mmol/l)	4.8±.1 (44)	11.7±.8 (46)	0.000
HbA1c (%)	5.2±.1 (44)	8.1±.2 (45)	0.000
testosterone (nmol/l)	22.7±.8 (43)	25.2±.9 (47)	0.036
SHBG (nmol/l)	27.9±1.47(44)	41.7±2.42 (46)	0.000
FAI (Tx100/SHBG)	86.7±5.1 (44)	67.5±3.5 (46)	0.002
DHEAS (umol/l)	7.5±.3 (44)	6.7±.3 (47)	0.189

We found a slightly increased T, a clearly increased SHBG, a decreased free androgen index (Tx100/SHBG) and an unchanged DHEAS in IDDM. These findings suggest that 1) there is no support for a direct connection between hyperinsulinemia or insulin resistance and DHEAS 2) peripheral hyperinsulinemia and insulin resistance are accompanied by unsuppressed SHBG and 3) the FAI and thus bioavailability of T is lower in longstanding hyperinsulinemia and insulin resistance, as a consequence of a strongly increased SHBG and less increased total T. Further statistical analysis, eg logistic regression will be performed on these factors and other involved hormonal factors.

1151

SEVERE INSULIN RESISTANCE IN PITUITARY APOPLEXIA.

M.J.M, Ursich, R.T.Fukui, M.E.R.Silva, G.B. Ruggeri, L.M. Barros, M. Knoepfelmacher, L.R. Salgado, B.Liberman and B.L.Wajchenberg. Laboratory of Medical Investigation, University of São Paulo Medical School, São Paulo, Brazil.

A 27 year old non diabetic acromegalic man developed severe insulin resistance after pituitary apoplexia. Large doses of human regular insulin (700-900 U/day) intravenously were necessary for glycemic control for 3 days when the insulin doses were progressively decreased and 14 days after the acute event the glycemic levels became normal without insulin therapy . During acute phase fasting C peptide was 4.63 nM , GH 85 μg/L, IGF-1 1730 ng/ml, and insulin antibody levels negative. To investigate if a factor present in serum could be responsible for this unusual insulin resistance, TNF α was measured (bioassay) and patient's sera during acute phase (S_1) and 30 days after apoplexia (S_2)(IGF-1 905 ng/ml) were incubated during 60 minutes with rat epididymal adipose cells. To avoid the IGF-1 influence a control serum (C) in which IGF-1 was added to reach similar concentration to that in patient's serum was also incubated with the adipocytes. After incubation cells were washed five times in Krebs-Ringer III buffer. Insulin binding was determined incubating ^{125}I -insulin with the adipose cells and glucose transport by incubation with D-U-^{14}C-glucose with increasing amounts of insulin for 60 minutes.

	Glucose transport(nmoles/2x10^{5}cells)			%Binding	TNFα
Ins (μU/ml)	0	50	100	(2x10^{5}cells	IU
S1	16.6	49.6	78.2	5.0	2,560
S2	19.6	80.3	124.1	3.8	4
C	20.2	86	117	4.6	<8

Impaired glucose transport was observed in spite of increased insulin binding in the adipocytes treated with the patient's serum with high TNFα levels. However when the cytokine level became normal, glucose transport was restored. TNFα at very high concentration was probably an important factor for the insulin resistance presented by the patient.

1152

ALBUMIN-SEX HORMONE-BINDING CAPACITY IN IDDM

FWF Hanna[1], WG Nicola[2], KM Ibrahim[2], J Peters[1] and A Rees[1]. (1) Department of Medicine, University Hospital of Wales, Cardiff, UK. (2) Endocrine and Diabetes Unit, National Research Centre, Cairo, Egypt

It has been recently recognised that the bioavailable testosterone (T) includes not only the free but also 55% of the albumin-bound fraction. Forty and 60 % of T and oestradiol (E2) respectively are carried by albumin. Our aim was to investigate if the albumin-bound T and E2 will be affected in IDDM and if there will be any correlation with the degree of albumin glycation. Twelve male and 18 female IDDM patients 38.5±6.6 years (mean±SEM) with a mean duration of DM of 15.1±5.4 were compared with 23 age & sex matched controls. Fasting blood samples were withdrawn from both groups for measurement of serum albumin, serum fructosamine (as an indicator of albumin glycation), serum total and albumin-bound T in males and E2 in females. Serum albumin was similar in controls and DM. Albumin-bound T in IDDM (mean+SEM nmol/L) was 2.4±0.7 compared to 5.17±0.2 in controls ($p< 0.001$). In females, albumin-bound was similarly reduced in IDDM compared to controls; 46.99 ± 2.83 pmol/L and 120.01 ± 3.82 respectively ($p< 0.001$). Serum fructosamine showed significant negative correlation with the albumin-bound sex hormone fractions with a correlation coefficient (r) of 0.62 in males and 0.87 in females. Glycated albumin sex hormone- carrying capacity is significantly impaired in DM, with a reduction in the bioavailable fractions. The clinical relevance and impact of DM control merit further investigation.

1153

PLASMA INSULIN GROWTH FACTOR 1 CONCENTRATION AND INSULIN ACTION IN HEALTHY CENTENARIANS

G.Paolisso,M.R.Rizzo,M.R. Tagliamonte, F.Turano,F. Saccomanno, A. Gambardella, A. Del Buono, C. Carella and F. D'Onofrio-II University of Naples-Naples-Italy.

Independently of anthropometric characteristics healthy centenarians (HC) have been shown to have an insulin-mediated glucose uptake (IMGU) better than aged subjects (AS). Since IGF-1 affects insulin action one can not exclude that difference in plasma IGF-1 concentration might provide an explication. Thus, in 30 (13M/17F) healthy AS (mean age=78±0.7 yrs) and in 19 (8M/11F) HC (mean age=102±0.8) anthropometric characteristics were assessed by bioimpedance analysis, plasma leptin,insulin,insulin growth factor I (IGF-1) and insulin growth factor binding protein-3 (IGFBP-3) concentrations determined by radioimmunoassay and insulin action measured by euglycemic glucose clamp. Total plasma IGF-1 concentration was not different between AS and HC (82±53 vs 65±49 μg/L p=NS) while plasma IGFBP-3 concentration was greater in AS than HC (2993±1129 vs 1789±1007 μg/L $p<0.001$). Consequently, plasma IGF-1/IGFBP-3 molar ratio, expression of unbound plasma IGF-1, was greater in HC than AS (0.18±0.08 vs 0.11±0.05 $p<0.02$). Similarly, IMGU was greater in HC than AS (32.4±0.8 vs 22.4±0.4 μmol/Kg FFM x min $p<0.01$).In HC plasma IGF-1/IGFBP-3 molar ratio correlated with body fat ($r=-0.62$ $p<0.003$), fasting plasma leptin ($r=-0.63$ $p<0.004$), fasting plasma glucose ($r=-0.46$ $p<0.02$), fasting plasma triglycerides (T) ($r= -0.58$ $p<0.01$) and fasting plasma free fatty acids (FFA) ($r=-0.64$ $p<0.005$) concentrations. The correlations between plasma IGF-1/IGFBP-3 molar ratio and plasma T ($r= -0.44$ $p<0.05$) and FFA ($r= -0.53$ $p<0.03$) concentrations persisted after correction for daily carbohydrate and fat intake and IMGU. Finally, in HC plasma IGF-1/IGFBP-3 molar ratio correlated with IMGU ($r=0.64$ $p<0.005$). This latter correlation persisted after adjustment for body fat, daily carbohydrate and fat intake and daily physical activity ($r= 0.55$ $p<0.009$) but not after further adjustment for plasma FFA ($r=0.33$ $p=0.17$). In conclusion, HC have unbound plasma IGF-1 concentration greater than aged subjects. Such difference might explain a better IMGU in HC through an inhibition of glucose-fatty acids cycle.

1154

The roles of DHEA and DHEAS in NIDDM patients : a possible modulator of glucose metabolism

K.Hamano, M.Ajima, R.Okazaki and Y.Totsuka, Kanto Teishin Hospital, Tokyo, Japan

Dehydroepiandrosterone (DHEA) and dehydroepiandrosterone sulfate (DHEAS) are the most abundant steroids and have been shown to ameliorate diabetes in experimental animals. Insulin seems to play a regulatory role in DHEA(S) metabolism according to the results from hyperinsulinemic clamp studies. However, the exact roles of these hormones in NIDDM have not been elucidated so far. To clarify this, DHEA and DHEAS levels were determined in various conditions in middle aged NIDDM male patients (n=21). When glycemic control was poor(FPG199±54mg/dl,mean±SD), basal morning DHEAS, but not DHEA levels were lower in NIDDM (1622 ±655ng/ml) when compared to the age and the BMI matched controls (2071±635,$p<0.001$). In the course of diabetic treatment period(29days), the DHEAS levels did not change significantly. Postprandial acute elevation of insulin levels, either endogenously or exogenously, caused a concomitant decrease in DHEA not in DHEAS. This was also observed after the glycemic control was achieved. However, there was no significant correlation between basal insulin and DHEA or DHEAS levels throughout the treatment course. In contrast, there was a significant positive correlation between DHEAS and fasting glucose both before($r=0.599$,$p=0.005$) and after($r=0.496$,$p=0.029$) treatment. In conclusion, 1) in the middle aged male NIDDM patients, the basal DHEAS levels were diminished compared to controls. 2) Acute elevation of serum insulin was accompanied with a decrease in DHEA irrespective of glucose levels. 3) There was a significant positive correlation between fasting glucose and DHEAS. From these observation,there is a difference between acute and chronic insulin action on adrenal androgen metabolism in diabetes. DHEAS may serve as a modulator of glucose metabolism in chronic hyperglycemic state.

1155

A RAPID RISE IN INSULIN-LIKE GROWTH FACTOR-I AND A DECREASE IN INSULIN-LIKE GROWTH FACTOR BINDING PROTEIN-1 AFTER ALCOHOL WITHDRAWAL.

M. Paassilta, K. Kervinen and Y. A. Kesäniemi. University of Oulu and Biocenter Oulu, Finland.

Moderate alcohol intake may improve insulin sensitivity, whereas insulin resistance has been reported in alcohol abusers. We studied the possible mechanisms behind the altered carbohydrate metabolism in alcoholics. Blood glucose, serum insulin, plasma insulin-like growth factor-I (IGF-I) and IGF-binding protein-1 (IGFBP-1) were measured in 27 male alcoholics at the end of a drinking period, and thereafter, during three consecutive days along the abstinence. A single blood sample was obtained from 26 healthy male controls. The groups were similar for age and BMI. Insulin/glucose (I/G) -ratio was higher in the alcoholics at the end of the drinking period compared with the controls (3.1±1.9 vs. 2.3±0.9, respectively, $p<0.05$), whereas IGF-I levels tended to be lower in alcoholics (8.8±2.9 vs. 10.3±4.3 nmol/L, p=NS). I/G -ratio increased by +61 %, and IGF-I increased by +41% during the alcohol withdrawal ($p<0.01$and $p=0.001$ after ANOVA, respectively). In alcoholics, an inverse correlation between insulin and IGFBP-1 ($r=-0.43$, $p<0.05$) was seen only at the end of the drinking period. Cessation of drinking induced a decrease of -59% ($p<0.001$) in IGFBP-1 levels. In conclusion, alcohol abuse is associated with decreased insulin sensitivity. Immediately after the cessation of drinking, insulin sensitivity is even more deteriorated. Acute alcohol intake has been suggested to stimulate the secretion of IGFBP-1 in the liver. Our data supports such an effect also in chronic alcohol abusers, since alcohol withdrawal is associated with a dramatic decrease in the IGFBP-1 plasma levels. A loss of the normal inhibitory regulation of IGFBP-1 by insulin during the withdrawal is suggested in the present study.

1156

DEHYDROEPIANDROSTERONE-INSULIN RELATIONSHIP IN MINIMAL MODEL BASED IVGTT ANALYSIS

Š.Svačina, M.Kvapil, T.Haas, D.Wichterle, D.Bendlová, P.Štolba, J.Šonka, 3rd Medical Clinic, 1st Medical Faculty, 1st Medical Clinic, 2nd Medical Faculty,Institute of Endocrinology, Charles University, Prague, Czech Republic

Dehydropepiandrosterone (DHEA) deficiency is related to aging, hypertension, obesity and diabetes. Possible DHEA-insulin interactions were investigated in 8 normal men and 6 diet treated normoglycemic type 2 diabetic men during intravenous glucose tolerance test (0.3g/kg glucose). A minimal model based calculation of insulin sensitivity (SI) was performed. A significant correlation between SI and basal DHEA level was found ($r=0.65$, $p=0.02$). Linear regression indicated that SI is linearly related to the basal DHEA level, SI= -0.534 + 0.105 x DHEA. An early DHEA elevation within first 30 minutes was observed in most patients. Using stepwise regression we obtained model where DHEA elevation area (DA) was a function of early insulin peak (IP) and early insulin peak time (IPT). DA = -159.7 + 2.885xIP -2.651xIPT. Age, BMI, SI and calculated remote insulin level failed to enter the equation. No changes in and correlation between DHEA-sulphate levels were found. We conclude that basal DHEA level is related to insulin sensitivity. DHEA response during IVGTT is induced by the first phase insulin secretion.

1157

ACUTE REGULATION OF FREE INSULIN-LIKE GROWTH FACTOR-I BY INSULIN.

B.L.G. Nyomba, L. Berard and LJ Murphy, University of Manitoba, Winnipeg, Manitoba, Canada.

Exogenous insulin-like growth factor (IGF)-I suppresses insulin secretion and causes hypoglycemia by an insulin-independent mechanism. Long term insulin treatment of type 1 diabetes results in increased circulating total IGF-I concentrations. Little is known, however, about the short term effects of insulin or glucose on circulating free IGF-I. We have evaluated the effects of a single bolus intravenous injection of glucose and insulin on serum free IGF-I in 11 normal subjects (6 men and 5 women, age 27.4 ± 7.4, BMI 23.2 ± 2.3 SD). After an overnight fast, subjects had a 180-min insulin modified frequently sampled glucose tolerance test (FSIGT) with injection of glucose at time=0 and of insulin at 20 min Serum free IGF-I, total IGF-I, IGF-binding protein (IGFBP)-1 and IGFBP-3 were measured by immunoradiometric assays. IGFBP-3 remained constant during the first 30 min, then slowly increased following insulin injection to 20% above the basal value by 180 min. IGFBP-1 remained constant during the first 60 min, but fell steadily thereafter, resulting in an undershoot by 100 min. IGFBP-1 then sharply increased to 3-fold the basal levels by 180 min. Total IGF-I remained constant during the 180 min of the experiment. Free IGF-I decreased by 20% below basal levels following glucose injection and decreased further by 40% after insulin injection. After insulin, but not glucose injection, the decrease of free IGF-I was concomitant to the rise of IGFBP-3, and the percent change of free IGF-I was greater than that of IGFBP-3. In a cross-sectional analysis, free IGF-I was inversely correlated with serum glucose ($r_s=0.55$, $p<0.05$) and IGFBP-1 ($r_s=0.64$, $p<0.025$). Free IGF-I, thus, is suppressed by insulin and may play a physiological role in glucose homeostasis.

1158

PERIPHERAL GLUCOSE METABOLISM IN POLYCYSTIC OVARIAN SYNDROME BEFORE AND AFTER TREATMENT WITH GnRH ANALOGUE.

M.C. Foss, M.T. Torquato, G.M. Paccola, L.M. Gouveia, F. Menezes, C.E. Piccinato, A.C. Moreira, C.E. Martinelli Jr, M.S. Villanova and M.F. Sá. School of Medicine of Ribeirão Preto - São Paulo University, Ribeirão Preto (SP), Brazil.

The aim of this study was to investigate the peripheral glucose metabolism and the serum levels of IGF-I, IGFBP-1 and insulin in patients with polycystic ovarian syndrome before and after treatment with GnRH analogue. Eight normal (N) women and sixteen patients with polycystic ovarian syndrome (PCOS) were studied after an overnight fast (12-14 h) and during 3 hours after ingestion of 75 g of glucose. Five PCOS patients were studied before and after treatment with 1 mg of leuprolide acetate daily during 8 weeks. The study was performed using the forearm technique combined with local indirect calorimetry. The hyperinsulinemia detected in the PCOS patients after the oral glucose stimulus (AUC-N = 4836 ± 902 vs PCOS = 11151 ± 1632 µU/3 h) did not determine a proportional increase in forearm glucose uptake and utilization, which were similar to the normal levels, suggesting an insulin resistance state in PCOS. Comparing the PCOS patients before and after the treatment with the GnRH analogue, the glycemic profiles did not change significantly and the forearm glucose uptake showed no significant difference in the PCOS patients before and after treatment. However, the serum insulin levels decreased significantly (AUC: 12948 ± 3449 vs 8589 ± 1130 µU/3 h, before and after, respectively), resulting in I/G index significantly different (131.3 ± 24.6 vs 108.7 ± 25.9 $\mu U.ml^{-1}/mg.100$ ml $forearm^{-1}$, before and after, respectively). The serum levels of IGF-I did not change significantly, but the serum IGFBP-1 concentrations showed a trend to decrease during the treatment. These data suggest that the suppression of the hyperandrogenism may decrease the insulin resistance of nonobese patients with polycystic ovarian syndrome.

1159

THE ROLE OF GLUCAGON ON GLUCOSE INTOLERANCE IN PATIENTS WITH ACROMEGALY

Chizuko Yokota, Yukichi Okuda, Shigeru Yatoh, Kamejiro Yamashita. Univ. of Tsukuba, Department of Endocrinology and Metabolism, Tsukuba, Japan.

It is known that the incidence of glucose intolerance with insulin resistance in acromegaly is high. Various factors are suggested to play a role in insulin resistance in acromegaly, and plasma glucagon (IRG) may be one of those factors. We investigated the effects of IRG on glucose intolerance before and after Hardy's operation, using 75g-OGTT in 6 patients (DM pattern; 1 patient, IGT pattern; 5 patients) with acromegaly. Serum GH levels were normalized in all patients after surgery. 1 patient still remained DM pattern and 3 patients, IGT pattern, but the degree of glucose intolerance was improved, and 2 patients with IGT returned to a normal pattern after surgery. The plasma IRG concentrations during OGTT (mean $\pm$ SE) before surgery were 0': 80 $\pm$ 27, 30': 86 $\pm$ 32, 60': 79 $\pm$ 22, 120': 60 $\pm$ 16 pg/ml, which were not inhibited even though plasma glucose levels were increased. After surgery, they were 0': 62 $\pm$ 43, 30': 47 $\pm$ 23, 60': 45 $\pm$ 24, 120': 42 $\pm$ 19 pg/ml, which were inhibited through the increment of plasma glucose. In conclusion, after the removal of pituitary adenoma in 6 patients with acromegaly, glucose intolerance was improved, and plasma IRG levels and response to increment of glucose were normalized concomitantly with normalization of serum GH levels. Thus, it is suggested that hypersecretion of IRG might play a role in insulin resistance in patients with acromegaly.

1160

SPECIFIC INSULIN SECRETION AND INSULIN SENSITIVITY IN SUBGROUPS OF WOMEN WITH POLYCYSTIC OVARIES (PCO) AND WOMEN WITH NORMAL OVARIES.

S Batty, V Anyaoku*, R Joseph-Horne, S Robinson*, D Johnston* and S Franks. Dept. Obstetrics & Gynaecology and Unit of Metabolic Medicine*, Imperial College School of Medicine at St Mary's, London W2 1PG.

Hyperinsulinaemia and reduced insulin sensitivity (S_i) are recognised features of PCOS. Insulin secretion measured using RIA has been shown to be abnormal in women with anovulatory PCO. We aimed to assess insulin secretion, S_i and glucose effectiveness (S_g) in both ovulatory (ov) and anovulatory (anov) women with PCO and controls, using an assay for specific insulin. 45 women with PCO (18 ov and 27 anov) were compared to 18 (BMI matched) control subjects (N). S_i and S_g were measured with an insulin modified, frequent sampling intravenous glucose tolerance test and minimal modelling. Median [interquartile range] given. Fasting insulin levels (F_{ins}) were higher in anov compared to N but not ov (ov 11[32] pmol.l^{-1}, anov 17[33] vs N 3[16] $p<0.03$). First phase insulin area (AUC) was greater in anov but not in ov compared to N (ov 523[1112] pmol.l^{-1}, anov 572[1044] vs N 282[403] $p<0.02$). S_i was lower in anov in comparison to N and ov (anov 4.27[12.35] x10^{-4}.min^{-1}.pmol.l^{-1}. vs ov 5.98[35.49] $p<0.04$ vs N 9.09[20.82] $p<0.03$). S_g showed no significant difference between groups (ov 0.033[0.028] min^{-1}, anov 0.024[0.015], N 0.023[0.015]). Anov had higher testosterone (T) levels compared to N but not ov (ov 2.0[0.8] mmol.l^{-1}, anov 2.5[1.25] $p<0.01$ vs N 1.6[0.7]). However, anov and ov were more hirsute than N (ov 9[11] {Ferriman Gallwey score} $p<0.03$, anov 18[10] $p<0.01$ vs N 5[1]). There was no correlation between T and AUC or F_{ins} in any group. Triglyceride levels in anov (but not N or ov) were correlated to AUC ($p<0.05$) and F_{ins} ($p<0.03$). HDL levels were negatively correlated in anov and N but not ov to AUC (anov $p<0.01$, N $p<0.05$) and F_{ins} (anov $p<0.01$, N $p<0.02$). In conclusion, hyperinsulinaemia and decreased S_i were confirmed in a group of anovulatory women with PCO in comparison to women with normal ovaries. S_g however, was similar in these groups. Although the group of ovulatory women with PCO were equally hyperandrogenaemic they did not display the same degree of insulin abnormalities. In this group of women, high testosterone levels were not associated with hyperinsulinaemia.

1161

INSULIN RESISTANCE IN CUSHING'S SYNDROME AND ACROMEGALY - THE ROLE OF ENDOGENOUS BETA-ENDORPHIN.

B.Krzyżanowska, M.Śmiarowska, M.Robaczyk J.Goździk and S.Czekalski. Dept. of Endocrinology, Pomeranian Medical Academy, Szczecin, Poland.

Insulin resistance and hyperinsulinemia (HI) are common features in Cushing's syndrome (CS), Cushing's disease (CD) acromegaly (A) and in human obesity with abdominal body fat distribution (ABF-D). It has been demonstrated that endogenous beta-endorphin (B-EP) may be responsible for HI in ABF-D obesity and that opioid receptors blockade by naloxone (NAL) decreases insulin (IRI) secretion and improves insulin sensitivity in obese subjects. To assess the possible influence of endogenous B-EP on the basal IRI secretion in patients with CS and CD and in A we evaluated IRI, cortisol (C), growth hormone (GH) and B-EP secretion and blood glucose concentration (as area under the 4 point's curve-AUC) during 60 min of 0.9% saline infusion (basal secretion) and during 60 min after NAL administration (0.8 mg iv.). Six patients with CS and impaired glucose tolerance (IGT), 8 persons with CD and normal glucose tolerance (NGT), 14 acromegalic patients (4 with NGT and 10 with type III diabetes) and 6 healthy subjects in similar age participated in the study. Serum or plasma hormone levels were evaluated by RIA. In all patients HI and insulin resistance were found. Patients with CS demonstrated markedly ($p=0.03$) lower basal IRI secretion than patients with CD. B-EP basal secretion was significantly higher only in patients with CD than in healthy subjects. Patients with A demonstrated lower basal IRI and C but higher basal GH secretion than patients with CD. NAL administration resulted in a marked decrease of basal IRI secretion in patients with CD and acromegalic patients with NGT (from 40.9 to 24.7 mU/l/min^{-1}, $p=0.003$ and from 27.4 to 23.6 mU/l/min^{-1} $p=0.04$ respectively) and basal C secretion (from 833.7 to 674.3 nmol/l/min^{-1}, $p=0.017$ and from 339.2 to 237.8 nmol/l/min^{-1} respectively). In all groups of patients NAL administration did not change blood glucose levels as well as basal secretion of GH and B-EP. These results suggest that endogenous B-EP may be in part responsible for HI in patients with CD and acromegaly with NGT and that opioid receptors blockade might improve insulin sensitivity in these syndromes.

1162

HYPERINSULINISM IN WOMEN WITH OVARIAN POLICYSTIC DISEASE ON TREATMENT WITH FLUTAMIDE.

P. Sanchez-Cervigón[1], C. Alonso[2], J.I. Fernandez[1], J.J. Gorgojo[1] and E. Cancer[1]. [1]Dept. Endocrinology Hospital General Gregorio Marañón. [2]Dept. Endocrinology Hospital Universitario del Aire. Madrid. Spain.

Hyperinsulinism has been depicted in association to policystic ovarian disease PCOD). In this study we have assessed the effects of flutamide, a non steroid antiandrogen on the glucose and insulin plasma levels on women diagnosed with hirsutism due to PCOD. A standard oral glucose tolerance test (OGTT) measuring plasma glucose and insulin every 30 minutes during 2 hours after oral administration of 75 g. of glucose was conducted in 12 nondiabetic and non obese women, BMI 22.3±2.4,aged 18 to 34, with mild to severe hirsutism secondary to PCOD, prior and after six monts of treatment with flutamide 250 mg bid. Contraception was guaranteed by means of an intrauterine device in 8 patients and by tube ligature in 4 cases. A control group of 10 women of the same age and BMI was also studied. Statistical study was done using the T-student test and the Spearman rank correlation coefficient. Plasma free testosterone which was elevated in the study group in relation to controls ($p<0.01$),significantly decreased after flutamide treatment ($p<0.01$). The basal plasma insulin levels did not change but the insulin levels at 120 minutes after OGTT significantly decreased after treatment (from 99.2±66.6 to 68.2±35.0,$p<0.05$), as well as the area under the curve of insulin (from 11875±7684.5 to 9132±3910, $p<0.05$). We found significant correlation between the plasma levels of free testosterone and the area under the curve of insulin (r :0.56, $p<0.05$). Hyperinsulinism associated to PCOD significantly decreases on treatment with the antiandrogen flutamide.

1163

THE PREDICTORS OF THE INCREASE OF BLOOD GLUCOSE IN HUMANS WITH NORMAL GLUCOSE TOLERANCE.

D.Piniewska, M.Bąk, W.Bonicki and A.Czyżyk. University School of Medicine, Warsaw, Poland.

The purpose of the study was to find the predictors of blood glucose levels (Bgl) during oral glucose tolerance test (OGTT) in insulin resistant patients (active acromegaly n=15) and in healthy people (n=30), both groups with normal OGTT according to WHO criteria. We considered fasting serum insulin (INS), C-peptide (CP), growth hormone (GH) and plasma glucagon (GG) as predictors of blood glucose in OGTT. Analysis of variance with repeated measurements was used in statistical analysis. From the above parameters fasting INS was the predictor of the higher values of blood glucose in OGTT in insulin resistant patients ($p<0.03$), but not in healthy people.

Insulin resistant group		Healthy group	
INS (pmol/l)	glucose in OGTT (mmol/l)	INS	glucose in OGTT
>59	5.4 8.6 8.7 6.9 5.0	>36	4.6 7.7 7.2 5.5 4.8
≤59	4.2 7.2 6.3 5.5 4.9	≤36	4.2 7.2 6.6 6.1 5.3

We found that interrelation among fasting molar INS, CP, GG concentrations expressed as the index = (CP/GG) / (INS/CP) occurred to be the predictor of increased Bgl in OGTT. Lower values of this index both in insulin resistant patients (<517) and in healthy people (<170) was significantly accompanied with elevated blood glucose levels in OGTT ($p<0.01$ and $p<0.056$ respectively).

Insulin resistant group		Healthy group	
Index	glucose in OGTT (mmol/l)	Index	glucose in OGTT
≤517	5.2 8.3 8.2 7.0 5.3	≤170	4.4 8.1 7.7 6.1 5.0
>517	4.1 7.1 5.5 4.8 4.5	>170	4.4 7.1 6.4 5.5 5.0

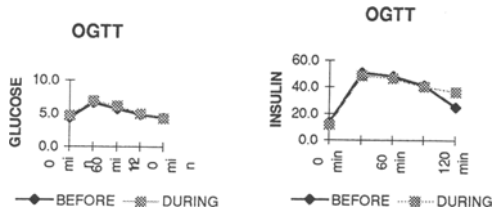
Conclusion: Proposed index allows to predict the inclination to development of impaired glucose tolerance in insulin resistant patients, furthermore indicates the group prone to the higher blood glucose in healthy people as well.

1164

ORAL GLUCOSE TOLERANCE TEST BEFORE AND DURING HORMONE REPLACEMENT THERAPY IN MENOPAUSAL WOMEN

Drezgić M, Vujović S, Milić G, Stojanović M, Penezić Z, Beleslin B. and Nešović M. Institute of Endocrinology, Belgrade, Yugoslavia

The main aim of this study was evaluating sex steroid concentration (estradiol and rogesterone) influences on glucose and insulin metabolism in menopausal women before and during hormone replacement therapy (HRT). We have examined 22 women 52±3 y's old, BMI=26.6±3, 85 kg/m^2, 2±1 year in the menopause. Standard 75g oral glucose tolerance test (OGTT), with glucose and insulin determination, was performed before and one year later during the HRT with Gynodian depot amp. I i.m. monthly. Insulin concentrations were detected by RIA. Statistics: Student's T test. Glucose and insulin, during OGTT were shown on Fig.1 & 2. CONCLUSION: There were no statistic significant differences in OGTT characteristics in menopausal women before and during HRT.



1165

MECHANISMS OF EFFECTS OF INSULIN AND HYPERTHYROIDISM TO MODIFY TISSUE PYRUVATE DEHYDROGENASE KINASE ACTIVITIES

M.C. Sugden, D.A. Priestman, E. Donald and M.J. Holness. Biochemistry Department, Queen Mary & Westfield College, London, U.K.

Pyruvate dehydrogenase kinase (PDHK) catalyses the phosphorylation (inactivation) of the pyruvate dehydrogenase complex (PDHC). PDHK activity in rat hepatic and cardiac mitochondrial extracts is increased ≈ 2 fold by the induction of hyperthyroidism by tri-iodothyronine (T3) administration. Studies with cardiomyocytes and hepatocytes have shown direct tissue effects of T3 to enhance PDHK activity which are opposed by insulin and by inhibition of mitochondrial β-oxidation. The aim was to determine whether increased PDHK activities elicited by hyperthyroidism are due to changes in enzyme concentration or specific activity, and thereby to gain insight into mechanisms by which insulin might suppress PDHK activity. Antibodies were raised to purified recombinant PDHKII. The antiserum was specific to PDHKII, with negligible cross-reaction to PDHKI as assessed by Western Blots. E.l.i.s.a. assays of PDHKII were conducted over a range of PDH activities (from 0.03 to 4 m-units/well). The amount of mitochondrial immunoreactive PDHKII in heart was unaffected by hyperthyroidism; however, the amount of mitochondrial immunoreactive PDHKII in liver was significantly increased (by 1.5 fold; $P<0.001$) together with a 2.2 fold increase in PDHK activity (1.7±0.1 min^{-1} to 3.6±0.3 min^{-1}; $P<0.001$). Total PDHC activity was unaffected. In conclusion, hyperthyroidism increases cardiac PDHKII specific activity, but has a long-term action to increase PDHK concentration in liver. Since the increase in hepatic PDHK concentration and activity occurs without a change in PDHC total activity, the results demonstrate that the expression of individual PDHC components are regulated independently. Additionally, hepatic PDHK can be added to the cohort of gene products whose expression is regulated by insulin and thyroid hormone.

1166

POSTMENOPAUSAL ESTROGEN REPLACEMENT THERAPY MAY IMPROVE GLUCOSE TOLERANCE?

A. Karjalainen[1], J. Heikkinen[2], A. Bäckström[3], M. Salinto[3] and YA. Kesäniemi[1]. Department of Internal Medicine and Biocenter Oulu, University of Oulu[1] and Oulu Deaconess Institute[2], Orion Corporation Orion Pharma[3], Oulu, Finland

Previous studies concerning the effect of estrogen replacement therapy (ERT) on glucose metabolism have suggested that non-oral delivery of estrogen might be more beneficial due to the bypass of the first-pass effect of liver, but the results have been controversial. To compare the effects of peroral estradiol valerate 2 mg/d with percutaneous estradiol gel 1mg/d, (Divigel, Orion Pharma), 79 hysterectomized, non-diabetic postmenopausal women aged 48 to 62 years were randomized to a double-blind, double-dummy trial. After overnight fast glycosylated hemoglobin ($GHbA_{1c}$) and standard 75 g oral glucose tolerance test including fasting and postchallenge blood glucose, serum insulin and C-peptide (at 30, 60 and 120 minutes) measurements, were determined at baseline and after six months of ERT. Area under the curve (AUC) was calculated for parameters of glucose tolerance test. Minor weight gain, +0.6 kg, and increased body mass index, +0.21 kg/m^2, were noticed in percutaneous estrogen group, but not in peroral therapy. Both percutaneous and peroral estrogen reduced $GHbA_{1c}$, mean change -0.15 % ($p<0.01$) and -0.17 % ($p<0.01$), respectively. The mean decrease of AUC for C-peptide (μg/l·h) was 0.95 ($p<0.05$) in gel group and 1.0 ($p<0.01$) in peroral group. No other significant changes were noticed in fasting or postchallenge glucose and insulin levels or AUCs for glucose and insulin. In conclusion, after six months of ERT both regimens reduced $GHbA_{1c}$ and AUC for C-peptide, but glucose and insulin levels remained unchanged. No differences between treatments were noticed. Decreased $GHbA_{1c}$ suggests long-term beneficial effects on glucose and insulin metabolism, which may be obtained by lower endogenous insulin (C-peptide) secretion as suggested by reduced AUC for C-peptide.

1167

RELATION BETWEEN THYROID FUNCTION AND CYTOKINE LEVELS IN DIABETIC PATIENTS.

Y. Ohno, Y. Kishitani, A. Nishimura, K. Ikeda, T. Saika and N. Aoki.
Department of Medicine, Kinki University School of Medicine, Osaka-Sayama, Osaka 589, Japan

In non-thyroidal illness including diabetes mellitus, euthyroid sick syndrome or low T3 syndrome is sometimes found. Recent reports demonstrated that several cytokines may modulate thyroid function. In an atempt to elucidate the mechanisms of abnormalities of thyroid hormone metabolism in diabetic patients, we have studied the relationship between thyroid function parameters and cytokines.

Subjects and Methods: Peripheral blood was obtained from 39 diabetic patients who had no endocrine disease including thyroid and autoimmune diseases. Serum TSH, free T4 (FT4), free T3 (FT3) and reverse T3 (rT3) were measured by radioimmunoassay kits. Plasma interleukin (IL) -1β, IL-6, IL-1 receptor antagonist (IL-1ra) and tumor necrosis foctor-α (TNF) were measured by ELISA kits. Results: TNF levels were positively correlated with HbA1c levels ($p<0.05$). TNF levels were neither correlated with thyroid hormones nor TSH. IL-6 levels were positively correlated with rT3 ($p<0.01$). IL-1ra levels were positively correlated with rT3 ($p<0.05$). IL-6 and IL-1ra were not correlateded with any diabetic control markers. IL-1β levels were not correlated with thyroid hormones and diabetic control states. All the cytokines measured were not parallelly associated with FT3 or FT4.

Conclusion: Our results suggest that IL-6 and IL-1ra may increase serum rT3 levels in diabetic patients.

1168

EFFECT OF TESTOSTERONE REPLACEMENT THERAPY ON INSULIN SENSITIVITY AND OTHER CARDIOVASCULAR RISK FACTORS IN MALES WITH IDIOPATHIC HYPOGONADOTROPHIC HYPOGONADISM (IHH)

D Tripathy, P Shah, AC Ammini. All India Inst Med Sci, New Delhi, INDIA

Background: Women in child bearing age have 2-3 times lower incidence of coronary heart disease (CHD) compared to men; the rates equalise after menopause, and, with hyperandrogenism. It is not clear whether testosterone is predisposing or oestrogen's are protective to CHD. **Aim:** to look at the role of testosterone in development of insulin resistance and other cardiovascular risk factors. **Design:** prospective, "before-after" study on ten IHH males pre- and post-testosterone replacement therapy; *outcome measures:* anthropometry, lipoprotein profile and M value (whole body glucose disposal rates on standard hyperinsulinaemic euglycaemic clamp; insulin infusion rate: 40mU/m^2). **Results:** Base line upper segment (77.8 ± 1.73cm), was less than lower segment (96.3±1.73); body span was 182 ± 2.96cm; mean weight was 62.1kg; BMI was 20.5 ± 1.86kg/m^2; waist-hip ratio was 0.865 ± 0.25; none had anosmia. Pre-treatment serum testosterone was 0.43 ± 0.24 ng/ml, LH was 1.29 ± 0.72IU/L and, FSH was 1.42 ± 0.79 IU/L. None had glucose intolerance. After replacement testosterone levels increased to 9.3 ng/ml ($p=0.0005$), weight increased by 5.0 kg ($p=0.140$), BMI increased to 21.7 ± 1.79 kg/m^2 ($p=0.285$), no change was seen in WHR (0.863 ± 0.266); skin fold thickness decreased (triceps to 24.3± 2.92 vs. 22.3 ± 2.84mm, $p=0.85$). There was no change in testicular volume $p=0.14$. M-value (mg/kg/min) did not change after testosterone therapy (5.72 ± 1.58 vs. 5.33 ± 1.26, $p=0.766$). Insulin levels (mU/L) achieved during the clamps were 89.5 ± 6.7 before and 146 ± 10.3 after androgen therapy ($p=0.127$). There was no change in glucose area under curve (mg.min.dL^{-1}) 14406 ± 39.8 vs. 12557 ± 51.1, $p=0.312$). On testosterone replacement therapy total and LDL cholesterol levels declined (123.1 ± 6.5 vs. 91.6 ± 3.94, $p=0.007$; 65.9 ± 31.7 vs. 39.4 ± 23.7, $p=0.045$); Ratio of total cholesterol to HDL ratio also decreased significantly ($p=0.05$). No changes were seen with triglyceride ($p=0.247$), HDL cholesterol levels ($p=0.198$). **Conclusions:** Testosterone replacement therapy of IHH was associated with decrease in total cholesterol, LDL cholesterol, and cholesterol to HDL ratio. There was no change in HDL and triglycerides. Insulin sensitivity did not decrease on testosterone replacement. The gender difference in coronary heart disease has to be explained by some mechanism other than testosterone causing insulin resistance.

1169

THE RELATIONSHIP BETWEEN THE GLYCEMIC CONTROL AND THE HYPOTHALAMUS-PITUITARY-THYROID AXIS IN DIABETIC PATIENTS

N.Gürsoy, E.Tuncel, E.Ertürk, Ş.İmamoğlu and A.Arıuık, University of Uludağ, School of Medicine, Department of Endocrinol & Metab, Bursa, Turkey

Diabetes mellitus, similar to other nonthyroidal illness, is associated with circadian rhythm abnormalities of serum TSH and thyroid hormones.

In this study, we investigated the effect of good and poor metabolic control on the nocturnal serum TSH peak and the TSH response to TRH stimulation in diabetic patients. 32 diabetic patients (insulin dependent,n=9; noninsulin dependent,n=23;18 men,14 women ; the mean age :45.8±10.5 yrs) with either poor glycemic control (n=22) or good glycemic control (n=10) were enrolled in this study. The nocturnal serum TSH peak (22^{30}-02^{00}h) was abolished in the poor glycemic control group ,whereas there was statistically significant peak in the other group($p=0.0001$).The morning serum TSH value in diabetics with the poor glycemic control group did not differ from that in the other group, but the serum TSH and TT4 were significantly higher in the good glycemic control group than the other group and no differences were found in the increase of the serum FT4,TT3 and FT3 levels between the two groups after TRH stimulation.The morning serum TT4 and TT3 levels were significantly higher in the good glycemic control group than the other group ($p=0.04$,$p=0.007$) whereas the morning serum FT4, FT3 and TSH values did not differ in the two groups.The increase of the serum TSH and TT4 levels after TRH stimulation were significantly higher in the good glycemic control group than the other control group whereas there were no difference in the increase of the serum TT3, FT4 and FT3 levels between the two groups.

In conclusion,the metabolic control affects the hypothalamus-pituitary-thyroid axis and the metabolic decompensation in diabetic patients leads to the impairment of TSH secretion, thyroid hormones secretion their response to TRH.

1170

GENDER DIFFERENCE IN THE RELATIONSHIP BETWEEN INSULIN RESISTANCE AND SHBG LEVELS IN SUBJECTS AT INCREASED RISK OF DEVELOPING NIDDM.

T.Goto, S.Kumagai, H.Sasaki, T.Hinata, T.Onuma and T.Suda,
Hirosaki University School of Medicine, Aomori, Japan.

Decreased plasma SHBG levels predicts noninsulin dependent diabetes, frequently accompanied with insulin resistance, in women but not in men. Thus the relationship between insulin resistance and SHBG may be different in men and in women. However, there has been few data in vivo on the relation of insulin resistance to SHBG in men. To clarify this issue, 119 subjects (56 men and 63 women) with borderline glucose tolerance, proposed by Japan Diabetes Society and proven to be at increased risk of developing NIDDM, received 2hr of euglycemic hyperinsulinemic clamp studies under primed and continuous infusion of insulin at a rate of 40 mU/m^2/min. Circulating SHBG levels were measured before and 2hr after the beginning of the clamp studies. Glucose infusion rate during the last 30 minutes of clamp studies (GIR) and basal SHBG levels correlated positively both in men ($r=0.40$, $p<0.01$) and in women ($r=0.45$, $p<0.01$). As expected, age, BMI and WHR correlated with SHBG and with GIR in men and/or in women. Multiple regression analysis, selecting SHBG as dependent variable and age, BMI, WHR and GIR as independent variables, disclosed that GIR related to SHBG independently in women but not in men. Thus the positive correlation between GIR and SHBG in men may be an epiphenomenon. On the other hand, during the clamp procedure, circulating SHBG levels decreased significantly only in women (60±39 nmol/L→50±34, M± SD, $p<0.025$) but not in men (30±14→28±12, $p>0.05$). These results indicate that the relationship between insulin resistance and SHBG, and acute effect of insulin on circulating SHBG levels are different in men and in women, which could explain the gender difference in the role of decreased SHBG predicting the development of NIDDM .

1171

INSULIN SENSITIVITY IN MALNUTRITION DUE TO ANOREXIA NERVOSA - RELATIONSHIP BETWEEN HORMONAL DISTURBANCES.

B.Krzyżanowska, M. Robaczyk, M. Śmiarowska, L.Majkowska, M.Gulińska and S.Czekalski. Dept. of Endocrinology, Pomeranian Medical Academy, Szczecin, Poland.

In obese persons with abdominal body fat distribution (ABF-D) and in some subjects with anorexia nervosa (AN) impaired insulin sensitivity and hyperbeta-endorphinemia were found. It has been demonstrated that endogenous beta-endorphin (B-EP) may be in part responsible for hiperinsulinemia (HI) and insulin resistance in ABF-D obesity. To assess the possible relatonship between insulin resistance and hormonal disturbances in patients with anorexia nervosa we evaluated basal serum/plasma insulin (IRI), glucose (G), growth hormone (GH), B-EP and cortisol (C) concentrations and their response to oral glucose load (OGTT). Eight patients with AN and normal glucose tolerance (NGT), 10 AN patients with impaired glucose tolerance (IGT) and 6 healthy subjects at similar age participated in the study. Serum or plasma hormone levels were evaluated by RIA and blood glucose by oxidase method. Patients with AN and IGT demonstrated markedly (p=0.03) higher basal IRI secretion than patients with NGT but insulin response to OGTT in both groups did not differ. In patients with AN and IGT insulin resistance assessed as IRI/G ratio in basal condition showed significant linear correlations with basal B-EP (r=0.76; p=0.01) and cortisol (r=0.68; p=0.03) plasma levels. In this group of patients basal plasma B-EP concentrations correlated with basal serum IRI levels (r= 0.70; p=0.01). In AN patients with NGT such correlations were not found. Both groups did not differ in terms of basal B-EP, GH, cortisol and glucose levels as well as BMI. These results suggest that increased opioid sensitivity and hypercortisolemia may be in part responsible for insulin resistance in some patients with anorexia nervosa.

1172

SEX DIFFERENCES IN GLUCOSE DISPOSAL IN NIGERIANS

A. Osa, A. E. Ohwovoriole and T.O. Johnson, Department of Medicine, Lagos University Teaching Hospital, Lagos, Nigeria.

There appears to be a dearth of studies on glucose disposal rate in Nigerians. This study was carried out to assess the effect of sex and anthropometric indices on glucose disposal rate, an index of beta-cell function. One hundred and two non-diabetic subjects (50 males and 52 females) aged 13 - 47 years were tested. Age, sex, body mass index, and waist hip ratio were recorded. Each subject had an intravenous glucose tolerance test using 25g of a 50% dextrose solution, and the decay in plasma glucose levels was utilised in deriving the glucose disposal rate. Females had a significantly higher mean (SD) glucose disposal rate [2.14 (0.56) % per minute in females, 1.9 (0.49) per minute in males, $p < 0.001$). Glucose disposal rates decreased with age ($r = -0.25$ in males, $p > 0.05$, $r = -0.17$ in females, $p > 0.2$); with body mass index ($r = -0.15$, $p > 0.05$ in males, $r = -0.29$, $p < 0.05$ in females). There was no correlation between glucose disposal rate and waist hip ratio. This study shows a significant sex difference in glucose disposal rates and that Nigerian females dispose of glucose more efficiently than the males.

1173

ACQUIRED INSULIN RESISTANCE IN EARLY HIV AND ASYMTOMATIC AIDS

R Arakaki, J McKeague, N Baker-Ladao, A Kindrick, and C Shikuma. University of Hawaii-Manoa, Honolulu, Hawaii, USA

HIV-infected individuals are susceptible to opportunistic infections as their immune system deteriorates in the face of increasing viral burden. It is now clear that there is a prolonged latency period of HIV infection with progressive deterioration of immune function prior to the onset of AIDS. Separate metabolic and endocrine evaluations of HIV-infected individuals at different stages of immune may allow for the characterization of processes that result in increased morbidity and mortality. Thus, we have performed anthropometric measurements and assayed for various endocrine and metabolic factors in HIV-infected individuals with various clinical manifestations. Five cohorts of male participants were established as follows; Controls (HIV seronegative individuals, N=4, BMI=24.8, Age=38), Early HIV(infected individuals with CD4 counts > 500 cells/mm3, N=5, BMI=23.7, Age=41), Asymtomatic AIDS (infected individuals with CD4 counts < 200 cells/mm3, N=9, BMI 24.4, Age 42), AIDS with wasting (N=3, BMI=19.5, Age 48), and AIDS with wasting and active opportunistic infection (N=4, BMI=18.6, Age 45). As compared to age and BMI matched controls, fasting plasma insulin levels [142.08±43.2 pmol/L vs 40.44±1.8 pmol/L ($p<.0055$)] and percent body fat [24.5±1.2% vs 17.9±2.6% ($p<.049$)] were significantly greater in Asymtomatic AIDS patients. In Early HIV individuals, insulin levels and percent body fat (52.8±12 pmol/L and 20.4±2.3 %, respectively) were increased compared to controls, but not significantly. Insulin levels were increased in both AIDS with wasting and AIDS with wasting and opportunistic infection cohorts despite smaller BMI and lower percent body fat as compared to controls, however these differences also did not reach statistical significance. Fasting blood glucose and triglyceride levels, and basal and stimulated cortisol and ACTH levels were similar among the five cohorts. The results of this small study suggest that fasting hyperinsulinemia/insulin resistance is observed among HIV-infected individuals with decreasing immune function. This acquired insulin resistance before the onset of wasting with and without opportunistic infection appears to be associated with increased percent body fat without an increase in weight. We speculate that progressive HIV infection and the resultant deterioration of immune function rather than increased glucocorticoid levels account for insulin resistance. We conclude that with new anti-retroviral therapy that increase long-term survival among the HIV-infected population, the acquisition of insulin resistance may present significant increases in glucose intolerance and cardiovascular disease.

1174

RELATIONSHIP BETWEEN DHEA-S AND INSULIN SENSITIVITY IN PATIENTS WITH NON-INSULIN DEPENDENT DIABETES MELLITUS.

Takashi Iizuka, Terukazu Miyamoto, Hiroko Ito, Masao Omura and Tetsuo Nishikawa. *Department of Medicine, Yokohama Rosai Hospital, Yokohama* City, Kanagawa 222, Japan.

The circulating level of dehydroepiandrosterone-sulfate(DHEA-S) which is thought to have anti-atherogenic action has been reported to be inversely related to death from any cause, especially cardiovascular disease in men. Little was known about the mechanism of the effect of DHEA-S on insulin sensitivity in the patients with NIDDM. We, therefore, attempted to investigate the effect of *DHEA-S on insulin sensitivity and lipid metabolism* in patients with NIDDM. Blood levels of DHEA-S and various lipids were estimated before hyperinsulinemic euglycemic glucose clamp(HEGC) in *158 patients with NIDDM*. Those subjects were divided to two groups according to the serum level of LDL-cholesterol(LDL-C) and HDL-cholesterol(HDL-C) as follows: 81 diabetics showed high level of LDL-C *more than 120mg/dl(H-LDL) and 77 cases did low level of LDL-C less than* 120mg/dl(L-LDL); 71 subjects showed high level of HDL-C more than 50mg/dl(H-HDL) and 87 cases did lwo level of HDL-C less than *50mg/dl(L-HDL)*. *M values during HEGC which are reflecting insulin* sensitivity in whole body were significantly higher in H-HDL than in L-HDL. It was also observed that serum levels of DHEA-S was significantly *decreased by aging. There was significantly a positive correlationship* between M values and serum DHEA-S levels in both of H-LDL(*) and L-LDL(*) groups, while there was not observed in L-LDL and H-HDL groups. *There was a significant and positive correlation between serun levels of* total cholesterol and DHEA-S in H-LDL(*) and L-HDL(*) groups. (*$p<0.05$). In conclusion, DHEA-S may play a crucial role in the regulation of insulin *sensitivity and lipid metabolism in diabetics.*

1175

DIFFERENCE IN BONE DENSITY ACCORDING TO SEX IN NIDDM

K. C. Sung, S.H. Kwon and S. J. Lee.
Kangbuk Samsung Hospital, Seoul, Korea.

Recently, study on relationship between diabetes mellitus and osteoporosis is gaining background due to increased interest in osteoporosis among general population. The authors achieved following results by comparatively analyzing bone mineral density (BMD) and number of factors considered to have influence on BMD in 137 participants. BMD measured by dual x-ray absorptiometry at lumbar spine. Among 24 men and 113 women, 8 men and 79 women had normal glucose tolerance but 16 men and 34 women had NIDDM. Men with NIDDM had BMD level similar to those men with normal glucose tolerance, whereas women with NIDDM had significantly higher BMD levels than age matched control group. The mean BMD in women with NIDDM compared with normoglycemic women was $1.08\pm0.1 g/cm^2$ vs $0.91\pm0.2 g/cm^2$ at lumbar spine. Both group and sex had similar body mass index and their mean age was 57.2 ± 9.9years. Mean estrone, SHBG, free testosterone level in women with NIDDM compared with control group are 129.13 ± 78.1pmol/L vs 95.8 ± 92.8pmol/L, 53.7 ± 30.5 nmol/L vs 81.5 ± 36.4nmol/L, 0.039 ± 0.013nmol/L vs 0.037 ± 0.009nmol/L, respectively. But the difference had no statistical significance. In female NIDDM patients, BMD and SHBG showed negative correlation. In conclusion, older women with NIDDM or hyperglycemia had better BMD than women with normal glucose tolerance but no difference in bone density by diabetic status were observed in men. Further study is suggested to clarify the relationship between sex hormone and BMD through extended study and appropriate analysis.

THYROID FUNCTION IN SUBJECTS WITH MALNUTRITION RELATED DIABETES MELLITUS

L. Ali[1], F. Mollah[2], M.A. Khaleque[3], J.M.A. Hannan[1], S. Ali[2], N.S. Chowdhury[1] and A.K. Azad Khan[1]. *[1]BIRDEM; [2]PGMR, [3]NDN, Dhaka, Bangladesh*

Patients with malnutrition related diabetes mellitus (MRDM, as defined by WHO Study Group), although clinically euthyroid, have earlier been shown to have significantly lower levels of both serum T_3 and T_4 and higher levels of TSH as compared to age-matched Control. NIDDM patients of similar age group showed only lowered levels: T_3, T_4 and TSH were similar to Control. The present study aimed to assess the thyroid function of MRDM patients by measuring the functionally important fractions of thyroid hormones (FT_3 and FT_4) and also to elucidate whether any change in these hormones are related to the serum levels of thyroxine binding globulin (TBG). Seventeen newly diagnosed MRDM (9 PDDM, 8 FCPD), 24 NIDDM and 20 Control subjects were studied. Serum C-peptide was measured by ELISA; T_3, T_4, FT_3, FT_4 and TSH by microparticle enzyme immunoassay (MEIA); TBG by radial immunodiffusion (RID), and HbA_{1c} by HPLC methods. T_3 in all diabetic groups were lower as compared to Control (NIDDM 1.88 ± 0.05, PDDM 0.99 ± 0.33, FCPD 0.66 ± 0.32 and Control 2.06 ± 0.34 nmol/l, M±SD). However MRDM subgroups showed the lowest values which differed significantly from Control as well as from NIDDM ($p<0.05$) patients. NIDDM group had values of FT_3 and FT_4 similar to Control, but MRDM subgroups still showed significantly deficient thyroid function (*FT3, pmol/l, M±SD*: Control 4.43 ± 0.54; NIDDM 4.33 ± 0.84; PDDM 2.68 ± 0.68; FCPD 2.56 ± 0.62; $p<0.05$, Bonferroni t-test and *FT4, pmol/l,M±SD*: Control 14.53 ± 2.30; NIDDM 16.96 ± 3.00; PDDM 12.30 ± 3.60; FCPD 13.08 ± 2.25; $p<0.05$). TBG was similar in all the groups (TBG, mg/l, M±SD: Control 8.93 ± 2.40; NIDDM 8.78 ± 3.00; PDDM 8.36 ± 2.50; FCPD 6.80 ± 1.60) showing that abnormalities of this transport protein may not account for the thyroid dysfunction in these patients. Serum T_3 and T_4 in all diabetic subjets showed a significant negative correlation with the degree of hyperglycemia as measured both by glucose and HbA_{1c}. Fasting serum C-peptide showed a positive correlation ($r=0.034$, $p<0.05$) with T3 in the diabetic subjects. The results suggest an abnormality of thyroid function in MRDM patients which may be related to their severe hyperglycemia and deficient insulin secretory capacity.

1177

AMYLIN INHIBITS PENTAGASTRIN-STIMULATED GASTRIC ACID SECRETION AND PROTECTS AGAINST ETHANOL-INDUCED GASTRIC MUCOSAL DAMAGE IN RATS

B.R. Gedulin, R.L. Lawler, C.M. Jodka, M.L. Grazzini, and A.A. Young, Amylin Pharmaceuticals Inc, San Diego, CA, USA

Amylin, a peptide hormone secreted from pancreatic β-cells in response to nutrient stimulation, is a physiological regulator of gastric emptying. To investigate whether amylin exerted other gastric actions, we examined its effects on pentagastrin-stimulated acid secretion and on ethanol-induced gastritis in fasted Sprague Dawley rats. To study acid secretion, rats chronically implanted with gastric cannulae were injected subcutaneously with 125μg/kg pentagastrin. Gastric contents obtained by flushing the cannulae every 10 min were titrated to measure acid production. 40 min after pentagastrin, rats were injected subcutaneously with rat amylin and the aggregate acid secreted over the next 60 min measured. Amylin suppressed acid secretion by 93.3% from that in saline treated rats (60 min after amylin; $P<0.001$; n=5,6). The ED_{50} for this effect was 0.027μg/rat ± 0.07 log units, a dose calculated to result in physiological changes in plasma amylin concentration. To study a potential gastroprotective effect of amylin, rats were injected subcutaneously with amylin 20 min before gavage with 1mL absolute ethanol and sacrificed 30 min later. The stomachs were excised, washed and everted for grading of injury by observers blinded to the treatment. Amylin reduced the injury score by up to 67%. The ED_{50} for the gastroprotective effect of amylin in this experimental system was 0.036μg/rat ±0.4 log units, similar to that for inhibition of gastric acid secretion. We propose that endogenously secreted amylin may play a role in restraining gastric acid secretion and the protection of gastric mucosa.

1178

MECHANISM OF KETOSIS RESISTANCE IN MALNUTRITION RELATED DIABETES MELLITUS

S. Parvin[1], L. Ali[1], M.A. Mottaleb[2], J.M.A. Hannan[1], N.S. Chowdhury[1], M.S. Ali[2] and A.K. Azad Khan[1]. *[1]BIRDEM; [2]Dept of Biochemistry, IPGMR, Dhaka, Bangladesh*

To understand the mechanism of charactersric ketosis resistance in malnutrition ralated diabetes mellitus we have studied the ketogenic responses of to oral fat in 17 MRDM subjects (FCPD 7 and PDDM 10) along with 15 age-matched NIDDM and 10 control subjects. Overnight fasting subjects were fed with a dairy fat 'Ghee' (1g per kg body weight) and serum was collected at 0, 120 and 240 min. Although the BMI of FCPD (Mean 13.7) and PDDM (16.2) patients were markedly lower than the NIDDM (21.4) and Control (21.6) and although FBG of FCPD (16.9±4.2, mmol/l, M±SD) and PDDM (18.1±3.1) patients were considerably higher than those of NIDDM (12.8±4.9) and Control (5.4±1.5), the fasting S β-HBA levels did not vary significantly among the groups (Median β-HBA, mg/dl: Control 1.5, FCPD 2.2, PDDM 1.6, NIDDM 1.5). β-HBA level was maintained in spite of very low S C-peptide in FCPD (0.4±0.3 ng/ml, M±SD) and PDDM (0.7±0.1) subjects (NIDDM 2.1±0.8 and Control 2.2±0.5). The S glucose response to oral fat was almost flat in Control, but there was a gradual rise at 120 min and gradual fall at 240 min in the 3 diabetic groups. The S C-peptide paralleled the rise and fall of glucose only in NIDDM; in FCPD and PDDM there was almost flat responses, and in Control there was a rise and fall of C-peptide. The β-HBA response in the Control clearly differed from the 3 diabetic groups with a sharp rise of levels at 120 min (about 62% increase) and equally sharp fall near the baseline at 240 min. In contrast β-HBA continued to rise at 240 min in the 3 diabetic groups which had similar levels and the values differed significantly ($p<0.05$) from that of Control. TG levels showed a similarity among all the 4 groups at all time points. Conclusions: a) Depleted body fat store do not lead to decreased fasting ketone bodies in MRDM, b) The effect of NEFA (from oral fat) on glucose metabolism varies between nondiabetic and diabetic subjects and MRDM subjects do not show any peculiarity in this respect, c) The β-cell function MRDM subjects is severely compromised, and d) Re-esterification and ketone body synthesis pathways seem to be comparable among MRDM and NIDDM and, thus, factor(s) other than these probably contribute to the development of ketosis resistance in MRDM subjects.

1179

STUDIES USING NEUTRALIZING ANTIBODY AND THE ANTAGONIST AC187 REVEAL THAT ENDOGENOUS AMYLIN INHIBITS GLUCAGON SECRETION.

B. Gedulin, A. Percy, C. Jodka and A. Young. Amylin Pharmaceuticals, Inc., San Diego, CA , USA.

The ß-cell hormone, amylin, like its partner hormone, insulin, inhibits pancreatic glucagon secretion. We have recently published that infused amylin can inhibit L-arginine-stimulated glucagon secretion by over 60% with an EC_{50} of 18 pM ±0.3 log units. To examine whether endogenous amylin tonically inhibits glucagon secretion, we measured plasma glucagon while blocking the effects of endogenous amylin by either neutralizing the ligand (amylin) by infusion of a specific amylin monoclonal antibody, or by neutralizing the receptor using the potent and selective competitive amylin antagonist, AC187. For the monoclonal antibody studies, we injected male Harlan Sprague Dawley rats intraperitoneally with 3mg of specific amylin monoclonal antibodies (n=5) or nonspecific antibodies (n=5) 24 hours before testing. For the amylin antagonist studies we infused with either AC187 at 3mg/h (n=8) or with saline (n=30) during testing. Testing comprised measurement of plasma glucagon in overnight-fasted halothane-anesthetized rats before and after 60 min of euglycemic clamp (glucose 5.8mM, primed/continuous insulin infusion of 12mU + 5mU/kg/min). In animals administered the specific (25-27) anti-amylin antibody the previous day, plasma glucagon levels were 61% higher throughout the clamp procedure than those in animals administered the non-specific (40-6) antibody (93±14 vs 58±5pM, $P<0.03$, t-test, Welch correction for different SD's). In animals infused with the amylin antagonist, AC187, or saline, plasma glucagon concentrations were similar before the clamp (82±9 vs 80±7pM, respectively, $P=0.9$). After 60 min, plasma glucagon had doubled in the AC187-infused group (160±30pM, $P<0.03$ vs t=0) and were higher than in the saline-infused group (103±9pM, $P<0.02$ between groups). Blockade of amylin action with a specific monoclonal antibody or with a selective amylin antagonist, AC187, increased glucagon secretion. Together, these data support the idea that endogenous amylin regulates glucagon secretion.

HYPERINSULINAEMIC EUGLYCAEMIC CLAMP STUDIES IN 'MALNUTRITION RELATED DIABETES MELLITUS'.

MK Garg[1], D Tripathi[1], P Shah[1], KC Samal[2], and BB Tripathi[2]. [1] All India Institute of Medical Sciences, New Delhi, and, [2] SCB Medical College, Cuttack, INDIA.

Background: High insulin requirements have been proposed as a diagnostic criterion for malnutrition related diabetes mellitus. This has been taken as a marker of insulin insensitivity.

Aim: to demonstrate whether these subjects have insulin insensitivity

Design: case control; *Cases:* ten ketosis resistant young onset (<30 years at onset) diabetic subjects; *controls:* six young onset classical ketosis prone diabetic subjects. *Outcome measure:* M value on hyperinsulinaemic euglycaemic clamps (40 $mU.m^{-2}$, intended insulin concentration 100$uU.ml^{-1}$) (mean c.v. for plasma glucose 60-120 min of clamp: 3.58%+/-0.38)

Results: The cases and controls were matched for age (23.4 ± 1.8 vs. 19.8 ±2.5 years) and BMI (16.7±0.6 vs. 18.5 ±0.6kg/m2). HbA1 (12.1± 0.5 vs 10.5± 1.2%), serum triglyderides(147±13 vs 110±9mg/dL) and cholesterol (145±11 vs 167±21mg/dL) of the cases and controls were comparable.With adequate euglycemia the glucose disposal rate (M value, mg.kg-1.min-1) were 7.06±0.80 in cases and 7.43 ± 1.34 in controls (p=0.67).

Conclusions: ketosis resistant diabetes of young (malnutrition related diabetes mellitus) is not associated with insulin resistance.

1181

COMPARISON OF EFFECTS OF AMYLIN, GLUCAGON-LIKE PEPTIDE-1 AND EXENDIN-4 TO INHIBIT PENTAGASTRIN-STIMULATED GASTRIC ACID SECRETION

B.R. Gedulin, R.L. Lawler, , C.M. Jodka and A.A. Young. Amylin Pharmaceuticals Inc., San Diego, CA, USA

Amylin, a peptide hormone secreted from pancreatic ß-cells, is a physiological regulator of gastric emptying. Exendin, a component of the venom of the Gila monster, is as potent as amylin in regulating gastric emptying, while glucagon-like peptide-1 (GLP-1) is ~20-fold less potent. Here we compared the effects of amylin, GLP-1 and exendin on pentagastrin-stimulated gastric acid secretion in rats. Acid production from the stomachs of chronically cannulated fasted rats was measured by titration of contents flushed every 10 min. Forty min after subcutaneous injection of 125µg/kg pentagastrin, rats were injected subcutaneously with rat amylin, human GLP-1[7-36]NH_2, or exendin-4 and the aggregate acid secreted over the next 60 min measured. Amylin potently inhibited gastric acid secretion with an ED_{50} of 0.027µg ±0.07 log units. GLP-1 was 180-fold less potent (ED_{50} 4.9µg ± log units). Exendin-4 failed to inhibit acid secretion at any dose. Thus, the order of potencies for inhibition of gastric acid secretion by amylin, GLP-1 and exendin (amylin>>GLP-1>>exendin) differed markedly from that previously obtained for gastric emptying (exendin≥amylin>>GLP-1). This result suggests that structures responsible for exendin-inhibition of gastric emptying are distinct from those responsible for inhibiting gastric acid secretion. Structural distinctions could include differences in access to receptors mediating gastric emptying vs. acid secretion, and could even indicate different receptor subtypes mediating these responses.

1182

SERUM AND ERYTHROCYTE MAGNESIUM IN NEWLY DIAGNOSED MALNUTRITION RELATED DIABETES MELLITUS SUBJECTS

S Sattar, L Ali, Z Hassan, AK Azad Khan; *Research Division, BIRDEM, Dhaka, Bangladesh*

Hypomagnesemia is implicated in the pathogenesis of insulin resistance in diabetic patients. Recent data from our group suggest that patients with Protein Deficient Diabetes Mellitus (PDDM) [a subgroup of Malnutrition Related Diabetes Mellitus (MRDM), the third major class of diabetes recognized by the WHO Study Group] suffer from a more severe degree of hypomagnesemia compared to NIDDM ones. Since these patients presenting with severe degree of hyperglycemia (serum glucose usually >16 mmol/l) need a relatively large amount of insulin for controling diabetes. It is important to study their Mg metabolism in a greater detail for a possible link with insulin resistance. The Erythrocyte (E) Mg content is a more specific marker of total body Mg compared to serum levels and this has been measured in the present study in 15 PDDM, 10 NIDDM and 12 age-matched nondiabetic Control patients. RBCs were washed twice with 300 mM ice-cold sucrose to get rid of extracellular Mg and the content of the element in the homogenized cells was measured by an enzymatic-colorimetric method. Protein content of the cells was measured by a detergent compatible Kit using spectrophotometric technique. Although NIDDM patients had lower S Mg compared to control (S Mg, mmol/l, M±SD, 0.89±0.04 in Control vs 0.86±0.76 in NIDDM) the two group did not differ statistically. However the level in PDDM Group (0.84±0.05) was significantly lower compared to Control (p= 0.004). The Mg content of RBC demonstrated the Mg deficiency in diabetic patients more unambiguously. The PDDM and NIDDM subjects showed similar values which were significantly lower than those of Control (E Mg, µmol/mg protein, M±SD, Control: 0.16±0.02, PDDM: 0.12±0.05, and NIDDM: 0.12±0.0). The closely similar E Mg values in PDDM and NIDDM patients were maintained in spite of marked difference in their S glucose values (S Gl, mmol/l, M+SD, Fasting : 18.17 in PDDM vs 10.62+3.79 in NIDDM; Postprandial : 26.34±8.01 in PDDM vs 19.27+4.54 in NIDDM). The results suggest the following: a) E Mg is a more sensitive marker of Mg-deficiency in diabetic subjects; b) Mg-deficiency may be related to the need for high deses of insulin in MRDM subjects and c) the theory is that hypomagnesemia caused by sequestration of Mg within RBCs as a consequence of hyperglycemia may not be compatible with the present findings.

1183

PLASMA AMYLIN CONCENTRATIONS IN RATS: UTILITY OF A MONOCLONAL IMMUNOENZYMOMETRIC ASSAY

W. Vine, E. Blase, P. Smith, R. LaChappell, A. Percy, J. Koda and A. Young. Amylin Pharmaceuticals, Inc., San Diego, CA USA

Reported values for plasma amylin concentrations in the rat vary widely. Some of this variation may be attributable to concentrations that are artifactually elevated, a difficulty often inherent in polyclonal antibody-based competitive RIA. We have measured basal and stimulated plasma amylin concentrations in a variety of rat strains using a monoclonal antibody-based fluorescent immunoenzymometric assay (IEMA). In the IEMA the capture antibody binds to the N-terminal and the detection antibody (alkaline phosphatase/4-methylumbelliferyl-PO4) to the C-terminal ends of amylin, and both have < 0.5% cross-reactivity to calcitonin or calcitonin gene-related peptide. The standard curve (0, 1.25, 2.5, 5.0, 10 pM) was fit by SD-weighted linear regression: relative fluorescent units (RFU)=pM*17.57+6.66, R^2=0.989. The zero standard (11.9±1.2 RFU (±SEM); n=53) was distinguishable from the 1.25 pM standard (22.4±3.1 RFU; n=12; P<0.001), enabling measurement into this range. Amylin concentrations (pM) in plasma obtained by cardiac puncture were lower in fasted vs fed anesthetized rats of different strains: Harlan Sprague Dawley (HSD): 1.40±.17 (n=8) vs 4.81±0.56 (n=8); P<0.0001: Lewis: 1.02±0.09 (n=11) vs 3.08±0.34 (n=8); P<0.0001: Wistar: 1.63±0.15 (n=9) vs 7.70±0.80 (n=9); P<0.0001. Plasma amylin concentration was significantly strain-dependent (ANOVA, P<0.01 for fasted animals; P<0.0001 for fed animals). Plasma amylin concentration increased by 1.88±0.28pM in fasted anesthetized HSD rats (n=9) after intravenous injection of 5.2mmol/kg of glucose (P<0.0001 vs saline-infused controls; n=8) and by 4.02±0.83pM in fed rats (n=6; P<0.005 vs controls; n=6). In conclusion, a sensitive monoclonal antibody-based IEMA revealed plasma amylin concentrations that were lower than values that have been reported using some other less sensitive assays, but which are internally consistent in regard to patterns of β-cell secretion after food or glucose stimulation of fasted or fed rats.

1184

NON DIABETIC SUBJECTS FROM MATERNAL INHERITANCE, DIABETES AND DEAFNESS FAMILIES DEMONSTRATE INSULIN RESISTANCE ON I.V. GLUCOSE TOLERANCE TESTING

DJ Holmes-Walker[1], GM Ward[2], J Burton[2] and SC Boyages[1]. Departments of Diabetes and Endocrinology, Westmead Hospital[1], Sydney and St Vincent's Hospital[2], Melbourne, Australia

Conflicting reports exist as to the precise pathogenetic mechanism of diabetes mellitus in subjects with the A3243G tRNAleu $^{(UUR)}$ mutation (the 3243 mutation) of mitochondrial DNA with some studies favouring islet cell failure and others suggesting insulin resistance. We aimed to determine whether nondiabetic subjects with the mutation demonstrated any abnormalities of insulin sensitivity (Si), insulin secretion (first phase, phi1) or glucose effectiveness (SG) as a precursor to the diabetic state. Initially we performed a 75g oral glucose tolerance test (GTT) in 12 subjects from four kindreds (all subjects carried the 3243 mutation) and twelve age, sex, BMI and lean body mass matched controls with no family history of NIDDM. We found subjects with the 3243 mutation had identical glucose and insulin responses compared with controls in the first 30 mins of the oral GTT but were more hyperinsulinemic and hyperglycemic from 90-180 mins. We used the IVGTT with minimal model analysis in six 3243 mutation subjects and their controls to determine the relative contributions of insulin secretion, Si and SG to overall glucose tolerance (Kg). There was no difference in Kg between the 3243 mutation and control groups (1.61±0.65 and 1.51±0.62, x 10^{-2} min^{-1} respectively; NS). The 3243 mutation group had reduced Si c.f. controls (5.98±3.99 vs 11.7±7.14 , x 10^{-4} min^{-1} per mU/L; p=0.05). Fasting insulin, however, was not increased in the 3243 mutation group (6.6±2.2 vs 6.7±2.3, mU/L,NS) nor was phi1 altered (4.0±2.0 vs 3.4±2.5 mU/L min^{-1} per mg/dL, NS). SG was increased in the 3243 mutation group but was not significant (2.03±1.05 vs 1.12±0.65, x 10^{-2} min^{-1}, p=0.15). Using regression analysis, Phi1 was strongly associated with Kg in the 3243 mutation group (regression coefficient -0.003, 95%CI -0.004 to -0.002, p=0.004, R^2 =0.83) as was SG (regression coefficient -0.50, 95% CI -0.1 to -0.9, p=0.02, R^2=0.83). There was no significant association between SG and Phi1 in the 3243 mutation subjects (R^2= 0.41, p=0.11) although there was in the controls (R^2= 0.75, p=0.03). Lastly, there was no difference in insulin mediated glucose disposal between the two groups (Si x Phi1, p=0.8). We conclude alterations in glucose disposal are present in nondiabetic subjects with the 3243 mutation. Abnormalities include insulin resistance and increased glucose effectiveness but normal insulin secretion. We conclude insulin resistance plays a pathogenic role in the development of DM in subjects with the 3243 mutation.

1185

ISLET AMYLOID FORMATION IS ASSOCIATED WITH DIMINISHED β-CELL FUNCTION IN FAMILIAL NON-INSULIN DEPENDANT DIABETES.

C.M.M°Namara, R.C.L.Page, R.C.Turner and A.Clark. Diabetes research Laboratories, Radcliffe Infirmary, Oxford, U.K

Islet amyloid is found in 96% of subjects with NIDDM at postmortem. The aim of this study was to try to determine the relationship between amyloid deposition and the physiological changes which take place in the development of NIDDM. As part of a longitudinal study of families with NIDDM, 5 male siblings underwent physiological testing using a 1 hour infusion of glucose in 1984 and again in 1994. At baseline the eldest sibling (D.Y.)-was already diabetic. The other siblings showed typical characteristics of the Metabolic Syndrome with obesity, hypertension, hyperinsulinaemia and dyslipidaemia. Mean fasting glucose was 4.7mmol/l(±0.16), mean %S was 48(32-78) and mean %β was 150(130-180). An esimate of %S and %β was made using CIGMA-(Continuous Infusion of Glucose with Model Assessment). During the 10 year follow-up period, D.Y. died and pancreas was obtained at postmortem. His identical twin E.Y. developed NIDDM in 1989. At follow-up in 1994 a third sibling R.Y. was also found to be diabetic. In 1994 %β had markedly declined in the two siblings who had developed NIDDM(<30%) but %S remained unchanged. Fasting proinsulin levels in the diabetic siblings were markedly elevated(>60pmol/l) compared with the nondiabetic siblings(<20pmol/l). Fasting IAPP (islet amyloid polypeptide)was raised in the newly diagnosed diabetic R.Y. but was below normal in E.Y. who was on sulphonylurea treatment. Sibling E.Y. subsequently died and pancreas was obtained at postmortem. Islet amyloid immunoreactive for islet amyloid polypeptide was found in all islets of postmortem pancreas in both diabetic subjects. In conclusion islet amyloid deposition is associated with a decline in β-cell function and elevated proinsulin secretion; IAPP levels appear to be elevated in the early stages of NIDDM.

1186

INSULIN RECEPTOR BINDING KINETICS IN PATIENTS WITH MYOTONIC DYSTROPHY.

B Casanova, M.N. Pulido, R Romero, A Suárez, F Arrieta, E Rodriguez and A Rovira. Fundación Jiménez Díaz (U.A.M.). Madrid. Spain.

Myotonic dystrophy (MD) is a multisystemic disease where endocrine abnormalities are found, and may be associated to insulin resistance. We studied the dissociation kinetics and the effect of pH upon insulin binding to lymphocytes transformed with Epstein-Barr virus in 6 patients with MD (BMI:17-22 kg/m^2; basal plasma insulin:8-78 µU/ml). Results were compared with those from healthy subjects (n=4, BMI:21-23 kg/m^2. basal plasma insulin:8-24 µU/ml). Either, maximal specific ^{125}I-insulin binding (34±2.7% /10^7 cells, Mean±SEM), maximal insulin binding capacity (0.8±0.3 nM/10^7 cells) and affinity (0.8±0.2 nM) in EBV-lymphocytes were within the normal range. Also, all the insulin binding parameters were within the normal range in partially purified receptors. The ^{125}I-insulin dissociation rate in the absence or in the presence of 500 or 100,000 ng/ml of insulin (20.7±2.1; 69.4±2.4; 37.2±1.2 %/5 min) was similar to that observed in control subjects. The ^{125}I-insulin dissociation rate at pH 6.8 and 6.0 (26.2±7.6 and 59.7±1 %/ 5 min at 4°C) was in the normal range. Our results suggests that the characteristics of the interaction between insulin and its receptor in MD patients is not different from normal subject and therefore the insulin resistance associated with this disease is due to defects located at post-receptor levels.

1187

COMPARISON OF CENTRAL AND PERIPHERAL ADMINISTRATION OF AMYLIN ON REDUCTION OF FOOD INTAKE IN RATS.

S. Bhavsar, J. Watkins and A.Young. Amylin Pharmaceuticals Inc., San Diego, USA.

Amylin, a 37 amino acid peptide co-secreted with insulin from pancreatic β-cells, is reported to decrease food intake in rodents. Amylin binds to certain areas within the central nervous system, including the area postrema and nucleus accumbens, and some of amylin's actions may be centrally mediated. To investigate the site of amylin's effect on food intake, we compared inhibition of food intake following intraperitoneal (IP) or intracerebroventricular (ICV) administration of rat amylin in Sprague-Dawley rats (weight 300-350g) in which lateral ventricular guide cannulae had been implanted. At least ten days after implantation, rats were injected just before the onset of the dark cycle with 0-10µg of rat amylin via either the ICV route (2µL/dose; n≥5/dose) or IP route (n=4/dose). Food intake was measured by the difference in food weight 2 hours after presenting it to the injected rats. ICV amylin totally inhibited food intake at the 10µg dose, and the ED50 was 0.19µg/rat ± 0.07 log units. The 10µg IP dose inhibited food intake by 34%, compared to saline-injected controls. Assuming that total inhibition of food intake could have eventually been obtained with a high enough IP dose, the ED50 for the IP route of administration was 10.2µg/rat ± 0.18 log units. Thus, ICV amylin was 53-fold more potent than IP amylin in inhibiting food intake. This result supports the idea that amylin may regulate food intake via a central structure in rats.

1188

Study of Insulin Receptor Gene Variations in Patients with Acanthosis Nigricans and Close Relatives

JW Chen, J Shen, GX Ding, M.Zhuang, H.Xia and Q.Yang. First Affilated Hospital of Nanjing Medical University Nanjing, China.

Insulin resistance clearly exists in patients with acanthosis nigricans(AN) so it is importamt to find thd defect in insulin receptor(IR) gene in the patients and their pedigrees. We used technique of PCR-SSCP and DNA direct sequencing to examine the mutations and polymorphisms in the exons 17 and 20 of IR gene in 9 patients with AN and their 23 first degree relatives. Among them, 7 patients with diabetes, 13 associated with obesity, 6 with hypertriglyceridemia, and 6 with hypertension. In total, 14 variant SSCP patterns were detected. Direct sequencing revealed eight point mutations and six silent polymorphisms. Seven mutations appeared not mentioned in the literatures, such as Val to Met 983 (GTG→ATG) Gln 1004 to Lys (CAG→AAG), a homozygous for Stop to Glu 1185 (GAA→TAA), a heterozygous for Arg to Gly 1185 (GGG→AGG), polymorphisms in Gly 1008(GGC→GGT), Glu 1034 (GAG→GAA) and Cys 981 (TGC→TGA), homozygous Ile to Met 1153 (ATG→ATC), missense mutations Gln 1004 → Lys (CAG→AAG), Glu 1035 to Stop (GAG→TAG), Lys 1004 for Gln (AAG for CAG), Gly 1023 → Lys (GAG →AAG)

1189

THE EFFECT OF 300 AND 600 MG OF VITAMIN E ON INSULIN ACTION IN OBESE TYPE 2 DIABETIC PATIENTS

G. Šindelka, J. Hilgertová and J. Škrha. Dept. of Internal Medicine 3, Faculty of Medicine, Prague, Czech Republic

Increased insulin sensitivity was described previously after pharmacological doses of vitamin E. We evaluated the effect of two doses of vitamin E administered in obese Type 2 diabetic patients in which the insulin resistance was documented. Diabetic patients on oral agents or on dietary regimen alone were treated 3 months either by 300 mg of vitamin E (Group A, n=6, BMI: 40.3±8.9 kg/m^2, age 50±8 yrs) or by 600 mg of vitamin E (Group B, n=11, BMI: 31.4±3.7 kg/m^2, age 46±9 yrs).Control group consisted of 12 healthy non-obese persons. Isoglycaemic hyperinsulinemic clamp on Biostator (insulin infusion rate I mU/kg/min) was performed during 90 min after previous 60 min stabilization phase in all of them before and after vitamin E treatment. The insulin receptor characteristics on erythrocytes were evaluated too. No significant changes of diabetes control expressed by fasting plasma glucose or glycated hemoglobin and of metabolic parameters like glucose disposal rate (M), metabolic clearance rate of glucose (MCRG) or insulin sensitivity index (M/I) were observed in Group A using 300 mg of vitamin E. On the contrary, 600 mg of vitamin E caused a decrease of basal serum insulin concentrations (29±15 vs 19±8 mU/l, p<0.01), glucose disposal rate (29.5±11.0 vs 22.6±9.0 umol/kg/min, p<0.02) and metabolic clearance rate of glucose (3.7±1.7 vs 2.9±0.8 ml/kg/min, p<0.05). An increase of insulin receptor binding capacity observed in Group A (268±65 vs 325±116 pmol/l, p<0.02) contrasted with a significant decrease of insulin binding capacity in Group B (284±84 vs 171±95 pmol/l, p<0.01).We conclude, that 300mg of vitamin E had no significant influence on metabolic parameters in obese Type 2 diabetic patients whereas further worsening of insulin action was demonstrated in patients treated with 600mg of vitamin E.

1190

INSULIN RECEPTOR DEFECT IN INDIAN WOMEN WITH TYPE A INSULIN RESISTANCE.

A.R.Marita, N.Sawant and N.Rais, Sir H.N. Medical Research Society, Mumbai, INDIA.

The study aims to identify erythrocyte insulin receptor defects in Type A insulin resistance using reticulocyte count to correct for changes in red cell age. Six Indian women with hypothalamic disorders and Type A phenotype (Acanthosis Ni gricans, Hirsuitism, Hyperandrogenism) and six normal women were given oGTT. Il25-Insulin binding to erythrocytes was measured.Subjects with Type A pheno type had impaired glucose tolerance, hyperinsulinemia and higher free fatty acid levels (680 ± 180 Vs 182 ± 28umol/L, $p<0.05$ and 783 ± 160 Vs 381 ± 97umol/L) in GTT. Maximal specific insulin binding was 6.46 ± 0.75%/3.5 x 10^9 erythrocytes in controls. Displacement curves revealed marginal reduction in Type A subjects when data are expressed in terms of red cell count. However, when binding was normalised for reticulocytes, a greater, 50% decrease was seen. Scatchard analysis revealed the presence of 180 receptors/cell with KD 5.5 x 10-9 M in controls. Subjects with Type A phenotype exhibited 60% decrease in receptor number with similar KD (3.1 x 10^{-9}M). The data suggest the presence of fewer receptors in erythrocytes of Type A subjects identified more precisely using reticulocyte count. Reduced receptor number and defective lipolysis are likely causes of syndrome "X" observed in these subjects.

1191

ANTIOXIDANT VITAMIN LEVELS IN WELL CONTROLLED TYPE 2 DIABETES MELLITUS

E. Szaleczky, L. Braun, B. Sármán, P. Pusztai, Zs. Tulassay and A. Somogyi. Semmelweis University, 2nd Department of Medicine, Budapest, Hungary

Oxidative stress may effect the development of the late complications in diabetes mellitus. Antioxidant vitamins, despite of their relatively low concentrations in plasma, play important role in protection against oxidation. The aim of the study was to find out weather the plasma level of the antioxidant vitamins (A, E and C) was different in well controlled type 2 diabetics from that in control subjects. The vitamin levels of 78 type 2 diabetic subjects (39 men and 39 women, mean age: 59,0±10,04 y. o.) were tested and compared with that of 44 healthy controls (19 men and 25 women, mean age 38,3±14,4 y. o.). The measurements were carried out by HPLC method. HbA1c levels were 4,66±0,04% in the control and 6,86±0,19% in the diabetic group. The patients were divided into four groups on the basis of lipid parameters: control, hyperlipaemic control, diabetes mellitus, diabetes mellitus with hyperlipaemia. Vitamin E levels were significantly increased in the diabetic group (Control: 28,55±1,388μM vs. DM: 32,14±0,941μM, $p<0.05$). Vitamin A concentrations were also higher in diabetic subjects (Control: 1,954±0,075μM vs. DM: 2,383±0,100μM, $p<0.01$) and in men. Vitamin E/cholesterol, Vitamin E/LDL, Vitamin A/cholesterol, and Vitamin A/LDL ratio did not differ in the two groups. In diabetics with hyperlipaemia both Vitamin E, and A levels were significantly elevated. A significant positive correlation could be observed between serum cholesterol, triglyceride, and the levels of the lipid soluble vitamins. The difference in Vitamin C levels (Control: 37,59±4,392μM vs. DM: 29,64±4,027μM) did not reach significancy. No correlation could be detected between parameters reflecting carbohydrate metabolism (fasting glucose and HbA_1c) and Vitamin A, E, C concentrations. We assume that the increased lipid soluble antioxidant vitamin concentrations in diabetes - due to the higher lipid levels - show only apparent relation with an increased antioxidant defence.

This work was supported by the PhD fellowship grant of Semmelweis University.

DIFFERENT PATHWAYS OF INSULIN ACTION IN LEPRECHAUNISM

A.Battezzati, E.Bonora, M.Muggeo and L.Luzi
Universities of Milan and Verona, Milan and Verona, Italy.

The insulin sensitivity of glucose and protein metabolism, and of circulating FFA, potassium (K) and c-peptide concentrations, were investigated in a leprechaun female (age 12 yr, weight 24 kg, height 130 cm). The subject has two mutant alleles of the insulin receptor gene, that inhibit the post-translational processing and the transport of the receptors to the plasma membrane. The mutations do not affect the insulin affinity and the insulin-stimulated phosphorylation of the receptors. The subject was studied with a primed-continuous infusion of [6,6-$^2H_2$] glucose and [1-^{13}C]leucine during a basal period followed by two steps of insulin infusion (1 and 10 mU/kg/min) of two hours each. The glucose concentration decreased from 131 mg/dl in the basal period to 116 and to 93 during the 1 mU and the 10 mU insulin steps respectively. Glucose flux was almost unaffected by insulin, decreasing from 3.84 to 3.62 and to 3.40 mg/kg/min. The endogenous leucine flux, an index of proteolysis, was completely insensitive to insulin (from 182 to 189 and 180 μM/kg/h). The FFA concentration changed from 1135 to 799 and 917 μM/l. In contrast, the concentration of K dropped from 4.1 to 3.2 and to 3.3 mEq/l during the 10 mU insulin step, and an infusion of 20 mEq/h of KCl was necessary to prevent further hypokalemia. Finally, the c-peptide concentration was suppressed from 1.85 to 0.97 and 0.29 pmol/ml. In summary 1) the insulin action on proteolysis is completely absent in leprechaunism, 2) the effect on glucose and FFA metabolism is severely impaired, 3) the insulin sensitivity of K concentrations is maintained and 4) the feed-back inhibition of insulin on its own secretion is still effective. These data suggest two possibilities: 1) the activation a minimal number of receptors is sufficient to elicit the insulin effects on circulating K and on insulin feed-back inhibition, but not sufficient to affect the intracellular signaling pathways for protein and glucose metabolism, 2) insulin can affect circulating K and can suppress its own secretion using pathways alternative to the activation of its own receptor.

1193

ANTIOXIDANT DEFENSES ARE REDUCED DURING OGTT IN NORMAL AND NIDDM SUBJECTS.

A. Russo, N. Bortolotti, A. Crescentini, E. Motz, S. Lizzio, Z. Ézsol, L. Tonutti, C. Taboga and A. Ceriello.University of Udine, and Udine General Hospital, Udine, Italy

Free radical production has been reported to be increased in patients with diabetes mellitus and it has been suggested that hyperglycemia may directly contribute to the generation of an oxidative stress. In this study an OGTT was performed in 10 NIDDM patients (7 males and 3 females; age 55.1±1.7 years, mean±SE; duration of diabetes 10.0±1.5 years; BMI 25.8±1.1 Kg/m^2) and in 10 healthy normal subjects (6 males and 4 females) matched for age (56.1±1.8 years) and body mass index (25.9±1.6 Kg/m^2). In diabetic patients, during OGTT, SH groups ($p<0.03$-0.005), and vitamin C ($p<0.01$) were significantly decreased at 30 to 120 min, and uric acid at 60 to 120 min ($p<0.05$-0.01).Total plasma radical-trapping activity (TRAP), which evaluates plasma antioxidant capacity due to known and unknown antioxidants present in the plasma as well as their mutual cooperation, was also significantly reduced at 30 to 120 min ($p<0.001$). Vitamin E was not affected. In normal subjects, during OGTT, TRAP ($p<0.05$-0.005), SH groups ($p<0.001$) and vitamin C ($p<0.05$) were significantly decreased at 30 to 120 min, uric acid ($p<0.01$) at 90 and 120 min, while vitamin E did not change. Adding glucose to a pooled plasma sample did not interfere with plasma TRAP assay (before: 827.5±45.2 μmol/l; after: 836.4±51.7 μmol/l).This finding supports the hypothesis that hyperglycemia may, even acutely, induce an oxidative stress.

1194

ACUTE EXPRESSION OF TNFα mRNA IN SKELETAL MUSCLE AND THE HEART: RELATION TO ENDOTOXIN-INDUCED INSULIN RESISTANCE

A. Virkamäki, T. Jaatinen, T. Nyman, T.Wahlström and H. Yki-Järvinen. University of Helsinki, Helsinki, Finland.

TNFα is an established insulin-antagonist, which may contribute to insulin resistance in both obesity and acute infections. We determined whether endotoxemia induced by lipopolysaccharide (LPS) acutely induces expression of TNFα in skeletal muscle and the heart. Chronically catheterized awake rats received an intavenous bolus injection of either LPS (1 mg/kg, LD_{10}, n=8) or saline (n=8) at 0 min. Insulin sensitivity was thereafter followed for 2 hours using the euglycemic insulin clamp technique (insulin infusion rate 18 mU/kg·min). At 2 hours, abdominis and heart muscles were freeze-clamped and analyzed for TNFα mRNA concentrations using a competitive reverse transcriptase PCR technique. Serum TNFα concentrations increased from 38 ± 23 pg/mL to a maximum of 16043 ± 2154 pg/mL at 60 min in the LPS rats but remained unchanged in the control rats (19 ± 17 vs 32 ± 23 pg/mL, 0 vs 60 min, NS). Whole body glucose uptake during hyperinsulinemia was 42 % lower in the LPS (90 ± 6 μmol/kg·min) than in the saline (156 ± 8 μmol/kg·min, p < 0.01) rats, and was inversely related to changes in circulating TNFα concentrations. In the heart, TNFα mRNA, normalized to actin mRNA, was 10-fold higher in the LPS than in the saline (TNFα/actin mRNA ratio 20±1 vs 2±0.1, LPS vs saline rats, p<0.001) rats. In abdominis muscle, TNFα/actin mRNA was 25-fold higher in the LPS (140 ± 37) than the saline (6 ± 2, p<0.001) rats. Immunohistochemical staining using a rabbit anti-ratTNFα antibody showed intense staining in Kupffer cells in the liver while no positive staining was observed in heart or skeletal muscle. These data demonstrate that TNFα mRNA is expressed acutely within 2 hours in skeletal and heart muscles during endotoxemia. During this time frame, whole body insulin resistance is, however, more likely to be due to circulating than locally produced TNFα.

EVALUATION OF OXIDATIVE STRESS IN STREPTOZOTOCINE DIABETES MELLITUS IN RATS

N. Ovcharova, P. Angelova-Gateva, D. Koev and G.Dachev
Clinical Center of Endocrinology and Gerontology, Sofia, Bulgaria

The aim of this study was to evaluate some indexes characterizing the oxidative stress in streptozotocine (STZ)-induced diabetes mellitus.

Methods: Diabetes mellitus was induced with a single dose of STZ 60 mg/kg b.w. in 21 Wistar rats aged 2 months, killed sixty days after the onset. Total tissue homogenates from the heart, liver and kidneys were prepared at pH 7.4. Total protein, superoxide dismutase (SOD) and total antioxidative capacity (TAOC) in the serum and homogenates were investigated. Controls were 21 animals at the same age.

Results: The blood glucose, serum fructosamine and HbA_1 values were significantly higher in diabetic rats compared to the controls. Serum SOD was 27,3±6,5 U/l in diabetic rats and 46,8±8,7 U/l in controls (p<0,001). There was a significant difference in SOD in kidney tissue homogenates between diabetic rats (37,8±2,8 U/g prot) and controls (51,6±8,7 U/g prot, p<0,05), while SOD in the livers and hearts tissues homogenates were similar in both groups. TAOC in the serum of diabetic rats was 29,2±7,1 $\mu mol/H_2O_2/ml/min^{-1}$ and 58,1±17,0 $\mu mol/H_2O_2/ml/ min^{-1}$ in controls. TAOC in kidney tissue homogenates was 82,7±23,3 U/g prot in diabetic rats and 145,2+25,6 U/g prot in controls (p<0,001). TAOC levels in livers and hearts homogenates were similar in both groups.

Conclusion: Antioxidative defense capacity in STZ-diabetes mellitus in rats is diminshed according to the SOD and TAOC levels in the circulation and kidneys. The similar SOD and TAOC levels in livers and hearts homogenates in diabetic rats and controls may be due to an adaption and mobilization of antioxidative defense systems.

ENDOTOXEMIA CAUSES A GLUT 4 TRANSLOCATION DEFECT IN RATS.

D.S. Hardin*,A. Virkamaki+,J. Karczewski* and H. Yki-Jarvinen+.
*University of Texas, Houston,Tx USA and +University of Helsinki, Helsinki, Finland.

Significance: Acute infection is associated with decreased insulin sensitivity. Our current study evaluates the hypothesis that the mechanism of decreased insulin sensitivity during infection is due to decreased function of the insulin-responsive glucose transport protein, GLUT 4. Methods: In order to test our hypothesis, 17 chronically catheterized, freely moving rats were injected with either lipopolysaccharide "LPS",(*S. typhimurium*, LD10, 1mg/kg i.v.) or saline "SAL". A hyperinsulinemic euglycemic (insulin 18mU/kg min) clamp (120min) was started immediately after the injection. Blood samples were withdrawn at 0,30,60, and 120 min for insulin concentrations. At 120 min, the animals were sacrificed. Heart (H) and rectus abdominis (A) were dissected and immediately freeze-clamped for subsequent determination of GLUT 4 translocation. To assess subcellular GLUT 4 localization, membrane subfractions were prepared using sucrose gradients and immunoblots. Radionucleotide counting was employed to determine GLUT 4 quantity in each subfraction. Results: Whole body glucose uptake (M) was decreased in LPS compared to SAL (LPS=88±5, SAL=135±23; p<0.01). Insulin stimulation resulted in decreased GLUT 4 in the 35% sucrose fraction (intracellular)and increased GLUT 4 in the 30% (intermediate) and 25% (plasma membrane) fractions to a greater degree in SAL than in LPS in both A and H (%GLUT 4 in layer 25:A SAL=13%,LPS=2%;p= 0.02; H SAL=18%, LPS=9%;p= 0.03). In LPS, recovery of GLUT 4 in sucrose layer 35 was higher than in SAL by 25% in H and 20% in A. In both LPS and SAL, GLUT 4 content in the 25% fraction was positively correlated with maximal glucose uptake (H:r=0.55, A:r=0.57). Summary: 1) GLUT 4 in the plasma membrane enriched sucrose fraction correlated with in vivo insulin responsiveness in both SAL and LPS; 2)When compared to SAL, LPS rats had less GLUT 4 in the plasma membrane enriched sucrose fraction and more GLUT 4 in the intracellular dense sucrose fraction indicative of an endotoxemic-specific abnormality in GLUT 4 trafficking. Conclusion: Defects in GLUT 4 translocation and trafficking in skeletal muscle may contribute to insulin resistance associated with acute infection.

NITRIC OXIDE INVOLVEMENT IN IMPROVEMENT OF GLUCOSE TOLERANCE WITH A CYTOKINE INDUCER IN KK-AY MICE

G. Muto, J. Satoh,Y. Muto, M. Sagara, S. Miyaguchi, T. Nakazawa, Y. Sakata, F. Ikehata and T. Toyota. Tohoku University, Sendai, JAPAN

Nitric oxide (NO) produced in the vascular wall was indicated to be involved in insulin sensitivity. Diminished NO response to insulin is a component of insulin resistance. Therefore we investigated whether NO is involved in improvement of glucose tolerance with cytokine inducers, complete Freund's adjuvant (CFA). We had found that CFA significantly improved glucose tolerance without affecting insulin secretion, indicating improvement of insulin resistance. In addition, long-term treatment with CFA inhibited development offatty liver and renal glomerular lesion in KK-Ay mice. However the mechanism remains unknown. We performed intraperitoneal glucose tolerance tests (2 g glucose/kg) of the mice which were treated 1 day before with or without CFA and/or NO synthase inhibitor (5 mg/kg of N-monomethyl arginine; NMMA) or saline for control. Postload 2h-glucose levels of the mice treated with saline, NMMA & CFA, CFA were14.0 ± 1.2, 8.6 ± 2.9, 4.7 ± 0.6 (mmol/L), respectively, significantly differing each other by ANOVA (P<0.001) . In addition, weekly CFA injections for a month recovered cyclic guanosine monophosphate (cGMP) production in the liver and muscle. cGMP contents in the liver & muscle of control KK-Ay, CFA-treated KK-Ay and Balb/c mice were19.4 ± 14.0 & 20.3 ± 6.4, 48.2 ± 32.8 & 35.0 ± 29.2, 132.6 ± 85.1 & 68.4 ± 62.8 (fmol/mg protein), respectively; significantly differing each other by ANOVA (P<0.05). In conclusion, CFA improve insulin resistance, which is reflected in glucose tolerance, partly by involvement of the sequential NO production.

1198

A TNF-α GENE POLYMORPHISM IS RELATED WITH INSULIN RESISTANCE, PERCENT BODY FAT AND INCREASED LEPTIN

C. Gutierrez*, W. Ricart, R. Casamitjana**, J. Biarnés, M. Fernández-Castañer***, J.Vendrell*, C. Richart*, J. Soler*** and J.M. Fernández-Real. Department of Endocrinology, Hospital of Girona, *Tarragona and ***Bellvitge, Barcelona. **Hormonal Laboratory, Hospital Clínic, Barcelona. SPAIN.

The aim of this study was to investigate whether the NcoI polymorphism of the TNF-α gene influences the relationship between insulin resistance, percent body fat and serum leptin levels. A sample of 26 subjects [(8 lean subjects, 4 females, age 33.6 ± 2.0; BMI 22.9 ± 2.0, range 19.1-25), and 18 obese, 10 females, age 37.1 ± 1.9; BMI 32.5 ± 0.6, range 30.1-37.9)] was divided into two groups on the basis of the NcoI genotype. Fifteen subjects were (+/+) homozygotes for the presence of the NcoI restriction site, 9 subjects were (+/-) heterozygotes and 2 (-/-) homozygotes for the absence of the restriction site. TNF-1 (+/+) and TNF-2 (+/- and -/-) groups of subjects were comparable in sex, age, proportion of lean/obese subjects, BMI, waist/hip ratio, and several skinfold measurements. Basal serum insulin was slightly greater (14.5 ± 2 vs 10.1 ± 0.8 mU/L, p=0.05) in the TNF2 group in the presence of comparable serum glucose concentration. The integrated area under the curve of serum insulin concentrations after oral 75 g glucose, and the percent body fat were significantly increased in TNF-2 subjects (276.6 ± 44.7 vs 170.9 ± 16.7 mU/L, p=0.021; and 37 ± 3.3 vs 26.3 ± 2.6%, p=0.01, respectively). TNF-2 subjects also showed a decreased insulin sensitivity index as determined by the frequently sampled intravenous glucose tolerance test with Minimal Model Analysis (1.6 ± 0.2 vs 3.13 ± 0.4 min^{-1}/mU/L, p=0.04). Paralleling the known relationship between insulin and leptin levels, serum leptin concentration was clearly increased in the TNF-2 group (22.3 ± 4.3 vs 12.3 ± 2 ng/mL, p=0.03). Therefore, (+/-) heterozygotes and (-/-) homozygotes may be more susceptible to develop insulin resistance and increased percent body fat. Results of the present study suggest that TNF-α-NcoI polymorphism may exacerbate the alterations in leptin levels normally found among insulin-resistant subjects.

1199

In vivo Studies of Nitric Oxide (NO) using S-Nitroso-Glutathione (GSNO) in Dog, Animal Model.

D. McGrowder, D. Ragoobirsingh and T. Dasgupta. Department of Biochemistry and Chemistry, U.W.I., Mona Kingston 7, Jamaica W.I.

This study investigated the pharmacological effects of GSNO (a carrier of NO) on blood glucose levels in ten mongrel dogs using the glucose oxidase method, and measured the plasma nitrate concentration(the oxidative product of NO) using an automated method. Each dog acts as its own control. Then results are expressed as Mean ± S.E., with $p<0.05$ as statistically significant. GSNO elicited a dose-dependent increase in blood glucose level which was parallel with an increase in plasma nitrate concentration (35-100%). Post-prandial blood glucose levels(after administration of 35mg/kg of GSNO and glucose load) after 2hrs and 2.5 hrs were significantly higher than in controls(7.2±0.9mmol/l and 7.1±0.7mmol/l. vs 5.3±0.3mmol/l and 4.6±0.2mmol/l, $p<0.05$). Post-prandial levels after administration of 50mg/kg of GSNO were 8.6±0.9 and 9.2±0.7mmol/l, $p<0.05$). The basal plasma nitrate concentration was 12.4±0.4µmol which increased on administration of 35mg/kg and 50mg/kg of GSNO to 16.8±1.0µmol and 24.0±0.5µmol respectively ($p<0.05$). Co-administration of Ascorbic Acid and GSNO enhanced the hyperglycaemic effect of NO(9.2±0.7mmol/l and 9.3±0.3mmol/l, $p<0.05$). This data provides evidence that GSNO caused persistent hyperglycaemia in normal dogs which is associated with an increase in plasma nitrate concentration.

1200

INSULIN RESISTANCE SYNDROME AND ENDOTHELIAL DAMAGE - ROLE OF ADIPOSE TISSUE DERIVED PROINFLAMMATORY CYTOKINES.

J.S.YUDKIN, C.D.A.STEHOUWER, J.J.EMEIS AND S.W.COPPACK. University College London Medical School, London, UK

Insulin resistance clusters not only with hypertension and dyslipidaemia, but also with fibrinogen, an acute phase protein. We have tested the hypothesis that circulating levels of proinflammatory cytokines, tumour necrosis factor-α and interleukin 6, are related to insulin resistance. Circulating concentrations of insulin, lipids, fibrinogen, C-reactive protein and cytokines, blood pressure and albumin excretion rate, were measured in 107 non-diabetic subjects. Concentrations of von Willebrand factor, thrombomodulin and cellular fibronectin were measured as markers of endothelial dysfunction. A sum score of insulin resistance variables was closely correlated to that of acute phase markers ($r=0.59$, $p<0.00001$), but more weakly to an endothelial dysfunction score ($r=0.32$, $p=0.0008$). There were correlations of each of the components of the insulin resistance cluster with levels of both TNF-α and C-reactive protein, and more weakly with IL-6. Moreover von Willebrand factor and fibronectin concentrations were related to levels of C-reactive protein and TNF-α. In pursuing the source of the cytokines, these levels and those of C-reactive protein were strongly related to measures of global and central obesity ($r=0.19$-0.51) but not (or weakly) to titres of Helicobacter, Chlamydia and cytomegalovirus. Adipose tissue expresses both TNF-α and interleukin-6. We have recently shown production of interleukin-6, but not TNF-α, by subcutaneous human adipose tissue in vivo, and this cytokine is largely responsible for hepatic production of C-reactive protein. Both cytokines increase lipolysis and may influence insulin signalling, as well as producing endothelial dysfunction. We propose that proinflammatory cytokines originating from adipose tissue may be responsible for the association of insulin resistance, endothelial dysfunction and cardiovascular risk.

1201

GLUTATHIONE EFFECTS ON INSULIN RESISTANCE IN NON-INSULIN-DEPENDENT DIABETES MELLITUS.

O. Laurenti, M. C.Bravi, M. Cassone Faldetta, C. Ferri,G. Bianco, A.Armiento and G.De Mattia. Institute of I Clinica Medica, University "La Sapienza", Rome,Italy.

Insulin resistance and increased oxidative stress are features of non-insulin-dependent diabetes mellitus (NIDDM). To investigate the relationship between insulin resistance and oxidative stress we evaluated the effect of an antioxidant agent, glutathione, on insulin action. We studied 10 lean NIDDM patients (7 M and 3 F; mean age 58,8±8,5 yrs; HbA1c < 7%). After an overnight fast, patients underwent a three hour euglycaemic clamp; during the last hour glutathione (1,35 g/m^2 Tationil, Boeringher Mannheim) was infused. After one week, a second euglycaemic clamp was performed with placebo (isotonic saline 0,9% NaCl) infusion in five patients, randomly selected from the above group. During each clamp, insulin sensitivity and erytrocyte GSH/GSSG ratio was evaluated at baseline, 120 min and 180 min. Total glucose uptake after glutathione infusion was significantly increased (M from 4,5±1,6 at 120 min to 5,5±1,8 at 180 min; $p<0,0001$; percentage increment 24,5±11,8 $p<0,002$ vs placebo group), consistently with an improvement in insulin sensitivity. No difference was found after placebo (M from 4,7±1,5 at 120 min to 5,1±1,7 at 180 min; p=ns; percentage increment 4,8±2,6). Moreover a significant erytrocytes GSH/GSSG ratio percentage increment after GSH infusion was found (42,9±22,5 $p<0,005$ vs placebo). Our data demonstrate that glutathione improves cellular redox status and insulin action in NIDDM patients supporting a link between oxidative stress and insulin resistance.

1202

DESYNCHRONIZATION OF CIRCADIAN RHYTHMS OF MELATONIN, ENDORPHINE, ACTH AND CORTISOL BY TRANSMERIDIAN FLIGHTS IN DIABETIC AND HEALTHY PASSENGERS.

B. Müller-Bardorff, M. L. Nielsen, W.-D. Thoma, B. Stumpp, M. Pfohl, W. Renn, C. Torkler, S. Rahmer, L. Bergau and R.-M. Schmülling. Univ. Tübingen, Germany.

In order to test the influence of desynchronisation of circadian hormones by time shift on the blood glucose metabolism of type-I diabetic patients (D) we transported 14 D and 14 normals (N) from Tübingen to Los Angeles - 9 hours western time shift - and to Tokyo - 8 hours eastern time shift -using airliners for an 11 hours non-stop flight. The hormones were analyzed by radio immuno assays, statistic analysis by MANOVA. In east-west direction it took one day for melatonin to adapt to the new time zone that is low values during sun light and high values at night. Endorphine, ACTH and cortisol are desynchronized to the new time zone until the 4th day but are in resonance to eachother. After flighing in eastern direction endorphin, ACTH and cortisol are synchronized on the 2nd day, but melatonin showed a disturbed rhythm during the hole 7 days stay at Tokyo with low values at night and high values in the morning. There were no clinically significant differences between the well controlled D (HbA1c 7,1%) and the N. Blood glucose(BG) control showed larger excursions in D during the first 4 days in the new time zone compared to the control period. The adaptation of NPH insulin to the time shift on the travel days prooved feasable. The reduction of normal insulin was necessary to prevent an increase of the the percentage of BG below 3,9 mmol/l (20% of 3812 measurements). The frequency of BG values over 13,9 mmol/l increased from 6 to 18%. We conclude that the adaptation of circadian rhythms is similar in diabetic and healthy persons. An east-west time shift with a prolongation of daylight is inducing a quicker adaptation of melatonin to the new time zone whereas the other hormones take longer to adapt to the new local time. A west-east flight with a shortening of the night provokes a distortion of the melatonin rhythm for at least 6 days while the other mentioned hormones are in resonance to the new local time in 2 days. The distorsion of internal rhythms is accompanied by a labilization of BG control in D which can be managed by adaptating the insulin dosage to the time shift.

PS 28
Oral Therapy in NIDDM

1203

PIOGLITAZONE AMELIORATES INSULIN RESISTANCE IN NIDDM.

R. Kawamori, J. Kinoshita, M. Ikeda,M.Kubota, M. Wada, T. Kanda, M. Ikebuchi,R. Todo and Y. Yamasaki, Tokyo and Osaka, Japan

To evaluate the effect of pioglitazone on the organ-specific insulin resistance in NIDDM, a double-blind placebo-controlled trial was carried out. By using euglycemic (5.2 mmol/l) hyperinsulinemic (1200pmol/l) clamp method combined with oral glucose load (Kawamori R et al : Diab. Res. Clin. Pract. 23 : 155, 1994), insulin-stimulated hepatic glucose uptake (HGU) and peripheral glucose uptake (PGU) were examined. Twenty-one subjects received 30 mg pioglitazone and nine subjects received placebo, once daily for 12 weeks. Patient background (mean age 58.5 yr, BMI 22.7) showed no significant differences between the two groups. Pioglitazone group showed ; 1) an increase in HGU from 28.53 $\pm$19.37 to 59.35$\pm$27.12 %, $p=0.010$; and 2) an increase in PGU from 8.23$\pm$2.23 to 9.20$\pm$1.99 mg/kg $\cdot$ min, $p=0.003$. Placebo group showed no significant change in either HGU or PGU. The increment of HGU was significantly greater in the pioglitazone group than in the placebo group ($p=0.042$), whereas no significant difference between the two groups in the increment of PGU was observed. The results indicate that pioglitazone is effective in ameliorating insulin resistance in NIDDM by enhancing hepatic glucose uptake after meal-intake as well as peripheral glucose uptake.

1204

THE ACARBOSE TREATMENT OF TYPE 2 DIABETES MELLITUS ASSOCIATED WITH LIVER CIRRHOSIS

S. Gentile, S. Turco*, M. Persico, A. Panariello, S. Conte, M. De Seta, L. Gesuè, E. Rossi and R. Torella. 1st * and 2nd University of Naples, Naples, Italy

The association between type 2 diabetes mellitus (**NIDDM**) and liver cirrhosis (**LC**) with hyperinsulinemia and insulin-resistance is well known. Acarbose (**Ac**) is an unabsorbable inhibitor of intestinal glucosidase activity, lowering both post-prandial hyperglycemia and hyperinsulinemia. ***AIM*** of the study was to evaluate the safety and efficacy of Ac treatment in a series of patients with NIDDM and well compensated LC. ***PATIENTS*** were 18F and 12M, with mean age 57±8 years; 19 were in Child's class B and 11 in class A; NIDDM duration was 7±5 years, without significant complications related to NIDDM. A doublle blind cross-over ***PROCEDURE*** was followed with two alternative two-month treatment schedules: **A)** Ac 100mg/ thrice daily, and **B)** placebo thrice daily (**Pl**). Pts with irritable bowel disease were excluded. At baseline and at 2-month intervals, assays of the blood levels of Hemoglobin A1c (**HbA1c**), fasting (**FG**) and post-prandial glucose (**PG**), postprandial C-peptide (**PC**), and routine serological tests of liver function (**RST**) were measured. ***RESULTS***: compared with Pl, Ac treatment significantly reduced HbA1c (-0.1% vs -0.9%, $p<0.05$), FG (-3% vs -11%, $p<0.01$), PG (-5% vs -19%, $p<0.001$), PC (-0.2 vs -9%, $p<0.05$) and, surpisiling, blood ammonia and clinical signs of enchephalopathy. No significant variations in RST were observed in both Pl and Ac treatment groups. ***CONCLUSION***: since Ac treatment improves glycemic control in NIDDM cirrhotics and reduces the intestinal ammonia-producers bacteria, and is neither absorbed by the bowel nor metabolized by the liver, we propose its use in the treatment of NIDDM in patients with liver cirrhosis.

1205

TROGLITAZONE IMPROVES ADIPOSE INSULIN RESISTANCE IN NIDDM RATS. S. Tagami, T. Honda, H. Yoshimura, S. Sakaue, K. Aoki, Y. Furuya, J. Ishii, J. Hirokawa and Y. Kawakami. First Department of Medicine, Hokkaido University School of Medicine, Sapporo, Japan

Several recent studies have provided evidence that protein-tyrosine phosphatases (PTPases) have integral role in the regulation of insulin signal transduction. In diabetes mellitus, PTPase activities in liver and skeletal muscle were well-investigated. However, PTPase activities in the adipose tissue are not well-known.

In the present study, the change of PTPase enzyme activities in adipose tissue from OLETF (Otsuka Long-Evans Tokushima Fatty) rats were investigated. Cytosol and particulate adipose fractions were prepared from visceral and epididymal, subcutaneous tissue of OLETF and their lean control rats. Troglitazone was given as a food admixture (0.2 %) for a week.

Cytosol PTPase activities of the viceral tissue (5.99 ± 1.03 vs 34.46 ± 2.80 mUnits/mg protein, mean ± SD) and the epididymal tissue (12.39 ± 2.01 vs 17.04 ± 2.71 mUnits/mg protein) were decreased in the diabetic tissue in comparison with normal subjects. Particulate PTPase activities of the visceral tissue (32.70 ± 1.90 vs 6.68 ± 0.75 mUnits/mg protein) and the epididymal tissue (16.44 ± 1.86 vs 8.60 ± 0.83 mUnits /mg protein) were adversely increased in the diabetic tissue in comparison with normal subjects. Troglitazone treatment restored these changes towards normal. Cytosol and particulate PTPase activities in the subcutaneous tissue were not changed. These results indicated that troglitazone normalizes the PTPase activities in the visceral and epididymal tissue.

1206

EFFECT OF ACARBOSE ON ADDITIONAL INSULIN THERAPY OF TYPE II DIABETICS WITH LATE FAILURE OF SULPHONYLUREA THERAPY

E. Standl, H.J. Baumgartl, M. Fuechtenbusch and J. Stemplinger. Institute of Diabetes Research and Department of Endocrinology, Academic Hospital Schwabing, Koelner Platz 1, Munich, Germany.

The aim of this 24-week study was to investigate the effects of acarbose on the primary success rate of a combination therapy with insulin and sulphonylurea (SU), and on the insulin requirements of patients with type II diabetes who had late-term failure of SU therapy. Forty-eight patients entered the study, which was double-blinded and placebo-controlled for acarbose. All patients had to be ≥ 40 years of age, with a duration of diabetes ≥ 5 years, SU therapy ≥ 3 years, a HbA_{1c} > 8.5%, fasting blood glucose ≥ 160 mg/dl, and 1-hour postprandial blood glucose ≥ 250 mg/dl. Morning fixed combination therapy with insulin (regular/NPH) was started, together with acarbose or placebo, the daily dose of which was increased in a standardized manner from 100 mg up to 600 mg. The main efficacy parameters were the number of responders and the daily insulin dose in these responders after 24 weeks. Responders had a final HbA_{1c} < 8%, or a HbA_{1c} level at least 15% below the patient's baseline value. There were significantly more responders in the acarbose-treated group compared with the placebo-treated group (20 out of 24 patients *vs* 10 out of 19 patients; $p < 0.05$). The decrease in mean HbA_{1c} did not differ between the acarbose-treated group (from 10.9 ± 1.0% to 8.5 ± 1.2%; mean ± SD) and the placebo-treated group (from 11.0 ± 1.2% to 8.6 ± 1.0%). Daily insulin requirements at the end of the study, however, showed a difference of borderline significance between the acarbose-treated group compared with the placebo-treated group (9.9 *vs* 16.5 IU/day; $p = 0.07$). These results suggest that acarbose may have utility in improving the response to additional therapy with insulin in patients with type II diabetes and SU failure, perhaps even at a lower dose of insulin.

1207

BRL 49653 PREVENTS PANCREATIC ISLET β-CELL DEGENERATION IN ZUCKER DIABETIC FATTY RATS.

RE Buckingham, CDN Toseland, MG Hughes, CA Lister and SA Smith. SmithKline Beecham Pharmaceuticals, Welwyn, U.K.

The Zucker Diabetic Fatty (ZDF) rat is an animal model for NIDDM, developing hyperglycemia, glycosuria and secondary complications such as nephropathy and cataract formation. To investigate the possibility that the PPARγ agonist, BRL 49653, may change the course of this disease process, the drug (~10 umol/kg body weight daily) was given in the diet to ZDF rats, aged 6 weeks (Prevention group; n=8) or 21 weeks (Intervention group; n=7) until termination at aged 28 weeks. Untreated ZDF (n=16) and lean (ZL; n=10) rats served as controls. At aged 28 weeks, the pancreata of ZDF controls, compared with ZL rats, contained fewer and smaller islets with a disorganised architecture involving changes to β-cell morphology, apoptotic β-cells (in the centre of some islets), a clear decline in insulin content and increased prominence of α-cells. The β-cell morphological changes comprised hypertrophy with a compartmentalization of the cytoplasm into a perinuclear, slightly acidophilic zone, and a peripheral basophilic region containing most of the residual insulin. In ZL rats, α-cells were confined to the periphery of the islet, but in ZDF controls these cells were located randomly in prominent apparently hyperplastic clusters, perhaps indicating an inward collapse of islet structure resulting from apoptosis of β-cells. Pancreata in ZDF control rats showed similar changes at aged 21 and 28 weeks. In the Prevention group, the islets displayed a normal morphology and were indistinguishable from those in ZL rats, but late Intervention treatment with BRL 49653 failed to influence the established changes. The results demonstrate that early treatment of ZDF rats with BRL 49653 prevents the series of events which results in pancreatic islet β-cell degeneration.

1208

ACARBOSE CAN ELIMINATE THE NEED FOR BETWEEN-MEAL SNACKS IN TYPE I DIABETES.

M. Frank[1], N. Sneige[2] and J. Köglmeier[2]. [1]Klinik 'Bergfried' Saalfeld, Zum Fuchsturm 20, Saalfeld and [2]Universitätsklinik Homburg, Homburg, Germany.

This study investigated whether acarbose, taken before breakfast, can obviate the need to split morning carbohydrate demands between a main breakfast and a mid-morning snack in patients with type I diabetes. Twenty-six patients on standard insulin regimens were randomized in a double-blinded, cross-over manner to receive either acarbose, 100 mg, or placebo with one of two meal regimens. Patients were studied on 4 days, each separated by a 1-week wash-out period. On days 1 and 2, patients received a single breakfast; while on days 3 and 4 the breakfast was split, with a third of the calorific value being taken 120 minutes after the first intake. Acarbose or placebo was taken before the first meal. Insulin doses were constant for the 4 study days and given 30 minutes before the first meal. Plasma glucose and insulin concentrations were measured at baseline (before the insulin dose); before the first meal ($t = 0$); and at 30-minute intervals for 210 minutes after the first meal. Comparison of the $AUC_{0-3.5\ h}$ for patients receiving a split meal plus placebo, with those receiving a single meal plus acarbose revealed no statistically significant difference between regimens (-3.84 mmol.h/l *vs* +0.35 mmol.h/l, respectively, $p = 0.062$). Comparison of the change in plasma glucose level between baseline and 90 minutes after the first meal, showed that acarbose induced a decrease (-1.09 mmol/l from 7.0 mmol/l baseline) in patients given a single meal, while an increase was seen in patients given placebo with a split breakfast (+1.05 mmol/l from 8.72 mmol/l). This difference between treatment groups was statistically significant ($p = 0.0034$). These results indicate that acarbose can eliminate the need for a split breakfast in these patients and prevent hyperglycaemia when breakfast is taken as a single meal.

1209

EVIDENCE FOR TROGLITAZONE, A NOVEL ANTI-DIABETIC AGENT, ACTING AS AN INSULIN ACTION ENHANCER.

E.A.Foot, S.Lettis and D.J.A.Eckland Glaxo Wellcome Research & Development Ltd., Greenford Road, Greenford, Middlesex. UB6 0HE UK

Insulin resistance is a key feature of type 2 diabetes which preceds and predicts its development in the non-diabetic population. Troglitazone represents a new class of compounds effective in improving metabolic control in type 2 diabetes primarily by enhancing the insulin sensitivity of the peripheral sites to insulin. Evidence in support of this was obtained from studies in euglycaemic healthy subjects. Using a double-blind, placebo-controlled, parallel-group study design, eighteen healthy adult male subjects (age 19-40yr, weight 64-92Kg) were randomised to receive troglitazone 200mg (n=12) or matching placebo (n=6), given three times daily with the relevant meal for 13 days. On days 0 and 13 blood samples for glucose and insulin were taken just prior to, and over the 3 hours following each of breakfast, lunch and dinner. The weighted mean and peak values, and ratio of weighted mean insulin to weighted mean glucose following each meal, were calculated. Analysis was performed on log transformed data using analysis of covariance allowing for effects due to baseline (covariate) and treatment. On day 13, no effect was observed for any glucose parameter but was associated with a clear trend for weighted mean and peak insulin, and the weighted mean insulin to weighted mean glucose ratio to be reduced. This suggests that insulin sensitivity was improved resulting in less insulin required to maintain euglycaemia. Results are presented as % change compared to placebo on day 13 (95% CI):

Time period	Wt. mean insulin	Peak insulin	Wt. mean insulin/ Wt. mean glucose
Breakfast	-13% (-32, 12)	-10% (-39, 32)	-9% (-26, 12)
Lunch	-3% (-27, 29)	-4% (-29, 30)	-8% (-28, 18)
Dinner	-20% (-43, 14)	-25% (-52, 18)	-20% (-38, 4)

Conclusions: these results in euglycaemic subjects provide evidence that troglitazone acts to improve insulin sensitivity and suggest that in type 2 diabetes the drug acts on the underlying pathophysiology of the disease to improve metabolic control.

1210

VOGLIBOSE DOES NOT MODIFY PHARMACODYNAMICS OR PHARMACOKINETICS OF WARFARIN IN HEALTHY MAN.

H. Fuder, P. Kleist*, E. Stridde*, A. Ehrlich, S. Emeklibas, W. Maslak, G. Wieckhorst, M. Birkel, and N. Wetzelsberger. Institute for Clinical Pharmacology Prof. Lücker GmbH, Grünstadt, and Takeda Euro R&D Centre*, Frankfurt, Germany

Voglibose (AO-128) is a new and potent inhibitor of disaccharidases used for treatment of diabetes mellitus. Since voglibose increases gastrointestinal motility, the aim of this study was to investigate its influence on the anticoagulant effect and the pharmacokinetics of warfarin under steady state conditions.

12 healthy male volunteers were given individually adjusted doses of warfarin over 15 days to achieve stable Quick's values of 30-40 % of normal. Between day 9 and 15, warfarin doses were kept constant. From day 11 to 15, 5 mg voglibose t.i.d. was administered additionally. Quick's values from days 15 and 16 (test) were compared to those of days 10 and 11 (reference). Pharmacokinetics of S- and R-warfarin of day 15 was compared with that of day 10. Lack of interaction was concluded if the point estimate and 90% confidence interval of the ratios (test/reference) for Quick's value, AUC and C_{max} was within the range of 0.8-1.25.

Mean (and 90% confidence interval) of ratio (test/reference):

Quick's value	S-Warfarin AUC	S-Warfarin C_{max}	R-Warfarin AUC	R-Warfarin C_{max}
0.97 (0.90-1.04)	1.05 (1.00-1.10)	1.08 (1.00-1.16)	1.01 (0.97-1.05)	1.04 (0.97-1.11)

It is concluded, that voglibose had no influence on the pharmacodynamics and the pharmacokinetics of warfarin enantiomers.

1211

EFFECT OF TROGLITAZONE ON INSULIN-INDUCED VASODILATION AND ENDOTHELIAL FUNCTION IN INSULIN-RESISTANT OBESE SUBJECTS

C.J.J.Tack, K.E.M. Ong, G. Vervoort and P. Smits#. Dept. of Internal Medicine and #Pharmacology, University Hospital, Nijmegen, The Netherlands.

Insulin-induced vasodilation is nitric oxide dependent and is diminished in type 2 diabetes and obesity and, might reflect endothelial dysfunction. Troglitazone, improves insulin resistance and may thus improve insulin-dependent and/or endothelium-dependent vascular function in insulin resistant obese subjects. Therefore, 14 obese subjects (8M:6F, age 37.2±4.9 yr, BMI 31.6±3.0 $kg \cdot m^{-2}$) were treated with troglitazone 400 mg od or placebo for 8 weeks, in a randomised, double-blind cross-over design. Forearm vasodilator responses [venous-occlusion plethysmography] to intra-arterially administered acetylcholine and sodium nitroprusside, insulin sensitivity and insulin-induced vasodilation [euglycemic hyperinsulinemic clamp] and vasoconstrictor responses to L-NMMA were investigated. Ambulatory 24-hour blood pressure (ABPM) was also measured. Baseline data (placebo) were compared with that of a matched group of 13 lean individuals (BMI 21.9±0.6 $kg \cdot m^{-2}$). Obese subjects were insulin resistant when compared with leans (whole body glucose disposal: 26.9±3.2 versus 53.9±4.3 $\mu mol \cdot kg^{-1} \cdot min^{-1}$, $p<0.001$). Troglitazone improved insulin sensitivity (to 31.8±3.6 $\mu mol \cdot dL^{-1} \cdot min^{-1}$, $p<0.05$). Insulin-induced vasodilation was blunted in obese subjects (increased flow 11.3±12.3%, versus 66.5±23.0% lean, $p<0.05$), but did not improve during troglitazone (to 2.2±4.9%, $p=0.71$). Vasodilator responses to acetylcholine and sodium nitroprusside, and vasoconstrictor responses to L-NMMA did not differ between the obese and lean group, nor between placebo and troglitazone. During troglitazone, ABPM systolic blood pressure remained unchanged, diastolic decreased (84.4±1.3 to 81.1±1.8 mmHg, $p<0.05$). Conclusion: whilst endothelial function was normal in insulin resistant obese subjects, insulin-induced vasodilation was impaired. Troglitazone did not affect vascular reactivity. These data do not support an association between insulin resistance and endothelial function.

1212

α-GLUCOSIDASE INHIBITOR (VOGLIBOSE) SAVES ENDOGENOUS INSULIN AND IMPROVES INSULIN SENSITIVITY

M. Taniyama, Y. Suzuki, C. Murata, E. Sugita, and Y. Ban
Showa University, Saiseikai central Hospital, Tokyo, Japan

To protect diabetic patients from cardiovascular diseases, management of blood glucose alone is not sufficient. Relief of insulin resistance is also important. We investigated the effect of Voglibose (α-glucosidase inhibitor) on the endogenous insulin secretion and insulin sensitivity in NIDDM patients. Twenty-seven patients (21 men and 6 women, aged 40-71 years) whose control of blood glucose was not sufficient with diet therapy alone or with sulfonylurea were given 4-6 mg daily of Voglibose for 6 months, and the fasting plasma glucose (FPG), HbA1c, fasting serum IRI, lipids, DHEA-S and urinary excretion of C-peptide were measured before and at the end of the study. FPG decreased from 9.3 mmol/L to 8.7 mmol/L, while decrement of HbA1c was very small. Fasting IRI decreased from 60 pmol/L to 43 pmol/L. U-CPR decreased from 28.2 nmol/day to 23.4 nmol/day. In male patients, DHEA-S, which is thought to be a marker for insulin sensitivity in male, significantly increased at 3 months but the increment was not significant at the end of the study (2.65, 3.13, 2.89 μmol/L respectively). Mean fasting TG level also significantly decreased. TG levels decreased in all 8 patients whose initial TG were high. The reduction of fasting IRI level as well as decrement of urinary excretion of CPR in the face of improvement of blood glucose control indicate that treatment with Voglibose saved endogenous insulin secretion and improved insulin sensitivity in glucose metabolism. Increase of serum DHEA-S and decrease of fasting TG levels also support the improvement of insulin sensitivity.

1213

TROGLITAZONE IMPROVES INSULIN SENSITIVITY THROUGH INCREASED MUSCLE GLYCOGEN CONTENTS IN ZUCKER OBESE RATS

Y. Oshida, M. Kako, L. Li, X.-C. Hu, N. Nakai, Y. Shimomura*, Y. Sato
Nagoya University, *Nagoya Institute of Technology, Nagoya, Japan

Recent studies have demonstrated that troglitazone has the capacity to improve insulin resistance. The present study was undertaken to determine the effect of troglitazone on in vivo insulin action, the activities of pyruvate dehydrogenase (PDH) complex and 3-hydroxyacyl-CoA dehydrogenase (HADH) in muscle, and muscle GLUT4 and glycogen contents in Zucker obese and lean rats. Rats were fed normal chow diet with and without troglitazone as a food admixture(0.3%). In vivo insulin action was measured by the sequential euglycemic clamp technique at two different insulin infusion rates, 6.0 (L) and 30.0 (H) mU/kg•min. Plasma insulin concentrations during the L and the H insulin infusion were 100-150 μU/ml and 1,000-1,400 μU/ml, respectively, and blood glucose was clamped at fasting levels by periodic adjustment of the *i.v.* glucose infusion rate. After the clamp studies, the activities of PDHcomplex and HADH and GLUT4 and glycogen contents in red gastrocnemius muscles and heart were determined. Troglitazone treatment produced a significant rise in glucose disposal rate (GDR) during the L insulin clamp study (14.7±2.2 vs 7.1±1.1mg/kg•min, P<0.05)in obese rats, but not in lean rats (26.5± 0.3 vs 29.0 ± 1.7 mg/kg•min). No effects of Troglitazone on GDR during the H clamp study, the activities of PDH complex and HADH or muscle GLUT4 contents were observed in obese and lean rats. However, Troglitazone increased muscle glycogen contents in obese rats (6.8±0.4 vs 5.4±0.4mg/g, P<0.05). These results suggest that troglitazone improves insulin sensitivity through increased muscle glycogen contents.

1214

ACARBOSE IN AMBULATORY TREATMENT OF NIDDM ASSOCIATED TO IMMINENT SULFONYLUREA FAILURE.

C. Piñol, B. Costa, N. García, C. Barajas and Acarbose and Diabetes Research Group. Institut Català de la Salut. DAP Reus-Altebrat. Hospital Móra d´Ebre. Tarragona. QF Bayer SA. Barcelona (Catalonia, Spain)

To asses the efficacy and safety of acarbose as an adjunct to high sulfonylurea (SU) doses, a randomised, multicentric, 6 month double-blind, parallel and placebo-controlled trial was performed in primary health care. NIDDM patients aged>40 year-old, BMI<35 kg.m^{-2}, HbA1c levels between 8-12% (N: 4-6%) and more than 3 years of diagnosed diabetes were included. After a month placebo run-in period, all patients were randomly allocated in two groups of treatment (acarbose 100 mg tid vs placebo). HbA1c levels, lipid profile, fasting and postprandial blood glucose levels were performed and adverse events were recorded. SPSS/PC as well as ANCOVA analysis were used. The study included 65 patients and 48 of them were randomized (22 for acarbose and 26 for placebo). No statistical differences were found on age (60.3 vs 61.7), BMI (28.6 vs 27.5) and SU doses (14.0 vs 14.5 mg glybenclamide/day). Acarbose-treated pacients significantly reduced HbA1c levels (9.1/8% vs 8.6/8.6%; p<0,01), based upon a marked decrease in mean postprandial plasma glucose levels (11.7/9.2 vs 12.6/11 mmol.l^{-1}; p=0,07). No significant differences among fasting plasma glucose (9.6/8.4 vs 10.7/10 mmol.l^{-1}), total cholesterol (5.7/5.5 vs 5.9/5.6 mmol.l^{-1}), triglycerides (2.1/1.6 vs 2.2/2 mmol.l^{-1}) and HDL cholesterol (1.5/1.5 vs 1.4/1.4 mmol.l^{-1}) were detected. Thirty patients (46.1%) of the total group presented adverse events, 10 (15.4%) placebo-treated patients and 20 (30.7%) acarbose-treated patients. In 14 (21.4%) patients of the second group it was probably or possibly due to acarbose, although no one was reported as severe event. Only 7 (10.7%) patients, 6 (9.2%) with acarbose and 1 (1.5%) with placebo, withdrew the study because of the adverse events. Thus, despite the side effects, acarbose seems to be a useful option in order to improve HbA1c levels in NIDDM with imminent SU failure.

1215

OVERVIEW OF THE SAFETY PROFILE OF TROGLITAZONE, AN INSULIN ACTION ENHANCING AGENT

S. Kench and P. Beranek. Glaxo Wellcome Research and Development Ltd., Greenford, U.K.

Troglitazone is a new insulin action enhancing agent, under development for the treatment of type 2 diabetes. Troglitazone (10-800 mg) has been investigated at once, twice and three times daily doses in more than 7706 patients to date in Europe / USA and 1058 patients in Japan. This abstract presents adverse event data collected from four phase II studies conducted in 1066 patients throughout Europe (age 39 - 85 years) for up to 16 weeks.

	Placebo [P] $n = 210$	Troglitazone [T] (all doses) $n = 856$
Patients with any adverse events	126 (60%)	405 (47%)
Patients with any drug-related adverse events	56 (27%)	230 (27%)

The incidence of adverse events was similar in the troglitazone and placebo populations. Most adverse events were mild to moderate in severity. The most common adverse events were malaise (P 11%, T 7.9%), thirst/fluid intake (P 8.1%, T 1.2%), and polyuria and diuresis (P 6.2%, T 0.5%). Adverse events, including drug-related serious adverse events (T 1% , P 1%), showed no age, sex, dose frequency or dose dependency. Although there have been three reports of symptomatic hypoglycaemia (1 P, 2 T) these were not verified by blood glucose measurements. In conclusion, troglitazone is well tolerated, with a good safety profile which supports the further investigation of troglitazone for long-term treatment of type 2 diabetes.

1216

Effect of metformin on impaired glucose tolerance patients

Chun-Lin Li, Ju-Min Lu, Chang-Yu Pan, et al.
Department of Endocrinology, 301 hospital, Beijing, China, 100853.

In order to evaluate the effect of metformin on glucose metabolism, insulin sensitivity and conversion rate of DM in IGT patients , a total of 70 subjects with IGT were given metformin in 33 or placebo in 37 each for one year period in a double-blind, placebo-controlled study. The dose of metformin was 0.25g, three times daily.

The results showed that 1 IGT patient converted into DM(3.13%) , 3 remained unchanged(9.38%) and 28 became normal(87.50%) one year later in metformin group. While in placebo group the above data were 7 (21.21%), 8(24.24%) and 18(54.55%), respectively (P<0 .05). Metformin treatment was associated with improvement of FBS (from 6.89±0.15 mmol/L to 6.23±0.15mmol/L, p<0.05) and insulin sensitivity (IAI) (from -3.27 to -3.01, P<0.01) at 3 months. At 6 months, both AUCg (from 19.67±0.53 to 17.75±0.51, P<0.05) and AUCi (from 42.66×/÷ 0.32 to 36.31×/÷0.29, P<0.01) were decreased significantly. After 12 months of metformin treatment, the FBS, IAI, AUCg and AUCi were further improved and the UAE was decreased from 5 .89× /÷0.36ug/min to 5.01×/÷0.34u g/min , WHR from 0.854±0.01 to 0.840±0.01 and BMI from 26.08±0.40 kg/m^2 to 25. 04 ± 0. 39 kg/m ^{2} with statistical significance(P<0.05) compared with placebo group.

Conclusion: Our results indicated that metformin, for one year treatment, could reduce the conversion rate of DM in IGT patients and could improve glucose metabolism, insulin sensitivity , BMI, WHR and UAE in the IGT patients. Therefore, metformin might be some benefit for intervention of IGT patients.

1217

ACUTE NON-INSULIN-LIKE STIMULATION OF GLUCOSE TRANSPORT BY TROGLITAZONE IN ISOLATED RAT MUSCLE.

C.Fürnsinn, M.Bisschop, M.Roden, B. Schneider* and W.Waldhäusl
Dept. Medicine III, Div. Endocrinology & Metabolism, and *Inst. Medical Statistics & Documentation, University of Vienna, Vienna, Austria.

Investigation of direct and acute action of troglitazone on glucose metabolism of rat soleus muscle strips revealed insulin-independent stimulation of glucose transport (cpm ^{3}H-2-deoxy-glucose/mg/h: control, 307±22; *vs.* 3.25 μM troglitazone, 380±32; p<0.01). Although an acute insulin-mimetic potential of thiazolidinediones has been suggested by others, our findings indicate that troglitazone mimicks the effects of hypoxia and muscle contractions rather than those of insulin in that: (i) Troglitazone-induced glucose transport was accompanied by increased glycolysis (μmol lactate released/g/h: control, 7.1±0.5; *vs.* 3.25 μM troglitazone, 12.3±0.7; p<0.01), but not glycogenesis (μmol glucose incorporated into glycogen/g/h: control, 1.40±0.09; *vs.* 3.25 μM troglitazone, 1.32±0.09; n.s.) demonstrating intracellular glucose handling in a catabolic non-insulin-like fashion beyond glucose transport. (ii) While insulin retained its stimulatory effect on glucose transport in hypoxia-stimulated muscle (cpm/mg/h: hypoxia, 852±77 *vs.* hypoxia + 100 nM insulin, 1229±75; p<0.01), troglitazone failed to increase glucose transport under hypoxic conditions (cpm/mg/h: hypoxia, 789±40 *vs.* hypoxia + 3.25 μM troglitazone, 815±28, n.s.) suggesting that hypoxia and troglitazone trigger glucose transport via an identical non-insulin-like mechanism. (iii) No differences of troglitazone *vs.* hypoxia were identified in respective interactions with insulin. It remains to be elucidated, whether such potential of troglitazone to acutely stimulate muscle glucose metabolism in a non-insulin-like fashion is instrumental for its long-term antidiabetic action *in vivo* or is to be regarded as an independent pharmacologic effect.

1218

REACTION OF METFORMIN WITH REDUCING SUGARS AND DICARBONYL COMPOUNDS

D. Ruggiero, M. Lecomte, N. Rellier, M. Lagarde and N. Wiernsperger.
LIPHA-INSERM U352, INSA, bldg 406, 69621 Villeurbanne Cedex, France

The reaction between reducing sugars and amino structures in proteins (also called Maillard reaction or glycoxidation) has been shown to play a role in the development of the characteristic tissue pathology of diabetes. Guanidine compounds such as aminoguanidine, inhibit this process by blocking the reaction of amino groups with glucose or the dicarbonyl compounds derived from glucose. Despite the fact that the antidiabetic metformin is a guanidine-like compound, it has never been investigated for possible inhibitory effects on the formation of advanced glycation end products (AGEs). Metformin was incubated in the presence of various reducing sugars and dicarbonyl compounds (glyoxal and methylglyoxal). Reaction kinetics were assessed by analysis of the spectrometric changes, and reaction products analyzed by TLC. The results showed that metformin reacts with glucose, fructose or glucose 6-phosphate. The metformin reactivity is 400-times higher with glyoxal (one of the main intermediates of the Maillard reaction), and even more strongly with methylglyoxal which is increased in diabetes mellitus. Reaction of metformin with glucose was oxygen dependent whereas glyoxal reaction was not. Glycoxidation of albumin by dicarbonyl compounds in the presence or absence of metformin was also studied. Albumin glycoxidation either by glyoxal or methylglyoxal, was decreased by about 30 % and 50% respectively, in the presence of 1mM metformin. These results suggest that besides its known antihyperglycaemic effect, metformin could also decrease AGE formation by reaction with reducing sugars or glycoxidation intermediates.

COMPARATIVE STUDY OF TROGLITAZONE WITH SULPHONYLUREAS : NO EFFECT ON CARDIAC MASS

M.M.R. Young[1], L. Squassante[1], W.D.H. Carey[2], R.H. Mohiaddin[3] and D.N. Firmin[3].
[1]GlaxoWellcome Research and Development Ltd., Greenford, U.K., [2]Chelsea and Westminster Hospital, London; [3]Magnetic Resonance Unit, Royal Brompton Hospital, London, U.K.

Troglitazone (TR) is a thiazolidinedione under development for the treatment of type 2 diabetes. In clinical studies TR reduces hyperglycaemia and is well tolerated. In animal studies compounds of this class have been associated with reversible increases in cardiac mass. Echocardiography data from early clinical studies indicated that TR had no adverse cardiac effects. Here, magnetic resonance imaging, a highly accurate method of determining anatomical and functional parameters of the heart, was performed to assess cardiac mass and function in patients receiving TR or a sulphonylurea (SU). Six month interim data from a 1 year study is presented. This study is a randomised, open, parallel-group design in which 34 type 2 diabetic patients, stable on glibenclamide or gliclazide either continued on pre-existing SU treatment (n=18) or switched to TR 600mg once daily (n=16) for one year. Left ventricular (LV) mass, right ventricular (RV) wall thickness and ventricular function parameters are being measured at baseline, 2, 6 and 12 months. A 6-month interim analysis of the LV mass index (LV mass corrected for body surface area) was performed using analysis of covariance allowing for effects due to treatment and baseline values.

	LV mass index (g/m^2)	
	TR (n=12)	SU (n=15)
Baseline mean	79.9	77.1
6 month adjusted mean	79.7	80.5

The difference between LV mass index for TR and SU was not statistically significant (95% CI: -7.8, 6.2). TR was well tolerated during this period. These data clearly demonstrate that, over the 6-month period, there was no difference in LV mass index between patients treated with TR and those taking a sulphonylurea. Changes in RV wall thickness or adverse effects on ventricular function are therefore not anticipated.

1220

DOUBLE-BLIND, PLACEBO-CONTROLLED, DOSE-RESPONSE STUDY OF METFORMIN HYDROCHLORIDE COMPARED TO PLACEBO IN TYPE II DIABETES MELLITUS D.Cryer,M.D.;J.Rohlf,M.D.;D.Mills,BSN; A.Garber,M.D.,Ph.D.; Princeton, N.J. and Houston, TX

Although metformin (M) has been used to treat type II diabetes for more than 30 years, a dose-response study was never undertaken. Following a three-week lead-in period, four hundred fifty-one patients were randomized to receive either placebo (P) or a single dose level of M for 11 weeks. The M doses used were 500, 1000, 1500, 2000, 2500 mg/day. Lab evaluations included FPG at baseline and wks 1, 2, 3, 7 and 11; and HbA_{1C} at baseline, and wks 7 and 11. Adverse event (AE) monitoring was done at each visit. Results: Compared to P, treatment with M resulted in dose-dependent decreases in FPG and HbA_{1C} at wks 7 and 11. Maximal reductions of FPG and HbA_{1C} were achieved at 2000 mg M and averaged -80.2 mg/dL and -2.01% at wk 11, respectively ($p<0.001$). There was no statistical difference between metformin and placebo in the number of patients reporting an AE. The most frequently reported AE was G.I. related symptoms which occurred 8% more frequently in M vs. P treated patients ($p=0.20$). Also, M treated patients exhibited a 12% increase of diarrhea vs P treated patients ($p=0.02$). Conclusion: All dose levels of M tested were well-tolerated and demonstrated statistically significant and clinically important decreases in FPG and HbA_{1C}.

1221

TROGLITAZONE HAS NO EFFECT ON THE RED CELL MASS OR OTHER ERYTHROPOIETIC PARAMETERS

M.M.R. Young[1], L. Squassante[1] and J. Werner[2]. GlaxoWellcome Research and Development Ltd., Greenford, U.K.; [2]Pharma Bio-Research Int. BV, Zuidlaren, The Netherlands.

Troglitazone (TR) is a novel treatment for type 2 diabetes. In large scale clinical trials TR reduced hyperglycaemia and was well tolerated. Minor, reversible decreases in red blood cell indices were observed, consistent with animal studies where this effect was thought to be associated with an increase in plasma volume. To formally assess these effects, 24 healthy male subjects (age 19-26yrs, weight 64-90kg) were randomised into 3 groups to receive TR 200mg or 600mg, or placebo once daily for 6 weeks in a double-blind, parallel-group study. Red cell mass, determined by dilution of radiochromium-labelled red blood cells and plasma volume, determined by dilution of radioiodinated albumin, were measured pre-study and after 6 weeks of treatment. Additional haematological parameters were also measured. Statistical analysis was performed using analysis of covariance allowing for effects due to baseline and treatment. Results showed no changes in haemoglobin, erythrocyte count or haematocrit. The red cell mass was not reduced, with adjusted mean values of 27.0 ml/kg (200mg group), 25.6 ml/kg (600mg group) and 25.1 ml/kg (placebo). These data, combined with a lack of effect of TR on reticulocyte count, erythropoietin or soluble transferrin receptors indicate that TR does not affect erythropoiesis. There was no evidence of increased red cell destruction or haemolysis. The adjusted mean plasma volume increased by 5.7% (2.5ml/kg, 95% CI -1.6, 6.6) in the 200mg group and by 7.8% (3.4ml/kg, 95% CI -0.8, 7.6) in the 600mg group compared to placebo (p=NS for both). **Conclusion:** Troglitazone had no effect on red cell mass. Dilutional effects, related to modest increases in plasma volume may explain the haematological changes seen in clinical studies.

1222

THE HYPOGLYCAEMIC EFFICACY OF METFORMIN. A META-ANALYSIS.

Klaus Johansen, Hvidovre Hospital, University of Copenhagen, DK-2650 Hvidovre, Denmark.

Background: The results of randomized, controlled trials of the effects of metformin on blood glucose regulation and body weight varies. In order to get a systematic overview a metaanalysis of the efficacy of metformin was performed by comparing metformin with both placebo and sulfonylurea.

Methods: All randomized controlled trials published since 1957 were selected by searching Current List of Medical Literature, Cumulated Index Medicus, Medline and Embase. Meta-analysis was performed using weighted mean differences in fasting blood glucose, glycosylated haemoglobin and body weight.

Results: Eight randomized, controlled trials comparing metformin with placebo and eleven with sulfonylurea were identified. The weighted mean difference between placebo and metformin in fasting blood glucose was 3,1 mmol/L (95% Cl-3.7;-2.6) and in glycosylated haemoglobin 1.3% (95% Cl -1.6; -1,0). Body weights were not different. Sulfonylurea and metformin lowered blood glucose haemoglobin equally while there was a lower weight (3 kg) after metformin treatment (95% Cl -4.1; -1.9).

Conclusions: Metformin lowers blood glucose and glycosylated haemoglobin significantly compared with placebo. Metformin and sylfonylurea have an equal effect on fasting blood glucose and glycosylated haemoglobin but the body weight was significantly lower after metformin.

1223

SUPPRESSIVE EFFECT OF TROGLITAZONE ON DEVELOPMENT OF TYPE I DIABETES INDUCED BY MULTIPLE LOW-DOSE STREPTOZOTOCIN INJECTION IN MICE.

T. Fujiwara, S. Takahashi, J. Ogawa, J. Fukushige, T. Hosokawa, S. Kurakata and H. Horikoshi. Pharm. & Mol. Biol. Res. Labs., Sankyo Co., Ltd. Tokyo, Japan

Troglitazone is a new class of antidiabetic agent that ameliorates hyperglycemia in NIDDM patients by enhancing insulin action. In the present study, the effect of troglitazone on development of type I diabetes and cytokine-induced pancreatic B cell dysfunction was investigated both in vivo and in vitro. Type I diabetes was induced by injecting DBA/2 mice with multiple low doses of streptozotocin(40 mg/kg/day for 5 days). In one group of diabetic mice, troglitazone was administered for 3 weeks as a 0.2 % food admixture(290 mg/kg/day) from the start of streptozotocin treatment. The second group received no additional treatment(control diabetic mice). Four weeks after the final streptozotocin injection, control diabetic mice had elevated plasma glucose(615±8 mg/dl, n=8) and their pancreatic B cells were infiltrated by lymphocytes. Troglitazone treatment markedly reduced hyperglycemia in diabetic mice(232±30 mg/dl, n=8) by suppressing lymphocyte infiltration. In vitro studies using hamster insulinoma cell line(HIT T-15 cells) revealed that TNF α (10 pg/ml) and IL-1 β (1 pg/ml) treatment for 7 days decreased insulin secretion and mitochondrial activity (as estimated by MTT assay). Troglitazone addition(0.3 μM) during cytokine treatment with TNF α and IL-1 β increased insulin secretion by 1.6 fold and mitochondrial activity by 1.5 fold compared with cytokine treatment. These findings suggest that troglitazone prevents development of type I diabetes by suppressing lymphocyte infiltration into pancreatic B cells and the subsequent TNF α and IL-1 β-induced B cell damage.

1224

METFORMIN IN INSULIN-DEPENDENT DIABETES MELLITUS WITH INSULIN RESISTANCE

Z.Rušavý, S.Lacigová, P.Těšínský, R.Kárová. University hospital, Pilsen, Czech Republic

Metformin potentiates the insulin action (sensitivity) in IDDM patients, hyperinsulinemia is probably a risk factor of atherosclerosis. Aim: To examine the effect of metformin added to established treatment of insulin-dependent diabetes mellitus (IDDM) patients with high daily insulin dose and poor glycemic control. Methods: In 20 young IDDM patients (Cpeptide<0,01nmol/l) with normal body weight (BMI=24), normal cholesterol and triglycerides level treated with intensified insulin therapy (IIT) (4-6 insulin doses daily), an euglycemic hyperinsulinemic clamp (insulinemia 100mIU/l) was performed together with measuring of energy expenditure by indirect calorimetry. A dosage of 850 mg of metformin twice a day was added to the established IIT. Second clamp with indirect calorimetry was repeated 3 month later. Results: There was a significant decrease of insulin dose (by 22%) in metformin treated patients, prandial requirement of insulin especially. The decrease was directly dependable on insulin dose at the beginning of the study. The glucose uptake was significantly higher (M=3.9±1.6, resp. 5.1± 2.1 $mg.kg^{-1}.min^{-1}$) which represented increase by 29%. There was insignificant decrease of body weight, no change in HbA1c, triglycerides, cholesterol, free fatty acids. The basal insulinemia remained unchanged as well as the energy expenditure. Patients reported lower frequency of hypoglycemia in the last month of the therapy compared to previous treatment. Only 3 patients did not tolerate the treatment well - diarrhea, dyspeptic problems. The level of lactate was not significantly changed. Conclusions: The treatment of IDDM patients with IIT and metformin is safe and it leads to decrease of insulin dose, mainly the prandial one.

1225

EFFECTS OF TROGLITAZONE ON BONE METABOLISM IN ZUCKER DIABETIC FATTY(ZDF) RATS.

M.Miyamoto,C.Fukuda,F.Okada, A. Kiyokawa, Y.Hagisawa and T. Fujiwara. Pharmacology and Molecular Biology Research Laboratories, Sankyo Co., Ltd. Tokyo, Japan.

Although the concept that IDDM is a risk factor for osteopenia is well established, little is known about the effects of NIDDM on bone metabolism. The aims of the present study were 1) to determine if Zucker diabetic fatty (ZDF) rats, a new animal model of NIDDM characterized by insulin resistance, have any disorders in bone metabolism; and 2) if so, to examine the effects of troglitazone, a novel antidiabetic agent, on their bone metabolism. When compared at 19 weeks of age, ZDF rats had significantly lower femoral bone mineral density (BMD)(157.0±2.2 g/cm^2, n=6) than control Zucker lean (Lean) rats(187.4±1.5 g/cm^2, n=6). Serum BGP, a marker for bone turnover, was also significantly lower in ZDF rats compared to Lean rats(8.4±2.2 vs.50.0±3.0 ng/ml). Treatment with troglitazone as a food mixture (132 mg/kg/day) for 13 weeks completely prevented diabetes onset and significantly increased femoral BMD and serum BGP in ZDF rats, while no changes in these parameters were observed in Lean rats. In contrast, pioglitazone, another antidiabetic agent assumed to share its mode of antidiabetic action with troglitazone, in a dose (53 mg/kg/day as a food mixture), which suppressed diabetes onset, markedly lowered femoral BMD both in ZDF and Lean rats after a 13-week treatment period. Pioglitazone slightly increased serum BGP in ZDF rats, but not in Lean rats. Histologically both agents promoted conversion of hematopoietic to fatty marrow in the femur of ZDF and Lean rats. With respect to the degree of the conversion, pioglitazone was far more potent than troglitazone. These results demonstrate that ZDF rats have osteopenia, which is ameliorated by troglitazone, but further aggravated by pioglitazone, indicating that these structurally similar antidiabetic agents have completely opposite effects on bone metabolism.

1226

METFORMIN IMPROVES METABOLIC CONTROL IN NON-INSULIN-DEPENDENT DIABETICS WITH ACARBOSE MONOTHERAPY

M. Hanefeld[1], K. Bär[2], G. Mertes[3] and R. Berlinghoff[4]. [1]University of Dresden, [2]Tessin, [3]Wuppertal, [4]Berlin

Acarbose has been proven to be an effective adjunct in NIDDM insufficiently treated with sulfonylureas or metformin alone. So far no data exist from prospective studies where metformin was used as the second antihyperglycemic agent in combination with acarbose. The rational of this treatment is a synergistic action of metformin on hepatic gluconeogenesis resulting in reduction of fasting blood glucose whereas acarbose mainly reduces postprandial hyperglycemia. We therefore tested in a double blind placebo-controlled prospective trial with NIDDM subjects successfully treated with acarbose as a first line drug whether addition of metformin could help to optimise metabolic control. Inclusion criteria were: response to acarbose pre-treatment $\geq$ 0.6 % points decrease in HbA_1 with $\geq$ 100 mg tid, prevalue > 8.5 % HbA_1. Major exclusion criteria: contraindications for metformin. Examination schedule: subjects with at least 12 weeks acarbose monotherapy, 6 weeks 100 mg acarbose tid plus 850 mg metformin or placebo. If after 6 weeks the HbA_1 level was still > 9.0 % the dosage of metformin was increased to twice 850 mg or placebo for the following 6 weeks. Evaluation: HbA_1, fasting blood glucose and 90' after a test meal, serum insulin, C-peptide, lactate, safety parameters, compliance and adverse events. 49 subjects were randomised, 47 of them were valid for the intention to treat analysis. Metformin reduced HbA_1 from 10.3 % to 9 % ($p < 0.001$). Placebo: 10.1 $\rightarrow$ 10.4 % after 12 weeks. Fasting blood glucose was decreased from 9.1 to 8.2 mmol/l but remained unchanged with placebo (9.8 vs. 9.7 mmol/l). The corresponding levels for pp BG were 11.4 and 9.6 with metformin and 12.3 vs. 12.6 mmol/l with placebo. Serum insulin and C-peptide levels were not affected. Neither metformin nor placebo changed average lactate levels. In three cases with metformin plus acarbose we observed gastrointestinal side-effects. There were no serious adverse event or drop out in both groups nor relevant changes in safety parameters. In conclusion: in Pat. with NIDDM and unsatisfactory acarbose monotherapy perfect metabolic control can safely be achieved by a combination with metformin.

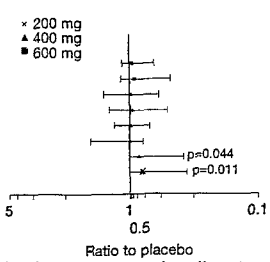
1227

TROGLITAZONE IMPROVES ALBUMINURIA IN TYPE 2 DIABETIC PATIENTS

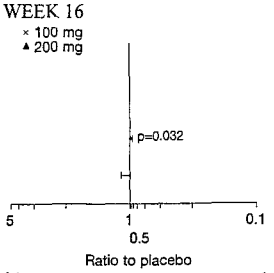
D.J.A. Eckland, L. Frith, M. Starkie and C. Alderton. Glaxo Wellcome Research and Development Ltd., Greenford, U.K.

Albuminuria is a risk marker for cardiovascular and renal disease in type 2 diabetes. Troglitazone is an insulin action enhancing agent in late phase III development for the treatment of type 2 diabetes. It has a therapeutic dose-range of 200-600 mg once daily. Week 12 urinary albumin levels from 219 type 2 diabetic patients taking troglitazone 200-600 mg daily or placebo in 3 dose-ranging, double-blind, placebo-controlled studies were collected. Urinary albumin to creatinine ratio was calculated for data collected after 16 weeks from 231 patients in a double-blind, placebo-controlled study of troglitazone 100 or 200 mg daily added to a sulphonylurea (SU). Adjusted geometric means are presented here as ratio to placebo (95% CI):

ALBUMINURIA, TROGLITAZONE MONOTHERAPY, WEEK 12



URINARY ALBUMIN TO CREATININE RATIO, TROGLITAZONE ADDED TO SU, WEEK 16



The improvements in albuminuria with troglitazone 200-600 mg daily compared to placebo provide further evidence that troglitazone may be of value in the prevention of complications associated with type 2 diabetes.

1228

EFFECTS OF STOPPING METFORMIN IN CHINESE NIDDM PATIENTS ON INSULIN-ORAL HYPOGLYCAEMIC AGENT COMBINATION THERAPY FOR SECONDARY DRUG FAILURE

C.C. Chow, J.K.Y. Li, G.T.C. Ko, V.T.F. Yeung, J.C.N. Chan, L.W.W. Tsang, L.N. Jorgensen* and C.S. Cockram. Diabetes and Endocrine Centre, Prince of Wales Hospital, Hong Kong; *Novo Nordisk A/S, Asia Pacific Centre, Singapore.

Recent evidence suggests that in NIDDM patients with secondary drug failure, insulin-oral hypoglycaemic agents (OHA) combination therapy can achieve similar glycaemic control at a lower insulin dose and less weight gain when compared to insulin therapy alone. The importance of metformin in insulin-OHA combination therapy, however, remains unestablished. As a second phase of a randomized, open, parallel trial, we examine the effects of metformin in Chinese NIDDM patients stable receiving combination therapy for secondary OHA failure. 45 subjects (20 on half maximal sulphonylurea and 25 on maximal sulphonylurea-for details see other abstract), after a 20-week insulin re-adjustment phase, entered into a second phase whereby subjects who were previously on metformin stopped the metformin (n=26) and were compared with subjects who had not been treated with metformin (n=19) for a duration of 5 weeks without any adjustment of insulin or other OHA. At baseline, the No-metformin group had a shorter duration of OHA therapy (9.9±4.9 vs 13.5±3.8 years, p=0.007) and a higher HbA_{IC} (8.8±1.2 vs 8.2±0.9%, p=0.039) despite using a larger dose of bedtime insulin (21.9±8.3 vs 13.3±6.7 U p<0.001). At the end of 5 weeks, the group stopping metformin showed a significant deterioration of glycaemic control when compared to the No-metformin group (ΔFPG 3.85±2.95 vs -0.58±1.75 mmol/l, p=0.0001; ΔHbA_{IC} 1.59±0.93 vs -0.02±0.44%, p=0.0001). We conclude that in insulin-OHA combination therapy for secondary failure, patients not on metformin need a significantly larger dose of insulin to maintain glycaemic control than those patients with metformin. Regardless of whether patients were using full or half maximal dose of sulphonylurea, stopping metformin induces a significant deterioration in glycaemic control within 5 weeks. Thus metformin is a useful and important component of insulin-OHA combination therapy regimes.

1229

TROGLITAZONE IMPROVES GLYCAEMIC CONTROL IN PATIENTS ON SULPHONYLUREAS ALONE

M. Buysschaert[1], G. Rayman[2], E. Bobbioni[3], J.C.N. Correa[4], M. Starkie[5] and L. Frith[5]. [1]Cliniques Universitaires UCL St Luc, Bruxelles, Belgium, Bruxelles, Belgium, [2]Ipswich Hospital, Ipswich, U.K. [3] Hopital Cantonal Universitaire, Geneve, Switzerland; [4]Hospital de Curry Cabral, Lisboa, Portugal; [5]Glaxo Wellcome Research and Development Ltd, Greenford, U.K.

Troglitazone is an insulin action enhancer which improves metabolic control of type 2 diabetic patients as monotherapy. This 16-week, multicentre, parallel-group, double-blind, placebo-controlled study investigated the addition of troglitazone (T) 100 and 200 mg once daily to sulphonylurea (SU). 259 type 2 diabetes patients (mean age 60 yrs, range 34-85 yrs) with fasting capillary glucose ≥ 7 and ≤ 12 mmol/l and taking a stabilised SU regimen were randomised. Median daily doses of SUs were not different between treatment groups. After 16 weeks', fasting blood concentrations (adjusted geometric mean) were:

	n	HbA_{1c} (%)	Glucose (mmol/l)	Insulin (μIU/ml)	Proinsulin (μIU/ml)
SU alone	79	8.2	11.5	9.1	15.2
SU+T100 mg	79	7.7*	10.4**	8.0*	14.0
SU+T200 mg	84	7.4***	9.2***	8.0*	12.5*

*p<0.05, **p<0.01,***p<0.001 vs. placebo

T was well tolerated. Symptoms of hypoglycaemia were not markedly different between the 3 groups (SU 12%, SU+100 mg 7%, SU+200 mg 15%, p=NS). Thus troglitazone added to a SU improved metabolic control without adversely influencing the safety profile.

1230

TROGLITAZONE IS SUPERIOR TO METFORMIN OR INSULIN IN ANTIDIABETIC EFFICACY AND ARRESTS PROGRESSION OF NIDDM IN ZDF RATS

M. A. Hashim, H. Brown, J. Binz, W. Harrington, P. Novak, R. Wiard, C. Goss, R. Crumrine, R. Harper, H. Pink, W. Faison, D. Reynolds, D. Anderson and K. Brown. Glaxo Wellcome, Inc., Research Triangle Park, U. S. A.

Antidiabetic efficacies of Troglitazone (Trog), metformin (Mtfn) and insulin (Ins) were evaluated in 9-week-old male Zucker diabetic fatty (ZDF) rats. Glucose (glu)-matched groups were treated twice daily for 14 days. Seven groups (n=10/group) received Trog (50, 150 or 500 mg/kg), Mtfn (50, 150 or 250 mg/kg; LD_{50}=1000 mg/kg/day) or vehicle (Veh; 0.5% methylcellulose) by gavage and 2 groups (n=16/group) received Ins or NaCl (154 mmol/l), s. c. Metabolic variables were monitored weekly and blood samples for fed glu, insulin, triglycerides (tg), NEFA, lactate and drug levels were obtained on days 0, 7 and 14. Unless noted otherwise, all values (mean ± SEM) given here are for day 14, expressed as % change from day 0, and significant at p<0.01. In Veh and NaCl groups, glu, tg and NEFA remained elevated while insulin levels declined (by 71 ± 4% due to loss of pancreatic β cell function). Trog at 150 and 500 mg/kg decreased glu (by 43 ± 10 and 69 ± 1%), tg (72 ± 8 and 90 ± 1%) and NEFA (39 ± 10 and 80 ± 2%). In contrast, Mtfn at 250 mg/kg decreased glu by 24 ± 8% (p<0.05) on day 7, but by only 5 ± 12% (NS) on day 14; tg and NEFA remained elevated while lactate increased by 108 ± 28%. Serum insulin declined in Trog and Mtfn groups similar to Veh group. Ins treatment lowered glu by 72 ± 3% and NEFA by 26 ± 9% but raised insulin levels by 635 ± 128% and did not lower tg. Histology revealed a normalization of pancreatic islet and renal morphology and an absence of cataracts with Trog or Ins, unlike all other treatments. Elevated tg with Ins treatment, despite decreased lipolysis in adipose tissue, is likely due to enhanced *de novo* hepatic lipogenesis. These findings suggest that derangements of glucose and lipid metabolism in the ZDF model of NIDDM are normalized by Trog but not by Mtfn or Ins and that Trog may reverse or at least arrest the progression of NIDDM by novel mechanisms which are manifest *in vivo* as enhanced glucose and lipid (meal) tolerance and increased insulin sensitivity as assessed by the glu/ins ratio.

1231

Troglitazone Restores Free Fatty Acids-Induced Insulin Resistance in Rat Muscles.

O.Mokuda, and Y.Sakamoto
Teikyo University, Ichihara-City, Japan

Effects of troglitazone on the peripheral insulin resistance were studied. Rats were maintained on the chow with/without 0.2 % troglitazone for 2 weeks. The hindquarter was isolated and re-perfused for 30 min (6cycles), using perfusate containing 15 mM glucose, 0-1000 μU/ml insulin, 0 or 1.0 mM palmitate. Under the palmitate-free conditions, glucose uptake by the hindquarter was similar between the control and the troglitazone-treated rat at each insulin level. The addition of palmitate markedly suppressed the glucose uptake in the control rat hindquarter, but did not reduce that in the troglitazone-treated rat hindquarter (58 ± 8 vs 101 ± 12 μmol at 1000 μU/ml, P<0.01). It is concluded that troglitazone restores the FFA-induced insulin resistance in the peripheral tissues.

1232

WEIGHT LOSS IN DIABETIC PATIENTS TREATED WITH METFORMIN.

D.Bell and M. Mayo. The University of Alabama at Birmingham, Birmingham, Alabama.

The availability of metformin in the USA allowed patients previously treated with insulin or sulfonylureas alone to be transferred to combination sulfonylurea and metformin therapy. A control group of non-insulin-dependent diabetes patients who remained on twice-daily mixed insulin were identified. Over an average of 10 months there was a loss of 0.3 kg (p=0.53) in the control group (C), a loss of 1.6 kg (p=0.03) in the group with metformin added to sulfonylureas(B) over 8 months and 4.7 kg (p=0.0001) in the group transferred from twice daily mixed insulin to combined sulfonylurea and metformin therapy(A) over 6 months. When subjected to multivariable analysis allowing for age, initial weight and length of follow-up there was still statistically significant weight loss in group A compared with groups B and C (p=0.0001). Weight gain was seen in 24 of 57 patients in group C, 15 of 46 in group B, and 6 of 56 in group A. Conclusion: Conversion from insulin to a metformin-utilizing regimen results in significant weight loss in the patient with non-insulin-dependent diabetes.

1233

PHARMACOKINETIC AND PHARMACODYNAMIC PROFILE OF TROGLITAZONE IN NIDDM PATIENTS WITH GLIBENCLAMIDE

K. Püchler, K. Sasahara, P. Laeis and A. Plenker, Sankyo Europe GmbH, Düsseldorf, Germany

A randomised, double-blind, double dummy, 3-way cross-over study was conducted in 26 NIDDM patients. After co-administration of troglitazone (T) and glibenclamide (G) safety, tolerability, pharmacokinetics and pharmacodynamics were assessed following daily oral doses of 200 mg T and 2 x 1.75 mg G alone or in combination for 12 days. The plasma pharmacokinetic profiles of T and G and insulin profiles were determined after the last dose of each treatment period and blood glucose concentrations were evaluated during treatment. All treatments were well tolerated with no major differences in ADRs. Those occured were mild or moderate in severity. The ratios of the mean $AUC_{0\text{-}24h}$ ($\mu g.h.ml^{-1}$), C_{max} ($\mu g.ml^{-1}$), T_{max} (median, h) and $t_{½}$ (h) were: T/T+G 7.5/7.2, 0.97/0.85, 2.0/1.0, 22.8/29.9; G/T+G 0.60/0.57, 0.22/0.21, 1.0/1.5, 2.4/3.1. The 90% confidence intervals (CI) caculated for the ratio of T+G/G and T+G/T for AUC and C_{max} were all within the acceptance ranges (ANOVA). Mean blood glucose profiles, including post prandial blood glucose concentrations were 20-30% higher after multiple doses of T alone, compared to G alone and G+T, whose values were similar. Compared with co-administration, plasma insulin concentrations were up to ca 30% lower after T alone and up to ca 30% higher after G alone with the greatest differences occurring up to *ca* 3.5 hr post dose. Overall, co-administration of T and G was well tolerated with no or little change in the pharmacokinetics of either drug. Administration of 3.5 mg G appeared to override the action of 200mg T during co-administration in accordance with the putative of both drugs, ie T increases the sensitivity of the insulin receptors resulting in a lower requirement for insulin to improve the metabolic status of the patient, whereas G stimulates insulin production by the pancreas.

1234

EFFECTIVENESS OF METFORMIN TREATMENT IN OBESE TYPE II DIABETIC PATIENTS

J.Pawelska, D.Zozulińska, E.Łukomska and B.Wierusz-Wysocka. Poznań Diabetic Center, Poznań, Poland

The aim of the study was to evaluate the effectiveness of metformin in the treatment of obese type II diabetic patients, who had been previously unsuccessfully treated with diet and glibenclamide. The study was performed in a group of 23 patients, aged 34 -72 years, 16 female and 7 male, with mean diabetes history 3.9±2.9 years. The model of treatment in the group was changed from diet and glibenclamide 3 times daily to diet and metformin given twice daily. Before and after 6 month of the study body mass index (BMI), blood pressure (BP), fasting plasma glucose (FPG), postprandial plasma glucose (PPG), HbA_{1c}, total cholesterol, HDL cholesterol, triglycerides (TAG) and fibrynogen (Fg) were estimated. We observed the blood pressure normalization, significant body mass reduction (BMI: 34.02±5.46 vs 32.91±5.14 kg/m^2, $p<0.05$), improved metabolic control of diabetes (no glycosuria, FPG: 10.66±1.96 vs 6.77±0.84 mmol/l, $p<0.05$, PPG: 11.70±2.35 vs 9.37±1.78 mmol/l , $p<0.05$, HbA_{1c}: 8.24±0.79 vs 6.71±0.52 %, $p<0.05$, Ch.: 6.16±1.16 vs 5.99±0.86 mmol/l , $p>0.05$, HDL: 1.05±0.20 vs 1.17±0.21 mmol/l , $p<0.05$, TAG: 2.73±1.00 vs 2.39±1.11 mmol/l , $p>0.05$) and decrease in Fg concentration from 4.36±0.91 to 4.14±0.94 mg/dl, $p<0.05$. The study performed indicates, that in obese patients with type II diabetes and short history of the disease metformin allows to reduce body mass and to reach good metabolic control of diabetes.

1235

TROGLITAZONE IS A PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR γ AGONIST: A NOVEL MECHANISM FOR AN ANTIDIABETIC AGENT

J. Cobb, S. Kliewer, J. Lehmann, S. Blanchard, D. Parks, L. Moore, J. Lenhard, K. Beck and S. Thomson Glaxo Wellcome Inc., Research Triangle Park, USA

Aim: To determine whether non-thiazolidinedione antidiabetic drugs activate Peroxisome Proliferator Activated Receptor γ (PPARγ). PPARγ is a member of the super family of ligand-activated nuclear receptors. It is most abundant in adipose tissue and plays a key role in adipocyte differentiation and in the expression of a number of genes involved in fuel metabolism. Recently we showed that the thiazolidinedione class of antidiabetic drugs were PPARγ agonists and that the potency of PPARγ agonism in vitro correlated with their antidiabetic action in vivo. These data suggest that PPARγ is the relevant biochemical target for the thiazolidinediones and that activation of PPARγ is responsible for the enhancement of insulin action seen with them *in vivo*. The most clinically advanced thiazolidinedione, troglitazone, is a PPARγ agonist with a Ki for binding to PPARγ of 3.0 μM, an EC_{50} of 0.43 μM for activation of PPARγ in a transient transfection assay and an EC_{50} of 0.48 μM in an adipogenesis assay. A number of alternative chemical classes of molecules with antidiabetic activity in NIDDM patients (or in rodent models of NIDDM) have been evaluated for potential PPARγ agonism. These include agents with known and unknown (e.g; glibenclamide (K_{ATP} Channel) and metformin, respectively) biochemical targets. The following drugs were found to have *no* effect on PPARγ (either in binding or *in vitro* functional assays) at 10 μM: sulfonylureas: glibenclamide, tolbutamide, glipizide; biguanides: metformin, phenformin; β_3 agonist: CL316243; miscellaneous: M16209, BM130907. Conclusion: When compared with a number of structurally different antidiabetic drugs, troglitazone and other thiazolidinediones are unique in their ability to activate PPARγ.

1236

COMPARATIVE ASSESSMENT OF THE EFFECTS OF METFORMIN AND SULPHONYLUREA.

R MISSOV, M PETKOVA and V KROUMOVA. Centre of Diabetes, Sofia, Bulgaria.

The purpose of the study is to compare the metabolic effects of Metformin with Sulphonylurea (Glipizide, Gliclazide). In a randomized parallel-group trial 57 obese type 2 diabetic patients are allocated to receive Metformin (29) or Sulphonylurea (28: Glipizide - 13, Gliclazide - 15) and are followed for six months. The inclusion criteria are: age ≤ 70 years, body mass index > 27 kg/m^2 (men) and ≥ 26 kg/m^2 (women), preprandial blood glucose ≤ 10 mmol/l, lack of contraindications for biguanides or sulphonylurea. After six months of follow-up the mean change in the body mass index, the levels of glycated hemoglobin, lipids (total and HDL cholesterol, triglycerides), liver enzymes (ALAT, ASAT), creatinine and lactate are compared across the two groups (two sample t-test or non parametric Mann-Whitney test are used). We find that Metformin has greater potential to reduce body weight: 1.25 v/s 0.5 kg/m^2 decrease in the body mass index ($p < 0.05$). The Metformin's effect on glycemic control seems to be less pronounced: glycated hemoglobin (Hbac) 8.91% v/s 7.87% ($p = 0.05$). No significant difference across the two groups is observed in the other characteristics.

1237

EFFICACY AND SAFETY OF ACARBOSE IN THE TREATMENT OF TYPE II DIABETES: A 2-YEAR SURVEILLANCE STUDY.

G. Mertes. Medical Department, Bayer AG, Leverkusen, Germany.

The aim of the study was to assess the efficacy and safety of acarbose in patients with diabetes over a 2-year period, focusing particularly on patients with type II diabetes. A total of 2035 patients were enrolled in the study; approximately 95% were classified as having type II diabetes. Physicians had sole control of the doses of acarbose prescribed to their patients. Efficacy and safety were evaluated by assessing changes in fasting blood glucose levels, 1-hour and 2-hour postprandial glucose levels, HbA_{1c} or HbA_1, glucosuria, and a range of other clinical parameters, such as blood cell counts and liver enzyme levels. Patients were ideally evaluated every 3 months. Over the 2-year study period, in patients with type II diabetes, the mean fasting blood glucose level decreased by 2.40 ± (SEM) 0.11 mmol/l, while mean 1-hour and 2-hour postprandial blood glucose levels both decreased by 3.57 ± (SEM) 0.17 mmol/l. There were also decreases in HbA_1 and HbA_{1c} values, of 2.0 ± (SEM) 0.44 and 1.1 ± (SEM) 0.14 percentage points, respectively. The drop of HbA_1/HbA_{1c} was sustained throughout the 2 years. These effects were generally achieved at relatively low, and hence well-tolerated, doses. The incidence of adverse effects and withdrawals was low, at 7.5% and 2.5%, respectively. There were no sustained adverse changes in laboratory parameters. The results of the study indicate that acarbose has a good efficacy and safety profile when used long-term in the day to day treatment of patients with type II diabetes.

1238

EFFECT OF 6 WEEKS TREATMENT OF METFORMIN ON INSULIN SENSITIVITY IN GLUCOSE INTOLERANT OBESE PATIENTS

Y. Morel, T. Lehmann, L. Vadas, C. Pasik and A. Golay. Treatment and Teaching Division for Chronic Diseases. University Hospital Geneva, Switzerland.

The biguanide metformin is still considered as the first choice treatment in non-insulin-dependent diabetes (NIDDM) associated with excess weight. Insulin sensitivity and blood lipid profile could be improved, as well as weight reduction. If this improvement could be applied to glucose intolerant patients, progression to overt diabetes mellitus which occurs in 30% of these patients after 10 years could be prevented.

19 obese subjects (BMI 36.5±1.3 kg/m2) aged 47±3 years, glucose intolerant (OMS criteria), received metformin (850 mg 2x/day) in a double blind study, cross over with placebo.

Insulin sensitivity was measured by a modified insulin suppression test and glucose oxidation rate by indirect calorimetry. Fasting plasma glucose improved significantly after metformin treatment (6.1±0.1 mmol/l vs 5.8±0.1 mmol/l; p = 0.02). This improvement was not due to an improvement in insulin sensitivity (13.4±0.7 mmol/L placebo vs 13.1±0.8 mmol/l metformin).

Body weight, blood lipid profile, basal plasma insulin and blood pressure did not improve after treatment. However, the systolic blood pressure was significantly improved after the metformin treatment ($p<0.01$).

In conclusion, 6 weeks metformin treatment improve significantly fasting plasma glucose in obese glucose intolerant. This effect was not due to an improvement in insulin sensitivity. Further studies are required to demonstrate if improvement in fasting plasma glucose with metformin could prevent, in obese glucose intolerant sujects, the progression to overt diabetes mellitus.

1239

EFFECT OF ACARBOSE ON GLUCOSE INTOLERANCE IN NIDDM PATIENTS. K. Noda. Harasanshin Hospital, Japan.

We evaluated the effect of acarbose, an α - glucosidase inhibitor, on glucose intolerance in patients with NIDDM. Acarbose was given orally (300 mg/day) for 24 weeks to 20 NIDDM patients. Data in 75 g OGTT were evaluated before and after 24 weeks of treatment using principal component analysis (PCA), a statistical method that can be used to reveal the general properties of multiple variables. Acarbose administration significantly reduced the postprandial plasma glucose during 24 weeks of treatment. PCA indicated an index of insulin response and insulin resistance and these indices separated our patients into responders (n = 14) and nonresponders (n = 6). The responders had a significantly smaller initial BMI than the nonresponders. There was a significant improvement of fasting and postprandial glucose level after 12 and 24 weeks of treatment in the responders, but not in the nonresponders. Plasma glucose level in the 75 g OGTT significantly improved after 24 weeks of treatment in the responders (Hotelling T^2 value = 47.098, P = 0.022500), but not in the nonresponders. The IRI level did not change in either group. Results thus indicated that acarbose improved insulin resistance in the responders.

1240

METFORMIN DECREASES BODYWEIGHT AND INSULIN LEVELS BUT NOT CIRCULATING LEPTIN LEVELS IN NON-DIABETIC SUBJECTS.

I Følling, SM Carlsen and V Grill. University Hospital of Trondheim, Trondheim, Norway.

Background: Metformin reduces bodyweight and insulin levels in obese type-2 diabetic as well as in obese non-diabetic subjects. Leptin, a recently discovered hormone produced in fat cells, has anorectic and weight reducing effects which are probably exerted at the hypothalamic level. Circulating leptin levels correlates well with BMI as well as fasting insulin levels. **Aim of the study:** To investigate whether metformin treatment influences circulating leptin levels. **Design:** Sixty non-diabetic men with coronary heart disease were treated with diet and lifestyle advice and lovastatin 40 mg/day during a four week run-in period. At week 0 metformin was added for twelve weeks in half of the subjects while lovastatin treatment was continued both in the metformin group (M) and control group (C). The mean daily metformin dose at week 12 was 1759 mg. **Results:** In non-obese subject (BMI < 27 kg/m^2) weight was unchanged both in the M and C group. In obese subjects (BMI > 27 kg/m^2) weight was reduced by 2.3 ± 0.6 kg ($p<0.005$) in the M group while in the C group weight increased insignificantly by 0.8 ± 0.5 kg. Fasting insulin decreased by 16.5% ($p=0.07$) in the M group while it increased insignificantly by 3.9% in the C group. However, metformin treatment did not affect leptin levels (means ± SEM; ng/ml):

Subjects	Treatment group	Change from week 0 to 4	P-values for difference from week 0	Change from week 0 to 12	P-values for difference rom week
All	C	-0.49 ± 0.34	ns.	-0.06 ± 0.49	ns.
	M	-0.34 ± 0.34	ns.	-0.10 ± 0.43	ns.
BMI < 27	C	-0.38 ± 0.34	ns.	0.12 ± 0.26	ns.
	M	-0.12 ± 0.37	ns.	-0.09 ± 0.32	ns.
BMI > 27	C	-0.60 ± 0.59	ns.	-0.24 ± 0.95	ns.
	M	-0.49 ± 0.52	ns.	-0.10 ± 0.71	ns.

Both in the M and C group changes in leptin levels correlated with changes in fasting insulin levels. Only in the C group BMI correlated with changes in leptin levels. During the study 55 to 75 % of variations in leptin levels was explained by BMI and fasting insulin (multiple linear regression analyses). **Conclusion:** Despite that metformin lowers bodyweight and fasting insulin levels, this treatment do not affect circulating leptin levels.

1241

LONG-TERM EFFECTS OF VOGLIBOSE IN NIDDM PATIENTS

T. Inoue, K. Nishino, O. Koshimura and Y. Sako. Shizuoka General Hospital, 4-27-1 Kita-Ando, Shizuoka, JAPAN

We investigated clinical benefits of long-term treatment with Voglibose, α-glucosidase inhibitor, in NIDDM patients.

Subjects; Ninety nine NIDDM patients at out-patient clinics of Shizuoka General Hospital undergoing diet and exercise therapy(59 male, 40 female). The average age was 58.1.

Methods; Voglibose(0.9mg/day) was administered for one year. BS, HbA1c, TC, HDL-C, TG, BMI were measured before and 3, 6, 12 months after the beginning of treatment. The subjects were divided in terms of age (65), HbA1c (8.5%), BMI (23) or combination (+/-) and the statistical analysis was performed between these groups.

Results; HbA1c and TG levels were decreased to the similar extent in not only younger group (age<65) but also elderly group (age>=65). The decrease rate of HbA1c level at 12M was greater in the higher goup of HbA1c levels (>=8.5%) than the lower group (<8.5%) (-22% vs -6.2%). In the obese group (BMI>=23), lower HDL level and higher TG level were observed and the decrease rate of HbA1c level in this group was similar to the non-obese group (-9.7% vs -10.7%). The difference in improvement of HbA1c level between Voglibose alone and combined with SU or insulin was not significant (-6.7% vs -13%). Nineteen cases dropped out.

Conclusion; In NIDDM patients, one-year treatment with Voglibose was very effective on not only glycemic control but also improvement of serum lipids levels despite of age, glycemic control levels, obese or non-obese and alone or combination.

1242

METFORMIN IMPROVES GLUCOSE OXIDATION IN NON-INSULIN-DEPENDENT DIABETES MELLITUS

H.G. Wahl, D. Overkamp, M. Stumvoll, A. Fritsche, H.U. Häring and R.M. Schmülling. Medizinische Universitätsklinik Abt. IV, Tübingen, Germany.

Although the metabolic effects of Metformin are still not fully understood it has been shown to improve insulin sensitivity. Metformin decreases hepatic glucose output by inhibiting gluconeogenesis and at the same time it increases the rate of lactate oxidation. The aim of our study was to investigate the effect of metformin on glucose oxidation in NIDDM patients by stable isotope methodology. U-13C glucose (7mg/kg) was used to asses total glucose oxidation in addition to hepatic glucose output (m+6 mass isotopomer) and glucose recirculation (m+3 mass isotopomer). 3-13C glucose (300 mg) was used in a second experiment to asses more specific the effects of metformin on the pyruvate dehydrogenase complex involved in the oxidative decarboxylation of pyruvate to Acetyl-CoA. Glucose oxidation was determined by indirect calorimetry (VCO_2) and mass spectrometry ($^{13}CO_2$) Patients were admitted to the clinic the night before the first experiment and stayed for three days until the end of the second tracer experiment. After 10 weeks of metformin treatment this experimental setup was repeated. The initial dose of 850 mg of metformin was increased every second week up to a final dose of 2550 mg unless the patient had a fasting plasma glucose (FPG) below 120 mg/dL, which did not happen in this first five patients (age 42 ± 8 years, duration of diabetes 5 ± 1 years). The effect of metformin on metabolic profile is shown in the following table (Chol=cholesterol, TG=triglyceride, FFA=free fatty acids).

	HbA1c [%]	FPG [mg/dL]	Insulin [pmol/L]	Lactate [mmol/L]	BMI [kg/m²]	Chol [mg/dL]	TG [mg/dL]	FFA [mmol/L]
before	8.7±0.6	177±13	213±50	1.22±0.04	42±5	209±7	251±63	1.3±0.3
after	7.5±0.1	155±14	202±33	1.68±0.31	41±4	184±6	195±43	0.5±0.1

The cumulative dose recovery of $^{13}CO_2$ over the six hours of experiment increased by 8% (p=0.03) for U-13C glucose and by 16% (p=0.04) for 3-13C glucose. This increased glucose oxidation with a lower insulin level after metformin treatment suggests improvement of insulin sensitivity in NIDDM patients. Differences in glucose oxidation increase between the two tracers 3-13C and U-13C glucose points to the pyruvate dehydrogenase complex as one possible site of metformin action.

1243

USEFULNESS OF VOGLIBOSE ADMINISTRATION ON DIABETIC PATIENTS WITH CHRONIC RENAL FAILURE.

H. Shimizu, A. Shouzu, T. Yonemoto, Y. Miyake, S. Tabata, T. Hayakawa S. Omoto, N. Sakaguchi, T. Tokoro, T. Takagi, M. Nishikawa and M. Inada. Kansai Medical University, Osaka, Japan.

Diabetic nephropathy resulting in chronic renal failure (CRF) often accompanies diabetic retinopathy leading to visual disturbance, and to the difficulty in frequent insulin injection. The purpose of the present study was to evaluate the effect of voglibose on diabetic patients with CRF. Nine such patients with poorly controlled blood glucose (7 treated with hemodialysis and 2 untreated) were selected: seven received voglibose plus insulin concurrently and two voglibose alone. The dose of voglibose was 0.2-0.6 mg/day. HbA1c was measured by HPLC at -1, 0, 1, 3 and 5 months after the administration. The mean HbA1c of the nine diabetic patients before the administration (9.1 ± 2.1%; Mean±SD) began to decrease one month after and significantly ($P<0.05$) decreased to 7.2±1.1% 3 months after the administration of voglibose plus insulin or voglibose alone. The mean HbA1c (7.3 ±1.1) five months after the administration was also significantly ($P<0.01$) lower than that before the administration. No severe adverse effects were noted other than mild abdominal fullness. The administration of insulin plus voglibose or voglibose alone was thus effective in controlling blood glucose. These findings indicate that voglibose is a useful therapy for diabetic patients with end stage renal insufficiency.

1244

TREATMENT WITH METFORMIN IN NIDDM PATIENTS LOWERS PLASMA AMYLIN LEVEL

B.Zapęcka-Dubno, A.Czyżyk, A.Dworak and M.I.Bąk
University School of Medicine, Warsaw, Poland.

This study was undertaken to investigate if the kind of oral treatment of NIDDM can affect the level of plasma amylin (AMYLIN). AMYLIN (Peninsula Lab.kits), serum C-peptide and insulin in fasting state and 6 min after 1 mg i.v. glucagon injection were measured in 3 study groups: healthy volunteers (CON, n=10), NIDDM patients with glibenclamide treament (GLIB, n=10) and patients with metformin treatment (MET, n=13). AMYLIN (in pM, mean±SEM) was: in CON 1.6±0.24 and 6.5±1.6, in GLIB 3.1±0.4 and 5.5±1.2, in MET 1.8±0.3 and 2.3±0.3, in fasting state after glucagon stimulation, respectively. In another group of 20 patients with newly diagnosed NIDDM the above test and measurements were carried out twice: before (GLIB-0, MET-0) and after 2 weeks of treatment with either metformin or glibenclamide (GLIB-2, MET-2).

The fasting and stimulated amylin levels in plasma were:

	0 min	6 min after glucagon
GLIB-0	2.5±0.2	3.3±0.4
GLIB-2	3.2±0.3	4.6±0.4
MET-0	2.6±0.6	3.5±0.6
MET-2	1.3±0.4*	2.8±0.9*

*There was a marked decrease in baseline and stimulated AMYLIN in metformine group. In the light that increased amylin level can contribute to insulinresistance the present results suggest that metformin therapy can be beneficial in this type of diabetes.

1245

EFFECT OF ACARBOSE COMBINED WITH SULPHONYLUREA AND BIGUANIDE; A DOUBLE BLIND, CROSSOVER STUDY.

S.K.Hong, C.S.Choi, J.Y.Park and K.U.Lee. University of Ulsan, Seoul, Korea.

Acarbose, an alpha-glucosidase inhibitor, is known to improve glycemic control in patients with non-insulin-dependent diabetes mellitus (NIDDM) managed with diet alone, or other antidiabetic agents. However, it is controversial whether this drug is effective when combined in patients treated with sulfonylurea and biguanide (metformin). This study was undertaken to test the efficacy of acarbose in combination with sulfonylurea and metformin. The trial was double-blinded, and consisted of a 4-week run-in period, a 12-week test period, a 4-week wash-out perid and a 12-week crossover-test period. Thirty patients with NIDDM, insufficiently treated with sulfonylurea (n = 10) or sulfonylurea plus metformin (n = 20) were randomized into two groups. During the test or crossover-test period, 100 mg of acarbose or placebo were given three times per day respectively. Before and after 12-week test and crossover-test period, mixed meal glucose tolerance test was performed. Twenty six patients completed the study. Among these, 9 were being treated with sulfonylurea (group A) and 17 with sulfonylurea and metformin (group B). Compared with baseline, acarbose treatment resulted in a significant decrease in the fasting and postprandial 1 and 2 hr serum glucose levels (11.5 $\pm$ 1.9 vs. 9.8 $\pm$ 2.2, 17.5 $\pm$ 2.2 vs. 14.5 $\pm$ 3.2, 16.5 $\pm$ 2.9 vs. 14.0 $\pm$ 3.8 mM, $P < 0.05$ respectively) and Hb A_1 level (11.8 $\pm$ 1.5 vs. 10.6 $\pm$ 2.0 %, $P < 0.05$). This improvement in glycemic control was noted both in group A and in group B. There was no statistically significant change in these values during the placebo period. The incidence of side effects (mainly gastrointestinal symptoms such as flatulance and abdominal pain) was higher in the acarbose treatment period (48 % vs. 11 %, $P < 0.05$) than in the placebo period, but there was no significant difference between group A and B. These results show that acarbose is effective in improving glycemic control in NIDDM patients when used in combination with sulfonylurea, or sulfonylurea and metformin.

1246

EFFECT OF SULFONYLUREA ON WASHOUT RATE OF ^{201}THALLIUM WITHIN MYOCARDIUM CELLS IN NEWLY DIAGNOSED NIDDM PATIENTS

G. Ayvaz, N. Çakır, İ. Yetkin, M. Kitapçı, S. Atavcı and M. Arslan. Gazi University Medical Faculty, Ankara, Turkey.

Functional K_{ATP} channels existing in cardiovascular system are closed or inactive under physiological circumstences. During hypoxia and/or ischaemia these channels are opened and leads the myocardium to relax in order to protect the myocardium against ischaemia and reperfusion damage. Because the endothelium cell function is disturbed in diabetes mellitus, this relaxation can not be observed as in the healthy subjects which may be attributed to the failure in opening the K_{ATP} channels. In the recent study we performed myocard perfusion scintigraphy with ^{201}Thallium which acts via K_{ATP} channels to 10 newly diagnosed diabetic patients and 10 healthy controls. The mean WORs (washout rate) of 10 diabetic patients before and 3 months after starting sulfonylurea were 43.05 and 27.01 respectively while the mean WOR of normals was 47.09. The washout of ^{201}Thallium in myocardium of diabetic patients was equal to the values of normal subjects ($p>0.05$) whereas after the treatment with sulfonylurea for 3 months the WOR of diabetics decreased to 27.01 that was statistically significant when compared to the pretreatment values ($p<0.05$). This preliminary study suggested us that sulfonylureas act as a K_{ATP} channel closer so the washout of ^{201}Thallium from myocardium decreased after treatment in diabetic patients.

1247

THE EFFECTS OF ACARBOSE ON INTESTINAL PROTEIN ABSORPTION

T.Miwa, M.Kume, J.Hayashi*, A.Amaya, A.Kanazawa, M.Kanazawa, Y.Notoya, and T.Hayashi. Tokyo Medical College, Kyorin University,* Tokyo, Japan.

Background It is well known that glucose absorption needs the energy derived from Na^+-K^+ ATPase at the basement membrane, and that sodium ion is mandatory for the glucose transport In these aspects, the absorption of amino acids and dipeptides is similar in nature to that of glucose. Therefore, we investigated the effect of the administration of acrabose, α-glucosidase inhibitor, on protein-metabolism. **Method** Sprague-Dawley rats aged eight weeks were divided into the following four groups: (1) normal control group (group C; n=8), (2) acarbose-treated normal group (group A; n=8), (3) non treated diabetic group (group DM, n=8), (4) acarbose-treated diabetic group (group DMA, n=7). Diabetes was induced by streptozotocine at 60 mg/kg (i.p.) Group A and DMA were fed with the same standard diet as given to group C and DM, except for supplementary acarbose at 200 mg/kg. These groups were observed for 28 days. During the last three days of the observation period, we measured food and intake, urine volume, and fecal volume. After freeze drying, physiological saline was added to a certain amount of each fecal specimen, homogenized, and centrifuged. The resulting supernatant was used as a fecal extraction solution for the quantification of total amino acids, total proteins, and glucose. Data were analaysed by Scheffe's multiple comparison; a *P* value less than 0.01 was considered to be statistically significant. **Result** **1)** Blood glucose levels did not differ between group C (101 $\pm$ 7.8 mg/dl, means $\pm$ SE) and A (67 $\pm$ 7.5) or between group DM (388 $\pm$ 35.4) and DMA (416 $\pm$ 51.3), showing no effect of the administration of acarbose. **2)** Total amino acids in feces significantly increased in groups DM (954 $\pm$ 121 nmol/day) and DMA (1331 $\pm$ 171), compared with group C (397 $\pm$ 104) and A (322 $\pm$ 58.9), but no significant differences were seen between group DM and DMA. **3)** Urine protein significantly increased only in group DM, whereas no significant differences were seen among other groups. **Conclusion** Our data suggested that diabetes may cause impaired protein absorption in the digestive tract, and that the administration of acarbose may influence not only glucose absorption, but protein absorption as well.

1248

GLIBENCLAMIDE BETA-CYTOPHILOUS EFFECT IN MICE UNDER DIFFERENT TREATMENT SCHEDULES

V. Natarov, A. Gladkih, V. Poltorack and O. Brindak. Ukrainian Scientific Research Institute of Endocrine Diseases Pharmaco-therapy, Kharkov, Ukraine

In our previous study pancreatic beta-cells alteration with auto-immune insulitis development has been shown in animals after long term glibenclamide (Glib) using. The aim of this study was to investigate whether Glib discontinuous treatment schedule can reduce the deleterious impact of chronic continuous treatment with Glib in C57BL/KsJY-db/m mice. Glib was given once daily *per os* (1 mg/kg) within 3 months (Group 1, n=10) or one-monthly courses three times each separated by four weeks (Group 2, n=8). The study was placebo controlled (n=12). Glib treatment in Group 1 decreased the tolerance to glucose (mean blood glucose levels were 5.8±0.2, 17.9±1.3, 18.3±1.2, 10.8±1.5, 6.7±0.2 mmol/l at 0, 30, 60, 120, 180 min after i.p. glucose challenge, respectively vs 5.2±0.2, 10.3±1.3, 9.1±1.0, 4.6±0.2, 4.3±0.3 mmol/l in controls, $p<0.05$ at 30, 60, 120 min), attenuated the insulinaemic reaction (integral immunoreactive insulin content over i.p. GTT at 0, 30, 60, 120 min was 345±25 vs 598±72 pmol/l in controls, $p<0.05$), increased (3 fold, $p<0.05$) the complement-dependent antibody-mediated serum cytotoxity (CDAMSC) directed to neonatal rats pancreatic islet cells, induced dystrophy in beta-cells of 70% islets and lymphocytic infiltration (mainly IA and IB grades) in the third part of islets. In Group 2 we did not observe a decrease in tolerance to glucose, any insulitis; dystrophic pancreatic islets were recognised in 12% and CDAMSC was increased by 1.5 fold. Thus the discontinuous treatment with Glib attenuated sharply the unfavourable beta-cytophilous impact of Glib chronic using.

1249

EFFECT OF A NEW α-GLUCOSIDASE INHIBITOR, VOGLIBOSE, IN DIABETIC PATIENTS WITH LIVER CIRRHOSIS

M. Yoshitsugu, T. Hiyoshi, and F. Akasu. Japanese Red Cross Medical Center. Tokyo, Japan.

In patients with liver cirrhosis, there is often postprandial hyperglycemia. The effect of a new α-glucosidase inhibitor (voglibose) on blood glucose levels was evaluated in 8 diabetic patients with liver cirrhosis. The patients received voglibose (0.6mg/day) orally immediately before each meal for 4 weeks. It significantly reduced postprandial blood glucose levels (after breakfast : 203.2 ± 62.2mg/dl to 141.0 ± 70.1mg/dl, $p < 0.02$, after lunch : 179.5 ± 99.8 to 141.5 ± 39.1, $p < 0.05$, after dinnner : 187.8 ± 78.6 to 147.0 ± 44.3, $p < 0.05$), accompanied by a decrease in HbA_{1c} (Before : 6.5 ± 2.8 %, After 4 weeks : 5.6 ± 1.7 %, not significant). Fasting Serum total cholesterol and triglyceride levels which were lower in pretreatment period tended to increase during 4 weeks but the differences were not significant, whereas fasting serum HDL cholesterol levels were unaffected. Fasting serum GOT (AST), GPT (ALT), γ-GTP, ChE and albumin levels tended to improve after voglibose treatment (not significant), but fasting blood ammonia levels were significantly decreased after the treatment (90.4 ± 29.9 μg/dl to 58.8 ± 17.4 μg/dl, $p < 0.01$). Blood ammania levels were increased following a meal in diabetic patients with liver cirrhosis. The peak values were seen at 1 hour after breakfast without voglibose treatment, but at 3 hours after breakfast with the treatment. Voglibose did not cause any side effects except for 2 cases who showed mild hypoglycemic attacks at the early stage of the treatment. These results suggest that a new α-glucoidase inhibitor voglibose has a beneficial effect on postprandial hyperglycemia and liver function tests in diabetic patients with liver cirrhosis.

1250

SULFONYLUREA EFFECT ON INSULIN RECEPTOR TYROSINE KINASE OF DIABETIC PATIENTS IN DIFFERENT CONDITIONS OF GLUCOSE CONTROL.

R.F.Santos, E.M. Oliveira , R. Nomizo,W.L.Wajchenberg.University of São Paulo, São Paulo, Brazil

The aim of the present study was to investigate the influence of plasma glucose concentrations on glyburide action on insulin receptor tyrosine kinase activity(IRTK)of patients with diabetes type 2(NIDDM). The patients were divided in four groups according to be or not under treatment, and according to their different plasma glucose concentrations.Group A without treatment, and B, C, and D under Glyburide.Plasma glucose, insulin and glycated haemoglobin(HbA1c) were measured. The insulin binding(Bmax) and(IRTK) toward PolyGlu(4:1)Tyr was evaluated in solubilized receptors from erythrocytes of the patients. Statistical analysis by ANOVA,P <0.05. Glucose(mMol/L) was for A(n=7)15.54 +/-2.49; B(n=12)6.35+/-0.31;C(n=10)9.31+/-0.28;D(n=9)14.16+/-1.00, P=0.001.Insulin(pMol/L), for A=78+/-15; B=68+/-10; C=120+/-38; D=70 +/-15; NS. HbA1c(%) for A=13.4+/-1.8; B=7.4+/-0.4; C=9.8+/-0.7; D=11.5 +/-1.1, P=0.004 .The Bmax(nMol/mg protein)was not different between the groups for A=1.13+/-0.31; B=1.35+/-0.25; C=1.80+/-0.31;D=1.25+/-0.23 ; NS. Kd(nM) for A=9.56+/-2.5; B= 4.23+/-0.94; C=4.80+/-01.10; D=5.11+/-1.20 It was higher in A than in B, P< 0.05. The IRTK activity stimulated by insulin(pMol/min/mg protein)was lower in untreated, than in treated groups: A= 10.5+/-2.5; B=24.0+/-2.7; C=29.8+/-5.3; D=22.4+/-3.6, P= 0.01. The Ka(nM) was lower in the treated group with best glucose control than, in treated and untreated groups with high glucose concentrations, for A=2.3+/-0.3; B=1.7+/-0.2; C=3.6+/-0.8; D=2.4+/-0.4, P=0.04. In conclusion,NIDDM patients treated with glyburide presented higher insulin-stimulated IRTK activity without significant changes in insulin binding. Plasma glucose concentrations did not interfer on insulin-stimulated IRTK activity of patients under glyburide treatment,but the treated patients with best glucose control presented higher sensitivity to insulin for IRTK activation.

1251

THE EFFECT OF α-GLUCOSIDASE INHIBITOR ON HYPERINSULINEMIA IN DUMPING SYNDROME

Chizuko Yokota, Joh-ichi Usui, Yuko Shimizu, Kaoruko Tada, Akimitsu Takahashi, Yasushi Kawakami, Chieko Bannai, Teruhiko Matsushima, Yukichi Okuda, and Kamejiro Yamashita. Univ. of Tsukuba, Department of Endocrinology and Metabolism, Tsukuba, Japan.

A 55-year-old, skinny woman was referred because of syncope attack. She had received partial gastrectomy 30 years ago. In recent years, she exhibited marked post-prandial hypoglycemia. An abdominal computed tomograph could detect no pancreatic tumor. Her thyroid and adrenal functions were normal. Anti-insulin antibodies were not detectable. 72 hour-fasting test did not induce hypoglycemia. Glucagon and arginine loading tests showed normal pancreatic β-cell functions. 50g-OGTT showed oxyhyperglycemia associated with insulin (IRI) hypersecretion (0'→60'; plasma glucose (PG): 90→237 mg/dl, IRI: 4→300 μU/ml). I.v.-GTT showed normal IRI secretion even though PG levels were as high as those in OGTT. Administration of α-glucosidase inhibitor (α-GI) showed desirable effects on loading of 400 kcal mixed meal (without α-GI; 0'→30'; PG : 79→174, IRI: 3→61, with α-GI; PG : 79→138, IRI: 2→22, respectively). These results suggest that the hypersecretion of IRI during OGTT was induced by glucagon-like peptide-1 (GLP-1), because GLP-1 is considered to play an important role in dumping syndrome. Our results also suggest that α-GI blunted hyperinsulinemia-reactive hypoglycemia, through inhibiting incretin secretion.

1252

PHARMACOKINETICS OF GLIBENCLAMIDE AND ITS METABOLITES IN DIABETIC SUBJECTS WITH NORMAL AND WITH IMPAIRED RENAL FUNCTION

Jönsson A, Rydberg T, Sterner G, Melander A. Departments of Internal Medicine, County Hospital Ryhov, Jönköping, Malmö University Hospital, The NEPI Foundation and the National Corporation of Pharmacies, Malmö and Stockholm, Sweden.

The pharmacokinetics of glibenclamide (gb), 4-*trans* -hydroxy-(M1) and 3-*cis* -hydroxy-gb (M2) were compared in 2 x 11 diabetic subjects with impaired (IRF iohexol clearance 7-42 ml/min/1.73 m^2) or normal renal function (NRF; iohexol clearance 75-140 ml/min/1.73 m^2). Serum (48 h) and urine (24 h) samples were obtained after administration of 7 mg gb orally. Concentrations of gb, M1 and M2 were determined by HPLC. All comparisons between groups were analysed by paired non-parametric Wilcoxon test, a two-tailed $p<0.05$ considered significant. Peak serum values of M1 (24-85 vs. 16-57 ng/ml), M2 (7-22 vs. <5-18 ng/ml) and M1 + M2 (32-100 vs. 23-76 ng/ml) were higher in the IRF group. Gb AUC (1153±241 vs. 2086±707 μgh/L) and Cmax (302±88 vs. 463±226 ng/L) were lower and Cl/F (6.31±1.30 vs. 3.70±1.15 L/h) higher in the IRF group. M1 AUC (307±140 vs. 210 ±117 μgh/L and Cmax (36±14 vs. 26±10 ng/L) were higher and Cl/F met (27.5±12.5 vs. 40.7±1.8 L/h) lower in the IRF group. Much lower amounts of the metabolites were excreted in urine in the IRF group than in the NRF group (7.2 vs. 26.4% in 24 h) and there was a strong correlation between metabolite excretion and renal function. No other pharmacokinetic differences were found. The differences in AUC, Cmax and CL/F of gb can be explained by a higher free fraction in the IRF group, which would increase metabolic gb clearance. The inverse findings regarding M1 can be explained by the fact that the metabolites are totally eliminated by the kidneys. After a single dose of gb, neither gb nor its metabolites seemed to accumulate in IRF subjects. As only small amounts of M1 and M2 were excreted in the urine, this indicates one or more complementary non-renal elimination routes (probably biliary excretion).

1253

THE USEFULNESS OF COMBINATION ON THERAPY WITH INSULIN INJECTION AND α-GLUCOSIDASE INHIBITOR IN NIDDM PATIENTS WITH SECONDARY FAILURE ON SULFONYLUREAS AGENTS

T.KANDA, E.IMANO, Y.YAMAZAKI and R.KAWAMORI*, Osaka, Tokyo*, Japan

We investigate the effect of combination thrapy with preprandial rapid-acting insulin injections and α-glucosidase inhibitor(α-GI), which is known to suppress postprandial hyperglycemic, on discontinuation of insulin treatment in non-obese NIDDM patients with secondary failure on oral hypoglycemic agents.

Thirty-six hospitalized patients with NIDDM who showed poor glycemic control during 2 weeks of diet and exercise therapy with almost maximal doses of sulfonylureas were divided into a group treated with rapid-acting insulin injection plus α-GI before each meal(group Ⅰ;n=19), and a group treated with rapid-acting insulin injection alone(group Ⅱ ;n=19). There were no significant differences in daily insulin requirements, FPG, HbA1c or serum fructosamine between groups Ⅰ and Ⅱ. However, both meal-related and premeal glycemia was normalization in group Ⅰ and the piriod of insulin treated was 12.7 days shorter than in group Ⅱ.

These obsevation indicate that combination therapy with preprandial rapid-action insulin injection and α-GI can shorten the period of insulin therapy and facilitate discontinuation of insulin treatment through normalization of postprandial hyperglycemia as well as the resting state of pancreatic beta cells in NIDDM patients with secondary failure on oral hypoglycemic agents.

1254

HAEMODYNAMIC EFFECTS OF GLIMEPIRIDE AND GLIBENCLAMIDE IN DOGS

I. Pósa, E. Kocsis, M. Z. Koltai and G. Pogátsa, National Institute of Cardiology, Budapest, Hungary

The aim of the study was to compare the haemodynamic effects of glibenclamide (GB; n=6) and those of the latest low daily dose sulphonylurea compound, glimepiride (GM; n=6) in the coronary circulation. Mean arterial blood pressure, heart rate, myocardial tissue flow, myocardial contractile force, and the rate of change of myocardial contraction and relaxation were measured in pentobarbital anaesthesia (Nembutal, CEVA, 133 $\mu mol*kg^{-1}$), during iv. administration (0.4-2-5-8 $\mu mol*kg^{-1}$) of the drugs in dogs. Furthermore, cardiac work was calculated. Both compounds proved to be hypotensive (GM: -21%, $p<0.001$; GB: -38%, $p<0.001$) and reduced the heart rate (GM: -6%, $p<0.05$; GB: -32%, $p<0.05$). Myocardial tissue flow was influenced oppositely by the compounds ($p<0.05$): it was increased by glimepiride (+14%, $p<0.05$), while it was diminished (-39%, $p<0.001$) by glibenclamide. Both compounds was found to be negative inotropic (GM: -52%, $p<0.001$; GB: -49%, $p<0.05$). The rate of change of myocardial contraction was reduced by glimepiride and glibenclamide (GM: -56%, $p<0.05$; GB: -52%, $p<0.05$), but the rate of change of myocardial relaxation was decreased only after glimepiride (-39%, $p<0.001$). Cardiac work was reduced by both drugs (GM: -21%, $p<0.001$; GB: -57%, $p<0.01$). According to the results, glimepiride decreases mean arterial blood pressure less, than glibenclamide does; this newly developed drug practically does not influences heart rate and its cardiac work lowering effect is weaker, than that of glibenclamide, although these differences in the present study were not significant. However, glimepiride exerts an obviously favourable side-effect on the microcirculation of the myocardium. Taking these findings and its very low daily dose into account, glimepiride may also be recommended for the treatment of non-insulin-dependent diabetes mellitus.

1255

EFFICACY OF MONOTHERAPY WITH ACARBOSE, GLIBENCLAMIDE, GLICLAZIDE, METFORMIN OR PLACEBO IN NIDDM PATIENTS

A.N.Kamel, B.Çetinarslan, A.R.Uysal, N.Başkal, D.Çorapçıoğlu, V.Tonyukuk
Ankara University Medical School, Department of Endocrinology & Metabolism

This study was planned to compare the different oral antidiabetic agents in NIDDM patients with dietary failure. 43 NIDDM patients (35-65 years of age, BMI<35 kg/m^2, HbA1c=7-9%, duration of diabetes>6 months) were randomized into five groups and treated for 24 weeks with acarbose (A) (n=10), gliclazide (Gc) (n=9), glibenclamide (Gb) (n=8), metformin (M) (n=6) or placebo (P) (n=10) and were evaluated every 6 weeks. No change during 24 weeks of treatment with P ($p>0.05$) could be seen for fasting plasma glucose (FPG), postprandial plasma glucose (PPG) and HbA1c levels (9.3±0.8 vs. 9.0±0.8 mmol/L; 10.6±1.0 vs. 10.3±0.4 mmol/L; 8.1±0.5 vs. 8.0±0.7%, respectively). Significantly lower mean values for FPG, PPG and HbA1c levels were obtained on treatment with A (9.6±1.4 vs. 7.8±1 mmol/L; 13.0±2.1 vs. 9.3±1.2 mmol/L; 8.5±0.8 vs. 7.0±0.7%, $p<0.001$, respectively), Gc (10.4±1.8 vs. 8.1±1.2 mmol/L; 13.4±2.1 vs. 9.7±1.3 mmol/L; 8.4±1.1 vs. 7.4±1.3 %, $p<0.001$, respectively), Gb (10.3±2 vs. 8.1±0.6 mmol/L; 13±2.1 vs. 9.9±2.5 mmol/L; 8.4±1.1 vs. 7.2±0.9 %, $p<0.05$, respectively), M (10.8±1.2 vs. 7.8±0.6 mmol/L; 12.5±1.8 vs. 8.7±0.6 mmol/L; 8.4±0.7 vs. 6.9±0.7%, $p<0.01$, respectively). While the significant increases were observed in the postprandial serum insulin levels following treatment with P, Gc, Gb (19.8±1.2 vs. 22±1.5; 20.5±1.2 vs. 31±1.6; 24.3±1.2 vs. 42±1.5 pmol/L, $p<0.05$, respectively), no significant changes were found following treatment with A and M (20.4±1.4 vs. 16.3±1.3; 21.6±5.5 vs. 16.3±6.2 pmol/L, $p>0.05$, respectively). No marked differences were observed between groups with respect to fasting serum insulin and c-peptide levels after treatment. Our results indicate that A, Gc, Gb and M are effective drugs for the monotherapy of NIDDM patients when diet alone fails. Because postprandial insulin increase has been shown to be associated with increased risk for cardiovascular disease, A and M may be superior to Gc and Gb, which elevates postprandial insulin levels.

1256

COMPARATIVE INVESTIGATIONS OF THE EFFECTS OF GLIBENCLAMIDE AND ACARBOSE ON CIRCADIAN INSULIN LEVELS IN NIDDM

S. Fischer[1], M. Hanefeld[1], C. Köhler[1], M. Spengler[2], P. Heyen[2], K. Fücker[1] and M. Menschikowski[1]. Medical Faculty, Technical University Dresden[1] and Bayer AG Leverkusen[2] Germany.

Glibenclamide as insulin secretion stimulating drug and acarbose as antihyperglycemic agent represent different mode of actions. Little is known of their effects on circadian levels of insulin and lipids under long term treatment. Therefore we investigated 76 NIDDM patients (average age 58.9 years, average BMI 27.6) before and after a 16 week treatment with acarbose (3x100 mg/d) or glibenclamide (3x1 mg/d) or placebo (3x1 tablet/d) in a double blind fashion. All patients were treated by diet alone, antidiabetic drug therapy was interrupted 4 weeks before the start of the investigation. 24 hours profiles of insulin, blood glucose and lipids (fasting and than of all 3 hours) were carried out under standardized diet and Metabolic Ward conditions. After 16 weeks acarbose therapy the insulin area under the curve decreased slightly (8.8 vs. 8.3 $nmol*l^{-1}*24h$, n.s.), whereas after glibenclamide therapy the insulin area under the curve increased significantly (9.6 vs. 12.1, $p < 0.001$) and under placebo it decreased (8.7 vs. 7.9, $p < 0.01$). Hyperinsulinemia persisted up to 4 a. m. in glibenclamide treated patients. In comparison with the initial values the blood glucose area under the curve decreased (after acarbose 317.8 vs. 289.9 $mmol*l^{-1}*24h$, $p < 0.01$, after glibenclamide 356.9 vs. 236.5, $p < 0.01$), but increased in the placebo group (339.2 vs. 346.3, n.s.), the triglyceride area under the curve decreased slightly under acarbose (66.5 vs. 65.9 $mmol*l^{-1}*24h$) more so under glibenclamide (71.6 vs. 62.5 $mmol*l^{-1}*24h$) and increased under placebo (52.8 vs. 61.8 $mmol*l^{-1}*24h$). Glibenclamide leads to long lasting hyperinsulinemia up to dawn whereas acarbose reduces hyperinsulinemia. Both drugs reduce hypertriglyceridemia obviously due to improved diabetes control.

1257

ACARBOSE IMPROVES THE METABOLIC ENVIRONMENT OF NIDDM PATIENTS WITH THE PLURIMETABOLIC SYNDROME.

R.Scott, C.Lintott, P.Zimmet, L.Campbell, K.Bowen, T.Welborn
The New Zealand and Australian Investigators c/o International Diabetes Institute, Melbourne, Australia.

NIDDM subjects (n=105; age 36-71) were randomised to acarbose (100mg tid) or placebo for 16 weeks, and changes in clinical and metabolic parameters indicative of the insulin resistance syndrome were monitored. Fasting levels of glucose, HbA1c, true insulin, proinsulin, fibrinogen, and lipids were measured 4 weekly, and glucose, insulin and triglyceride responses to a standardised 1.6MJ breakfast were determined at 0, 1 and 2 hours post meal. Analysis of data was by ANOVA with repeated measures on an intention to treat basis. The placebo and acarbose treated groups were similarly matched at baseline for age / sex distribution, duration of diabetes, hip:waist ratio but BMI was higher in acarbose (31±3) than placebo group (29±3) group. Acarbose resulted in significant reductions to fasting levels of glucose ($p<0.0001$), triglycerides ($p=0.03$), and HbA1c ($p<0.003$) over the 16 weeks of treatment. The mean HbA1c level was 0.4% different ($p=0.003$) between groups with respect to baseline change. Fasting insulin or proinsulin levels did not change with Acarbose treatment, but in response to the standard breakfast meal, insulin ($p=0.06$) and glucose ($p<0.0001$) responses were reduced. There were no significant treatment differences for fibrinogen, fasting cholesterol, HDL, BP, weight, waist:hip ratio over time. These data show that Acarbose reduces glucose and triglyceride levels, and limits the insulin response to a mixed meal in NIDDM subjects with the plurimetabolic syndrome. **Acarbose may have potential to limit the rapid progression of atherogenesis associated with insulin resistance and diabetes mellitus.**

1258

GLIBENCLAMIDE AND DAILY BLOOD PROFILES; COMPARISON OF A SINGLE-DOSE AND DIVIDED-DOSES SCHEDULES

K.Oba, K.Okazaki, T.Suzuki, K.Sasai, H.Nakano, and S.Metori,
Nippon Medical School, Tokyo, Japan.

The aim of this study is to clarify the optimal administration schedule of glibenclamide. Daily blood glucose profiles were measured in 65 Type 2 diabetic patients, on glibenclamide in single-dose (n=39) , on glibenclamide in 2 divided-doses (n=26). Daily blood glucose profiles with before breakfast plasma glucose concentrations ≧ 200mg/dl were excluded. Plasma glucose concentrations were determined at 08.00 (before breakfast), 10.00, 12.00 (before lunch), 14.00, 18.00 (before dinner), 20.00, 24.00, 03.00, 06.00, 08.00 hours. Mean Plasma glucose values at 08.00, 10.00, 20.00, 24.00, 03.00, 06.00 hours were not significantly different between single-dose group and divided-doses group, but those at 12.00, 14.00 , 18.00 hours and mean day (08.00~18.00) blood glucose area under the daily profile were significantly lower in single-dose group than in divided-doses group. The mean total (all day) and night (18.00~08.00) blood glucose areas under the daily profile were not significantly different between single dose-group and divided-doses group, but mean night / total blood glucose area ratio was significantly lower in divided-doses group than in single-dose group . In multiple regression analysis, night/total blood glucose area ratio positively correlated with single-dose administration schedule.

These results suggest that blood glucose levels in the night were lower in the divided-dose schedule than in the single-dose schedule.

1259

INTERRELATION BETWEEN THE EFFECT OF α-GLUCOSIDASE INHIBITOR AND URINE C-PEPTIDE IN NIDDM.

J. Nakamura, T. Hara, F. Sakakibara, R. Kitoh, Y. Hamada, H. Sasaki, S. Chaya, T. Komori, E. Nakashima, K. Naruse, K. Kato, Y. Kasuya, N. Koh and N. Hotta. Nagoya University, Nagoya, Japan.

α-Glucosidase inhibitors (α-GIs) are useful agents for maintaining good glycemic control by reducing postprandial hyperglycemia. However, it may cause hypoglycemia by the combination with insulin treatment. Whether or not the patients develop hypoglycemia seems to depend on their abilities of insulin secretion. This study was conducted to examine the interrelation between the expression of the effect of α-glucosidase inhibitor and urine C-peptide excretion. 40 patients with NIDDM receiving insulin therapy were hospitalized and administered α-GI after 3 wks when their glycemic control become stable. Patients were divided into two groups: high urine C-peptide (>15μg/day) group (HCP) and low urine C-peptide (<15μg/day) group (LCP). Although α-GI treatment improved circadian variation in blood glucose levels, resulting in a decrease in M value in both group, the effect was significantly more prominent in HCP (M value; HCP: 13.2 ± 0.9 to 3.3 ± 0.4, LCP: 14.7 ± 1.8 to 5.7 ± 0.6). To prevent hypoglycemia, the dosage of insulin was reduced in both group. The rate of the reduction in insulin dosage was significantly higher in LCP than in HCP. These observations suggest that the effect of α-GI can be expressed even in patients with a severe deficit in insulin secretion, and that 15μg/day of urine C-peptide in NIDDM patients treated with insulin can be an indicator of reducing the insulin dosage.

1260

Pharmacokinetics and bioavailability of repaglinide, a new OHA for patients with NIDDM

S. Oliver and S. Ahmad, Besselaar Clinical Research Unit, Leeds, UK, K. Winfeld and V. Hatorp, Clinical Development, Novo Nordisk, Denmark.

In this open-label, randomised, four-period, crossover Phase I study using a replicate design, key pharmacokinetic parameters (AUC, C_{max}, t_{max}, $t_{1/2}$) and mean residence time (MRT) were determined following repaglinide (REP) 2 mg in tablet form and as an oral solution. Twenty-four healthy male volunteers each received a single dose of REP 2 mg (either tablet or oral solution) on four different occasions, separated by a washout period of ≥ 7 days. All subjects received each formulation twice. For 24 hours after dosing, subjects were monitored and blood samples were collected for a 20-point REP serum concentration-time profile. REP was rapidly absorbed after administration of both formulations (t_{max} solution 32 min (SD 6.47), and t_{max} tablet 50.15 min (SD 31.31)). The extent of absorption was similar in both groups, and there was no significant difference between the tablets and oral solution with regard to the intra-subject variation in AUC (36.03 *vs* 32.79 ng/ml*hours; $p = 0.1127$) and C_{max} (30.96 *vs* 34.46 ng/ml; $p = 0.9217$). The relative bioavailability ($AUC_{tablet}/AUC_{oral\ solution}$) was 1.10 (or 110%) with a 95% confidence interval of 1.03–1.17. Although the total amount of REP absorbed was significantly higher for the tablets than for the oral solution, the difference between the two formulations was negligible. The elimination half-life based on subject means was approximately 32 minutes, ranging from 20–60 minutes. The half-lives determined from the individual REP profiles ranged from 11 to 110 minutes. In conclusion, REP pharmacokinetics demonstrate rapid absorption and elimination, and the total availability of REP was the same for the two formulations, though the rate of absorption was 57% lower for tablets, leading to a 10% lower C_{max} and 35% longer MRT.

1261

Acarbose improves insulin sensitivity in obese patients with IGT.
Laube,H.,Uhlmann,M.,Linn,Th.,Spengler,M.*
Giessen,Germany.

Insulin sensitivity is impaired in obese pat, with IGT and accompanied by hyperinsulinemia, which is supposed to be a risk factor for atherosclerosis and early ß-cell exhaustion.
In a double blind placebo controlled study,12 m. patients(BMI > 28),mean age 52 yrs,with impaired glucose tolerance and fasting hyperinsulinemia (> 27µu/ml)were treated with Acarbose loomg tid or placebo for 6 mo.Before and 24hrs after Acarbose treatment insulin sensitivity was measured by minimal model and euglycemic clamp.Insulin, c-peptide and proinsulin were monitored as well. Following Acarbose,c-peptide was lowered insign. from 3.1 to 3.ong/ml compared to placebo(2.9 vs. 3.2ng/ml).Proinsulin,however,decreased sign.from 2o.3 to 13.6µu/ml(placebo:21.9 vs21.3).Insulin sensitivity rose sign.after 6 mo Acarbose treatment:SI 1.3 to 2.8;glucose infusion rate 3.6 to 5.2 GIR.compared to placebo:SI 1.9 to 1.7 and GIR 4.8 vs 3.8.
Conclusion:Acarbose improves insulin sensitivity and lowers proinsulin in obese pat.with IGT.and may be helpful to slow down further progression from IGT to NIDDM.

1262

Repaglinide *vs* glibenclamide: a 14-week efficacy and safety comparison

R. Landgraf, Klinikum Innenstadt der Universität München, Munich, Germany, and H.J.G. Bilo, Hospital "de Weezenlanden", Zwolle, the Netherlands.

Repaglinide (REP) is a new short- and fast-acting insulin releaser. This European, multicentre study compared the efficacy and safety of REP with the commonly-used sulphonylurea, glibenclamide (GLIB). A total of 195 non insulin-dependent diabetes mellitus (NIDDM), sulphonylurea-treated patients (94 on REP and 101 on GLIB) participated, of whom 161 completed the study. Prior to the study, all subjects had an HbA_{1c} value of between 6.5 and 12 %, and a fasting blood glucose (FBG) value of between 6.2 and 12 mmol/l. The double-blind, randomised, parallel-group study included an initial screening visit, a 1- to 2-week washout period, a 4-week titration period, and a 10-week maintenance period. Repaglinide (0.5 mg, 1.0 mg, 2.0 mg or 4.0 mg) was administered preprandially with the three main meals, and GLIB (1.75 mg, 3.5 mg, 7.0 mg or 10.5 mg) was administered in the morning, with the exception of the 10.5 mg dose (7.0 mg in the morning and 3.5 mg in the evening). Mean HbA_{1c} values decreased from 7.8 % to 7.5 % in the REP group, and from 8.0 % to 7.6 % in the GLIB group (NS between groups). FBG decreased from 13.1 mmol/l to 10.2 mmol/l in the REP group, and from 13.5 mmol/l to 10.1 mmol/l in the GLIB group (NS between groups). There was a statistically significant difference in mean BG (p = 0.0003) and in the 2-hour post-breakfast BG (p = 0.09) between the treatment groups (mean BG REP = 11.2 ± 0.1 mmol/l *vs* GLIB = 11.7 ± 0.1 mmol/l; post-breakfast BG REP = 12.2 ± 0.2 mmol/l *vs* 13.1 ± 0.2 mmol/l), as shown by the 8-point BG profiles. No significant difference was shown between the two groups in fructosamine levels, lipid profiles, or fasting levels of either C-peptide, insulin or pro-insulin. Both treatments were well tolerated and the frequency of all hypoglycaemic episodes was low (35); 20 in the REP group and 15 in the GLIB group. No significant difference in body weight was detected between the two groups. In conclusion, REP is as well tolerated as GLIB and equally effective in controlling FBG and HbA_{1c} levels, together with a significant improvement in meal-related BG levels in comparison with GLIB.

1263

An Asian multi-centre clinical trial on acarbose monotherapy in NIDDM patients

JCN Chan, A Chan, M Emborg, LT Ho, MC Fuh, R Sheaves, TH Lee, A Panelo, DK Kim for the Asian Acarbose Monotherapy Study Group.

This is a multi-centre study involving 7 centres in Hong Kong, Taiwan, Singapore, Philippines, Malaysia and Korea. The objective of the study is to evaluate the efficacy and tolerability of acarbose in Asian NIDDM patients previously treated with diet. The design is one of randomised, double-blind and placebo-controlled. Eligibility criteria included history of NIDDM of more than 3 months, HbA_{1c} level between 7% and 10%, body mass index ≤35 Kg/m^2, no previous anti-diabetic therapy except diet, and no severe diabetic complication. Patients were randomly assigned to receive acarbose (50 mg tid for four weeks followed by 100 mg tid for twenty weeks) or placebo in a double-blind fashion. After the 24-week treatment period, an intention-to-treat analysis showed a statistically significant difference in the mean decrease in HbA_{1c} between the two treatment groups: 0.74% for the 63 patients in the acarbose group and 0.26% for the 63 patients in the placebo group (P=0.014). Mean fasting plasma glucose concentrations changed from 8.4 mmol/l to 8.0 mmol/l in the acarbose group and from 8.3 mmol/l to 8.8 mmol/l in the placebo group (P=0.017). Mean one-hour postprandial plasma glucose concentration changed from 12.8 mmol/l to 11.7 mmol/l in the acarbose group and from 12.9 mmol/l to 13.7 mmol/l in the placebo group (P=0.005). Incidence of diarrhoea was 14% in the acarbose group and 13% in the placebo group. Eleven patients from the acarbose group prematurely withdrew from the study, six of them because of adverse reactions but none of them was serious and one was due to a lack of efficacy. The results have confirmed the clinical efficacy of acarbose in the management of NIDDM patients of Asian origin.

1264

REPAGLINIDE DIFFERS STRUCTURALLY FROM THE SULPHONYLUREAS GLIBENCLAMIDE AND GLIMEPIRIDE.

W.Grell, M.Mark, P.Luger§, H.Nar, H. Wittneben and P.Müller. Preclinical Research and Development, Boehringer Ingelheim, Biberach/Riss; Freie Universität Berlin§, Berlin; Germany.

Repaglinide (repa), (S)(+)-2-ethoxy-4-[2-[[3-methyl-1-[2-(1-piperidinyl) phenyl]butyl]amino]-2-oxoethyl]-benzoic acid, and the sulphonylureas (SU) glibenclamide (glib) and glimepiride (glim) bind to the SU-receptor. Based on structure-activity relationships, we suggested a model for receptor binding involving three pharmacophoric groups ($COOH/SO_2NH$; NHCO/CONH; piperidino/MeO or α-oxo). To gain insight into the structural basis for recently reported differences in binding modi between repa and glib, we examined the X-ray structures and analyzed conformational space, electrostatic and lipophilic potentials. The X-ray structures show an extended conformation for glib, and a more compact shape for repa; in a superposition, the pharmacophoric groups do not significantly overlap. Therefore, we looked for further low energy conformations via molecular mechanic calculations (SYBYL®). Three areas of low energy conformations were identified and further optimized (Gaussian 94®) for repa: I (global minimum; ≡ X-ray), II and III (2.6 and 1.8 kcal/mol higher in energy). For glib two low energy conformations were found: I (≡ X-ray) and II (1.3 kcal/mol). In a superposition of repa-II and glib-II, the pharmacophoric groups fit well; the amidic oxo-groups are located to enable hydrogen bonding to the same binding site of the SU-receptor. To repa's (S)-isobutyl, no counterpart is found in glib. The ethoxy (repa) and cyclohexyl (glib) groups marginally overlap. The hydrophobic potentials calculated for repa-II and glib-II differ significantly. We conclude that conformations II may represent a common binding conformation, and that different binding may be due to lipophilic differences. In addition, we determined the X-ray structure of glim. An analogous comparison repa/glim gave similar results as obtained for repa/glib.

1265

EFFECTS OF ACARBOSE ON BLOOD GLUCOSE LEVELS IN TYPE II DIABETICS

M. Dönmez, B. Kavaklı , K. Tuncer
Kartal Training Hospital, Clinic of Internal Medicine,
İstanbul, TURKEY.

Acarbose is an antidiabetic agent that produced a dose dependent reduction in postprandial plasma glucose levels following a starch meal. 100 obese outpatients with type II diabetes (48 men, 52 women, mean age 56, mean body mass index 31.3 kg/m^2, without serious complication) were selected for the study. The average duration of disease was 3 years. They were treated with only diet. They were treated with only diet. They were devided into two groups: the control group (50 patients) were treated with diet (1200 calories/day for women, 1500 calories/day for men) and placebo. The treatment group were treated with diet as the same with the control group and acarbose (300 mg/day) for three months. The mean baseline fasting plasma glucose levels were 198 mg/dl at both groups. At the and of study, acarbose produced significantly decrement in fasting plasma glucose level from 198 to 141 mg/dl in treatment group ($p< 0.001$). In the control group, fasting plasma glucose level decreased from 198 to 180 mg/dl (Insignificant compared with baseline level). In conclusion, we stated that acarbose was effective in controlling the fasting plasma glucose levels in type in type II Diabetes Mellitus.

1266

ADDITIONAL TREATMENT WITH REPAGLINIDE PROVIDES SIGNIFICANT IMPROVEMENT IN GLYCAEMIC CONTROL IN NIDDM PATIENTS POORLY CONTROLLED ON METFORMIN

Moses R, Slobodniuk R, Wollongong, Aus., Boyages S, Colagiuri S, Kidson W, Carter J, Sydney, Aus., Donnelly T, Moffitt P, Newcastle, Aus., Hopkins H., Novo Nordisk-Aus.

This multicentre, randomised trial was designed to compare the effect on glycaemic control of repaglinide (REP) given in combination with metformin (MET) against the effect of either drug given as monotherapy in patients not well controlled on MET alone (mean HbA_{1c}: 8.5) .Eighty three patients were included in this three-armed, double blind, double dummy parallel group study. After a 4-5 week run-in period on their usual dose of MET, patients were randomised to either REP therapy, MET therapy, or REP+MET therapy, and the REP dose was determined through a 4-8 week titration period (initial REP dose: 0.5 mg t.i.d.a.c.; maximum dose: 4 mg t.i.d.a.c.), followed by a 3-month maintenance period. The MET dose was kept constant throughout the study (1-3 g/daily). From the baseline to final visit, MET/REP provided statistically significant ($p< 0.005$) improvement in glycaemic control in comparison with the two monotherapies (mean change in HbA_{1c}: -1.41% (MET/ REP),- 0.38% (REP), -0.33% (MET), mean change in fasting blood glucose (mmol/l): -2.18 (MET/REP), 0.49 (REP), -0.25 (MET). No statistical differences were seen between the two monotherapies and MET/REP with respect to fasting insulin and C-peptide levels, and the lipid profiles. MET and MET/REP treatment caused more gastrointestinal side effects than REP treatment. No severe hypoglycaemic events were observed in any group. There were no major side effects and a total of 9 patients withdrew from the study for various causes unrelated to treatment. In conclusion, REP treatment provided the same glycaemic control as MET with less gastrointestinal side effects. REP/MET therapy induced significant improvements in metabolic control in contrast to either REP or MET bringing HbA_{1c} down into the range of acceptable control . The data also suggest that the combination of REP and MET may have synergistic properties in this type of patients.

1267

EFFECT OF ACARBOSE ON BODY MASS INDEX IN TYPE II DIABETICS

S. Aktaş, B. Kavaklı, K. Tuncer
Kartal Training Hospital, Clinic of Internal Medicine,
Istanbul, TURKEY.

In the treatment of obesity, many methods are used either alone or in combination. On this study, the effect of acarbose on body mass index in type II diabetics have been evaluated. 100 obese outpatients (48 men, 52 women, mean age 56) were selected for study. They were classified into two groups as diet plus placebo (the control group) and diet plus acarbose (the treatment group). Diets were 1200 calories/day for women and 1500 calories/day for men. Acarbose was administered 300 mg/day for three months. Their disease duration was three years approximately and they have had no serious complications. Mean baseline body mass index was 31.3 kg/m^2. Acarbose significantly decreased body mass index from 31.3 to 28.0 kg/m^2 in the treatment group compared with control group. In controls, weight reduction was only minimal and insignificant compared with baseline value (The control group's body mass index decreased 30.3 kg/m^2). This study has shown that acarbose is usefull in the treatment of obesity with mild diabetes and impaired glucose tolerant.

1268

EFFECT OF ACUTE ADMINISTRATION OF GLICLAZIDE ON INSULIN RELEASE IN NIDDM.

JJM Ligtenberg[1], WD Reitsma[1] and TW Van Haeften[2]. Groningen[1] and Utrecht[2] University Hospital, The Netherlands.

Sulphonylureas (SU) show variations in stimulating insulin release. We studied the effect of acute administration of 160 mg gliclazide on insulin release during a hyperglycemic clamp in 12 NIDDM patients, (mean$\pm$sem) age 50$\pm$2.6 yr, NIDDM duration 5.5$\pm$1.4 yr, BMI 24.1$\pm$0.6 kg/m^2. Home SU were stopped for 3 days. Baseline blood glucose levels were 9.6$\pm$0.6 mmol/l. After a 3.5 hr hyperinsulinemic euglycemic clamp (blood glucose 4.6$\pm$0.04 mmol/l) and a 60 min wash out period, a hyperglycemic clamp at 8 mmol/l was started. One hour before the start of the hyperglycemic clamp, gliclazide or placebo (randomized, double blind, cross-over) was administered. The insulin- and C-peptide levels did not differ from 0-10 min (first phase) (both $P>0.5$). So, it is likely that this moderate hyperglycemia does not provoke a first phase in these NIDDM patients. However, second phase insulin release (30-240 min) was significantly enhanced by gliclazide and very poor on placebo. Plasma insulin levels (log-transformation) were significantly higher from 1 hr onwards (all $P<0.05$); geometric mean (95% CI) insulin increased from 13(10-18) vs 10 (7-15) mU/l at the start of the clamp to 17(13-22) vs 11(9-13) at 1 hr, and 20(15-27) vs 13(11-18) mU/l at 4 hr (gliclazide vs placebo). Mean (95% CI) C-peptide levels were also increased from 0.42(0.30-0.60) vs 0.28(0.24-0.33) nmol/l to 0.94(0.65-1.35) vs 0.75(0.59-0.96) nmol/l at 4 hr (gliclazide vs placebo). In conclusion, in long-standing NIDDM gliclazide markedly enhances second phase insulin release at a moderately elevated blood glucose level.

1269

EFFECTS OF ACARBOSE ON LIPID PROFILE IN TYPE II DIABETES MELLITUS

B. Kavaklı, K. Tuncer
Kartal Training Hospital, Clinic of Internal Medicine
İstanbul, TURKEY.

It has been demonstrated that acarbose leads to an improvement in insulin sensitivity by reducing postprandial plasma glucose levels, hyperinsulinemia and hypertriglyceridaemia. Efficiency of acarbose on lipid metabolism was evaluated in 100 type II diabetic patients (48 men, 52 women, mean age 56). They were classified into two groups as diet plus placebo (the control group) and diet plus acarbose (the treatment group). Diets were 1200 calories/day for women and 1500 calories/day for men. Acarbose was administered 300 mg/day for three months. Their disease duration was three years approximately, and they have had no serious complications. They don't have any antilipemic treament. Acarbose decreased total cholesterol and LDL cholesterol level significantly compared with pretreatment and control value (pretreatment total cholesterol: 239 mg/dl, control total cholesterol: 227 mg /dl, treatment group total cholesterol :219 mg/dl, $p< 0.01$; pretreatment LDL cholesterol: 151 mg/dl, control: 142 mg/dl, treatment group: 132 mg/dl, $p< 0,001$). HDL cholesterol level increased significantly compared with pretreatment and control value (pretreatment 41.14 mg/dl, control: 41.46 mg/dl, treatment: 43.56 mg/dl, $p< 0.001$), Triglycerid level slightly decreased in this study, probably the treatment duration is not enough for this effect. As a result, acarbose leads to a reduction in total cholesterol and LDL cholesterol levels and to an increasement HDL cholesterol level. Thus the results suggested that acarbose might be a favorable effect for the treatment of diabetes mellitus.

1270

CLINICAL CHARACTERISTICS AND OUTCOME OF NIDDM PATIENTS WITH ORAL HYPOGLYCEMIC AGENT FAILURE.

Y-S. Peng, J-H. Juang and H-S. Huang. Division of Endocrinology and Metabolism, Chang Gung Memorial Hospital, Taipei, Taiwan, R. O. C.

To investigate oral hypoglycemic agent (OHA) failure in NIDDM and the relationship between β-cell function and the outcome of short-term insulin therapy, we studied 44 NIDDM patients treated with OHA. Of these, 25 failed to response OHA while the other 19 responded well. The patients with OHA failure had lower body mass index (BMI), longer duration of diabetes as compared with those with OHA success. The β-cell function between 2 groups was not statistically significant. Patients with OHA failure were further divided into poor β-cell function (Gr. A, n= 9/25) or fair β-cell function (Gr. B, n=16/25) according to their C-peptide responses to intravenous glucagon stimulation. Age at diagnosis, duration of diabetes, fasting plasma glucose (FPG) and glycohemoglobin (HbA1c) were similar in both groups. In contrast, Gr. A had lower BMI ($P< 0.03$). Five patients in Gr. A and 8 patients in Gr. B underwent glucagon stimulation test 1-24 months after insulin therapy. The β-cell function was still poor in 4/5 patients in Gr. A, however, it was stationary in all patients in Gr. B. Successfully switching to OHA therapy was observed in 1 patient in each group and sustained for 10 and 4 months, respectively. In OHA failure patients who had poor β-cell function, 3/5 and 1/5 patients had positive antimicrosomal antibody and antithyroglobin antibody, respectively. However, 2/2 patients had negative insulin antibody and only 1/2 patient had HLA DR3. In conclusion, (1) most OHA failure patients need long-term insulin treatment; (2) patient's β-cell function can't predict the success of conversion to OHA after short-term insulin therapy.

1271

EFFECT OF ACARBOSE ON HbA_1C LEVELS IN TYPEII DIABETES MELLITUS

K.Tuncer, B. Kavaklı
Kartal Training Hospital, Clinic of Internal Medicine,
İstanbul, TURKEY.

HbA_1c level is one of the parameters of optimal diabetic control. We studied the effect of acarbose on HbA_1c level in type II Diabetes Mellitus. The patients were selected from the outpatients whom didn't receive any insulin or sulfanilurea treatment and doesn't have any serious diabetic complication. 100 obese outpatients with type II diabetes (48 men and 52 women, mean age 56) were taken in the study . They were classified into two groups as diet plus placebo (the control group) and diet plus acarbose (the treatment group). Diets were 1200 calories/day for women and 1500 calories/day for men. Acarbose was administered 300 mg/ day for three months. Their disease duration was three years approximately. Initially, their average HbA_1c levels was 9.13 %. In the treatment group , HbA_1c level decreased to 7,08 %. This result were statistically significant compared with baseline and the control value ($p< 0,001$, control group's HbA_1c level is 9,02 %). We concluded that acarbose was effective in controlling glycaemic levels and also protective from complication in type II Diabetes Mellitus.

1272

BLOOD GLUCOSE LOWERING EFFECTS OF REPAGLINIDE IN RATS AND DOGS.

M.Mark, M.Epple and W.Grell. Preclinical Research and Development, Boehringer Ingelheim, Biberach/Riss, Germany.

Repaglinide is a novel non-sulphonylurea compound for the treatment of NIDDM. The glucose lowering effects of repaglinide were investigated in fasted Wistar rats and fasted beagle dogs. Furthermore, effects of repaglinide in rats were compared to those of glibenclamide and glimepiride. Compounds were administered orally via gavage (rats) or capsules (dogs) and blood glucose and insulin were determined at several time points p.a.. In rats repaglinide was administered in a dose range of 0.003 mg/kg to 0.3 mg/kg, and both glibenclamide and glimepiride were tested in a dose range of 0.03 mg/kg to 10.0 mg/kg. ED_{50} values were calculated for the effects after 120 min, the time where the maximal glucose lowering effects were obtained with all three substances. Repaglinide was the most potent antihyperglycaemic compound in rats (ED_{50} 9.9 µg/kg). Its potency was 18 times higher than that of glimepiride (ED_{50} 182.1 µg/kg) and 25 times higher than that of glibenclamide (ED_{50} 254.9 µg/kg). In dogs repaglinide (doses tested 0.01, 0.03, 0.1 mg/kg) caused a pronounced antihyperglycaemic effect (ED_{50} 28.3 µg/kg). Insulin levels were only transiently elevated. Maximal increase (about 3 fold increase versus control) was seen at 60 and 90 min after administration with control levels being reached after 4 and 6 hours p.a.. The activity profile of this novel, very potent, antihyperglycaemic compound makes repaglinide a promising new treatment for NIDDM.

REPAGLINIDE, A NEW RAPID AND SHORT ACTING NON-SULPHONYLUREA INSULIN SECRETAGOGUE INHIBITS ATP-SENSITIVE POTASSIUM CHANNELS (I_{KATP}) IN ISOLATED HEART MUSCLE CELLS

W. Diederen and W. Kolb, Preclinical Research and Development, Boehringer Ingelheim, Biberach/Riss, Germany

The effect of the non-sulphonylurea insulin secretagogue repaglinide (repa) on I_{KATP} was investigated in single isolated guinea pig ventricular myocytes and compared with the sulphonylurea insulin secretagogues glibenclamide (glib) and glimepiride (glim). Currents were measured using the whole cell voltage clamp technique and a negative voltage ramp from +60 to -100 mV (-20 mV/s). I_{KATP} was induced by superfusing the myocytes with 30 µmol/l cromakalim in the presence of 3, 10, 30, and 100 nmol/l repa, glib, and glim. Baseline currents present at the beginning of the experiment were substracted to separate I_{KATP} from other currents. At maximum drug effect, concentration response curves were constructed using peak I_{KATP} and IC_{50} values (the concentrations of half maximal inhibition of the I_{KATP}) were calculated. The slope of the concentration response curves did not significantly differ among the tested drugs. IC_{50} values (95 % confidence interval) were: repa 10.4 (8.3-13.0) nmol/l, glib 9.2 (6.8-12.6) nmol/l, glim 25.4 (17.8-36.4) nmol/l. The IC_{50} of repa and did not significantly differ from the IC_{50} of glib, however, both IC_{50} were significantly ($p<0.01$) lower than the IC_{50} of glim (about 2.5 times). In conclusion: There were no qualitative differences between the non-sulphonylurea insulin secretagogue repa and the sulphonylurea insulin secretagogues glib and glim in their ability to inhibit I_{KATP}. The relative potency of the tested drugs to block I_{KATP} in cardiac cells corresponds to that in pancreatic β-cells, however, the absolute potency was about 100 to 200 fold less.

1275

COMPARISON OF THE CLINICAL EFFECT OF DIFFERENT INITIAL DOSES OF ACARBOSE IN DIABETES WITH RESISTANCE TO SULFONYLUREA THERAPY

G. Okuno, Itami City Hospital, Itami, Japan

Improvement of glycemic control by suppression of postprandial hyperglycemia using acarbose (Glucobay®: GB) has been well documented, but a problem lies in the occurrence of gastrointestinal side effects, especially abdominal distention and flatulence. In this study, the effect on glycemic control and the incidence rate of adverse reactions were compared for initial GB doses of 300 mg/ day and 150 mg/ day. **[Methods]** GB was given at 300 mg/ day (study A) or 150 mg/ day (study B) as the initial dose together with a sulfonylurea (SU) in NIDDM patients with SU resistance. Study A (20 patients) was continued for a mean period of 6.3±1.7 months, and was followed by study B (8.3±1.7 months) including 19 patients different from those in study A. **[Results]** In study A, 3 patients stopped treatment due to severe side effects and the dose was decreased to 200 or 150 mg/ day in 9. In study B, all patients could tolerate the initial dose and the dose was increased to 300 mg/ day in 7 cases. The incidence of initial side effects was 76.5% in study A and 78.5% in study B. Side effects were far less severe in study B as compared with study A. FPG was lowered by 15.6% in study A and by 18% in study B, while HbA1c fell by 13% and 16%. Another study is now in progress using an initial dose of 100 mg/ day. **[Conclusion]** Acarbose was administered in combination with SU therapy to diabetics with SU resistance. When acarbose was started at a low dose and increased after an appropriate period, side effects decreased but the improvement of glycemic control was similar to that achieved at a high initial dose if the treatment period prolong.

1276

GLUCOSE-DEPENDENCY OF THE GLUCOSE LOWERING EFFECTS OF REPAGLINIDE.

M.Mark and M.Epple. Preclinical Research and Development, Boehringer Ingelheim, Biberach/Riss, Germany.

Repaglinide is a novel antihyperglycaemic compound which is currently evaluated in phase III clinical trials. The aim of the present study was to investigate the glucose lowering activities of repaglinide under normoglycaemic as well as hyperglycaemic conditions. Therefore, fasted Wistar rats were orally dosed with repaglinide together with 0, 0.5, 1.0, 2.0 and 3.0 g/kg glucose as a bolus. Blood glucose levels were determined at several time points after administration. Glucose levels were significantly decreased under all experimental settings with doses of $\geq$ 0.01 mg/kg repaglinide p.o.. With dosages of $\geq$ 0.1 mg/kg repaglinide, the initial increase in blood glucose which was seen after the glucose boli was totally blunted, and glucose levels even fell below starting values. The ED_{50} values calculated for the effects after 120 min were: 12.3 (0.5 g glucose/kg), 9.9 (1.0 g glucose/kg), 14.5 (2.0 g glucose/kg) and 12.8 µg/kg p.o. (3.0 g glucose/kg), respectively. The amount of repaglinide needed to achieve a decrease in blood glucose of 1 mmol/L was calculated to be 10.3, 9.3, 7.0, 8.4, and 7.2 µg/kg p.o. after glucose loads of 0.0, 0.5, 1.0, 2.0, and 3.0 g/kg, respectively. This means that less repaglinide is needed in the hyperglycaemic state to achieve the same reduction in blood glucose levels. As also supported by published in vitro data, repaglinide turns out to be more effective in lowering blood glucose levels in the hyperglycaemic state.

1277

BLOOD GLUCOSE CONTROL WITH ACARBOSE (COMPARISON WITH SULFONYLUREAS OR INSULIN THERAPY)

T. Osonoi, M. Saito and A. Boku, Mito Kyodo General Hospital, Mito, Japan

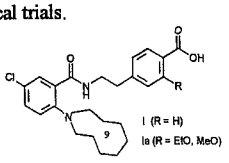
Acarbose is an α-glucosidase inhibitor expected to possess many advantages as a novel means of controlling blood glucose levels, quite distinct from sulfonylureas (SUs) and insulin preparations. To investigate the advantages of acarbose, patients well-controlled (mean HbA1c over three months < 7.5%) on either diet alone, relatively low doses of SUs (≦glibenclamide 2.5 mg/day) or insulin (≦10 U/day), were subsequently treated for one year with acarbose (300 mg/day) and results compared to prior treatment. Subjects consisted of 77 NIDDM outpatients with 24, 23 and 30 cases, respectively, who had previously been controlled on SUs (Group S), insulin (Group I) or diet therapy (Group D). Mean age was 59.5 years, while the mean duration of NIDDM was 8.2 years. Improved HbA1c levels were noted in the D group, but remained unchanged in the S or I group. Total cholesterol (TC) and HDL (HDL-c), had increased from 187.7±28.4 and 49.8±45.4 mg/dl to 200.1±33.3 and 57.3±18.2 mg/dl, respectively, while triglycerides (TG) decreased from 96.3±45.4 mg/dl to 80.4 ±30.5 mg/dl. In Group I, both TC and TG remained unchanged, while HDL-c increased from 49.8±12.5 to 54.1±14.3 mg/dl. Baseline TC and HDL-c in the D group increased from 200.7±35.0 and 53.4±11.8 mg/dl to 217.7±34.6 and 57.7±12.2 mg/dl, respectively, while TGs decreased from 113.3±43.7 to 84.3 ±33.8 mg/dl. Apoprotein-AI in group S increased from 108.4±19.7 to 115.1± 20.8 mg/dl and apoprotein-B in groups S and I decreased from 91.9±20.6 and 85.8 ± 22.1 mg/dl to 82.2 ± 19.0 and 80.2 ± 19.5 mg/dl, respectively. Improvement was also noted in the 19 patients with abnormal urinary protein excretion (trace albumin ≧30 mg/g.Cr); urinary albumin levels falling from 51.5±37.6 to 30.7±22.8 mg/g.Cr. Acarbose (300 mg/day) is as effective as 2.5 mg/day of glibenclamide or 10 U/day of insulin for controlling the blood glucose level. Acarbose also showed a potential to improve serum lipid profiles and reduce urinary excretion of proteins.

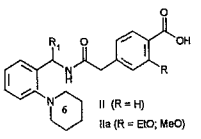
1278

REPAGLINIDE, A POTENT AND ORALLY ACTIVE HYPOGLYCAEMIC BENZOIC ACID DERIVATIVE.

W.Grell, R.Hurnaus, G.Griss+, E.Rupprecht, M.Mark and P.Luger§. Preclinical Research and Development, Boehringer Ingelheim, Biberach/Riss; Freie Universität Berlin§, Berlin; Germany.

Aiming to improve hypoglycaemic activity and pharmacokinetic properties of benzoic acid derivatives I and II, we have investigated the effect of an additional ethoxy or methoxy substituent (compounds Ia, IIa). The compounds, synthesized by acylation of the corresponding amines, were orally administered to fasted female rats via gavage. Blood glucose was determined at several time points post administration (p.a.). Compounds Ia were found to be less active than I, whereas compounds IIa (R_1 = alkyl, phenyl) showed higher activity and longer duration of action than II. Structure activity relationship studies revealed that hypoglycaemic activity of IIa is optimal when R = ethoxy and R_1 = lower alkyl, ω-alkenyl, or (cycloalkyl)methyl. Racemic AG-EE 388 ZW (R = OEt; R_1 = isobutyl) represents one of the most active compounds IIa; maximum hypoglycaemic activity was observed 2 hours p.a. (ED_{50} = 22 µg/ kg). Its R-enantiomer, AG-EE 624 ZW, lowered blood sugar only marginally after 1 mg/kg, whereas the S-enantiomer, AG-EE 623 ZW (repaglinide), was found to be highly active (ED_{50} = 9.9 µg/kg). Being more potent than the sulphonylureas glibenclamide (ED_{50} = 255 µg/kg) and glimepiride (ED_{50} = 182 µg/kg), repaglinide was selected for development and is currently undergoing phase III clinical trials.





1279

THE BLOOD GLUCOSE LOWERING EFFECT OF ACARBOSE IS NOT INFLUENCED BY A SIMULTANEOUS THERAPY WITH MAALOX®70

M.Höpfner[1], B.Durani[1], M.Spengler[2] and U.R.Fölsch[1]. Department of Medicine, University of Kiel[1], Medical Department, Bayer AG, Leverkusen[2].

Aim of this single-centre 4-fold double-blind crossover study was to investigate the influence of 10ml Maalox®70 (antacid) on the pharmacodynamics of the α-glucosidase inhibitor acarbose after administration of 75g sucrose. 24 healthy male volunteers were randomized in four treatment groups and received 100mg acarbose, or a placebo tablet, or the combination of 100mg acarbose plus 10ml Maalox®70, or a placebo tablet plus 10ml Maalox®70. Wash out phases of 6-10 days separated the various successive treatments. Venous blood glucose concentration was determined using the hexokinase method and serum insulin was determined by radioimmunoassay. Standard laboratory investigations for the judgement of safety were done before and after the study. To assess a possible interaction of 10ml Maalox® 70 and acarbose, postprandial blood glucose and serum insulin levels were compared as maximal concentrations and „area under the curve" (AUC) over 4 hours. Integrated blood glucose and serum insulin response were calculated using the log linear trapezoidal approximation. Decision of bioequivalence (= no pharmacodynamic interaction) was based upon two one-sided t-tests. Adverse events (flatulence, diarrhoea) were reported from 14 resp. 15 out of 24 volunteers in the acarbose treatment groups. Only 1 resp. 3 volunteers in the placebo groups (headache, flatulence) reported side effects. No trends in the other laboratory parameters were detectable. No significant difference in blood glucose and insulin between acarbose or acarbose plus Maalox®70 or placebo and placebo plus Maalox®70 could be found. Testgroups receiving acarbose showed a significant decrease in postprandial blood glucose and serum insulin increment ($p<0.01$). AUC- and Cmax values of acarbose plus Maalox®70 and acarbose were almost identical. No influence of Maalox®70 in addition to acarbose or placebo was seen. Conclusion: Maalox®70 need not to be classified as contraindication when medicated together with acarbose.

1280

ORAL ANTIDIABETIC DRUGS ARE GIVEN BOTH INAPPROPRIATELY AND CARELESSLY.

K.R. Hunter. Derriford Hospital, Plymouth, U.K.

A survey was made to assess the quality of initial prescribing of oral antidiabetic drugs, with particular regard to the firm recommendation in the British National Formulary that they should not be given until patients have been shown not to respond adequately to at least three months' dietary restriction. The clinical histories of 100 consecutive patients with diabetes of more than one year's duration attending a hospital diabetic clinic were analysed. Patients taking insulin were excluded. Most had received their initial advice elsewhere, either from their general practitioner or from another hospital department: 14 were being treated with diet alone, 46 had taken a proper period of diet followed by tablets and 40 had started tablets immediately at the time of diagnosis. There was no instance of inappropriate early prescribing of tablets by members of the Diabetic Clinic team. Sulphonylurea-induced hypoglycaemia can be an important problem. Therefore the 81 patients in this survey who were taking sulphonylureas were asked if they had been warned about this when they started taking the drug: 24 (30%) remembered receiving advice, 57 (70%) did not. Sixteen (20%) had suffered from symptoms which probably had been due to hypoglycaemia. There was no significant difference between the incidence of these symptoms in the groups which could or could not remember receiving advice about hypoglycaemia. It appears that when doctors who do not specialise in diabetes mellitus initiate treatment in a newly diagnosed patient too many prescribe oral antidiabetic drugs too early and give advice about hypoglycaemia too late.

1281

CHOLESTYRAMINE DOES NOT IMPAIR THE EFFECTS OF VOGLIBOSE (AO-128) ON GLUCOSE AND INSULIN

K.M. Eckl[2], T. Thomsen[2], H.P. Hucke[3], P. Kleist[1], Y. Suzuki[1] and M. Möller[2]. [1]Takeda Euro R&D Centre GmbH, Frankfurt, Germany; [2]Pharm PlanNET Contract Research, Mönchengladbach, Germany; [3]Gesellschaft für angewandte Statistik mbH, Neuss, Germany

Voglibose(V) is a new α-glucosidase inhibitor for treatment of non-insulin-dependent diabetes mellitus. This randomised, parallel group study was aimed at investigating whether cholestyramine(CH), which is known to bind drugs, interacts with voglibose and thereby reduces its effects on the postprandial rise in blood glucose(G) and insulin(I). 24 healthy subjects received 5 mg V three times daily from day 1 through the morning of day 21. 12 of the volunteers additionally received 4 g CH once daily on day 7 and 4 g CH twice daily from day 8 through the morning of day 21. On days 7 and 21 the volunteers received a carbohydrate rich standard breakfast. Blood samples of 10 ml were taken at -0.25, 0.25, 0.5, 1, 1.5, 2, 3 and 4 h relative to dose intake for the determination of G and I. The effect of CH on the postprandial G and I control of V was investigated by means of the $AUC_{0\text{-}4h}$ (linear trapezoid rule) and C_{max} of G and I by means of an ANCOVA (SAS 6.11) with baseline G and I as a covariate. There was no statistically significant difference in G and I on day 7 and day 21 with respect to $AUC_{0\text{-}4h}$ (V/V+C day 7; day 21: 370/366; 347/356 mg*h/dl and 65/47, 73/52μU*h/ml) and C_{max} (V/V+C day 7; day 21: 103/105; 104/103 mg/dl and 25/20; 30/23 μU/ml). The adverse event spectrum was similar in both dosing groups. It can be concluded, that the combination of 5 mg V three times daily and 4 g CH twice daily is safe and CH does not impair the effects of V on the postprandial rise in G and I.

1282

BIOTRANSFORMATION OF [14C]REPAGLINIDE IN HUMAN, CYNOMOLGUS MONKEY, DOG, RABBIT, RAT AND MOUSE

E. Bauer, K. Beschke, T. Ebner, A. Greischel, R. Heinle, A. Prox, H. Schiller-Rankewitz, J. Schmid, J. Stangier, H. Wachsmuth, H. Wolfinger. Preclinical Research and Development, Boehringer Ingelheim, Biberach/Riss, Germany.

Repaglinide is presently under development as a new oral antidiabetic insulin secretagogue. After oral or IV administration of [14C]repaglinide (AG-EE 623 ZW) or the racemate [14C]AG-EE 388 ZW, the radioactive metabolite profiles in plasma, urine and bile or feces were analyzed using radio-HPLC and MS. The compound was very well absorbed after oral administration in the rat, dog and human (80 - 100 %). In the rabbit, absorption was 50 - 100 %, in the mouse about 45 %. In all species, total radioactivity was excreted mainly with bile, and the excretion in urine was comparatively low: rat and dog 1 % of the dose, mouse 3 %, monkey 6 %, human 8 % and rabbit 30 %. Repaglinide was metabolized to various degrees according to the following pathways: conjugation to yield the acyl-glucuronide (M7) or tauride (M6), oxidative opening of the piperidine ring (M2), oxidative N-dealkylation of M2 with formation of the aromatic amine (M1), hydroxylation of the piperidine ring (M4) and N-oxidation (M12). In plasma of all species the parent compound represented 56 - 98 % of the radioactivity. The other metabolites mentioned above comprised up to 0.5 - 7 %. Repaglinide was excreted almost exclusively metabolically in all species. Biliary or fecal clearance of the metabolites was the most dominant route. M2 formation was the major pathway in human (68 % of the dose), monkey (82 %) and rabbit (46 %). The further formation of M1 was the second pathway in human (14 %) followed by hydroxylation of the piperidine ring (M4). The major pathway in the dog (70 %) and in the rat (53 %) was the conjugation with glucuronic acid (M7). M2 represented the second important metabolite fraction (dog 20 %, rat 32 %).
The metabolic clearance of repaglinide and the excretion of the metabolites with bile may represent an important safety aspect in patients with impaired renal function.

Insulin Therapy in IDDM

1283

EFFECT OF DAILY DOSE OF INSULIN ON METABOLIC CONTROL AND DEVELOPMENT OF LATE DIABETIC COMPLICATIONS IN TYPE I DIABETES.

JA Piniés, E Ugarte, B Perez, and JA Vazquez. Department of Endocrinology. Cruces Hospital. Baracaldo. Spain.

Introduction: Type I diabetic patients with low daily dose of insulin have preserved ß cell function or an enhancement in insulin sensitivity. The effect of low daily dose of insulin on metabolic control and late diabetic complications have not been well established in type I diabetic patients. **Objective:** The aim of the study was to determine whether daily dose of insulin in patients with type I diabetes is related with metabolic control, chronic complications, and preserved ß cell function. **Patients, material, and methods:** Patients with type I diabetes (n=380) were identified from the out-patients' clinics of the Cruces Hospital. To be included, patients had to have diabetes onset before age 32, were ketosis prone, and were treated continuously with insulin. Two groups of patients with more than 10 yr. of diabetes evolution were selected according to their daily dose of insulin: group 1 (n=16) with high dose of insulin (> 0.7 UI/Kg) and group 2 (n=15) with a low dose (< 0.5 UI/Kg). Clinical data (including the presence of chronic complications), metabolic control (HbA1c) and preserved ß cell function were studied in the two groups. Basal and after glucagon C peptide test was done to measure ß cell function. **Results:** No differences were found between the two groups of patients in the sex, body mass index, years of evolution of type I diabetes (22±9 vs. 22±8 yr. respectively), and diabetic late complications with exception of no proliferative diabetic retinopathy (NDPR).

Group	age (yr.) at diagnosis	Ketoacidosis (100 patients/yr.)	daily dose of insulin (UI/Kg)	C-peptide test (nmol/l) 0'	6'	HbA1c (%)	NDPR (%)
1	13±10	9.1	0.97±0.22	0.13±0.19	0.16±0.19	9±1	25
2	21±8	3.2	0.38±0.06	0.13±0.16	0.16±0.23	8±1.3	60
	p<0.05	**p<0.001**	**p<0.001**	**p=ns**	**p=ns**	**p<0.05**	**p<0.01**

Conclusions: 1. Differences in the daily dose of insulin have been found in type I diabetic patients. **2.** Patients with a low daily dose of insulin were older at disease onset than those with a high dose. **3.** The degree of metabolic control was better in patients with a low dairy dose of insulin than in those with a high dose. Severe ketoacidosis was more frequent in the later group. **4.** There were no differences in the residual ß cell cell function after 10 yr. of diabetes evolution between patients with low and high daily dose of insulin . **5.** Suprinsingly, non proliferative diabetic retinophaty was more frequent in type I diabetic patients with a low daily dose of insulin than in those with a high dose.

1284

SEPARATE VERSUS SINGLE GLUCOSE-INSULIN-POTASSIUM INFUSION REGIMENS IN DIABETICS UNDERGOING HEART SURGERY

C. Neves, A.P. Barbosa, D. Carvalho, P. Freitas, P. Bastos and J.L. Medina. Endocrinology Unit and Cardiothoracic Surgery Center. Oporto Medical School, University of Oporto, São João Hospital, Oporto, Portugal.

Diabetic patients undergoing heart surgery, particularly coronary artery by-pass grafting, have an increased morbidity and mortality as compared with nondiabetic patients. Despite the existence of a great variety of perioperative regimens devised for the treatment of diabetics, we aimed to compare the efficiency of 2 different perioperative insulin regimens in diabetic patients undergoing heart surgery. Seventeen diabetic patients (group 1) (G1) received a single intravenous (IV) 5% glucose, regular insulin and potassium infusion plus regular insulin intramuscularly every 4h according to the value of the capillary blood glucose. Sixteen diabetic patients (group 2) (G2) received a separate IV infusion of 30% glucose (20 mL/h) and 0,9% saline containing regular insulin according to the hourly value of the capillary glycemia (0,5-12U/h), delivered by independent pumps. The results are expressed as mean ± SD. To compare the results we used the Student's *t* test and the Fisher's exact test. There were lower mean glycemic levels in G2 (201.81 ± 59.84 mg/dl) than in G1 (228.31 ± 100.75 mg/dl); however, these differences did not reach statistically significant values ($p > 0.05$). The frequency of ketosis was significantly higher in G1 than G2 (7 episodes/16 patients vs. 1 episode/16 patients; $p = 0.04$). Regarding the hypoglycemia, there was no significant difference between the two groups (G1 - 2 episodes; G2 - 0 episodes; p = NS). The doses of insulin given in the first 12h post-operatively were significantly higher in G2 than in G1 (49.40 ± 15.44 U vs. 22.76 ± 8.87 U; $p < 0.0001$). We conclude that despite demanding technical equipment and specialised personnel, the separate glucose and insulin infusions regimen makes possible to give the adequate insulin needs in insulinresistant states, like heart surgery and to obtain a better glycemic control with less complications.

1285

INCIDENCE OF IATROGENIC HYPOGLYCAEMIA IN VARIOUS TYPES OF INSULIN -TREATED DIABETES

A. Gürlek and O. Gedik., Hacettepe University Department of Endocrinology, Ankara, Turkey

Hypoglycaemia is a common and potentially dangerous side effect of treatment with insulin in diabetic patients. The present study was designed to evaluate retrospectively the incidence of mild and severe hypoglycaemic episodes in various types of insulin-treated diabetes. A total of 165 patients'medical records were analysed. The patients were cathegorized into 3 groups as follows: 1) juvenile-onset IDDM (age at onset <30 yrs, n=33), 2) adult-onset IDDM (age at onset ≥30 yrs, n=18), 3) NIDDM (n=114). All patients were taking conventional (mixture of short-intermediate acting insulins twice daily) therapy for at least one year. Incidence of mild hypoglycaemic episodes were found to be significantly lower in NIDDM group (1.02 episodes.patient^{-1}.year^{-1}) compared with juvenile (3.45 episodes.patient^{-1}.year^{-1}) and adult (1.78 episodes.patient^{-1}.year^{-1}) onset IDDM groups ($p<0.0001$ and $p<0.001$, respectively). However, the incidences are similar when compared between the two IDDM groups. In contrast, incidence of severe hypoglycaemic episodes were comparable among juvenil/adult-onset IDDM and NIDDM groups (0.20 episodes.patient^{-1}.year^{-1} vs. 0.10 episodes.patient^{-1}.year^{-1} vs. 0.15 episodes.patient^{-1}.year^{-1}, respectively; p=NS). These data suggest that while mild iatrogenic hypoglycaemia due to conventional insulin therapy is a less frequent problem in NIDDM compared with juvenile/adult-onset IDDM, severe iatrogenic hypoglycaemic episodes are encountered as frequently as in juvenile/adult-onset IDDM.

1286

CHARACTERISTICS AND OUTCOME OF KETOSIS-ONSET DIABETICS IN TAIWAN.

J-S. Hwang, J-H. Juang and H-S. Huang. Division of Endocrinology and Metabolism, Chang Gung Memorial Hospital,Taipei, Taiwan, R.O.C.

The occurrence of diabetic ketoacidosis (DKA) has generally been considered as significant β-cell damage and patients with ketosis-onset are usually classified as insulin-dependent diabetes mellitus. To known the characteristics and outcome of these patients, we studies 36 cases who had DKA at diagnosis. There were 19 males and 17 females, with age between 13 ~ 73 years old, body mass index (BMI) 12.4 ~ 33.7 kg/m^2, HbA1c 5.2 ~ 15 % and fasting C-peptide 0.10 ~ 4.58 ng/ml. At 1 ~ 2 weeks after DKA, these patients received glucagon stimulation test and were treated with or without insulin according to their β-cell function. Eleven patients (Gr. A) whose incremental C-peptide (Δ CP) > 0.7 ng/ml were treated with diet (n=1) or oral hypoglycemic agents (OHA, n=10).Twenty-five patients with Δ CP < 0.7 ng/ml were treated with insulin (Gr. B). During 0.5 to 5 year follow-up, only 1 patient in Gr. A needed insulin treatment. At initial, Gr A had high BMI (23.8 ± 1.5 vs. 19.8 ± 0.8 kg/m^2, P <0.02) as compared with Gr. B. The age and HbA1c were not significantly different between 2 groups. Our data indicate that not all ketosis-onset diabetic patients need permanent insulin treatment. Those with higher BMI and better β-cell function may control their diabetes with diet and/or OHA.

1287

CAPILLARY GLYCATED HAEMOGLOBIN ASSAY AND IMPROVED METABOLIC CONTROL IN DIABETIC PATIENTS.

J.P.LeFloch, J.L.Thomas, L.Simon, J.L.Errant and L.Perlemuter. Hospital Manhès and University Hospital Mondor, Paris, France.

Because the results are available at the time of the visit, capillary assays of glycated haemoglobin could help physicians in the ambulatory management of diabetic patients. In order to test the outcome on insulin prescription and metabolic control, a prospective study was conducted in 50 insulin-treated diabetic patients with $Hb_{A1c} < 8\%$, randomised into two groups. In the first group, patients and physicians were informed of the result of the capillary assay (group I). In the control group (C), the assay was performed but the result was kept unknown until the end of the study. Hb_{A1c} (HPLC, with a delay in result delivery), and capillary monitoring of blood glucose were performed and used by physicians. Both groups were followed up over 4 months. Results were compared with the chi-square test, and with the analysis of variance. At inclusion, clinical and biological characteristics of patients did not differ significantly between groups. After 4 months of follow-up, Hb_{A1c} (HPLC) improved in (I) (mean±SE: -0,14±0,13%), whereas it was worse in (C) (+0,30±0,14%; $p<0,05$). Insulin doses were most frequently changed in (I) during visits ($p<0,05$). The number of hyperglycaemia decreased in (I) (-4,5±2,5 vs. +1,6±2,1; $p<0,05$). The number of hypoglycaemia did not change significantly. These results suggest that capillary assay of glycated haemoglobin with immediate result could help for managing insulin treatment in ambulatory follow-up of diabetic patients. An improvement of metabolic control could be obtained by reducing the frequency of hyperglycaemia. The improved understanding of the results of Hb_{A1c} by patients could also be involved.

1288

INTENSIFIED THERAPY AFTER DCCT.

Ľ. Barák, Michalková D..
Children Diabetes Center of the Slovak Republic

The main interest of our study was based on the fact, that division of insulin application from two to three or four daily injections, can improve metabolic compensation of diabetes, without any other changes in therapeutic approaches. The aim of the study was also to clarify notions as intensified therapy (IT) and multiple insulin injections (MII).

In our study group was 51 children and adolescents with type I diabetes, treated and followed-up for 5 years in Children Diabetes Center of the Slovak Republic. Treatment of patients was started conventionally by two injections per day, after that, patients were switched for MII (3 or 4 daily injections). We compared markers of metabolic compensation, such as glycated hemoglobin (HbA1c) and fructosamine (FAM), levels of C-peptide (CP) and insulin autoantibodies (IAA) at the time of the start of the study and later on, every sixth month period. We didn't find any significant difference.

Our study group was divided into subgroups, according to certain criterias, which can influence metabolic control, as family history of diabetes, ketoacidosis and age of the onset of diabetes, keeping diabetic diet and physical activity. We found the fact, that the worth metabolic control was in the subgroup of patients, who have diabetes in parents or siblings. We prove importance of keeping diabetic diet and physical activity.

1289

FAILURE OF HIGH-DOSE INSULIN TREATMENT TO IMPROVE B-CELL FUNCTION IN DIABETIC NOD MICE.

I. Bache, K.H. Jørgensen and K. Buschard. Bartholin Instituttet, Kommunehospitalet, Copenhagen, Denmark.

High-dose insulin treatment in the first period after clinical onset of insulin-dependent diabetes mellitus (IDDM) has been found to improve beta-cell function in humans. The aim of the present study was to examine whether this finding could be reproduced in an IDDM animal model, the spontaneously diabetic NOD mice, since, if so, the possibility of investigating the underlying mechanism would be provided.

Newly diagnosed diabetic female NOD mice were randomized into three groups composed of a conventionally insulin-treated group (n=10) injected subcutaneously with 15 IU/kg per day of NPH for 14 days followed by five days without insulin, a high-dose insulin treated group (n=8) injected subcutaneously with 150 IU/kg per day of Actrapid for 14 days followed by five days without insulin and an untreated group (n=11). A reference group of age matched non-diabetic untreated female NOD mice (n=11) was included in the study.

The amount of insulin extracted from the total pancreas, presumed to give an indirect measure of beta-cell function, was found to be not significantly different between the three diabetic groups, but at a level of about 100 fold less than in the non-diabetic group. No significant differences between the groups of diabetic mice were found in blood glucose values at the end of the study.

We conclude that no improvement of beta-cell function could be demonstrated in newly diagnosed diabetic NOD mice after early high-dose insulin treatment.

1290

SAFETY AND METABOLIC CONSEQUENCES OF THE TRANSFER OF INSULIN REQUIRING DIABETICS (IDDM AND NIDDM) FROM RAPITARD MC 40 IU/ML TO INSULIN MIXTARD HM 40 IU/ML

H. El Ghomari, M.R. Ababou, J.D. Bensouda, R. Belyazid, A. Mikou, A. Seddik, A. Wadjinny,
1. Endocrinology and Metabolic Diseases, University Hospital, Ibn Rochd Casablanca, Morroco
2. Private Clinic for Endocrinology - Diabetology Morocco.

The study was performed in order to assess the safety and metabolic consequences of the transfer of insulin requiring diabetics from the mixed animal insulin preparation to the human insulin preparation. The study was an open, uncontrolled, multicenter trial with a duration of 16 weeks. In the 4 week run-in period, the patients were treated with Rapitard MC and in the 12 week human insulin.The study was performed at 6 different centers. Totally, 86 patients were included in the trial Of these, 83 patients completed the study. Three patients dropped out the study.

The patients included in the study were IDDM (61 patients) or NIDDM (25 patients) with an average duration of treatment of 2.86 years, SD 2.19 years. Metabolic control was generally stable with HbA1c levels less than 25 % above the normal ranges for the laboratory of the center in question.During the study, the number and severity of hypoglycaemic episodes were recorded in patient's visiting booklets. At visits to the clinic, the following parameters were recorded : Adverse events, blood glucose profiles (fasting blood glucose and preprandial blood glucose in the evening taken the day before the visit), insulin dose, HbA1c, and weight. During both study periods, the number of episodes reported per patient was generally low. Very few severe hypoglycaemic episodes were reported and there were no reports of hospitalisations due to hypoglycaemic episodes. There were no statistically or clinically significant differences between the number of episodes reported in treatment periods. There also seemed to be no difference in the severity of the episodes reported. For the IDDM patients and preprandial blood glucose at the end the human insulin period was on average approximately 20 mg/dl lower as compared with the end animal treatment period. The decrease was apparently not related to a simultaneous increase in insulin dose. This decrease in blood glucose level is, however, not reflected in a decrease in HbA1c level, which did not differ significantly at the end of the 2 study periods. For the NIDDM patients the change did not result in any changes in metabolic control as evaluated. In conclusion, transfer of patients (IDDM and NIDDM) from the animal source insulin preparation to the human insulin, is not associated with any change or increase in the frequency or severity of hypoglycaemic episodes nor in metabolic control. Therefore, patients can safely be changed from Rapitard MC to Mixtard 30 HM whilst maintaining the same total daily insulin dose.

1291

Is Sweating a Useful Indicator of Nocturnal Hypoglycaemia?

J Everett, D Cavan and D Kerr. Metabolism Unit, Royal Bournemouth Hospital, Bournemouth, UK.

Many IDDM patients eschew tight glycaemic control because of a justified fear of severe nocturnal hypoglycaemia. As sweating is frequently considered a "classical" warning symptom, we have evaluated the potential of a nocturnal alarm system which measures small amounts of perspiration equivalent to a resistance of 75 kohms/cm^2.

12 IDDM patients (3 male, aged 22 - 52 yrs, duration of diabetes 23 [11 to 25] yrs; median [IQ]) of whom 4 had a history of hypoglycaemia unawareness, used the alarm each night over 4 weeks. Patients also recorded blood glucose levels on retiring, on waking and during any symptomatic episodes of hypoglycaemia during the night. The alarm sounded **correctly** for only 50% of the 14 symptomatic episodes (blood glucose <3.5mmol/l). The "missed" episodes were recorded by 5 individuals of whom 3 already had hypoglycaemia unawareness. The alarm sounded **incorrectly** 17 times (blood glucose ranging between 4 - 19mmol/l). We were concerned to note that in patients with unawareness, 50% of retiring blood glucose values were <7 mmol/l and 20% of waking values were <4mmol/l, suggesting a high rate of nocturnal hypoglycaemia.

In conclusion, detection of sweating is not a particularly helpful aid to the prevention of nocturnal hypoglycaemia. More effort should be directed at manipulation of diet and insulin dose adjustment to prevent hypoglycaemia, on the basis of recorded blood glucose levels, in patients with hypoglycaemia unawareness.

1292

NIGHT INJECTIONS OF REGULAR INSULIN IMPROVE DIABETES CONTROL IN C-PEPTIDE NEGATIVE PATIENTS.

R. Chlup, R. Menzel, H. Keilacker, P. Heinke and E. Jutzi, IInd Dept. of Medicine, Palacky University and Hospital Olomouc, Czech Republic

The main aim of the present randomized over-cross study was to compare the short-term effects of two intensive insulin regimens differing just in overnight therapy: 1.(R) = regular insulin at 10 p.m. and at 2.30 a.m.; 2.(L) = long acting (Ultratard HM) at 5.30 p.m. During day, preprandial boluses were adapted according to selfmonitoring in both regimens. Doses of Ultratard HM were calculated individually. Thirty five type 1 (insulin-dependent) diabetic men (aged 19-41 years, diabetes duration 3-26 years) were randomized (odd numbers started with regimen R) and treated with each regimen for 2 weeks. At the end of each test-period blood glucose (BG) and free insulin (FIRI) profiles (16 estimations/d) and insulin dose/kg body mass/d (INS) were registered. In the whole group the mean BG (MBG) and the INS was lower with the R than with the L (7.78±0.323 vs. 9.05±0.375 mmol/l and 673±27 vs. 763±29 mU/kg body mass/d). There was no difference in FIRI-medians between both regimens (0.189±0.011 vs 0.212±0.013 nmol/l, p>0.05), however, the FIRI at 19.00 h, 20.00 h and 22.00 h was higher with the L and at 5.00 h with the R. In 25 patients the regimen R resulted in lower MBG than the L (6.88±0,413 vs 9.85±0.381 mmol/l, p<0.01) even though the INS here was also lower (0.67±0.033 vs 0.800±0.052 u/kg/d, p<0.01). In 10 patients the R resulted in higher MBG than the L (9.19±0.704 vs 6.99±0.489 mmol/l, p<0.05), however, under the R less insulin (0.667±0.052 vs 0.744±0.055 u/kg/d) was injected in this group. Conclusion: night injections of regular insulin result in better diabetes control than Ultratard HM in 71 percent of estimations. The lower insulin dose in the R shows better efficacy of this regimen.

1293

The pharmacokinetics of sc Semitard MC, human NPH ge, Rapitard MC and human NPH 30:70 ge insulin in normals.

S. D. Luzio[1], L George[1], K deAbrew[1], P Beck[1], P Chester[2] and D.R.Owens[1]. [1]Diabetes Research Unit, Llandough Hospital, Cardiff, UK. [2]Novo Nordisk Pharmaceuticals Ltd, Crawley, UK

The insulin kinetics and blood glucose responses to Semitard MC, Rapitard MC, human NPH ge and human NPH 30:70 ge were compared in healthy, non-diabetic male subjects (n=12). Mean (SD) age was 33.9±11.1 years and BMI of 24.9±2.9 kg/m^2. All were involved on four study days each one week apart. After basal (fasting) samples were taken 0.2U/kg of the allocated insulin was injected subcutaneously as a bolus into the anterior abdominal wall and blood samples were taken at frequent intervals over the next 24 hours.

Exogenous Insulin	Semitard	NPH	Rapitard	30:70
T_{max} (h)	6.17	8.02	1.88	3.15
C_{max} (mU/l)	13.05	5.76	10.62	13.81
AUC_{0-24} (h.mU/l)	149.60	89.96	69.49	121.40
Glucose				
T_{min} (h)	11.60	21.00	9.58	6.00
ΔC_{min} (mmol/l)	-1.85	-1.55	-1.59	-1.85
AUC_{0-24} (h.mmol/l)	-31.03	-22.73	-22.50	-29.96

The C_{max} for exogenous insulin concentration was significantly higher ($p<0.05$) with Semitard vs NPH and NPH 30:70 vs Rapitard, the T_{max} being different only between NPH 30:70 and Rapitard ($p<0.05$). The transfer of patients from Rapitard to NPH 30:70 may require a dose reduction, whereas switching from Semitard to NPH a dose increase may be needed.

1294

EEG CHANGES IN NORMOGLYCEMIC IDDM PATIENTS TREATED WITH HUMAN COMPARED TO PORCINE INSULIN.

A. Teuscher[1)], C. Roth[2)], HP. Landolt[2)], P. Achermann[2)] and A.A. Borbély[2)]. 1) Diabetes Clinic Lindenhof, Bern, Switzerland. 2) Institute of Pharmacology, University of Zürich, Zürich, Switzerland.

Eight IDDM subjects (mean age 39.4 ± 2.1 y. [SEM], mean duration of diabetes 21 ± 3.6 y., mean HbA1c 7.7 ± 0.5 %, C-peptide < 90 pmol/l and no longterm complications) with history of serious neuroglycopenic episodes on treatment with human insulin (1986/87) participated in a crossover trial with human (HI) vs porcine (PI) insulin to investigate different effects on brain functions under normoglycaemia. Sleep and sleep-EEG was ascertained in three consecutive sessions on PI, followed by HI and again on PI. Mean blood-glucose values before (HI: 8.8 ± 1.1; PI: 7.0 ± 0.7), during (HI: 8.0 ± 1.9; PI: 6.6 ± 0.6) and after sleep (HI: 9.8 ± 1.6; PI: 7.9 ± 1.0) (mmol/l ± SEM) were not different. *Results:* The insulin effects consisted in changes of nonREM sleep EEG in the 14-Hz bin spindle freqency range. PI and HI may produce different effects on spindle generating mechanisms in the thalamocortical system and in sleep.

	PI_1	PI_2
mean EEG power density as % change PI vs HI	17.1	10.9
standard error mean [SEM]	3.15	4.50
p-value (compared to HI)	< 0.001	0.047

Statistics: Analyses of variance for repeated measures was done and post-hoc testing by paired student's t-test with Bonferroni adjustment. *Conclusions:* PI and HI have different effects on the 14-Hz spindle frequency component of the sleep EEG and therefore affect differently specific functional aspects of the brain under normoglycemic conditions. It is not unreasonable to conclude that also other brain functions could be differently affected by the two types of insulin.

1295

TWICE DAILY VS THRICE DAILY INSULIN REGIME IN POST RENAL TRANSPLANT NIDDM PATIENTS.

S.R. Aravind & Shoba A. Diacon Hospital, Bangalore, INDIA.

Glycaemic control in Post Renal Transplant patients has always been a challenge. A sharp raise of Blood Glucose towards evenings (4–7 pm) & normal to low Fasting Blood Glucose values are being observed consistently. Use of high doses of T.Prednisolone during day time is thought to be the cause. The Aim of the study was to see the effectiveness of Twice Daily Vs Thrice daily regime of Insulin in Glycemic control. 16 cases of post renal transplant are being followed up since July 1990. 10 patients are on thrice daily regime (3 times short acting with addition of intermediate acting Insulin added to the night dose) and 6 are on twice daily regime (split mix of short and intermediate acting Insulin). Tab. Glipizide 5 mg tid is also being continued. FBS & PPBS are being done every month and HbA1c once in 3 months in all the patients. Dosage adjustments based on SMBG has been taught to all the patients. Though the FBS and PPBS values appear to be well within the target (FBS < 120 mg/dl and PPBS < 180 mg/dl) in both the groups, mean HbA1c values are significantly higher in the twice daily regime group (Mean HbA1c 8.2) compared to the thrice daily regime (Mean HbA1c 7.6). To conclude HbA1c values predict Glycemic control better than FBS and PPBS values and thrice daily Insulin regime is better than twice daily regime.

1296

Somatostatin and Insulin Therapy for the Treatment of Diabetic Ketoacidosis

Cho J.H., Lee H.C., Park C.S., Chang K.H., and Huh K.B., Korea

The presence of increased concentrations of growth hormone and glucagon accentuate diabetic ketoacidosis(DKA), so suppression of those hormone by somatostatin may be beneficial in patients with DKA.

The effect of somatostatin analogue, octreotide, injection plus low-dose insulin infusion in diabetic ketoacidosis (DKA) was compared to that of low-dose insulin infusion.

In fifteen patients of DKA, randomly we treated 5 patients while they received octreotide, 50 μg every 6 hour, subcutaneous injection and low-dose insulin infusion(4U/h). Ten patients were treated with low-dose insulin infusion only in addition to conventional fluid therapy. 24 hour serum glucose, urinary ketones and blood pH were monitored as parameters of successful treatment.

All patients were recovered without episode of late hypoglycemia or severe complications. The median time that serum glucose levels dropped to less than 7.8 mmol/L in octreotide and insulin group(group1) was 20 hour and in insulin group(group2) was 72 hour ($p<0.01$). Ketoacidosis disappeared in octreotide and insulin group in 19.6 ± 7.5 h and in insulin group in 79.5 ± 19.5 h ($p<0.01$). The exponential course of glycemic decline between two groups were evaluated and the logarithmic slopes were respectively -0.77 in group1 and -0.52 in group2.

Addition of octreotide to treatment with low-dose insulin infusion reduced and resolved acidosis in a shorter time.

1297

MULTIPLE INSULIN INJECTION DURING FASTING RAMADAN IN IDDM PATIENTS

A. Al Nakhi, M. Al Arouj, A. Kandari* and M. Morad*. Diabetic unit and *Laboratory Department Amiri Hospital - Kuwait

Fasting the Holy Month of Ramadan represents one of the five pillars of Islam. People with insulin-dependent diabetes mellitus (IDDM) are usually advised against fast, to avoid potential complications of fasting and insulin therapy, such as hypoglycemia or diabetic ketoacidosis (DKA). Despite this advise some patients insist on fasting thus, exposing themselves to these complication. This trial was conducted in a group of IDDM patients, who insisted to fast, to assess the outcome of fasting Ramadan regarding the acute complications and glycaemic control. A group of 15 patients (male:9 - famale:6), 11 IDDM and 4 insulin treated non-insulin-dependent diabetes (NIDDM), with a mean duration of diabetes of 8.5 years (5-12 years) were studied. All had a full clinical, and laboratory assessment for body mass index (BMI), HbA1 and Lipid profiles before and after Ramadan. They were started on three insulin injections a day, 2 before meals (sunset and dawn) of short acting and one in the late evening of intermediate acting insulins. They performed daily capillary blood glucose monitoring (4-6 times/day) and frequent daily urine testing for ketones. They had free access to the team members throughout the study. All the 15 patients completed the month uneventfully, with no serious acute complications (no hypoglycemia or DKA). Although some patients showed some improvement in HbA1, BMI and Cholesterol values, it did not however reach statistical significance. We therefore conclude that, Multiple insulin injection therapy can safely be used, with proper self-monitoring and close professional supervision in IDDM patients insisting to fast Ramadan, without deteriorating the glycaemic control. Larger controlled studies are needed to further support these findings.

1298

DIABETIC KETOACIDOSIS
A STUDY OF 75 EPISODES

Ghaly I, Salah N, Hafez M, Atteya M, El Mougy F.
Diabetic Metabolic Pediatric Unit, Children Hospital,
Cairo University

Abstract: Seventy five episodes of diabetic ketoacidosis (DKA) were admitted to New Children Hospital, Cairo University from January 1993 to January 1995 and managed on two protocol oriented systems were analyzed. Fourty five episodes (60%) occurred in newly diagnosed diabetics and 30 episodes (40%) in known diabetics. The most common precipitating factors in known diabetics were omission of insulin (86%), infection (36%) and stress (4%). Blood sugar levels at admission was significantly correlated to the degree of dehydration ($P<0.05$). The mean pH was 6.97 = 0.16 and was significantly correlated to the respiratory rate. The serum potassium was positively correlated to the blood glucose and negatively correlated to the pH value. Although the serum osmolality was higher in comatosed patients compared to conscious patients, the difference was not significant ($P> 0.05$). On the other hand a significant correlation was noticed between consciousness level and both blood glucose concentration and degree of acidosis ($P<0.05$). At admission, no significant correlation was observed between hyperglycemia and either hyperketonemia or bicarbonate level. Therefore, alleviation of hyperglycemia should not be interpreted as an indication of reduction in insulin infusion rate. This was also confirmed by the shorter duration of reversal of ketoacidotic state when insulin infusion was not reduced and dextrose 10% added if acidosis still existed (protocol II), compared to reducing the insulin dose and adding dextrose 5% whenever pyperglcemia is corrected even in the presence of acidosis. (Protocol I). Four patients succumbed giving a mortality rate of 5.3% and one patient developed severe neurologic sequelae giving a morbidity rate of 1.2%.

1299

A TRIAL OF INSULIN-LIKE GROWTH FACTOR-I AS AN ADJUNCT TO MULTIPLE INJECTION THERAPY IN INSULIN DEPENDENT DIABETES

C.L. Acerini[a], C.M. Patton[a], A. Kernell[c], M.O. Savage[b], O. Westphal[d] and D.B. Dunger[a]. University Departments of Paediatrics [a]John Radcliffe Hospital, Oxford; [b]St Bartholomew's Hospital, London, UK; [c]University Hospital, Linköping, and [d]Östra Hospital, Göteborg, Sweden.

53 adolescents with IDDM (26M, median age(range) 16.1yr (10.8 to 20.6)) were randomised in a multicentre, double-blind, placebo-controlled trial of subcutaneous rhIGF-I (Pharmacia) at two doses (40µg $kg^{-1}day^{-1}$, n18 ; 20µg $kg^{-1}day^{-1}$, n18), compared with placebo (n17) for 6 months. All were on multiple injection insulin regimens. Baseline mean(sem) HbA1c (40µg kg^{-1} 7.9%(±0.4); 20µg kg^{-1} 7.7%(±0.5); placebo 7.7%(±0.3)), insulin dose (40µg kg^{-1} 1.11(±0.08); 20µg kg^{-1} 1.02(±0.06); placebo 1.04(±0.07) units $kg^{-1}day^{-1}$), and duration of diabetes (40µg kg^{-1} 7.0yr(±2.2); 20µg kg^{-1} 8.0yr(±2.0); placebo 9.3yr(±2.5)) were comparable. Nine subjects withdrew (40µg kg^{-1} 1; 20µg kg^{-1} 4; placebo 4). IGF-I levels were significantly increased at 6 months following rhIGF-I: 40µg kg^{-1} 362(±22)ng/ml, 20µg kg^{-1} 263(±22)ng/ml vs. placebo 187(±30)ng/ml ANOVA p=0.001. At 3 months HbA1c values were lower following rhIGF-I (40µg kg^{-1} 7.4%(±0.4), 20µg kg^{-1} 7.8%(±0.5) vs. placebo 8.0% (±0.3)), reflecting dose-related reductions from baseline : ΔHbA1c median(range) 40µg kg^{-1} -0.5%(-2.8 to +0.5), 20µg kg^{-1} +0.1%(-1.4 to +1.6) vs. placebo +0.3%(-1.0 to +1.5) ANOVA p=<0.05. Sustained improvements were less evident at 6 months (ΔHbA1c 40µg kg^{-1} 0.2%(-2.8 to +1.5), 20µg kg^{-1} 0.7%(-1.1 to +3.1), placebo 0.8%(-0.7 to +2.9), p=ns). No differences in insulin requirements, BMI, GFR or Ua/Uc were seen (ANOVA p>0.05). Retinal appearances and hypoglycaemia frequency were unaffected by treatment allocation. In conclusion rhIGF-I is well tolerated and at 40µg $kg^{-1}day^{-1}$ can improve glycaemic control even in well controlled adolescents on multiple injection therapy.

ALLERGY TO HUMAN BIOSYNTHETIC INSULIN; Morales Pérez F.M., Gonzalo M.A, Barquero Romero J, Alvarez Barreiro J.A and Díaz-P. de Madrid J. Hospital Regional Universitario "Infanta Cristina", Badajoz., Spain.

Introduction: Immunologic and allergic reactions used to be common with the first preparations of animal insulin. Nowadays, however, are very unusual due to the use of biosynthetic insulin. Immune reactions and allergy to insulin could be under genetic control. In addition, its appearance may be related to intermittent administration of the insulin. **Case report:** A 32-year's old woman was diagnosed of Type I Diabetes Mellitus in November 1995. She was put on treatment with human biosynthetic insulin (Actrapid® at breakfast and lunch time, and Mixtard 30® before dinner). Six weeks later, she began to present, five minutes after insulin administration, an oedematous reddish itchy lesion in the injection site that reached 8-10 cm of diameter in hours. This lesion disappeared progressively, persisting after 48 hours an indurated zone. Patient had no previous history of atopic syndrome or allergy to drugs. She showed positive Prick cutaneous tests for all preparations of human insulin, while Prick protamine latex tests were negatives. Patient had normal serum levels of total IgE, but high levels of IgE specific for human insulin (8.11 kU/L), and also for porcine (6.78 kU/L) and bovine (7.78 kU/L) insulin. A cutaneous biopsy showed findings compatibles with angiodema (perivascular mononuclear, non eosinofilic, infiltration and oedema in deep dermis). Treatment with antihistaminics (cetirizine 10mg/day) was started with marked improvement of symptoms, but therapy could not be discontinued to date. **Summary:** We present an extremely unusual case of local allergy to human biosynthetic insulin in an IDDM patient not previously sensitization and that had been treated continuously. Specific IgE levels and cutaneous tests demonstrate IgE mediated sensitization to insulin. In this case permanent treatment has partially improve symptoms.

1301

THE INFLUENCE OF INTENSIFIED DIABETES MANAGEMENT ON COMPLICATIONS INCIDENCE IN THECOURSE OF PREGNANCIES IN WOMEN WITH INSULIN DEPENDENT DIABETES MELLITUS.

Sobczak M., Wilczyński J., Cypryk K., Hincz P., Pawełczyk T., SDM Group-Łódź, Polish Mother's Memorial Hospital, Łódź, Poland.

OBJECTIVE: The aim of this paper was to evaluate the influence of Staged Diabetes Management (SDM) on the complications incidence in pregnant women with type I diabetes mellitus (IDDM).

STUDY DESIGN: 176 pregnant women with IDDM took part in the study, divided into two groups: SDM group: 88 women with well controlled diabetes (average blood glucose level (BG) in the 24 hours glucose profile BG<95 mg/dl) and non SDM (NSDM) group: 89 pregnant women before Staged Diabetes Management program application (BG>95 mg/dl). The average age and duration of diabetes between the groups was comparable..

RESULTS: The most frequent complications in the groups were urinary tract infections (UTI): i.e. asymptomatic bacteriuria and pyelonephritis. The incidence of UTI was: 21.6 % in SDM group and 36 % in NSDM group ($p<0.05$). The SDM group patients had a lower risk of infection primarily in the third trimester. The NSDM group had elevated infection risk during all trimesters of pregnancy. Neither infant weight nor the time of delivery was affected by the course of infection. NSDM group patients had a higher rate of poorly controlled diabetes with a high predisposition to hyperglycaemia ($p<0.05$). Preeclampsia was diagnosed in 6.9% of SDM patients, and 18% of NSDM patients ($p<0.05$). Ketoacidosis and polyhydramnion occurred over two times more commonly in NSDM women. The SDM group had longer mean pregnancy duration (37,28±2,8 weeks) compared with NSDM group women (36.3±3.36 weeks), ($p<0.05$). The caesarean section rate decreased from 50% (NSDM group) to 29.9% (SDM group), ($p<0.05$). Apgar scores differed (SDM group: 8.01±1.51 points; NSDM group: 7.49±1.69 points).

CONCLUSIONS: Good metabolic control in pregnant type I diabetes using SDM increases the duration of pregnancy and decreases the incidence of serious complications, i.e. urinary tract infections and preeclampsia. It has also a positive influence on pregnancy duration and newborn health.

1302

NOVOPEN® 1.5 IN INDIAN WOMEN WITH GESTATIONAL DIABETES MELLITUS.

V Seshaiah, Madras India, N Rais, Bombay India, L John, Bangalore India, SR Moorthi, Novo Nordisk India, LN Jorgensen, JP Sorensen, Novo Nordisk A/S - Asia Pacific Centre, Singapore.

The acceptance and clinical results of insulin treatment with NovoPen® 1.5 and syringe were compared in 52 Indian women with GDM. Gestational age was 20-30 weeks at recruitment, and GDM was defined according to WHO criteria. Insulin (Actrapid® HM or Mixtard® 30HM) was instituted at fasting plasma glucose > 90 mg/dl and 2 h - post 50g glucose level > 160 mg/dl). Insulin was administered using NovoPen® 1.5 with G28 needle, or syringe. The patients were followed every 2 weeks until delivery.

Results:

	NovoPen® 1.5	Syringe	P value
Insulin dose	25 U/day	22 U/day	0.47
HbA_{1c}- change	-0.8%	-0.7%	0.75
weight - change	+4.7kg	+4.7kg	0.99

There was no difference in frequency of hypoglycemia. The overall operation and convenience of using NovoPen® 1.5 was rated high by the majority of the patients. 32%of respondents reported that NovoPen® 1.5 caused "less pain than expected", and 68 reported that it caused "no pain".

Conclusion: NovoPen® 1.5 - and syringe administration of insulin caused similar improvement in glycemic control in Indian GDM patients. NovoPen® 1.5 was well accepted, and considered either painless or to cause less pain than expected by the patients.

1303

THE INFLUENCE OF INTENSIFIED DIABETES MANAGEMENT ON NEONATAL COMPLICATIONS INCIDENCE IN INFANTS OF WOMEN WITH INSULIN DEPENDENT DIABETES MELLITUS.

Wilczyński J., Sobczak M., Cypryk K., Hincz P., Pawełczyk T., SDM-Group-Łódź, Polish Mother's Memorial Hospital, Łódź, Poland.

OBJECTIVE: The aim of this study was to investigate the influence of intensified diabetes management according to Staged Diabetes Management (SDM) on the complications incidence in newborns of mothers with type I diabetes mellitus (IDDM).

STUDY DESIGN: 155 infants took part in the study, divided into two groups. SDM group (n=81) was composed of infants whose mothers had average blood glucose level (BG) in the 24 hours glucose profile of BG<95 mg/dl. NSDM group (n=74): children which were born before Staged Diabetes Management program application (24 hours glucose profile average BG > 95 mg/dl). The ages and diabetes duration in mothers of infants included into different groups were comparable.

RESULTS: We found significant differences between the two groups for duration of pregnancy (SDM group: 37.28±1.98 weeks; NSDM group. 36,3±3,36 weeks). Neonates from SDM group had significantly higher umbilical cord blood pH (pH=7.297±0.088) than those from NSDM (pH=7.268±0.105). Postpartum hypoglycaemia and hyperbilirubinaemia were two times more common in NSDM group. RDS was seen more frequent in NSDM group children (19.8%) than in SDM group (11.1%). Congenital foetal malformations occurred almost two times less frequently in the SDM group than in the NSDM (5.4% versus 9.8% respectively). Early newborn death was seen only in NSDM group (incidence rate: 3.8%).

CONCLUSIONS: Good metabolic control archieved after Staged Diabetes Management program application in the IDDM pregnant women decreased the incidence of serious neonatal complications: newborn death, foetal congenital malformations, hypoglycaemia and RDS .

1304

CLINICAL ASPECTS IN THE TREATMENT OF IDDM

R.Hagura, Y.Yoshida, A.Kawai and Y.Akanuma. The Institute for Diabetes Care and Research, Asahi Life Fondation, Tokyo, Japan.

We studied the clinical characteristics concerning treatment of 207 IDDM patients with a mean age of 49 yrs and a mean duration of 15 yrs. These patients were categorized into the abrupt-onset type (A), 131 cases, and the slowly -progressive type (S), 76 cases. The mean HbA1c for the latest 2 yrs was 7.8 ±1.5%. The distribution of the patients with mean HbA1c value of <7, 7~, 8~, 9% ≦ was 27, 40, 19 and 14%, respectively. The insulin dose (M±SD) was 34 ±14 U/day, and 70% of the subjects used more than 4 times injections daily. The amount of insulin in the poor glycemic control group [HbA1c ≧9%, 30 cases, mean 10.4%] was significantly larger than that in the good glycemic control group [HbA1c <7%, 55 cases, mean 6.5%] (39 vs 30U, $p<0.01$). BMI was also significantly larger in the poor glycemic control group (22.7 vs 20.1, $p<0.01$), as was the frequency of BMI larger than 23 (37 vs 9%). The amount of insulin injected daily in the A and S groups was 35 vs 31U, $p<0.05$. The distribution of patients with more than 4 insulin injections a day was 76 vs 58% (ns) in the A and S groups, respectively. Among the subjects with duration of diabetes more than 10 yrs, the prevalence of retinopathy, nephropathy and neuropathy was higher in the poor glycemic control group (n=17) than in the good glycemic control group (n=37); 77 vs 65%, 53 vs 24 and 59 vs 33, respectively. However, these differences were not significant. These diabetic complications were not significantly different between A and S. In summary, in our IDDM patients, 27% were under good control and when the fair control cases were added, the rate was 70%. Compared with the good control group, the poor control group used a larger insulin dose and revealed a higher mean value of BMI. Thus, overeating was speculated in the poor control group.

1305

ORAL REHYDRATION IN THE DIABETIC CRISIS

Arguedas C., Jiménez F., Salazar S and López L. Service of Internal Medicina, Hospital México, San José, Costa Rica.

The DM is one of the main causes of medical consultation and hospital admition in Costa Rica. Only the cost of admition are over $500.000 per year. This study show our experience with the oral rehydration (OR) applied to diabetic patients with glycemias over 250 mg/dl, and no cetosis. 18 pts were treated with 250 ml of water every 15 min and 5 to 10 uds of cristaline insulin/hour.

	Average	St D	p
Age	49.8	19.6	
IMC	28.1	5.7	
Initial Glyc	442	90.4	
Glyc 1 hr.	364	90.6 (-17%)	NS
Glyc 2 hrs.	342	103 (-22%)	NS
Glyc 3 hrs.	266	102 (-39%)	0.03
Glyc 4 hrs.	233	101 (-47.2%)	0.003
Glyc 24 hrs.	230	91 (-47.9%)	0.003
Glyc 48 hrs.	246	105 (-44%)	0.003
Insulin	8.3 UI		
Water	5333 ml		

It is showed the lowest levels of glycemia reached during the 4 hours procedure are still present 48 hours later. Without this program all the patients, otherwise would be addmited.

1306

HOW DO PATIENTS WITH DIABETES MELLITUS TYPE I HANDLE THE INJECTION-MEAL INTERVAL IN DAILY LIFE?

L. Heinemann, H. Overmann and I. Mühlhauser; Dept. of Metabolic Diseases and Nutrition, Heinrich-Heine-University of Düsseldorf, Germany

In order to compensate for the delayed onset of action of regular insulin an injection meal interval (IMI) is often recommended for insulin treated diabetic patients. Nevertheless, how and if diabetic patients practice the IMI in daily life was evaluated only in a limited number of studies with selected patient groups. Within a population-based public health study with 684 adult patients with diabetes mellitus type 1 a random sample of 202 patients (41 % women, age 35±10 years (mean±SD)), duration of diabetes 18±11 years) was asked about their handling of the IMI. 10 patients who practiced only long-acting insulin were excluded from the analysis. 12 patients adapted their IMI so frequently, that they could not give a mean value for it. Of the remaining 180 patients 64 % reported to practice an IMI of 0-15 min, 13 % used an IMI of 20 or 25 min and only 23 % used an IMI of 30 min or longer. A flexible IMI was practiced by 134 patients (70 %), whereas 58 patients (30 %) used a fixed IMI. 122 (91 %) of the 134 patients using a flexible IMI stated that the usual interval was 15 (0, 60) min [median (range)]. 62 % of these patients practiced an interval of 0-15 min, 16 % an IMI of 20 to 25 min and 21 % an IMI of 30 min and longer. From the patients using a fixed IMI, 67 % used an interval of 0-15 min, 7 % one of 20 or 25 min and 26 % one of 30 min and longer. Their median IMI was 8 (0, 60) min. The patients who used a flexible IMI made the choice of the IMI according to the following criteria: preprandial glycaemia 73 %, time of day 37 %, physical exercise 34 %, carbohydrate content of meal 25 %. 69 % of the patients selected the IMI according to the actual situation. Patients using a flexible/fixed IMI receive information about the choice of the IMI from: treatment and teaching programmes 62/47 %, own experience 55/38 %, physician 26/34 %. Up to now this is the largest questionnaire for the use of IMI and the first in a randomly selected group of patients. It shows, that more than 60 % patients with type I diabetes in daily life only practice a short injection meal interval between 0 and 15 min.

1307

TEMPORAL RELATIONS OF GLYCOSYLATED HAEMOGLOBIN HbA1c WITH BLOOD GLUCOSE LEVELS AND FLUCTUATIONS

B. Karamanos, G. Chaliotis, E! Husban Taisir, Ch. Tountas, N. Mavrogiannaki and A. Kofinis. Diabetes Center, Hippokration Hospital, Athens, Greece.

Glycosylated Haemoglobin (HbA1c) is widely used as index of diabetic control but its exact temporal relations with the daily glycaemic excursions are not fully elucidated. In order to further investigate the above relations we studied 78 diabetics who did self-monitoring of their blood glucose (BG) 2-5 times/daily, at 08:00, 11:00, 17:00, 20:00 and 23:00, alternatively, for two months, while HbA1c was measured by HPLC at the end of this period. HbA1c showed a good correlation with the mean BG of the 2-month period, r =.5953, p<.001 and also with the mean BG at each time point, r =.5256, r =.4474, r =.3717, r =.4797 and r =.6020, respectively, p<.001. Thus an HbA1c value of 5.3% reflects mean 2-month BG of 5.8 mmol/L, a value of 6.0% mean BG of 7.3 mmol/L, HbA1c value of 7.0% mean BG 9.6 mmol/L and HbA1c value of 8.4% reflects mean BG of 12.5 mmol/L. Dividing the 2-month period in four 2-weeks periods, HbA1c showed good correlation with the mean BG of each of them, r =.4890, r =.5321, r =.5595 and r =.5498, from the first to the fourth respectively, p<.001. Dividing the patients in those with great daily glycaemic excursions i.e. 5.0 mmol/L (Group A) and those with small, 1.1 mmol/L, (group B), we found that the correlation coefficient between HbA1c and mean BG over the two months was r =.5750 for group A and much stronger, r =.7142, for B, p<.001. The other correlations between HbA1c and glucose values within each group showed similar differences, beeing always stronger for group B, which had the smallest BG diurnal variations. **Conclusion:** In Type 1 diabetics **a)** HbA1c is associated with the mean glucose over 2 months and also with the mean BG at different time points during the day **b)** The association is much stronger in patients with stable control than in those with great daily glucose excursions, a fact which must be considered when interpreting the HbA1c results.

1308

GLUCOSE EFFECTIVENESS ON CSII THERAPY IN NEWLY DISCOVERED IDDM PATIENTS : MINIMAL MODEL ANALYSIS

M.Šumarac-Dumanović, D.Micić, Dj.Macut, A.Kendereški, S.Zorić and M.Čolić. Institute of Endocrinology, Diabetes and Diseases of Metabolism, Beograd, Yugoslavia.

It was shown that hallmark of states of reduced glucose effectiveness appears to be the insulopenic state. The aim of our study was to evaluate the effect of CSII treatment (Novo Nordisk Infuser MKII using Velosulin) in a group of 22 newly discovered IDDM patients (age: 22.23 ± 1.19 years; BMI: 21.19 ± 0.53 kg/m^2) on glucose effectiveness. Glucose effectiveness (Sg; 10^{-1} x min^{-1}) was calculated using MINMOD program (copyright R.N.Bergman) at 0, 2 and 12 weeks. Obtained results were presented as mean ± SE. Student t-test was used for statistical analysis. Patients were divided into two groups: group A (patients entering into clinical remission; n = 6; age: 23.83 ± 2.68 years; BMI= 22.6 ± 1.52 kg/m^2) and group B (without remission; n = 16; age: 21.63 ± 1.33 years; BMI= 20.66 ± 0.42 kg/m^2). Comparing Sg in group A and B following results were obtained: 0 week (A vs. B; 0.102±0.038 vs. 0.232±0.091, p > 0. 05); 2 weeks (A vs. B; 0.270±0.052 vs. 0.158±0.023, p < 0.05); 12 weeks (A vs. B; 0.133±0.029 vs. 0.206±137, p > 0.05). Statistically significant increase (p<0.05) for Sg in patients entering remission was found only after 2 weeks of CSII in comparison with patients without remission. We did not obtained increase for Sg in 2 and 12 weeks on CSII in comparison with the beginning of treatment in groups A and B. In conclusion, our results showed that CSII therapy had some effects on glucose effectiveness, but this could be only one among the relevant factors that determined the outcome of the disease in IDDM patients.

1309

INTENSIVE INSULIN THERAPY DOES NOT INCREASE THE INCIDENCE OF HYPOGLYCAEMIA

D.Zozulińska, S.Markiewicz, D.Naskręt and B.Wierusz-Wysocka. Poznań Diabetic Center, Poznań, Poland

We aimed to analize the episodes of hypoglycaemia in a group of well educated patients with diabetes, who adjust doses of rapid acting insulin before meals. 60 patients with type I diabetes, 26 female and 34 male, aged 16-52 years, mean diabetes duration 10.74±8.67 years, treated with intensive insulin therapy for 1.8±1.6 years, HbA_{1c} 7.4±0.6 % were entered into the study (group A). 60 patients with type I diabetes treated conventionally, with HbA_{1c} 9.6±1.2 %, were used as controls (group B). We evaluated the number of hypoglycaemic episodes per week distinguishing between mild (no third person's help required) and severe hypoglycaemia (first aid given by family/doctor). We noticed significantly fewer hypoglycaemic events, both mild and severe, in group A in comparison with group B (mild hypoglycaemia 1.16±0.68 vs 3.20±1.86 episodes/week, $p<0.05$; severe hypoglycaemia 0.00 vs 0.03±0.01 episodes/week, $p<0.05$). The results of our study suggest that intensive insulin therapy in educated patients who adjust the doses of rapid acting insulin before meals not only allows for more free life style and better metabolic control of diabetes, but also decreases the incidence of hypoglycaemia.

1310

BETA CELL SECRETION DURING CSII THERAPY IN NEWLY DISCOVERED IDDM PATIENTS ENTERING REMISSION

Dj.Macut, D.Mićić, M.Šumarac, A.Kendereški, S.Zorić and M.Čolić. Institute of Endocrinology, Diabetes and Diseases of Metabolism, Beograd, Yugoslavia.

The aim of our study was to evaluate long effects of CSII treatment (Novo Nordisk Infuser MKII using Velosulin) in a group of 22 newly discovered IDDM patients (age: 22.23 ± 1.19 years; BMI: 21.19 ± 0.53 kg/m^2) on basal and stimulated beta cell secretion. Glucagon stimulation test (Glucagon, 1 mg iv, Novo Nordisk) was performed at 0, 2, 12, 24 and 52 weeks and C-peptide (RIA Inep, Zemun; nmol/l) determined at 0 and 6 min. Results were presented as mean ± SE. Student t-test was used for statistical analysis. Patients were divided into two groups: group A (patients entering into clinical remission; n = 6; age: 23.83 ± 2.68 years; BMI= 22.6 ± 1.52 kg/m^2) and group B (without remission; n = 16; age: 21.63 ± 1.33 years; BMI= 20.66 ± 0.42 kg/m^2). Comparing basal beta cell secretion in group A and B following results were obtained: 0 week-0min (A vs. B: 0.186 ± 0.047 vs. 0.178± 0.029, $p>0.05$); 0 week-6min (A vs. B: 0.252 ± 0.052 vs. 0.276 ± 0.0469, $p>0.05$), 2 weeks-0min (A vs. B; 0.110 ± 0.037 vs. 0.184 ± 0.033, $p>0.05$); 2 weeks-6min (A vs. B; 0.174 ± 0.063 vs. 0.270 ± 0.043, $p>0.05$); 12 weeks-0min (A vs. B: 0.220 ± 0.066 vs. 0.171 ± 0.057, $p>0.05$); 12 weeks-6min (A vs. B: 0.602 ± 0.204 vs. 0.282 ± 0.0295, $p>0.05$). There was no statistically increase in C-peptide levels (basal or stimulated) between groups A and B after 2 and 12 weeks on CSII therapy in comparison with 0 week ($p>0.05$). In conclusion, patients entering into clinical remission during CSII therapy increased stimulated beta cell secretion over course of three months. This increase was not statistically significant comparing with stimulated C-peptide levels at 0 week as well as comparing with beta cell secretion in patients without clinical remission.

1311

THE *GETREM* STUDY: NEW PRELIMINARY FINDINGS FOR THE CLINICAL REMISSION IN IDDM USING LOGISTIC REGRESSION

P.D. Browne, E. Lampeter, I. De Leeuw, D. Iafusco, C. Ionescu-Tirgoviste, S. Kolouskova, T. Linn, J. Ludvigsson, L. Madascy, A. Mrozikiewicz, T. Podar, M. Prisco, J. Vavrinec, B. Vialettes, N. Visalli, T. Yilmaz and P. Pozzilli. (Getrem Study Group)

Strict metabolic control within the first year of insulin dependent diabetes (IDDM) is thought to be a key factor for achieving clinical remission (i.e. suspension of insulin therapy according to the parameters issued by the International Diabetes Immunotherapy Group). The aims of the GETREM project are two fold: (i) to evaluate the frequency and duration of spontaneous clinical remission in an European population of newly diagnosed IDDM patients (aged 5-35 years), who are followed up for a period of 36 months, with a common protocol and without any adjunctive immuno-intervention; and (ii) to identify the predictive factors for remission of IDDM patients diagnosed between 5 and 35 years of age. A total of 189 consecutive patients with newly diagnosed IDDM according to WHO criteria were recruited in a participating centres (Belgium, Czech Republic, Estonia, France, Germany, Hungary, Italy, Poland, Romania, Sweden and Turkey) over an extended period of 36 months. Various clinical characteristics (age, gender, etc), history (severity, diabetic siblings, etc) and integrated parameters of metabolic control (HbA1c, blood glucose, total home insulin dose adjusted for body weight, etc) were obtained. So far, 33 patients (17.5%) experienced full clinical remission; mean duration of remission was 7.4±5.8 SD months, but there was some variation between centres. Contingency table analysis showed statistically significant associations ($P<0.05$) between remitted patients and all the above measurements, except age. The 'best' logistic regression fit for remission included predictive factors such as study centre, total home insulin dose adjusted for body weight, and gender, in that order of importance, which predicted 90 % of the patient outcomes correctly. We conclude, that logistic regression analysis provides useful results for the identification of factors, that are predictive of clinical remission in recent-onset IDDM.

1312

DEFINING INSULIN NEEDS BY MEANS OF CONTINUOUS SUBCUTANEOUS INSULIN INFUSION (CSII) IN TYPE I DIABETES MELLITUS.

G Petraroli, F Dani, G Grassi, G Maghenzani, L Monge, S Pinach, E Benaduce and Q Carta. - Diabetes Unit - A.O. San Giovanni Battista of Turin - Turin, Italy

In the treatment of Type I diabetic outpatient, even in multi-injectional therapy, we often encounter difficulties in defining specific insulin requirements. For the purpose of re-defining insulin doses and launching an optimized insulin treatment program according to the DCCT model, 20 C-peptide deficient Type I diabetic patients with poor diabetes control (age 40.7±16, duration of diabetes 18±10yrs, BMI 23.2±3, HbA1c 9.0±1.2%) who were undergoing a therapy of four injections a day (with intermediate insulin at bed-time) were treated by our division. Upon entry, subcutaneous insulin infusion (CSII) (Microjet Quark U100, Bayer) was initiated using the following parameters: initial basal rate correspondent to 40% of the total daily dose administered, and the remaining 60% divided into boluses given at meal-time and based on carbohydrate intake and the foreseen insulin requirements. No modification to previous dietary habits which consisted of three meals a day were made. The resulting carbohydrate amounts were: breakfast 38.5±19gr, lunch 95.5±33gr, supper 90.5±30gr. During treatment the capillary-glucose levels were verified daily (One-Touch H, Lifescan). The basal insulin requirements, which resulted as 0.25±0.09 U/Kg/die, was defined by researching the dose which - in the absence of nocturnal glycemia <90 mg/dl or episodes of hypoglycemia - allowed us to bring the glycemia to a level between 100 and 130 mg/dl at 7am, bringing daily changes which are not superior to 10% of previous dose. The insulin requirements obtained were therefore divided into four injections a day with 60% of the daily dose given as intermediate insulin at bed-time and the remaining 40% divided and administred as an adjunct to the three prandial boluses of regular insulin.

The method was simple and easy. It allowed for brief periods of recovery (8.5±2.8 days) and helped us to establish that the total dose of insulin/kg/die upon release from the hospital (POST) was significantly lower that the one at time of entry (PRE)(PRE 0.74±0.26 vs POST 0.65±0.19U $p<.005$). In particular, this was more relevant for the bed-time dose (PRE 12.4±5.0 vs POST 9.5±2.9U $p<.005$), but also significant to the dose given at supper time (PRE 12.4±4.9 vs POST 10.4±3.4U $p<.025$). The ratio between carbohydrates and insulin (breakfast 5.0±2.3, lunch 7.9±2.4, supper 9.2±2.8 gr/U confirmed that the major need of insulin was during breakfast ($p<.005$).

1313

A NOVEL APPROACH FOR COMMENCING PATIENTS ON INSULIN THERAPY

T. Peto, S. Partington, M. Hensley, P. Moffitt and K. Bowen; Diabetes Education Centre, Royal Newcastle Hospital, Newcastle, NSW, Australia

We recently conducted an Australia-wide survey showing that inpatient or 1:1 outpatient education are the predominant strategies used when commencing NIDDM patients on insulin. However, in Newcastle, NIDDM patients with Secondary Oral Failure (SOF) are converted to insulin in an innovative group education program if SOF is confirmed following a month-long pre-course assessment period. The uniqueness of this course has prompted us to assess the epidemiological characteristics of patients seen during the first 4 years of the course. A follow-up was conducted at 1-5 years after initial attendance to see if the course met its educational and therapeutic objectives. Patients' satisfaction with the course and costs to the patients and the health system were also measured. During the 4 year study period the Diabetes Education Centre converted 251 patients (129 male and 122 female; age 63±5.5yrs; duration of NIDDM 9.4±3.7 years) with SOF to insulin. Pre-course 82% of the patients were symptomatic, with an average HbA1c of 9.2±1.6% and a mean fasting glucose of 12.4±5.1 mmol/L. Twenty six patients died in the interim and 8 were lost to follow-up. Of the 217 patients available for follow-up 172 completed questionnaires on different aspects of diabetes care and had their HbA1c measured. The number of symptomatic patients, HbA1c and fasting glucose levels decreased significantly during the follow-up period (39%, 8.1%±1.3; 10.5±4.3 mmol/L; respectively, p<0.001). Only six patients were admitted to hospital for hypoglycaemia, but all were aware of the precipitating cause. All but one patient could manage injections at home without help. The patients stated that the course met their expectations and patient satisfaction levels were high. As expected, weight gain 1-5 years after conversion to insulin was significant (10.2±3.5kg). The course proved to be cheaper than other commonly utilised education approaches. In conclusion, the objectives of the course were met while providing a satisfying and inexpensive alternative to either inpatient or 1:1 outpatient conversion to insulin.

1314

LONG TERM EFFECT OF CSII THERAPY ON INSULIN SENSITIVITY IN NEWLY DISCOVERED IDDM PATIENTS : MINIMAL MODEL ANALYSIS

D.Micić, A.Kendereški, M.Šumarac, Dj.Macut, S.Zorić and M.Čolić. Institute of Endocrinology, Diabetes and Diseases of Metabolism, Beograd, Yugoslavia.

It was postulated that strict metabolic control at the beginning of IDDM may have effect on the subsequent outcome of the illness. The aim of our study was to evaluate the effect of CSII treatment (Novo Nordisk Infuser MKII using Velosulin) in a group of 22 newly discovered IDDM patients (age: 22.23 ± 1.19 years; BMI: 21.19 ± 0.53 kg/m^2) on insulin sensitivity. Insulin sensitivity (Si; 10^{-4} x min/mU/l) was calculated using modified MINMOD program (copyright R.N.Bergman) at 0; 2; 12; 24 and 52 weeks. Data are presented as mean ± SE while t-test was used for statistical analysis. Patients were divided into two groups: group A (patients entering into clinical remission; n = 6; age:23.83 ± 2.68 years; BMI = 22.6 ± 1.52 kg/m^2) and group B (without remission; n = 16; age: 21.63 ± 1.33 years; BMI = 20.66 ± 0.42 kg/m^2). Comparing insulin sensitivity between group A and B following results were obtained: 0 week (A: 0.383 ± 0.078 vs. B: 1.85 ± 0.506; p > 0. 05); 2 weeks (A: 1.592 ± 0.715 vs. B: 2.651 ± 0.396; p > 0.05); 12 weeks (A: 2.783 ± 0.814 vs. B: 4.501 ± 0.984; p > 0.05); 24 weeks (A: 3.280 ± 0.741. vs. B: 2.451 ± 0.563; p > 0.05) and 52 weeks (A: 5.445 ± 0.944 vs. B: 4.865 ± 0.667; p > 0.05). Statistically increased Si in comparison with 0 week was achieved in group A after 12 weeks (0.383 ± 0.078 vs. 2.783 ± 0.814; p < 0.05) as well as in group B after 12 weeks (1.85 ± 0.506 vs. 4.501 ± 0.984; p < 0.05). In conclusion, insulin sensitivity was significantly increased in newly discovered IDDM patients after 3 months of CSII therapy. There was no significant difference in insulin sensitivity between patients entering remission and patients without remission after long term (52 weeks) follow up.

1315

AN EVALUATION OF 158 DIABETICS WITH INTENSIFIED TREATMENT ACCORDING TO THE BASIS BOLUS INSULIN THERAPY REGIMEN

M.Francesconi
Rehabilitation Center for Diabetes, A-2534 Alland, Austria

A total of 158 diabetics (D) on basis bolus insulin therapy regimen (BBIT) could be evaluated in our Diabetes Center (DC). Of these 81 had been already admitted with the BBIT regimen (group A=gA), 77 were transfered from several less intensified treatment strategies to the BBIT regimen during their stay at the DC (group B=gB). The underlaying diagnoses (gA+gB) were: in 117 cases diabetes mellitus (dm) type 1, in 17 dm type 2a, in 12 dm after pancreatitis, in 6 dm type 2b, in 3 gestational dm, in 3 cases no allocation to a certain type of diabetes was possible. Mean duration of dm was in gA 13,9±3ys (range:1-42ys), in gB 11±3ys (range:1-41ys). During a period of 20 days patients underwent a structured educational program counting 22 units of appr. 1 hour. Seven units were necessary to explain basic algorhythemes, 4 for the handling of monitoring and injecting devices, during the rest of the units general aspects of diabetes were discussed. The mean dayly insulin dose at admission was 52,9±7 IU in gA and 40,9±6 IU in gB. A dose reduction could be achieved to 32,2±5 (-39,2%) IU by means of improved algorhythmes in gA and to 30,6±5 (-25%) IU by transfere to the BBIT regimen in gB. The mean number of blood glucose tests per day (both groups) counted 7,2 (range:5-10). As expected the mean HbA1c levels at admission were lower in gA (8,2±2) than in gB (9,1±2). At discharge this value did not differe significantly in the two groups (gA:7,6±2 gB:7,9±2). The results of this analysis prove that a stay at the DC is a good means to transfer insulin treated D to the BBIT regimen and to improve glycemic control in patients already running on BBIT.

1316

7 YEARS EXPERIENCES OF INTRAPERITONEAL INSULIN INFUSION

C.Riedel, and E.Austenat, Diabetes Institut Berlin, Germany

116 patients (69 female,47 male) have been treated by the CIPII using a Titanium-Portsystem.The Portsystem was implantated intraoperative.Insulin-infusion is regulated by an insulinpump which is connected with the system at the Titan-button and an i.p.double score catheter.The insulin effect is directly. **Reasons for CIPII:** Brittle-Diabetes, severe hypoglycaemia,skin reactions under CSII-therapy, late complications. **Basic data:** Typ 1 n = 100 (86,2%), Type 2 n = 16 (13,8%), average of age 36,1±11,7 years, diabetes duration 16±9,6 years, CIPII treatment time 4,2±2,0 years. **Results:** Laboratory data: In comparison to CSII we didn`t find any significant difference for creatinine,GOT, GPT, Cholesterol, HDL, Apolip A and B until 36 month follow up.g-GT (start 13,4 ± 12,4,follow up 4 years17,7±17,4 - p <,0001) and Triglyceride (start 106±64,follow up 4 years 130±97, p ,0006) shown statistical differences.Using CSII HbA1c <8% in 59,5%, using CIPII < 8% in 73,7%. 48 cases had to be explantated during treatment time of 2,85 years. Reasons:catheter occlusion, fibrin coat around the catheter (10%) or other catheter problems (18%), skin infection (30%) ,intraabd.infection (15%), penetration of titan button through the skin(7%),intraabd.adhaesion (18%),briden(2%).Skin infection might be based on mechanical irritation.Predominant Staph.aureus was found (detail data will be shown). In less than 15% the infection is manifestated within the first 30 days after the implantation, in nearly 50% within one year and more. The titaninum doesn`t seem to be a good material for a long time i.p. insulin delivery via port system.To avoid problems with the intraperitoneal catheter it is usely to change the catheter ambulatory (data will be shown).The Port-System-acceptance is very high. Patients are content because of direct effect of insulin,get more flexibility and spontaneous lifestyle without severe hypoglycaemia.**Conclusion:** For now this Titanium-Port seems to be limited because of the complication events which are discribed.Nevertheless we are convinced that the CIPII-therapy has to become a fixed part in diabetes treatment.

1317

POSITIVE ATTITUDES AMONGST PATIENTS AND NURSES TOWARDS 'DIAS'- A TOOL FOR PROVIDING INSULIN DOSE ADVICE

Meeking D.R.[a], Cradock S.[b], Dowell J.[c], Hovorka R.[c] and Cavan D.A.[a]. [a]Dept. of Endocrinology, St Thomas' Hospital, London, UK [b]Dept. of Medical Informatics, Aalborg University, Denmark. [c]MIM Centre, City University, London, UK.

DIAS is a computer model of glucose metabolism which is designed to provide insulin dose advice for IDDM patients based upon data collected from home (dietary intake, insulin dosage and blood glucose measurements). To assess the attitudes of patients and specialist nursing staff towards the use of DIAS as a clinical tool, 35 Diabetes Specialist Nurses (DSNs) and 20 IDDM patients (10 males and 10 females aged 36.3 ± 3.7 yr) were given a demonstration of the system and asked to complete a structured response form. Responses to written statements were recorded using a five-point Likert scale; where '1' = 'strongly disagree' and '5' = 'strongly agree'. The attitude of DSNs was positive. Most felt that by using DIAS they would feel more confident about altering insulin doses (Mean Likert Score (MLS) = 3.2) and would examine blood glucose levels more specifically (MLS= 3.5). They also felt that DIAS was 'a good idea' (MLS = 4.03) which they would want to use in their patient group (MLS = 3.6). Compared to DSNs, patient attitudes were more strongly positive, agreeing that DIAS would improve their glycaemic control (4.0 +/- 0.13 (patients) vs. 3.27 ± 0.12, (DSNs), $p < 0.01$), enable them to cope more with changes in their normal routine, (4.0 ± 0.15 vs. 3.20 ± 0.16, $p < 0.01$) and make them more likely to monitor blood glucose levels (3.6 ± 0.22 vs. 2.91 ± 0.13, $p<0.01$). Patients also agreed that by using DIAS it would be easier to monitor their diabetes (MLS = 4.2) and they would feel more confident about adjusting their insulin dosages (MLS = 4.1). The previous use of computer systems to assist in providing insulin dose advice has proved relatively unsuccessful. The benefits of analysing attitudes towards DIAS prior to implementation are twofold; firstly by providing an indication of its likely acceptance by potential users and secondly by highlighting important concerns which can be addressed before the technology becomes generally available

1318

EXPERIENCE OVER THE LAST 11 YEARS WITH CONTINUOUS SUBCUTANEOUS INSULIN INFUSION (CSII)

E. Austenat, A. Hotzwik, C. Riedel, M. Scherwinski and S. Semmler, Diabetes Institut Berlin, Germany

Since 1985 1033 patients got the CSII.All patients get an each hour preprogramable pump (H-TronV®) and surface stabilized insulin (H-Tronin®). **Basic data:** male n= 496 (48%), female n= 537 (52%),diabetes mellitus typ 1, n=875 (85%), diabetes typ 2, n=158 (15%),age in years, (std.,range) 34,4 (± 13,4, 9 - 78),diabetes duration in years,(std., range)12,6 (± 9,4, 0-50),CSII treatment time in years,(std., range)3,5(±3,1, 0,3 -11). 383 patients (41,2%) are treated longer than 4 years. Average duration of hospitalisation in the Nightclinic (mix from in-and outpatient management) is in nights (std, range)10,7 (±3,9, 1-30). Indications for treatment in the Nightclinic are find out the basalrate configuration and praeprandial insulin dosage,train pump handling and further education.**Results:**890 patients (86,2%) accept CSII and stay at our center.36 patients (3,5%) stopped the therapy, 84 patients (8,1 %) leave center and 23 patients (2,2 %) deceased. Reduced arrise of biochemical hypoglycaemic blood sugar levels compared with the intensive conventional therapie regime (ICT) are observed.The mean HbA1 value before start of CSII is 10,2% (std, range), (± 2,2, 6 -19). After 5 years of CSII treatment mean HbA1 value is 8,7% (std., range),(± 0,9, 6,2-12,1).Each basalrate configuration ist strictly individual.Target is blood sugar (fasting conditions / 24 hours). We observed no correlation between basalrate (BR) and Body Mass Index (r-squared o,51), BR and summary IU before CSII (r-squared 0,18). **Conclusions:**CSII with H-Tron® is well accepted by more than 85 %.The risk of severe hypoglycaemia is lower than under ICT.The mean HbA1 value shows a reduction of more than 1,5% in comparison to further therapy. Pump treatment is the best subcutaneous insulin strategy for insulin treated diabetic patients but it is not indicated in case of non compliance, drug abusus, handicaped persons (mental/physical) and good metabolic control by other insulin therapies.

1319

EFFICACY AND SAFETY OF HUMAN INSULIN COMPARED TO LOCALLY-PRODUCED CHINESE INSULIN

XX Zhu, Shanghai Medical University, LN Jorgensen, Novo Nordisk A/S- Asia-Pacific Centre, Singapore.

Human insulin from Novo Nordisk is currently being introduced in China. A number of diabetes clinics participated in a prospective observational cohort-study, with the aim to collect data on patients who were transferred from Chinese produced animal insulin to Novo Nordisk highly purified insulin. The Chinese insulins were from "Xuzhou Biochemical" and "Shanghai Biochemical". The patients were evaluated before transfer to human insulin and 3 months after. 43 clinics submitted data on 630 patients.

Results	Before Human Insulin (HI)	After 3 months HI	Difference	Unit
Insulin dose	37	30	-22%	median u/day
HbA_{1c}	9.1	7.2	-18%	median %
Mild hypo.	0.40	0.26	N.S.	events/pt/mth
Severe hypo.	0.53	0.19	N.S.	events/pt/yr
Local injection reaction	110	5	-95%	total no. of cases

Conclusion: The data should be interpreted with care; the study was an open observational study with many possibilities for bias, and there was no quality control of source data. However, taken as a whole, the data shows a marked improvement in glycemic control, despite a reduction of the insulin dose. Concurrently, the frequency of local adverse reactions dropped markedly. The recommendation to reduce the insulin dosage by 10-30% after transfer to human insulin is supported by the study, confirming the higher bioavailability of highly purified human insulin compared to animal source insulin of lower purity. The benefits in efficacy and safety of transferring patients from locally-produced animal insulin to highly purified Novo Nordisk human insulin were clearly demonstrated.

1320

INSULIN LISPRO IMPROVES GLYCEMIC CONTROL IN IDDM PATIENTS UNDER CONTINUOUS SUBCUTANEOUS INSULIN INFUSION (CSII)

U. Hoss[1], M. Salgado[1], F. Sternberg[1], H. Rinne[2] and E.F. Pfeiffer[1].
[1]Institute of Diabetes Technology at the University of Ulm, Ulm, Germany.
[2]Boehringer Mannheim, Mannheim, Germany.

The application of insulin lispro (LP) on CSII in IDDM patients seems to be an ideal method for simulating physiological insulin secretion. The rapid onset of action accounts for lower postprandial glucose values, the shorter duration of action reduces the frequency of hypoglycemic episodes. The aim of this study was to investigate the effect of LP with CSII by contiuous tissue glucose monitoring under daily life condition. We included 10 IDDM patients under CSII treatment with regular insulin (RI) in the study. 24 hours continuous tissue glucose monitoring has been performed twice on each patient, the first day with RI and the second with LP. For changing from RI to LP the patients have been advised to keep the basal rate of the insulin pump as before and to reduce bolus infusion to about 80% of their usual dosage. Continuous tissue glucose measurement has been performed via microdialysis using the "Ulmer Zuckeruhr" system. One tissue glucose value per minute has been measured. All patients measured capillary blood glucose with their own glucose meters and decided independently about insulin dosage and food intake. Glucose profiles have been evaluated by following parameters: mean blood glucose (MBG), Schlichtkrull M-value (M) and number of hypoglycemic episodes. All investigated metabolic parameters have been improved under lispro insulin therapy. MBG was reduced from MBG_{RI}=138+/-13mg/dl to MBG_{LP}=132+/-6mg/dl, M-value was significantly ($p<0.05$) improved from M_{RI}=24.1+/-4.3 to M_{LP}=16.8+/-1.9, indicating a more stable metabolic control. The frequency of hypoglycemic episodes decreased not significantly from 1.1 hypo/day in the RI group to 0.33 hypo/day in the LI group. We conclude that lispro insulin improves metabolic control in IDDM patients under CSII.

1321

CIRCULATING INSULIN ANTIBODIES IN THREE TYPES OF YOUNG DIABETICS ON BOVINE INSULIN THERAPY.

R. Goswami, A. Jaleel, N Jayasuryan and N. Kochupillai. Dept. of Endocrinology, All India Institute of Medical Sciences, New Delhi, India.

The WHO classifies diabetes mellitus of the young in developing countries into IDDM and malnutrition related diabetes(comprising of protein deficient pancreatic diabetes(PDPD) and fibrocalculous pancreatic diabetes(FCPD). 42% of the young diabetic (age < 30 years) we see are IDDM, while 28% and 13% of them are PDPD and FCPD respectively. Immune modulation is reported in malnutrition. However, there is no information on insulin antibody (IA) response in different categories of young diabetics treated with bovine insulin. We studied 52 consecutive young diabetics(IDDM,n=26; PDPD,n=17; FCPD, n=9) on bovine insulin therapy. IA was measured using radioligand assay and expressed in standard deviation scores (SDS) above healthy controls. On participation in the 5th IA proficiency program (University of Florida, U.S.A.), our assay had 100% specificity and 90% sensitivity. The three groups of diabetics were comparable in age. The mean BMI in IDDM, PDPD and FCPD were 16.7 ± 2.5, 16.0 ± 3, 17.1 ± 2.3 Kg/m2 respectively. The IA SDS in the three groups were 70 ± 23; 65 ± 28; 72 ± 19 respectively. The differences observed were statistically not significant. However, the IA SDS of the entire group correlated inversely with their BMI ($P < 0.05$). Total insulin dose (IU/day) required for acceptable glycemic control was significantly higher ($P < 0.05$) in the patients with IDDM (35 ± 7) when compared to patients with PDPD and FCPD (26 ± 12 and 21 ± 4). There was no significant relationship between IA positivity and the presence or absence of microvascular complications such as retinopathy and nephropathy. To conclude, antibody response to bovine insulin therapy is comparable in three groups of young diabetics and there was no relationship between IA SDS and microvascular complications in them.

EFFICACY OF CONTINUOUS INSULIN INFUSION: WHOM AND WHEN?

A.M.Şengül, M.Sargın, N.Dinççağ, İ.Satman, K.Karşıdağ, F.Salman, Ş.Karadeniz and M.T.Yılmaz.
Division of Diabetes, Istanbul Faculty of Medicine, and Institute for Experimental Medicine, Diabetes Research Unit, Istanbul University, Istanbul-TURKEY.

This study was done to test efficiacy of continuous subcutaneous insulin infusion therapy (CSII) in 19 diabetic patients (13 chronic resistant type 1 and 6 newly diagnosed type 1 diabetics with ketoacidotic episode) whom we could not be able to achieve metabolic regulation with either conventional or multiple insulin injections regimen. CSII was performed in chronic resistant type 1 diabetic patients (mean chr. age 22±9 years, mean duration of diabetes 7.4±8.1 years) for 9 to 60 days (mean 38±16 days), in newly diagnosed type 1 diabetics (mean chr. age 21±8 years, mean duration of diabetes 1.5±1.4 months) for 14-40 days (mean 24±9 days). Before CSII therapy, daily insulin requirement was 0.88±0.24 IU/kg/day in chronic resistant type 1, 0.71±0.21 IU/kg/day in newly diagnosed type 1 diabetics. Insulin requirements of both group to obtain normoglycemia is reduced by 31% following CSII therapy and became 0.61±0.18 IU/kg/day; 0.49±0.13 IU/kg/day respectively. Although there were no significant side-effects, we observed local skin inflammation on catheter implantation area in one patient, hypoglycemic attack in another and a mild ketoacidosis in another one during CSII therapy. This study shows that CSII therapy is useful and effective in newly diagnosed type 1 diabetics with ketoacidosis, on the other hand in chronic resistant type 1 patients CSII therapy may lead to rebound phenomena at the end of therapy. However, we believe development of new techniques is needed to eliminate the inconvenience during the switch over to conventional insulin therapy from CSII therapy.

1323

RELIABILITY OF THE BLOOD GLUCOSE DATA AND ITS INFLUENCE ON GLYCAEMIC CONTROL DURING TREATMENT OF DIABETIC PREGNANT WOMEN

J.Wójcicki, J.Krzymień*, P.Ładyżyński, E.Jóźwicka*, J.Blachowicz and A.Czyżyk*
Inst. Biocyb. & Biomed. Eng., *Clinic Gastroent. & Met. Dis.MA, Warsaw, Poland.

Pregnant diabetic women have been classified as the most motivated group of patients for realization of the intensive insulin treatment. In order to check reliability of the data collected by this group of patients at home and those reported to physician during routine clinical assessment of the current metabolic control, a study of 20 pregnant diabetic women has been carried out.. Study group was treated by multi-injection technique with minimum 4 blood glucose (BG) measurements per day and clinical assessment every 3 weeks. All data were recorded automatically into memory of the Bayer glucometer M+ without knowledge of the patient. Comparison of the data reported by the patients and recorded by glucometer M+ led to following results: as an average for whole study group 181 values of BG per patient were recorded by glucometers and 239 BG values per patient were reported by patients. Generally only 53.9% of BG measurements recorded automatically by glucometers were reported by patients. Remaining values were changed (26.7%) or not recorded (19.4%) in the registration form. Influence of reliability of the data on realization of the intensive insulin treatment was assessed based on comparison of the glycaemic control described by "J" and "MBG" indices for both group of the data. Mean values of both indices were respectively: 35.0 and 137 mg/dl for recorded values and 26.2 and 127.0 mg/dl for reported values by patients. Much higher and statistically significant difference was calculated for an universal "J" index (related in part to BG variations). In conclusion obtained results indicated, that for highest motivated group of patients in diabetes treatment reliability of data reported to physician is low and could led to wrong realization of the treatment regarding to diet and insulin doses. An application of the direct transmission of the BG data from patient home to the control unit in the hospital could be in this case beneficial. Project related to evaluation of the efficiency of the stated above telematic transmission of the data has been started in 1996 and will be terminated in 1998.

1324

WHAT ABOUT ANTI INSULIN IMMUNOGENICITY ON A LONG TERM IN DIABETIC PATIENTS TREATED WITH IMPLANTABLE INSULIN PUMP?

P. Belicar, V. Lassmann-Vague, C. Alessis and Ph. Vague. Timone Hospital, Marseille - France.

Treatment with implantable pump for peritoneal insulin delivery is associated in some cases to an important increase of anti insulin antibodies (AIA). This increase does not seem to have a deleterious metabolic effect but it has to be carefully evaluated on a long term. We examined the evolution of AIA level and possible influence on metabolic and clinical parameters over a long implantation duration. In 20 type I IDD patients (m age ± SD=37y ± 13, m duration of diabetes = 19y ± 14) we studied AIA level before and until 54 months after implantation of a programmable pump (Minimed* M 2001) delivering insulin peritoneally (U 400 21 PH Hoechst*). We examined influence of discontinuous pump use on AIA level in 10 patients who temporarily stopped insulin pump treatment owing technical problems. AIA level (measured by RIA) observed 42 months after pump implantation was correlated with HbA1c, fasting plasma free insulin, incidence of hypoglycemia (n of glycemia < 65 mg/dl/month) and daily insulin requirements. AIA level significantly increased as soon as the 3rd month after implantation and this increase was sustained throughout the study period (M0=20 ± 17% (m ± SD) M3= 28±24%*,M12= 32 ± 29%* M24= 33 ± 29%* M36= 37± 25%* (n=12) M48= 42±19%* (n=8) M54=43±17%* (n=6)*p<0.05 vs M0). In patients who temporarily discontinued implanted pump use, AIA level tended to decrease 3 months after switching from IP to SC insulin infusion (35±25 % vs 30±19 % (NS)). But recovery of IP insulin infusion was associated with a significant rebound of AIA level (45± 25 % $p < 0.05$). In 10 patients, under IP treatment we did not observe any correlation between AIA level measured 42 months after pump implantation and concordant clinical and metabolic parameters. Despite what was suggested in some previous studies, AIA level do not tend to decrease over long term IP insulin.Moreover, discontinuation of IP insulin infusion has a stimulating effect. This rise of AIA level does not induce significant metabolic consequences.

1325

GLYCAEMIC CONTROL IN DIABETES MELLITUS WITH OPEN LOOP INSULIN INFUSION PUMP

A.Mutha, S.Bhatia, Sasoon General Hospitals, Poona, India.

Open Loop insulin infusion therapy for earlier and smooth control in uncontrolled diabetes was employed in patients with ketoacidosis, infections, pregnancy or going for surgery. All the patients underwent detailed physical examination & routine investigations for diabetic complications before they were put on infusion therapy. Out of 101 patients included in study 42 patients had ketoacidosis and infections or both. 7 were pregnant diabetics and rest were requiring earlier control for surgical intervention. Insulin infusion was started with Nikisso Myfuser Pump and 50 patients received intravenous while 51 received subcutaneous insulin infusion. Initial glycemic control was achived in 3 to 7 hours with minor side effects as headache, flushing, giddiness, sweating, leg cramps, etc. This was followed by intensive conventional therapy which made surgical intervention or discharge possible in 2 to 5 days. When subjected to statistical analysis, significant increase in insulin requirement was observed with longer duration of diabetes, poor previous control of diabetes, ketoacidosis and infections. In this study employing short term use of open loop infusion followed by intensified conventional therapy not only the initial glycemic control was smooth but it also facilitated earlier surgical intervention or control of infection and ketoacidosis. Application of correlation coefficient provided us with mathematical equations to predict dose of conventional insulin therapy from the initial insulin requirement.

1326

FACTORS PREDICTING CLINICAL REMISSION IN AUTOIMMUNE DIABETES MELLITUS

A Schölin, C Berne, E Schvarcz[1], F A Karlsson and E Björk.
Departments of Medicine, Uppsala University Hospital and Örebro Medical Centre[1], Sweden.

Objective: The aim of the study was to describe the course of clinical remission in adult patients with autoimmune diabetes mellitus treated with multiple insulin injection therapy and to identify factors predictive for the occurrence and the length of remission periods.
Material and methods: Sixtytwo consecutive adult patients, 43 men and 19 women, with a mean age of 26.5 years, were analyzed retrospectively. The patients, who had their diagnosis in 1986-1991, received treatment with multiple insulin injections. Remission was defined as maintenance of HbA_{1c} <6.5% with an exogenous insulin requirement of <0.4 U/kg/24 h for a minimum of one month.
Results: Thirty-eight (61%) of the patients entered remission between 1-18 months following diagnosis, with a peak prevalence at 5 months. The duration of remission was longer in males than females (10±12 vs. 2±3 months; p<0.01). Long duration of symptoms prior to diagnosis was associated with shorter remissions (p=0.05) and sub-normal serum bicarbonate levels at onset were predictive for both shorter (p<0.01) and less frequent remission periods (p<0.01). Age, BMI, HbA_{1c} and blood glucose at onset did not significantly influence the frequency or the duration of remission.
Conclusions: Multiple insulin injection therapy induces remission in a majority of adult patients with autoimmune diabetes mellitus. Gender as well as the length and extent of beta-cell demand prior to diagnosis influence the duration of the remission periods.

Insulin Therapy in NIDDM

1327

INSULIN THERAPY IN NIDDM: EFECTS ON THE ARTERIAL BLOOD PRESURE AND THE ENDOTHELIN-1 PLASMA LEVELS

L. Flores,J. Manzanares,M. Fernández, E. Esmatjes and R. Gomis.
Endocrinology and Diabetic Unit. Hospital Clinic. Barcelona - Spain.

Clinical and experimental evidences have suggested that insulin has hypertensive effect. Stimulation of vasoconstrictor endothelin-1(ET-1) secretion may be the involved mechanism. The aim of this study was to evaluate the possible effect of insulin treatment on arterial blood presssure (BP) and the ET-1 plasma levels in NIDDM. Patients: Seven NIDDM patients(5 males, and 2 females, mean age 64±7 years, diabetic duration 7±5years) admitted to hospital to initiate insulinization due to secondary failure of oral hypoglucemic drugs (SFOH) were studied. 24-hour arterial blood pressure monitorization (MAPA, SpaceLabs 90207) and body mass index(BMI) were measured before (time a), after three days (time b) and 1year(time c) after insulinization. Moreover ET-1 plasma levels were determined in times a and b. Results: Insulin treatment didn't produce any variation on systolic (124±11/120±7/127±13 mmHg in the times a, b and c, respectively) and diastolic (72±5/71±3/71±5 mmHg in the times a, b and c, respectively) 24-H BP. We found no difference in the systolic day/night differences, 8±11/7±7/11±13 mmHg, nor in diastolic day/night differences, 8±9/8±6/10±7mmHg in the times a, b and c, respectively. There were no significant differences among ET-1 plasma levels in the times a and b and no differences in the BMI were found. Conclusions: In our patients with SFOH 1) Insulinization did not induce an increase in BP in the short or medium term. and 2) Short term evaluation of insulinization did not result in any variation of plasma ET-1 levels. Therefore, our data do not support the hypothesis of exogenous insulin as a risk factor for hypertension.

1328

EFFECTS OF COMPLEMENTARY INSULIN THERAPY ON SERUM LIPID, LIPOPROTEINS AND APOPROTEINS

H.Vaverková, R.Chlup, D.Novotný and J.Bartek, Palacký University and Hospital, Olomouc, Czech Republic

The aim of this prospective study was to evaluate the effects of complementary insulin therapy, consisting of a bolus of 1 to 8 units of short-acting insulin before each meal (4-6x daily) and sometimes at 2.30 a.m., on concentrations of serum lipids, lipoproteins and apoproteins in type 2 (non-insulin-dependent) diabetic patients, unsatisfactorily controlled with longacting insulin 1-2x daily (INS 1-2x/d). A group of 34 type 2 diabetic patients (age 61,8±0,97 years, duration of diabetes 13.35±8.07 years, C-peptid 2.5±0,15 ng/ml) completed the study. After 8-10 weeks of complementary insulin therapy, the dose of insulin per day was reduced (49.6±22.5 U/d vs. 36.6±13.3 U/d, p<0.001) without significant change of the glycemic control (HbA1c 9,2±0,37 vs. 8,9±0,35, p>0,05). However, the number of proatherogenic and antiatherogenic lipoprotein particles was improved (decreased apo B: 1.7±0.52 g/l vs. 1.5±0.94 g/l, p<0.01, apo AI/Lp AI: 2.9±1.01 vs. 2.3±0.98, p<0.01 and increased Lp AI particles: 0.6±0.10 g/l vs. 0.7±0.12 g/l, p<0.0001) and BMI also decreased (29.4±4.28kg/m^2 vs.28.9±4.24 kg/m^2, p<0.05). Compared means±SD. These results demonstrate that complementary insulin therapy probably induces antiatherogenic lipoprotein changes in type 2 diabetic patients previously treated by INS 1-2x/d. Thus, this type of therapy should be used more often and start earlier, and should be preferred to longacting insulins. Supported by grants MZ ČR IGA 1617-3 and 0715-3.

1329

HYPOGLYCEMIC EFFECTS OF ORAL ADMINISTRATION OF REGULAR INSULIN BY SONICATED LIPOSOMES IN TYPE II DIABETES.W.de la Torre,R.Narváez,A. Guerrón,L.Ocampo,M.Arroyo,P.Pérez, and N. Bernal.Hospital de la Policía and SOLCA,Av.Mariana de Jesús, Quito-Ecuador.

We studied the hypoglycemic effects of Oral administration of Regular Insulin (1Qu/ml) incorporated in to Sonicated Liposomes (ORISL) to type II diabetic patients (n=14;age of 59+/-8 years);seven newly diagnosed and seven with 5+/-4 years of disease (Basal C peptide of 2,3+/-0.7 ng/ml;Hb A1 9,8/-1% and fasting blood glucose of 231+/-32 mg/dl)in a double blind placebo controlled fashion. Preprandial glycemia (n=8/48h) and glycosuria (n=4/48h) were determined at stage 1 (washing),stage 2 (administration of ORISL or placebo),and stage 3 (washing). Patients were hospitalizated and isocaloric diet (30 Kcal/Kg of weight:1825+/-155 Kcal/day) was given.
Body weight ramain stable in both groups throughout the entire study period. The glycosurias did fall at stage 2 and 3 (p=-0.05),and specially in stage 2 of the ORISL group (351+269 mg/l) that placebo group (566+/-318 mg/l)p=-0.05. Capilar glycemia fell in the same groups and same stage 2 (-16% vs -7%, Chi^2: 3,9;p=0.04).
In summary,hypoglycemic effects were observed associated to ORISL administration, however,its clinical significance remain preliminary. Miscellaneous circunstances such as preparation,storage,administration,biodisponibility,etc should be taken in to account when interpreting results of ORISL. It has been demostrated that selective hepatic insulinization occurs associated to use of liposomes as drug carriers. On this basis results are encouraging for continuing the search of an alternative way to subcutaneous administration of insulin.

1330

LONG TERM CONTROL AND WEIGTH GAIN AFTER INSULIN TREATMENT IN ORAL HYPOGLYCEMIC AGENTS FAILURE IN TYPE 2 DIABETES.
I.Goicolea,J.Pinies,G.Villar,Y.Alonso and J.Vazquez.Hosp.Cruces.Baracaldo.Spain.

Insulin therapy after oral hypoglycemic agents (OHA) failure in type 2 diabetes is controversial because a good metabolic control is difficult to achieve and side effects,as macrovascular risk factors can be worsened.The aim of the study was to measure the long term metabolic control achieved by insulin treatment in a routine management and the evolution of lipid,weigth and blood pressure. A hundred and three type 2 diabetic patients (mean age 63,6+/- 9,6 years,14+/- 8 years of mean diabetes evolution) were trasfered to insulin treatment because unaceptable glycemic control (74 patients) or metabolic symptons of hyperglycemia (28patients).After a year of insulin treatment ,Hba1c changed from 9,8+/-1,6% to 8,08+/-1,4% (p<0,001) and to 8,38+/-1,4% after 2 years (p<0,001).Mean weigth increment after one year was 5+/-3,8 kg (p<0,001) and 6,8+/-4,4 kg after 2 years (p<0,001).Weigth gain was related to Hba1c decrement after one (r=0,49 IC 95% 0,28-0,66) and two years (r=0,46 IC 0,31-0,73)(p<0,05) but not with insulin daily dosage.Hba1c reduction after one year was related to Hba1c at insulinization (r=0,70 IC 0,54-0,81)and inversely to insulin dosage (r=-0,36 IC-0,56-0,12). Plasma triglycerides were lowered by insulin treatment (p<0,05) but not plasma cholesterol or blood pressure. At the moment of insulin introduction,patients with metabolic symptons have higher Hba1c (p<0,01)and weigth loss (p<0,05) than patients without, getting a similar weigth and Hba1c after a year.After two, a new derangement in metabolic control (p<0,05)was found.Nor diabetic education,previous or after insulin therapy,nor glycemic autoanalysis has effect on postinsulin Hba1c.In conclusion ,a better but modest metabolic control can be reached with insulin treatment in OHA failure without other risk factors derangements.

1331

Comparative study of night time vs day time single dose Insulin in NIDDM.
Dr. A. K. Sarma, MD, IOC, Guwahati Refinery Hospital.
OBJECTIVE: To compare the efficacy of a single premixed Human insulin (Neutral: Isophane=30:70) before breakfast or dinner in Non Insulin Dependent diabetes mellitus(NIDDM) with secondary failure to oral hypoglycemic agents. DESIGN & METHODS: Fourty four NIDDMpatients were randomised to treatment with either pre-breakfast(Group A) or pre-dinner(group B) single dose Insulin alongwith Gliclazide 80mg daily. Metabolic profiles were done at 0,8,16 and 24 weeks. RESULTS: Glycemic control was improved significantly in both the groups after 6 months. Fasting blood glucose was significantly lowered compared with the baseline in both grouyps. The mean change ± SD in Group A was -60.5± 12.5mg% and in Group B -42.5± 9.5mg%, the reduction being more prominent in Group A than Group B($P < 0.001$). Glycosylated haemoglobin was lowered from 9.6± 1.6mg% to 7.2±1.4mg% in Group A($p < 0.002$) and from 9.5±1.5mg% to 7.8±1.6mg% in Group B(p 0001).Total serum cholesterol and triglycerides were also lowered significantly from the baseline value in both groups. The weight gain was more pronounced in the Group B(3.5±0.4Kg) than Group A(1.8±1.6Kg; A vs B, $p<0.001$) and the change was inversely correlated with initial weight. CONCLUSION: The night dose administration of premixed Human Insulin has better control on glucose level and serum lipids in NIDDM with combination therapy. Weight gain was more prominent in patients given Insulin at day time compared to the patients using Insulin at night time.

1332

TRANSIONS TO INSULIN THERAPY DURING A 25 YEAR PERIOD, IN IKEDA HOSPITAL
M. Kodama, K. Ida, M. Ohno and M. Ikeda.
Ikeda Hospital, Amagasaki, Japan
Ikeda Hospital has contributed to the care and management of diabetes for the past 25 years. Insulin therapy has made rapid advances in the fields of diabetes treatment and insulin delivery systems. Transitions to insulin therapy in Ikeda Hospital were investigated during this 25 year span. The number of diabetic patients that visit Ikeda Hospital for the first time, shows a marked yearly increase,119 in 1972 and 1889 in 1996, respectively. The ratio of insulin-treated diabetic patients to all diabetic patients was 16% in 1972, and 48% in 1996, respectively. The number of insulin-treated diabetic patients has increased markedly since 1990. In the majority of cases, insulin was the sole source of drug treatment until 1985. Thereafter, combination therapy of insulin and sulfonylurea increased. However, recently combination therapy of insulin with α-glucosidase inhibitors, Basen® and Glucobay®, has increased. With regard to types and daily insulin injections,intermediate insulin was injected once a day before 1980, in the majority of cases. Later, the frequency of pre-mixed and rapid-acting insulin usage, (twice a day) gradually increased. In 1990, the pen-type insulin delivery system, the Novopen®, was introduced in Japan, resulting in an increase in the frequency of intensive insulin therapy. Nowadays, 95% of insulin-treated diabetic patients use the pen-type system, and 70% of them inject insulin two or more times a day. The mean dosage of insulin has changed from 29U/day in 1972 to the present value of 18~20U/day. The mean age of insulin introduction has changed from 40 years in 1972 to 58 years in 1996. Mean fasting plasma glucose levels have changed from 170~180mg/dl in 1972 to 140~150mg/dl in 1996. The rate of progress in insulin therapy has been especially noteworthy these past ten years. It is imperative to manage diabetic patients correctly.

1333

Intensified insulin therapy improved metabolic control without changes of hypoglycemia in 64 insulin treated patients with non insulin dependent diabetes mellitus (NIDDM)

B. Mertes, I. Franke*, U. A. Müller*, K. Höffken*, F. J. van der Woude

V. Medizinische Klinik, Fakultät für Klinische Medizin Mannheim der Ruprechts-Karls-Universität Heidelberg; *Klinik für Innere Medizin II, Friedrich-Schiller-Universität Jena; Germany

Introduction: As a result of the successful treatment of patients with insulin dependent diabetes mellitus (IDDM) with intensified insulin therapy (IIT), many diabetes care centres started to apply IIT also on younger patients with NIDDM. However, hardly anything is known about the efficacy of such a insulin treatment. The aim of this study was to evaluate the long-term success of the treatment of 64 NIDDM patients with IIT. Patients and Methods: 64 insulin treated patients with NIDDM participated consecutively in a structured diabetes treatment and teaching programme for IIT [Scholz et al. 1992]. 83 % of them could be examined 16,7 ± 6,2 month later. Data before participation: age 52,8 ± 6,2 years, time since diagnosos of NIDDM 13,8 ± 5,6 years, HbA1c 9,95 ± 2,13 % (HPLC Diamat, normal range 4,5 - 6,3 %), body mass index (BMI) 27,57 ± 4,02 kg/m^2, number of blood glucose self controls (BGSC) 3,9 ± 8,7 per week, insulin dose (ID) 0,53 ± 0,17 IU/kg, injections 3,4 ± 1,3 per day, ID self adoption (IDSA) 0,5 ± 1,8 per week. Results: HbA1c levels decreased significantly (8,53 ± 1,63 %, p = 0,0001). BMI (28,5 ± 3,52 kg/m^2), BGSC (17,5 ± 10,5 per week), ID (0,67 ± 0,28 IU/kg), injections (4,5 ± 1 per day) and IDSA (4,6 ± 4,3 per week) increased significantly (p = 0,0001). The incidence of severe hypoglycemia remained unchanged (0,0077 per patient and year). Patients with good metabolic control (HbA1c < median minus one SD) changed significantly more often the ID and had significantly lower BMI than patients with bad metabolic control (HbA1c > median plus one SD). Conclusion: Younger insulin treated NIDDM patients were able to adopt the strategies of IIT and succeeded in improving their metabolic control. Patients changing more often their ID and heaving lower BMI achieved better merabolic control.

1334

EFFECTS OF INSULIN TREATMENT IN TYPE-2 DIABETIC PATIENTS: THE AUSTRIAN INSULIN INTERVENTION STUDY.

T.R. Pieber, G. Biesenbach, G. Kacerovsky, R. Mihaljevic, A. Siebenhofer, G. Schernthaner. Internal Medicine, University Graz, Linz, Vienna, Austria.

Aim: In a prospective multicenter intervention trial the effects of 4 different therapeutic strategies in Type-2 diabetic patients insufficiently treated with sulfonylureas alone were evaluated after one year.
Methods: 134 patients (age [mean±SD] 63±5 years, diabetes duration 12±4 years) with an HbA1c between 8-11% received randomly sulfonylureas + metformin (S+M), bedtime NPH insulin + sulfonylureas (I+S), premixed insulin twice daily (I) or premixed insulin twice daily + metformin (I+M).
Results: At present 93 patients reached 1 year, data of 86 subjects were evaluated.

Group	S+M (n=23)	I+S (n=21)	I (n=23)	I+M (n=19)
HbA1c Baseline	9.6 ± 1.0	9.6 ± 0.8	9.5 ± 1.0	10.0 ± 0.8
HbA1c after 1 year	8.9 ± 1.5	8.7 ± 1.6	8.3 ± 1.9**	8.2 ± 1.4**
Δ HbA1c	- 0.7	- 0.9	- 1.2	- 1.3
p value vs. Baseline	<0.001	<0.001	<0.001	<0.001

Mean ± SD, **p<0.01 vs. S+M

Metabolic control improved in all 4 groups, however, insulin given twice daily showed the most favourable outcome. 6 patients in the S+M group were switched to insulin after a mean of 8,2 months because of insufficient metabolic control. BMI increased in all groups (S+M: +0.5, I+S: + 1.1; I: +1.3; I+M + 1.1).
Conclusion: Insulin therapy has a better metabolic effect compared to metformin in type-2 diabetic patients insufficiently treated with sulfonylureas, however, this is achievement is hampered by an relevant increase in body weight in this group.

1335

COMPARISON OF THE EFFECTS OF TWO PREPARATIONS OF INSULIN IN NIDDM PATIENTS WITH SECONDARY SULPHONYLUREA FAILURE

DQ Wang,L Xu,JM Ren and YL Chen.Dept.of Endocrinology,Affiliated Hospital of Shandong Medical University, Ji Nan, P.R.CHINA

The aim of the study was to investigate the effects of Actropid HM (Novo Nordick A/S) and Regular Insulin (Qing Dao Biochemical Pharmaceutical Company). 16 cases of NIDDM patients with secondary sulphonylurea failure were divided into two groups which had no differences in age, sex, height, body weight, duration and severity (with homogenous Fasting Blood Glucose, 2-hour postprandial Blood Glucose and 24 hour urinary glucose) of the disease. During the clinical trial, all patients were administrated with stable diet calories and activity and were prevented from hypoglycemic agents such as Metformin and Glucobay etc. Patients of group A were injected Regular Insulin 12, 8, 8 unites, while group B were injected Actropid HM 12, 8, 8 unites, both subcutaneosly and 30 minutes before 3 meals each day. 3-5 days after, blood glucose control parameters (as we described in Chinese Medicine Journal in 1989;69:108) were evaluated. Blood glucose were assessed by One Touch II (Life Scan Company). The following data of the two groups:1.Fasting Blood Glucose(FBG); 2. 2 hour Postprandial Blood Glucose(PBG);3.Mean Blood Glucose (MBG); 4.Mean Amplitude Glycemic Excursions (MAGE);5.M-value (Modified Schlichtkrull's); 6.Mean Indices of Meal Excursion(MIME); 7.24 hour urinary glucose all had significant differences (P<0.05 or P<0.01 respectively). It was found that Actropid HM had better effects than domestic Regular Insulin in NIDDM patients with secondary sulphonlurea failure.

1336

OBESE NIDDM PATIENTS SHOW A PROGRESSIVE INCREASE OF INSULIN RESISTANCE THAT CAUSES SECONDARY FAILURE OF ORAL AGENTS. AE. Pontiroli, PM. Piatti, M.Pacchioni and R. Camisasca, Istituto San Raffaele, Università degli Studi di Milano, Milan, Italy

The pathogenesis of secondary failure of oral agents (SF) is still a matter for debate; a few studies have shown that SF is due to a progressive red-uction of insulin release in lean NIDDM, but not in obese NIDDM, sug-gesting that, in the latter, SF is due to a progressive increase of insulin resistance, likely mediated by obesity, ageing, duration of NIDDM, and chronic hyperglycemia, hyperlipidemia, hyperinsulinemia. To test this hypothesis, 46 obese (BMI 26-46 kg/m^2) NIDDM patients aged 35-65 yrs (15 on sulphonylureas, and 31 on insulin after being treated by diet and by oral agents) were evaluated for insulin resistance by the HOMA index (insulin/22.5$^{-\ln \text{glucose}}$). Patients on sulphonylureas were younger (49.9±2.8 vs 55.8±1.0 yrs, p<0.05) had shorter duration of NIDDM (5.7±1.5 vs 16.8±1.6 yrs, p<0.01), and showed lower fasting BG (6.3±0.4 vs 9.6±0.4 mmol, p<0.01), and lower HOMA (4.6 ±0.7 vs 9.8±1.4, p<0.01) than patients on insulin; BMI, fasting insulin and trig-lycerides were similar; HOMA and duration of NIDDM were the only significant risk factors for SF at multiple regression analysis. In 6 patients with a significant reduction of body weight, withdrawal of insulin and reduction of HOMA occurred, with no change of insulin levels. To evaluate the role of obesity per se, HOMA was calculated in 65 obese subjects with normal glucose tolerance, similar for age and for BMI, with obesity lasting <10 to >30 yrs; in these subjects increasing dur-ations of obesity were not accompanied by an increase of HOMA (ave-rage 3.2±0.3, p<0.01 vs NIDDM). These data suggest that a progres-sive increase of insulin resistance, linked to duration of NIDDM, is the main cause of SF in obese NIDDM patients, reversible after weight loss.

1337

CSII IN POORLY CONTROLLED NON-INSULIN-DEPENDENT DIABETIC PATIENTS

R. Vanamo, R. Härkönen: South Karelia Central Hospital, Finland.

It is evident that tight diabetic control can reduce cardiovascular morbidity and mortality in NIDDM patients. Insulin is often needed to achieve acceptable balance. The most efficient way to deliver insulin conventionally is multiple insulin injection therapy. Sometimes even this therapy seems to be ineffective. We treated 8 such resistant patients with continuous subcutaneous insulin infusion (CSII) using insulin pumps (Nordisk Infuser MII, Hoechst Infusor V100). Mean HBA1c decreased from 10.8 % to 8.4 % in 24 months. Mean body weight increased from 95.5 kg to 97.0 kg (BMI 34.7 – 35.6). Mean insulin dose increased from 86.5 U/d to 93.5 U/d. Only minor technical problems were met. The patients were very pleased with pump treatment. No ketoacidosis or hypoglycaemia was seen. One old patient died of myocardial infarct. One very obese patient was resistant to even this kind of intensified therapy.
Conclusion: CSII with insulin pump is an effective, reliable and handy way to treat the most insulin resistant NIDDM patients.

Coincidence of insulin-dependent diabetes mellitus and coeliac disease.

Karczewska K.,P.Jarosz-Chobot,G.Wiedermann T.Chorzelski,J.Sulej,B.Schneiberg,J.Porębska, A.Żabka,S.Ronczkowski,J.Kwiecień,A.Dyduch, J.Kasner.Silesian School of Medicine,Katowice School of Medicine in Warsaw,Poland.

The authors performed prospective assessment concerning IgAEmA serum presence in 201 children with IDDM chosen randomly among 600 patients from Diabetic Outpatient Clinic.In 7,5% of children serum IgAEmA were found.In 3,5% IgAEmA and villous atrophy were found.In these children the only clinical was growth deficit or/and body mass deficit.In children with IgAEmA and villous atrophy silent coeliac disease was diagnosed. These children were put on modified diabetic diet based on gluten-free products.Children with IgAEmA and normal intestinal mucosa will need observation and further genetic tests (a latent coeliac disease was diagnosed in them).

1339

ARTERIAL HYPERTENSION IN CHILDREN AND YOUTHS WITH TYPE I DIABETES MELLITUS

J.Vortherms, N.Lotz and R.Petzoldt, Herz- und Diabeteszentrum NRW, Bad Oeynhausen, Germany

Arterial hypertension contributes significantly to the progression of diabetic sequelae such as retinopathy and nephropathy. Early registration and therapy are thus extremely important for prevention. The frequency of arterial hypertension (1-3% in non-selected children) in diabetic children and youths, as well as its relationship to clinical parameters in this group as one at risk of cardiovascular diseases, should be examined. 110 children and youths (aged 7-18 years) with type 1 diabetes mellitus (diabetes duration 0-16 years) underwent ambulatory blood pressure monitoring (ABPM) under clinical conditions, with the cuff size especially adjusted. Measuring intervals of 20 minutes by day and 30 minutes by night were selected. The activity protocol and the actual times of falling asleep were taken as a basis for calculating the mean values. Patients with sleeping disorders were excluded from the evaluation. The results from the workgroup "pediatric hypertension" served as reference values. From 107 patients who could be evaluated (45 boys and 62 girls), 11 (10%) showed pathological mean RR values (mean value by day increased: n=11; mean value by night increased: n=11). The diastolic mean values by night correlated with the diabetes duration ($r=0.32$, $p<0.001$). A diabetic retinopathy or nephropathy existed in two of the patients in each case. In diabetic children and youths, increased blood pressure mean values occur during ABPM more often than in a non-selected group (10% vs. 1-3%). Due to the cardiovascular complications to be expected, prospective investigations must confirm these results and consistent therapy guidelines be drawn up.

1340

COELIAC DISEASE IN CHILDREN WITH IDDM.

EA Westman, GR Ambler, M Royle, P Greenacre, NJ Howard.
Royal Alexandra Hospital for Children, Sydney, Australia.

We aimed to assess the prevalence and characteristics of children with coeliac disease (CD) in a major paediatric and adolescent diabetes clinic. Children with IDDM and biopsy-proven CD, aged < 17.0 years were included and compared with control IDDM subjects without coexisting illness, matched for sex, age and duration of diabetes. 30 patients (22 females, 8 males, age range 7.4-16.9 yrs) with CD were identified from a total clinic population of 1148 (prevalence 2.6%). Two CD subjects had coexisting autoimmune hypothyroidism which was adequately treated. Age at IDDM diagnosis (overall mean ± SD 4.9 ± 3.4 yrs) and IDDM duration (7.2 ± 3.2 years) were similar in both groups. Age at diagnosis of CD was 8.7 ± 3.1 years (range 2.8 - 13.9 years), with the diagnosis being made 3.8 ± 3.1 years (range 0 - 10.8 years) after onset of IDDM. Adequate HbA1c and growth data were available in 26 CD subjects and their controls. Current HbA1c was 8.9 ± 1.2 % in CD subjects and 8.7 ± 0.8 % in controls (p=NS), with no differences between groups when analysed by age categories (< 13 and 13-17 years). HbA1c measured 8.6 ± 0.9% (range 6.8 - 10.3, n=19) in CD subjects on the determination closest and prior to coeliac diagnosis. These values were not different from overall total clinic HbA1c means of 8.6 ± 1.3 % (age 5 - 17), 8.8 ± 1.4 % (age 13-17) and 8.5 ± 1.2 % (age 5-12.9). Current height standard deviation score (SDS) was -0.15 ± 1.10 in CD subjects vs 0.12 ± 0.87 in controls, weight SDS was 0.26 ± 0.85 vs 0.51 ± 0.67 and BMI SD was 0.10 ± 0.73 vs 0.27 ± 0.63 (all p=NS). HbA1c and growth parameters were not influenced by either duration of IDDM or CD. Thus, in a large paediatric and adolescent diabetes clinic the prevalence of coeliac disease was 2.6 %. HbA1c and growth parameters were not different to controls; trends toward higher HbA1c, and lower SDS for weight, height and BMI in coeliac subjects were not significant.

1341

EARLY TUBULAR INVOLVEMENT IN CHILDREN WITH DIABETES MELLITUS TYPE 1.

A.Šufliarska, D. Michalková, E. Tomečková, A.Vasilenková, P.Ponťuch and L.Kovács.
Comenius University Bratislava, Slovak Republic

Early tubular alterations were studied in a cross sectional study of 44 children with diabetes mellitus type 1 (IDDM) and normoalbuminuria. The patients were divided into 4 groups according to the duration (5-10 respectively 10-15 years) and to the metabolic compensation (mean level of HbA_{1C} for the last 5 years < 9% respectively ≥9%). 32 aparently healthy children served as normal controls. From the overnight urine collections, the urinary excretion of epidermal growth factor (EGF), retinol binding protein (RBP) and N-acetyl-β-D glucosaminidase (NAG) were used as an index of renal tubular function. The ratio of EGF/creatinine in urine was significantly lower in all children with IDDM when compared to controls (p<0,0001). The excretion of EGF was lower in children with poor control of metabolic compensation, independently from the duration of the disease however the difference was not statistically significant (p<0,06). We did not find a significant difference between the groups when comparing the excretion of albumin, RBP and NAG. No significant correlation was found between glomerular and tubular functions. Under conditions of maintained glomerular integrity the decrease in urinary excretion of EGF could indicate a functional tubular damage caused by diabetes itself or be a sign of early renal involvement. Furthermore, the present study suggests that the predictive value of the other markers of tubular function is relatively low for evolution of diabetic nephropathy.

1342

HYPEROSMOLAR NON-KETOTIC DIABETES AFTER HEART LUNG TRANSPLANT IN A CYSTIC FIBROSIS CHILD.

R.M. Hillson. Hillingdon and Harefield Hospitals Uxbridge, England.

A 13 year old boy with cystic fibrosis, hepato-splenomegaly, and end-stage respiratory dysfunction had an orthotopic heart-lung transplant. Pre-transplant fasting glucose was 4.6 mmol/L, weight 32.9 Kg, height 1.35 m. Post-operative broncho-pneumonia was treated with antibiotics and pulsed methyl prednisolone. At discharge random glucose was 7.5 mmol/L. He was taking acyclovir, nystatin, taurine, ursodeoxycholic acid, cotrimo-xazole, colistin, pancrease, vitamins, frusemide, azathioprine and cyclosporin. Six weeks later he was re-admitted too weak to move, with severe malaise, nausea, thirst (drinking sugary fluids) and polyuria. Pulse was 132 bpm, blood pressure 107/61 mmHg. The transplanted organs appeared to be functioning well. Urinalysis showed a trace of ketones, pH was 7.3, venous plasma glucose 86.8 mmol/L, sodium 136 mmol/L, potassium 6.3 - mmol/L, urea 26.4 mmol/L. He was treated with continuous intravenous Actrapid insulin, 0.9% then 0.45% saline infusion, and eventually 5% dextrose infusion. Potassium was added to the infusions. Recovery was complicated by hyper-natraemia (162 mmol/L) and abdominal pain due to severe constipation. He remains well on 21 units of Mixtard 30 pen insulin twice daily. He weighs 35.2 Kg. Hyperosmolar non-ketotic diabetic states are rare in children.

1343

PREVALENCE OF DYSLIPIDAEMIA IN DIABETIC CHILDREN AND YOUNGS. EFFECT OF IMPROVED GLYCAEMIC CONTROL.

G.Carreras, A.Pérez, A.Caixàs, A.Caballero, J.Ordóñez-Llanos, J.Querol, JM Pou and A.de Leiva. HSCSP. UAB. Barcelona. Spain.

We studied the prevalence of dyslipidaemia in 264 children with insulin-dependent diabetes (IDDM) (53% males, mean age 13.8 ± 3.3 years [range 3 to 18], mean diabetes duration 4.0±3.8 years; mean HbA_{1C} 8.3 ± 2.1%) and in 321 control subjects (53% males, mean age 13.8 ± 3.4 years). In addition, we examined the effect of 3 months glycaemic control optimization on dyslipidaemia in a subgroup of 77 poorly controlled IDDM subjects. Cut-off for hypercholesterolaemia, hipoalfalipoproteinaemia and desirable LDL-cholesterol were the proposed by the National Cholesterol Education Program. Hypertriglyceridaemia was defined as the mean + 2 SD of control population

	IDDM patients	Control group
Cholesterol >5.2 mmol/L	20.3% *	6.5%
Triglycerides >1.5 mmol/L	5.0%	2.5%
HDL-cholesterol <0.9 mmol/L	7.4%	3.7%
LDL-cholesterol >2.9 mmol/L	44.5% *	15.3%

(* p<0.00001. χ^2)

Compared to control subjects, diabetic boys, but not girls, showed a higher prevalence of hypoalfalipoproteinaemia (12.9% vs 4.5% ; p<0.01; χ^2). After glycaemic control optimization (HbA_{1C} decreased from 9.3 ± 2.4 to 6.1 ± 1%. p<0.0001; paired t-test), the prevalence of dyslipidaemia was similar to that in healthy children. In conclusion, hypercholesterolaemia is common in children and young subjects with IDDM, but disappears after glycaemic control optimization.

1344

IS SENSITIZATION TO LATEX THROUGH INSULIN INJECTIONS A PROBLEM FOR CHILDREN WITH DIABETES ?

T. Danne, B. Niggemann, U. Wahn and B. Weber

Children´s Hospital, Humboldt University, Berlin, Germany

The potential induction of allergic sensitization to latex from insulin vial tops stimulated an investigation of the prevalence of specific IgE to latex in serum and the relationship to atopic disease in children with diabetes.

In a cross-sectional study, serum samples of 112 children with type I diabetes (age: 15 (5 -18 years); diabetes duration: 6 (1 - 14) years; median (range)) were investigated for total IgE, IgE screening for inhalational and nutritional allergens, and specific IgE to latex.

Specific IgE for inhalational and/or nutritional allergens was found in 42 (38%) children (atopic group). 7 children (6%) exhibited specific IgE (0.61 (0.40-3.84) kU/L) to latex in serum although none reported clinical symptoms of latex allergy. All latex sensitized children were found in the atopic group. This prevalence of latex sensitization of 17% (7/42) in atopic children with diabetes is comparable to the frequency described in atopic children without diabetes. These seven patients had higher serum total IgE levels (328 (113-1000) kU/l) than atopic patients without latex sensitization (n=35; 124 (24-857) kU/L; $p<0.05$) or patients without atopy (n=70; 33 (2-339) kU/l; $p<0.001$). No differences in age or diabetes duration were observed between either group.

Sensitization to latex is found exclusively in children with atopic sensitization and appears to be related to atopic disease and not to frequent contact to latex through insulin injections. However, atopic patients may be at risk for reactions secondary to latex from insulin vials and syringes.

1345

CHILDHOOD INSULIN-DEPENDENT DIABETES AND ST VINCENT DECLARATION

S. Paiva, A. Fagulha, L. Ruas, D. Rodrigues, L. Barros, C. Batista, M. Carvalheiro, M.M.A. Ruas. Department of Endocrinology, Diabetes and Metabolism, University Hospital of Coimbra, Coimbra, Portugal.

Aim: Based on the goals of the St Vincent declaration, a multidisciplinar team was created in our department in 1992, to provide treatment and follow-up for diabetic patients previously followed by our non specialised consultations. The goal of this work is to evaluate the results of this approach on the follow-up of this patients. Materials and Methods: We selected a population of 69 patients (38 M and 31 F) with a mean age of 13.8 ± 6.6 years upon diagnosis. In 42 cases the diagnosis was done before the creation of this team and after in the remaining 27. We evaluated and compare clinical and laboratorial parameters before and after the creation of this unit. Results:

	Diagnosis before 1992			Diagnosis after 1992
	<1992	1992-95	p	
Age at diagnosis (y)	12.0+7.4	___	___	16.6+3.9
Duration of diabetes(y)	5.5±5.4	9.4±5.4	<0.05	1.9±1.0
BMI (kg/m2)	20.0±2.0	23.6±2.1	<0.05	21.4±3.0
BP systolic (mmHg)	116.7±12.9	117.6±20.7	ns	115.0±10.9
BP dyastolic (mmHg	72.4±10.9	77.3±7.3	<0.05	71±15.2
HbA1c (%)	8.7±2.2	8.2±1.6	ns	7.6±1.5*
Retinopathy (%)	11.9	26.1	ns	0
Nephropathy (%)	2.3	23.3	<0.05	0
Hypoglycemia/pt/y		0.012		0.018+

*vs HbA1c before 1991, $p<0.05$; +vs hypoglycemia 1992-95, ns

Conclusions: After the creation of the multidisciplinary team an improvement in HbA1c values was observed in patients whose diabetes was identified before 1992, although not statistically significant. The lowest value of HbA1c was attained by diabetic patients diagnosed after 1992 (the difference vs the other group was significant). This multidisciplinar approach had ensured a better care of these patients and a more complete achievement of the goals of St Vincent declaration.

1346

INTENSIVE INSULIN THERAPY AS A METHOD OF CHOICE FOR TYPE I DIABETIC TEENAGERS ACTIVELY PRACTISING SPORT.

A.Majchrzak, D.Zozulińska and B.Wierusz-Wysocka. Poznań Diabetic Center, Poznań, Poland

The aim of the study was to evaluate the effectiveness of intensive insulin treatment in a group of type I diabetic teenagers with an active sport practice. For the study, we recruited 31 patients with type I diabetes, aged 11 - 19 years, with mean diabetes duration 5.8±4.0 years. 13 patients (group A) were treated with intensive insulin therapy, where doses of rapid acting insulin were adjusted according to planned meal and physical activity. 18 patients treated conventionally were used as control subjects (group B). We evaluated: fasting plasma glucose (FPG), mean blood glucose (MBG) and HbA_{1c}. Moreover, we estimated daily insulin demand and incidents of hypo- and hyperglycaemia (>15 mmol/l). We observed that patients in group A in comparison with group B presented better metabolic control of diabetes (HbA_{1c} 6.76±0.68 vs 8.70±1.71 %, $p<0.05$, FPG 6.56±0.90 vs 8.96±2.89 mmol/l, $p<0.05$, MBG 8.00±1.56 vs 11.13±3.68 mmol/l, $p<0.05$), significantly fewer incidents of hypoglycaemia (0.58±0.61 vs 1.63±1.44 incidents/week, $p<0.05$) and hyperglycaemia (0.38±0.05 vs 2.34±2.32 incidents/week, $p<0.05$). Our results suggest, that in the group of young patients with type I diabetes, who actively practise sport, intensive insulin therapy seems to be the method of choice.

1347

METABOLIC CONTROL AND SOCIAL SECURITY IN CHILDHOOD

O. Ramos, M. Ferraro and C. Cañada. Children Hospital Pedro de Elizalde, Buenos Aires, Argentina.

At the Nutrition and Diabetes Unit of the Elizalde Hospital , infant-juvenile diabetic patients are cared for. They come in 85% of the cases from the Urban Cone of Buenos Aires; many of them with serious economic difficulties. We part from the supposition that belonging to a Social Security means work for the father or person that is the economic support of the home, the possibility to go to the appointments and the better accessibility to the necessary expenses for the control and treatment. This would lead to a better metabolic control. With the purpose of evaluating this hypothesis, we took 186 infant-juvenile diabetic patients treated in our Unit and considered their dependence to some social cover , relating it with the metabolic control submitted in 1995(X of 2 or more HbA1c measured by ion capture, IMX Abbot).We classified the metabolic control as : very good(X under 7.2), good (X of 7.2 to 7.99),fair(X 8 to 8.99), bad (X over 9).70% of the patients did not have social cover. When classified, the patients of very good control, in half of the cases (47.83%) did not have social cover. This proportion increases in the measure that the metabolic control worsens (81.41% in patients with HbA1c equal or over 9%, p 0.01).The fulfilment to the programmed appointments was considered, and it was greater in patients with social cover (ns), and it was verified that the insufficient number of appointments (3 or less) is two times greater in patients without social cover. Of the 59 patient with Social Security, half (50.83%) had very good or good control and the rest of them (49.17%) had fair or bad control. The 127 patients without Social Security presented fair or bad control in 74% of the cases. Conclusion: The metabolic control in children and young diabetic is a variate related to situations of familiar risk, educational, emotional and economic. The accessibility to medication and to control elements should be a right for all persons carrying diabetes mellitus.

1348

EFFICACY OF TWO TIMES BASAL INSULIN INJECTION IN INTENSIVE INSULIN THERAPY OF IDDM CHILDREN

Y.Miki. Department of Pediatrics, University of Tokyo, Tokyo, Japan

In Japan, the incidence of IDDM is very low, therefore insulin therapy is not developed well. Many pediatricians still treat IDDM children by twice daily injection instead of multiple daily injection (MDI). Recently, MDI (four times injection is common in Japan) is recommended for prevention of diabetic complications. However, starting and continuing MDI (RRR/N) instead of twice injection is very difficult for IDDM children, because they must be taken to hospital for starting intensive therapy and they sometimes forget bed time injection when they feel sleepy. We tried three times injection for nine IDDM children ; mixture type insulin or regular plus NPH insulin before breakfast and supper, regular insulin before lunch. Two of nine children can not control their glucose level by four times injection. They can easily accept new treatment at out patient clinic, and their HbA1c level significantly decreased. It is likely that basal insulin level is more stable at twice basal insulin injection comparing single bed time insulin . The division basal insulin into two (three times injection treatment) is very useful for glucose control in IDDM children.

1349

MICROALBUMINURIA/CREATININURIA RATIO IN A POPULATION OF INFANT-JUVENILE DIABETICS.

O. Ramos, M. Ferraro and C.Cañada. General Children Hospital Pedro de Elizalde, Buenos Aires, Argentina.

At our Nutrition and Diabetes Unit the detection of microalbuminuria is done in a 12-hours urine nocturnal collection. Taking into account the uncertainty of the gathering in infant-juvenile patients with results no very reliable our **objective** is to validate the use of the microalbuminuria/ creatininuria ratio in a random urine sample in this population. First we determinate the microalbuminuria/creatininuria ratio in a normal population of 50 healthy children and adolescents with normal urine. The mean value found was 0.019 ± 0.003 (range 0.07 to 0.029). In 1995-96 , 354 microalbuminurias were done with the Randox inmuno-turbidimetic method; 120 samples were detected with pathologic values over or equal to 15 microg/min, on the other hand all these samples had a microalbuminuria/creatininuria ratio also pathologic over or equal to 0.03. From these, 23 patients registered 2 or more pathologic values (persistent microalbuminuria). All of them were postpuberal and had a duration of diabetes of over 4 years, (X age 17.46 , range 14.05 and 21.55 years; X duration 9.02, range 4.2 and 15.83 years). We **conclude** that the microalbuminuria/creatininuria ratio is useful in the infant juvenile diabetic patient. In our experience we value as pathologic a ratio that is distant more than 3 standard deviation from the mean of the normal population. Persistent microalbuminuria was not found previous to puberty or before 4 years of desease.

1350

PATIENT PREFERENCE FOR INSULIN LISPRO VERSUS HUMULIN R IN ADOLESCENTS WITH TYPE I DIABETES.

J. Holcombe, S. Zalani, V. Arora, A. Gill, S. Headlee. Eli Lilly and Company, Indianapolis, IN, USA

Insulin lispro (LP) (Humalog®), an analogue of human insulin, is faster absorbed and has shorter duration of action than regular human insulin (HR) (Humulin R®). At the end of a randomized, crossover, open-label, phase III study of LP versus HR involving 481 adolescents with diabetes, patients and their parents completed a questionnaire to explore their impressions of LP and HR. Pubertal males and females ages 9 to 18 years were studied. Treatment periods were 4 months, and consisted of either LP or HR before meals, in addition to NPH insulin given 1,2 or 3 times/day. More than 82% of patients and their parents indicated that LP made the patient's activities easier. Similarly, more than 85% of patients indicated their preference to use LP in the future ($p<0.001$).

	% of Patients Responding			
Patients' Responses to "Which rapid-acting insulin.."	**HR**	**LP**	**No Preference**	**p value**
made the patient feel better?	11.21	65.2	23.6	<0.001
made the patient's activities easier?	6.5	82	11.4	<0.001
did the patient like the best?	9.6	85.8	4.7	<0.001
is the patient likely to use in the future?	7.7	85	4.2	<0.001
Parents' Responses to "Which rapid-acting insulin.."				
better "controlled" the patient?	10.2	69.3	20.5	<0.001
made the patient's activities easier?	4.4	85	10.4	<0.001
is the patient likely to use in the future?	6.3	87.4	3.2	<0.001
made life easier?	3.2	85.3	11.6	

In conclusion, adolescent patients with diabetes prefer LP over HR for their pre-meal insulin, and their parents agree.

1351

OXIDATIVE STRESS AT ONSET AND IN THE EARLY STAGES OF DIABETES MELLITUS TYPE I IN CHILDREN AND ADOLESCENTS.

A.Carrascosa, E.Ruiz, M.Gussinyé, C.Dominguez.
Children's Hospital Vall d´Hebron. Autonomous University of Barcelona and Biochemistry and Molecular Biology Research Centre. Barcelona. Spain.

Oxidative cell damage (OxCd) was evaluated in 45 diabetic type I patients. Twenty-four were prepubertal 2-12 yr. old (PrpD), and 30 were adolescents and young adults 13-24 yr. old (AdD) without clinical symptoms of neuropathy, retinopathy and nephropathy. OxCd was evaluated one week after the onset of clinical symptoms in PrpD and 2-22 years after the onset of diabetes in AdD. The results were compared with those of 60 healthy age- and sex-matched controls.

Plasma values of malondialdehyde (HPLC evaluation), protein carbonyl groups and superoxide dismutase erythrocyte activity were higher than in controls at the onset of diabetes ($p<0.001$) and in the AdD group ($p<0.001$). In contrast, plasma values of alpha-tocopherol, ß-carotene, erythrocyte glutathione peroxide activity and glutathione erythrocyte content were lower than controls at the onset of diabetes ($P<0.002$) and in the AdD group ($p<0.002$).

In summary, our results show that an imbalance between oxidant-antioxidant status is already present at the clinical onset of diabetes in children and that this imbalance continues thereafter resulting in increased oxidative stress in diabetic patients . The clinical significance of this higher oxidative damage in the development of vascular complications in type I diabetic patients remains to be elucidated.

1352

COMPARATIVE STUDY OF INSULIN LISPRO AND REGULAR INSULIN IN 481 ADOLESCENTS WITH TYPE I DIABETES.

J. Holcombe, S. Zalani, and V. Arora. Eli Lilly and Company, Indianapolis, Indiana, USA.

Insulin lispro (LP) (Humalog®), an analogue of human insulin, is more rapidly absorbed and has a short duration of action compared with regular insulin. The safety and efficacy of LP and regular human insulin (HR) (Humulin R®) were compared in 481 pubertal children (mean age 14.9, range 9.1 - 18.9 years) with Type I diabetes in a multinational, crossover, randomized, open-label study. Males and females who had achieved at least Tanner Stage II puberty were studied. Treatment periods were 4 months, and consisted of either LP or HR before meals, in addition to NPH insulin given 1,2 or 3 times/day. Eight-point glucose profiles were measured at home before each visit. After breakfast, the 2 hour post prandial (2h PP) glucose values were 9.7 mM and 10.6 mM during treatment with LP and HR, respectively ($p<0.001$). After the evening meal the 2 h PP glucose values were 8.6 mM and 9.3 mM for the LP and HR groups, respectively ($p=0.003$). After breakfast, the changes in the 2h PP, as a percentage of the premeal glucose, were 0.4% and +17.5% during LP and HR treatments, respectively. Similarly, after dinner the percent changes in 2h PP glucose values were -10.9% and +10.4% during LP and HR treatments, respectively ($p<0.001$). Although HR, compared with LP, lowered glucose values at bedtime, 3 am, and fasting ($p<0.005$), the hypoglycemia rate from midnight to 6 am was lower during treatment with LP compared with HR ($p<0.001$). The number and types of adverse events did not differ between the treatment groups. In conclusion, insulin lispro reduces nocturnal hypoglycemia and improves post-meal glucose control in children ages 9-18 years.

Combination Therapy

1353

GLYCAEMIC CONTROL OF POORLY CONTROLLED INSULIN TREATED TYPE II DIABETIC PATIENTS IS IMPROVED BY METFORMIN THERAPY.

A.C.J. Robinson, D.G Johnston, S. Robinson, J. Burke and R.S. Elkeles. Unit of Metabolic Medicine, Imperial College School of Medicine at St. Mary's, London.

Secondary failure to oral hypoglycaemic medications is common and leads to insulin therapy, often resulting in weight gain and sub-optimal glycaemic control. We hypothesised that, in this group of diabetic patients, the addition of metformin to their insulin regimen would improve glycaemic control. A double blind, placebo controlled, crossover study was employed; after a 6 week run-in period recruited patients were randomly allocated to receive either metformin 1 gm bd. or placebo for twelve weeks at which point crossover took place. At baseline and at six week intervals during the treatment periods fasting venous blood was taken for HbA1c, glucose, triglyceride, HDL and total cholesterol measurement. Results are given as medians *(quartiles)* and Wilcoxon-rank-sum tests were used for statistical analysis after an order effect was excluded.

Baseline characteristics: **n=19**, **age 64yrs** *(57&67)*, **BMI 28kg/m^2** *(26&31)*, duration of diabetes 14 yrs, **total cholesterol 5.7mmol/l** *(5.2-6.3)*, **HbA1c 8.6%** *(8.3&9.8)* and fasting plasma **glucose 10.5mmol/l** *(8.1&14.9)*. Significant improvement in glycaemic control was seen after metformin treatment; median fall for **HbA1c 0.9%** *(0 &1.9)* $p<0.003$, and for fasting plasma **glucose 4.4 mmol/l** *(6.7&-0.2)* $p=0.008$. Furthermore total cholesterol improved with a median fall of 0.5mmol/l $p=0.02$. There were no significant changes during the placebo period. We conclude that metformin is an effective treatment for sub-optimally controlled insulin treated Type II diabetes. The striking fall in fasting glucose as compared to the more modest fall in HbA1c suggests that the principal effect is to reduce hepatic glucose output.

1354

USEFULNESS OF COMBINATION THERAPY WITH SULFONYLUREA AND α-GLUCOSIDASE INHIBITOR IN NIDDM.

T.Iijima,T.Makino,H.Takahashi,Z.Miyazaki,H.Amano K.Furukawa,K.Ohmori,M.Uchida,T.Takahashi and S.Kuribayashi. Urayasu Hospital of Juntendo Univ and Toukatsu Nambu Voglibose Resurch Group.Chiba 279,Japan.

Purpose: Effect of α-glucosidase inhibitor (Voglibose) alone or combined with sulfonylurea (SU) therapy in patients with NIDDM in whom SU therapy had failed was investigated.

Methods; Subjects were 71 patients with NIDDM in failure glycemic control under SU therapy. Concerning the administration method, initially, SU were discontinued or halved of daily doses. After 2 weeks administration of Voglibose alone or with SU was started. Patients were followed 20 weeks. Criteria for the effect of reducing the dose of SU were follows; SU was no longer required, the dose of SU was decreased or the SU could be changed another SU with a weaker activity.

Results; A reduction of SU was obtained highly in 76.1% (54of 71 patients). Levels of postprandial blood glucose, HbA1c and 1,5AG improved significantly from 223.4±59.5 to 184.9±53.6mg/dl from 7.8±1.5 to 7.2±1.2% and from 7.0±6.3 to 9.8±7.6μg/ml respectively.

conclusion; These findings suggest that this regimen is useful as a therapy for reducing the dose of SU, father moderate the exhaustion of pancreatic ß cell.

1355

GLYCOSYLATED HEMOGLOBINS ARE BETTER ON COMBINATION ORAL THERAPY WITH OR WITHOUT EVENING OR NIGHT INSULIN THAN ON TWICE DAILY MIXED INSULIN. D. Bell and M. Mayo. The University of Alabama at Birmingham, Birmingham, Alabama.
100 of 130 C-peptide positive non-insulin-dependent diabetes mellitus patients on insulin were successfully transferred to combination oral hypoglycemic therapy with glyburide and metformin. (A) - a primary failure rate of 23%. Secondary failure occurred in 17 patients (17%) after a mean of 6.4 months (range 2-16 months). Two patients restarted insulin because of cost. Of the primary failures 6 were due to side effects, 6 were successfully managed on combination oral therapy plus night or evening insulin (B)and 16 on twice daily insulin with Metformin (C). Of the secondary failures, 12 were controlled on regimen B and 5 on regimen C. There was no difference in C-peptide regimen levels between regimens A,B,or C. Glycosylated hemoglobin levels (Al N5-8%) were significantly less on A (9.8v8.3% p=0.0001), B(11.2%v9.7% p=0.001), and less on C(10.3% v 9.8% p=0.45) when compared with twice daily insulin alone. Conclusion: Improvement in glycosylated hemoglobin in insulin-utilizing non-insulin-dependent diabetes mellitus patients can be obtained on combination oral therapy alone or on combination oral therapy with once daily evening or night insulin

1356

THE COMBINATION OF INSULIN AND METFORMIN IN TREATMENT OF NON-INSULIN DEPENDENT DIABETES MELLITUS (NIDDM)
A. Chaudhuri, R. Tomar, P. Mohanty, E. Szudzik, A. Bandyopadhyay, M. Arian, K. Thusu and P. Dandona. State University of New York at Buffalo, Buffalo, N.Y.

Metformin is used alone or in combination with sulphonylurea in the treatment of non-insulin dependent diabetes mellitus (NIDDM). We have now examined whether in NIDDM 1) metformin with insulin can safely cause a fall in HbA_{1c} to 7% or less and 2) if this may result in weight loss and lower insulin dose when compared to insulin treatment alone. Forty NIDDM patients on insulin on their first visit to the Diabetes Center were identified by retrospective chart reviews of all the patients seen in the past year. These were divided into groups who were on insulin (Group I) or insulin + metformin (Group 2) at the most recent visit. Group 2 was subdivided into those with BMI of either ≤ 30 (Group 2A) or > 30 (Group 2B). Blood glucose, HbA_{1c}, insulin dose and weights were collected from their initial and most recent visit. HbA_{1c}decreased from $10 \pm 2.7\%$ to $7 \pm 1.1\%$ ($p < 0.01$) in Group 1 and from $9.8 \pm 2.1\%$ to $7.2 \pm 1.4\%$ ($p < 0.01$) in Group 2. However, the magnitude of decrease in HbA_{1c} was not different between the two groups. Total insulin dose increased from 45 ± 16 units/day to 56 ± 15 units/day ($p < 0.05$) in Group 1 while it decreased from 80 ± 45 units/day to 73 ± 38 units/day in Group 2. The median increase in insulin dose was 8 units in Group 1 while the median decrease was 3 units ($p < 0.05$) in Group 2. Similar decreases were noted in Group 2A. Individuals in Group 1 increased their weight from 75 ± 8.6 kg to 77.7 ± 9 kgs ($p < 0.01$) while weight decreased from 100.4 ± 23.6 kg to 98.6 ± 22.7 kgs in Group 2. A decrease in weight was seen even in Group 2A. The increase in weight was 3 ± 3.3 kgs in Group 1 while weight decreased by 2 ± 4 kgs in Group 2 ($p < 0.01$). We conclude that insulin + metformin is safe and is as effective as insulin alone in improving glycemic control in NIDDM obese and non obese patients. However, it lowers insulin dose and prevents weight gain which might be of importance in lowering the cardiovascular risk factors in these subjects.

1357

EFFECTS OF THREE DIFFERENT THERAPEUTICS REGIMENS ON GLUCOSE AND C-PEPTIDE RESPONSE TO A MIXED MEAL IN NIDDM PATIENTS.
A.C.Santos, M.F. Gonçalves,T.Dimetz, H.Gazzola and M.B.Gomes. State University of Rio de Janeiro, Rio de Janeiro, Brazil.
The effects of 3 different therapeutic regimens (2 months for each) with glicazida 320 mg (G), G and insulin (GI) and insulin (I) on glucose and C-peptide response to a mixed meal (317 Kcal: 55.7% CHO, 14.8% protein,29.5% fat), body weight (BW) and metabolic control was evaluated in 25 NIDDM patients (18 F), age 46.1 ± 7.6 yr, diabetes duration 10.6 ± 9.6 yr. During phase2 (GI) 6-10 U of NPH insulin (bedtime) was added, at phase3 (I) only insulin was given.The following parameters of C-peptide and glucose curve were studied: FBG, basal C-peptide (BC-p), area under the curve for glucose (AUCg) and C-peptide (AUCp), peak value for glucose (VPg) and C-peptide (VPp). Stastical analysis was done by Friedman and Wilcoxon test (Bonferroni correction). The results expressed in median (range) were:

	G	GI	I
BW (Kg)	64,8 (43,1 - 98,9)	66,7*(42,8-101,4)	65,8(42,7-104)
FBG(mg/dl)	242,5(138,5-449,5)	155 ** (86-384)	189(85-358)
Vpg(mg/dl)	290(183-535)	214*** (150-448)	278(147-479)
AUCg($x10^4$) mg/dl.min	3,0(1,18-5,97)	2,1(1,46-5,12)	2,8(1,63-5,2)
BC-p(ng/ml)	2,05(0,4-3,8)	1,9(0,6-4,8)	1,2(0,1-4,9)
Vpp(ng/ml)	2,97(0,6-5,9)	2,72(0,7-8,2)	2,54(0,7-8,2)
AUCp (ng/ml.min)	311,25 (50,4-581,7)	256,8 (56,25-648,75)	203,25 (54,75-669,75)
NPH(U)		12 **** (12-30)	18(11-60)
HbA1C(%)	9,2(6,8-13,8)	8,8(5-12,5)	8,8(5,5-13,4)

*p<0.005vsG;**p<0.001vsG and p=0.01vs I;*** p<0.002vsG and I, ****p<0.0001vsI

We concluded that combined therapy resulted in better glicemic response to a mixed meal without increment in C-peptide and with a significant weight gain.

1358

EVALUATION OF GLYCAEMIC CONTROL IN NIDDM PATIENTS TREATED WITH ORAL HYPOGLYCAEMIC AGENTS VERSUS COMBINATION WITH NPH INSULIN.
P S van der Wal, A. Scheen, L. VanGaal, H. Schmitt, R.J. Heine and the SWIM study group, Amsterdam, The Netherlands; Liege, Antwerp, Brussels, Belgium.

In a multicentre study we compared the fasting and 2 hours post breakfast blood glucose (FBG and PBG) and HbA1c levels with the weighted mean blood glucose level as calculated from home blood glucose monitoring (HBGM) in 79 NIDDM patients (38 males) who were switched from oral (15mg glipizide and 1800mg metformin daily; ORAL) to combined oral and bedtime-NPH-insulin (COMB) therapy. Mean age was 59.6 (SD 8.4) years, diabetes duration 10.3 (11.3) years. On ORAL therapy, HbA1c was 1.37 (0.31) times the upper limit of the laboratory reference range (ULR), mean FBG 9.9 (2.2), PBG 11.8 (2.9) and mean 24 hours HBGM level 10.3 (2.4) mmol/l. On COMB, mean HbA1c was 1.28 (0.26) ULR, mean FBG 7.7 (1.8), PBG 9.8 (2.8) and mean HBGM level 9.0 (2.3) mmol/l. In a linear regression analysis, to evaluate the effect of the therapeutic regimen on glycaemic parameters, we used HBGM-value as dependent variable revealing a beta of 0.76 (CI 0.57 - 0.95) for FBG explaining 49.9% (R^2) of the variance of HBGM in ORAL treated subjects versus a beta of 0.55 (0.36 - 0.74) explaining 36.2% when on COMB treatment. PBG explained 46.4% of the HBGM variance (beta=0.56) when on ORAL treatment and 58.3% (beta=0.45) after transfer to COMB treatment. The same regression analysis revealed lower values when comparing HbA1c with HBGM: beta=5.0 with R^2 33.6% in ORAL and beta=3.6 with R^2 33.2% in COMB treatment. With HbA1c value as dependent variable R^2 was lower than 22% for all glycaemic variables. We conclude that in NIDDM patients with secondary failure to ORAL treatment the fasting and two hours post breakfast blood glucose levels reflect glycaemic control as measured with HBGM but not with HbA1c (gold-standard). When bedtime insulin is part of the therapeutic regimen, post load blood glucose levels best reflect overall glycaemic control as assessed with HBGM but not with HbA1c. Concordance between HBGM and HbA1c values is low in these NIDDM patients on ORAL and on COMB treatment.

1359

COMBINATION THERAPY WITH HUMAN INSULIN AND SULFONYLUREA IN INDIAN NIDDM.

V Mohan, Madras-India, CS Yajnik, Pune-India, JK Joshi, Novo Nordisk India, LN Jorgensen, JP Sorensen, Novo Nordisk A/S - Asia-Pacific Centre, Singapore.

The aim of this study was to compare three different treatment regimens in 66 Indian NIDDM patients with insufficient glycemic control on maximal doses of sulfonylurea alone. The following regimens were administered for a period of 6 months:

A: Insulin only (Mixtard® 30 HM twice daily). (n=25)

B: Sulfonylurea plus insulin (bedtime Monotard) (n=23)

C: Sulfonylurea plus insulin (morning Monotard) (n=18)

Baseline values (mean, SD) were as follows:

Age: 52 years (7.7), duration of diabetes: 9 years (4.6), body weight: 64 kg (9.9) , HbA_{1c}: 10.2 (1.4).

Results after 6 months:

	A	B	C	P value
Insulin dose	57 U/d	18 U/d	22 U/d	0.0001
HbA_{1c}, change	-1.5%	-1.5%	-1.8%	0.800
Weight, change	+2.8kg	+2.4kg	+2.2kg	0.696

Conclusion: Full insulin substitution as well as the two modes of combination therapy resulted in comparable improvements in metabolic control, and comparable weight gains, in Indian NIDDM patients with unsatisfactory control on sulfonylurea only.

1360

BEDTIME VERSUS PRE-PRANDIAL INSULIN THERAPY FOR SULFONYLUREA FAILURE IN NIDDM.

G. Perriello, S. Pampanelli, L. Epifano, A. Di Vincenzo, G. Calabrese, P. Brunetti, G. B. Bolli. University of Perugia, Perugia, Italy.

It is presently controversial whether bedtime insulin (BI) or multiple insulin (MI) therapy is more effective in NIDDM patients, in whom oral hypoglycemic agents have failed. To assess the effects of BI vs MI on glucose control and metabolism, and insulin sensitivity (2-step, hyperinsulinemic-euglycemic clamp, 60 and 240 $pmol \cdot m^{-2} \cdot min^{-1}$), we studied 14 NIDDM patients (10M, 4F; BMI=27.2±0.8) according to a randomized cross-over design. Following a run-in period of 2 weeks, during which body weight (BW) and fasting plasma glucose (FPG) remained stable, NIDDM subjects were assigned to BI or MI for 3 months and subsequently switched to the other insulin regimen for other 3 months. Both treatments decreased FPG (BI, -4.4±0.8 and MI, -3.2±0.4 mmol/L) and hepatic glucose production (3-^{3}H-glucose, BI, -2.61±0.79 and MI, -2.08±0.32 $\mu mol \cdot kg^{-1} \cdot min^{-1}$) to a similar extent (p=NS). However, mean 24-h plasma glucose concentration (BI, 12.1±0.7 vs MI, 9.2±0.6 mmol/L, $p<0.05$) and Hba_{1c} (BI, 8.6±0.3 vs MI, 7.2±0.2 %, $p<0.05$) were significantly lower after MI. Moreover, 24-h plasma insulin concentration (BI, 156±12 and MI, 171±12 pmol/L), body weight (BI, 79±2 and MI, 80±2 kg) and insulin sensitivity (M, 60 $pmol \cdot m^{-2} \cdot min^{-1}$, BI, 4.43±0.53 and MI, 4.95±0.70 $\mu mol \cdot kg^{-1} \cdot min^{-1}$; 240 $pmol \cdot m^{-2} \cdot min^{-1}$, BI, 28.69±1.50 and MI, 27.49±2.04 $\mu mol \cdot kg^{-1} \cdot min^{-1}$) did not differ after BI or MI (all, p=NS). In conclusion, MI can be considered a better treatment in sulfonylurea failure NIDDM, because determines a greater improvement in glucose control without inducing further hyperinsulinemia and increase in body weight.

1361

EFFECTS OF HALVING SULPHONYLUREA DOSAGE IN CHINESE NIDDM PATIENTS ON INSULIN-ORAL HYPOGLYCAEMIC AGENT COMBINATION THERAPY FOR SECONDARY DRUG FAILURE

C.C. Chow, J.K.Y. Li, G.T.C.Ko, V.T.F. Yeung, J.C.N. Chan, L.W.W. Tsang, L.N. Jorgensen* and C.S. Cockram. Diabetes and Endocrine Centre, Prince of Wales Hospital, Hong Kong; * Novo Nordisk A/S, Asia Pacific Centre, Singapore.

Recent evidence suggests that in NIDDM patients with secondary drug failure, insulin-oral hypoglycaemic agents (OHA) combination therapy may achieve similar glycaemic control at a lower insulin dose and with less weight gain compared to insulin therapy alone. The minimum effective dose of sulphonylurea and the long term efficacy of combination therapy, however, remain unanswered. In a 2-phase randomized, open, parallel trial, we evaluate the effects of halving sulphonylurea dosage in 66 Chinese NIDDM patients on combination therapy. After a run-in period of 12 weeks whereby subjects already on combination therapy were reviewed and stabilized, they were randomized to either maximal sulphonylurea dose (Full-SU) or half the maximal dose of SU (Halved-SU) for a period of 4 weeks without change of insulin dosage, followed by a 20-week insulin re-adjustment phase. 47 subjects (duration of DM 12.5±4.7 years and on insulin-OHA combination therapy for 14.7±15.6 months) were included for final analysis. Both groups (25 Full-SU, 22 Halved-SU) had similar basal glycaemic control (FPG 7.8±3.7 vs 7.5±2.2 mmol/l, NS; HbA_{1C} 8.5±1.2 vs 8.6±1.1%, NS) with slightly lower basal bedtime insulin requirement for the Full-SU group (12.8±6.0 vs 16.7±6.8 U p=0.037). At the end of 4 weeks, the 2 groups did not show any significant difference in terms of glycaemic control, body weight parameters, blood pressure and lipids compared to baseline. In the subsequent 20-week insulin re-adjustment phase, neither group differed in their insulin requirement to achieve similar glycaemic control to baseline (increment 1.64±2.96 vs 3.10±4.22, NS). In conclusion, we confirm our previous report of the efficacy of low dose insulin-OHA combination therapy (mean Insulatard® dose of 16 U bedtime) to achieve good stable glycaemic control for a extended mean duration of 24 months. Halving the dose of sulphonylurea after stabilization of combination therapy had no deleterious effect on glycaemic control or other cardiovascular risk factors during a 6-month follow-up.

1362

Meal-time insulin versus glibenclamide in type 2 diabetic patients with diet failure.

D.K.G. Andersson (1), A. Kempe (2), B. Vessby (3) and C. Berne (4). University of Uppsala (1,3,4) and Härnösand Hospital (2), Sweden.

We compared a short-acting meal time insulin regime with sulfonylurea treatment during 12 months in a group of newly detected type 2 diabetic subjects, aged < 70 years at diagnosis and not adequately controlled on diet alone. The primary objective of the study was to evaluate parameters of glycemic control, insulin secretion and insulin sensitivity. A secondary objective was to study the feasibility of the treatment regimes including side effects and tolerability. The study was approved by the regulatory authorities and the local ethics committee. Fifty-six patients with persistent fasting blood glucose values ≥ 6.7 mmol/l were recruited from two centres. The subjects were randomised to either short-acting meal time insulin or glibenclamide. At randomisation there were no significant differences between the two groups regarding age, sex distribution, body mass index, waist-hip ratio, HbA1c or fasting C-peptide values. After one year, 52 patients had completed the study. Both treatments reduced HbA1c (insulin 1.16 % versus glibenclamide 0.90 %) and increased weight (1.68 kg versus 1.96 kg). In intention to treat analyses no differences could be seen between the insulin or glibenclamide treated patients in respect to HbA1c (6.47 % versus 6.51 %) and glucose values before and during a 75 g OGTT. Fasting C-peptide values were lower in the insulin treated group (p=0.05), but not so after 120 minutes in the OGTT. Insulin sensitivity as measured with an intravenous insulin tolerance test was not significantly different between the groups. Urinary albumin excretion tended to be lower in the insulin-treated group, but not in the glibenclamide group (p=0.19). No serious adverse events were reported and both treatments were equally well accepted. At the end of the study all patients felt motivated to continue the regimes to which they had been randomised. In conclusion, both short-acting insulin and glibenclamide regimes produced similar results concerning glycemic control and insulin sensitivity with a tendency for the insulin treatment to be associated with lower fasting C-peptide values. A longer follow up or a larger study cohort will probably be needed to further evaluate these findings.

1363

IGF-I AND INSULIN: LONG-TERM CO-THERAPY IN NIDDM.
B.C. Hansen, N. Levin, B. Taylor, and N.L. Bodkin. Obesity and Diabetes Research Center, University of Maryland, Baltimore, MD and Genentech, Inc., San Francisco, CA, USA.
The potential value of the treatment of NIDDM patients with recombinant human insulin-like growth factor-I (IGF-I) and insulin has been suggested by the reports of possible abnormalities in the IGF-I axis of NIDDM patients and by reports of improvements in insulin sensitivity in IGF-I treated subjects. In the present study, we have examined long-term treatment of NIDDM by IGF-I and insulin co-therapy in nonhuman primates with spontaneous type 2 noninsulin dependent diabetes using the highest effective dose found in humans to be associated with minimal side effects (40 µg/kg b.i.d.). This dose produced a 2.5 fold rise in fasting plasma IGF-I levels (269±26 ng/ml vs 673±38 ng/ml, $p<0.0001$), and no change in IGF-I binding protein 3 (IGFBP-3) as measured by RIA. Simultaneously, insulin doses (mean±SE: 44.4±8.3 U/day or 4.6±0.8 U/kg/day) were reduced and adjusted as needed to maintain a consistent level of moderate glucose control. At weeks 18-24 of treatment, insulin dose was stable at 26.1±7.2 U/day or 2.8±0.7 U/kg/day. This average reduction in insulin dose (-32.2%) resulted in no significant increase in fasting plasma glucose levels (basal vs weeks 18-24: 231±21 vs 239±21 mg/dl; p=n.s.) and no change in body weight. Maintenance of the reduced insulin dose level after termination of IGF-I treatment at 26-30 weeks showed a significant rise in fasting plasma glucose, 24 hour urine glucose, triglycerides and other parameters. We estimate that rhIGF-I can be used as an adjunct to the clinically indicated insulin dose and reduce overall insulin requirement by 20 to 25% without reducing glucose control. Importantly, wide variation was seen in IGF-I efficacy, with some monkeys requiring nearly their full pretreatment insulin dose and others successfully maintained with a 70% reduction in insulin dose.

1364

What kind of patient will benefit from treatment with a combination of premixed insulin b.i.d. and sulfonyulrea?
L. Landstedt-Hallin, P Arner, J Bolinder, H Olsen, M Carlsson, L Groop and the SISU Research Team. Danderyds and Huddinge Hospitals, Stockholm and Dept of Endocrinology, University of Lund, Malmö, Sweden, Finland and Norway.

Although the combination of insulin (INS) and sulfonylurea (SU) has been used in the treatment of NIDDM for long, there is no information available on which patient might benefit from the combination. To address this question, 175 patients (62 F/ 113 M; age 59 ± 9 yrs, BMI 26.8 ± 3.0) in a randomized double-blind multicenter study (SISU, 8 centers) treated with glibenclamide (GB) were started on premixed insulin (Isuhuman Comb 25/75, Hoechst AG, Germany) b.i.d. (30 ± 16 U) in addition to previous GB treatment (10.5 mg/d) for 4 mo. During this period, fasting BG (13.1 → 8.7 mmol/l) was decreased by 33%, HbA_{1c} (9.63→ 7.95 %) by 25%, serum triglycerides (2.67 → 1.91 mmol/l) by 29%, serum C-peptide (0.70 → 0.59 nmol/l) by 15%, while free insulin (21 → 33 mU/l) conc rose by 50%. In order to identify the patients who really showed benefit from the combination therapy , 75% of the patients were given INS+ placebo, whereas 25% continued with INS+GB for another 4 mo. A deterioration of 40% in FBG/HbA_{1c} during insulin +PL was considered as proof of a beneficial effect (RESP). Using this definition, 152 patients could be classified as RESP or NONRESP. 67 of 113 patients (60%) who received INS+PLA deteriorated vs 5 of the 39 patients (13%) who continued with INS+GB ($p<0.001$). Therefore, about half of them were true RESP to combination therapy. Baseline measurements/recordings of insulin sensitivity (insulin tolerance test) , fasting insulin, C-peptide, blood pressure, BMI, age, duration of diabetes were included in a multivariate analysis to identify predictors of RESP (dependent variable). Neither insulin sensitivity nor insulin secretion predicted the outcome. Only a long duration of diabetes was significantly assocaited with RESP ($p=0.0008$). In conclusion, combination therapy with premixed INS b.i.d + SU is effective in about 50% of patients who have failed on SU alone, particularly in patients with long diabetes duration. To avoid unnecessary treatment, a trial of SU withdrawal is indicated after a few months of combination therapy.

1365

RATE OF SECONDARY FAILURE TO SULPHONYLURIA TREATMENT IN TYPE 2 DIABETICS AND FACTORS WHICH ARE RELATED TO IT.
A. Kofinis, A. Mavrogiannaki, Ch Tountas, El Husban Taisir, G. Chaliotis, G. Hadjigeorgiou, E. Antoniadou and B. Karamanos.
In order to investigate the rate of secondary failure to oral antidiabetics in type II diabetics, we followed 100 patients with mean age of 58.5 years and mean duration of diabetes 7.5 years for 10 years. From these, 65 were still on tablets for the whole study period and form Group A, while 35 had started insulin and form Group B. At the beginning the two groups did not differ in BMI 28.0vs27.6, Systolic Blood Pressure 144.4vs135.6mmHg, Diastolic Blood Pressure 82.6vs82.6 mmHg, Cholesterol 5.9vs6.0 mmol/L,Tg 1.7vs1.9 mmol/L, while the mean annual blood glucose was higher in group B 8.5vs11.3 mmol/L and diabetes duration was longer 6.5vs9.0 years. Also no difference was found in the presence of diabetes in first degree relatives 44.6vs54.2%, smoking 26.2vs31.4%, hypertension 26.2vs40.2% and proteinuria 26.1vs45.7% (Albustix positive). The rate of secondary failure was more or less the same during the 10 years, being 3-4% per year. During the 10 years follow up period the patients were examined two to three times per year. The trend of the differences concerning all the parameters studied was the same and is reflected to the comparison of the data at the end of the study. Thus comparing group A and B at the 10th years we found that group B had higher BMI 26.5vs28.3 p>.05, higher mean blood glucose 9.5vs12 mmol/L p<.001 and proteinuria 26.1vs45.7%. Morover patients in group B had increased their systolic blood pressure during follow up period for 135.6 to 144.4 this difference being statistically significant. Conclusion: 1. In type II diabetics the rate of secondary failure was 35% per 10 years. 2. Factors possibly related to this condition were a) longer diabetes duration b) higher mean blood glucose values at the beginning. 3) Insulin treatment was associated with an increase of the systolic blood pressure and an increase in the prevalence of proteinuria (Albustix positive).

1366

TREATMENT OF NIDDM – PROGRESSIVE REQUIREMENT FOR POLYPHARMACY TO ATTAIN GLYCAEMIC GOALS
C A Cull, R R Holman, R C Turner for the UK Prospective Diabetes Study (UKPDS) Group, Diabetes Research Labs. University of Oxford, Oxford, UK

To prevent complications of diabetes, the American Diabetes Association have suggested additional therapy when $HbA_{1c} > 8\%$, aiming for $HbA_{1c} < 7\%$. The 5102 patients with newly diagnosed NIDDM recruited into the UKPDS, ages 25 - 65 yrs, from 23 centres across the UK, are representative of NIDDM in the general population. Patients, mean (SD) age 52 (9) yrs, BMI 29 (6) kg/m^2, median (iqr) fasting plasma glucose 11.5 (9.0, 14.4) mmol/l and HbA_{1c} 9.1 (7.5, 10.7) %, were randomly allocated to monotherapy with diet, sulphonylurea, metformin or insulin. The proportion (%) of patients who achieved $HbA_{1c} < 8\%$ (< 7%) were :

Therapy	3 years	6 years	9 years
Diet	37 (25)	17 (10)	8 (5)
Chlorpropamide	55 (46)	35 (27)	21 (13)
Glibenclamide	52 (43)	38 (25)	16 (10)
Insulin	48 (41)	35 (27)	21 (18)

In obese patients, the efficacy of metformin was similar to that of glibenclamide. In conclusion, at 3 years only half of NIDDM patients can achieve $HbA_{1c} < 8\%$ on monotherapy and at 9 years only one in five. Polypharmacy needs to be considered early if glycaemic control is to be maintained. Even with insulin therapy, continued hyperglycaemia is common.

1367

PANCREATIC FUNCTION AND METABOLIC CONTROL OF NIDDM PATIENTS WITH SECONDARY FAILURE TO ORAL HYPOGLYCEMIC AGENTS.

O.Sánchez-Vilar, MA.Gonzalo, I.Moreno, C.Del Peso, S.Azriel, JI.Lara, A.Rovira and JL.Herrera-Pombo. FUNDACION JIMENEZ DIAZ (UAM). MADRID. SPAIN.

In NIDDM patients with secondary failure to oral hypoglycemic agents (SF) insulin therapy is a current indication. We have evaluated changes in metabolic control in patients with SF treated with insulin. 43 patients (age at diagnosis:47.8±1.9yr; evolution time up to SF:10.3±1.1 yr; body mass index (BMI):26.6±0.7 kg/m^2; mean±SE) were studied. Plasma C-peptide before (BCP) and 6 min after iv glucagon (6PC) were measured at starting insulin therapy (n=38) and after two years (n=17). HbA1c(%) before treatment (9.2±0.2, n=43) decreased at one (7.4±0.2, n=43, p<0.001), at three (8.0±0.2, n=28, p<0.05) and at five years (8.5±0.6, n=10, p=ns). Cholesterol, triglycerides, HDL, LDL and uric acid levels remained unchanged during the follow-up. BMI only increased at one year (27.7±0.7 kg/m^2, p<0.01). BCP decreased after treatment (0.63±0.07 vs 0.44±0.17 p<0.05) while 6CP (0.89±0.1 vs 0.66± 0.1) and CP increment (6CP-bCP) did not change. In conclusion, insulin therapy in NIDDM patients with SF improved the glycemic control during the first three years, regardless of a progressive deterioration in pancreatic function.

1368

EFFICACY OF COMBINATION OF INSULIN AND SULFONYLUREA IN NIDDM PATIENTS WITH SECONDARY SULFONYLUREA FAILURE

H.Komori, K.Oi and H.Kajinuma. Toho University, Tokyo, Japan

We studied the efficacy of combination of insulin and sulfonylurea (SU) in the treatment of NIDDM patients with secondary SU failure. 37 NIDDM patients were randomly allocated to Group A (NPH insulin in the morning), B (NPH insulin at bedtime), C (long-acting insulin at bedtime) and D (insulin only). A, B and C were given SU. Fasting blood samples were collected at 0, 2, 12 and 52 weeks. HbA_{1C} showed a trend to decrease in C but the trend didn't affect statistics. In A, B and D HbA_{1C} was significantly improved but there was no significant difference among the three groups. CPR and lipids did not change. BMI did not change significantly in A, B and C but increased at 52 weeks in D (20.70±2.70 at start vs 23.40±1.98 at 52 weeks p<0.01). The daily insulin doses were increased at 2 weeks in D, with a trend towards a further increase thereafter (16.4±4.3 u/day at 2 weeks vs 19.7±6.6 u/day at 52 weeks, p<0.001). In A the insulin doses were increased significantly but the dose gain was more pronounced in D than A. B and C needed only 6~7 u/day of insulin. In conclusion, 1) combination therapy except for C and insulin only improved HbA_{1C} and there was no significant difference among the three groups; 2) combination of bedtime insulin and SU needed only a small amount of the daily insulin dose; 3) insulin only patients needed a large daily insulin dose and weight gain was pronounced. We recommend combination of bedtime NPH insulin and SU in secondary SU failure patients.

1369

A STUDY OF MODES OF TREATMENT IN TYPE II PATIENTS WITH DIABETES ATTENDING OUTPATIENT CLINIC

PRADEEP G. TALWALKAR, TALWALKAR CLINIC, MUMBAI, INDIA

We studied the modes of treatment in 483 consecutive patients with Type II diabetes attending an out-patient clinic. All the patients received detailed diet and exercise prescriptions and were subjected to periodic educational programmes. In addition, Oral Hypoglycemic Agents (OHA) and/or insulin were administered as per the individual requirement. Inspite of detailed discussion on benefits of persistent good control of blood glucose and advice regarding acceptance of insulin in those whose blood glucose is inadequately controlled with Diet+OHA therapy, tremendous resistance was encountered when insulin therapy was adviced. The main causes for reluctance to accept insulin included - 1)injection phobia, 2)cost of insulin therapy, 3)fear of "addiction to insulin" and 4)fear of severe hypoglycemia. The objections and misconceptions were overcome using all the persuasive skill developed over the years. 36.3% patients were on insulin (5% on insulin alone, 31.3% were on insulin + OHA therapy. 2% were on diet + exercise while 28.8%, 7.2%, and 25.7% were on sulphonylurea(S), Biguanide (B), B+S therapy respectively. We conclude that with type II diabetes we used insulin in 36.3% patients. Even though most of the patients had strong objections to the use of insulin, they were overcome by detailed patient education and use of persuasive skill.

1370

TROGLITAZONE ADDED TO A SULPHONYLUREA SHOWS A DOSE-RESPONSE CONSISTENT WITH MONOTHERAPY

M.A. Young, M. Starkie, S. Lettis and D.J.A. Eckland. Glaxo Wellcome Research and Development Ltd., Greenford, U.K.

Troglitazone is a novel once daily, oral anti-diabetic agent for the treatment of type 2 diabetes. Clinical studies used daily doses in the range 10 to 800 mg. Using a pharmacodynamic model, analyses of combined data from two double-blind, placebo-controlled, dose-ranging studies in type 2 diabetic patients have shown, in terms of HbA_{1c}, fasting serum glucose (FSG) and triglyceride reductions, an effective dose range of 200-600 mg od. Dose-response data from a 16-week, double-blind, placebo-controlled study adding troglitazone (T) 100 or 200 mg od to stable sulphonylurea (SU) therapy (baseline fasting capillary blood glucose ≥ 7 and ≤ 12 mmol/l) are presented. Ratio to placebo at week 12 (95 % confidence intervals) are as follows:

	HbA_{1c}	FSG	Triglycerides
T 100 mg + SU *n*=79, **n*=80	0.97 (0.93, 1.02)	0.88 (0.82, 0.94)	1.01* (0.9, 1.14)
T 200 mg + SU *n*=84	0.91 (0.87, 0.96)	0.79 (0.74, 0.84)	0.95 (0.85, 1.07)

Triglyceride and FSG values fit on the existing dose-response curves. HbA_{1c} values, sensitive to random variation, were similar and within existing confidence intervals. When added to SUs, troglitazone displays dose-response characteristics consistent with monotherapy, where 200 mg represents the minimum effective therapeutic dose.

Insulin/Amylin Analogs

1371

GENERALIZED ALLERGY TO HUMAN INSULIN TREATED WITH INSULIN LISPRO

F.Hermoso[1],M.Vázquez[1],G.Chaves[1],J.Reviriego[2] and R.Andión[1]. [1]Department of pediatric. Hospital of Valladolid. [2]Clinical Research Deparment. Lilly, S.A. Madrid. SPAIN

Nowadays, insulin allergy is an uncommon complication specially in chilhood.We communicate an 11 year-old girl with an IDDM evolution of 8 months and poor metabolic control even after trying different ways of insulin therapy. She had ketoacidosis and local skin reaction at insulin injection areas(pain, reddening, swelling). Skin prick tests were carried out with positive reaction to human, porcine and beef insulins, as well as to protamine and available commercial insulin formulations. An intravenous insulin infusion (1,68 UI/kg/day) and oral antihistamines were started. Ketoacidosis disappeared, and blood glucose ranged from 200 to 300 mg/dl during 15 days. Treatment with insulin lispro was initiated (0.96 UI/Kg/day); after 48 h. blood glucose ranged from 60-100 mg/dl with symptoms of clinical hypoglycemia. Subcutaneous insulin lispro administration before the four main meals was started after 72 h, and two doses of Ultralente insulin were used to cover basal insulin requirements (total daily insulin = 1 U/Kg).After four months of treatment metabolic control was markedly improved, with HbA1c levels decreased from 13,5% to 7,8%. Insulin specific antibodies kept always high (99%,92,1%). The inflammation areas became gradually better with a posterior atrophy of the subcutaneous cellular tissue. There were no local reactions.It's important to notice that in spite of the high range of antiinsulin antibodies, insulin lispro achieve a good metabolic control. Since insulin lispro is rapidly absorbed from the cellular subcutaneous tissue, it might avoid the total inmunological destruction process.

1372

ACTION OF INTRAVENOUS AND SUBCUTANEOUS ACYLATED HUMAN INSULINS IN CONSCIOUS SWINE. J. Radziuk, J. Davies, S. Pye, D. Flora, L. Vignati, R. DiMarchi and R. Chance. Ottawa Civic Hosp., Ottawa, CAN; Lilly Res. Lab., Indianapolis, USA

[N^{ε}–palmitoyl Lys(B29)]human insulin (C16 insulin, n=6), [N^{ε}–myristoyl Lys(B29)]human insulin (C14 insulin, n=5) and [N^{ε}–myristoyl Lys(B28)Pro(B29)]human insulin (C14 insulin, n=6) were compared (means±sem) to regular human insulin (n=5) during a 3h i.v. infusion at 0.01nmol/kg–min in 20h fasted pigs with a concurrent infusion of somatostatin (0.3µg/kg–min) and euglycemic clamp. Total glucose requirements were similar for (a) insulin: 3.9±0.3, (b)C16 insulin: 3.8±0.7 (c) C14 insulin: 4.4±0.5 (d) C14 lispro: 4.1±0.5 g/kg. Peak total insulin (IRI) was (a) 0.28±0.02 (b) 8.0±0.7 (c) 3.3±0.7 (d) 6.1±0.4 nmol/L. Extension of action was characterized by the time after termination of the glucose infusion at which it was 10% of maximum: (a) 103±12 (b) 471±34 (c) 313±19 (d) 399±37min. A similar prototcol was implemented for 840 min after s.c. injection of 3 nmol/kg of the acylated analogs or NPH human insulin. Glucose requirements were (a) NPH: 5.4±1.1 (b) C16 insulin: 2.8±0.5 (c) C14 insulin: 6.9±0.5 (d) C14 lispro: 3.8±0.6 g/kg. Peak total IRI levels were (a) 0.16±0.01 (b) 2.40±0.29 (c)1.77±0.17 (d) 2.08±0.22 nmol/L. Peak mean glucose requirements were (a) 11.8±2.1 (b) 5.3±1.3 (c) 14.5±3.1 (d) 7.9±1.5 mg/kg–min. The ratios of final (840min) to peak glucose infusion rates were (a) 0.35 (b) 0.49 (c) 0.19 (d) 0.19 suggesting both lower peaks and longer action for NPH and C16 insulin ($p<0.05$). These data show that for acylated insulins, increased albumin binding, indicated by extension of action and higher total IRI levels after i.v. infusion, predicts a decreased bioavailability as indicated by IRI levels and glucose requirements after s.c. injection ($p<0.05$). C14 insulin is the most bioavailable and C16 insulin has the flattest response.

1373

C-PEPTIDE EVOLUTION IN NIDDM PATIENTS TREATED WITH LISPRO INSULIN FOR SECONDARY FAILURE TO ORAL HYPOGLYCEMIC AGENTS. MA.Gonzalo, C.Del Peso, O.Sánchez-Vilar, S.Azriel, JI.Lara, A.Rovira and JL.Herrera-Pombo. FUNDACION JIMENEZ DIAZ (UAM). MADRID. SPAIN.

In patients with NIDDM and secondary failure to oral hypoglycemic agents (SF) the administration of insulin may improve insulin secretion. We have evaluated the pancreatic ß-cell function and the metabolic control in five NIDDM patients (age:58.6±2.7 yr; evolution of disease: 10.6±1.3 yr; mean±SE) with SF before and after treatment with intensified insulin therapy (NPH and LIS(B28) PRO(B29) analogue, total daily dose of 0.65±0.07 U/kg) during four months. HbA1c values declined after insulin therapy (10.3±0,4% vs 8.4± 0.6%; $p<0.05$). Basal C-peptide and 6 min after 1 mg iv glucagon were 0.53±0.1 and 0.79±0.19 nmol/L before and 0.54±0.11 and 0.88± 0.28 after insulin treatment (p=ns). Body mass index (BMI) increased from 29.0±2.6 to 30.0±0.1 kg/m^2 ($p<0.001$). It was observed a significant improvement in triglyceride and HDL-c levels. Only two patients reported hypoglycemia once. In conclusion, the intensive treatment with human rapid insulin analogue (Lispro) and NPH insulin improves metabolic control without changes in the pancreatic ß-cell function in patients with NIDDM and secondary failure to oral hypoglycemic agents.

1374

ACTIVITY PROFILES OF NPH HUMAN INSULIN AND [N^{ε}–PALMITOYL LYS(B29)] HUMAN INSULIN IN SUBJECTS WITH IDDM. J. Radziuk, L. Vignati, P. Roach, R. DiMarchi, R. Chance, B.Bradley, S. Pye and J. Braaten. Ottawa Civic Hosp., Ottawa, CAN; Lilly Res. Lab., Indianapolis, USA

[N^{ε}–palmitoyl Lys(B29)]human insulin is an acylated analog of insulin which demonstrates an extended action compared to insulin alone when infused intravenously (IV) secondary to binding of this analog to circulating albumin. The acylated insulin (A) was compared with respect to duration and activity profile in a crossover fashion to NPH insulin (B) following subcutaneous (s.c.) doses of (A) 6nmol/kg and (B) 1.2 nmol/kg in 9 subjects with IDDM. After overnight IV infusion of regular human insulin, a.m. glucose was (A) 6.8±0.1 and (B) 7.1±0.1 mmol/L. After the s.c. injection, IV human insulin or glucose was infused to maintain near–basal glycemia and tracer glucose was infused for the separate assessment of hepatic glucose production (HGP). An activity profile was deduced for each study by expressing the glucose infusion rate at each time point, as a positive fraction (%) of the basal (measured) HGP, and the IV insulin infusion rate as a negative fraction (%) of the basal requirement and summing the two fractions. Basal insulin infusion rates were (A) 0.99±0.09 and (B) 1.25±0.09 pmol/kg–min and the basal concentrations were (A) 318±84 and (B) 200±45 pmol/L. Mean insulin requirement fell to < 10% of basal by (A) 200 min and (B) 150 min. During the 13h study (A) 0.42±0.06 and (B) 1.35±0.14 mmol/kg of additional glucose were needed. Mean endogenous glucose production was (A) 10.1±1.5 and (B) 7.8±0.9 µmol/kg–min (n.s). The activity profile at 3, 6, 9 and 12h was (A) 10±10, –9±7, –9±15, and –3±3% and (B) 12±10, –6±15, 27±18, 26±14% ($p<0.05$). These data indicate that both forms of insulin administration exert an extended (12h minimum) action which moreover remains stable over this period.

1375

REDUCTION OF SNACKS WHEN SWITCHING IDDM PATIENTS FROM REGULAR INSULIN TO LISPRO INSULIN

T. Rönnemaa and J Viikari, Department of Medicine, University of Turku, Turku, Finland

The small or no improvements in HbA1c during insulin lispro treatment despite of better postprandial glucose control may be due to inadequate dietary adjustments. We tested whether reduction of snacks and increasing correspondingly the energy in the main meals results in improved metabolic control when switching to lispro treatment. We studied 141 IDDM patients, mean age 36 (SD 9) yrs, diabetes duration 14 (10) yrs, BMI 24.5 (2.4) kg/m^2. All had two daily NPH injections throughout the study. After baseline visit the patients used regular insulin before main meals thrice daily for 12 weeks. Thereafter they were switched to lispro (injections immediately before meals), and advised to transfer at least 50% from their snack carbohydrates to preceeding main meals. After the regular period and the 12-week lispro period, HbA1c was 7.81 and 7.70 % ($p=0.088$), weight 73.4 and 72.9 kg ($p<0.001$), NPH dose 25.9 and 27.2 U/day ($p<0.001$), and short-acting insulin dose 23.9 and 23.3 U/day ($p=0.035$), respectively. In those patients who diminished their snacks exactly as advised (n=67), HbA1c decreased from 7.91 to 7.66% ($p=0.014$). In patients with high HbA1c (>7.5%) after regular insulin and who reduced their snacks properly (n=46), HbA1c decreased from 8.49 to 8.13% ($p=0.004$). The number of hypoglycemias (blood glucose <2.5 mmol/l) was lower during lispro period (2.1 vs 1.4 episodes, $p=0.004$). We conclude that when switching from regular to lispro insulin, transfer of snack carbohydrates to main meals is safe, and results in improved HbA1c especially in patients with unsatisfactory metabolic control.

1376

PREMIXED FORMULATION OF B28ASP AND NPH-INSULIN: PHARMACODYNAMIC PROPERTIES OF A 30/70-STABLE MIXTURE

C. Weyer, T. Heise and L. Heinemann. Dept. of Metabolic Diseases and Nutrition, Heinrich-Heine-University of Düsseldorf, Germany

The pharmacodynamic properties of the novel 30/70 mixture of soluble and protamin-retarded B28Asp have not been investigated yet, whereas the time-action profile of the rapid acting insulin analogue B28Asp has already been studied. We compared in a double-blind study the pharmacokinetic and pharmacodynamic properties of a 30/70 mixture of soluble and protamin-retarded B28Asp with a 30/70 mixture of soluble and protamin retarded human insulin (Actraphane HM, Novo Nordisk, Denmark). 24 healthy male volunteers (age 26±2 years, BMI 23,7±1,7 kg/m^2; mean±SD) received a s.c. injection of 0.3 U/kg body weight of either preparation into the abdominal wall on two study days during euglycaemic glucose clamps (target blood glucose 5.0 mmol/l, baseline i.v. insulin infusion 0.15 mU/kg/min). Glucose infusion rates (GIR) and serum insulin concentrations (INS) were determined the following 24 h. Injection of the premixed formulation with B28Asp resulted in an earlier and more pronounced increase in metabolic activity. The metabolic effect within the first 4 h after injection was 37 % higher, while the overall-effect was similar.

	30/70 B28Asp	30/70 Actraphane
GIR_{max} (mg/kg/min)	9.7±2.3	7.4±1.7*
t_{max} (min)	127±24	185±52*
AUC 0-240 min (g/kg x 240 min)	1.77±0.43	1.29±0.34*
AUC 0-1440 min (g/kg x 1440 min)	4.49±1.52	4.74±1.29
INS C_{max} (pmol/l)	183±12	101±8*
INS t_{max} (min)	115±3	177±13*
AUC 0-240 min (nmol/l x 240 min)	32.9±11.2	21.1±7.6*
AUC 0-1440 min (nmol/l x 1440 min)	59.3±24.7	61.9±16.1

(mean±SD), * P<0.0001

Subcutaneous injection of a stable 30/70 B28Asp protamin retarded mixture resulted in a more pronounced metabolic effect in the first hours after injection than an equivalent mixture with human insulin. The overall metabolic effect of both preparations was comparable.

1377

LOCALISATION OF ALBUMIN BINDING SITE(S) FOR NN304

T.Kjeldsen, P.Kurtzhals, A.F.Pettersson, L.Drube, S.Havelund, I.Jonassen and J.Markussen. Insulin Research, Novo Nordisk A/S, DK-2880 Bagsvaerd, Denmark.

NN304: LysB29-tetradecanoyl des(B30)-insulin, is a new soluble, long-acting insulin analogue that is protracted by interaction with the protein albumin. Albumin is a multifunctional protein that binds and transport various endogenous molecules including fatty acids as well as certain drugs. The NN304 insulin analogue interact with albumin by binding to the long-chain fatty acid binding sites. The association constant for binding of the NN304 insulin analogue to human albumin is in the order of 10(5) M-1. The binding affinity of NN304 to albumin is lower than that of the free fatty acids. Domains of recombinant human albumin was expressed in yeast to investigate the site of interaction between NN304 and albumin as well as the difference in binding affinity between free fatty acids and NN304. Tetradecanoic acid and NN304 binding affinities to purified recombinant human domains I and III were determined. Tetradecanoic acid was found to have high affinity binding to domain III and insignificant binding to domain I. NN304 was found to bind to recombinant human domain III and to have minor binding to recombinant human domain I. We conclude that the mechanism for albumin binding of tetradecanoic acid and NN304 to be cognate and that NN304 is likely to associate with the fatty acid high affinity binding site on human albumin domain III.

1378

IMPROVED GLUCOSE CONTROL WITH INSULIN LISPRO DEMONSTRATED BY REDUCING GLUCOSE VARIABILITY

R.L. Brunelle, M. Trautmann, V. Koivisto and L. Vignati, Eli Lilly and Co. Indianapolis, IN, USA and Helsinki University Hospital, Helsinki, Finland

Accurate assessment of daily blood glucose is important in evaluating new therapies and in estimating the sample size for a clinical trial. The variability of a multiple daily 7 point blood glucose profile was evaluated in a large 6 month randomized, multicenter crossover study comparing insulin lispro (LP) to human regular insulin (HR) in patients with IDDM (n=379) and NIDDM (n=328). A variance components analysis was performed to estimate the within and between patient variability in blood glucose measurements. A large decrease in variability was observed by increasing daily glucose readings which allows one to decrease the overall sample size of a similar study.

2hr Post-Breakfast Blood Glucose Measurements in mmol/L.

Glucose	Standard Deviation		Sample Size*	
Readings	IDDM	NIDDM	IDDM	NIDDM
1	4.25	3.76	145	113
4	3.10	2.95	77	70
% Decrease	27.1	21.5	46.7	38.5

*(alpha=0.05 two-tailed, Power=80%, detectable difference=1)

Using all 4 daily blood glucose measurements, a decrease in the mean 2 hr postbreakfast blood glucose measurement was observed during LP therapy (LP mean 8.58 sd 3.05 vs HR mean 9.75 sd 3.11, $p<0.001$).

1379

THE FIRST CLINICAL EXPERIENCE WITH INSULIN LISPRO IN RUSSIA

M. Antsiferov, A. Majorov, S. Ristic, V. de Verga, A. Sergeev, and I. Dedov. Academy of Medical Science, Moscow, Russia and Eli Lilly Vienna, Austria.

The aim of the study was to assess efficacy, safety and acceptance of insulin lispro in patients on intensive insulin treatment. Thirty-nine IDDM patients with moderately good metabolic control (HbA1c < 10%) participated in this study. The age of the patients was 25±9.7 years. Duration of diabetes was 113±70.4 months. At the beginning of the treatment with insulin lispro, patients were instructed to use basal insulin (Humulin NPH) twice a day. The dose and number of injections of lispro insulin were adjusted by patients based on home blood glucose monitoring. Postprandial blood glucose control was assessed by 1- and 2- hour blood glucose after the standard meal. After the two month treatment period with insulin lispro significant improvement in 2-hour postprandial blood glucose was achieved compared to the prestudy values (13.5±5.2 vs. 10.9±5.4 mmol/l, p=0.032). One-hour postprandial blood glucose decreased from 15.0±5.0 to 12.8±5.9 mmol/l. HbA1c decreased from 8.4%±1.4 to 8.0±1.5% . Severe hypoglycemic episodes were not reported during the two month study period. Treatment preference questionnaire (insulin lispro vs. regular insulin) showed that 27/39 (69%) patients observed improvement in metabolic control on insulin lispro, 18/39 (46%) observed improvement in hypoglycemia, 21/39 (54%) experienced benefits in planning daily activities. When the study was completed 30/39 (75%) patients decided to continue using insulin lispro . In patients on intensive insulin treatment insulin lispro was preferred and superior in controlling postprandial blood glucose to their previously used prandial insulin.

1380

THE CARDIOVASCULAR SAFETY PROFILE OF INSULIN LISPRO (LP)

B. Glazer, S. Zalani, S. Symanowski, G. Uminger, J. Anderson, and E. Bastyr, Lilly Research Laboratories, Indianapolis, Indiana USA

Cardiovascular (CV) disease is a cardinal complication of diabetes. We examined the safety profile of LP (Humalog®), the first insulin of the rapid acting class of insulin analogs, as it related to CV disease and sudden death. Ten pivotal studies including 3634 patients (> 2000 patient years) were conducted. Adverse events were recorded at baseline and throughout the trials and assigned a COSTART term (specific for CV disease and subsets). There was no difference between LP and regular insulin (HR) in the number of patients developing a new CV disease event.

	n	LP	HR	p-value
All CV Events	3634	108	92	0.216
Cerebrovascular	3634	13	9	0.399
Cardiac	3634	45	39	0.508
Peripheral Vascular	3634	16	16	1.000

Patients were classified to a low or high risk group for developing a new CV event based upon a history of a CV event prior to entry. The highest CV risk group was identified as those high CV risk group patients who had a prolonged QTc interval at baseline. When either a newly developed CV event or an increase in severity of an existing CV event were considered, there was no statistical difference (Fisher's Exact test) between LP and HR therapy for any of the three risk groups.

Risk Group	n	Event Risk Rate	LP	HR	p-value
Low	2381	4%	54	38	0.089
High	1253	10%	65	66	0.927
Highest	80	16%	6	7	0.764

Sudden cardiac death was evaluated as observed death from ventricular tachycardia or fibrillation within 24 hours of the event. Eight cases of sudden cardiac death were reported in the controlled and long-term trials. There was no statistical difference between the LP versus the non-LP treated patients (3 vs. 5, p = 0.274).

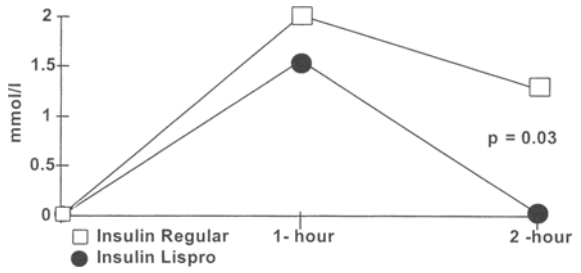
In conclusion, there no clinical or statistical difference between LP and HR treated patients for the development of new CV events or sudden cardiac death.

1381

INSULIN LISPRO REDUCES HYPERGLYCEMIA AFTER A TEST MEAL BASED ON TRADITIONAL NUTRITION OF CENTRAL EUROPE

S. Ristic and V. de Verga. Eli Lilly Vienna, Austria.

The objective of the study was to compare insulin lispro with human regular insulin in regard to glycemic control of diabetic patients on intensive insulin treatment. 62 patients (age 35.7±9.3; BMI 24.6±3.5; 55 patients Type 1) from 8 centers in the Czech Republic, Slovenia and Slovak Republic participated in a 4 month open, randomized, cross-over study. Fasting, 1- and 2-hour blood glucose after a test meal were measured for insulin lispro and regular insulin. The test meal (220-400kcal) was based on local and individual dietary habits and consistent for each patient throughout the study. Insulin lispro was injected immediately before the test meal while human regular insulin was administered 30 minutes before the meal. Fasting blood glucose value for insulin lispro was 10.2±4.2; regular insulin 10.3±4 mmol/l. Blood glucose excursions are presented in figure below. The HbA1c (7.6±1.5 vs. 7.4±1.5 %), frequency of hypoglycemia's and daily insulin dose (0.67+0.11 vs. 0.65±0.11 U/kg) did not differ significantly between insulin lispro and human regular insulin treatment groups. The study shows that insulin lispro is more effective than regular insulin in reducing hyperglycemia after a traditional Central European breakfast.



1382

OPTIMAL COMBINATION OF INSULIN LISPRO AND BASAL INSULIN IMPROVES GLYCEMIC CONTROL IN IDDM

P. Ebeling, P-A. Jansson, U. Smith, I. Conget, M.J. Coves, R. Gomis, C. Lalli, G.B. Bolli, V.A. Koivisto. Helsinki University Central Hospital, Helsinki, Finland; University Hospital, Göteborg, Sweden; Endocrinology and Diabetes Unit Hospital Clinic, Barcelona University, Spain; University of Perugia, Italy.

The short-acting insulin analog, insulin lispro (Humalog™) has recently become available for clinical use. We examined, if the use of Humalog will improve HbA_{1c} if basal insulin is optimally adjusted. 84 IDDM patients first used Humalog as premeal therapy for 5 months. They were then randomized for another 4 months to either continue with Humalog or to switch to human regular insulin (Humulin Regular). Insulin doses were adjusted according to glucose self-monitoring. During Humalog period, HbA_{1c} decreased from 8.8±0.1 to 7.9±0.1% (p<0.001), mean daily glucose level decreased from 9.5±0.2 to 8.6±0.2 mmol/l (p<0.001), premeal insulin decreased from 27±1 to 22±1 U/d (p<0.001) and basal insulin (NHP) dose increased from 20±1 to 27±1 U/d (p<0.001). The number of NPH injections increased from 1.4±0.1 to 2.7±0.1 per day (p<0.001). The hypoglycemia rate remained unchanged. During the second period, in Humulin group premeal insulin dose increased by 3.4±0.9 U (p<0.01), NPH dose decreased by 5.6±0.7 U (p<0.001), mean blood glucose increased by 0.7±0.1 mmol/l (p<0.02) and HbA_{1c} rose by 0.3±0.1% (p<0.01). In Humalog group, premeal and basal insulin doses, blood glucose and HbA_{1c} remained unchanged. In conclusion: 1) Humalog with optimal basal insulin lowers HbA_{1c} and mean blood glucose concentration without an increase in hypoglycemia, 2) Improved control can be maintained better with Humalog than with Humulin Regular insulin.

1383

COMPARISON OF THE EFFECT OF USING INSULIN LISPRO WITH ULTRALENTE AND NPH BASAL REGIMENS IN IDDM PATIENTS.

J. Llewelyn[1], M. Birkett[1], B. Boggs[1], M. Roder[1], C. Berne[2] and A. Prange[3]
Lilly Research Centre, Windlesham, UK[1]; University Hospital, Uppsala, Sweden[2]; Kolding Hospital, Kolding, Denmark[3].

Insulin lispro (LP) has a more rapid onset and shorter duration of activity than regular human insulin. The objective of this open label study was to compare the effect of using preprandial LP, with both NPH and Ultralente (UL) basal insulin regimens, on metabolic control. 167 IDDM patients (mean age 34.8 years, mean duration of diabetes 11.4 years) participated in this crossover study. There was a 1 month run in period (LP/NPH) and each treatment period was 3 months in duration. UL and NPH could be given in any regimen. Measurements included HbA1c, eight point blood glucose profiles, and the incidence of hypoglycaemic episodes. There was no significant difference in overall metabolic control at endpoint as measured by HbA1c (mean±SD) (7.0±0.9% [NPH] vs. 7.0±1.1% [UL], p=0.330). Breakfast premeal glucose levels were significantly lower with NPH (8.7±2.8mmol/L vs. 9.6±3.4mmol/L, p=0.007) and with ultralente before the evening meal (9.1±2.9mmol/L vs. 8.2±3.0mmol/L, p=0.003). However, 2hr postprandial blood glucose excursions were not significantly different between treatment groups after any meal. The incidence rate of hypoglycaemia (number of hypoglycaemic episodes/patient/treatment) was significantly lower between midnight and 6AM with UL (1.2±1.9 vs. 0.8±1.5, p=0.001) and between 6PM and midnight with NPH (1.6±2.6 vs. 2.9±4.5, p<0.001), but there was no difference in the overall incidence rate of hypoglycaemia (8.1±8.9 [NPH] vs. 9.1±10.9 [UL], p=0.158). The same trends were observed whether one or more basal insulin injections were used. The number of severe hypoglycaemic episodes did not differ between treatment groups (NPH, n=9 in 4 patients; UL, n=9 in 6 patients). In conclusion, LP is suitable for use in varied intensive regimens with NPH and UL basal insulins and use with UL may reduce nocturnal hypoglycaemia. The choice of basal regimen did not affect overall glycaemic control in this study.

1384

IMPORTANCE OF BASAL INSULIN TO IMPROVE CONTROL WITHOUT INCREASING HYPOGLYCAEMIA IN INTENSIVELY TREATED IDDM USING A SHORT-ACTING INSULIN ANALOG AT MEALS.

P. Del Sindaco, M. Ciofetta, C. Lalli, E. Torlone, G. Perriello, P. Brunetti and G.B. Bolli. University of Perugia, Perugia, Italy.

In previous studies the short-acting insulin analog Lispro has improved 1- and 2-h postmeal blood glucose (BG), but not long-term BG control (HbA1c) as compared to human regular insulin (Hum-R). To test the hypothesis that Lispro improves HbA1c in IDDM only when basal insulin is optimally replaced, 12 IDDM patients on long-term intensive therapy (run-in HbA1c 6.46±0.14%) were studied. Patients were assigned to either Lispro injected at mealtime (n=6) or Hum-R injected 10-30 min prior to meals (n=6) (bedtime NPH continued on both occasions) for 3 months and thereafter crossed over. With Lispro, NPH was added to Lispro at breakfast and lunch (N=9) and also at supper (N=3) to optimize pre-meal and bedtime BG. With Hum-R, NPH was added to Hum-R at lunch (N=7) to optimize pre-supper BG. The total daily insulin units were no different in the two treatments, but in the Lispro+NPH treatment patients used 26% less short-acting insulin at meals (5.2±0.7 U/day), but 34% more NPH (4.4±0.7 U/day) vs Hum-R+NPH (p<0.05). The bedtime NPH dose was no different. With Lispro+NPH, postprandial BG was lower than after Hum-R+NPH (8.3±0.2 vs 8.9±0.2 mmol/l, p<0.05) whereas pre-meal BG was no different (8.3±0.4 vs 8.4±0.3 mmol/l); HbA1c was lower (6.19±0.16 vs 6.59±0.15%) (p<0.002), but the frequency of hypoglycaemia (BG <3.3 mmol/l) was no different (4.1±0.9 vs 3.7±0.9 episodes/patient-month, p=NS). It is concluded that, if basal insulin is optimally replaced, mealtime injection of Lispro improves the 24-h BG and, longterm, HbA1c as compared to Hum-R injected 10-30 min prior to meals. The lower HbA1c with Lispro+NPH is not associated with increased frequency of hypoglycaemia

1385

ALGORITHM ADAPTATION UNDER FUNCTIONAL INSULIN TREATMENT DURING SWITCH-OFF FROM REGULAR TO INSULIN LISPRO

K. Howorka, J.Pumpria and Ch.Schlusche. University of Vienna, Austria

Aim: To investigate the necessity of dosage adaptation to pre-defined criteria during ambulatory switch-off from regular insulin ***R*** to insulin lispro ***L*** under flexible,functional insulin treatment FIT, discriminating between prandial, basal and correctional use of insulin. **Methods:** 28 insulin-dependent patients (age: 41±16, diabetes duration:16±9, FIT-duration: 5±4 years) who routinely make acute corrections of hyperglycaemic blood glucose levels, have been switched to ***L*** after a run-in period (***R***, baseline investigation 1) and were evaluated after 2 weeks (investigation 2, early adaptation) and after 11 weeks of observation period with ***L*** (investigation 3). **Results:** Basal insulin including either human insulin ultralente in the morning and NPH (51% of cases) or lente type insulin late be-fore sleeping (32%), twice daily ultralente (11%) or twice daily NPH (6%) was suitable for ***L*** with the exception of the latter option. The neces-

Algorithms \ Investigations	**1: regular**	**2: lispro,** *2wk*		**3:lispro,** *11wk*	
Basal delayed-act. ins.morning *U*	11,4±4,4	11,4±4,4	*0,60*	11,8±4,0	*0,79*

Mean fasting BG *mmol/l*	8,3±1,8	8,2±1,8	*0,45*	8,3±1,4	*0,71*
Mean postprandial BG *mmol/l*	9,3±2,1	8,2±2,1	***0,02***	7,9±2,0	***0,01***
% BG values <3,3 mmol/l	8,0±5,9			6,9±4,7	*0,06*
HbA1c *%, range 4,2-6,6%*	7,48±0,91			7,25±1,01	***0,05***
Interval used injection: meal *min*	9,3±8,5			3,8±7,0	***0,01***

sary algorithm adaptation was of minor degree *(intraindividual comparison, p vs investigation 1)*. **Conclusions:** FIT allows safe ambulatory switch-off to ***L***, a slight decrease in the morning dose of short-acting insulin is recommendable.

1386

HUMALOG REDUCES THE INCIDENCE OF SEVERE HYPOGLYCEMIA IN IDDM PATIENTS

RL. Brunelle, J. Llewelyn, L. Vignati, J. Anderson, VA. Koivisto. Lilly Research Laboratories, Indianapolis, IN, USA and Department of Medicine, Helsinki University Hospital, Helsinki, Finland

A short-acting insulin analog, Humalog (insulin lispro), is absorbed more rapidly, has a higher peak and a shorter duration of activity than human regular insulin. In large clinical trials premeal therapy with Humalog has reduced postprandial rise in plasma glucose, when compared to regular human insulin. There was a consistent reduction in severe hypoglycemic episodes (resulting in coma, or requiring glucagon or intravenous glucose) during Humalog therapy, although this was not statistically significant in any of the separate studies. A cumulative meta-analysis using Cochran-Mantel-Hanenzel odds ratio test was performed combining the data from all 8 large Humalog IDDM clinical trials. The studies were 6-12 months duration, 5 with cross-over design, using regular human insulin as a control. Each of these clinical trials used a similar method to collect information on hypoglycemic episodes. After combining these studies, 2327 patients used Humalog and 2339 patients regular human insulin. At least one severe hypoglycemic episode occurred during Humalog therapy in 72 (3.1%) patients, and during regular human insulin treatment in 102 (4.4%) patients (p=0.024). The mean HbA_{1c} level was similar in the two groups. In conclusion: 1) Humalog reduces the incidence of severe hypoglycemia by 30% compared to regular human insulin in IDDM patients. 2) This is probably due to a narrow time action profile of Humalog for postprandial period with less overlapping with basal insulin.

1387

EVALUATIONS 1- AND 2-HOUR POSTPRANDIAL GLUCOSE EXCURSIONS AS INDICES OF POSTPRANDIAL GLUCOSE CONTROL. J.R. Woodworth, R.K. Yordy, and L. Vignati, Eli Lilly and Company, Indianapolis, IN.

The use of 1- and 2-hour postprandial glucose measurements and the change of glucose from a premeal baseline (glucose excursions) can provide a means of evaluating the rapid glucose control provided by insulin and insulin lispro immediately following a meal. These measurements may also be indices to evaluate glucose control beyond 2 hours, establishing a means to evaluate an entire blood glucose profile with just one or two postprandial measurements. Two previously performed studies in which multiple postprandial glucose measurements were monitored in response to insulin and insulin lispro were used to evaluate this premise (Howey et al, *Clin. Pharmacol. Ther.*, 58, 459-69, 1995 [N=12]; Heinemann et al., *Diabet. Med.* 13, 625-9, 1996 [N=10]). Both studies were designed to monitor postprandial glucose control in patients with diabetes. The mean doses of insulin and insulin lispro were identical in both studies. The maximum postprandial excursion (GE_{max}), the time to GE_{max} (TGE_{max}), and hourly incremental areas under the glucose excursion curve (AUC_{ex}) were calculated from all data. Correlations were then attempted between these data and the 1- and 2-hour postprandial glucose excursions. Both the 1- and 2-hour excursion values correlated with the GE_{max} values, although the 2-hour postprandial excursion provided a better correlation (r^2=0.39 and 0.59, respectively). AUC_{ex} from 0 to 4 hours postprandial correlated well with the 2-hour postprandial excursion measurement in both studies, with nearly identical slopes from both studies (r^2=0.77 and 0.82, respectively). These correlations were independent of the type of insulin administered. Correlations were present beyond 4 hours, although the regression of 0-5 hour AUC_{ex} with 2-hour postprandial excursions was not as predictive as that with the 0-4 hour AUC_{ex}. TGE_{max} could not be reliably predicted. In conclusion, 2-hour postprandial glucose excursions serve as an excellent indicator parameter for evaluating glucose control allowing assessments of 0-4 hour AUC_{ex}.

1388

PREFERENCES FOR, AND IMPROVEMENTS IN ASPECTS OF QUALITY OF LIFE (QoL) WITH, INSULIN LISPRO IN A MULTIPLE INJECTION REGIMEN.

J.M. Janes [1]., C. Bradley [2] and A. Rees [3]., Lilly Industries, Basingstoke UK [1], Royal Holloway, University of London, UK [2], University of Wales, Cardiff [3]

The rapid action of human insulin analogue Lispro allows injection immediately before meals. 97 IDDM patients, participating in a 6 month, multi-centre, randomised, cross-over trial of Lispro injected immediately pre-meal compared with standard soluble insulin injected 30 minutes pre-meal, completed the Diabetes Treatment Satisfaction Questionnaire (DTSQ) and Well-being Questionnaire (WBQ) (Bradley, 1994). Significant treatment differences for the WBQ and 3/4 subscales, together with the DTSQ total scale and treatment convenience item score all favoured Lispro.

	Mean Diff. favouring Lispro	p	95% CI	Possible Range
WBQ Total	4.50	0.002	1.58 to 7.42	0-66
Depression subscale	-1.20	0.006	-2.06 to -0.34	0-18
Anxiety subscale	-1.50	0.001	-2.40 to -0.60	0-18
Energy subscale	0.72	0.001	0.30 to 1.14	0-12
Positive Well-being subscale	0.36	n.s.	- 0.22 to 0.94	0-18
DTSQ Total	2.89	0.001	1.31 to 4.47	0-36
Convenience score	0.71	0.001	0.35 to 1.07	0-6

There was no significant difference in HbA_1c. More detailed analyses of psychological outcomes suggest that disappointment at allocation to standard insulin contributed to the results and that experience with Lispro was followed by marked reduction in satisfaction with standard insulin. On completion of the study, 83% of eligible patients elected to continue using Lispro, supporting patient preference and QoL data favouring Lispro.

1389

EFFECT OF CIRCULATING FREE FATTY ACIDS ON THE *IN VIVO* KINETICS OF NN304

U. Ribel, H.B. Jensen-Holm, S. Havelund and I. Jonassen.
Novo Nordisk, Bagsvaerd, Denmark.

The prolonged effect of the new basal insulin analogue NN304 (LysB29-tetradecanoyl des(B30)-insulin) is ascribed to its high affinity for serum albumin in the interstitial fluid at the s.c. injection site and in blood. Because NN304 is bound to serum albumin at the long chain fatty acid binding sites, variation of the concentration of free fatty acids may affect the equilibrium and hence the time action of NN304. In the present study we examined the effect of high levels of circulating free fatty acids on the kinetics of 125I-labelled NN304 injected i.v. or s.c. to pigs. Healthy subjects show serum values of free fatty acids between 0.1 and 0.6 mmol/l. Low levels of free fatty acids (0.1-0.2 mmol/l) were obtained in fed pigs (n=4, 96-108 kg), whereas high levels (1.6-2.5 mmol/l) were induced in the same pigs after i.v. infusion of the beta1-agonist, dobutamine 10 µg/kg/min for 105 min. Both the disappearance course of 125I-labelled NN304 from a subcutaneous depot (0.2 µCi and 2 U) measured by external gamma-counting, and the elimination of trichloroacetic acid (TCA) precipitable radioactivity in plasma after i.v. injection of the labelled insulin analogue (25 µCi and 0.5 U) were similar with and without elevated levels of free fatty acids. In conclusion, elevated circulating levels of free fatty acids do not alter the pharmacokinetics of NN304.

1390

INSULIN LISPRO CHANGES TREATMENT SATISFACTION UNDER FLEXIBLE *FUNCTIONAL INSULIN TREATMENT*

K. Howorka, J. Pumpria, Ch. Schlusche, D. Wagner-Nosiska, M. Gabriel, S. Reischl and C. Bradley[1] University of Vienna,Austria,[1]University of London,UK

Aim: To investigate and quantify the subjectively perceived advantages of insulin lispro ***L*** vs. regular insulin ***R*** for Functional Insulin Treatment (FIT), discriminating between basal, prandial and correctional use of insulin. **Method:** 55 FIT-patients (age: 41,8±16,0, diabetes duration:16,0±9,6, FIT-duration: 5,4±3,2 years) who routinely make acute corrections to their blood glucose levels with extra insulin as required were recruited and randomized into two study groups. Educational update in FIT was provided together with information on ***L*** pharmakokinetics. After a run-in period of 8 weeks, parallel periods of 11 weeks each (either with ***L*** or ***R***) were compared. Psychological measures included status **(S)** and change **(C)** versions of the *Diabetes Treatment Satisfaction Questionnaire (DTSQ of C.Bradley 1994)* extended with items designed for FIT. The *DTSQ(C)* relates the present treatment satisfaction of the subject to that in the preceeding phase of investigation. **Results:** While the ***R*** group did not change significantly, the ***L*** group increased *treatment satisfaction* in *DTSQ(S)* (intragroup comparison) in total satisfaction (p=0,01), and specifically in all categories related to correctional (speed: p<0,001; accuracy: p=0,001; general: p=0,001) and prandial use of insulin (efficiency to deal with blood glucose after meals; necessary timing of injections; general; all p-values <0,001). Increased predictability (p=0,047) and controllability (p=0,022) of blood glucose levels and increase in satisfaction with ability to perceive hypoglycaemia (p=0,035) were also found with lispro. DTSQ*(C)* augmented these perceived advantages with ***L*** (intergroup comparison) particularly in categories „satisfied-with-your-current-treatment" (p=0,01), convenience (p=0,047) and flexibility of treatment (p=0,008), understanding of diabetes /blood glucose course/ (p=0,043), and „wish-to-continue-this-kind-of-treatment" (p=0,006). HbA_{1c} decreased significantly with ***L*** from 7,5±0,9 to 7,2±1,0 (p=0,049), while remaining unchanged with ***R*** (p=0,9). Percentage of low blood glucose values tended to decrease with ***L*** (p=0,06). **Conclusion:** Insulin lispro improves treatment satisfaction under flexible, functional use of insulin while reducing HbA_{1c}.

1391

PHARMACOKINETIC AND GLUCODYNAMIC ASSESSMENTS OF N-PALMITOYL, LYS(B29) HUMAN INSULIN IN HEALTHY VOLUNTEERS.

D.C. Howey, J.R. Woodworth, R.R. Bowsher, and J. Reviergo, Eli Lilly and Company, Indianapolis, IN, USA.

N-acylated insulins may provide a means of creating a sustained activity of insulin in a soluble preparation, potentially providing less inter- and intra-patient variability in absorption than current intermediate- or long-acting insulins. We performed a dose-ranging trial in healthy volunteers (N=23) with N-palmitoyl lys(B29) human insulin (C16-HI). Subcutaneous doses from 0.03 to 0.57 nmol were tested in this 24-hour, Biostator-controlled glucose clamp trial. Blood samples were collected over the 24 hourperiod for assessment of total and unbound C16-HI serum concentrations. Maximum serum concentrations (C_{max}), time to C_{max} (t_{max}), area under the curve from 0 to infinity (AUC), and half-life ($t_{½}$) were determined from the serum concentrations. Maximum glucose infusions (R_{max}), time to R_{max} (TR_{max}), and total glucose infused (G_{tot}) were documented from the clamp. AUC values were linear with dose (r^2=0.85). Protein binding of C16-HI was high, with 1.32%±0.60 (mean±SD) unbound 4 hours after dosing. Glucodynamic response was low and, although linear across doses, highly variable (r^2=0.35), reflecting a potency of 20-25% of NPH based upon published values. The table summarizes mean±SD data once normalized to a 0.48 nmol dose.

	C_{max}, pM	t_{max}, hr	$t_{½}$, hr	AUC, nM•hr	R_{max}, mg/min	TR_{max}, hr	G_{tot}, gm
bound	4259±1346	5.2±1.9	4.34	47.4±9.83	221±86.9	5.6±2.3	75.1±65.1
unbound	65.2±39.4	4.6±2.2	4.20	0.58±0.28	-	-	-

Attempts to relate G_{tot} values with total drug exposure (AUC) resulted in a minimal correlation (r^2=0.31), which improved only slightly when related to unbound AUC (r^2=0.40). In conclusion, C16-HI showed a highly reproducible and linear pharmacokinetic profile. The glucodynamic response was consistent with an intermediate-acting insulin and linear across doses, but the time-action profile was highly variable.

1392

COMPARISON OF THE METABOLIC ACTIVITY OF THE INSULIN ANALOGUE B28ASP WITH SOLUBLE INSULIN IN U40 AND U100 CONCENTRATION

K. Rave, C. Weyer, O. Stiefelhagen, M. Rauhaus, T. Heise, L. Heinemann, Dep. of Metabolic Diseases and Nutrition, Heinrich-Heine-University Düsseldorf, Germany

It is well known that rapid-acting insulin analogues like B28Asp show a faster onset and a shorter duration of action than currently available U100 soluble insulin preparations. Since this effect is mainly due to a lower concentration of slow-absorbable hexamers, the metabolic profile of human insulin in lower concentration (e.g. U40 insulin) might be more similar to that of B28Asp. Therefore, we compared the pharmacodynamic and pharmacokinetic properties of U40 soluble insulin with B28Asp (U100) and with U100 human insulin. 8 healthy volunteers (age 26±2 years, BMI 22.8±2.1 kg/m²) received at different study days s.c. injection of B28Asp and U40 insulin (0.2 U/kg body weight) under euglycaemic clamp conditions (blood glucose 5 mmol/l, basal i.v. insulin infusion 0.15 mU/kg/min). Glucose infusion rates (GIR) and serum insulin concentrations (INS) were measured the following 600 min. In a second study, U40 and U100 soluble insulin was administered to 9 other volunteers (age 25±1 years, BMI 22.6±2.1 kg/m²; N.S.) under similar conditions. No significant differences were observed between the summary measures of U40 and U100 insulin. B28Asp showed a faster onset and a shorter duration of action than U40 insulin.

	U40	**U100**	**P**	**U40**	**B28Asp**	**P**
GIR_{max} (mg/kg/min)	8.9±2.0	9.5±2.3	0.296	9.5±2.6	10.5±2.6	0.151
t_{max} (min)	144±23	156±29	0.228	146±18	108±15	0.006
early $t_{50\,\%}$ (min)	61±11	65±15	0.523	60±11	43±7	0.001
late $t_{50\,\%}$ (min)	345±68	387±68	0.088	360±75	271±35	0.008
AUC 0-120 min	515±170	533±216	0.798	556±225	789±251	0.008
AUC 0-600 min	2663±512	3011±547	0.122	3002±1084	2724±558	0.395
INS C_{max} (pmol/l)	205±62	196±41	0.612	231±76	334±42	0 018
INS t_{max} (min)	111±35	129±36	0.268	97±21	71±11	0.005
AUC 0-120 min	17.7±6.5	16.1±4.0	0.622	19.8±6.3	29.9±3.0	0.007
AUC 0-600 min	52.0±10.8	52.9±5.9	0.806	54.7±17.8	53 3±7.6	0.824

The metabolic activity of human insulin in concentrations of U40 and U100 is comparable. S.c. injection of the insulin analogue B28Asp leads to a faster onset and a shorter duration of action even in comparison to U40 insulin.

1393

CROSS-OVER INSULIN PUMP STUDY WITH HUMAN INSULIN ANALOGUE [LYS(B28), PRO(B29)]

Schmauß,S and Landgraf,R, University of Munich, Munich, Germany.

The short-acting insulin analogue LP ([LYS(B28), PRO(B29)]) is absorbed from the subcutis more rapidly than regular insulin (R) because of its monomeric structure. To compare the clinical effectiveness of LP vs. R, 11 IDDM patients with continuous subcutaneous insulin infusion (CSII) therapy (6 F, 5 M, age 30±2,5 years, diabetes duration 14±1,0 years, BMI 24,0±0,8 kg/m^2, HbA_{1C} 6,5±0,2%) were studied in an open, randomised cross-over study for 6 months (3 months LP and 3 months R or vice versa). Mean fasting blood glucose was not significantly different in both regimens (6,5±0,4 vs. 7,5±0,6 mmol/l), but during LP 2 hours postprandial blood glucose levels were significantly lower compared to the R phase (6,8±0,3 vs. 8,5±0,4 mmol/l, p<0,01). There was no significant difference concerning hypoglycaemic episodes between the two groups. No significant differences concerning HbA_{1C}-levels between the two groups at month 0 were found (LP:6,3±0,2 vs. R:6,7±0,4). Among the patients treated first with LP HbA_{1C}-levels improved significantly compared to the group treated with R (at month 3: 5,7±0,3% (LP) vs. 6,5±0,3% (R), p=0,03). In the second phase of therapy HbA_{1C} decreased from 6,5±0,3% to 6,3±0,3% under LP regimen and increased from 5,7±0,3% to 6,2±0,2% in R phase. It can be concluded that LP in CSII-treatment is safe and further improves metabolic control.

1394

TIME-ACTION PROFILES OF PREMIXED FORMULATIONS OF INSULIN LISPRO AND NPL-INSULIN

T. Heise, C. Weyer, A. Serwas, S. Heinrichs, J. Osinga, P. Roach*, J. Woodworth* and L. Heinemann; Dept. of Metabolic Diseases and Nutrition, Heinrich-Heine-University of Düsseldorf, Germany; *Eli Lilly and Company, Indianapolis, IN, USA

Stable mixtures with insulin lispro (LP) can be prepared with the novel NPL-insulin, i.e. a protamine-retarded formulation of LP. In an open randomised study we investigated the time-action profile of pure LP and NPL-insulin and of three different mixtures: High Mixture (HM) 3:1 (LP/NPL); Mid Mixture (MM) 1:1, Low Mixture (LM) 1:3. 30 healthy volunteers (12 female, 18 male, age 27±2 years, BMI 23.0±2.3 kg/m² (mean±SD)) received a s.c. injection of 0.3 U/kg of one of these preparations on five study days, separated by at least one week. Glucose infusion rates (GIR) were registered during euglycaemic glucose clamps (target blood glucose level 5.0 mmol/l, i.v. insulin infusion 0.15 mU/kg/min) for 1440 min or 600 min (LP). Whereas the maximal metabolic activity decreased with lower LP content, the time point of maximal and of early half-maximal metabolic activity was comparable between the three mixtures. Higher proportions of LP resulted in a more rapid decline to late half-maximal activity and in higher AUCs within the first 360 min after injection. Serum insulin concentrations showed a similar behaviour. This study shows, that the pharmacodynamic and pharmacokinetic properties of insulin lispro are preserved in stable mixtures with NPL-insulin.

	GIR_{max}	t_{max}	early $t_{50\%}$	late $t_{50\%}$	$AUC_{0\text{-}360\ min}$	INS-C_{max}	t_{max}

IGF-I RECEPTOR-MEDIATED SIGNALLING OF THE HUMAN INSULIN ANALOGUE HOE 901

L. Liu, M. Koenen, G. Seipke* & J. Eckel, Molecular Cardiology, Diabetes Research Institute, Düsseldorf and *Hoechst AG, Frankfurt, Germany

HOE 901 is a novel human insulin analogue with protracted action being a promising candidate for basal insulin substitution with a daily single injection. Insulin receptor signalling of this analogue is not significantly different from native insulin, however, differential interaction with IGF-I receptors may modify the mitogenic properties of insulin analogues. H9 cardiac myoblasts, a cell line expressing a high level of IGF-I receptors with undetectable amounts of insulin receptors, were used to investigate IGF-I receptor signalling of HOE 901 and to compare it to native insulin and the supermitogenic Asp(B10)-insulin. Competition experiments indicated a higher affinity of HOE 901 for the IGF-I receptor when compared to regular human insulin (IC_{50} values: 44, 70 and 101 nM, for Asp(B10), HOE 901 and insulin, respectively). However, the mitogenic activity of Asp(B10), as determined from ^{3}H-thymidine incorporation, was significantly higher than the effect of HOE 901 with the latter being esssentially equipotent to native insulin. H9 cells were then labelled with ^{33}P-orthophosphate and stimulated with the peptides for 24 h. 2D-analysis indicated the presence of three major phosphoproteins (40-70 kDa) being largely dephosphorylated in the presence of insulin and HOE 901. In contrast, Asp(B10) induced a marked increase of additional phosphoproteins not detected in the presence of HOE 901 and insulin. Postreceptor signalling was analysed at the level of IRS-1 and Shc. Tyr-phosphorylation of IRS-1 increased 2 fold for both insulin and HOE 901 both after 10 and 60 min, with a significantly higher effect of Asp(B10) at 60 min (2.6 fold, p=0.026,n=5). One Shc protein with a molecular mass of 52 kDa was detected in H9 cells. Both insulin and HOE 901 did not modify the tyr-phosphorylation of Shc, whereas Asp(B10) produced a 50% increase in tyr-phosphorylation of this adapter protein.

In conclusion, IGF-I receptor signalling by HOE 901 is essentially identical to native insulin. Activation of Shc and sustained activation of IRS-1 by Asp(B10)-insulin may explain the higher mitogenic activity of this insulin analogue. Complete understanding of the action profile of insulin analogues must include analysis of IGF-I receptor signalling.

1396

EFFECTS OF THE AMYLIN ANALOGUE PRAMLINTIDE ON THE GLUCOSE RESPONSE TO A GLUCAGON CHALLENGE IN IDDM

L. Ørskov[1], B. Nyholm[2], K.Y. Hove[2], C.H. Gravholt[2], N. Møller[2], O. Kolterman[3], K.G.M.M. Alberti[4] and O. Schmitz[2]. [1]Dept. of Medicine C and [2]M, University Hospital of Aarhus, Denmark, [3]Amylin Pharmaceuticals Inc., San Diego, CA, USA and [4]Dept. of Medicine, Framlington Place, Newcastle-upon-Tyne, England.

Hepatic glycogen stores have been shown to be depleted, and glucagon stimulated hepatic glucose production (HGP) reduced in IDDM subjects, possibly contributing to deficient counter-regulatory responses to hypoglycaemia in these patients. Co-administration of amylin and insulin has been shown to replete hepatic glycogen stores in diabetic animal models. To investigate the effect of amylin replacement, employing the analogue pramlintide (Pr), on hepatic glucagon responsiveness, 13 IDDM males were studied in a double-blind placebo-controlled cross-over study after 4 weeks of subcutaneous Pr (30μg*4) or placebo (Pl) administration. Following an overnight fast plasma glucose was kept above 5 mM from 0-240 min (baseline=210-240 min), with an insulin infusion rate of 0.3 mU/kg/min. To control portal glucagon levels, somatostatin was infused at a rate of 200 μg/h, and basal GH (2 ng/kg/min) and glucagon levels (0.7 ng/kg/min) were replaced. Glucagon infusion was increased to 2.1 ng/kg/min at 240-360 min (step 1) and to 4.2 ng/kg/min at 360-420 min (step 2). Baseline mean plasma glucose (5.59 ± 0.16 vs 5.67 ± 0.25 mM) and HGP rates (1.32 ± 0.22 vs 1.20 ± 0.13 mg/kg/min) were similar and glucagon responsiveness was unaffected by pramlintide (glucose: step 1; 6.01 ± 0.31 vs 5.94 ± 0.38 mM, step 2; 6.00 ± 0.37 vs 5.96 ± 0.50 mM, HGP: step 1; 1.91 ± 0.18 vs 1.83 ± 0.15 mg/kg/min, step 2; 2.08 ± 0.17 vs $1,96\pm0.16$ mg/kg/min, Pr vs Pl). Glucose disposal rates were similar at baseline (2.44 ± 0.13 vs 2.28 ± 0.09 mg/kg/min; Pr vs Pl) as well as during the glucagon challenge ($p>0.20$). In conclusion: Co-administration of pramlintide (120 μg/day) and insulin to IDDM subjects for 4 weeks does not change the plasma glucose - or hepatic glucose production response to a glucagon challenge, following an overnight fast. In addition, pramlintide administration does not appear to alter insulin-mediated glucose disposal. Additional studies are required to assess the impact of pramlintide therapy on glucagon physiology in the postprandial state.

1397

Pramlintide Improves Glycemic Control in Patients with Type II Diabetes Requiring Insulin

R.THOMPSON*[1],L.PEARSON*[1],S.SCHOENFELD*[1], and O. KOLTERMAN*[1]. Amylin Pharmaceuticals, Inc. San Diego, CA

The effects of 4 weeks of subcutaneous administration of pramlintide, (Pr) an analog of human amylin, on glycemic control in 203 patients with Type II diabetes mellitus requiring insulin were examined in a randomized, double-blind, placebo-controlled, parallel-group trial. Statistically significant reductions in serum fructosamine concentration were observed in the Pr 30 µg QID group (17.5±4.9 µmol/L), the Pr 60 µg TID group (24.1±4.9 µmol/L) and the Pr 60 µg QID group (22.6±4.1 µmol/L) compared to placebo (PBO) (3.5±3.8 µmol/L). There also were statistically significant shifts in the proportion of patients with an abnormal serum fructosamine concentration at baseline that normalized at Week 4 within the Pr 60 µg TID group (28%) and the Pr 60 µg QID group (31%) compared to PBO (10%). Consistent with the reduction in fructosamine, there were also statistically significant reductions in HbA_{1c} in the Pr 30 µg QID group (0.53±0.07%), the Pr 60 µg TID group (0.58±0.07%) and the Pr 60 µg QID group (0.51±0.08%) compared to placebo (0.27±0.08%). Based on RBC lifespan, and assuming stable glycemic control, these reductions in HbA1c in the Pr groups should increase over the following 2-3 months. The reductions in fructosamine and HbA_{1c} were accompanied by a statistically significant reduction in fasting total and LDL cholesterol. In contrast to treatment with insulin alone, there were trends towards decreased body weight in the Pr 60 µg TID and 60 µg QID groups. Furthermore, the incidence of hypoglycemia was no greater in any Pr group than in placebo. In conclusion, measurement of similar changes in both serum fructosamine concentration and HbA_{1c} suggests that pramlintide therapy for 28 days improves glycemic control in patients with Type II diabetes mellitus requiring insulin.

1398

THE HUMAN AMYLIN ANALOGUE PRAMLINTIDE INHIBITED GLUCAGON SECRETION IN TYPE I DIABETIC SUBJECTS

M.S. Fineman, O.G. Kolterman, R.G. Thompson, J.E. Koda. CA, USA

It has been reported that Type I diabetic patients of greater than 5 years duration have a decreased glucagon response to hypoglycemia despite elevated basal and post-prandial glucagon secretion compared to non-diabetic controls. Rat amylin has been shown to inhibit the glucagon secretion elicited by an intravenous bolus of L-arginine in non-diabetic rats. Limited data, however, exists in humans. We measured plasma glucagon from patients who were treated with the human amylin analogue, pramlintide, to determine if similar glucagonostatic effects can be seen in human patients with Type I diabetes. The study utilized a randomized, placebo controlled, single-blind, 2-visit crossover design in which 16 patients received a 5 hour intravenous infusion of pramlintide at either 25µg/hr or 50µg/hr. Patients started the infusion at T=0 and received their normal morning insulin dose subcutaneously at T=30 mins. At T=60 mins, patients were given a 355 kcal standardized liquid meal challenge (Sustacal®). Plasma glucagon concentrations were measured by RIA (Linco Research Inc.) and plasma pramlintide concentrations were measured by IEMA. Mean steady state plasma pramlintide concentrations were 116 pM (110 pM - 125 pM) and 227 pM (207 pM - 253 pM) respectively [mean (range)]. Glucagon secretion from the time of Sustacal® administration to the end of the pramlintide infusion (60-300 minutes) was significantly reduced in both groups when on active treatment. The mean ± SEM plasma glucagon $AUC_{60\text{-}300}$ for placebo (N=16) was 15994 ± 1295 pg*min/ml compared to 14873 ± 2518 pg*min/ml and 12956 ± 72.6 pg*min/ml for the 25 µg/hr (N=8) and 50 µg/hr (N=8) pramlintide infusions respectively ($p<0.001$, crossover ANOVA). Additionally, a slight reduction in fasting (pre-Sustacal) plasma glucagon concentrations was seen after pramlintide infusion. The mean ± SEM change in fasting glucagon post infusion was -0.69 ± 1.10 pg/ml for placebo compared to -3.80 ± 1.31 pg/ml and -4.79 ± 0.80 pg/ml for the 25 µg/hr and 50 µg/hr treatments respectively (p=0.11 and p=0.09, crossover ANOVA). Although these individual comparisons did not reach significance, the pooled pramlintide results vs. placebo were statistically different (p=0.02). We conclude that the administration of the human amylin analogue, pramlintide, significantly reduced the elevated basal and postprandial secretion of glucagon seen in patients with Type I diabetes. This mechanism may contribute to the lowering of the post-prandial blood glucose that has been reported in previous studies.

1399

PHARMACOKINETIC EFFECTS OF SYRINGE MIXING PRAMLINTIDE, ISOPHANE INSULIN, AND SOLUBLE INSULIN.

E. Redalieu*, D. Blake, A. Nuttall, and R. Thompson. M. Hurley & Associates, Inc.*, Murray Hill, NJ, and Amylin Pharmaceuticals, Inc., San Diego, CA, USA.

The pharmacokinetics (AUC, C_{max}, and T_{max}) of pramlintide, free insulin and glucose following subcutaneous injections of 30 µg pramlintide, isophane insulin (I) and soluble insulin (S), given separately or syringe-mixed in various combinations within 5 min prior to injection, were compared in 28 patients with Type I diabetes mellitus. In a randomized, open-label, five-way crossover trial, there were five treatment regimens with a 1-week washout between each treatment: (1) placebo+I+S; (2) pramlintide+I, separate S; (3) pramlintide+S, separate I; (4) pramlintide, I, S, all separate; (5) pramlintide+I+S. Breakfast and lunch were given after the morning pramlintide and insulin administration, and blood samples were collected for 10 hours (5 hours for pramlintide analysis). Pramlintide was rapidly absorbed and eliminated following separate injection or various combined injections. When mixed with I, pramlintide appeared to have increased bioavailability compared to the other treatments. The free insulin profile following combined pramlintide+I+S injection was similar to that following separate injections of pramlintide, I and S. Glucose C_{max} values were significantly lower and T_{max} values were delayed following combined pramlintide+I+S injection compared to combined placebo+I+S injection. Up to 180 min after administration, the four pramlintide treatments resulted in lower glucose profiles compared to placebo treatment. Over the entire period (0-600 min) the glucose profile was clinically optimal with the combination pramlintide+I in one syringe, with or without S, compared to the other treatments. These results support the mixing of pramlintide with isophane and/or soluble insulin in the same syringe prior to subcutaneous self-administration.

RELIABLE BLOOD GLUCOSE MEASUREMENT WITH THE APEC GLUCOSE ANALYSER

L. Heinemann, C. Weyer, M. Stoffels, U. Schaden and T. Heise, Dept. of Metabolic Diseases and Nutrition, Heinrich-Heine-University of Düsseldorf, Germany

In contrast to the large variety of glucose meters for patients' use, there is only a small selection of glucose analysers available for rapid, reliable and cheap glucose measurements on the ward. The APEC glucose analyser (Ruhrtal Labor Technik, Möhnesee-Delecke, Germany) estimates glucose concentrations by measurement of the oxygen decline with a polarographic oxygen electrode employing the glucose oxidase reaction. This desk top analyser allows glucose measurements in blood, serum, plasma, urine (in 10 µl samples) and in haemolysed blood (mixture of 40 µl blood, drawn up with a heparinised capillary and 590 µl reagent) within 30 s (46 s with blood), prints out the measurement results, performs a number of self tests and prints error analyses in case of problems. The costs for a single blood glucose measurement are 0.35 DM. We evaluated the reliability of the APEC glucose analyser in comparison to the Beckman Glucose Analyser (Beckman, Munich, Germany) by parallel measurement of 429 venous blood samples. Plasma glucose concentrations measured by the Beckman analyser were corrected by subtraction of 10 % to blood glucose concentrations (5.0±2.1 (1.7-17.2) mmol/l; (mean±SD (range)). These values were comparable to the results with the APEC analyser from haemolysed blood samples (5.0±2.1 (1.1-17.3) mmol/l, p=0.129, paired t-test), the absolute difference being 0.0±0.4 mmol/l. Linear correlation gave a regression line of y=0.983x+2.07 and a correlation coefficient of r=0.982. With the error grid analysis 426 (99.3 %) of all results with the APEC analyser are in zone A/a, in which differences between the results have no clinical implications. Only one value was in zone B and two in zone D, i.e. only three results showed clinically relevant or not acceptable deviations. The APEC glucose analyser allows rapid and reliable blood glucose estimations in small blood volumes.

1401

VALIDITY OF HbA_{1c} MEASUREMENTS IN DIABETIC PATIENTS WITH A HIGH DEGREE OF HYPERGLYCEMIA

R. Zinnat, N. Kamal, L.Ali, A.K. Khan; *Research Division BIRDEM, Dhaka, Bangladesh*

Although HbA_{1c} is now routinely used as an indicator of long-term (2 months) glycemic status in diabetic patients, its validity in rising degrees of hyperglycemia becomes increasingly difficult to be ascertained in human subjects *in vivo* due to obvious ethical reasons. Like many tropical developing countries Bangladesh has a group of patients termed as malnutrition related diabetes mellitus (MRDM), who presents with an extreme degree of hyperglycemia (fasting blood glucose values usually above 18mmol/l and 2-hr post prandial values >25 mmol/l) and even without any treatment, they do not develop ketoacidosis. In the present study HbA_{1c} level of 16 MRDM (12 FCPD and 6 PDDM), 26 NIDDM (of same age group) and 54 age-matched nondiabetic control subjects were measured to explore the applicability of the test in MRDM patients. A three sample OGTT was also performed in each subject. Glucose was estimated by Glucose-oxidase method and HbA_{1c} was estimated by an automated HPLC technique based on cation-exchange (Variant, Bio-Rad, USA). HbA_{1c} in MRDM subgroups (%,M±SEM: FCPD: 17.1±1.12) and PDDM: 16.4±1.9) were much higher than those in Control (4.7±0.1) and NIDDM (10±0.6). The values reflect the wide difference in fasting serum glucose levels between the MRDM subgroups (mmol/l, M±SEM, FCPD: 20.2±1.8 and PDDM: 16.9±2.5) and the NIDDM group (11.4±1.0) as well as between the MRDM subgroups and Control (3.5±0.1). The mean (±SEM) postprandial 1-hr glucose levels were 6.6±0.4, 30.9±2.2, 27.1±3.4 and 21.3±1.5 mmol/l and the mean (±SEM) postprandial 2-hr glucose levels were 5.6±0.3, 32.3±2.1, 28.3±3.3 and 23.0±1.6 mmol/l in control, FCPD, PDDM and NIDDM patients respectively. Significant difference ($p<0.001$) was found between all the diabetic groups and the nondiabetic one but not between FCPD and PDDM regarding serum fasting and postprandial glucose and HbA_{1c} levels. The NIDDM patients had significantly ($p<0.001$) lower values compared to FCPD patients in all cases. HbA_{1c} correlated with fasting serum glucose in FCPD ($r=0.71$, $p<0.01$) and in NIDDM ($r=0.8$, $p<0.001$) cases.The results demonstrate that HbA_{1c} is a reliable indicator of glycemic status in all types of diabetes including those with very high blood glucose levels.

1402

LOCAL ADVERSE EVENTS DURING LONG TERM TREATMENT WITH IMPLANTABLE INSULIN PUMPS IN TYPE I DIABETIC PATIENTS

N Jeandidier*, P Belicar**, S Boivin*, M Pinget* for the EVADIAC Study Group. *Service d'Endocrinologie, HU Strasbourg, **Service de Medecine Interne, La Timone Marseille, France

The aim of the study was to assess the frequency of local adverse events during long term therapy using implantable insulin pump, their clinical impact and the predisposition factors. From 1989 to 1995, 352 IDDM patients were treated with either Minimed MIP 2001(n=466), Infusaid M1000 (n=52) or Siemens Promedos ID3 (n=30) devices. Local incidents, implantation procedure, patients' characteristics, usual physical activity and history of allergy were recorded in a retrospective multicentric study. Cumulative follow-up was 1180 patients.years. At least 1 local pump pocket complication occured in 84 patients after a mean implantation duration of 11.2 months (1-28). Mean rate of these events was 7.1 per 100 pts.yrs, 24% of the patients were affected.Wide variations (ns) were observed between large centers (eg>24 patients) and small centers (6.9 vs 13.9 per 100 pts.yrs, 22.5 vs 30.9%). Main local complications were inflammatory reactions (34.5%), skin erosions (44%) and infections (9.5%) requiring pump explantations in 64.4 % of these cases. None of the factors such as gender, age, BMI, diabetes duration, physical activity, history of allergy, pump model or implantation procedure was correlated with the occurence of local complications. They occured for 60.2% in patients implanted for the first time, of the non affected patients 35% were primo-implanted ($p<0.05$). No prophylactic antibiotherapy was prescribed in one of the large center with the highest frequency of local events (28.7%). Cutaneous complications were significant regarding their frequency and their consequences (pump explantation). No major causal factor involving patients characteristics or clinical procedure was found.

1403

VALIDATION OF A VASCULAR GLUCOSE MONITORING SYSTEM USING SODIUM CITRATE ANTICOAGULATION.

D Stein and R Dobbins. UT Southwestern, Dallas, TX USA

The use of heparin anticoagulation in metabolic studies may be undesirable due to a coagulation disorder or, more generally, artifactual elevations in plasma FFA due to its effect on plasma lipoprotein lipase. We tested the compatibility of using localized sodium tricitrate (NaCit) anticoagulation with a recently US-FDA approved in-line vascular glucose sensor (VIA Model 121, VIA Medical, San Diego, CA) during hyper-(11.1), eu-(5.3) and hypo- (2.5mM) glycemic clamps in 16 subjects. We substituted NaCit for heparin at 1.1 mg/dl in the isolyte flush solution that was infused at 60 cc/hr. The external sensor was attached via an 18-20 gauge catheter to an arterialized hand vein. Blood was sampled at 5-10 minute intervals per our usual clamp protocol from the sensor's stop cock blood drawing port and plasma glucose measured on a Beckman autoanalyzer. We compared values for 21 consecutive studies (439 data points) with a glucose range of 2.3 to 16.1 mM. For the group as a whole, the bias (percent error) was 0.9% with a precision (standard error of the mean) of 2.25%, and an R^2 of 0.985. In conclusion, sodium tricitrate anticoagulation is effective in maintaining vascular line patency when frequent blood sampling is required during physiologic studies and this additive does not affect the accuracy of glucose measurement when using the VIA model 121 real time monitor.

1404

INTRAVENOUS INSULIN PUMP AND AUTOMATIC RATE ADAPTATION BY MEANS OF NEURAL NETWORK. PRELIMINARY STUDIES

S. Boivin*, M. Milgram**, O. Catu***, N. Jeandidier* and M. Pinget*. Service d'Endocrinologie, Hôpitaux Universitaires - Strasbourg, **Université Paris VI, *** S.E.T. Médical, FRANCE.

Intraveinous (iv) insulin infusion is often required in the management of acute situations in type I and II diabetic patients. The lack of suitable algorithm for dose adjustment in function of capillary blood glucose (CBG) represents a limitation for this treatment, especially in non diabetologic units. We developed a new pump in order to allow i) iv insulin infusion, ii) automatic rate adaptation in function of patients characteristics and discontinuous CBG measurements (10/day). The system is based on neural networks, educated by means of a bank of data (10,000 examples of rate adjustments in function of CBG, and the resulting CBG), obtained by collecting data of 711 type I or II patients (1990 to 1994). A : Retrospective safety and feasibility study, using another bank of data (similar conditions, more than 10,000 examples). Correlation between the system propositions (SP) and the mecical propositions (MP) : $R = 0.979$, $p < 0.001$. B : prospective on-site study : when SP and MP were different, the physician selected the rate to be applied. Correlation between SP ans MP : $R = 0.969$, $p < 0.001$. When SP was applied (78.3 % cases), 70.15 % of the CBG obtained were between 60 and 150 mg/dl, 4.03 % were lower, 25.46 % were upper. When the rate choosen was MP, 81.5 % CBG were between 60 and 150 mg/dl, 4.6 % were lower, 13.9 were upper. The significant correlation was observed as early as the first day of treatment. There was no severe hypoglycemia. A larger study is necessary to validate the system before its use in non diabetologic units.

1405

LONG-TERM CLINICAL APPLICATION OF WEARABLE ARTIFICIAL ENDOCRINE PANCREAS IN DIABETIC PATIENTS

M.Sakakida, K. Nishida, S. Shimoda,T.Uemura,Y.Konno,K.Ichinose and M. Shichiri. Department of Metabolic Medicine, Kumamoto University School of Medicine, Kumamoto, Japan

To achieve the long-term blood glucose regulation and clinical application of the closed-loop system in ambulatory diabetic patients is essential. However, two major problems should be solved for long-term application of wearable artificial endocrine pancreas.

1.Development of stable and reliable subcutaneous glucose sensor: With a ferrocene-mediated glucose sensor covered with highly biocompatible membrane, 2-methacryloyloxyethyl phosphorylcholine-co-n-butyl methacrylate (MPC-co-BMA) membrane, subcutaneous tissue glucose concentrations could be monitored precisely and continuously for up to 7 days without any in vivo calibrations. and for 14 days with one-point in vivo calibrations.

2.Development of subcutaneous insulin infusion algorithm: Considering the management and safety of insulin delivery route when wearable artificial endocrine pancreas is applied to ambulatory diabetic patients for long-term basis, subcutaneous insulin infusion algorithm has been developed by analyzing by analyzing the dynamics of subcutaneously injected short-acting insulin analogue (Insulin Lispro)by three compartment model. By applying subcutaneous insulin infusion algorithm using Insulin Lispro which is absorbed 2 to 3 times faster than usual regular insulin, near-physiological glycemic control could be achieved in diabetic patients without showing any delayed hyperinsulinemia nor hypoglycemia.

In conclusion, wearable artificial endocrine pancreas is now recognized as an excellent therapeutic tool for regulating blood glucose excursions physiologically in ambulatory diabetic patients on long-term basis.

1406

GLUCOMETER®DEX™ - A NEW SMBG SYSTEM

(J.O.Noell, M.K.Musho and K.F.Yip. Bayer Corp., Elkhart, IN, USA)

The Glucometer DEX Diabetes Care System is a convenient and accurate home use device for the self-monitoring of blood glucose (SMBG). The system consists of an instrument, reagent sensor discs and control materials. It is conceptually the same as other Glucometer products currently available for blood glucose testing. The unique aspect of the system is that the test sensors are not packaged individually. Rather tests are packaged ten at a time (individually sealed) in an aluminum formed blister (Test Sensor Disc). The user never handles the actual test sensor. The DEX test sensor is comprised essentially of electrodes capable of making an amperometric measurement and a reagent deposition of the enzyme, glucose oxidase, and the electron transfer agent, potassium ferricyanide. The DEX test sensor uses a capillary for sampling. The volume of the capillary is 3-4 µl. Testing time for each sample is 30 seconds. The DEX test sensor has a linear response to glucose from 10 - 600 mg/dL. The DEX system exhibits good precision across the whole response range (less than 3mg/dL as one sd below 50mg/dL and 3-5% CV above 50mg/dL) when tested either with whole blood samples or controls. The test results from the DEX system correlate very well with the SMBG devices currently available on the market (with correlation slope between 0.957 and 1.02, correlation intercept between -3.3 and 6.9, and standard error of estimation between 8.8 and 16.2 mg/dL). The system exhibits minimal bias from hematocrit effect, oxygen, temperature and common interference in whole blood.

HUMORAL IMMUNE RESPONSE TO POLYMERIC GLUCOSE SENSOR MEMBRANES AS PARAMETER OF BIOCOMPATIBILITY TESTING

Schlosser, M., Ziegler, B., Abel, P., Ziegler, M. Institute of Diabetes "Gerhardt Katsch", University of Greifswald, D-17495 Karlsburg, GERMANY

There are numerous reports on implanted glucose biosensors showing that the loss of sensitivity to glucose after implantation is one of the major problems. One of the possible reasons for this might be the bioincompatibility of materials used for sensor preparation, resulting in thrombogenic, inflammatory and immunological responses to the implant. In a preliminary study after implantation of glucose sensors, we have detected IgG-antibodies against the outer sensor membrane consisting of cellulose acetate suggesting a specific immune response against polymeric materials. Therefore this study was aimed to compare the immunogenicity of different polymeric membranes (polyimide, pellethane, polycarbonate, PTFE) potentially suitable for covering biosensors. Sterilized pieces of 10x10 mm were subcutaneously implanted into female LEW.1A rats on days 1, 21 and 42. The time course of antibody formation was analyzed on days 1, 10, 21, 28, 35, 42 and 49. IgG-antibodies were detected by means of a specially developed enzyme immunoassay technique using the respective membrane immobilized at the bottom of a 96-well MINIFOLD I. The cut-off for antibody positivity was calculated from mean O.D.+2SD of control animals for each antigenic target. On day 49 antibodies to polymeric membranes were detectable by 40% (4/10) with the PTFE membranes, 36% (5/14) with pellethane, 20% (3/15) with polycarbonate, and 13% (2/15) with polyimide. Except polyimide the antibody prevalence against all materials could be significantly enhanced by one intraperitoneal application of complete Freund's adjuvant on day 1 (100% (4/4) with PTFE, 60% (3/5) with pellethane and 80% (4/5) with polycarbonate). All membranes tested in cell culture showed no cytotoxic effect. The results demonstrate a significant but individually varying IgG-antibody formation against different biomaterials. Polyimide has shown the lowest immunogenicity and therefore it might be highly biocompatible. We conclude that immunogenicity should be generally involved in biocompatibility testing for selection of sensor membranes to improve the functional stability of biosensors implanted.

1408

ACCEPTANCE AND EFFECT OF A COMPUTER-BASED BLOOD GLUCOSE MONITORING DEVICE IN ADOLESCENTS WITH TYPE I DIABETES.

S. Müther, R. Hartmann, R. Lauterborn and W. Burger. Dept. of Pediatrics, Virchow Medical Center, Humboldt University of Berlin, Berlin, Germany.

Adolescents with insulin-dependent diabetes mellitus (IDDM) often have problems with therapy and metabolic control. Intensive support may be useful for this age group. **Objectives:** To investigate the acceptance of a computer-based blood glucose monitoring device (Accutrend DM, Boehringer Mannheim, Germany) and to evaluate the influence of using this device on understanding of disease, metabolic control, and therapy. **Methods:** A prospective randomized study was conducted in patients (pts) with IDDM aged 12-18 years over a period of 10 months. 57 of 162 pts were interested in participating. They were randomly divided into an interventional group of 29 pts receiving blood glucose monitoring systems and into a control group of 28 pts with unchanged self-monitoring. Two pts of each group were lost to follow-up. Thus, 27 pts of the intervention group (12m, 15f, age 15.3±1.4 yrs, diabetes 5.2±4.1 yrs) and 26 pts of the control group (12m, 14f, age 15.3±1.9 yrs, diabetes 4.8±3.6 yrs) were evaluable. At begin and end of study, expectations and perceptions of pts and parents were documented. HbA_{1c}-level, frequencies of metabolic control and insulin injection, and handling and judgement of the monitoring device were registered every 3 months at regular visits. **Results:** 67% of the pts rated the handling of the blood glucose monitoring device as good, 12% had problems. 32% used the internal statistic program, and 71% reported an improved understanding of their diabetes treatment. 67% were motivated to increase the metabolic control. 65% of the intervention group and 60% of the control group performed three or more blood glucose tests per day (n.s.). Numbers of insulin injections were increased in 10 of 20 pts of the intervention group with initially less than 4 daily injections vs. 4 of 19 pts of the control group (p=.06). HbA_{1c}-levels were not significantly different between both groups at any time, but improved during the course of study in both groups. Results were not influenced by sex, age or school education. **Conclusions:** In the majority of adolescents, acceptance of the blood glucose monitoring device was positive. Within 10 months, there were either no or only small differences in frequencies of metabolic control, insulin therapy and HbA_{1c} between pts with and without monitoring device.

1409

NO DIFFERENCE IN PAIN PERCEPTION WHEN TWO TYPES OF LANCETS FOR BLOOD GLUCOSE TESTING WERE USED

R. Hanas, M. Hallman, P. Hanas, B. Järlöv-Hjelm and AS. Karttunen. Department of Pediatrics, Uddevalla, Mölndal and Kungsbacka, Sweden.

Aiming for a better glycemic control inevitably requires frequent blood-glucose testing. Previous lancets are of 23G size but a 28G lancet has recently been introduced. The aim of this study was to evaluate if a thinner lancet would reduce the finger-pricking pain. At a diabetes summer camp we performed a double-blind, crossover study with 29 IDDM children aged 9-13 years. The lancets were used only once. Pain was registered on a 10 cm VAS scale with faces and endpoints marked "No pain" and "Much pain". The mean VAS pain score was for the 23G lancets (Ames Surelite, 0.65 mm diameter, 3 mm length) 1.5 ± 1.1 cm and for the 28G lancets (Becton-Dickinson Microfine +, 0.36 mm diameter, 4 mm length) 1.6 ± 1.1 cm (n.s. t-test). The residual pain (pain when pressing the finger the next day) was for the 23G lancets 0.6 ± 0.8 cm and for the 28G lancet 0.3 ± 0.4 (n.s. t-test). 11.0% of the 23G needles needed repricking to obtain enough blood with the Glucometer GX meter (needs 30 - 40 μl of blood) compared to 2.8% with the 28G needle (p=0.055 Chi^2). 5.6% of the 23G needles needed repricking to obtain enough blood with the Glucometer Elite meter (needs 3 μl of blood) compared to 6.8% with the 28G needle (n.s. Chi^2). 27.9% of the prickings with 23G lancets needed extra wiping of blood after the test compared to 40.0% of the 28G needle (p=0.036 Chi^2). There was no difference in which lancet the children preferred using. In conclusion, we did not find any difference in pain perception or patient preference when two lancets with considerable difference in size were tested. The 28G lancet is thinner but also longer which might cancel each other out in pain perception. The longer lancet needed more wiping but also slightly less frequent repricking when used with a meter needing more blood for measuring. It seems as if the length of the lancet is more important than the diameter for how much blood is obtained when pricking. In this camp setting, where the group pressure of accepting blood glucose testing is larger than at home, the children were indifferent to the types of lancets tested.

1410

Rapid Fructosamine Test for Use in Diabetes Clinics. G. Neyer, C. Carter, S. Miller and V. Noetzel. LXN Corporation, San Diego, California, USA.

Diabetic patients achieve better glycemic control when health professionals are aware of their glycated protein levels. Now, an instrument for the determination of glycated protein (fructosamine) has been developed (LXN Corporation) which allows patients or health care professionals to use a simple procedure to obtain rapid test results from a fingerstick drop of blood. The potential of various interfering substances to affect system accuracy has been studied. System accuracy was unaffected by hematocrit values within normal physiological ranges (between 20% and 65% hematocrit). Also, no significant effect on accuracy was observed when ascorbic acid (to 1.5 mg/dL), bilirubin (to 8.0 mg/dL), hemoglobin (to 200 mg/dL), glucose (to 1200 mg/dL), uric acid (to 17 mg/dL), triglycerides (to 800 mg/dL) and glycerol (to 88 mg/dL) were tested within and above physiological ranges. These results show that the LXN Fructosamine Test is a viable alternative to laboratory-based testing.

1411

GASTRIC BANDING AND TYPE 2 DIABETES
T.Haas, S.Svacina, J.Fried, M.Peskova, J. Sonka
3rd Medical and 1st Surgical Clinic, 1st Medical Faculty, Charles University, Prague, Czech Rep.

22 patients (7 diabetics, 15 non diabetics) indicated for gastric banding were followed for 3 years. 7 patients had less than 10 kg weight loss, 15 patients successfull weight loss, some with weight regain later - 7 patients. Anova with repeated measures found no difference between DM and nonDM in BMI: Diabetics 43.8...41.0...39.6...40.1 kg/m^2, non diabetics 45.1...41.3 ...39.6...39.0 kg/m^2. In Fisher test the only variable which had borderline significance for ability to lose weight was the family history of type 2 diabetes. Stepwise regression analysis for BMI changes was performed for every interval of weight change. The only significant result was (BMI change during whole 3 years)= -7.88 + 2.39 (BMI change in 6 months). All other initial variables: BMI, gender, history of weight oscilations, insulin, blood glucose, T3, T4, triglycerides failed to enter the models.
Conclusion: 1. Difference in weight change cannot be explained by diabetes or basic metabolic and hormonal characteristic of patients. 2. The only type of patients with greater benefit of the operation are non-diabetics with family history of DM. 3. The early weight loss can be used to predict the final result.

1412

TELEMEDICINE IN THE CARE OF IDDM PATIENTS
E. Kilkki[1], L. Riihelä[1], K. Nyholm[2], J. Pajunen[3] and V.A. Koivisto[4].
[1]Kuusankoski District Hospital, [2]Technical Research Centre of Finland, [3]Medicom Finland and [4]Department of Medicine, Helsinki University Hospital, Helsinki, Finland.
Self blood glucose monitoring is important for good control in IDDM patients. The use of telematic information transmission could save time and expenses related to outpatient visits. We examined the usefulness of this method in 10 IDDM patients (age 36 yrs, rage 17–50 yrs, duration of diabetes 12 yrs, range 1–23 yrs, mean insulin dose 31 U/d, range 10–54 U/d). They all had previous experience in personal computers. A software was developed to store, transfer and print out self blood glucose monitoring data in different forms (numbers, figures). A two–way transfer of messages was possible as well. After initial education, the patients had a 3 month run–in period followed by a 12 months study. Data on home blood glucose monitoring, symptoms and large glucose excursions were transferred, and HbA_{1c} was determined at outpatient visits at 3–5 month intervals. The number of home glucose determinations varied from 206 to 1902 and telematic transmissions from 2 to 26 per patient/year. No significant changes were observed in HbA_{1c} level, total insulin dose or major fluctuations in glycemia as compared to a 6 month period before the study. No patients had any emergy visits to hospital due to hypoglycemia or ketoacidosis. 9/10 patients were pleased with the system and willing to continue it after the trial. In conclusion: 1) Telematic data transmission can be utilized in the management of IDDM patients familiar with computer technology. 2) The two–way use of this technology may enhance safety, help in every–day care and save time and expenses of outpatient visits.

1413

ACCEPTABILITY OF A 'PATCH LIKE' DEVICE FOR CONTINUOUS BASAL INSULIN SUPPLY.
J. Llewelyn[1], J. Martin[1], M. Birkett[1], R. Michels[2] and G. Rayman[3] Lilly Research Centre, Windlesham, U.K.[1], Academic Medical Center, University of Amsterdam, the Netherlands[2], The Ipswich Hospital, Ipswich, UK[3]
Due to their relatively short time action profiles and large variations in absorption rates, currently available basal insulin preparations are not ideal. Subcutaneous insulin infusion pumps may provide good basal insulinisation but are technically sophisticated and not suitable for many patients. The objective of this study examined patient acceptability of wearing a 'patch like' device for continuous delivery of basal insulin. 38 IDDM and 7 NIDDM insulin using patients (20 female, 25 male, mean age 38 yrs) from 2 centres tested 4 prototypes (2 different shapes and 2 different adhesives). All prototypes were non functional and did not have a needle attached. Each patient tested each prototype for a period of one week in a randomised order. Patients collected information throughout the study period in a diary and completed a series of six questions using a visual analogue scale (VAS 1-10) at the end of each week to assess acceptability. Patients continued to take their usual insulin regimen throughout the study period (pen device n=38, syringe n=7). 14 patients (31%) reported problems with fixation of the prototypes (28 reports) and 26 patients (58%) reported a prototype becoming detached (44 reports). Detachment was most commonly associated with a bath, undressing or occurred overnight. 20 patients (48%) reported minor skin reactions, including pruritis. There was no detectable device or adhesive effect on acceptability but there was an observable period effect with patients more likely to accept the prototype tested in week two. Overall, 58% of patients said that they would consider changing their current regimen to use a 'patch like' device (VAS score >5). In conclusion, there remain technical difficulties with the use of this device but if these can be overcome they may offer a feasible alternative for basal insulin delivery.

1414

ACCURACY OF HOME BLOOD GLUCOSE METERS WITH SPECIAL RESPECT TO DIFFERENT GLYCAEMIC RANGES

G. Sendlhofer*, M. Ellmerer**, G.A. Brunner*, A. Wutte*, L. Schaupp**, Z. Trajanoski**, P. Wach**, and T.R. Pieber*. *Department of Internal Medicine, Diabetes and Metabolism, University of Graz, Austria, **Institute of Biomedical Engineering, University of Technology, Graz, Austria

AIM: Aim of this study was to investigate the accuracy of 6 home blood glucose meters with special respect to different glycaemic ranges (low range <3,89 mmol/l, acceptable range 3,89-9,99 mmol/l, high range >9,99 mmol/l.

METHODS: In total 1146 blood glucose monitor readings [Reflolux S (Boehringer Mannheim), One Touch II (LifeScan), Glucocard Memory (Menarini), Precision (Medisense), HemoCue (HemoCue) and Accutrend α (Boehringer Mannheim)] and 191 reference values (Beckmann Glucose Analyzer 2) were analysed. Arterialised blood samples were obtained from 5 subjects under controlled conditions (glucose clamp technique). The correlation coefficients for each glucose meter in total and according to the different glycaemic ranges and the percentage of measurements outside 20% were as follows:

RESULTS:

	<3,89 r	3,89-9,99 r	>9,99 r	total r	total > 20%
Reflolux S	0,60	0,88	0,62	0,96	32%
OneTouch II	0,73	0,96	0,90	0,99	7%
Glucocard M.	0,78	0,97	0,86	0,99	13%
Precision	0,61	0,94	0,79	0.98	30%
HemoCue	0,67	0,94	0,41	0,97	8%
Accutrend α	0,70	0,96	0,81	0,98	12%

CONCLUSION: Accuracy of blood glucose meters shows substantial differences according to defined glycaemic ranges. Therefore we suggest separation into different glycaemic ranges, whenever accuracy of home blood glucose meters is evaluated.

1415

On-Line Continuous i.v. Glucose Monitoring in Diabetic Patients during Hemodialysis

M.I. Salgado[1], F. Sternberg[1], U. Hoss[1], J. Bican[1], D. Bundschu[2], R. Krämer[2], E.F. Pfeiffer[1]
[1]Institut für Diabetes-Technologie an der Universität Ulm, Ulm, Germany
[2]Kuratorium für Dialyse und Nierentransplantation, Ulm, Germany

Introduction: Diabetes mellitus is one of the major causes of end stage renal failure. The practice of continuous i.v. glucose monitoring during hemodialysis may show the actual metabolic state of the patient and may help correct possible hypo/hyperglycemias. Aim: To evaluate the feasibility and profits of the on-line continuously monitoring of blood glucose during hemodialysis in NIDDM using the i.v. Glucosensor Unitec Ulm. Methods: A catheter for continuous blood extraction(v=20-40µl/min) was inserted into the tubes of the artificial kidney, located immediately after the inlet of the heparin supply pump. Blood was diluted 1:5 with a heparin saline and pumped into a flow chamber, where a glucose oxidase membrane was attached to a Ag/Pt electrode polarised at 700mV. The extracted blood glucose was oxidised to H_2O_2. The latter releases e^- to the electrodes proportional to the blood glucose concentration and are measured as electric current. In this fashion blood glucose was continuously monitored in 6 NIDDM patients(2 women and 4 men) during hemodialysis. Results: Mean blood glucose was 197±83mg/dl. In 2 patients blood glucose was corrected with i.v. insulin injection during hemodialysis The sensor signal correlated very well with the reference glucose values. The major problem was the interruption of the continuous blood extraction due to blood clotting in the tubing system of the glucosensor (n=3). However, this problem could be avoided in further experiments by perfusing 2000U/ heparin in the artificial kidney before starting the monitoring. Conclusions: On-line continuous blood glucose monitoring is feasible during hemodialysis and allows a better metabolic control of diabetic patients.

1416

INFLUENCE OF HYPERBARIC OXYGENATION ON THE LEVEL OF COUNTERINSULIN HORMONS IN IDDM.

Gubkina V.A, Dreval A .V ,Tischenina R.S,Molchanova G.S,Kiselev S.O,Kolesnichenco N.V,Zafarullah khan, Moscow Regional Research Clinical Institute, Moscow, Russia

AIM: To eualuate the possible hormonal changes in newly diagnosed IDDM after GBO therapy which was used as adjunctive to intensified insulinotherapy to improve tissue oxygenation and preserve residual insulin secretion. METHODS :Blood level of IRI ,C-peptide ,cortisol, GH ,TSH, T3, T4 were estimated by immunoassay. Urine excretion of Ad and Nad was detected by flurometry and 17- OCS by Porter-Silber method. 53 patients were treated by HBO (10 cessions duration 40 min at 2 ATA):mean age 24.6+67, disease duration mean 5.61+4.1.20 patients were matched control.RESULTS. GBO enable to compensate IDDM in short period .Just after GBO the level of C-peptid was increased from0.53+0.09 to 0.91+0.09 ng/ml. Increased Adr excretion before GBO was in 82 % of patients(109.0 +13.2nmol/l)and significantly lowered after GBO (to 84.5+10.2nmol/l). Nad excretion remained unchanged.Therefore Nad/Ad ratio became normal. Increased cortisol level preserved after GBO, but 17 -OCS excretion was in normal range, probably as a result of disturbed cortisol metabolism.GH level was increased only in group of patients with retinopathy and decrease to normal after GBO. The level of other hormons did not change significantly .Data revealed may prove the efficasy of including the GBO in the complex IDDM therapy.

1417

HABITUAL INSERTION VELOCITY OF INSULIN NEEDLES IN DIABETIC PATIENTS

H Egekvist[1], P Madeleine[2], L Arendt-Nielsen[2], P Bjerring[1] and H H Lervang[3]. Dept. of Dermatology, Marselisborg Hospital, Aarhus[1], Center for Sensory-Motor Interaction, Aalborg University[2], Dept. of Endocrinology, Aalborg Hospital[3], Denmark.

The movement characteristics during needle insertion of diabetics have not previously been described. This information is needed for optimal design of automatic needle insertion devices and to perform experimental and clinical studies investigating insertion of insulin needles - mainly related to discomfort and pain. Different movement phases were investigated in 28 patients with IDDM (12 female, 16 male, mean age 40.9±10.8 years, mean duration of IDDM 18.2±10.2 years) during 10 habitually performed insertions in each patient with G30 (0.3 mm outer diameter) 8 mm insulin needles. A motion analysis system with infra-red cameras (MacReflex System, Qualisys, Sweden) was used to describe the insertion movement. The overall mean velocity of needle insertion was 18.6 mm/s (SD 19.9), overall range: 1.0-133.3, range of individual means 2.1-43.6. The mean velocity of needle insertion in the thigh was 20.6 mm/s (21.9) and in the abdominal region 16.1 mm/s (17.0). The mean velocity of needle insertion performed with a 45 degree angle of insertion was 15.5 mm/s (16.4) and with a 90 degree angle 23.2 mm/s (23.6). Statistical analysis of variance showed significant difference between insertion with 45 and 90 degree angle ($p<0.05$). No significant difference between the velocity of needle insertion in the thigh and in the abdominal region was found. There was no correlation between the velocity of insertion and the duration of IDDM.

In conclusion these data suggest a considerable degree of individual variability of insulin needle insertion velocities. The velocity of insertion was related to the angle but not to the anatomical region of insertion.

1418

INCONSTANT RELIABILITY OF BLOOD GLUCOSE SENSORS WITH ALTITUDE.

P. Reboul, S. Bekka and D. Huzer. Clinique "Les Sorbiers", Jallans, France.

It is clearly established that IDDM- patients can practice even extreme sports like mountaineering. Still, reliability of blood glucose sensors with altitude has not been assessed. In this view, we have climbed Kilimandjaro (5895 meters) with 4 IDDM - patients and controlled our capillary blood glucose with different glucose sensors (One Touch Basic, One Touch Profile, Glucometer 4, Exatech Sensor) from 1500 meters to the top. We were the healthy references and visual measurement of capillary blood glucose was done each time with BM test 20800 strips. Our capillary blood glucose values during fast at 1500 meters are from 061 to 1.05 g/l according to visual measurement and much lower from 0.39 to .44 g/l at the top (visual measurement : 0.8 g/l). Diabetic patients have glycemics values with sensors near the one found with visual measurement for near normal values. Dispersion of the values when hyperglycemia occurs is much more important : one subject at the thop has 2.5 g/l with visual strip, 1.92 g/l with Glucometer 4 and 4.3 g/l with One Touch Profile ! This variability seems to be more important with height. We have not found one sensor better than the others. In conclusion, reliability of blood glucose sensors with altitude is bad and visual strips should be used during mountaineering.

1419

DEPENDENCE OF THE DELAY BETWEEN BLOOD GLUCOSE AND SUBCUTANEOUS GLUCOSE DYNAMICS ON INSULIN.

K. Rebrin , C. Kruse-Lee , W.P. Van Antwerp and J.J. Mastrototaro. MiniMed Inc., Sylmar, California, USA.

Subcutaneous (sc) glucose sensors have the potential to greatly improve glucose monitoring by diabetic patients. However, a sensor signal reflects sc interstitial fluid not blood glucose. The extent to which sc glucose differs from the plasma is not fully known. In the present study, sc amperometric enzymatic sensors were used to monitor glucose (MiniMed; in vitro sensitivity 0.2-0.5 nA/(mg/dl), T½<30 sec). The dynamics of the in vivo sensor current were studied during hyperglycemic clamps performed in 4 normal dogs. Each dog had up to 4 sensors inserted in the neck area 3hrs prior to the clamp. During the clamp blood glucose was increased from basal to ~180 mg/dl for two hours and then allowed to return. Insulin concentration increased ~10 fold in response to glucose infusion. In a separate set of 4 experiments somatostatin was infused to suppress insulin secretion. The in vivo delay in sensor current was identified by a differential equation (dI/dt= -p2xI + p3xGlu) from which the T½=1/p2 and the sensitivity=p3/p2 were estimated by least-squares fits of the data separately for rise and fall in glucose (mean±SEM). T½ was slower during the rise than the fall (4.52±1.22 vs 0.97±0.2 min, n=14; p=0.026). With somatostatin T½ was equal to 4.71±0.8 (n=14) for the rise of glucose. The in vivo sensitivity of the sensors (0.35±0.02, n=28) was similar to in vitro values. In conclusion, the time delay T½ of ISF glucose is typically only ~5min and decreases substantially with increasing insulin (<1min). Thus, interstitial glucose kinetics obtained with sc sensors should be appropriate for glucose control and hypoglycemic warning in patients. Advantages in correcting for the time delay remain to be studied.

1420

SAFETY AND ACCURACY OF BLOOD GLUCOSE MEASUREMENT IN HEIGHTS ABOVE 3 000 METER AND TEMPERATURES BELOW 0 ° C ON A HIKING TRIP WITH INSULIN - DEPENDENT DIABETICS

U. Thurm and R. Landgraf, Diabetes Centre, University Clinic, Munich, Germany

The aim of this study was to evaluate the accuracy of self testing of blood glucose on a hiking trip to the Vincent Pyramid (4215 m) and establish practical guidelines for insulin - dependent diabetics to hike safely. Six diabetic hikers , age between 26 to 45 years with a diabetes duration between 5 - 41 years and six age, sex and hiking experienced matched control persons took part in this expedition. Before and after every hike blood glucose, lactate, blood pressure, pulse rate and fluid intake was measured. On the hike the diabetics and non - diabetic control persons measured blood glucose every two hours with four blood glucose meters and collected 20 µl blood in an end to end capillary in a prepitted hemolysate sample. Below 4 000 m the average difference between the four blood glucose meters (Basic, Glucotouch, One Touch II and Profil) and the laboratory results was 13.5%. We found differences regarding the testing skills of the participants and divided all hikers in two groups regarding experience and accuracy in the use of the four Lifescan meters. The self - monitored blood glucose results differed in the experienced group by 11± % from the laboratory results and by 16 ±% in the less trained group in heights from 1 950 m to 3 650 m and temperatures up to - 15 ° C. Above 4000 m the average difference of the four blood glucose meters to the laboratory control was 46 ±%. There was no difference between the diabetic and the non - diabetic hikers regarding lactate, adaption to the height, blood pressure, fluid intake or pulse results. All diabetics reduced their short - and long - acting insulin between 20 - 50 % and increased their carbohydrate intake up to 300 %. During the whole trip no severe problems occured regarding the diabetes treatment. The meters tested in our study proofed to be reliable under those extreme conditions below 4 000 meters, but the users of the blood glucose meter have to undergo an intensive training and education programme to learn how to use their meter properly.

1421

Development of non-invasive determination of blood sugar level using the FT-IR

M.kanazawa, T.Inada, T.Inamura, A.Tanaka, T.Takahashi, R.Ito, Y.Notoya, T.Hayashi, K.Aizawa*, 3rd department of internal medicine, 2nd department of physiology* Tokyo Medical College, Tokyo Japan

To prevent the development of complication in the diabetic patients, a strict control of blood glucose level is the essential. For that purpose, measurement of blood glucose level with frequent blood sampling is necessary, which gives pains to the patients. We have developed a non-invasive determination system of blood glucose level using the Fourrier-transform infrared spectra.

[Method]Infra red spectra was measured at diamond 20(Nihon Denshi,Tokyo) using the multi-reflection method by prism. Since C-O-C structure of glucose had a characteristic absorbance at wave number 1039cm-1, glucose concentration could be determined quantitatively by applying the peak intensity. To determine the glucose level the fifth finger is adhere to the prism surface. At the same time the blood glucose level was measured by the glucose oxidase method to compare the values obtained by our method.

[Result]In in vitro examination, the absorbance of infrared rays increased depending on the glucose levels and it was indicated that the determination was possible for glucose concentration of 3.5 mM to 35mM. In the first in vivo study using the skin of finger, when the blood volume of the finger was constant, the determined values of glucose coincided with those of glucose levels measured by the glucose oxidase method, but the determined values varied when the finger was cooled or when the blood stream was blocked. In the second study we developed a non-invasive determing method of blood glucose level by obtaining the blood volume in finger using the amount of hemoglobin by the near infrared rays and correcting the determined values with the amount of hemoglobin.

1422

CLINICAL EVALUATION OF THE GLUCOMETER® DEX™ BLOOD GLUCOSE MONITORING SYSTEM

S.K. Garg, M.K. Jennings and A.M. Tideman. Barbara Davis Center, Denver, CO and Bayer Corporation, Elkhart, IN, USA.

This study evaluated a new blood glucose monitoring system in young adults with Type I diabetes and health care professionals (HCP). The meter sensor uses a glucose oxidase / electrochemical method. Five males and 15 females, 15-35 years old, participated in the study. Capillary blood results obtained with meters referenced to plasma/serum glucose values (PS) were compared to results of the Hitachi 747, a hexokinase chemistry analyzer (glucoses: 2.6-32.1 mmol/L). Whole blood referenced meter results (WB) were compared to results of the YSI 2300 Stat Plus, a glucose oxidase / electrode method (glucoses: 2.3-26.9 mmol/L). The hematocrit range was 36-50%. Linear regression results were:

Operators	Meter	N	Slope	Intercept	Std. Error	R
20 Patients	PS	105	0.94	0.50	1.01	0.98
2 HCP	PS	105	0.95	0.62	1.03	0.98
20 Patients	WB	109	0.99	0.38	0.85	0.99
2 HCP	WB	109	1.00	0.46	0.84	0.99

The pooled coefficients of variation for the paired patient and HCP meter results were 6.5% and 6.4% for the PS and WB systems, respectively. Features enhancing the clinical utility for self-monitoring included: automatic calibration, ten-test disc put in the meter resulting in less individual strip handling, only 3-4 µL of blood required, and results in 30 seconds. The meter system was found to have acceptable performance and clinical utility for self-monitoring of blood glucose.

1423

EFFECTS OF LASER THERAPY ON THE IMMUNE STATUS OF PATIENTS WITH DIABETES MELLITUS

S.G. Onuchin, Y. V. Benenson, S.S. Belousov, Y.L. Onuchina. Kirov State Medical Institute, Kirov, Russia.

The goal of our study was to research effects of low energy heli-neon laser therapy (LEHNLT) on the immunological status (IS) of 78 patients with insulin-dependent diabetes mellitus (IDDM) and 26 patients with non-insulin dependent diabetes mellitus (NIDDM) (the age range: 14 - 64 years; duration of the disease: from 1 month to 19 years). The control group included 30 healthy individuals of the same age range and the comparative group consisting of 100 patients with diabetes mellitus (DM) who had undergone routine treatments. LEHNLT was performed cutaneously on the pancreas for 6 minutes and IV for 30 minutes. The treatment included 10-15 procedures. The amount of T-and B-lymphocytes, T-subpopulation and immunoregulation index, levels of IgM, IgA, IgG, the immune complex (IC), functional activity of lymphocytes (spontanious B-lymphocyte activation and proliferative activity in response to T-and B-mitogens) estimated by luminoscent microscopy were used to evaluate the immunological effects of LEHNLT. Before the treatment essential changes in the IS had been revealed only in the IDDM patients. Our findings show that those who had suffered from IDDM for five years exhibited high autoimmunity, and changes in other organs were revealed in those who had had IDDM for over 5 years. Minimal immunological changes in the patients with NIDDM resulted from metabolic disturbances at the background of decompensation of DM or overdosage of insulin. Routine treatments for DM without immunocorrecting drugs did not improve their IS. The LEHNLT improved significantly the IS in over 70% of the IDDM patients ($p<0,05$). The best immunocorrecting effect was revealed in the patients with a short-term IDDM history (up to 5 years), it was stable for 3 months, correlated with a high level clinical-metabolic remission of IDDM, and then it decreased to the initial level within 3-6 months. To sum up, LEHNLT is effective in our complex therapy for DM to correct the IS in IDDM patients.

PERFORMANCE EVALUATION OF A NEW GLUCOMETER ENCORE® QA+ WORKSTATION IN NEONATAL, LABORATORY AND WARD SITES

D. Parker, N. Bradburn, J. Baum, R. Valdes, J. Eckfeldt and G. Mecklenburg. St. Vincent Hospital, Indianapolis, IN; University of Louisville School of Medicine, Louisville, KY; University of Minnesota Medical School, Minneapolis, MN; Bayer Corporation, Elkhart, IN, USA.

A Glucometer Encore® QA+ Workstation, with optical system and calibration algorithm enhancements developed to deal with a wide variety of hematocrit and glucose combinations, was evaluated in the hands of intended clinical users. Encore® reagent strips were used to test heelstick capillary bloods (4 neonatal nurses, 4 meters), fingerstick capillary bloods (2 ward nurses, 2 meters) and venous bloods (2 analysts, 2 meters) for glucose in comparison to the laboratory method at each site. Results were reported as mmol/l plasma glucose. Coefficients of variation with controls ranged from 5.3 to 9.6% (low), 4.3 to 5.4% (normal) and 3.4 to 5.5% (high). Hematocrits ranged from 25 to 68%, 26 to 49% and 24 to 60% at neonatal, ward and laboratory sites, respectively. No hematocrit effects on meter glucoses were noted with neonatal bloods. Encore® QA+ glucoses compared to laboratory plasma glucoses as follows:

	n	Regression	Syx	r	Bias	±15%	±20%
Neonatal wards	97	y=0.96x+0.03	0.36	0.951	-0.13 [c]	96.9%	99.0%
Diabetes ward	99	y=0.96x -0.23	0.83	0.986	-6.4%	93.0%	98.0%
Laboratory (lot 1)	70	y=0.96x+0.05	0.82	0.994	-1.7%	94.0%	100%
Laboratory (lot 2)	70	y=1.01x-0.006	0.75	0.995	1.6%	99.0%	100%

Plasma glucoses ranged from 0.7 to 8.0 mmol/l, 2.2 to 24.6 mmol/l and 0 to 26.3 mmol/l at neonatal, ward and laboratory sites, respectively. With Encore QA+ neonatal specimen glucoses ≤ 2.8 mmol/l, all were within 12% of the laboratory plasma glucose results. The new Glucometer Encore QA+ Workstation system performed well in these studies with neonatal heelstick bloods, adult capillary fingerstick bloods, and venous bloods from the laboratory site in comparison to the laboratory plasma glucose methods at the three sites.

1425

HELI-NEON LASER THERAPY WITH ROUTINE DRUG TREATMENTS IN PATIENTS WITH DIABETES MELLITUS

S.G. Onuchin, S. S. Belousov, E. V Benenson, Y.L. Onuchina. Kirov State Medical Institute, Kirov, Russia.

The main aim of our study was to investigate pathogenetic efficacy of low energy heli-neon laser therapy (LEHNLT) in combination with routine drug treatments in patients with diabetes mellitus (DM). Influence of LEHNLT was researched on the basis of clinical, laboratory and immunological findings in 104 patients with DM (78 insulin-dependent and 26 non-insulin dependent DM; their age spectrum: 14-64 years; the duration of DM: 1 month - 19 years). The control group consisted of 30 healthy individuals (the age range: 17-50 years), and the comparative group included 100 DM patients who had undergone routine medication therapy (diet, intensive insulin therapy or tablet-form hypoglycemic medications or their insulin and tablet combinations). Cutaneous and intravenous laser treatments were performed. The course of treatment consisted of 10-15 procedures. It was revealed and properly estimated that LEHNLT in patients with DM is effective and can be characterized by clinical remission accompanied by decrease of average daily glycemia and total compensation in 79% of the insulin-dependent and 81% of the non-insulin dependent patients. In addition to the total compensation, decrease of daily insulin doses was 45,3% ($p<0,001$) in the patients with insulin-dependent DM, and decrease of requirements for tablet-form hypoglycemic drugs was 58% ($p<0,001$) in the patients with non-insuline dependent DM. The laser treatment resulted in increase of insulin secretion activity of the pancreas ($p<0,005$), reliable hypolipedimic effect ($p<0,05$) and reliable immunocorrecting effect in 80% of the patients with insulin-dependent DM, mostly with 5-year duration of DM. The best effect was revealed in the patients with the 2-3 year duration of insulin-dependent DM. The above-mentioned positive effects remained for 6 months. To conclude, we consider the use of LEHNLT to be a necessary component of our complex treatment of patients with DM.

1426

CALIBRATION OF HbA_{1c} DETERMINATION
BY HbA_{1c} VALUES OF NON-DIABETIC SUBJECTS

P. Compagnucci, M.G. Cartechini, G.W. Mazzoli and MG Negroni. Diabetes Clinic, Camerino, Italy. On behalf of the "Gruppo di Studio S.I.D.-Marche per la Standardizzazione dell'HbA_{1c}".

HbA_{1c} is widely accepted as a valuable indicator of long-term blood glucose control. At present, however, inter-laboratory comparison of HbA_{1c} values is not possible and calibration is extensively investigated. Here we propose the use of HbA_{1c} values found in non-diabetic subjects as a simple mean for calibration. Oral glucose tolerance tests (OGTT) and HbA_{1c} determination in duplicate have been performed in ten Diabetes Clinics of the Marche region of Italy. Only non diabetic subjects (with normal OGTT response) have been considered. For comparison, HbA_{1c} has been assessed in a lyophilized material at low and high concentration, and re-determined again 1-2 months apart. Intra-assay, inter-assay and inter-laboratory coefficients of variation (CV) have been evaluated. HbA_{1c} has been determined by High Pressure Liquid Chromatography (HPLC). 208 non-diabetic subjects have been examined and mean (±SEM) HbA_{1c} value was 5.10±0.07% (range 3.4-6.6%). Mean intra-assay CV (duplicate samples in the same laboratory) was 2.18%, 2.13% and 1.57% for non-diabetics and for the lyophilized at low and high HbA_{1c} concentration. Inter-assay CV in each laboratory was respectively 1.98%, 2.07%, and 1.83%. Inter-laboratory CV was higher (13.04% in non diabetics; 17.41% and 13.12% in the lyophilized at low and high concentration). Calibration reduced the mean inter-laboratory CV to 5.83% wen based on the values of the lyophilized material, and to 5.77% wen based on the values of the non diabetic subjects. In conclusion, calibration of the HbA_{1c} determination greatly reduces the inter-laboratory CV and makes comparable the results obtained in different laboratories. Similar results can be obtained with HbA_{1c} values of both non-diabetic subjects or a lyophilized material, but the latter is at present not available in a stable and ubiquitous form.

A HEART RATE VARIABILITY MEASUREMENT SETUP

Matti Huotari, Lauri Honkala, Ville Ruikka
University of Oulu, Dept. Physical Sciences
Linnanmaa, FIN-90570 OULU, FINLAND

A purpose of this case work is to demonstrate an application of a time-voltage converter as a heart rate variablity (HRV) monitoring device. In HRV analysis technique this device detects burst-type signal and continuous activity and represents the results as rate vs. time directly. HRV fluctuates over time with a personal manner depending the balance between the sympathetic and parasumpathetic nervous control. In diabetes this fluctuation is changed because of e.g. neuropathy. However, the primary cause of the phenomenon is not known. HRV could be cured by a surgery operation if it is of anatomical origin. The heart rate measurement was realised in a convertional way. The instantaneous HRV was measured with a means of a time-voltage converter (Tektronix TVC501 TIME-VOLTAGE CONVERTER). Three volunteer subjects were measured and their HRV was analyzed based on the time-voltage converter measurement. In the healthy subjects heart rate was 0.86 and in the diabetec 2.05 beats/s. In the healthy subjects HRV was steady and in the diabetec random in supine position. The HRV clearly shows that the respirator rhythm causes finger prints which can be left also in the diabetec HRV power spectrum based on time-voltage conversion. The peaks in the HRV power spectrum move to high frequency in diabetes.

1428

INVESTIGATION OF COMMON INTERFERENCES ON HbA_{1c} USING THE A. MENARINI DIAGNOSTICS - KDK HA-8140 ANALYSER.

W. G. John. Clinical Biochemistry Department, The Royal London Hospital, Whitechapel, London. E1 1BB. UK.

The measurement of glycated haemoglobin has become of central importance in the evaluation of glycaemic control. Since the introduction of the clinically useful methods for glycated haemoglobin measurement, techniques have been refined to improve their reproducibility and more recently their level of automation. Although methods have improved significantly over recent years, the presence of interfering substances remain a major problem with associated with some techniques. A significant problem is associated with haemoglobinopathies and with increased levels of fetal haemoglobin; additionally the labile Schiff base remains a problem. A number of major haemoglobin variants were studied using the HA-8140 (A. Menarini Diagnostics - KDK), including HbS, HbC, HbE and thalassaemia. The range of HbA_{1c} results in normal individuals did not differ significantly from that found in non-diabetics with haemoglobinopathy. True peak separation was not always achieved in patients who have HbE present, although in all cases this abnormality could easily be recognised as a shoulder on the HbA_0 peak. Schiff base interference was investigated by incubating (for a limited time period) red cells in phosphate buffered saline containing a high concentration of glucose. Haemoglobin A_{1c} results obtained confirmed that this interfering compound was removed by the analyser; Schiff base is removed by incubation the sample in tetrapolyphosphate buffer, this is performed automatically on the HA-8140 analyser. The effect of fetal haemoglobin was investigated by spiking cord blood into samples collected from a number non-diabetic and diabetic subjects, this procedure resulted in an increase in HbF to 19%. Increased fetal haemoglobin had no significant affect on the measured HbA_{1c}. The results of this investigation show that the HA-8140 analyser is not affected by interfering compounds that adversely affect other systems.

1429

COMBINATION THERAPIES WITH INSULIN LISPRO IN NIDDM PATIENTS AT ORAL AGENT FAILURE.

U.GUDAT*1, M.TRAUTMANN *1, A.PFÜTZNER *1, J.ANDERSON *1, L. VIGNATI *1, Lilly Deutschland GmbH, Bad Homburg, Germany and Eli Lilly & Company, Indianapolis, USA.

Insulin lispro (LP), an analog of human insulin, shows pharmacokinetics that may be advantageous in the treatment of type II diabetic patients with oral agent failure. A multinational 3 way parallel study was designed to compare the efficacy of preprandial LP when combined with once daily NPH Insulin (LP/NPH) or sulfonylurea (LP/SH), with sulfonylurea plus NPH-Insulin (SH/NPH). 57 patients in Germany were randomised to one of the three treatments (31 females and 26 males, age 58±8.1 (mean±sd) years, duration of diabetes 11±7.4 years, body-weight 81±18.5kg, HbA1c 9.8±1.6%). After 8 weeks, efficacy of the treatments was evaluated by HbA1c.

	LP/NPH	LP/SH	SH/NPH
HbA1c (%)	8.1±1.3	7.7±1.2	7.9±1.6

If at this time metabolic control did not meet strict criteria (fasting blood glucose < 7.8 mmol/l, blood glucose 2 h postprandially > 10 mmol/l) treatment was intensified by addition of NPH insulin and withdrawal of sulfonylurea. Ten patients with LP/NPH were changed to preprandial LP and NPH twice daily (LP/NPH bid); 11 patients with LP/SH and 10 patients with SH/NPH were changed to LP/NPH. After 8 weeks HbA1c was reassessed.

Treatment change	N	HbA1c (%) before change	HbA1c (%) after change
LP/NPH to LP/NPH bid	10	8.6 ± 1.8	8.0 ± 1.5
LP/SH or SH/NPH to LP/NPH	21	8.2 ± 1.2	7.9 ± 1.1

In all treatment periods prandial blood glucose excursions were lowest when LP was administered before meals.
The data indicate that LP is suitable for patients with oral agent failure, and that use of LP is associated with better prandial blood glucose excursions.

Plasma ouabain concentration in Chinese NIDDM patients

JCN Chan, *A Butt, *YK Semra, CS Ho, CS Cockram and *R Swaminathan. The Chinese University of Hong Kong, Hong Kong and *Guy's and St. Thomas Hospital, London, UK.

Diabetes related hypertension is associated with increased exchangeable body sodium and abnormal transmembrane sodium transport. Inhibition of the activity of the Na^+,K^+,ATPase by endogenous sodium transport inhibitor (ESTI) may lead to increased intracellular sodium concentration. The latter in turn can lead to increased intracellular pH and calcium with increased vascular tone and smooth muscle cellular proliferation. We examined the clinical, biochemical and hormonal parameters in 152 Chinese NIDDM patients with normal renal function (plasma creatinine <120 μmol/l) on 3 occasions during a 6-week period when all antihypertensive medications were withdrawn. We also measured the plasma concentrations of ESTI by 2 non-specific assays [inhibition of purified Na^+,K^+,ATPase (ATPI) and as digoxin-like immunoreactivity (DLS)] and by immunoassay using antibodies against ouabain. Hypertension was defined as a mean arterial pressure (MAP)>100mmHg. Hypertensive patients (n=69) had higher plasma Na^+ (141 vs 139 mmol/l, p<0.001), atrial natriuretic peptide (ANP) (49 vs 35 ng/l, p<0.001), serum angiotensin converting enzyme (ACE) activity (74 vs 55 U/l), ATPI (7.5 vs 5.8 mmol/l, p<0.001), ouabain (0.92 vs 0.68 pmol/l) and lower plasma renin (31 vs 49 ng/l, p=0.02) than normotensive patients (n=83). DLS were similar between the groups. Using stepwise regression analysis, MAP was independently related to plasma ouabain (r^2=29.6, β=0.42, p<0.001), plasma Na^+ (r^2=12, β=0.22, p=<0.01), ANP (r^2=4.2, β=0.23, p<0.001), ACE (r^2=2.2, β=0.16, p=0.01) and K^+ (r^2=1.9, β=–0.14, p=0.03). These findings emphasis the importance of salt repletion and abnormal sodium transport in NIDDM associated hypertension.

1431

EFFECTS OF PERINDOPRIL ON MICROALBUMINURIA IN HYPERTENSIVE PATIENTS WITH NIDDM

X.Zhu, M.Z.Zhang, Y.C.Rong, Z.H.Pan, Z.J.Zhou and J.C.S.Hou. Xin Hua Hospital,SSMU,Shanghai, PR China

To determine the efficiency of ACEIs-Perindopril on microalbuminuria in hypertensive patient with NIDDM. Of 20 cases were enrolled the study, 12 males & 8 females, with mean age 57.4±8.9 yrs, mean duration of hypertension & NIDDM as 6.8±6.1 yrs & 4.2±4.4 yrs respectively. Perindopril (Servier, France) were given 2 mg daily for 6 months in those patients. The mean values of MBP (diastolic BP+1/3 pulse pressure), AER (urinary albumin excretion rate), PRA (plasma renin activity),GFR,ERPF,HbA_1%, FBG & FBI (blood glucose & insulin), BU & CR (blood urea & creatinine) & serum potassium(K^+) at the start & end of the therapeutic period were compared. Perindopril therapy were associated reduce in mean MBP (from 115.9±4.6 mmHg to 97.6±4.5 mmHg, P<0.01) & AER values (from 76.1±30.1 ug/min to 54.3±30.3 ug/min, P<0.01). Within the total cohort the mean FBI & hyperfiltrative GFR were improved (18.4±7.1 uU/ml vs 12.6±6.2 uU/ml & 111.9±23.1ml/min/1.73m^2 vs 86.5±23.7ml/min/1.73m^2 respectively, P<0.01). The mean PRA value was increased (from 0.5±0.58ng/ml/h to 1.56±1.3ng/ml/h, P<0.01). There were no significant changes in mean HbA_1%, FBG, ERPF, BU & CR and K^+ levels during this study period. In conclusion, Perindopril has a significant reducing effect on urinary albumin excretion in hypertensive NIDDM patient.

1432

ENALAPRIL ENHANCES INSULIN SENSITIVITY IN THE OFFSPRING OF HYPERTENSIVE PARENTS.

Z.Vlasáková, J.Válek, T.Pelikánová. Institute for Clinical and Experimental Medicine, Prague, Czech republic.

Insulin resistance is considered to be an underlying pathogenetic mechanism of several metabolic abnormalities increasing the risk of atherosclerosis. Familiar predisposition toward the IR syndrome may be the cause of increased cardiovascular complications also in families of hypertensive patients. The aim of the study was to evaluate the possibility of changing insulin sensitivity in a group of middle-aged men from predisposed families, after two-year lifestyle changes and subsequent administration of angiotensin converting enzyme inhibitor (ACEI). Euglycaemic hyperinsulinaemic clamp (75 μU/ml) lasting 3 hours was performed in a group of 15 offspring of patients with hypertension (OHP) at the baseline and after 6 week of ACEI administration (enalapril 10 mg/day), and compared to age-, weight- and sex-matched healthy controls (n=18). At baseline the metabolic clearance rate of glucose (MCRglu) was significantly lower in OHP compared to controls (7.98 ± 3.21 vs 9.24± 2.25 ml/kg.min; p<0.01). Enalapril administration significantly increased the MCRglu in OHP (7.98 ± 3.21 vs 9,7 ± 3,04 ml/kg.min; p<0.05) to values, which were comparable to the control group. We conclude that short-term enalapril administration improved insulin sensitivity in offspring of hypertensive patients.

1433

RENAL-PROTECTIVE EFFECT OF TEMOCAPRIL, A BILIARY EXCRETIVE ACE INHIBITOR, IN DIABETIC NEPHROPATHY.

K. Kato, S. Midorikawa, S. Shigetomi and K. Mizuno.
Third Dept. of Internal Medicine, Fukushima Medical College, Fukushima, JAPAN

Objective There is a high incidence of hypertension as a complication of diabetic nephropathy. The recently developed angiotensin converting enzyme inhibitor (ACEI) of biliary excretive type is expected to be the agent that inhibits directly and more strongly advancement of nephropathy. We studied the effects of various antihypertensive agents on proteinuria in diabetic nephropathy.

Materials and Methods Temocapril 2 mg/day (T, 6 patients), enalapril 2.5 mg/day (E, 8 patients) or nifedipine 20 mg/day (N, 10 patients) were administered orally for 12 weeks. Blood pressure was measured every two weeks, and excretion amount of urinary protein in a day, blood sugar, renal function and lipids were measured before the administration and 1, 2 and 3 months after the administration.

Results From 2 weeks after the administration, both systolic and diastolic pressures dropped (p<0.01) in all patients. The antihypertensive effect continued thereafter. Excretion amount of urinary protein in a day decreased significantly after the administration of T and E compared to that before administration. In changing rates of urinary protein calculated with preadministration values, the rates decreased in T, E and N throughout the test periods with significant differences observed in T and E. Three months after the administration, the decreasing rate of urinary protein in T was significantly larger (p<0.05) than that in E. No side effects were observed in all patients during or after the administration of each agent.

Discussion ACEI has the stronger effect of decreasing urinary protein than the calcium antagonists. Its mechanism seems to be in lowering systemic blood pressure and correcting glomerular hypertension by inhibition of angiotensin II production. With its strong inhibitory action against ACE and the possible maintenance of effective blood concentrations without being excessive owing to biliary excretion, it is demonstrated that T has strong renal protective effect in diabetic nephropathy.

1434

CARTEOLOL IMPROVES BODY WEIGHT AND VISCERAL FAT WEIGHT GAINS IN OLETF RATS, A MODEL OF NIDDM WITH MILD OBESITY

Y. Saitoh, T. Tani, Y. Asahi, Z Man, K. Kawano and H. Takahashi*.
Otsuka Pharmaceutical Co., Ltd., Tokushima and Kansai Medical Univ., Moriguchi*, Japan

In order to examine the effect on body weight and carbohydrate and lipid metabolism, a non-selective β-blocker with ISA, carteolol, was administered to Otsuka Long-Evans Tokushima Fatty (OLETF) rats, an animal model of spontaneous NIDDM with visceral obesity and late onset of disease. A high dose of 0.02% carteolol admixed in a pellet diet suppressed body weight gain without affecting food and water consumption until the appearance of glycosuria. Carteolol tended to reduce the cummulative incidence of glycosuria after 26 weeks of administration: 55% in the control, 17% at the low dose (0.002%) and 25% at the high dose. Although plasma glucose and triglyceride levels in non-fasted rats were elevated with age, carteolol delayed the increases in these parameters. Carteolol also suppressed the increase in plasma glucose level, which indicated the diabetic pattern, in a 25th week OGTT. At the 26th week of administration, carteolol decreased visceral fat weight (retroperitoneal and epididymal adipose tissue), whereas the liver and the kidney were not affected. In the in vitro study, carteolol exhibited binding affinity (Ki=135$\pm$11 nM) for the membrane in a recombinant cell line (293/p220-B4) expressing the human β3-adrenoceptor, suggesting that the drug might act by activating the β3-adrenoceptor in rats. These findings indicate that carteolol induces improvement in body weight and carbohydrate and lipid metabolism in an obese condition. Consequently, carteolol may be useful for the treatment of hypertention with obesity in order to prevent cardiovascular events.

1435

BLOOD PRESSURE VARIABILITY DURING 24H BLOOD PRESSURE MONITORING AND AUTONOMIC DISORDER IN NIDDM.

A.Iacovoni,E. Lattanzi,D.Damiani,A.Fava and D.Di Michele.Departement of Internal Medicine "G.Mazzini"Teramo Hospital,ITALY.

It has been known for a long time that the autonomic neuropathy represents a complication from diabetes . The increase in diurnal pressure variability and tachycardia seem to be an early sign of autonomic disorder but often it is impossible to verify this alteration with more specific tests that could investigate the vagal and simpatic cardiovascular function.In this study we have submitted to a 24h blood pressure monitoring(BPM),both sistolic(SBP)and diastolic(DBP),and to heart rate (HR), 25 individuals with NIDDM in an age group between 53±12 who have been affected by diabetes for more than 8 years,and with normal blood pressure,plus 25 individuals in a control group,age 50±12,also whit normal blood pressure. Afterwards they underwent an evalution of the autonomic cardiovascular function with the following tests:deep-breathing,standing to lying, postural hypotension.The subjects with diabetes showed, conpared to the control group, a singnificant increase($p<0,005$) in the variability (standard deviation SD) of the diurnal SBP(SD SBP day=18,1±7 vs, 14,3±3,5);a significant increase($p<0,005$)of the diurnal and nocturnal HR(HR day 84±8 vs 81±9,12:HR night 70±7,2 vs 65± 6,2), while the differences in the (SDSBP) and the differences in both diurnal and nocturnal (SDHR) were not significat between the two groups. Moreover 22(88%) of the 25 subjectes with diabetes showed at least 1 of the tests as pathological; this fact leads to the conclusion than the diurnal pressure variability and both diurnal and nocturnal tachycardia are good indication of autonomic cardiovascular alteration and they correlate in most cases(88%) with the positivity of more specifc tests that investigate the function of the vagal-simpatic nervous paths in the heart.

1436

LONGTERM TREATMENT WITH CANDESARTAN CILEXETIL DOES NOT AFFECT GLUCOSE HOMEOSTASIS OR SERUM LIPID PROFILE IN PATIENTS WITH MILD HYPERTENSION AND TYPE II DIABETES.

P. Trenkwalder, District Hospital, Starnberg, Germany, K. Dahl, Trondheim, Norway, M. Lehtovirta, Helsinki, University Central Hospital, Helsinki, Finland and H. Mulder, Medish Onderzoekcentrum GCP, Rotterdam, Netherlands for the MC Study Group.

Many hypertensive patients also have diabetes mellitus or dyslipidemia disorders, which increase the overall cardiovascular risk. The aim of the study was to assess the effects of candesartan cilexetil (cand.cil.) a novel angiotensin II antagonist selective for AT_1 receptors with long lasting antihypertensive effect on glucose homeostasis and serum lipid profile in mild hypertensives with type II diabetes.

Men and women, aged 30-75 years with mild hypertension (sitting diastolic blood pressure (BP) 90-100 mmHg) and type II diabetes (HbA1c 5.5-9.0%), both measured after a 4 week placebo run-in period were randomised to double-blind treatment with cand.cil. 8 mg once daily (o.d.) (n=83) or placebo o.d. (n=78) (dose increased to 16 mg o.d, if diastolic BP>90 mmHg). At randomisation and after 12 weeks treatment HbA1c (primary endpoint), blood glucose and serum lipid profile (total CH, LDL-CH, HDL-CH, TG, ApoA1 and ApoB) were assessed. The analysis of the differences between treatments was based on the changes from randomisation to the end of the study.

Cand.cil had no adverse effect on HbA1c, blood glucose and serum lipids compared to placebo. The median HbA1c both at baseline and after 12 weeks was 7.1% in patients on cand.cil. The corresponding values were 7.2% and 7.1% in the placebo group. The 95% confidence interval for the median difference in change between the groups was narrow (-0.250; 0.160), excluding any clinically important difference. The same held true for blood glucose (-1.10; 0.20), total-CH (-0.40; 0.20), and the other lipid parameters. Approximately 60 % of patients reached a diastolic BP <90 mmHg. Adverse events and withdrawals were similar in both groups.

In patients with mild hypertension and type II diabetes, cand.cil. 8 to 16 mg o.d. for 12 weeks does not adversely affect glucose homeostasis or serum lipid profile. Blood pressure was controlled in most patients and cand.cil was well tolerated.

1437

AMBULATORY BLOOD PRESSURE RELATIVE TO GUIDE-LINES FOR THE MANAGEMENT OF HYPERTENSION.

N. W. Rodger, D. DeVries and E. Rose, University of Western Ontario, London, Canada.

To evaluate Canadian guidelines for the management of hypertension in diabetes mellitus, we studied 10 volunteers with diabetic retinopathy; age 26-78 y; 6 type I, 4 type II; mean (SEM) HbA1 (DCA 2000, Bayer Inc, ref .041-.053).085±.01. BP (in 8/10) and diabetes medications were continued. Conventional (conv) BP was measured 4 times prior to and after ambulatory BP (ABP, SpaceLabs, Model 90207) q30 min, x24h with 78-100 (median 95)% successful readings and analysis by day (D,0800-2200h) and night (N,2200-0800h). Conv BP (range) was 163-110/95-61 mm Hg.

Guide Class	Compromised >150/90	Acceptable ≤150/90	Optimal <140/90

mmHg

Classification of systolic BP (SBP) and diastolic BP (DBP) in 5 subjects was concordant using conv BP or ABP. For SBP, 3 cases were discordant (conv BP over-classified); for DBP 3 cases were discordant (conv BP under-classified in 2, over-classified in 1). Thus, under-classification was confined to DBP. During ABP abnormal N/D ratios (SBP >0.092, DBP>0.9) were found for SBP in 2/4, and for DBP in 3/4 subjects with optimal SBP/DBP suggesting that this qualitative problem remains to be resolved.

1438

CANDESARTAN CILEXETIL, A NOVEL ANGIOTENSIN II ANTAGONIST REDUCES MICROALBUMINURIA IN PATIENTS WITH TYPE II DIABETES MELLITUS AND MILD HYPERTENSION.

C. Forsblom, Helsinki University Central Hospital, Helsinki, Finland, P. Trenkwalder, District Hospital, Starnberg, Germany, K. Dahl, Trondheim, Norway, and H. Mulder, Medish Onderzoekcentrum GCP, Rotterdam, Netherlands for the MC Study Group.

Microalbuminuria is a predictor of nephropathy in patients with type I or type II diabetes mellitus and interventions that decrease albuminuria are likely to postpone the development of severe renal impairment. Blocking the renin-angiotensin system via ACE inhibition has been effective in this respect. The more direct route of inhibiting the effects of angiotensin II by means of an angiotensin II receptor antagonist is expected to provide at least similar reductions of albuminuria. This study assessed the effect of candesartan cilexetil (cand.cil.), a novel, long-acting angiotensin II antagonist, selective for the AT_1 receptor, on microalbuminuria in patients with type II diabetes and mild hypertension.

The analysis was performed in a subset of patients (n=35) who had microalbuminuria (10-100 mg in an overnight urine sample) at randomisation in a large double-blind, placebo controlled study, investigating the effect of cand.cil. on blood glucose homeostasis and blood lipid profile in patients with stable type II diabetes, mild hypertension (diastolic blood pressure (BP) 90-100 mmHg) and serum creatinine below 150 µmol/l for men and 120 µmol/l for women. Patients were randomised, after a 4 week placebo run-in period, to 12 weeks double-blind treatment with cand.cil. 8-16 mg (n=83) or placebo (n=78) once daily. The difference between treatments in change in albuminuria from randomisation to the end of the study was analysed.

Cand.cil. did not influence blood glucose homeostasis or blood lipid profile compared to placebo. The body weight remained unchanged in both treatment groups and in patients in whom GFR (iohexol decrease) was assessed (placebo n=32, cand.cil. n=39) there was no significant change in GFR. The median urinary albumin excretion decreased from 28.5 to 12.2 mg/12 h (57%) in patients treated with cand.cil., (n=15) while it increased from 30.2 to 32.8 mg/12 h (9%) in the placebo group (n=20, p=0.03 for the difference between treatments). In this subset of patients the mean diastolic BP reduction was 6.4 mmHg in the cand.cil. group and 3.6 mmHg in the placebo group.

In this placebo controlled study, 12 weeks treatment with the angiotensin II antagonist cand.cil. reduced microalbuminuria in patients with stable type II diabetes and mild hypertension. Thus, cand.cil. appears to have a nephro-protective potential in this patient category.

HYPERTENSIVE NIDDM PATIENTS AND ANGIOTENSIN I-CONVERTING ENZYME: ACTIVITY, INHIBITION, AND ACE GENE POLYMORPHISM

T.Demidova[1], L.Demurov[2], A.Ametov[1], and V.Nosikov[2], [1]Russian Academy for Advanced Medical Studies and [2]National Research Centre "GosNII Genetika", Moscow, Russia

Accumulating data indicate influence of insertion/deletion (ID) polymorphism of angiotensin I-converting enzyme (ACE) gene on clinical benefit of ACE inhibition (ACEI) as reno- and cardioprotective therapy. The aim of this study was to evaluate hypotensive effect of ACEI Perindopril in NIDDM patients with regard to serum ACE activity (ACEA) and ID/ACE genotypes. 44 essentially hypertensive NIDDM patients with the following characteristics (mean±SD): age 53.1±6 yr; NIDDM duration 7.7±4 yr; body mass index (BMI) 31±4.3; waist-to-hip ratio (WHR) 0.94±0.07; received Perindopril during 3 months. Initial ACEA was measurated by RIA-KIT. ID/ACE genotyping was carried out using polymerase chain reaction technique. Blood pressure (BP) and glycated haemoglobin (HbA1c) were measured before and after ACEI treatment. Reduction (%) of basal values of BP was calculated and statistical differences analysed using Student's t-test. Patients were considered as II (n=8), ID (n=16), and DD (n=20) genotype carriers, respectively. We could not find significant difference in ID/ACE allele/genotype distribution in hypertensive NIDDM patients and reported earlier general Moscow population. Also, all the above mentioned characteristics did not differ signifacantly in various genotype carriers, even in homozygous for I and D alleles. Moreover, basal ACEA levels were similar in II, ID, and DD groups of NIDDM patients: 51.5; 45.3; and 52.6 ACE-units, respectively. Overall patients possessed evident reduction of BP after ACEI treatment (21.9% for systolic and 18.9% for diastolic) but decrements of systolic and diastolic BP did not, however, differ significantly in II, ID, and DD groups. The only variables to be influenced by ID/ACE gene polymorphism, as revealed by regression analysis, were BMI, WHR, ACEA and diastolic BP reduction. Only in II genotype carriers the following correlations were observed: BMI/WHR r=0.718; WHR/ACEA r=0.804; ACEA/dPB reduction r = -470. Conclusions: 1) ID/ACE gene polymorphism is not associated with essential hypertension in NIDDM Russian population; 2) regardless ID/ACE genotypes and/or serum ACEA, Perindopril is effective hypotensive drug in NIDDM patients; 3) the most evident correlation between physical, biochemical and clinical parameters were observed in II genotype carriers.

THE EFFECT OF TEMOCAPRIL ON MICROALBUMINURIA IN HYPERTENSIVE PATIENTS WITH AND WITHOUT GLUCOSE INTOLERANCE

H. Shionoiri, H. Oda*, S. Hiroto*, T. Takizawa, M. Naruse, S. Ueda, I. Takasaki and G. Yasuda. Internal Medicine 2, Yokohama City University, and *Yokohama City Bayside Hospital, Yokohama 236, Japan.

Microalbuminuria may be a marker of early dysfunction of glomerulus or of intrarenal vasculatures in hypertension and diabetes mellitus. This study was conducted to examine the effect of long-term treatment with temocapril, a new angiotensin converting enzyme (ACE) inhibitor, on microalbuminuria.

The subjects were 100 hypertensive patients with or without impaired glucose tolerance (49 men and 51 women, mean age 59.7 years) who had been consuming antihypertensives either diuretics or calcium channel blockers except for ACE inhibitors. Their blood pressure was controlled 149.6/88.4 (means) mmHg. Serum creatinine (s-Cr), fasting plasma glucose (FPG) levels, and urinary excretion ratio of microalbumin (UAE) (mg/L) to creatinine (g/L) were evaluated, then the antihypertensive agents were switched to temocapril (2 to 4 mg) once daily. Of 58 the patients had glucose intolerance (IGT group) and 42 had normal glucose tolerance (NGT group) at baseline period.

After long-term (12 months) therapy with temocapril, their blood pressure and FPG were maintained as well. On the other hand, s-Cr (mg/dl) decreased significantly from 0.85 to 0.75 in IGT, and from 0.8 to 0.75 in NGT, respectively. UAE (mg/g Cr) was also significantly decreased from 43 to 28.1 in IGT, and 43.6 to 26.6 in NGT, respectively.

Long-term beneficial effects of temocapril on UAE and s-Cr are confirmed in hypertensive patients with and without glucose intolerance, despite similar antihypertensive efficacy with the previously used agents.

1441

THE RELATIONSHIP OF BLOOD PRESSURE TO SODIUM AND POTASSIUM EXCRETION IN THE EURODIAB IDDM COMPLICATIONS STUDY.

H Colhoun, LK Stevens, F Collado Mesa, JH Fuller and the EURODIAB IDDM Complications Study Group

The INTERSALT study reported a significant association between blood pressure and both sodium and potassium intake as measured by urinary electrolyte excretion. People with IDDM are at increased risk of hypertension but the relation between electrolyte intake and blood pressure in IDDM is unknown. Therefore the relations between 24 hr urinary electrolyte excretion and blood pressure were studied in a cross-sectional sample of 3250 IDDM patients from 31 centres across Europe (EURODIAB IDDM complications study). HbA_{1c}, urinary electrolytes and urinary albumin excretion rate (AER) were measured centrally. Relations between electrolyte excretion and blood pressure were studied within each centre using regression analysis and results were pooled to give a summary regression coefficient for all centres. For a difference of +10 mmol/24hr sodium excretion, SBP was 0.1 mmHg lower in men ($p<0.05$) and 0.1 mmHg higher in women($p=0.2$) (age adjusted). For a difference of +10 mmol/24hr potassium excretion, SBP was 0.3 mmHg lower in men ($p<0.05$) and .04 mmHg higher in women ($p=0.8$). On adjustment for confounding variables the associations between electrolytes and SBP in men were no longer significant. The analyses were repeated excluding those on antihypertensive therapy (10%) and those with micro or macro-albuminuria i.e. AER≥20 ug/min (30%), as these patients may have been expected to reduce their sodium intake following diagnosis, and no significant association was found. In conclusion, in this group of IDDM patients across Europe, neither sodium nor potassium excretion were significantly associated with blood pressure, in contrast to the findings in a random population sample in INTERSALT.

1442

RAMIPRIL INCREASES SPECIFIC INSULIN BINDING AND METABOLISED GLUCOSE RATE IN NON-INSULIN-DEPENDENT DIABETICS WITH HYPERTENSION

V.Profozić[1], F.Coce[1], D.Babić[1], Ž.Metelko[1], S.Schinzel[2] and M.Reuter[2]
[1] Vuk Vrhovac Institute, Zagreb, Croatia
[2] Hoechst AG, Pharmaceutical Division, Frankfurt, Germany

The aim of the study was to compare the effect of ramipril with that of atenolol and placebo on glucose metabolism in non-insulin-dependent diabetics with moderate hypertension treated with glibenclamide. In euglycaemic hyperinsulinaemic clamp the specific insulin binding (SIB) at the erythrocytes receptors and peripheral metabolised glucose (MG) were examined before and after six weeks. Four groups of patients were compared: ramipril 2.5 mg/die (group A-20 patients), ramipril 5.0 mg/die (group B-20 patients), atenolol 50 mg/die (group C-20 patients), and placebo (group D-10 patients).
The results: SIB (%), the baseline level, before and after 6 weeks:
(A): 6.78±1.29 and 7.92±1.61 (+1.13±1.54); (B): 7.58±2.51 and 7.85±2.16 (+0.28±2.61); (C): 7.66±1.78 and 7.52±2.04 (-0.14±1.83); (D): 8.56±1.62 and 7.06±0.88 (-1.50±1.53). Comparison ramipril 2.5 mg (A) vs.placebo (D) was significant ($p<0.05$).
MG (mg/kg/min) between 90 and 120 min., before and after 6 weeks:
(A): 3.68±1.16 and 4.03±1.79 (+0.36±1.31); (B): 3.02±1.12 and 3.90±1.35 (+0,88±1.18); (C): 4.72±2.04 and 5.05±1.87 (+0,33±1.22); (D): 3.79±1.80 and 3.60±1.63 (-0.19±0.59). Ramipril 5.0 mg vs. atenolol 50 mg was significant ($p<0.05$).
CONCLUSION: (1) The significant difference between increase in SIB after 2.5 mg/die of ramipril and SIB decrease after placebo during the 6 weeks was achieved. (2) The increase in MG in the group (B) was significant as compared to atenolol 50 mg. These findings favour the usage of ramipril in hypertensive diabetics treatment.

1443

OSCILLOMETRIC MEASUREMENT OVERESTIMATES BLOOD PRESSURE IN NON-COMPLICATED IDDM.

G.Vervoort, J.Wetzels, L.Elving, J.Lutterman, J.Berden, P.Smits. University Hospital St. Radboud, Nijmegen, The Netherlands

In the management of IDDM accurate control of blood pressure (BP) is of great importance. As such the method of BP measurement deserves more attention. Measurement by office sphygmomanometry (sphygmo) is increasingly replaced by new methods. We performed a study in which we compared intra-arterial BP (i.a.), sphygmo BP, 24 hours BP (ABPM, Profilomat®, auscultatory) and oscillometric BP (dinamap®) in non-complicated IDDM (DP) and healthy controls (C). The i.a recordings were used as golden standard. We studied 42 C and 51 DP. I.a. BP was registered for 5 min. (>300 registrations) in supine position. Sphygmo BP was measured 3 times after 10 min. in supine position. ABPM was recorded on a working day. BP between 10.00-22.00 was averaged as "day BP". BP between 02.00-06.30 was averaged as "night BP". Dinamap® registration was performed during 10 min. in supine position. Results are expressed as means±SE. Data are analyzed by *t*-test.

	Controls			Diabetic Patients		
	SBP	DBP	MAP	SBP	DBP	MAP
I.a	115.6±1.2	63.2±0.9	83.4±1.1	116.2±1.2	61.7±0.8	82.8±0.9
Sphygmo	116.5±1.5	67.8±1.3		117.7±1.3	69.8±1.3	
APBM						
day	120.4±1.5	83.7±1.0		120.9±1.2	84.4±0.9	
night	103.4±1.5	69.1±1.3		102.4±1.2	69.3±0.9	
Dinamap	113.4±1.4	65.0±1.0	83.3±1.0	*118.6±1.3	66.6±0.7	**85.6±0.7

* $P=0.01$,** $P=0.05$ DP versus C.

There was no difference in i.a., sphygmo or ABPM BP between C and DP. Dinamap BP was significantly increased in DP. In C dinamap MAP was not different from i.a. MAP (mean difference -0.10 mmHg) whereas it exceeded i.a. MAP by 2.8 mmHg (95% CI 0.7 to 4.5 mmHg) in DP ($P<0.01$). It is concluded that i.a. BP is similar in non-complicated DP versus C. Results of BP measurements are dependent on the method used. Auscultatory methods were comparable in C and DP (sphygmo and ABPM). In contrast the oscillometric device (dinamap®) overestimated BP in DP. We hypothesize that this difference may be caused by changes in vessel wall characteristics in non-complicated IDDM.

1444

UNCHANGED INSULIN SENSITIVITY WITH VERAPAMIL SR PLUS TRANDOLAPRIL IN LOW-DOSE COMBINATION IN NIDDM WITH STAGE 1 HYPERTENSION.

K. Rett and M. Wicklmayr. University of Tübingen, Tübingen and Schwabing Hospital, Munich, Germany

Objective: Angiotensin converting enzyme (ACE)-inhibitors have been shown to increase both skeletal muscle blood flow and insulin sensitivity. Calcium antagonists also increase muscle blood flow without affecting insulin action. Since muscle blood flow might link insulin sensitivity and blood pressure, combination therapy with both substances might have additive effects on both haemodynamics and insulin sensitivity. **Research Design and Methods:** This was a randomized double-blind placebo-controlled parallel group study in 46 insulin resistant subjects with NIDDM and mild essential (predominantly stage 1) hypertension. The effect of sustained release (SR) verapamil (180 mg) and the ACE-inhibitor trandolapril (1 mg) during 8 weeks monotherapy or combination on insulin sensitivity and blood pressure was compared with placebo using the isoglycemic glucose clamp technique and both conventional and ambulatory blood pressure monitoring. **Results:** Concerning blood pressure lowering, there was no difference between the treatment groups, no additive effect of the combination, and no difference from placebo. Insulin sensitivity (MCR) increased by 47% with trandolapril ($p=0.0015$) and remained unchanged in all other groups. **Conclusion:** For the first time in a controlled study in a homogenous insulin resistant group of caucasian subjects with NIDDM and predominantly stage 1 hypertension, combined treatment with a heart rate-moderating calcium antagonist plus an ACE-inhibitor in apparent sub-pressor dose is shown to be neutral in terms of clamp-derived insulin sensitivity. The insulin -sensitizing effect of ACE-inhibitor monotherapy with its theoretical risk of hypoglycemia is completely neutralized in the combination.

1445

TREATMENT OF LEFT VENTRICULAR DYSFUNCTION WITH PROLONGED QT INTERVAL IN ELDERLY PATIENTS WITH DIABETES TYPE II .

Siniscalchi N., Bellinfante E., Del Gatto A., Mirante E., Olivieri F., Oliviero F., Cerciello T., Carbone L.
Dipartimento di Gerontologia , Geriatria e Malattie del Metabolismo. II Università di Napoli Italy.

Elderly patients (PS) with diabetes II and asymptomatic diastolic left ventricular dysfunction (LVD) show an increased risk of cardiac death. In these PS the lenght of QT interval may be considered a target for prevention of arrhythmic death.The aim of this study was to identify high risk elderly diabetic PS and evaluate Ramipril capacity of reducing the lenght of QT interval and of improving diastolic LVD.18 elderly diabetics PS (mean age 58±7 years), both males and females, having Doppler - Echocardiographic evidence of diastolic LVD and prolonged QT interval, were studied by an open study with a parallel randomized group design. After two weeks of pharmacological wash out, PS were randomly recruited to either Ramipril 5 mg /day or placebo, and followed for 12 weeks. All patients were investigated at the beginning of the study and after 4, 8 and 12 weeks of follow up with blood samples for hematology, urea, electrolites, creatinine.12-lead ECG was carried out and QT interval was corrected with Bazett's formula and QT dispersion was calculated.Chest X-ray and Doppler- 2 Dimensional Echocardiography were performed at the beginning and at the end of the study.Exercises tollerance was evaluated using bycicle ergometer during the run-in period and after 6 and 12 weeks of therapy. All PS completed the study.Ramipril improved significantly ($p< 0,05$) diastolic ventricular function parameters and improved exercise tollerance after 12 weeks of therapy.Finally in 9 PS we observed the correction of QT dispersion.

1446

THE EFFECTS OF NITRENDIPINE AND ENALAPRIL ON LEFT VENTRICULAR MASS IN HYPERTENSIVE PATIENTS WITH NIDDM.

T.A. Gerritsen, A.A.A. Bak, R.P. Stolk, J.J.C. Jonker and D.E. Grobbee.
Department of Epidemiology, Utrecht University and Rotterdam Medical Research Foundation (ROMERES), the Netherlands.

Hypertension is a main factor promoting left ventricular hypertrophy (LVH), and there is also a well documented increased cardiovascular risk in hypertensive diabetics. It has been suggested that ACE-inhibitors are more effective than other antihypertensive drugs in decreasing left ventricular mass (LVM). This randomized, placebo-controlled trial was designed to evaluate the effects of nitrendipine and enalapril on LVM-index in patients with NIDDM and hypertension.

The study population comprised of patients with NIDDM treated by general practitioners with diet and/or drugs. Inclusion criterion for blood pressure was a diastolic blood pressure (DBP) ≥ 90 and ≤ 115 mmHg and a systolic blood pressure (SBP) ≤ 200 mmHg, and not using blood pressure lowering drugs for 3 weeks. LVM was measured by M-mode echocardiography. 121 patients were randomly allocated to receive nitrendipine (n=40, 10 or 20 mg b.i.d.) or enalapril (n=40, 10 or 20 mg o.d.) or placebo (n=41). If DBP remained ≥ 110 mmHg, acebutolol was added in either treatment group. The treatment period was 48 weeks.

Mean age was 63 ± 9 years. Nitrendipine and enalapril resulted in a significant and almost identical reduction of SBP (157 ± 2 vs 154 ± 3 mmHg, mean ± SE) and DBP (84 ± 1 vs 84 ± 2 mmHg). In the placebo group there was no change in SBP or DBP. Nitrendipine resulted in a significant decrease of LVM-index from 146 ± 6 to 132 ± 5 g/m^2. Enalapril did not change LVM-index. In the placebo group LVM-index increased from 140 ± 5 to 151 ± 5 g/m^2. The difference between nitrendipine and placebo remained statistically significant after adjusting for age, gender, LVM-index baseline, SBP baseline and difference in SBP after 48 weeks.

These results indicate that in patients with NIDDM and hypertension nitrendipine reduces LVM-index. Enalapril appears not to induce regression, but may prevent progression with an effect that is intermediate between nitrendipine and placebo.

1447

CLINICAL EVALUATION OF AMLODIPIN EFFECT ON HBP FOR PEOPLE WITH DIABETES

PR. DRAOUI F., PR HAITEM N. - RABAT - MOROCCO.

The authors are presenting the results of retrospective study including 42 diabetic subjects with HBP, aged 37-42 years, taking a unique dose of Amlodipin as monotherapy over a 24 months period. In 92,4% of the cases, the subject showed an evaluation of a 4 year period for the HBP and a 6 year evolution for the diabetes. The majority of patients have undergone several hypotensive therapies in polytherapy with no real respect of sodium retriction.

The retrospective study of the 42 cases of patients taking Amlodipine allows us to note following facts :

1- stabilization of HBP with no evolutive accident ,
2- a better metabolic balance with any given hypoglycaemic drugs,
3- an excellent Amlodipin tolerance with the observance of the treatment in the majority of cases, no particular secondary effect has been noted such as orthostatic pressure, vertgoes cephalic troubles,
4- a monthly cost of the treatment reasonably supported by the majority of patients.

The authors insist on the advantage of Amlodipin use as an antagonistic remedy of calcium in the treatment of the HBP for diabetic people, with the prevention of coronary insufficiency ; the one doses monotherapy is as well adapted in the case of diabetes as a chronic invalidating and costhy disease which often necessitates other associated therapies along with the hypoglycaemic treatment.

1448

EFFECT OF TEMOCAPRIL ON INSULIN SENSITIVITY AND MICROALBUMINURIA IN HYPERTENSIVE NIDDM PATIENTS

M. Lerch, A. U. Teuscher, M. P. Ho, P. Gerber, C. Beretta-Piccoli †,
P. Eckenberger, A. Kaemmereit and P. Weidmann. University of Berne, Berne, Switzerland.

In contrast to other ACE inhibitors, the metabolism of temocapril seems to be independent of renal function. In addition, temocapril has been found to be more potent in lowering blood pressure (BP) and to have a faster onset of action than other ACE inhibitors. To investigate the metabolic and antihypertensive effects of this new ACE inhibitor in diabetic hypertensives, 30 NIDDM patients with mild to moderate hypertension (diastolic BP 90 to 115 mmHg) and without azotemia (plasma creatinine <180 µmol/l) were evaluated during a randomized double-blind treatment with either temocapril, 20 mg daily (n=19), or placebo (n=11) for 6 weeks. Insulin sensitivity index (SI), determined by the Minimal Model method of Bergman, serum lipoproteins, plasma renin activity, fibrinogen and microalbuminuria were assessed at the end of the placebo run-in phase and the double-blind treatment phase, respectively. Temocapril treatment produced a significant decrease in supine BP (152/92±5/3 vs. 162/98±5/2 mmHg, p<0.01). SI tended to increase on temocapril (1.44±0.4 vs. 0.95±0.2 x10^{-4}/min/mU/l), although the difference did not reach statistical significance. During administration of temocapril or placebo, no significant changes in fasting plasma glucose, insulin, serum levels of total triglycerides, cholesterol or lipoprotein cholesterol fractions and fibrinogen were observed. Microalbuminuria decreased significantly on temocapril treatment (48.6±10 vs. 78.6±16.5 mg/24 h, p<0.01) but not on placebo. These findings demonstrate that in hypertensive NIDDM patients, temocapril is at least neutral with regard to insulin sensitivity, insulin, glucose, and lipoprotein metabolism and significantly reduces microalbuminuria.

1449

PRESENCE OF NEPHROPATHY INFLUENCES THE CHOICE OF ANTI-HYPERTENSIVES IN INSULIN-DEPENDENT DIABETES.

S. Jelic, S. Dimkovic, M. Kocijancic, N. Kostic, G. Bojkovic. Z. Caparevic and V.Diligenski. CHC "Dr Dragisa Misovic", Belgrade, Yugoslavia

During one-year period we have examined anti-hypertensive, anti-proteinuric and metabolic effects of calcium channel blockers (nifedipine or nisoldipine) or angiotensin converting enzyme (ACE) inhibitors (captopril) in 45 hypertensive type I diabetes patients. Among them 15 patients were normoalbuminuric **(A)**, 20 were microalbuminuric **(B)** and 10 were macroalbuminuric **(C)**. Only in patients with overt nephropathy **(C)** compared with healthy controls (n=10) statistically highly significant (p 0.01) decrease of plasma renin (0.17±0.07 vs. 0.28l±0.08 pmol/L/sec) and aldosterone (0.12±0.05 vs. 0.29±0.09 nmol/L) with insufficient response to upright posture (renin: 0.34±0.11 vs. 1.3±0.52 pmol/L/sec; aldosterone: 0.26±0.15 vs. 1.03±0.34 nmol/L). In this group of patients tendency toward hyperkalemia during captopril treatment was demonstrated as well as significant, although transient rise of albuminuria. At the same time calcium channel blockers express optimal antiproteinuric effect particularly in this group (633.8±284 mg/24h before treatment; 266.2±146.2 mg/24 h after one-year treatment). Meanwhile, ACE inhibitors were the treatment of choice in incipient nephropathy.

1450

A COMPARISON OF CARVEDILOL AND ATENOLOL IN PATIENTS WITH NIDDM AND HYPERTENSION

D. Giugliano, F. Nappo, P. Ziccardi, N. De Rosa and F. D'Onofrio. Department of Geriatrics, Naples, Italy

The aim of this study was to compare the metabolic and cardiovascular effects of carvedilol, a beta-blocker with vasodilating properties, and atenolol in patients with NIDDM and hypertension. This was a randomised, double-blind, 24-week trial with parallel groups. After a 4-week run-in placebo period, 42 NIDDM patients with a diastolic blood pressure (dBP) between 90 and 105 mmHg were assigned to carvedilol (25-50 mg/day) and atenolol (50-100 mg/day). Systolic and diastolic blood pressure and left ventricular mass significantly decreased with both drugs, without difference between the groups. Total glucose disposal (euglycemic clamp) increased by 9.5 umol/kg·min (95% CI, 3.5 to 15.5, p=0.02) in the carvedilol group more than in the atenolol group. After carvedilol, triglyceride levels decreased by 0.57 mmol/L (95% CI, -1.02 to -0.12, p=0.01) and HDL-cholesterol increased by 0.12 mmol/L (0.02 to 0.22, p=0.04) more than atenolol. After carvedilol, lipid peroxidation (thiobarbituric acid reactive substances) decreased by 0.24 umol/L (95% CI, -0.44 to -0.04, p=0.04) more than atenolol. Glucagon and epinephrine responses to insulin (0.15 U/kg) were similar before and after treatment with both drugs. Carvedilol may offer advantages in patients with NIDDM and hypertension by improving glucose and lipid metabolism and by reducing lipid peroxidation.

α-LIPOIC ACID ENANTIOMERS AND GLUCOSE METABOLISM IN INSULIN RESISTANT RAT SKELETAL MUSCLE.

E.J. Henriksen, S. Jacob, R.S. Streeper, D.L. Fogt, and H.J. Tritschler. University of Arizona, Tucson, U.S.A.; Eberhard-Karls-Universität, Tübingen, Germany; and ASTA Medica, Frankfurt, Germany.

The racemic mixture of the biological antioxidant α-lipoic acid (ALA) enhances insulin-stimulated glucose metabolism in insulin-resistant humans and animals. The present study determined the individual effects of the pure R-(+) and S-(-) enantiomers of ALA on glucose metabolism in skeletal muscle of an animal model of insulin resistance — the obese Zucker (*fa/fa*) rat. Obese rats were treated intraperitoneally for 10 days with either 30 mg/kg/day of R-(+)-ALA or 50 mg/kg/day of S-(-)-ALA (maximally effective doses). While chronic R-(+)-ALA treatment significantly ($p<0.05$) reduced fasting plasma insulin (-17%) and free fatty acids (-35%) relative to vehicle-treated obese animals, chronic S-(-)-ALA treatment further increased fasting plasma insulin (+15%) and had no effect on fasting plasma free fatty acids. Insulin-stimulated glucose transport activity in the isolated epitrochlearis muscle was increased by 35% in obese animals treated with R-(+)-ALA, whereas S-(-)-ALA treatment resulted only in a 16% improvement. Chronic R-(+)-ALA treatment elicited a 26% increase in insulin-stimulated glycogen synthesis and a 37% enhancement in insulin-stimulated glucose oxidation. No significant increase in either of these parameters was observed following chronic treatment with S-(-)-ALA. These data indicate that chronic in vivo treatment with the biological antioxidant ALA enhances in vitro insulin-stimulated glucose transport and non-oxidative and oxidative glucose metabolism in insulin-resistant rat skeletal muscle. Moreover, the R-(+) enantiomer is much more effective than the S-(-) enantiomer in bringing about these beneficial adaptations in skeletal muscle glucose metabolism.

1452

EFFECTS OF THREE NEPALESE PLANTS ON SERUM GLUCOSE LEVELS OF NORMAL AND DIABETIC MODEL RATS

M. Nur-e-Alam[1], B. Rokeya[1], N.S. Chowdhury[1], L. Ali[2], M. Mosihuzzaman[2], N. Nahar[2], A.K. Azad Khan[1]. [1]Research Division, BIRDEM; [2]Department of Chemistry, University of Dhaka, Dhaka, Bangladesh

We have recently published an experimental approach for screening the oral hypoglycemic effects of plant materials in rat models. The experimental result can also indicate possible mode of action of an active extract. Following this apprach 3 medicinal plants (Asparagus resemusus, Allium wallichi and Scorparia dulcis), used by the traditional practitioners in Nepal, were tested on nondiabetic and, both IDDM and NIDDM model rats. Following procedures standardized in our laboratory, freeze-dried juice (250 mg/rat) of the plants were fed at various prandial states. Serum glucose was measured by glucose-oxidase method. No extract showed any effect on the fasting serum glucose levels of any rat models. In nondiabetic rats, when the extracts were fed simultaneously with glucose no effect was seen. However, when fed 30 min before oral glucose load A resemusus showed significant antihyperglycemic effects (sum of increments of over basal value, M+SEM: 4.87+0.73 in the Control vs 3.81+0.55 in the A resemusus groups, p=0.004). In NIDDM model rats, in the postprandial state, when the extract were fed simultaneously with glucose, A wallichi showed highly significant effect (sum of increment over basal value, M+SEM; 32.14+2.29 in the Control vs 6.13+1.77 in the A wallichi group, $p<0.001$). In this condition, A resemusus also showed a marginal effect, but S dulcis had no effect. In IDDM model rats, A wallichi showed significant antihyperglycemic effect (p=0.019); other two extracts did not effect the serum glucose. The results suggest that these three Nepalese plants may contain different principles which may serve as potential sources of antidiabetic agents.

1453

IN VITRO AND IN VIVO EVALUATION OF POLYAMINES INHIBITORY EFFECT ON OXIDATIVE STRESS IN EXPERIMENTAL DIABETES MELLITUS

D. Pavlović, G. Bjelaković, G. Kocić, T. Galabova and S. Ribarov.University of Niš, Niš, Yugoslavia and University of Sofia, Sofia, Bulgaria.

Streptozotocin (ST) and aloxan (AL) as a selective β-cell toxins, are used for induction of experimental diabetes, acting through a common mechanism including generation of oxygen-derived free radicals. The occurrence of high contents of polyamines, particularly of spermidine in rat islets, as well as the fact that pancreas contains relatively low activities of radical scavenging enzymes, compared to the other rat's tissues, suggests that polyamines may play a role in stabilizing islet β-cell against oxidative destruction. Based on these findings the protective radical-scavenger effect of polyamines in vitro and in vivo was investigated.The inhibitory effect of polyamines on in vitro induced lipid peroxidation in xanthine-xanthine oxidase system, as a source of superoxide radicals, was observed in a dose-dependent manner measured by luminol-dependent chemiluminescence. With a concentration of spermidine (Spd) and spermine(Sp), similar to those found in pancreatic islets the inhibition was in range of 65-75%. For in vivo investigation, the rats were allocated to the following groups:I-control; II-treated with single dose of ST(50mg/kg BW) or AL(170mg/kg BW); II-treated simultaneously with Spd (50 μmol/kgBW) was given ip. 1h before administration of ST and AL as wll as continually with single daily dose following 15 days; IV-treated with the Spd only in mentioned dose.

VARIABLES	ST	AL	Spd-ST	Spd -AL	Control
glucose(mmol/l)	30.2±7.84***	33.8±5.64***	9.36±2.7 °°°	6.87±1.82 °°°	6.55±0.9
MDApl(μmol/l)	16.49±2.3*	17.7±1.29*	12.9±2.05 °°	12.8±2.02 °°	11.83±1.8
MDApancreas (nmol/mg prot.)	13.5±1.32**	15.7±2.47**	11.88±1.48 °	12.08±2.0 °°	9.9±1.17

*p<0.05; **p<0.001; ***p<0.001compared with the controls

° p<0.05 °°p<0.001 compared with the ST or AL diabetic groups

Administration of Spd alone didn't alter any of the investigated parameters. Obtained results demonstrated that pretreatment the animals with Spd abolished the rise in MDA and glucose induced by ST or AL. The results suggest that Spd might provide antioxidative protection in the recovery of ST/AL-damaged islets β-cells in vivo. It could point to possible examination of therapeutic significance.

1454

CHARACTERIZATION OF THE HYPOGLYCEMIC EFFECTS OF DIFFERENT EXTRACTS FROM FIVE ANTIDIABETIC PLANT MATERIALS

N.S. Chowdhury[1], M. Mosihuzzaman[2], A.K. Azad Khan[1], B. Rokeya[1], L. Ali[1] and N. Nahar[2]. *[1]Research Division, BIRDEM; [2]Dept of Chemistry, Dhaka University, Bangladesh*

As a part of an attempt to characterize the chemical nature and the possible mode of action, the cold and hot water extracts and soluble dietary fibre (SDF) from *Plantago ovata, Spirulina platensis, Trigonella foenumgraecum, Syzizium cumini* and *Musa paradisiaca* were tested for antihyperglycemic effects on NIDDM model rats following procedures standardized in our laboratory. All the test materials were fed simultaneously with glucose and blood samples were collected at 0, 30 and 75 minutes. The cold water extracts of *S platensis, S cumini* and *M paradisiaca* had no significant antihyperglycemic effect, but the same extracts of *P ovata* and *T foenumgraecum* were equally highly potent ($p<0.008$-0.001). The hot water extracts of all the plants showed effects exactly parallel to those of cold water extracts. Since SDF is known to delay the absorption of glucose from the gut, it was invesigated whether the antihyperglycemic effects of these extracts were due to SDF fractions. Although there was a definite tendency in case of SDF from *P ovata* and *T foenumgraecum*, no SDF from the five plant materials showed any significant antihyperglycemic effect. The results showed that the hypoglycemic effects of *S platensis, S cumini* and *M paradisiaca* found in this laboratory are not due to water soluble compounds. Whereas, *P ovata* and *T foenumgraecum* may act as sources for antidiabetic agents and although SDF of *P ovata* and *T foenumgraecum*, may contribute to their hypoglycemic properties, other water-soluble active principles are present in these two plants.

1455

LONG-TERM IMPACT OF L-ARGININE ON GLYCEMIC PATTERN AND OXIDATIVE STATUS IN DIABETIC RATS

O. Borodina, V. Poltorack, N. Gorbenko, A. Gladkih, N. Ustenko and V. Lipson. Ukrainian Scientific Research Institute of Endocrine Diseases Pharmacotherapy, Kharkov, Ukraine

The imbalance between pro- and antioxidants in diabetes provides the justification for antioxidant treatment. It has been shown that L-arginine (L-Arg) possesses superoxide scavanging properties in vitro. The aim of the present study was to determine effect of long-term treatment with L-Arg on glycemic pattern and oxidative status in diabetic rats. Male Wistar rats were given i.p. streptozotocin (STZ) at dose 65 mg/kg. One group of diabetic animals was untreated to act as control. The other group received L-Arg (50 mg/kg/day) in the diet for 4 weeks. Oxidative status was assessed in plasma by spectrophotometric determination of malonic dialdehyde (MDA), diene conjugates (DC) and reduced glutatione (GHS) levels. Administration of L-Arg decreased basal hyperglycemia (7.9±0.8 mmol/l vs 14.7±0.9 mmol/l, $p<0.01$), increased plasma immunoreactive insulin level by 40 % ($p<0.02$) and protected from body weight loss (160.0±3.8 g vs 130.0±5.1 g, $p<0.05$) compared to non-treated diabetic animals. After 4 weeks treatment with L-Arg DC content was significantly reduced (133.0±14.1 μmol/ml vs 173.2±13.5 μmol/ml, $p<0.05$) and GHS level was increased 2 fold ($p<0.01$) in comparison with diabetic control. However, MDA concentration was not changed in any groups. The results allow the conclusion that long-term treatment with L-Arg improves metabolic control and suppresses oxidative stress in diabetic rats. We suggest the use of L-Arg may have potential therapeutic benefit in the diabetes treatment.

1456

RETARDATION OF INTESTINAL CARBOHYDRATE ABSORPTION BY HOT WATER EXTRACT OF *TRIGONELLA FONUMGRAECUM* IN RATS

JMA Hannan[1], S. Haque[1], L. Ali[1], N. Nahar[2], M. Mosihuzzaman[2], A.K. Azad Khan[1]; *[1]BIRDEM, [2]Dept of Chemistry, University of Dhaka, Dhaka, Bangladesh*

Trigonella foenumgraecum has been shown to possess hypoglycemic activity in both animal models and human diabetic subjects, but the exact chemical nature of the active principle(s) and the mechanism of the effect is still unclear. Previous reports from our Group suggest that hot water extract of *T foenum graecum* and its main constituent SDF suppressed flattened the postprandial rise of blood glucose in both IDDM and NIDDM model rats were investigated. In the present study the effects of the hot water extract on carbohydrate digestion and absorption in NIDDM model rats. Carbohydrate absorption was evaluated in NIDDM model rats by measuring the amount of sucrose remaining in 6 different parts of the gastrointestinal tract of rats after oral feeding of sucrose. Sucrose solution (2.5 g/kg body weight) was fed to 20 hrs fasted rats with or without extract (500 mg/kg body weight). The GITs of rats, sacrificed at 60 min, were removed and washed with ice-cold normal saline. The wash-out fluid, acidified by H_2SO_4 and neutralized by NaOH, was analyzed for its glucose content (by enzymatic-colorimetric methods) liberated from sucrose (estimated by back calculation of glucose). Sucrose loading in control rats sharply increased the blood glucose levels and was accompained by rapid disappearance of sucrose from the upper small intestine. In the Control Group sucrose loading led to a rapid increase of blood glucose (mmol/l, fasting 7.12±0.13 and 1 hour 14.21±0.32) whereas in the Extract Group the blood glucose response was considerably flattened (fasting 7.79±0.21 and at 1 hour 9.19±0.41). The change in the blood glucose were inversely related by the gastrointestinal sucrose content of the 2 groups of rats [Sucrose, 1 hour, mg, M±SEM, stomach (2.96±0.72), upper 20 cm (0.52±0.17), middle small intestine (0.90±0.05), the lower 20 cm (0.60±0.12), cecum (0.44±0.09) and large intestine (0.98±0.01) in Control group vs 20.22±0.91, 2.86±0.38, 2.52±0.20, 0.62±0.05 and 0.68±0.04 respectively in Extract Group]. The results reconfirms the hypoglycemic effect of trigonella fonumgraecum and they also indicate that this effect may be related to the delaying of glucose absorption from the gut by agent(s) present in the hot water fraction, probably SDF. Further experiments with different timings (30, 60, 120 and 180 min) and also experiments with oral glucose load seems to strengthen this conclusion.

1457

EFFECTS OF *STACHYS RECTA* ON METABOLIC CONTROL AND OXIDATIVE STATUS IN DIABETIC RABBITS

Gorbenko V., Hvorostinka V., Gorshunska M. and Gopcziy T.[1].
Kharkov State Medical University, [1]Kharkov Agricultural University, Kharkov, Ukraine

Stachys recta (tuber) is widely used in traditional medicine as hypoglycemic agent. The aim of the study was to assess the impact of *S.recta* powder (S) on glucose pattern and oxidative status in rabbits with absolute insulin insufficiency. Male chinchilla rabbits were made diabetic by i.v. injection of dithizone (35 mg/kg). One group of diabetic animals was untreated to act as control (D) and other group received S (200 mg/kg per os) for 4 weeks. At the end of study fasted rabbits were subjected to a glucose tolerance test (GTT, 2 g/kg i.v.). Plasma samples were collected from ear vein at timed intervals (0,3,5,10,30,60 min) and analysed for glucose by glucose oxidase method and for insulin by RIA. The treatment with S decreased basal hyperglycemia by 30% ($p<0.05$), increased basal plasma insulin level (160.1±10.2 pmol/l vs D: 100.3±9.2 pmol/l, $p<0.02$) and protected from body weight loss ($p<0.05$). Administration of S improved glucose tolerance (integral glycemia over i.v. GTT was 80.0±4.7 mmol/l vs D:119.2±6.2 mmol/l, $p<0.02$). Oxidative status was assessed in plasma by spectrophotometric determination of diene conjugates (DC), vitamins A and E contents. S has been shown to suppress oxidative stress reducing DC levels (0.9±0.1 μmol/l vs D:2.8±0.2 μmol/l, $p<0.01$) and increasing 1.5 fold ($p<0.02$) vitamin E contents. However, vitamin A concentration was not changed by S. The results indicate that S possesses hypoglycemic and antioxidant properties in diabetic rabbits and may serve as potential source of antidiabetic agents.

1458

POTENT AND SPECIFIC ACTIVATION OF GLYCOGENESIS IN RAT SKELETAL MUSCLE BY LITHIUM: COMPARISON TO INSULIN.

C.Noe, R.Herdlicka, M.Roden, W.Waldhäusl and C.Fürnsinn.
Dept.Med.III, Div.Endocrinol.Metab., University of Vienna, Austria.

Lithium is frequently used for the treatment of mood disorders, but also affects glucose metabolism. To elucidate lithium's antidiabetic potential, its stimulatory effects on glucose metabolism of isolated rat soleus muscle were compared to those of insulin. Increment over basal glycogen synthase activity induced by 20 mmol/l lithium chloride was 4.8-fold more pronounced than that induced by 10 nmol/l insulin (nmol/l UDP-glucose incorporated into glycogen in synthase activity assay/g/min: lithium, +22.1±1.8 *vs.* insulin, +4.6±3.9; $p<0.01$). In parallel, lithium was less efficient than insulin in stimulating glucose transport (cpm ^{3}H-2-deoxyglucose/mg/h: lithium, +211±19 *vs.* insulin, +311±57; $p<0.05$) and anaerobic glycolysis (μmol lactate released/g/h: lithium, +1.0±0.5 *vs.* insulin, +3.9±0.5; $p<0.01$), while similar increments in glycogen synthesis were induced (μmol glucose incorporated into glycogen/g/h: lithium, +3.32±0.43 *vs.* insulin, +3.46±0.47; n.s.). Hence, lithium differs from insulin in that it much more specifically activates the glycogenic pathway. Further evidence for differences in mechanisms of action was derived from experiments demonstrating additivity of stimulatory effects and divergent dependency on phosphatidylinsositol 3-kinase activation (relative decrease in glycogen synthesis induced by 100 nmol/l wortmannin, an inhibitor of phosphatidylinositol 3-kinase: basal, -27±8%; lithium stimulated, -21±5%, n.s. *vs.* basal; insulin stimulated, -80±3%, $p<0.01$ *vs.* basal). Lithium may therefore be regarded a candidate for the treatment of forms of diabetes mellitus associated with primary deficits in the glycogenic pathway.

1459

GLP-1 RECEPTOR / Gs - COTRANSFEKTION : A NEW TOOL IN SCREENING FOR GLP-1 AGONISTS.

L. Bjerre Knudsen and B. Schjellerup Wulff. Novo Nordisk, Dept. of Molecular Pharmacology, Måløv, Denmark.

The GLP-1 receptor is a very exiting new target for the treatment of NIDDM. Unfortunately, GLP-1 is a 30 amino acid long peptide that has to be administered by injection. Therefore, an agonist for the GLP-1 receptor is a very interesting drug candidate. Today, functional screens where cAMP is measured directly after adenylyl cyclase stimulation of plasma membranes expressing the receptor, are difficult to use because of a rather small fold induction in an assay. This study aimed at producing a new cell line with an higher fold of induction for screening purposes. Human GLP-1 receptor was transfected into a Baby Hamster Kidney cell line previously transfected with the rat long form of the Gs-protein. Cells were transfected using the lipofectamine method. Clones were selected by western blotting with an antibody against the Gs-protein. A cell line expressing a high level of Gs-protein were transfected with the GLP-1 receptor. GLP-1 receptor expressing clones were selected on high induction following GLP-1 stimulation in a whole cell cAMP assay. The pharmacology of the related peptides glucagon and GLP-1(1-37) on the GLP-1 receptor / Gs cell line matched that of the GLP-1 receptor expressed in the same type of cell line. When using plasma membranes from this cell line in a microtiter plate format functional assay,a 25-fold (24.5 ± 3.72) induction was obtained. Plasma membranes from a normal GLP-1 receptor cell line in a similar setup only had an 8 (7.9 ± 2.1) fold induction. This cell line will make screening for agonists for the human GLP-1 receptor much more feasible. The higher induction in the assay will decrease the error on the samples and results in less false positive and false negatives. Thus, the chance of finding agonists for this very important target will be increased.

1460

DISTINCT CATABOLIC ACTION OF THE INSULIN SENSITITZER BM 13.0913xNa ON ISOLATED RAT SKELETAL MUSCLE.

R.Herdlicka, M.Bisschop, M.Roden, W.Waldhäusl and C.Fürnsinn
Department of Medicine III, Division of Endocrinology & Metabolism, University of Vienna, Vienna, Austria.

BM 13.0913xNa ("**BM**"; from Boehringer Mannheim, Germany) belongs to a new class of compounds referred to as activated carbon acids and exhibits distinct antidiabetic effects, when orally administered to hyperglycemic mice (ED_{50}-plasma levels: ~70 μM). The direct acute effects of **BM** on insulin-stimulated (10 nM) glucose metabolism of isolated soleus muscle strips obtained from healthy Sprague-Dawley rats were investigated. A concentration of 10 μM **BM** in the incubation medium increased the rate of insulin-stimulated ^{3}H-2-deoxy-glucose transport (cpm/mg/h: control, 778±36 *vs.* **BM**, 1033±48; $p<0.005$). In contrast to actions expected from an insulin-mimetic and/or insulin-sensitizing agent, elevated glucose transport was associated with blunted glycogen synthesis (glucose incorporated into glycogen, μmol/g/h: control, 4.58±0.36 *vs.* **BM**, 3.42±0.21, $p<0.025$), and with a distinct glycolytic response (μmol lactate released/g/h: control, 16.8±1.1 *vs.* **BM**, 26.1±1.3, $p<0.001$; CO_2 released from μmol glucose/g/h: control, 0.41±0.04 *vs.* **BM**, 1.70±0.11, $p<0.001$). At 300 μM **BM**, decreased rates of glucose transport (cpm/mg/h: control, 783±55 *vs.* **BM**, 184±31; $p<0.001$) and glycogen synthesis (μmol/g/h: control, 4.81±0.35 *vs.* **BM**, 0.19±0.03; $p<0.001$) were observed resulting in markedly decreased muscle glycogen content after 90 min of exposure (μmol glucosyl units/g: control, 12.9±0.4 *vs.* **BM**, 2.9±0.3; $p<0.001$). It remains to be elucidated, whether such acute catabolic potential of **BM** is instrumental for its long-term antidiabetic action *in vivo* or is to be regarded as an independent and potentially negative effect.

1461

POTENT ANTIHYPERGLYCAEMIC EFFECT OF AN IMIDAZOLINE DERIVATIVE S-22068 IN A RAT MODEL OF TYPE II DIABETES.

A. Pele[1], X Wang[2], F. Rondu[2], C. Illic[1], C. Hellary,[1] A Lamoury[2], E. Touboul[2], R Dokhan[3], S. Marc[3], B. Pfeiffer[4], D. Manechez[4], P. Renard[4], B. Guardiola-Lemaître[4], J-J Godfroid[2], L. Pénicaud[5] and A. Ktorza[1].
[1]Lab. Physiopathology of Nutrition, University Paris 7, France; [2]Lab. Molecular Pharmacochemistry, University Paris 7, France; [3]LDK France, Gif-sur-Yvette, France; [4]IRIS, Courbevoie, France; UPRESA 5018, Toulouse, France.

Several recent data suggest that some imidazoline derivatives can lower glycaemia in experimental animal models of diabetes. We studied the activity of the imidazoline derivative S-22068 in a rat model of type II diabetes obtained by i.v. injection of a low dose of streptozotocin (35 mg/kg). These rats, called STZ rats, exhibited moderate basal hyperglycaemia, glucose intolerance and impaired glucose-induced insulin secretion. We performed glucose tolerance and insulin tolerance tests to study a possible effect of the compound. Glucose tolerance and insulin secretion were measured as the ΔG and the ΔI, i.e. the respective increase over the basal value in the glycemia and insulinemia over 30 to 120 min after the glucose load. The insulinogenic index, was calculated as the $\Delta I/\Delta G$ and the rate of glucose disappearance as the K. After an i.p. injection of S-22068 (24 mg/kg), ΔG (mmol/l/min) was decreased (91.67 ± 5.83 vs 120.5 ± 3.65; $p<.001$), whereas K was increased (1.74 ± 0.09 vs 1.18 ± 0.05; $p<.001$). Insulin secretion was not improved: ΔI and $\Delta I/\Delta G$ were similar in the two groups. Oral administration of the product was even more effective on glucose tolerance and a chronic treatement (15 days) with S-22068 increased its efficiency. In both cases, glucose tolerance was improved and the basal hyperglycaemia was much lowered. Morever, even used at a high dose, the product did not provoke hypoglycaemia. In the view of these data, S-22068 can be considered as a potential antihyperglycaemic agent in diabetes, probably acting through an extra-pancreatic effect.

1462

DOSE-DEPENDENT EFFECT OF MOXONIDINE ON GLUCOSE TRANSPORT IN INSULIN-RESISTANT RAT MUSCLE.

E.B. Youngblood, E.J. Henriksen, S. Jacob, D.L. Fogt, and J. Gödicke. University of Arizona, Tucson, U.S.A.; Eberhard-Karls Universität, Tübingen, Germany; and Beiersdorf-Lilly, Hamburg, Germany

High blood pressure (BP) is frequently associated with insulin resistance. Moxonidine (MOX) lowers BP centrally by modulation of I_1-imidazoline receptors and a decrease in sympathetic outflow. We investigated the chronic effect of two doses of MOX — a higher dose (6 mg/kg) that decreases BP and a lower dose (2 mg/kg) that does not — on insulin action in the obese Zucker rat, a model of glucose intolerance and insulin resistance. Animals were treated orally for 21 days with either vehicle, 2 mg/kg MOX, or 6 mg/kg MOX. In the 6 mg/kg MOX-treated animals, fasting plasma insulin and free fatty acids were 17% and 36% lower ($p<0.05$), respectively, compared to obese controls. During an oral glucose tolerance test (OGTT), the glucose response (area under the curve) was 47% lower in the 6 mg/kg MOX-treated group, while the insulin response was 19% less. Glucose transport activity (2-deoxyglucose uptake) in isolated epitrochlearis muscle stimulated by insulin (13.3 nM) was 39% greater than control. In contrast, the lower dose of MOX did not decrease significantly fasting plasma insulin or free fatty acids. While the glucose response of these animals during the OGTT was 42% lower, this was likely partly related to the slightly greater (+11%) insulin response. Insulin-stimulated muscle glucose transport activity was not increased significantly following treatment with 2 mg/kg MOX. Therefore, in this animal model of insulin resistance, the ability of MOX to improve glucose tolerance, lower plasma insulin and lipids, and enhance insulin-stimulated skeletal muscle glucose transport is dose-dependent and may be related to its sympatholytic effects.

1463

TREATMENT OF OBESITY AND DIABETES IN ob/ob AND db/db MICE BY DOPAMINERGIC AGONISTS

P. Scislowski, S. Phaneuf, E. Tozzo, Y. Liang, M. Lubkin, R. Prevelige and A. Cincotta. ErgoScience Corp. Boston, MA, USA.

We examined the combined effectiveness of SKF38393 (SKF), a D_1 receptor agonist, and bromocriptine (BC), a D_2 receptor agonist, in treating obesity and diabetes in *ob/ob* and *db/db* mice. Daily drug injections were administered to female C57BL/6J *ob/ob* and C57BL/KsJ *db/db* mice 1 hr after light onset for 14 days. Drug treated groups received BC (16 mg/kg) plus SKF (20 mg/kg), whereas pair fed groups (food adjusted to drug treated groups' intake) and control groups received the vehicle. Oxygen consumption was measured in metabolic cages on day 11 or 12 of treatment. Plasma glucose, FFA, and insulin levels, were measured on day 14. In the *ob/ob* mice statistically significant results included: controls gained 6.9 ± 1.3g of body weight, while the treated mice lost 7.4 ± 0.4g. The average daily food consumption of controls was 6 ± 0.2g versus 2.8 ± 0.1g of treated. Oxygen consumption for controls and treated was 1277 ± 240 ml/kg/hr and 1623 ± 230, respectively. Plasma glucose levels were 471 ± 42 mg/dl in controls, and 164 ± 13 in treated. FFA levels were 1.27 ± 0.1 mM in controls, and 0.37 ± 0.05 in treated. Plasma insulin were 63.5 ± 17 ng/ml in controls, and 37.3 ± 6.6 in treated. Similar statistically significant results were observed in *db/db* mice: controls gained 6.6 ± 0.4g, of body weight versus 3.4 ± 1.3g in the treated. The average daily food consumption of controls was 10.7 ± 2.8g versus 5.9 ± 0.5g of the treated. Oxygen consumption for control and treated was 898 ± 250 ml/kg/hr and 2322 ± 283, respectively. Plasma glucose levels were 485 ± 29 mg/dl in controls, and 390 ± 55 in the treated. FFA levels were 1.49 ± 0.2 mM in controls, and 0.45 ± 0.04 in treated. Plasma insulin were 9.4 ± 1.3 ng/ml in controls group, and 46.7 ± 8.1 in treated. Results from pairfed animals (in both *ob/ob* and *db/db* mice) indicate that the above drug-induced metabolic changes are not primarily the consequence of decreased food consumption. Our data strongly suggest for the first time that, hyperphagia, hyperglycemia and hyperlipidemia in animals lacking either leptin (*ob/ob*) or a functional leptin receptor (*db/db*) can be treated with the combined administration of D_1 and D_2 receptor agonists.

1464

STEREOSELECTIVE ANTIHYPERGLYCAEMIC EFFECTS OF THE BENZOIC ACID DERIVATIVE AG-EE 388 IN VIVO.

M.Mark, M.Epple and W.Grell. Preclinical Research and Development, Boehringer Ingelheim, Biberach/Riss, Germany.

AG-EE 388 ZW [(±)-2-ethoxy-4-[2-[[3-methyl-1-[2-(1-piperidinyl) phenyl]butyl]amino]-2-oxoethyl]-benzoic acid] is a racemate and was shown to be a potent insulinotropic and glucose lowering compound when tested in vitro and in vivo. Within this class of compounds enantioselective effects have been described in vitro. It was the aim of the present study to investigate the antihyperglycaemic effects of the S-enantiomer, AG-EE 623 ZW, and the R-enantiomer, AG-EE 624 ZW, after oral as well as intravenous administration to fasted Wistar rats. In both experimental settings, AG-EE 623 ZW turned out to be a potent antihyperglycaemic agent (ED_{50} 3.4 µg/kg (i.v.) and 9.9 µg/kg (p.o.)) whereas AG-EE 624 ZW displayed only weak glucose lowering activity (active in doses > 0.1 mg/kg (i.v.) or > 1.0 mg/kg (p.o.)) in rats. Since the glucose lowering effects of AG-EE 624 ZW cannot be explained by residual AG-EE 623 ZW (which was 0.005 - 0.007 % (Annemarie Reinhardt Varming, Novo Nordisk A/S)), AG-EE 624 ZW itself must exert antihyperglycaemic activity. It is concluded that the glucose lowering activity of the racemate AG-EE 388 ZW mainly resides in the S-enantiomer AG-EE 623 ZW which displays, in the rat, a ≥ 100 times higher potency than the R-enantiomer AG-EE 624 ZW. For this reason the S-enantiomer AG-EE 623 ZW (repaglinide) has been proposed for further development.

1465

THE EFFECT OF CILOSTAZOL ON INSULIN RESISTANCE IN A RAT MODEL OF NON-INSULIN DEPENDENT DIABETES MELLITUS

BY Cha, SA Chang, SJ Yoo, KH Song, JH Han, JM Lee, KW Lee, HY Son and SK Kang. Catholic University Medical College, Seoul, Korea

The effect of cilostazol treatment on insulin resistance in Wistar Rats with streptozotocin(STZ)-induced, non-insulin dependent diabetes mellitus (NIDDM) was examined. Two day old neonate rats were injected intraperitoneally (i.p.) with streptozotocin (STZ) and maintained for six months at which time they were compared with age-matched control rats for glucose tolerance, insulin secretion in response to i.p. glucose loading (i.p. glucose tolerance test, i.p. GTT) and for insulin resistance during glucose infusions (GINF) in euglycemic, hyperinsulinemic glucose-clamp studies. In the i.p. GTT studies plasma glucose levels of STZ-induced diabetic rats were significantly higher and plasma insulin levels significantly lower than those of age- matched control rats. Insulin resistance was increased in STZ-induced diabetic rats since the GINF rates of these animals were significantly lower than those of age-matched control rats. After a four week treatment with cilostazol (100 mg/kg/day) in the feed chow, the plasma glucose and insulin levels of the STZ-induced diabetic rats after the i.p. GTT were not significantly different from those of age matched control rats. Similarly, cilostazol treatment reversed the decreased insulin resistance of STZ-induced diabetic rats since the GINF rates observed during the glucose-clamp experiments were not significantly different from those of the control rats. It is suggested that the improvement in glucose tolerance and insulin resistance by cilostazol in STZ-induced diabetic rats is due to the vasodilatation and accompanying increase in peripheral blood flow brought about through the phosphodiestrase inhibitory effects of cilostazol on peripheral vascular smooth muscle.

1466

POTENTIATION OF THE INSULINOTROPIC AND HYPOGLYCEMIC ACTIONS OF GLIQUIDONE BY SUCCINIC ACID ESTERS

J.A. García-Martínez, M.L. Villanueva-Peñacarrillo, I. Valverde, F. Björkling* and W.J. Malaisse†. Fundación Jiménez Díaz, Madrid, Spain, *Leo Pharmaceutical Products, Ballerup, Denmark, and †Laboratory of Experimental Medicine, Brussels Free University, Brussels, Belgium.

Esters of succinic acid are currently under investigation as potential insulinotropic tools for the treatment of NIDDM. The methyl esters of succinic acid, first examined in this perspective, may lead to the undesirable generation of methanol by intracellular hydrolysis. In recent studies, however, several esters, not susceptible to generate methanol, were found to remain potent insulinotropic agents. We have now explored whether these novel esters are able to potentiate the insulinotropic and hypoglycemic actions of the hypoglycemic sulfonylurea gliquidone. The monoethylester, monopropylester and monoisopropylester of succinic acid were administered intravenously (2.0 μmol/g body weight) together with gliquidone (0.2 mmol/g body weight) to fed male Wistar rats. At the 2nd min of the test, the increment in plasma insulin concentration above paired basal value averaged 17.5 ± 1.3, 13.3 ± 1.6 and 16.8 ± 2.0 ng/ml when gliquidone was administered together with the monopropyl, monoethyl and monoisopropyl ester, respectively, as distinct from only 8.2 ± 1.2 ng/ml after injection of gliquidone alone. Over 30 min observation, the hypoglycemic action of gliquidone was not significantly affected by either the monopropyl or monoethyl ester of succinic acid, but almost doubled by the monoisopropyl ester. These observations reinforce the idea that succinic acid esters could be used to improve the insulinotropic potential of hypoglycemic drugs. Moreover, the finding that some of these esters may potentiate the hypoglycemic action of antidiabetic agents indicate that their possible role as gluconeogenic precursor in the liver is not an insurmountable obstacle to their use in a therapeutic perspective.

BROMOCRIPTINE/SKF38393 TREATMENT IMPROVES PANCREATIC ISLET FUNCTION IN THE *db/db* MOUSE.

M.Lubkin, Y.Liang, E.Tozzo, P.Scislowski, S.Phaneuf, R.Prevelige, A.Meier, and A.Cincotta. Ergoscience, Boston, USA

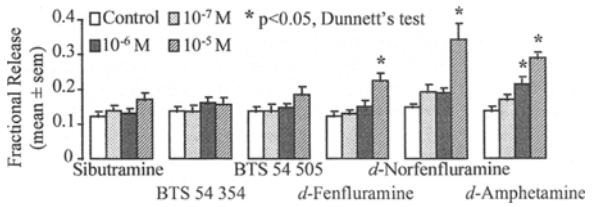
Pharmacological intervention with bromocriptine improves glucose and lipid metabolism in NIDDM animals and patients. The influence of such treatment on pancreatic islet function has not been investigated. Here we studied the effect of D_2/D_1 receptor agonists—bromocriptine/SKF38393 (BC/ SKF) on islet function in this diabetic model. Female *db/db* mice (30±1g) were treated daily for 2 weeks at 1 hour after light onset with 1) BC (16 mg/kg) plus SKF (20 mg/kg), 2) vehicle only (controls), or 3) vehicle plus feed restriction to match the reduced food consumption of treated mice (pair fed). The BC/SKF treatment reduced blood glucose (347±28 vs. 606±31 mg/dl in controls, P<0.01) and plasma free fatty acids (0.6±0.1vs.1.1±0.1 mM in controls, P<0.01) levels, and increased plasma insulin level by 3-fold compared with that in controls (49±5 vs. 16±2 ng/ml, P<0.01). In pair fed mice there was a more modest (30%) reduction (P<0.01) of blood glucose but no change in plasma insulin and a 20% increase in plasma free fatty acids compared with control levels. The insulin release response of pancreatic islets to secretagogues was tested in vitro. Insulin release from incubated islets stimulated by glucose (8 and 15 mM), arginine (10 mM) and acetylcholine (10 μM) was each 3-4 fold greater in the treated group compared with that in controls (P<0.05). Contrariwise, secretagogue-induced insulin release from incubated islets of pair fed mice were similar to those in controls. Furthermore, similar BC/SKF treatment had no effect in normal mice. Addition of BC/SKF directly to the islet incubation buffer did not enhance insulin release from db/db mouse islets. These results demonstrate that BC/SKF given in vivo markedly enhance islet function in the *db/db* but not the normal mouse. This effect is not attributable to either a direct action on islet function or inhibition of feeding. Available evidences from our lab suggests that this treatment ameliorates abnormalities within the hypothalamic-neuroendocrine-axis regulating metabolism.

1468

SIBUTRAMINE AND ITS ACTIVE METABOLITES DO NOT RELEASE [^{3}H]-NORADRENALINE FROM RAT BRAIN SLICES *IN VITRO*.

Aspley S, Prow MR, Martin KF and Heal DJ. Knoll Pharmaceuticals Research & Development, Nottingham, NG1 1GF, UK.

Sibutramine is a noradrenaline (NA) and serotonin reuptake inhibitor which is an effective weight-loss agent. In overweight, non-insulin dependent diabetics sibutramine improves glycaemic control and reduces weight, while in obese hyperglycaemic (ob/ob) mice repeated sibutramine improves glycaemic control without weight loss. Sibutramine acts *in vivo* predominantly via its secondary and primary amine metabolites (BTS 54 354; BTS 54 505). The aim of this study was to determine whether sibutramine and its metabolites release central NA *in vitro* and to compare their effects with those of other weight-loss agents. Rat frontal cortical slices, loaded with [^{3}H]-NA in the presence of pargyline, were superfused with Krebs buffer with or without drug (sibutramine, BTS 54 354, BTS 54 505, *d*-amphetamine, *d*-norfenfluramine or *d*-fenfluramine, 10^{-7}-10^{-5} M). Sibutramine, BTS 54 354 and BTS 54 505 did not evoke release of [^{3}H]-NA (Figure 1). *d*-Fenfluramine and *d*-norfenfluramine enhanced [^{3}H]-NA overflow at 10^{-5} M, whilst *d*-amphetamine dose-dependently released this monoamine (Figure 1).



These results provide clear evidence that sibutramine, BTS 54 354 and BTS 54 505 are not CNS NA releasing agents. These data clearly support the hypothesis that CNS NA release does not contribute to the pharmacological action of sibutramine and its metabolites. These data also suggest that sibutramine will be a safe, efficacious treatment for obese diabetic patients.

1469

A NOVEL HUMAN β3-ADRENOCEPTOR AGONIST AD-9677

H. Kawashima, A. Nomura, M. Ohue, H. Kato, J. Kuwajima, Y. Furutani and K. Hosoki. Dainippon Pharmaceutical Co., Ltd., Osaka, Japan.

β3-adrenergic receptor (β3-AR) plays a role in regulating energy balance. β3-AR agonists are shown to increase energy expenditure by stimulating lipolysis, and to normalize hyperglycemia and hyperinsulinemia in diabetic rodents. Thus the β3-AR selective agonists that were discovered by screening for anti-obesity effects in rodent are potential anti-obesity and anti-diabetic drug. However, due to structural differences between human and rodent β3-ARs, many of these agents are poor agonists against the human receptor. To discover agents with potent activity to human β3-AR, we have established CHO cell line stably expressing human β3-AR as well as rat β3-AR. Among hundreds of compounds screened by measuring intracellular cAMP accumulation, AD-9677, which showed the strongest activity to human β3-AR, was selected. The EC_{50} values of AD-9677 to human and rat β3-ARs were 0.062 nM and 0.016 nM, respectively, and therefore the compound is seems to be one of the most active β3-AR agonist so far known. We also have established human β1- and β2-AR-expressing CHO cell lines to evaluate β3-AR selectivity. As cAMP accumulating activities of AD-9677 in human β1- and β2-AR-expressing cells were quite low, AD-9677 is a highly selective β3-AR agonist. Preliminary experiment of chronic administration of AD-9677 to obese-diabetic rodents certified that AD-9677 had anti-obesity and anti-diabetic effects *in vivo*. Thus, AD-9677 will be a useful agent for treatment of type II diabetes and obesity.

1470

D-FENFLURAMINE-INDUCED DEPLETION OF RAT BRAIN 5-HT IS PREVENTED BY SIBUTRAMINE OR FLUOXETINE PRETREATMENT.

Aspley S, Butler SA, Prow MR, Martin KF and Heal DJ. Knoll Pharmaceuticals Research & Development, Nottingham, NG1 1GF, UK.

Sibutramine (SIB) is a serotonin (5-HT) and noradrenaline reuptake inhibitor, and weight-loss agent. Weight-reducers which release 5-HT, viz. fenfluramine; *d*-fenfluramine (*d*FEN), cause profound brain 5-HT depletion in both rodents and non-human primates. This study compared the effects on rat brain 5-HT of *d*FEN with those of SIB and the selective serotonin reuptake inhibitor, fluoxetine (FLU). Male SD rats (80-100g) received vehicle, *d*FEN 10 mg/kg p.o., SIB 9 mg/kg p.o. or FLU 10 mg/kg i.p. for 4 days, *b.i.d.*, alone or in combination (SIB or FLU 1 h prior to *d*FEN); 14 days later, brain tissue 5-HT content was determined by HPLC-ED. *d*FEN decreased 5-HT levels in all regions. In striking contrast, FLU and SIB did not alter brain 5-HT levels (Table 1) and actually prevented the *d*FEN-induced decreases in 5-HT in the majority of areas (Table 1).

	Frontal cortex	Hippocampus	Striatum	Hypothalamus
Saline/H_2O	509 ± 29	420 ± 32	446 ± 40	947 ± 55
FLU	513 ± 29	446 ± 33	596 ± 54	912 ± 53
*d*FEN	176 ± 10 **	151 ± 11 **	250 ± 22 **	673 ± 39 **
FLU/*d*FEN	507 ± 29 ††	448 ± 34 ††	534 ± 48 †	873 ± 50
H_2O/H_2O	675 ± 39	525 ± 30	401 ± 25	802 ± 43
SIB	644 ± 38	552 ± 32	346 ± 22	756 ± 42
*d*FEN	234 ± 14 **	214 ± 12 **	220 ± 13 **	579 ± 31 **
SIB/*d*FEN	534 ± 31 * ††	480 ± 28 ††	354 ± 22 ††	704 ± 39 †

5-HT levels (ng/g wet tissue weight) mean ± s.e. mean (n=8-18). Comparisons with vehicle, *p<0.05 **p<0.01, Williams' test. interactions between drugs, †p<0.05, ††p<0.01, Multiple t-test.

These data confirm that *d*FEN persistently depletes brain 5-HT, but the monoamine reuptake inhibitors, SIB and FLU do not. Taken together with evidence from microdialysis studies which show SIB and FLU inhibit *d,l*FEN from releasing 5-HT, the data argue that SIB and FLU prevent the 5-HT depleting effects of *d*FEN by blocking its entry into 5-HT nerve terminals.

1471

JTT-501 IMPROVES INSULIN RESISTANCE INDUCED BY GLUCOSAMINE AND TNF-α IN CULTURED MYOTUBES FROM HUMAN NIDDM SKELETAL MUSCLE.

T. Komori, N. Koh, J. Nakamura, Y. Hamada, T. Hara, H. Sasaki, S. Chaya, E. Nakashima, K. Naruse, K. Kato, N. Takeuchi, Y. Kasuya and N. Hotta. Nagoya University, Nagoya, Japan.

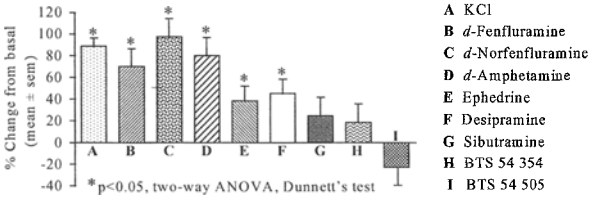
Insulin resistance in skeletal muscle has been regarded as one of the most important pathogenic factors of NIDDM. In this study, the effect of a novel hypoglycemic agent, JTT-501(JT), on glucose transport was investigated in cultured myotubes from human NIDDM subjects from the view point of insulin signal transduction system and intracellular Ca^{2+}. Glucose transport rate (GTR)was expressed by 2-deoxy-D-[^{3}H]glucose uptake, and the number of cell surface facilitated glucose transporters (GTN) was evaluated by [^{3}H]-cytochalasin B binding capacity. Glucosamine(G) significantly reduced the basal and insulin (Ins)-stimulated GTR (Basal: 100±3.2%, G: 86.4±6.9, Ins: 143.5±10.3, Ins+G: 108.7±8.5, $p<0.05$). JT significantly ameliorated G-induced decrease in GTR (G+JT: 94.7±5.8, Ins +G+JT: 122.3±9.8, $p<0.05$). G significantly reduced GTN, and JT ameliorated the reduction of GTN in the presence of Ins. Wortmannin, a PI3-kinase inhibitor, abolished the effects of Ins and JT on GTR and GTN, however dantrolene, an inhibitor of Ca^{2+} mobilization, had no effects. Ins and JT demonstrated similar effects on insulin resistance induced by TNF. These results suggest that JT exerts its action by ameliorating not only the translocation of glucose transporters mediated through the activation of PI3-kinase, but also the expression of glucose transporter mRNA, and that JT is a useful agent for the treatment of NIDDM with insulin resistance.

1472

SIBUTRAMINE AND ITS ACTIVE METABOLITES DO NOT RELEASE [^{3}H]-NORADRENALINE FROM RAT HEART SLICES *IN VITRO*.

Aspley S, Broughton D, Martin KF and Heal DJ. Knoll Pharmaceuticals Research & Development, Nottingham, NG1 1GF, UK.

The noradrenaline (NA) and serotonin reuptake inhibitor, sibutramine, is an efficacious weight reducing drug which acts *in vivo* mainly via its metabolites, BTS 54 354 and BTS 54 505. In overweight, non-insulin dependent diabetics sibutramine improves glycaemic control and reduces weight, while in obese hyperglycaemic (ob/ob) mice repeated sibutramine improves glycaemic control without weight loss. In contrast to other weight modifying agents, sibutramine and its metabolites do not release NA from brain tissue. The present study examined the effects on NA release from rat heart *in vitro* of sibutramine and its metabolites, in comparison with other weight-loss agents. Rat heart slices, loaded with [^{3}H]-NA in the presence of pargyline, were superfused with Krebs buffer with or without drug (50 mM KCl, *d*-fenfluramine, *d*-norfenfluramine, *d*-amphetamine, ephedrine, desipramine, sibutramine, BTS 54 354 or BTS 54 505, all 10^{-5}M). Sibutramine, BTS 54 354 and BTS 54 505 had no effect on [^{3}H]-NA release (Figure 1). KCl (50 mM) and *d*-fenfluramine, *d*-norfenfluramine, *d*-amphetamine, ephedrine and desipramine all enhanced [^{3}H]-NA overflow at 10^{-5} M (Figure 1).



These results clearly support the hypothesis that sibutramine, BTS 54 354 and BTS 54 505 are not sympathomimetic drugs and, in contrast to other weight-loss agents (*d*-amphetamine; *d*-fenfluramine) the NA effects of sibutramine are mediated via uptake inhibition, not release. These data also suggest that sibutramine will be a safe, efficacious treatment for obese diabetic patients.

1473

STUDY ON THE MECHANISM OF HYPOGLYCEMIC EFFECT OF OLEANOLIC ACID IN STREPTOZOTOCIN DIABETIC RATS

Shinan Yin and Jiaqing Zhang 304th hospital Beijing China

To study the effect of oleanolic acid(OLA) on the glucose metabolism, insulin secret and the glucose transporter 4 gene expression in streptozotocin diabetic rats.The animals were divided into the following experimental groups of 10 animals: ① Control ② STZ-induced diabetic ③ OLA-treated STZ-induced diabetic(OD). After STZ was injected seven days OD group was injected OLA(50mg/kg.d) subcutaneous for 7d. In the 14th experimental day all animal were killed. The whole blood were collected and the soles muscle from each leg was removed intact, clamp-frozen in liquid nitrogen, and stored at -80 ℃ until analysis. Plasma insulin concentrations were determined by RIA. Plasma glucose were detected by Reflolux IIM (Germany) glucose meter. Total tissue RNA was extracted using a guanidine thiocyanate method. Using the GLUT4 cDNA as probe , the GLUT4 mRNA content in skeletal muscle in STZ diabetic rats was detected by Dot blot analysis. The GLUT4 mRNA contents of skeletal muscle decreased 27%($P<0.05$) in STZ-induced diabetic rats. In OLA treated STZ-induced diabetic rats blood glucose decreased from 22.20±2.53 to 16.92±1.41mmol/L($P<0.01$), plasma insulin increased from 25.40±8.23 to 30.67±7.01pmol/L ($P<0.05$), the GLUT4 mRNA increased 15.2% in the skeletal muscle($P<0.05$) The mechanism of hypoglycemic effect of oleanolic acid in streptozotocin diabetic rats was probably due to the improvement of insulin secretion and /or due to the relieved of whole-body insulin resistance.

1474

SUCCINIC ACID ALKYL ESTERS-NEW GENERIC ORAL ANTI-DIABETIC AGENTS IN ALLOXAN AND STZ DIABETIC RATS

R.Korec.Diabetes Research Labor.Fac.of Medicine of Univ.Košice,Slovakia

In 1988 McDonald with Fahien discovered the insulin secretagogue activity of succinic acid monomethyl ester(SAMME) and Malaisse with coll.reported in 1993-95 further new effects of SAMME and other alkyl esters in STZ diabetic rats.Author has tested the hypoglycemic activity of SAMME in alloxan diabetic rats in acute and chronic stage with hyperglycemia between 12 and 25mmol/l.In the acute stage with glycemia over 17mmol,SAMME was ineffective in 14 rats,but in mild acute diabetes 1mmol/kg of SAMME by gavage depressed glycemia of 9 to 4-5mmol in one and two hours.In the chronic stage of diabetes,1mmol/kg of SAMME administered by gavage,depressed hyperglycemia in 4 groups of rats,each of ten,determined at one,two and four hour:In the first group from 9 up to 2.9,in the second from 13.6 to 7.6,in the third from 16.9 to 9.6, 9.3 and 7mmol/l and in the fourthfrom 25.2up to 8.9mmol.SAMME administered in drinking water or by gavage exhibited no signs of toxicity or depression of food intake.Conclusion:SAMME has hyperglycemia and glycosuria depressing activity in alloxan and STZ diabetic rats at unchanged food intake and without signs of toxicity and succinic acid alkyl esters could be tried as generically new antidiabetic agents in human diabetes.

1475

CATALASE INACTIVATION IN THE PRESENCE OF 3-AMINO-1,2,4-TRIAZOLE:EFFECT OF DIABET AND NICOTINAMIDE.

O.Olijarnyk, N.Gamazina and M.Veliky.University of Lviv, Lviv, Ukraine.

In investigation of irreversible catalase inactivation by 3-amino-1,2,4 triazole (AMT) was used the model of streptozotocine induced diabetes of rats. Sharp catalase inactivation started by AMT - concentration 20 mM for control rats and 10 mM for streptozocine diabetic rats. After nicotinamide injections (250 mg/kg during 14 days) catalase inactivation started by AMT - concentration 10 mM but was not strong.

With blood haemolysates it could be shown that incubation with 50mM AMT did not cause any diminution of the catalatic activity in comparison with liver suspension. However, the addition of ascorbic acid could effectively inhibition of catalase in the presence of AMT.

Increase of catalase inhibition in the erythrocytes of streptozotocine diabetic rats from 40±1,2% to 54±0,9% by concentration of ascorbic acid according from 25 to 100 μM in comparison to control rats: from 11±0,8% to 19±1,3%. Injections of nicotinamide to streptozotocine diabetic rats dicreased the catalase inhibition (from 16±0,6% to 36±1,4%).

Rat liver suspension and blood haemolysates exposed in the presence of AMT undergo AMD-dose dependent and ascorbic acid-dose dependent inactivation of catalase. Effect of nicotinamide was realised during descrease of catalase ihnibition of streprozocine diabetic rats.

1476

VANADATE CANNOT REPLACE INSULIN IN ALLOXAN,STZ OR BB DIABETIC YOUNG OR ADULT RATS

R.Korec.Diabetes Research Labor.Fac.of Medicine of Univ.,Košice,Slovakia

Aim:To show how erroneous may be estimation of effectivity of an antidiabetic agent from results in vitro and extrapolate them to whole organism or of diabetes from glycemia only neglecting food intake and output of glucose in urine.Author administered 1,2 up to 4mmolar ammonium metavanadate(V+5 NH4VO3) in drinking water to 12 young(90-110g)and 12 adult ALL,21young STZ and 10 BB diabetic adult rats,both sexes aa,and determined daily,up to one month,their glycemia,glycosuria,food and water intake,volume of urine and glycosuria,body mass and compared these parameters with intermittently administered insulin.In all these three types and age groups of diabetic rats with hyperglycemia 18-22mmol/ldaily food intake 15-25g,V+5containing water intake of 40-90ml/d,urinary volume 30-70ml and glycosuria 3-4g/d,the drinking of V+5 water caused a decrease in food intake and glycemia but not an increase in glucose utilization,calculated from ingested carbohydrate and eliminated glucose.On the contrary,intermittently administered insulin increased food intake,assimlation of glucose,depressed glycemia,glycosuria,water intake and urinary volume ,promoted growth of young rats while V+5 retarded it.Conclusion:Although more than 11 authors on the basis of experiments in vitro in unphysiological media and high concentrations of vanadate,noxious to rats,claimed insulin-like effect of V+5,my results show that vanadate cannot replace insulin in diabetic rats.

1477

TUNGSTATE NORMALIZES DIABETIC STATUS BY INCRESING BETA CELLULAR MASS.

J.Fernández-Alvarez, A.Truc, B.Nadal,[1] M.Garcia, [2]A.Barbarà, [2] J.Guinovart and R.Gomis. Endocrinology and Diabetes Unit, [1] Hormonology Unit, Hospital Clinic, Universitat Barcelona, Barcelona. [2] Dep.Biochemestry and Molecular Biology, University Barcelona, Spain.

It has been described that administration of tungstate (T) to an animal model of NIDDM, the neonatally STZ-injected diabetic rats, normalize glycemia with concomitant increase in insulin-secretion and insulin-content. Moreover, T treatment increase the B-cell mass in the pancreas. The aim of the study is to investigate whether this increase in B-cell mass is accompained by B-cell regeneration from pre-existing B-cells or from ductal cells.The animals treated with T were given a solution of 2 mg/ml of sodium T in distilled water during 1 month. Morphometric studies were made using indirect immunofluorescence. Beta-cell replication rate was estimated from in vivo incorporation of 5-bromo-2'-deoxyuridine (BrdU) in B-cell and double immunofluorescence with anti-BrdU and anti-insuline antibodies. **Results**: T normalized glycemia in diabetic animals (4.8±0.1 mmol/l v.s 8.3±1.2 mmol/l; $p<0.05$) and this normalization in glycemia was correlated with an increase in blood insulin levels (18.8±6.7 uU/ml v.s 60.0±5.1 uU/ ml; $p<0.005$). Concomitantly a recovery in the number of B-cell in the pancreas was observed (0.86±0.07% v.s 1.67±0.31; $p<0.05$). The BrdU experiments are described in the following table:

	Intra-islet (%)	Extra-islet (%)
Healthy rats		
Untreated (4)	4.52±0.07[a]	9.23± 0.90[b]
Treated (4)	17.54±2.99	33.89±2.92
Diabetic rats		
Untreated (4)	6.60±1.2	6.60±0.92
Treated (4)	3.03±0.03[c]	59.26±7.94[d]

[a] $p<0.001$ v.s H.Treated; [b] $p<0.001$ v.s H.Untreated; [c] $p<0.001$ v.s H.Treated; [d] $p<0.001$ v.s H.Treated.**Conclusions**:Tungstate-induced normalization of metabolic status,in diabetic animals, is associated with an increase in beta-cell replication from extra-islet precursor cells.

1478

IN MODEL DIABETIC CATARACT, PROTECTION BY R-α-LIPOATE INVOLVES MAINTENANCE OF LENS GLUTATHIONE.

Trevithick, JR, Handelman, G.*, Tsang, K.*, Traver, K., and Packer, L.*, Department of Biochemistry, University of Western Ontario, London, Ontario, Canada, *Department of Molecular and Cell Biology, University of California, Berkeley, CA.

Aims: In previous work dihydrolipoic acid (DHLA) levels in rat lenses treated in an *in vitro* model of diabetes with R-, S- and Racemic-α-lipoic acid (LA) were identical, although only the R-α-LA reduced the cataractous damage (opacity and leakage of lactate dehydrogenase). This work extends the work to monitor glutathione (GSH) levels and medium lactate in this model.

Methods: Lenses from 200 g female Wistar rats were incubated in 5.5 and 55.6 mM glucose with added R-, S-, or racemic-LA. Glutathione levels of lens homogenates were determined by DTNB, lactate by an enzymic method, and DHLA and LA by HPLC.

Results: At 24 hr the GSH levels of lenses incubated with R-LA (1292 ± 116 μmol/mg) were not significantly different from normal controls (1222 ± 213 μmol/mg) but were significantly greater than for lenses incubated with S-LA (778 ± 112 μmol/mg) or racemic LA (738 ± 254 μmol/mg). At 24 hr, the levels of LA and DHLA were not significantly different in lenses treated with R, S or racemic-α-LA. By 48 hr Lactate levels in the medium were elevated above the 24 hr level but no significant differences between control and LA-incubated lenses were observed.

Conclusions: This result is consistent with specific protection of glutathione by R-α-LA.

Supported by Asta Medica, Frankfurt.

INSULIN RELEASING EFFECTS OF SOME PURE COMPOUNDS FROM *HEMIDESMUS INDICUS* ON ISOLATED RAT ISLETS

B. Rokeya[1], L. Ali[1], A. Banerjee[3], A.K. Azad Khan[1], M. Mosihuzzaman[2], S.M. Moinuddin[2], N. Nahar[2], N.S. Chowdhury[1] and J.M.A. Hannan[1]. *[1]Research Division, BIRDEM, [2]Department of Chemistry, University of Dhaka, Bangladesh; [3]Dept of Chemistry, Science College, Calcutta University, India.*

Hemidesmus indicus roots are used by traditional practitioners for the treatment of diabetes. Alcohol extract of *H indicus* root was tested on nondiabetic, IDDM model and on NIDDM model rats for hypoglycemic effect and was found to have significant antihyperglycemic effect. Four compounds (HI01, HI02, HI06 and HI07), isolated from *H indicus* root extracts by repeated chromatography and identified by spectroscopic methods, were tested for insulin secretion on islets from male Long-Evans rats isolated by collagenase digestion. Batches of 7-10 islets were studied under static incubation at 37oC for 60 minutes in 400 ml of HEPES buffered medium supplemented with 1mg/ml bovine serum albumin. The compounds, dissolved in DMSO, were used at a final concentration of 1mM and the media contained either 3 or 11mM glucose at a pH of 7.4. Insulin concentration in the supernatant was measured by an ELISA technique and the protein content of the islets were measured by a detergent compatible protein assay kit. The results were expressed as ng insulin secreted per mg of protein and the values of the experimental groups were compared with the control by Mann-Whitney test. The median value of the insulin at 3mM glucose concentration was 4.22 (Min 1.059-Max 15.213) and it increased to about 5 times in response to 11mM glucose (median 21.35, Min 12.791 - Max 39.362). None of the compounds had any significant effect on insulin release at 3mM glucose concentration. However, at 11mM glucose, compounds HI01 and HI07 were found to possess a significant stimulating effect on insulin release ($p<0.04$ and <0.004, respectively). The results showed that *H indicus* roots have hypoglycemic properties which may at least partly be due to the insulin releasing properties of these compounds.

1480

EFFECTS OF VANADATE AND INSULIN ON THE ACTIVITY OF AMINO TRANSFERASES IN THE RETICULOCYTES OF DIABETIC RATS.

Salimuddin, B.L. Gupta and Najma Z. Baquer School of Life Sciences, Jawaharlal Nehru University, New Delhi INDIA.

The enzymes of gluconeogenesis and protein catabolism increased in diabetes leading to an increase in the amino acid pool and TCA cycle intermediates in the cell. Alanine and aspartate aminotransferases play an important role in the degradation of amino acids. A significant increase in the activity of both alanine and aspartate aminotransferases was observed in reticlocytes isolated from diabetic animals. The administration of insulin and vanadate was found to reverse the activity of these enzymes almost to the control values. The present results show that there is an enhanced process of ageing in diabetes as shown by the increase in activity of the enzymes of protein catabolism. Vanadate is shown to be a potential insulin mimetic and antidiabetic agent and was found to normalize the altered state of diabetes.

APPROACHES TO THE THERAPY OF DIABETIC CHEIROARTHROPATHY
Denissov L., Kuraeva T., Match E., Remisov O.
Institute of Rheumatology of RAMS(Director-Acad.V.Nassonova;Research Center of Endocrinology(Director-Acad.I.Dedov)

According to our data limited Joint mobility(LJM)was found in 10.7% of examined children. There is no specially developed treatment for diabetes mellitus(DM)patients. Adequate and timely dose of Insulin lessens vascular disorders, prevents LJM progress, improves their general condition. Taking into account pts' complaints, clinical manifestations and microcirculatory disturbances, for the first time 40 pts were treeated with Plidol (soluble acetylsalicilic acid with buffer of "Pliva" company and Trental). Control group consisted of 15 pts. Pts had Plidol 0.3 x 3 times a day for 10 days and then 0.3 x 2 times a day for 1.5-2 months.Pts were repeatedly examined in 3-6 months after treatment,which resulted in decreasing of pain syndrome and constraining of motions, increasing of their functional ability. Comparing to the control group practically all children demonstrated increasing of initial blood circulation,decreasing of sensitivity to sympathetic stimulation and response to local heating increased, though not in all cases these indices coinsided with the norm. There 65% of cases where we found that constrained motions and discomfort decreased. Active and passive joints motion increased.
Conclusion:Adequate Insulin therapy combined with the above additional methods of treatment results in noticeable improvement of clinical symptoms of diabetic cheiroarthropathy.

1482

EFFECT OF YOGA ON INSULIN SENSITIVITY.
V.Simha, P.Shah, G.Modi, U.Sachdeva and R.L.Bijlani. Depts. of Physiology and Endocrinology, All India Inst of Med Sc,New Delhi.

In order to examine the effect of Yoga on insulin sensitivity, a demonstrative study was conducted on five male NIDDM subjects of mean(±SE) age 54.1(±2.74) years and having detected diabetes for 7 7±2.2 years. Clinical examination, anthropometry, 3 hour OGTT and hyperinsulinemic euglycemic clamp studies at serum insulin levels of about 100uU/ml (CV plasma glucose 5.24±0.37) were performed before and after three days intensive Yoga training camp and home practice (30 minutes/day) for 8 weeks which had been reinforced by a follow up camp after 15 days. The mean insulin stimulated glucose uptake (M values) were 2.92±0.72 mg/kg/min and 3.69±0.8 mg/kg/min respectively (p=0.29). The fasting glucose (170.2±15.7 and 176.5±14 mg/dl, p=0.59), and insulin levels (16±3.4 and 24±7.1 uU/ml, p=0.07) or the glucose and insulin response to 3 hour OGTT (752.3±28.2 and 787.5±46.2 mg.h/dl, p=0.25; 58.4±10.2 and 99.8±27.5 uU.h/ml, p=0.07 respectively) were not significantly different. The changes in BMI (25.8±1.2 and 25.6±1.3 kg/meter square, p=0.358), waist hip ratio (1.05±0.02 and 1.06±0.02, p=0.86) and triceps and subscapular skin fold thickness (35.8±4.5 and 36.1±5 mm, p=0.86) were not significant. There was a marginal decline in the diastolic and systolic blood pressures (4±1.16 mm Hg, p=0.01 and 3.67±1.96 mm Hg, p=0.11 respectively). Though Yoga intervention tends to induce beneficial effects, the significance will have to be proven by a randomized trial.

1483

THE BENEFICIAL EFFECT OF NICOTINAMIDE ON BETA CELLS FUNCTION IN INSULIN DEPENDENT DIABETICS
M.Zamaklar,A.Jotić,N.Lalić,K.Lalić,N.Rajković,Lj.Lukić,M. Bogić and P.Djordjević.Institute for Endocrinology ,Belgrade,Yugoslavia
It has been shown previously that a different treatment in recent onset IDDM patients might have beneficial effect on beta cells function.Nicotinamide may induce clinical remission, as it was shown.The aim of this study was to estimate residual beta cells function(by measuring C-peptide before &6 min.after 1mg Glucagone)during the first year of IDDM duration.Investigation were performed in IDDM patients before and after clinical remission:12 were treated with insulin pump and with 250mg/day Nicotinamide (group A)and 10 were treated with insulin pump only(group B). Patients from group A were ages 20,28+/-4,16 yr. and from group B 16,78+/- 5,12 yr. Glucagon test were performed at time of diagnosis,at time of remission, and in 3rd,6th and 12th month after. Duration of clinical remission in group A was 4,3+/-3,6months and in group B 4,6+/-2,3 months.Mean C-peptide values(nmol/l) in 0 and 6th minutes for both groups are shown on the table:

Group	Time of Dg	Remission	3mo	6mo	12mo
A	0 min	0,33+/-0,13	0,39+/-0,03	0,48+/-0,14	0,39+/-0,17	0,33+/-0,12
B	0 min	0,22+/-0,09	0,43+/- 0,11	0,39+/-0,14	0,24+/-0,18	0,14+/-0,12
	p	<0,05	>0,05	<0,05	<0,05	<0,05
A	6 min	0,56+/-0,23	0,68+/-0,13	0,67+/-0,13	0,57+/-0,23	0,47+/-0,20
B	6 min	0,36+/-0,10	0,70+/-0,22	0,57+/-0,21	0,35+/-0,23	0,17+/-0,15
	p	<0,05	>0,05	>0,05	<0,05	<0,05

Our results suggest that in spite of similar duration of remission, patients from group A who were treated with small doses of Nicotinamide had better preservation of beta cells function during the first years of duration of IDDM(basal & after stimulation Glucagon).

1484

RHIGF-I IMPROVES CORONARY RISK FACTORS IN TYPE II DIABETES.
A. Moses#, L. Phillips%, P. Martha*, P. Compton*, B. Zysow* for the RINDS & RICIS Groups, #Beth Israel Hospital, Boston, %Emory Univ, Atlanta, *Genentech, Inc, South San Francisco

Type II diabetics suffer from an insulin resistance syndrome which predisposes them to premature atherosclerosis. rhIGF-I increases insulin sensitivity in patients with impaired glucose tolerance and overt hyperglycemia. Effects of rhIGF-I on known cardiovascular (CV) risk factors were investigated in clinical trials. In one trial, 212 patients taken off prior therapy (insulin/ oral agents) were randomized to receive placebo or rhIGF-I: 10, 20 40 or 80 µg/kg BID for 12 weeks. There was a statistically significant, dose-dependent decrease in fasting triglyceride levels (p=0.0013). Despite significant dose-dependent decreases in HbA1c there was no increase in body weight. In a second trial, 139 insulin-requiring type II patients instructed to alter their insulin regimen to meet aggressive glycemic goals were randomized to receive co-therapy with placebo or rhIGF-I: 20/20, 40/40 or 80/40 (am/pm) µg/kg. Preliminary results demonstrate that despite a significant decrease in HbA1c in all rhIGF-I treated groups vs placebo, weight did not increase. However, visceral fat, determined by CT scan, decreased by 14.7% in the 20 µg/kg BID dose groups as compared to a 0.14% increase in the placebo (p=0.023) group . PAI-1 and fibrinogen levels decreased in all rhIGF-I treated arms; these trends did not achieve statistical significance. Insulin use decreased in the 2 highest rhIGF-I dose groups. The most commonly reported adverse events related to drug treatment in both studies were edema and jaw pain. There was no increase in incidence of CV events (angina, arrhythmia, myocardial infarction or stroke).

1485

LATE PHASE II STUDY OF A NOVEL ORAL HYPOGLYCEMIC AGENT, A-4166 IN NIDDM SUBJECTS IN JAPAN

M.Kikuchi, Y.Akanuma, T.Kuzuya, Y.Ohashi, Y.Shigeta, S.Tarui, T.Toyota and K.Kosaka. Tokyo, Japan.

A new oral, non-SU, hypoglycemic agent, A-4166, was found to evoke a more rapid and short-lived insulin release than SU and to decrease the postprandial rise in plasma glucose. In a randomized double-blind four arm comparative clinical trial, the optimal dose and safety of A-4166 were studied in 184 NIDDM subjects, whose glycemic control was not adequately controlled (FPG≥120mg/dl) with diet therapy. They were randomly assigned to receive either 30, 60, 90 or 120mg A-4166. The tablets were administered 5-10min before each meal for 3 months. After treatment, the mean postprandial plasma glucose level was lowered at all time points and the decrements were progressively greater up to 60min (90mg; -57.2±37.7mg/dl at 60min). Fasting plasma glucose level and HbA1c were reduced over the treatment period with the two higher doses (90mg; -15.5±23.0 mg/dl and -0.77±0.95 % at 12 wks). The plasma insulin level was raised to twice the baseline value at 30min, with progressively smaller increments thereafter (90mg; 38.1±24.0 μU/ml at 30min vs baseline; 17.6±10.0 μU/ml). The decrease in plasma glucose response (AUC) and HbA1c and the increase in plasma insulin response were maximal with 90mg A-4166 and over. No accumulation of the drug was found in the blood. No alteration in body weight was observed during the treatment period. 21 possibly drug-related adverse events were observed. They were reversible and not severe, and half of them (5% of the patients studied) were probable hypoglycemic symptoms. In conclusion, these results indicate that administration of 90mg A-4166 before each meal is optimal in treatment of NIDDM.

1486

Effect of an aldose reductase inhibitor on membrane abnormalities of erythrocytes in NIDDM.

MASATOMI TSUJI, MITSURU ADACHI.
1st department of internal medicine
Showa university school of medicine. Tokyo JA.

We examined alteration in erythrocyte membrane fluidity in non-insulin dependent diabetic patients and the effects of aldose reductase inhibitor (ARI) on these changes by means of electron spin resonance(ESR) and spin-label technique.Electoron spin resonance spectra foa a fatty acid spin label-agent(5-nitroxy stearate) in membranes were obtained. The values of hyperfine splitting and order parameters of the spectra were significantly higher in erythrocyte from diabetic patients than non-diabetic controls.(hypersplitting 60.66±2.38 VS 55.21±1.60 $P<0.05$, order parameters 0.778±0.009 VS 0.620±0.01 $P<0.05$)
The effects of aldose reductase inhibitor on the erythrocyte membrane fluidity in non-insulin dependent diabetic patients without nephropathy and anemia were also studied.(aldose reductase inhibitor 150mg/day × 28days) Aldose reductase inhibitor decreased the values of the hyperfine splitting and order parameters of the spectra. (hyperfine splitting pre-treatment 60.66±2.38 → 58.71±1.10, order parameters pre-treatment 0.778±0.009 → 0.743±0.010) These findings indicate that the erythrocyte membrane fluidity might be decreased in diabeic patients and aldose redutase inhibitor might improve thease membrane fluidity.

1487

RHIGF-I REDUCES GROWTH HORMONE SECRETION, LIPID LEVELS & INSULIN REQUIREMENTS IN ADULTS WITH IDDM.

[1]PV Carroll, [1]AM Umpleby, [1]GS Ward, [1]S Imuere, [2]E Alexander, [3]D Dunger, [1]PH Sönksen and [1]DL Russell-Jones. [1]Division of Medicine, St. Thomas' Hospital, London, UK. [2]Cephalon Inc., California, USA. [3]John Radcliffe Hospital, Oxford, UK.

Insulin dependent diabetes mellitus (IDDM) is associated with elevated circulating levels of growth hormone (GH) but reduced insulin-like growth factor-I (IGF-I). The effects of subcutaneous recombinant human IGF-I (rhIGF-I) on glycaemic control, insulin requirement, plasma lipid concentration and GH secretion were studied in 6 adults (35±4, years, mean±SEM) with IDDM. Patients received either placebo or rhIGF-I (50 μg/kg BID) for 19 days in a randomised, double blind, placebo controlled trial. Overnight GH profile, serum free insulin, IGF-I, fructosamine and lipid profile were assessed at regular intervals during rhIGF-I therapy. RhIGF-I therapy increased IGF-I concentration (111.7±14.2 v 257.1±41.2, ng/ml, $p<0.01$, day 1 v day 20). Plasma fructosamine concentration was unchanged (439±32 v 429±35, μmol/l) and insulin requirement decreased by approximately 45% (0.67±0.08v 0.36±0.07, U/kg/day, $p<0.005$) following 19 days of rhIGF-I treatment. After 4 days of rhIGF-I therapy, there was a decrease in free insulin levels (8.38±1.47 v 4.98±0.84, mU/l, $p<0.05$), mean overnight GH concentration (12.6±3.3 v 3.8±2.1, mU/l, $p<0.05$) and total cholesterol and triglycerides (4.68±0.31 v 4.25±0.35, mmol/l, $p<0.05$, 1.27±0.19 v 0.95±0.21, mmol/l, $p<0.001$, respectively). This study demonstrates that subcutaneous administration of rhIGF-I decreases insulin requirements and improves the plasma lipid profile while maintaining glycaemic control in adults with IDDM. GH secretion is also decreased by rhIGF-I therapy. Exogenous rhIGF-I therapy may have a role in the treatment of adults with IDDM particularly in the setting of abnormal lipids and a high insulin requirement.

1488

ERGOSET IMPROVES PLASMA GLUCOSE AND LIPID PROFILE AND BODY COMPOSITION IN WEIGHT MAINTAINED OBESE WOMEN.

A. H. Cincotta, C. Jones, J. Yip, V. Kamath, A. H. Meier, G. Reaven, and I. Chen. South San Francisco, CA.

Bromocriptine, a sympatholytic dopamine D_2 agonist has been shown to reduce obesity and glucose intolerance in animals in part by resetting circadian hypothalamic neural activities known to regulate metabolism. Ergoset, a quick release formulation of bromocriptine, in combination with a moderate hypocaloric diet has been demonstrated to improve glucose tolerance and reduce body weight in obese subjects when compared to individuals treated with diet alone. The present study evaluated the metabolic response of obese patients to Ergoset while they were on a weight maintaining diet. Following a two week run in period, thirteen obese (BMI= 33.2 ± 0.8 kg/m^2), hyperinsulinemic, nondiabetic women were given Ergoset once daily (1.6-4.8 mg) at 0800 for 8 weeks and were instructed to follow a weight maintaining diet throughout the entire study. Prior to the initiation and following termination of treatment, body composition was determined by hydrodensitometry and circulating levels of glucose, insulin, triglyceride and free fatty acid (FFA) were measured hourly over a 24 hour period with standardized meals eaten at breakfast, lunch, and dinner. Ergoset treatment reduced fasting plasma glucose (5.6 ± 0.1 vs 5.0 ± 0.1 mM) fasting triglyceride (2.4 ± 0.5 vs 2.0 ± 0.4 mM) fasting cholesterol (5.2 ± 0.3 vs 4.8 ± 0.2mM) ($P< 0.05$) and cholesterol to HDL cholesterol ratio (5.9 ± 0.6 vs 5.1 ± 0.5) ($P=0.06$). In addition, plasma levels of glucose, triglyceride, and FFA measured hourly over a 24 hour period were reduced on average by approximately 5%, 15%, and 10%, respectively ($P<0.05$). Plasma insulin levels were unaffected by treatment other than an approximate 30% decrease in fasting and post-lunch values which did not quite reach statistical significance. Furthermore, body density (lean to fat mass ratio) increased following treatment (0.981 ±0.002 vs 0.982 ± 0.002 kg/L) ($P<0.05$) associated with a decrease in body fat (43.7 ± 2.2% vs 43.2 ± 1.4%) even though body weight was maintained throughout the study as intended (74.2 ±1.3 vs 73.9 ± 1.3 kg). The results of this short term (8 weeks) study indicate that chronic treatment with Ergoset could have substantial multiple benefits in various clinical conditions of obesity, hyperglycemia, and/or dyslipidemia independent of dietary intervention, which however, may amplify these effects.

1489

THE EFFECTS OF DEXFENFLURAMINE ON CARBOHYDRATE METABOLİSM IN OBESE NIDDM PATIENTS

A.N.Kamel, B.Çetinarslan, A.R.Uysal, N.Başkal, D.Çorapçıoğlu, G.Erdoğan
Ankara Unıversty Medical School, Department of Endocrinology and Metabolism.

To observe the effects of dexfenfluramine, two groups of obese NIDDM cases with poor glycemic regulation under treatment with either diet alone or sulfonylurea along with appropriate diabetic diet were investigated.After an eight week period during which the patients in both groups were observed for the state of glycemic regulation, dexfenfluramine in group 1 (16 patients, 12 females and 4 males; mean age 50,1 ± 7,1 years) and placebo, in group 2 (14 patients; 11 females and 3 males; mean age 48,4 ±8 years) was added to treatment and the patients were followed for 24 weeks and evaluated every six weeks.In group1,as compared with pretreatment values, significantly lower mean values were obtained after treatment with dexfenfluramine for body mass index (BMI) (33.3±4.6 v.s. 30.1±5.0 kg/m^2;$p<0.001$), HbA_{1c} (8.9±1.2 v.s. 6.7±0.5%;$p<0.001$),fasting plasma glucose (FPG) (10.6±2.6 v.s. 7.07±0.8 mmol/L;$p<0.001$) and two hours postprandial plasma glucose (PPG) (12±3.4 v.s. 7.7±1.3 mmol/L;$p<0.001$) levels, serum total cholesterol (TC) (12.9±1.4 v.s. 10.9±1.1 mmol/L;$p<0.001$) and serum triglyceride (TG) (12.1±4.3 v.s. 8.1±1.7 mmol/L;$p<0.001$) levels. In group 2, no significant change was observed, following treatment with placebo, in the mean levels of FPG (9.6±1.1 v.s. 9.3±1.6 mmol/L;$p<0.05$), PPG (10.9±2.5 v.s. 11.2±1.5 mmol/L;$p>0.05$), HbA_{1c} (8.8±1.4 v.s. 8.3±1.5 %;$p>0.05$) and TC (12.5±1 v.s. 12.3±1.1 mmol/L;$p>0.05$), while there were significant decreases in the mean BMI (32.1±2.7 v.s. 30.7±2.6 kg/m^2;$p<0.001$)and serum TG (11.4±5.3 v.s. 10.8±4.6 mmol/L;$p<0.05$) values. No significant changes were found following treatment in the fasting and 2 h. postprandial serum insulin levels which could be measured in 4 patients from group 1 (20.3±12.4 v.s. 18.2±10.4 pmol/L;50.5±23.9 v.s. 46.7±22.4 pmol/Lp>0.05,respectively)and in 6 patients group 2 (16.3±9 v.s. 14.9±7.6 pmol/L;51.4±27.9 v.s. 46.9±27.1 pmol/L,p>0.05,respectively). Although the two groups were similar with respect to the mean BMI, FPG, PPG, HbA1c,TC and TG values before treatment, significant differences came about between groups with respect to the mean FPG, PPG, HbA_{1c} and TC levels ($p<0,01$).Our results suggest that dexfenfluramine can help in glycemic regulation and in the correction of lipid anomalies in NIDDM.

1490

THE EFFICACY OF PIRENZEPINE IN REDUCING POSTPRANDIAL GLUCOSE LEVELS IN PATIENTS WITH NIDDM FOLLOWING TWO WEEKS OF THERAPY

B.G. Issa [a], N. Davies [a], B.M. Lewis [a], K. Hill [b], F. Dunstan [b], J.R. Peters [a] and, M.F. Scanlon [a]. [a]Departments of Endocrinology and Diabetes and [b]Statistics, University Hospital of Wales, Cardiff, Wales, UK.

Acute cholinergic muscarinic blockade with pirenzepine (PIR) induces dose-related reductions in plasma glucose (PG) and insulin after mixed meals in normals and patients with NIDDM. We have investigated further the effects of PIR in NIDDM. 24 patients (12 M, 12 F), on no oral hypoglycaemics for at least 2 weeks, received PIR (50 mg b.d.) or placebo for 2 weeks (randomised, double blind, crossover with 2 week washout period between treatment arms). At the beginning and end of each treatment period, blood was sampled over 12 hours during which the patients received standard breakfast, lunch and dinner. The mean (± SEM) AUC (145 ± 9 vs 155 ± 9), peak (16.5 ± 0.9 vs 17.7 ± 1.0) and nadir (9.1 ± 0.6 vs 9.9 ± 0.7) PG levels (mmol/L) were all significantly less ($p < 0.05$) after PIR for 2 weeks compared with placebo whereas insulin was unchanged.. The drug was well tolerated. In conclusion this low dose of PIR causes a small, but significant and sustained reduction in PG levels in NIDDM, unaccompanied by any rise in insulin levels. On the basis of previously reported acute dose-response studies, higher doses of PIR will probably produce greater lowering of plasma glucose and significant reduction of insulin levels in NIDDM. These studies should now be undertaken.

1491

EFFECT OF VITAMIN E (E) AND PLACEBO (P) SUPPLEMENTATION (SUPPL) ON PLATELET AGGREGABILITY(PA) AND LIPID PEROXIDE (LP) LEVELS IN TYPE-1 DIABETIC PATIENTS (D).

SK Jain, S Krueger, E Brown, R McVie, JJ Jaramillo, M Palmer and T Smith. LSU Medical Center, Shreveport, Louisiana, USA

Hyperaggregability of platelets is a major risk factor in the development of thrombotic disease in diabetic patients. This study examines whether E suppl has any effect on PA and LP levels in D. After written informed consent, D were suppl with DL-α-tocopherol (E) capsule (orally,100 IU/day) or P for 3 months in a double-blind clinical trials. Alternate D were assigned to E or P during regular visits to the clinic. Fasting blood was collected before the start and after the E or P suppl from each D. Plasma E and LP (as MDA, a product of LP) were determined by HPLC; PA by the competitive ELISA immunoassay of the stable thromboxane analogue (TxB_2); and platelet counts by Coulter Counter. After the analyses and code opening data were analyzed using the paired 't' test on 12 D on E and 12 D on P suppl. Level (±SE) after E suppl versus before suppl are as follows: E 29±1.8 vs 17±1.2 nmol/ml, $p<0.001$; LP 0.33±0.03 vs 0.42±0.05 nmol/ml ($p<0.05$);TxB_2 771 vs 1569 pg/ml ($p<0.03$); there was no differences in these parameters after P suppl vs before suppl. There was no effect on platelet counts after P or E-suppl in D. There were no differences in the ages (12.7±1 vs 12±1yrs) or duration of diabetes (5.7±1vs 4.7±0.8 yrs) between P- and E- groups. This study suggests that E suppl significantly lowers cellular oxidative damage and platelet aggregation, and may be beneficial in reducing risk of thrombotic disease in diabetic patients.

1492

EFFECTS OF SEROTONIN RE-UPTAKE INHIBITORS IN NIDDM.

A.Sanz-París, A.Guallar, I.Salazar, L.Calvo and R.Albero
Miguel Servet Hospital, Zaragoza, Spain

Considering the role of serotoninergic systems in the control of food intake of obese patients, we studied the effect of: 30 mg/d of dexflenfluramine (Df), 20 mg/d of fluoxetine (Fx) and 75 mg/d of venlafaxine (Vx) on metabolic control in 3 groups of 10 obese NIDDM for 3 months by the Kruskal-Wallis test. There were side effects that led to the interruption of treatment in the following cases: 1 patient in the Df group (sickness); 2 in the Fx group (anxiety and sleepless) and 8 in the Vx group (vomiting, anxiety, hypertension). Dx significantly reduced ($p<0.05$): body weight (9.6±2 Kg versus 7.2±1 for Fx and 2.2±1 for Vx), plasma triglycerides (62±12 mg/dl versus 11±2 for Fx and 0 for Vx), insulin requirement (10.5±2% versus, 5.1±1% for Fx and 0 for Vx) and C-Peptide plasma levels (1±0.5 ng/ml versus 0.2±0.8 for Fx and 0 for Vx). The reduction in blood pressure was not significant. Plasma levels of 3-OH butirate and aceto-acetate were within normal ranges. The reduction of C-Peptide plasma levels to normal ranges appears after the first month with only 3±1 Kg weight loss. In conclusion, this appears to indicate important differences between different types of serotoninergic drugs in anorexic treatment.

1493

EFFECT OF MEDIUM CHAIN TRIGLYCERIDE AND UNIQUINONE ON METABOLIC PHASE.

Kohzuki, E., Hyogo College of Medicine, Nisinomiya, Japan.

This experiment was performed to examine a metabolic effect of medium chain triglyceride and unique upon diabetes millitus. A test diet, MCT diet which is containing 28.05g of MCT was administered to the subjects after for 12 hours. Blood samples were collected before, 30, 50, 90, and 120 minutes after the diet was administered, and observed blood lenels of sugar, acetone body, NEFA, and total cholesterol. Thus the administration of MCT diet to patient of disbetics seems to aggravate an acidotie tendency uhiquinone was administered to the diabetes patients for checking a ketotic tendency which may be caused by MCT administration. The MCT tolerance test was restrained by the daily administration of 120mg of Co. Q. by the oral route. In the normal cases after administration of MCT diet with Co. Q., changing rates of blood sugar, acetone body, total cholesterol were not increased, but NEFA was increased. In the case of diabetes millitus an increase in changing rate of blood sugar was observed, where as the rates of acetone body and total cholesterol were decreased, but the rate of NEFA was no difference. It can be assumed that therapeutic effect of MCA with Co. Q., administration may be significant for the supply of dietary fat to mild diabetics.

1494

BRADIKININ AS A FACTOR OF THE IMPROVEMENT OF INSULIN RESISTANCE IN NIDDM, HYPERTENSIVE PATIENTS.

T.Demidova, A.Ametov, G.Yarovaya, V.Dotsenko, E.Neshkova, V.Trusov, E.Khatchatrian. Russian Academy for Advanced Medical Studies, Russia, Moscow

In the larger group of NIDDM patients the dominant defect is an impairment of the tissue sensitivity to insulin. The insulin resistance syndrome which includes obesity, NIDDM, hypertension, hyperinsulinemia and dislipidemia is a major and increasing cause of morbidity and mortality. The reasons why all these disorders co-exist so frequently are still the subject of intensive research. We have examined 51 patients with NIDDM and essential hypertension on different hypoglycaemic therapy. All of them were comparable at age, BMI, duration of NIDDM and hypertension, without renal failure. We evaluated parameters of β-cell function and tissue sensitivity by measuring of C-peptide, IRI, glucose levels in serum (fasting, 60, 120 min after carbohydrate nutrition) during standard test with meal stimulation. We also have studied a possible contribution of plasma kallikrein, prekallikrein, ACE activity, proteas inhibitors, elastase-like activity, thromboxan B_4 in connection with improvement of insulin sensitivity by ACE-inhibitor. All these tests were repeated after 3 months treatment by Perindopril 4-8 mg. We determined that all the patients had high levels of basic hyperinsulinaemia, as well as after meal stimulation which were accompanied by high C-peptide and glucose levels, high activity of ACE, high blood pressure, as well as activity of kallikrein-kinin system (KKS) and increased of elastase-like (1,7 times) in plasma. Furthermore, we evaluated the influence of ACE-inhibitor Perindopril on tissue insulin sensitivity using hyperinsulinaemic euglycaemic clamp test in 7 patients which improved markedly after 60 min taking it per os. The activation of KKS certainly means increased concentration of bradikinin in plasma, which destroys quickly if the ACE activity is high. After Perindopril administration ACE activity sharply decreased but activity of KKS preserved at the same level, so as a result bradikinin effect prolonged that was linked with decreasing of blood pressure and concomitant improvement of glucose utilisation can be the consequence of insulin-like action of bradikinin itself both during clamp test and after 3 month treatment. Improvement of insulin sensitivity was proved by marked decreasing of hyperinsulinaemia (IRI, C-peptide, glucose levels) and HbA1c.

1495

THE EFFECT OF DIABETIC COMPLICATIONS AND DRUGS FOR Na-Li COUNTERTRANSPORT ACTIVITY IN RED CELLS.

K. Tsuchida, Z Makita, K. Yanagisawa, T. Itoh*, W. Fujii**, S. Kadota**, T. Koike, Internal Med. II, Hokkaido Univ. School of Med., Tomakomai Med. Lab.* and Tonan Hospital**, Sapporo, Japan

A growing body of evidence suggests that sodium-lithium countertransport (SLC) in red blood cells (RBC), a marker of risk for essential hypertension (HT), can serve as a maker for the risk of renal disease in IDDM. However, the findings of SLC in NIDDM are conflicting. The purpose of this study was to evaluate the relation of SLC activity and diabetic complications (nephropathy, neuropathy, retinopathy, hypertension) in Japanese NIDDM. We also investigated that the effect of insulin, antihypertensive drugs (ACE inhibitor: captopril, lisinopril, Ca antagonist: diltiazem, barnidipine, nicardipine, amrodipine, α β blocker: amosulalol, α_1 blocker: doxazosin) and protein kinase C (PKC) inhibitor (calphostin C) for SLC activity in vitro. The levels of SLC, BP, albminuia, TG, total cholesterol (Tch), LDL, HDL, VLDL in 142 subjects; 24 normal controls (C), 27 non diabetics with HT, 32 diabetic without HT (DM), 59 diabetics with HT (DM-HT) were assessed. SLC values was significantly higher in DM-HT (0.39±0.02 mmol/lRBC/hr) than in the C (0.19±0.002, P<0.0001) or in the DM (0.22 ±0.01, P<0.0001). SLC were related to TG (P<0.005), systolic BP (P<0.0001), and to diastolic BP (P<0.005). No statistical association were seen between the levels of SLC and the levels of Tch, HDL, or VLDL. SLC was statistically higher in NIDDM patients with retinopathy (0.4±0.02) than in those without retinopathy (0.22±0.02, P<0.0001), however, there was no difference in neuropathy. SLC was higher in the NIDDM with microalbuminuria (0.36±0.17) than in those without microalbuminuria (0.29±0.15, P<0.05). In *in vitro* study, only Ca-antagonist, diltiazem and PKC inhibitor, calphostin C significantly lowered SLC activity. These findings suggest that over activity of SLC is associated with a higher blood pressure in NIDDM and SLC may serve as a useful marker for the risk of renal disease and retinopathy in patients with NIDDM. Ca-antagonist diltiszem and PKC inhibitor has an effect to lower SLC activity.

1496

OPEN STUDY OF CILOSTAZOL AMONG NON-INSULIN DEPENDENT DIABETES MELLITUS PATIENTS WITH ARTERIOSCLEROSIS OBLITERANS.

D.C.BLACK,MD AND M.O.SISON, MD, A.D. LITONJUA, MD.
Makati Medical Center, Makati City, Philippines

Cilostazol is a new antiplatelet agent and also acts as a direct arterial vasodilator. The purpose of this study is to determine the clinical effectiveness, safety and usefulness of Cilostazol in NIDDM patients with chronic arterial occlusion.

NIDDM patients diagnosed as having arterioslerosis obliterans with a most frequent manifestation of Intermittent Claudication and doppler Ankle Brachial Index of less than 0.9 were included. Patient were given Cilostazol 100 mg PO BID for 12 weeks, Primary outcome measures included walking performance by getting the Initial Claudication Distance (ICD) and Absolute Claudication Distance (ACD) on standardized treadmill testing. Hematologic exams were done every 2 weeks as well as urinalysis. Repeated measures Analysis of variance ANOVA was used to compare clinical test results over time.

This interim report of 19 patients 12 of which are male and 7 female age ranged from 41 to 69 (mean 59.4 SD 7.4) showed significant improvement in treadmill walking performance (ICD and ACD). Presenting symptoms of pain, numbness and cold sensation were ameliorated.

Cilostazol was considered safe in 18 patients (one patient had elevated liver function test which improved on discontinuation of the medicine) Inspite of the adverse experience Cilostazol was still evaluated as usefull and safe for this kind of disease.

1497

HAEMOSTASIS SYSTEM IN DIABETIC PATIENTS ON BACKGROUND OF TREATMENT WITH TOPINAMBUR

R. A. Kasimalieva. Republic Endocrinology Centre , Almaty, Kazakstan

The opportunities of corrections of infringements in varios links of haemostasis system among IDDM and NIDDM patients , with topinambur , included in conventional treatment complex investigated. The patients took topinamibur 150-200 g as a salad at breakfast and lunch. Duration of diet therapy-21 day. 198 patients who took topinamibur were examined. 79 were IDDM patients, 64 NIDDM patients had obesity, 55 NIDDM patients didn't have it. Analogous groups of 105 patients were control. Adding topinamibur had a clear clinical effect, after the course of diet therapy all paticnts noted improvement : decrease or vanishing of diabetes' symptoms. Fasting plasma glucose decreased from 9,2 mmol/L to 5,6 mmol/L. HbA1c level - from 6,66% to 5,04% . Several IDDM patients had their insulin dose diminished. Lipids level IDDM - from 5,76 to 5,66 g/L, NIDDM - from 5,01 to 4,84 g/L. Cholesterol level IDDM - from 6,47 to 5,51 mmol/L ($p < 0,05$), NIDDM - from 7,2 to 5,5 mmol/L($p < 0,05$). B-lipoproteids level NIDDM - from 43,6 to 27,1 mmol/L ($p < 0,05$), IDDM - from 59,5 to 42, mmol/L($p < 0,05$). Adding topinamibur led to a decrease of the daily insulin dose for 10 of 16 paticats for 4-6 IU. In the control group a decrease of the insulin dose was possible only for 5 patients , 4 patients had it increased. General lipids and cholesterol's level during topinamibur treatment diminished from 5,2 to 5,7 mmol/L and from 5,52 to 5,15 mmol/L. Adding topinamibur to the patients' ration resulted in weakening of initial thrombocytes hypercoagulation and hyperagregation and in fibrinolysis' normalisation. The course of treatment led to an increase in coagulation time. The level of fibrinogen in blood plasma was higher than that in the control group. The treatment resulted in decrease fibrinogen level to a norm. The therapy had a decrease of dissolved fibrin-monomer complexes level as a result. Initially decreased a number of trombocytes increased during the course.Including topinambur in medical complex doesn't just improve the general condition, but also promotes weakening of initial thrombocytes ' hypercoagulation and hyperagregation and fibrinolysis' activation. Received data allow to recommend wide usage of topinamibur during diabetes.

1498

THE EFFECT OF NORMOBARIC HYPOXIA ON OXYGEN-TRANSPORT SYSTEM IN PATIENTS WITH DIABETES MELLITUS.

Sokolov E.I.,Davydov A.L., Starkova N.T.,Koroleva A.V.
Moscow Medical Stomatology Institute. Russia.

The tissue hypoxia and disturbance of oxygen - transport influence on development of complications of diabetes mellitus. The aim of the work was to evaluate the effect of interval hypoxic training (IHT) on oxygen-transport system and index of tissue hypoxia in patients with non-insulin-dependent diabetes mellitus (NIDDM).The examination was carried out before and after the IHT course. The IHT (10-11,5% O_2) was performed for 19-21 days using a hypoxicator. 21 patients 35-55 years old (2-m, 19-f) with mild and moderate NIDDM,with good metabolic control were examined. All patients were treated with oral hypoglucemic agents,dosages remained unchanged during the IHT. The control group consisted of 21 healthy women (35-55 years).
After the IHT course in NIDDM patients increase of hemoglobin Hb (g/l) 120,2±3,42 - 138,0±4,31 ($p<0,05$),reticulocytes 1,2±0,13 - - 13,9±0,33 ($p<0,001$); decrease of anomalous fraction of hemoglobin HbF (%) 2,04±0,08 - 1,11±0,06 ($p<0,001$), HbA_{fc}(%) 8,2±0,94 - 7,6±0,53; decrease of index tissue hypoxia: lactate (mmol/l) 2,5±0,16 - 1,7±0,12 ($p<0,01$), pyruvate (mkmol/l) 75,6±0,64 - 57,1±0,9 ($p<0,001$)were observed. The data as compared to the control group were statistical significant. Therefore the IHT is a non-drug method, which exerts a beneficial effect on oxygen-transport system and tissue hypoxia in NIDDM patients.

1499

TREATMENT OF IDDM WITH IMMUNOMODULIN

S.S. Abubakirova. Republic Endocrinology Centre, Almaty, Kazakstan

Clinical imvestigations of immunomodulin efficiency in the treatment of newly diagnosed IDDM has been carried out. Immunogram, fasting and postprandial glucoses, HbA1c, serum C-peptide concentration were examined immuno-modulin is a preparation which consists of 16 highly purified natural peptides (molecular weight 1-6 kDa), prepared from lambs fetuses' and infants' thymus. 10 patients (aged 29,5±14) took immunomodulin at the dose of 1,0 ml 0,01% sol - 10 injections for a course (first 5 injections - in a day, the rest - twice a week). Clinical criteria corresponded to IDDM. The diabetes duration 1 week - 3 years. The daily dose of insulin 36±5 IU, fasting plasma glucose - 10.7±3.8 mmol/L, 2-h postprandial glycaemia - 11.6±4.5 mmol/L. After the course of treatment with immunomodulin patients with diabetes duration up to 6 months (8 patients) had been noted to have regular hypoglycaemia, a new daily dose of 20±8 IU was enough to compensate diabetes. Insulinotherapy for 2 patients was abolished. The patient with diabetes duration 1,5 yrs (daily dose 38 IU didn't conmensate diabetes, fasting plasma glucose 13,6 mmol/L, 2-h postprandial glycaemia - 21,6 mmol/L noted night hypoglycaemia, accordingly has insulin dose been reduced to 35 IU. The fasting plasma glucose had decreased to 6,1 mmol/L, 2-h postprandial glycaemia up to 6,0 mmol/L. A female patient with diabetes duration of 3 yrs hadn't had her daily insulin dose changed but for the 1st time compensation had been reached (fasting plasma glucose 5,4±1,1 mmol/L, 2-h postprandial glycaemia- 6,4±1,1 mmol/L). The HbAlc had reduced on the average from 6,9±0,41% to 5,8±0,5%. Serum C-peptide concentration had increased from 0,078±0,035 mg/ml to 0,28±0,17 mg/ml; the earlier the treatment had started the higher increase was (patients who started to take immunomodulin straight after manifestation had their Serum C-peptide concentration more than 5 times increased, 2 patients had it returned to normal, a patient with diabetes duration of 3 yrs had it insignificantly decreased). Immunogram indexes had improved. All patients have been examined for more thar 6 months, their condition hadn't changed glycaemic level suits limits of diabetes complication criterias, insulin dose is the same. Thus, accordind preliminary data, the immunomodulin usage for IDDM has positive effect on carbo-hydrate exchange, insulin secretion and immune system.

1500

TREATMENT INEFFECTIVENESS OF RECTAL GLUCAGON DELIVERY IN HYPOGLYCAEMIA.

Parker DR, Bargiota A and Corrall RJM. Department of Medicine, Bristol Royal Infirmary, BS2 8HW, England.

Introduction: Glucagon secretion in response to hypoglycaemia is absent in patients with more than a ten year history of insulin-dependent diabetes mellitus (IDDM). Previously we have shown that witepsol H15 base suppostories containing 100mg indomethacin and 1mg glucagon produce significant plasma glucose increments in fasting healthy volunteers. We assessed the usefulness of rectal glucagon delivery for treating insulin-induced hypoglycaemia in IDDM patients. **Method:** Five male patients with uncomplicated IDDM of at least 10 years' duration (age 21-38 years) were studied supine after an overnight fast on two separate occasions at least 14 days apart. After 45 minutes rest, baseline blood samples were taken for measurement of concentrations of glucose, glucagon and catecholamines Hypoglycaemia was induced by intravenous insulin infusion (2.5 mU/kg/min) which was stopped when plasma glucose concentration reached 2.5 mmol/l As soon as subjects described hypoglycaemic reaction (R), they inserted a suppository containing 100mg indomethacin (placebo) or 100mg indomethacin plus 1mg glucagon (glucagon) into their rectum. Measurements were repeated at intervals for 120 minutes. Local ethics committee approval was granted for this study. **Results:** (Mean[sem] plasma concentration; paired t-test used to compare between-group differences. **p=0.006).

	Glucose nadir (mmol/l)	Peak glucagon (ng/l)	Glucose recovery rate (mmol/l/hr) Over 60 minutes	Over 120 minutes
Placebo	1.8[0.3]	99.2[9.4]	0.63[0.11]	1.47[0.15]
Glucagon	2.1[0.5]	175.8[12.8]**	0.63[0.18]	1.69[0.42]

Summary & Conclusion: Rectal glucagon administration at R induced plasma glucagon concentrations of the order seen following hypoglycaemia in healthy volunteers. However, this had no effect on glucose recovery rates. We conclude that rectal delivery of glucagon is ineffective in treating insulin-induced hypoglycaemia in patients with IDDM

1501

INDUCIBLE INSULIN EXPRESSION IN A HUMAN HEPATOMA CELL LINE

A. M. Simpson*, S. Andrews*, R. Hill#, G. Hannan# and B. E. Tuch¶. University of Technology, Sydney*; Commonwealth Scientific & Industrial Research Organisation#; Prince of Wales Hospital¶; Sydney, Australia

Somatic gene therapy is one strategy being considered to correct patient blood glucose concentrations in Type I diabetes. An earlier study by this group revealed that the stable transfection of insulin cDNA under the control of a constitutive promoter into a liver cell line (HEP G2) resulted in synthesis, storage and acute regulated release of insulin. The aim of the present study was to investigate insulin expression and secretion under the control of inducible promoter systems. A cDNA for human insulin (pC_2) has been inserted into the dexamethasone (dex)-inducible mammalian expression vector pMAM-*neo* (HEP G2-mam cells) and an ecdysone-inducible promoter pSP72-EcRE-insulin (HEP G2-EcR cells). The ecdysone promoter isolated from *Drosphilia melanogaster* has been shown to be inducible in CHO cells by exposure to the ecdysone analogues ponasterone A (pon) and muristerone A (mur). The HEP G2 cells were transfected by electroporation and stable transfectants were selected following exposure to selective antibiotics. In the presence of 1 μM dex (pro)insulin (ins) secretion of HEP G2-mam cells increased from 0.33 ± 0.05 pmoles/ 10^5 cells/ day to 2.1 ± 0.4 (n=6). Increasing concentrations of dex produced no rise in the level of ins secretion. The ins content of HEP G2-mam cells grown in the presence of 1 μM dex (3.2 ± 0.2 pmoles/ 10^5 cells) was significantly ($P < 0.01$, n=5) higher than in its absence (0.8 ± 0.1), indicating that both the transcription and translation of the insulin gene have been stimulated. Gel mobility shift assays indicated that HEP G2-EcR cells were capable of expressing biologically functional ecdysone receptor protein which bound to EcRE DNA in a hormone-dependent manner. HEP G2-EcR cells grown in the presence of 50 μM pon or mur overnight indicated that mRNA transcription was induced by the presence of the hormones, none being detected in unstimulated cells. Our results indicate that the introduction of insulin cDNA under the control of an inducible promoter system results in transcription and translation of the insulin message.

1502

THE EFFICACY OF D-400 IN THE TREATMENT OF NON-INSULIN DEPENDENT DIABETES MELLITUS

V. Balaji, V. Sundaram, A. Moses and V. Seshiah, Apollo Hospitals, Madras, India.

D-400 is an indegenous herbomineral formulation. To evaluate its efficiency in controlling blood sugar in NIDDM, an open clinical trial was conducted. The study group comprised of freshly deducted cases between 30 and 60 years, without any complications (n = 15, 7 males and 8 females) who failed to respond to meal plan and exercise for a period of 3 months. D-400 was given at a dose of 2 tablets three times a day for 6 months. D-400 significantly reduced ($p<0.001$) fasting blood sugar from 186.67 ± 3.6 mg/dl to 109.5 ± 5.4 mg/dl and post prandial blood sugar from 279.13 ± 0.9 mg/dl to 176 ± 9.4 mg/dl. Reduction ($p<0.001$) in Glycated haemoglobin was observed from 9.4 ± 0.22% to 7.0 ± 0.16%. There was an increase in fasting and post prandial plasma insulin levels. Reduction in LDL and Serum Cholesterol ($p<0.001$) level was seen. There was no change in HDL and triglyceride levels. No alteration was seen in Body Mass Index, blood pressure, renal and liver function tests. No adverse effect has been reported. It can be concluded that D-400 is an useful first line drug in treating NIDDM patients who failed to respond to diet and exercise.

DIET AND THE ENDOCRINE PANCREAS

S.A. Wolfe-Coote, J. Louw, and C. Woodroof. Experimental Biology Programme, MRC, Parow, South Africa.

Endocrine cell volumes of pancreases of Vervet monkeys (*Cercopithecus aethiops*), maintained on an atherogenic diet (Group A), were compared with those of monkeys on a stock diet (Group S). Endocrine cell types in pancreas sections were immunolabelled for the four major pancreatic peptides. Using Global Lab image software, the area of immunoreactive cells was traced for each cell type in an average of 300 islets per monkey. It was assumed that the ratio of the area of each endocrine cell type to the total endocrine cell area would be equivalent to the ratio of the volumes and these data were used for statistical analysis. A significant reduction was noted in B cell volume ($p<0.02$) in Group A monkeys (20.65±1.31) compared with Group S (34.72±2.59). A significant increase in A cell volume ($p<0.05$) was found in Group A monkeys (55.72±5.18) compared to Group S (29.52±4.61), interestingly accompanied by a significant decrease in PP cells ($p<0.004$). The concomitant volume increase in A cells with decrease in PP cells supports our hypothesis that A and PP cell volume changes represent differential gene expression of a body of cells that are immunoreactive for both glucagon and PP. The decrease in B and increase in A cell volumes in Group A monkey pancreases reflects a pattern of events that could lead to non-insulin dependent diabetes.

1504

DIABETES NUTRITION AND TARGETS OF DIABETES MANAGEMENT

The Diabetes and Nutrition Study Group of the Spanish Diabetes Association (GSEDNu). Spain

In order to know the nutritional pattern of people with diabetes mellitus in Spain, their adherence to international nutrition recommendations and the relationship with the targets for metabolic control 337 diabetic patients, 144 IDDPts (M/F 70/74) and 193 NIDDPts (M/F, 81/112), satisfactorily completed the 7-day food record diaries from May 1993 to December 1994. The median energy intake of Spanish diabetic subjects was between 2217 and 1453 Kcal/day distributed as follows: CHO between 38-40%; Protein between 19-23%; Fat between 36-41% (SFAs between 11-13%, PUFAs between 4.6-5.8% and MUFAs between 19.7-21.9 %). More than 90 % of diabetic subjects achieved the recommended PUFAs intake but only 45% consumed a proportion of CHO and MUFAs >60%, 20% consumed <10% from SFAs, and 25% consumed <300 mg/day of cholesterol. In spite of it, 69% of patients had a cholesterol level <5.6 mmol, 97% had a HDL-cholesterol level >0.9 mmol, 85% had a triglycerides level <1.7 mmol, while less than 36% of patients had an HbA1c value >8%. In conclusions, despite poor adherence to nutrition recommendations our patients have a near-optimal serum lipid levels and maintain a reasonably good blood glucose control.

1505

DIFFERENCES IN THE DIETS OF TWO POPULATIONS WITH HIGH AND LOW PREVALENCE RATES OF DIABETES MELLITUS IN RURAL INDIA

V.R.R. Kodali, Diabetes Clinic, Mustoor, India

We have reported a high prevalence of diabetes mellitus in rural to rural migrants compared to indigenous populations(9.1% *vs* 2.2%) in South India. However, the causal factors for this are unknown. We, therefore conducted a study to know the differences in the diet and nutritional status in these heterogeneous populations living together in villages in Gangavathi Taluk in Karnataka State. In a house to house survey all the dietary components were measured in weighment and 24 hr recall methods. Heights and weights of one adult from a family were taken. *Results* (M±SE)- Indigenes:n=154, Age=40.2±1.1yrs, high income (>3000Rs/mo)=4% and hard physical activity=27%. Migrants: n=152, Age=40.3±0.9, high income=17% and hard physical activity=1%. Migrants had higher BMI than indigenes:21.2± 0.3 *vs* 18.9±0.2, t=6.3, p<.001). Dietary components calculated per Consumption Unit based on physical activity, age, sex and physiological status (eg., for sedentary adult male C.U=1) in the indigene and the migrant are-Energy:1843±18.1 *vs* 2221.8±18.5 Kcal, p<.001;Carbohydrates:355.6± 3.7 *vs* 381.9±4.5gms, p<.001, Protein: 48.3±0.5 *vs* 54.3±0.6gms, p<.001, Fat:19.1±.2 *vs* 40.4±0.1gms, p<.001 respectively. Migrants consume refined cereals. The indigenes were using unpolished cereals and millets and hence had significantly high fibre in their diets, i.e.,18.2± 0.2 *vs* 4.6±0.1gms, p<.001). Since, multiple logistic regression failed to identify migration as a variable in the causation of diabetes, these differences in the dietary intakes and nutritional status are important and might account for the higher prevalence of diabetes noted in these populations rather than the stress of migration.

1506

The effect of dietary carbohydrates and lipid lowering agent, probucol, on opioid peptide receptors in SHR/N-cp rat - a genetic model of obesity, diabetes and hypertension. S.J. Bhathena, O.E. Michaelis, IV and C.T. Hansen. Agricultural Research Service, Beltsville, Maryland and Nation al Institutes of Health, Bethesda, Maryland, USA.

The obese SHR/N-cp rat, a model of type II diabetes, devrelops severe hyperlipemia. The lean phenotype is hypertensive but is not diabetic and does not develop hyperlipemia. Hyperlipemia in obese rats is worsened by dietary sucrose compared to starch. Opioid peptides acting through their receptors have been shown to regulate carbohydrate and lipid metabolism. Probucol has been shown to lower hyperlipemia. We tested the hypothesis that the hypolipidemic effect of probucol may be via changes in opiate receptors and that different opiate receptors may show differential response to either dietary carbohydrate and/or probucol. Weaning male SHR/N-cp lean and obese rats were fed either 54% starch or sucrose with and without 50 mg/kg/day probucol for 32 weeks. Total and μ, δ and κ receptors were measured from cerebral cortex membranes using specific ligands. Scatchard and competition-inhibition plots were constructed to quantify receptor number and affinity. Dietary carbohydrates showed differential response on opiate receptors in lean and obese rats in that dietary sucrose compared to starch lowered total as well as μ, δ and κ receptors in lean rats. In obese rats, dietary sucrose increased total opiate receptors as measured by etorphine binding and δ receptors but not μ or κ receptors. Probucol showed small but significant increase in total opiate receptoirs as measured by naloxone binding and μ receptors in obese sucrose fed rats but not in starch fed rats. The data show that dietary carbohydrates have differential effect on opiate receptors in different phenotypes and that though opioid peptides are involved in lipid metabolism, the effect of probucol on lipid metabolism is apparently not via changes in opiate tone.

1507

NUTRITIONAL INTAKE AND QUALITY OF LIFE IN THE DÜSSELDORF-PARIS-NAPLES (DPN) INTER-VENTION TRIAL IN NIDDM PATIENTS.

A. Buyken[1], M. Toeller[1], G. Slama[2], G. Riccardi[3], S. Brämswig[1], M.J. Haardt[2], G. Heitkamp[1] and A.A. Rivellese[3]. [1] Diabetes Research Institute, Düsseldorf, Germany [2] Dept. Diabetes, Hotel-Dieu Hospital, Paris, France [3] Institute of Internal Medicine and Metabolic Diseases, Naples, Italy.

97 NIDDM patients (43 males, 54 females; age: 42-69 years; diabetes duration: 1-24 years; 41 from Düsseldorf, 25 from Paris, 31 from Naples), insufficiently controlled (HbA_1>8%) by oral antidiabetic drugs, were included in a six-month educational intervention program, which aimed at modifications towards a healthier lifestyle. The present study evaluated to what extent changes in dietary intake (4-day dietary records) and aspects of quality of life (four validated scales) could be achieved. At the end of the intervention period patients had significantly reduced their energy intake (1772±614 vs 1587±636 kcal; p=0.0001) and their body mass index (29.8±3.5 vs 29.3±3.6 kg/m²; p=0.0001). For patients from Naples and Düsseldorf significant changes were observed in intakes of saturated fat (12.7±4.5 vs 11.3±4.7 % of energy; p=0.0048), cholesterol (318±182 vs 237±135 mg/day; p=0.0001) and fibre density of the diet (13.8±6.1 vs 16.5±7.9 g/1000 kcal; p=0.0001). Pattern of nutrient intakes differed between the three centres, both at baseline and after six months, reflecting local eating habits. After six months patients reported a better management of their diabetes in daily life (25.3±8.3 vs 22.4±8.7, p=0.002) and a more internal control over diabetes-related health outcomes (30.9±8.3 vs 28.7±8.1, p=0.007). Mental and physical well-being improved significantly (10 (6,16) vs 9 (4,14), p=0.03 and 16 (6,25) vs 12 (5,21), p=0.0001, respectively) in patients from Düsseldorf and Naples (no data from Paris). In conclusion, NIDDM patients from Düsseldorf, Paris and Naples, treated with an education programme involving regular attention by a physician, managed to reduce their energy intake and body weight within a period of six months. Overall, modifications of nutritional intake towards a more favourable pattern were achieved. These lifestyle modifications were accompanied by positive effects on the overall well-being

1508

NUTRITIONAL PROFILE OF NIDDM IN URBAN-WESTERN INDIA

H.B. Chandalia, M.T. Nathani, D. Vasani and S. Peswani; Grant Medical College, Bombay, India.

Nutritional profile of 622 NIDDs seen during 1995-96 was studied. 424(68.2%) patients were lacto-vegetarians (LV) and 198(31.8%) were non-vegetarians(NV). Most people in NV group partook of 1 serving of 50-100 gm of lamb meat or fish on alternate days. The average kcal/d and %kcal from carbohydrate, protein and fat intake in the preconsultation period vs prescribed diet were 1391 vs 1458, 65.5 vs 67.8, 14.3 vs 13.9 and 20.2 vs 18.3 respectively. Upward and downward revision of diet by 500 kcal was called for only in 8.2% and 5.5% of patients respectively. The most common diet prescribed was about 1500 kcal/d. The BMI of 5.3,43.8, 34.4,10.1 and 6.4% of LV group and 4.6,42.1,32.1,14.2 and 7.0% of NV group was <19,19.1-25,25.1-30,30.1-35, >35 respectively.

Only 7.5% of patients were controlled on diet alone. The treatment modalities, the metabolic control (total GHb, normal < 8%; mean ± SD, LV:9.9 ± 1.3%, NV:10.1 ± 1.4%; P:NS) achieved and complications like hypertension, angina, myocardial infarction, neuropathy and nephropathy were not significantly different (Chi square test) in the LV and NV groups.

This study brings out the prevalence of undernutrition and obesity in NIDDs. It describes the pre-consultation dietary patterns and the common diets prescribed. It shows that metabolic control and complications are not different in LV and NV group thus requiring equal efforts to improve control and minimise complications in both groups.

1509

W-3 POLYUNSATURATED FATTY ACIDS IN TREATMENT AND PROPHYLAXIS OF DIABETIC ANGIOPATHIES

A.A.Serhiyenko,L.M.Serhiyenko,A.N.Nesterovich,Y.M.Vendzylovich, R.N.Kovalchuk, Y.S.Erin,A.M, Novosad,Y.I.Murin and Z.Y.Kozytsky. Department of Endocrinology, Lviv Medical University,Lviv,Ukraine

Dietary supplementation with fish oil,a source of highly long chain marine polyunsaturated fatty acids has been proposed as an antithrombotic and antiatherosclerotic therapy.High dietary intake of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) is of special interest in the possibility of influencing the metabolism of lipids and synthesis of eicosanoids.The aim of this study was to assess the long term effect of EPA and DHA on the activities of protein-kinase C (PK-C), Na^+,K^+-ATPase, Ca^{2+},Mg^{2+}- ATPase, levels of phospholipids and fatty acids in the membranes of erythrocytes and the levels of the ^{125}I-6-ketoprostaglandin F_{1a} (6-ketoPGF$_{1a}$) and ^{125}I-thromboxane B_2(TXB$_2$) in the blood plasma, activities of hexokinase (HK), pyruvatkinase (PK), lactatedehydrohenase (LDH) glucose-6-phosphatedehydrohenase (G-6-PDH) in the RBC in NIDDM patients. 47 patients (5♂+6♀, ages 25m-48m) were allocated into two treatment groups. The 1st group (n=25) was receiving capsules of fish oil (1,5 g EPA 1,5 g DHA and 0,1% a-tocopherol acetate) and the 2nd group (n=21) was receiving placebo capsules of olive oil. All patients were on the same diet.Dietary adherence (7-day dietary history was good). After 2 months of treatment there was a decrease in TXB$_2$ level (136,5±19,8 pg/ml,p<0,001),activities of HK,LDH,G-6-PDH with simultaneous increases in EPA level, EPA/arachidonic acid (AA) ratio (from 0,4 to 0,7), activities of PK-C (from 13,2±3,41 to 22,49±3,13 pmol ^{32}P/mg protein per 1 min, p<0,001), Na^+,K^+-ATPase (from 0,04±0,002 to 0,07±0,003 mMol Pi/ mg protein per 1 hour,p<0,001), Ca^{2+},Mg^{2+}-ATPase and the concentration of 6-ketoPGF$_{1a}$ in the first group.Increases in the level of EPA and EPA/AA ratio in the membrane lipids and the activities of membrane-bound enzymes of the blood cells lead to an increase in their deformability and a decrease in the ability to aggregate.This effect is conditioned also by increase prostacyclin I_2 production as well as by inhibition of platelet activity Therefore it seems that a 3,5 g fish oil treatment during following 2 months result the tendency of normalising the state of prostacyclin I_2-thromboxane A_2 system,activeness of membrane-bound enzymes in NIDDM patients.In conclusion, EPA and DHA at moderate doses may exert antithrombic effects and may be used for prophylaxis and treatment of diabetic angiopathies.

1510

INSULIN RESISTANCE AND N-3 FATTY ACID (FISH OIL) SUPPLEMENT ATION.

P. Pacy, A.C.J. Robinson, S. Venkatesan, P.Bordin, R.Gray, V.Anyaoku and D Johnston. Unit of Metabolic Medicine, St Mary's Hospital, London, UK.

It has been observed that supplementation with n-3 fatty acids (fish oil) may, by reducing insulin sensitivity, increase blood glucose. Abnormalities of glucose homeostasis might reflect impaired hepatic lipogenesis or increased proteolysis which provide substrate for gluconeogenesis. This study was designed to examine this. We studied serial (0, 2, 4 and 6h) fasting glucose, lipids and insulin and whole body protein (WBP) kinetics, measured by continuous L-(1-^{13}C) leucine infusion, in 10 normolipidaemic non-diabetic males (age 32 ± 6 years; weight 71 ± 10 kg; body mass index 23 ± 2 kg/m^2) given n-3 fatty acid (Maxepa 10g/d) for one month. Numbers are mean ± SD. Statistics by paired t-test. Supplementation reduced fasting glucose (4.9 ± 0.4 versus 4.8 ± 0.3 mmol/l; p< 0.05), insulin (19 ± 20 versus 10 ± 11 pmol/l; p< 0.05) and triglyceride (1.0 ± 0.3 versus 0.8 ± 0.2 mmol/l; p< 0.001) but there was no effect on WBPbreakdown (108 ± 8 versus 108 ± 8 μmol/kg/h), synthesis (90 ± 8 versus 87 ± 9 μmol/kg/h) or balance (-19 ± 6 versus -21 ± 6 μmol/kg/h). Body weight and fat free mass remained unchanged. These findings imply n-3 fatty acids promoted rather than inhibited insulin action on carbohydrate and lipid but appeared not to influence whole body protein metabolism.

1511

DIETARY HABITS OF INDIVIDUALS WITH NIDDM

LG Lambropoulos, TE Coursoumba, M. Mavromati, P. Dogani, E. Panagopoulou,
CL Petrogiannopoulos and I. Poulikakos. Second Medical and Dietetic Depts, Hellenic Red Cross General Hospital, Athens, Greece.

The aim of this study is to describe the dietary habits of individuals with NIDDM who are admitted in our hospital or are followed in the outpatient clinic. This report is a preliminary part of a detailed analysis of eating habits performed by the dietetic dept. Material and Methods: They were 182/389 men and 207/389 women, with mean age 65,4±20 years, BMI 27.59±9 and mean daily caloric intake 1400 kcal. Results: Written dietary instructions had got 199 of them and 63 had attended dietary education. The number of daily meals was six for 28 of the individuals, five for 126, four for 42 and three for 193. Constant meal time had got 203 of our diabetic persons. Forty nine of them used special "diabetic food". Sugar was used by 84 of them and was avoided by the rest 304. Milk and dairy products were used in the skimmed form by 35, in the semiskimmed form by 91 and with total fat by 263 of them. Salad was eaten daily by 315, seldom by 35 and was not eaten at all by 49. Legumes were used daily by 238, seldom by 105 and were not used at all by 46. Sixtythree of our diabetics ate peanuts every day, 196 of them often ate and 130 never ate peanuts. Alcoholic beverages drank 105 persons daily, 77 persons rarely and 207 of them never drank. Finally, 343 of them had had breakfast daily and 46 had not breakfast. Conclusions: The reported numbers are almost similar with those mentioned in other studies elsewhere. Unfortunately, most people with NIDDM do not follow the dietary instructions. Most of them have got incomplete dietary education or lack it completely.

1512

DIETARY HABITS IN NORMALS AND DIABETICS IN THE MEDITERRANEAN BASIN.

The Mediterranean Group for the Study of Diabetes (MGSD) Multinational Nutrition Study

The Mediterranean Diet is considered by many as the Golden Standard of Healthy Nutrition and most of the dietetic recommendations for diabetics are based on it, although its composition is poorly defined, mainly from data gathered several decades ago. The MGSD Nutrition Study Group in order to compare the dietary habits of populations of different ethnic origin (non-diabetics and diabetics) living in the Mediterranean basin organized a multicenter study in 6 Countries of this region. Randomly selected normals and diabetics were studied. The protocol required anthropometric measurements, fasting blood samples and completion of a dietary Questionnaire comprising 74 questions. Serum lipid measurements and the analysis of the dietary questionnaires were done in one Center. The validity of the dietary questionnaire was assessed by comparison to the 3-days diet diary in 119 subjects and found very satisfactory. In total 3680 subjects were studied, i.e 1746 normals, 1934 diabetics. In normals, daily energy intake varied significantly among Centers i.e. Italy-1 1702, Greece 2340, Egypt 2430, Italy-2 2509, Algeria 2668, Bulgaria 2865, Kcal/day, p<.001, or expressed as Kcal/Kg BW, 24, 30, 31, 36, 38 and 38 respectively. The carbohydrate(CHO) contribution to the energy intake was for Bulgaria 43.2%, Algeria 46.9%, Greece 47.5%, Italy-2 50.4%, Italy-1 50.9% and Egypt 58.2%, p<.001, while the Fat contribution was Egypt 26.4%, Italy-1 31.2%, Italy-2 33.0% Algeria 35.1%, Greece 38.8% and Bulgaria 40.3%, p<.001. In all Centers energy intake, Kcal/Kg BW, was significantly lower in diabetics by 7-12 Kcal/Kg BW, p<.001. CHO contribution to total energy was significantly lower in diabetics by 2-7 percent units i.e. 48vs50% the lower in Italy-1 and 41vs48% the higher in Greece. Fat contribution was not different in 3 Centers (Italy-1, Italy-2, and Bulgaria), while it was higher in the others, Algeria 37vs35%, Egypt 29vs26% and Greece 40vs37%, p<.001. **Conclusions: a)** Total energy intake and diet composition in normals differ among Mediterranean countries, making thus the definition of "The Mediterranean Diet " difficult **b)** Diabetics in general, compared to normals, consume less energy and less CHO, while in some regions more fat.

1513

Low Glycemic Index Foods and Management of Diabetes

Leonora N. Panlasigui, Food Science & Nutrition Dept., CHE, Univ. of the Philippines, Diliman, Quezon City, Philippines

The latest local survey indicated a diabetes prevalence rate of 4.8% or roughly a total of 3,130,000 cases. With the crude birth rate of 3%, about 36,000 new cases will be added to existing cases annually. Foods with low glycemic index (GI) have been shown to be beneficial in the management of diabetes. The objective of the study is to determine the glycemic effects of locally available foods using normal and NIDDM subjects. Local food studied include legumes, mixed meals and foods incorporated with rice bran and seaweed extracts which were fed to the subjects after an overnight fast. Blood samples were collected at regular intervals and analyzed for glucose using the oxidase method. Results indicated that these foods have significantly lower ($p<.05$) glycemic responses compared with the control samples. It is concluded that these foods may be beneficial not only in the dietary management of NIDDM but for the general population as well.

1514

EFFECTS OF INHIBITION OF B-OXIDATION ON HEPATIC AND PERIPHERAL INSULIN RESISTANCE IN HIGH-FAT-FED RATS

GJ Cooney, ND Oakes S Camilieri, DJ Chisholm and EW Kraegen
Garvan Institute of Medical Research, Darlinghurst, NSW Australia

To elucidate mechanisms of hepatic and peripheral insulin resistance induced by excess dietary fat we studied conscious, chronically high-fat-fed (HFF) and control rats during euglycemic-hyperinsulinemic clamps. In HFF rats hyperinsulinemia (560pM) significantly suppressed circulating free fatty acids but had no effect on the 3-4 fold higher levels of long chain fatty acyl CoA esters in skeletal muscle. Acute blockade of B-oxidation using etomoxir increased insulin-stimulated glucose uptake in muscle from HFF rats via a selective increase in glycolysis but etomoxir did not reverse the defect in glycogen synthesis or restore the decreased glycogen synthase activity observed in HFF rats (HFF 3.1±0.1 vs CON 3.9±0.1 and HFF 6.6±0.3 vs CON 8.8±0.3nmol/min/mg protein at 0.1mM and 10mMG6P respectively). Etomoxir did not significantly alter the elevated hepatic glucose production (HGP) seen in clamped HFF rats but induced substantial depletion of hepatic glycogen content. This implies that the other source of glucose for HGP (gluconeogenesis) had been reduced by inhibition of hepatic fatty acid oxidation and that factors independent of increased gluconeogenesis are involved in the elevated HGP in HFF rats. This independent mechanism may involve the reduction in hepatic glucokinase (GK) activity seen in HFF rats and the inability of insulin to acutely lower glucose-6-phosphatase (G6Pase) activity in HFF rats during the clamp. Overall a 76% increase in the activity ratio G6Pase/GK (HFF-clamp 3.0±0.5; Con-clamp 1.7±0.2, $p<0.05$) was observed which would favour net hepatic glucose release in HFF rats. In conclusion B-oxidation is responsible for some but not all of the components of insulin resistance induced by chronic high-fat-feeding.

1515

THE EFFICIENCY OF DIET THERAPY BY THE COMBINATION OF VERY LOW CALORIE DIET(VLCD) AND LOW CALORIE DIET(LCD) IN OBESE ADOLESCENTS

Y. Ohki, M. Kishi, H. Orimo, M. Irie, M. Yamamoto. Dept of Pediatrics, Nippon Medical School, Tokyo, Japan

Thirteen adolescents of simple obesity ($\bar{x}$ age 13.4 years, $\bar{x}$ wt 79.6kg) were hospitarized and placed on diet therapy combining VLCD and LCD for 30 days (group A: GA) or 10 days (group B: GB). They took 420 kcal of 'Optifast 70' every day and meals containing carbohydrate, protein and lipid in the ratio of 55: 20: 25(%). Total calorie/day was changed every 6 days in GA and every 2 days in GB which was 1200, 820, 420, 820 and 1200 kcal, succesively.

Following parameters monitored for change on a daily bases showed greater decrease in GB than those in GA: body weight (BW), %IBW; GPT, GOT, γ-GTP; triglycelide, atherogenic index; plasma glucose (PG) score based on the diabetes standard of children by the Japanese Ministry of Health and Welfare, ΣPG during oral glucose tolerance test; systolic and diastolic blood pressure.

Conversely, total cholesterol, ΣIRI, ΣCPR showed greater improvement in GA.

%FAT measured by impedance-fatmeter showed no change in either group during hospitalization, but markedly decreased from 36.0% to 27.3% in pts. whose BW either decreased or remained stable at 6 months after discharge. Two of 6 and all of 7 pts. in GA and in GB, respectively, could be followed up on an outpatient basis after discharge. None of 6 pts. in GA and 3 of 7 in GB desired to undergo the diet therapy with hospitaliztion again.

We conclude that the diet therapy by short-term hospitarization might be better method for children in terms of much improvement of the daily value of each parameter, less stress, higher compliance and acceptability.

1516

The effect of n -3 fatty acids on peripheric nerve in diabetic rats: a morphologic study.

İ.Okar, C.Fıçıcıoğlu , Ü. Zeybek. Marmara University ,Department of Histology and Embryology,University of İstanbul, Cerrahpaşa Medical Faculty, Department of Pediatrics , İstanbul, Turkey.

Forty Wistar Albino rats were included into the study. 20 of them were injected streptozotocin to make them diabetic. 10 of the diabetic rats were in group 1 which were given MaxEPA [Eikosapentonoik acid (EPA) + Dekosaheksanoik acid (DHA)] , 10 mg EPA and 7 mg DHA per day)]. The other 10 diabetic rats were in group 2 which were not on MaxEPA therapy. 20 rats were selected as the control group. 10 of these rats were in the group 3 which were on MaxEPA. The other 10 rats of the control group were not given MaxEPA (group 4). After 4 months , their sciatica nerve examined with electronmicroscopy. The structure of peripheric nerve was normal in the control group (group 3-4). In the group 2 , there was dissociation and fragmentation in myelin level in places , in addition to the normal appearance of myelin sheath . Some findings of leukodistrophic degeneration were also seen. We found diffused degeneration findings in diabetic rats using maxEPA in the group 1 .

In conclusion, the damage seen in the peripheric nerves was more serious in the diabetic rats using n-3 fatty acids than the diabetic rats .

1517

PREVENTION OF DIABETIC ANGIOPATHY BY TREATMENT WITH INSULIN AND DIETARY FIBER

M.Yoshida,J.Sawa,T.Hozumi and K.Doi. Himeji College of Hyogo,Japan.

Aim : We evaluated histological changes in the eye and kidneys in diabetic rats that were given a high concentration of cholesterol (Ch) and treated with insulin (Ins) or Glucomannan (Gm), a soluble dietary fiber. Methods : STZ(50 mg/kg, iv) was administered to SD male rats, and diabetic rats showing an FBS of 150mg or more after 4 weeks were divided into 4 groups. Group I received no treatment. Group II was treated with Ultralente Ins (15 u/kg/day). Group III was given 1.5% Ch food. GroupIVwas given 1.5% Ch and 15% Gm food. Group V consited of normal controls. After 12-week maintenance, blood was collected during fasting. The eye and kidneys were removed, and observed by light and electron microscopy. Results: The blood glucose levels decreased after administration of Ins or Gm. The Ch level increased in Group III (322±106mg/dl), but markedly decreased after Gm administration in Group IV(96±12mg/dl). Histologically, Group III given a high concentration of Ch showed dilatation of retinal blood vessels, atherom of A.chorioidea and A.iridis suggesting diabetic rubeosis and basement membrane thickening of glomeruli. These changes were marked in Group III, but slight in Group IV treated with Gm. Slightly thickening of basement membrane was found in Group I and II. Conclusion : After administration of a high concentration of Ch to diabetic rats , i.e. , in the presence of impairment in both glucose and lipid metabolism , diabetic complications tended to occur easily , and dietary therapy seems to be important.

1518

The effect of the ethanol on the fasted- and prandial glucose level in conscious dogs.

K.Igawa,S.Mashiko,R.Takahashi and F.Sakurai. Kagawa Medical School, Institute for the Metabolism about Diabetes, Sun Labo, Kagawa and Tokyo, Japan

We investigated the effect of the ethanol on the glucose level (GL) before and after the glucose load. Subjects were conscious over-fasted dogs with a gastric tube and the catheter inserted into the femoral artery. After a 15-min. basal period, a 120-min. experimental period followed in which the ethanol(15%,5ml/kg) (E,n=5),the glucose(2.5g/kg) (G n=5) or the mixture of ethanol and glucose(E+G,n=5) was given via the gastric tube at 0 min. In the E,G and E+G group, respectively,the mean ± se of the fasting GL was 81±5 ,84±3,95±6mg/dl and the maximum GL was 85± 4 at 75 min.、209±24 at 60 min. and 308±17mg/dl at 45min.、AUC above the basal level was 7185,12173 and 16421min. · mg/dl. The glucose level of the E+G group increased more acutely and higher significantly than that of the G group between 30 and 75min. after the glucose load. In summary, the ethanol couldn't change the GL alone, but enhanced the increase of the prandial GL by interacting with the glucose.

1519

COMPUTER AIDED INTERACTIVE NUTRITION ASSISTANT - A UNIQUE TOOL FOR IMPROVING DIABETES NUTRITION MANAGEMENT

A. Kapur* and K. Kapur. *Novo Nordisk (India) Pvt Ltd., Bangalore, India.

Nutrition management remains an ineffective tool due to inadequate knowledge, both, amongst patients and health care professionals. Services of nutritionists are not readily available and there is a crying need for a cost effective, comprehensive, customizable and interactive tool for diabetes nutrition management. We have developed a computer based interactive nutrition assistant to meet this need. The program is modular. The first module records anthropometeric and medical data. Using internationally accepted nomograms and based on height, weight, waist, hip, skin fold measurementsas well as age, sex and activity, the program records BMI, WHR, BMR, % Body Fat, Risk indication and energy requirements. The program records diagnosis and associated conditions such as hypertension, cardiac, renal, pregnancy, obesity, malnutrition etc. requiring special nutritional assistance in respect to energy, salt and protein intake as well as, medications including creating a graphic visual representation of the insulin algorithm. The second module records a 24 h dietary recall, using simple pull down screens and lists (can be customized by the user to suit local and regional dietary habits), provides household measures help and necessary prompts for an effective recall. The recall is brokenup into Calories, CHO, Protein, Fat (Sat and Unsat), Na^+ K^+, fibre etc and is also presented as bar diagram plotted against time to allow visual comparison between insulin algorithm and 24 caloric spread. The third module is nutritional advice. Based on calculated energy requirements program suggests energy intake which can be modified to accommodate changes based on clinical needs. Thus a patient with renal failure on protein restriction will get options of protein restricted diets only. Based on current dietary recommendations an exchange based spreadsheet is generated which can be modified to suit individual patient and generate a daily meal plan. The daily plan can be modified by simply replacing one food item with another in the same calorie exchange to provide variety on different days. Additional features include flexibility to customize database, language preference, screen specific help, easy to use screen design and graphics. Also a diet query where nutritive value of a given food item from the data base can be accessed as well as the feature allowing nutritive value of a known recipe to be calculated. We and others who have used the program believe that it will be useful not only in day to day work but also as a research tool.

1520

REGULATION OF FATTY ACID SYNTHASE ACTIVITY : EFFECTS OF DIETARY N3 AND N6 FATTY ACIDS (PUFA) IN INSULIN RESISTANT RATS

S.W. Rizkalla, E. Petit Jean, M. Kabir, S. Berni Canini, J. Luo, A. Chévalier and G Slama, Department of Diabetes, INSERM U 341, Hôtel-Dieu Hospital, Paris, France

To elucidate the mechanisms implicated in decreased plasma triglycerides by dietary n-3 PUFA (fish oil) compared to n-3 PUFA (sunflower), fatty acid synthase (FAS)activity was evaluated in the liver and adipose tissue of insulin resistant rats. Thirty two male Sprague Dawley rats were randomized into 4 groups. Three groups were submitted to a diet containing (w/w) : 57% sucrose and 14% lipids as either Fish Oil (FO), Sunflower Oil (SO) or a mixture of Standard Oils (STO). The control group was fed a diet containing 57% starch and 14% standard oils (C) After 3 week diet , body weight was comparable in the four groups, but adipose tissue weight was decreased in the FO and SO-fed rats (STO=0.9±0.1, SO= 0.7±0.02, FO= 0.6±0.03 g/100g B.W $p<0.01$). The sucrose fed rats showed high glycemia compared to the control group ($P<0.05$) Fish oil corrected the sucrose- induced hyper insulinemia (ANOVA,$p< 0.01$) but had no effect on plasma glucose. Plasma lipids were lower in the FO fed rats than those fed SO or S/STO diet (triglycerols $p<0,0005$, free fatty acids, $p<0.01$). In the liver, FAS activity increased in the STO fed rats as compared to C. Fish oil decreased this activity by 80% and sunflower oil by 33% (C= 0.98±0.13, S/STO= 1.74±0.16, S/FO=0.37±0.06 nmol/min/g of tissue). FAS activity in adipocytes was weaker in STO than in C. This activity increased by FO diet, but unaffected by the SO (C= 0.36±0.06, STO=0.2±0.02, SO=0.12±0.02, FO= 0.43± 0.09, $p<0.05$). In conclusion , 3 weeks of a n-3 PUFA rich diet given to sucrose-fed rats : 1) decreased hyperinsulinemia and hypertriacylglycerolemia, 2) prevented the increase in FAS activity in the liver, and prevented any decrease in this activity in the adipose tissue. N-3 PUFA decreases plasma lipids by an effect on FAS activity, and its effect was superior to that of n-6 PUFA .

1521

METABOLIC CHANGES AFTER INGESTION OF DIFFERENT KINDS OF FAT (PRELIMINARY DATA).

G. Michailidou, A. Antonopoulos, D. Perea, V. Alevizou, P. Karayanakos and N. Katsilambros. 1st Dept of Propaedeutic Medicine, Athens' University School of Medicine, Athens, Greece.

It was investigated if there is any difference in the postprandial metabolic changes observed in diabetic subjects following the ingestion of different kinds of fat. Two test meals were given on separate days to 7 type-2 diabetic patients (diet alone) after a 12-hr fast. The meals contained 100g of white bread with either 42g of butter on day 1 (mainly saturated fat, SAFA) or olive oil (35g, mainly monounsaturated fat, MUFA) on day 2. Plasma glucose, triglycerides, insulin and C-peptide were measured at 30 minute time intervals for a total of 6 hours after meal ingestion. Areas under triglyceride curves were significantly lower after the olive oil-meal (514±110mmol.min) as compared to the butter-meal (617±192, $P<0.05$). There was also a trend for lower glucose values after olive oil intake (3668±978 vs 4165±933 mmol.min). No significant differences were observed in the insulin and C-peptide values. Thus, in type-2 diabetic persons the ingestion of MUFAs is associated with a lower prostprandial triglyceridemia as compared to SAFAs.

1522

METABOLIC EFFECTS OF ALTERATIONS IN MEAL FREQUENCY IN NON-INSULIN-DEPENDENT DIABETES

J.I. Mann, L. Arnold and M. Ball. Department of Human Nutrition, University of Otago, Dunedin, New Zealand

Thirteen free-living men and women with non-insulin-dependent diabetes participated in a randomised crossover study to determine the extent to which meal frequency influences measures of glucose and lipid metabolism. During experimental periods, each of 4 weeks duration, participants consumed their daily food intake as either 3 or 9 meals per day. Nutrient intake was assessed and fasting plasma lipids and lipoproteins, glycated haemoglobin and glucose, insulin and triglyceride responses to a 75 g oral glucose load were measured during the experimental periods. Nutrient intakes and all laboratory measurements were virtually identical on the 3 and 9 meal regimens. Thus the results of this longer term controlled study could not confirm the findings of acute experiments in people with diabetes and comparable 4 week studies in non-diabetic individuals which suggest possible benefits of increased meal frequency. However, as there were no adverse effects of consuming 9 meals each day it would seem appropriate that meal frequency in those with non-insulin-dependent diabetes should be left to personal choice provided energy balance is maintained.

1523

THE EFFECT OF A NOVEL DIETARY FIBRE ON POST-PRANDIAL GLUCOSE AND INSULIN RESPONSES IN HEALTHY INDIVIDUALS

Z.X. Lu, J.G. Muir, T. Mascara and K. O'Dea
Deakin University and Bunge Industrial Cereals, Melbourne, Australia

Although dietary fibre may play an important role in the prevention and management of non-insulin dependent diabetes (NIDDM), high fibre diets are not well accepted. The effect of a novel dietary fibre (NF, patent pending) on post-prandial glucose and insulin responses was therefore examined. NF extracted from cereal grains was incorporated into white bread loaves at 5% and 10% dry weight. NF breads closely resembled white bread in appearance and were highly palatable. Three isocaloric breakfast meals with either white or NF bread were given to ten healthy individuals (4 males, 6 females). Each meal comprised 75g of available carbohydrate (50g starch, 25g sugars), 10g protein and 14g fat. Plasma glucose and insulin levels were monitored for 120 minutes postprandially. Fasting glucose and insulin levels did not differ significantly before each of the three breakfast meals. (Data: mean ± SEM)

Bread type	White	5% NF	10% NF	*p* ANOVA
Peak glucose (mmol/l)	7.22±0.33	6.35±0.42	5.83±0.33*	0.003
Peak insulin (µU/ml) #	54.8±1.2	52.7±1.1	36.8±1.2	0.072
Incremental glucose area	100.0±20.4	76.7±16.5	63.0±14.9*	0.022
Incremental insulin area #	3715±2	2981±2	2253±2*	0.009

geometric mean ± SEM, *$p<0.05$ vs white bread (*t* test with Bonferroni correction)

Consumption of NF reduced peak glucose levels and incremental glucose and insulin areas in a dose-dependent fashion, although only the 10% NF bread produced a statistically significant reduction compared to white bread. There was a trend towards a reduction in peak insulin response following NF consumption. Given the high palatability and acceptability of NF breads, there is potential for incorporation of NF into a wide range of cereal products which could be used to improve metabolic control in people with NIDDM.

1524

EFFECTS OF FRUCTOOLIGOSACCHARIDES ON LIPID AND GLUCOSE METABOLISM IN INSULIN RESISTANT RATS

S. Berni Canini, S.W. Rizkalla, N. Agheli, M. Kabir, M. Guerre-Millo J. Luo, A. Chevalier, F.R.J. Bornet and G. Slama . Department of Diabetes, INSERM U 341 , Hôtel Dieu hospital, INSERM U 465, Paris, France, and Eridania Beghin-Say, Vilvoorde, Belgium. .

Fructooligosaccharides (FOS) is a relatively new bulking and sweetener agent used by food industry. It is a nondigestible fermentable product, having thus some properties of dietary fibers. Therefore, we aimed at studying the effects of FOS on glucose and lipid metabolism in insulin-resistant rats. Twenty four Sprague Dawley rats, 5 weeks old, were randomized into three groups fed either a 57% sucrose rich diet. (S) ,the same sucrose diet supplemented with 10% FOS (S/FOS), or a standard diet (control group :C) : After 3 weeks of such diets there was no difference in body weight between groups. The S fed rats had heavier liver and retroperitoneal adipose tissue and higher plasma triglyceride levels than the control group. **Effects on lipid metabolism:**The addition of FOS for 3 weeks to the S diet resulted in decreased liver weight gain by -11% ($P<0.05$) and retroperitoneal adipose tissue weight gain by -25% (NS). Plasma triglycerides, chylomicrons + VLDL, and IDL concentrations were also lower by 22%, 15%, and 45% respectively, but NS. The addition of FOS lowered plasma free fatty acids by 28% ($P<0.001$) as compared to S fed rats. In the liver the fatty acid synthase (FAS) activity was higher in S fed rats than that of controls. The FOS supplementation prevented this increase. In the adipose tissue, however, this activity was low in the sucrose-fed rats compared to controls and increased after the FOS diet. **Effects on glucose metabolism:** The presence of FOS decreased postprandial plasma glucose (S= 1.41± 0.05, S/FOS= 1.28± 0.05 g/l, $p<0.05$) and fasted plasma insulin (S= 82± 5, S/FOS=47± 5 µU/ml, $p< 0,0005$). Maximal insulin-stimulated glucose transport showed a nonsignificant increase in the adipocytes of S/FOS fed rats. The quantity of both GLUT 4 proteins and their mARN were increased after S/FOS diet in adipocytes but not in the muscle. Plasma acetate was 26% higher in S/FOS than the S fed rats. Propionate and butyrate were not different. **In conclusion:** Three week addition of 10% FOS to insulin resistant rats 1) prevented some lipid disorders observed in the sucrose fed rats and showed a tendency to normalize FAS activity., 2) restored the quantity of GLUT 4 protein and their mARN. The use of FOS may be of interest from a preventive and therapeutic point of view for the pathology related to insulin resistant status and hyperlipoproteinemia.

1525

EFFECT OF A SHORT TIME OF DIET THERAPY ON SERUM LIPID IN NIDDM PATIENTS. Y. Higuchi and K. Noda. Harasanshin Hospital, Japan.

To evaluate effect of diet therapy on serum lipid, we investigated change in TCH, HDL-ch and TG for 2 weeks of educational hospitalization in 91 NIDDM patients. In this period, patients were given diabetic diet (appropriate Calorie, cholesterol < 250 mg/day, P/S > 1.0). Change in these parameters during 2 weeks were evaluated using principal component analysis (PCA), a statistical method that can be used to reveal the general properties of multiple variables. All three parameters were significantly decreased during 2 weeks ($p < 0.001$, decrease rate: TCH 15.9 %, HDL-ch 12.6 %, TG 43.8 %). These decreases were not correlated with improvement in blood glucose control. PCA indicated an index increasing when levels of TCH and TG were high and level of HDL-ch was low. The principal component scores in 75 patients were reduced after 2 weeks of educational hospitalization. In conclusion, Three parameters were significantly decreased with a short time of diet therapy. PCA suggested that the diet therapy led our patients to a preferable pattern of serum lipid.

1526

EFFECTS OF LONG-TERM HIGH VS LOW GLYCAEMIC INDEX STARCHY DIET IN NORMAL AND DIABETIC RATS. M. Kabir, S. W. Rizkalla, J. Luo, G. Slama, Department of diabetes, INSERM U341, Hôtel-Dieu hospital, Paris, FRANCE.
We previously found that short periods (3-5 weeks) of a high vs low glycaemic index starchy diet led to deleterious effects on lipid metabolism. We aimed to study the effects of the same diets after a longer period of time (14 weeks) on glucose and lipid metabolism. Sixteen normal and 16 diabetic (postnatal Streptozotocin-n2) male Sprague Dawley rats were submitted to a diet containing 57% starch as either waxy corn starch in the high glycaemic index diet (HGI) or Mung bean starch in the low glycaemic index diet (LGI). After the 14 week diet, body weight was comparable with no change in either adipose tissue or liver weights in the LGI vs HGI. Variation in the type of starch had no effect on plasma glucose levels in either normal or diabetic rats. The plasma insulin to glucose ratio was also nonsignificantly different.There was no change in plasma triglycerides. Plasma free fatty acids, however, were lower after the LGI diet especially in normal rats (normal rat: 0.22±0.02 vs 0.38±0.05, diabetic rat: 0.31±0.04 vs 0.38±0.06 mmol/L, LGI vs HGI, ANOVA $p<0.01$). Fatty acid synthase activity tended to be decreased after the LGI diet in normal (35±7 vs 54±9 mU/mg protein) but not in diabetic rats. There was no detected modification in the activity of this enzyme in the adipose tissue. At this stage, we can only conclude that a long term low glycaemic index diet led to only slight modifications: in normal rats to decreased plasma free fatty acids that was associated with a trend to decrease fatty acid synthase activity in the liver.

1527

ALCOHOL INTAKE DOES NOT INFLUENCE SHORT TERM METABOLIC CONTROL IN TYPE-I-DIABETIC PATIENTS
C.Maisch, C.Damm, H.Hardin, V.Hofmann, N.Benda* and D.Luft, Department of Internal Medicine IV and *Institute for Medical Biometrics, University of Tübingen, Tübingen, Germany.
Background: Epidemiological evidence suggests that increased alcohol intake may impair metabolic control in diabetic patients due to insulin resistance and increased hypoglycaemia unawareness. We tried to find correlations between measures of metabolic control and alcohol intake. Research design and methods: We investigated 91 randomly selected type-I-diabetic out-patients (mean age 39 ± 10 ys., mean duration of diabetes 19 ± 8 ys., mean HbA1c 7.6 ± 1.1%; x ± SD). Alcohol intake was estimated with an interview, the concentration of carbohydrate deficient transferrin (CDT), mean corpuscular erythrocyte volume (MCV), and the activity of γ-glutamyltransferase (γ-GT) as well. Metabolic control was characterized by self-reported hypoglycaemic episodes in the last 4 weeks before the investigation and the HbA1c concentration. Results: Reported daily alcohol consumption varied from 0 to 187 gr. and correlated with CDT ($r=0.51$, $p<0.0001$) but not with MCV and γ-GT-activity. There were no correlations between alcohol intake (or surrogate variables of alkohol intake) and the number of hypoglycaemic episodes or the HbA1c concentration. Medical history did not give any indication of increased hypoglycaemia unawareness. Conclusion: Even excessive daily alcohol intake does not detoriate short-term metabolic control in otherwise healthy, well educated type-I-diabetic patients treated with an intensified conventional insulin therapy in a diabetes centre.

1528

THE EFFECT OF LOW GLYCAEMIC INDEX DIET ON INSULIN SENSITIVITY IN WOMEN WITH A FAMILY HISTORY OF HEART DISEASE.
G. Frost[a], A. Dornhorst[b], G. Trew[c], R. Margara[c] and A. Leeds[d]. [a]Departments of Nutrition and Dietetics, [b]Metabolic Medicine and [c]Women and Children's Services, Hammersmith Hospitals NHS Trust, London W12 0HS, [d]Department of Nutrition King's College University of London, Campden Hill Road, London W8 7AH
Decreased insulin sensitivity (IS) is a feature of both non insulin dependent diabetes (NIDDM) and coronary heart disease (CHD). Non diabetic children with a NIDDM parent have decreased IS. We investigate whether children with a parent with CHD also have decreased IS, and if so, whether this is influenced by diet. Twenty-two women (12 with a family history of CHD (HHD) and 10 without (NHHD)) were recruited and studied at least two weeks prior to elective tubal-surgery. In-vivo IS was assessed twice using the short insulin tolerance test (SITT) on day 14 and one day prior to surgery. Subjects were then randomised to a high (HGI) or low (LGI) glycaemic index diet after the initial SITT. In-vitro IS was assessed by insulin stimulated glucose uptake in subcutaneous (SC) and omental (OM) fat cells obtained at surgery. The two groups were similar for age, BMI, waist:hip ratio, fasting lipids. Results are expressed as medians comparisons made by Mann-Whitney U Test. A increase in in-vivo IS occurred in 7/11 women on a LGI diet verses 3/11 women on the HGI diet. Comparison of in-vitro glucose uptake in OM and SC adipocytes in the group with, verses those, without a family history of CHD was significantly less following the HGI diet, however with a LGI diet in-vitro IS was similar in both groups. These results demonstrate that women at risk of CHD have decreased IS in both peripheral and visceral adipose tissue, and that this can be favourably modified by a LGI diet.

	NHHD				HHD

GLUCOSE AND INSULIN RESPONSES TO INGESTED CARBOHYDRATE AND FAT COMBINATIONS AS TWO MEALS IN NIDDM PATIENTS

D.Gogas,Ö.Ersöz, N.Ercan and S.Akalın.Marmara University ,Istanbul, Turkey.

Plasma glucose and insulin responses to various nutrient combinations are different between diabetic and normal individuals.In normal subjects, ingestion of butter with potato results in considerably lower blood glucose levels but similar or higher insulin consentrations compared with those observed after patato ingestion alone,while in subjects with NIDDM there is no change in glucose levels despite a greater insulin response.We studied the effects of various patato-butter combinations given as two meals in NIDDM patients. Eight untreated NIDDM patients (6 female ,2 male ,mean age 62.2±10) enrolled in the study.Subjects ingested two meals consisting of potatoes containing 50 gr carbohydrate either alone or with 50gr fat as butter,in four combinations on four different days. Meals were ingested at 8:00 AM and noon.Plasma glucose, glucagon, and C-peptide, serum insulin, triglyceride and NEFA concetrations were determined over an eight hour period. Mean fasting plasma glucose was 7.59±0.02 mmol /l. Peak glucose level was reached at 60 minutes after potato ingestion in the first meal,while patato plus fat ingestion caused a delayed glucose peak level at 120 minute. A potato -fat combination in the first meal caused a delayed glucose peak at 120 minute after the second meal consisting of only potatoes. Plasma glucose area responses were significantly lower after the first meal ccmparing potato-butter with only potato (7.99±0.85 vs 11.68±1.25 mmol.h/l, $p<0.05$). This was not observed after the second meal. Plasma insulin and C-peptide responses were correlated ($r=0.59, p<0.0001$),but not different for the first and second meals. Plasma NEFA levels following the four combinations were not different either. In summary, fat added to carbohydrate causes a delayed plasma glucose peak after both meals and a lower plasma area response only after the first meal in NIDDM patients. As there are no differences between insulin area responses, this effect of added fat may be due to delayed gastric emptying time.

1530

DIABETES AND STARCHES : EVALUATION OF THE USE OF CARBOHYDRATES EXCHANGES AND COMPARISON BETWEEN IDDM, IRDM (INSULINO REQUERANT) AND NIDDM PATIENTS.

BACLET N., ROMAND D., VEXIAU P., GAUTIER JF., CATHELINEAU G. Diabetes Department, Saint-Louis Hospital, 75010 Paris, France.

Dietetic education messages about starches are: to know quantities, to make carbohydrates exchanges, and to eat starches in each meal. Aim of the study: check whether diabetic patients know and use these 3 notions. 163 diabetics (57 IDDM, 42 IRDM 64 NIDDM ,82 BMI <25, 81 BMI ≥ 25 Kg/m^2) answered a questionnaire and served themselves different portions of starches: starches often eaten (Of), starches rarely eaten (Ra), mixed starches (Mi) (ex: pizza). Then they were asked to select an equivalent quantity of bread (Br). Results : 1/ Questionnaire: a) Starches are eaten at each meal in 100%, 95% and 79% of IDDM, IRDM and NIDDM, respectively ($p<0.0003$); b) 61% IDDM, 59% IRDM and 34% NIDDM know the recommended quantities ($P< 0.0047$); c) 61% IDDM, 59% IRDM and 44% NIDDM think they know how to evaluate the quantities (NS); d) 30% IDDM, 21% IRDM and 11% NIDDM weigh starches ($p<0.03$). 2/Behaviour: a) 45% IDDM, 40% IRDM and 37% NIDDM serve theirselves a correct quantity of (Of) (NS); b) 54% IDDM, 62% IRDM and 40% NIDDM make a correct exchange with (Ra) (NS); c) 51% IDDM, 66% IRDM and 39% NIDDM make a correct exchange with (Mi) (NS); d) 44% IDDM, 57% IRDM and 53% NIDDM make a correct exchange with bread (Br) (NS). conclusion: IDDM and IRDM patients eat more starches, evaluate quantities better than NIDDM patients.

1531

THE EFFECTS OF SOME FOOODS ON POSTPRANDIAL BLOOD GLUCOSE AND INSULINE LEVELS

T. GÜRCAN[1], Ü. KORUGAN[2], M. PALA[3], T. YARDIMCI[4] and M. HACIBEKİROĞLU[5] **1** TÜBITAK Marmara Research Centre, Dept. of Food and Refrigeration Technology Gebze-Kocaeli/Turkey, **2** Istanbul Univ. Cerrahpasa Medical Fac. Dept. of Endocrinology, Metabolism and Nutrition Istanbul/Turkey, **3** Yıldız Technical Univ. Dept. of Chemical Engineering Istanbul/Turkey, **4** Marmara Univ. Fac. of Pharmacy, Dept. of Biochemistry Istanbul/Turkey, **5** Istanbul Univ. Cerrahpasa Medical Fac. Fikret Biyal Lab. Istanbul/Turkey

It has been demonstrated that carbohydrate-rich foods result in different plasma glucose responses when eaten alone by normal subjects and patients with non-insulin-dependent diabetes mellitus. This study was designed to determine and compare the glycemic and insulinemic responses of 14 different foods in non-diabetic subjects and to examine the relationship between the indices and food constituents. Fifty-gram carbohydrate portions of the foods or glucose were fed to volunteers after an overnight fast in randomized order. The resultant plasma glucose and insulin responses were determined and compared with glucose load. The calculated glycemic indices were highest for banana (77±3) and potato (79±8) and lowest for white bean (28±4) and pear (29±2). The insulinemic indices ranged from 20±4 for apple to 137±26 for macaroni. Insulinemic index values didn't have the same order with glycemic index values. The main effect on the glycemic index values was obtained by soluble dietary fiber expressed as g/100g dry weight of food which explained about %39 of the variability of glycemic indices ($p<0.05$). A significant negative correlation ($p<0.05$) was obtained between the uronic acid content in soluble dietary fiber and insulinemic index values.

1532

T_3 COMPENSATES FOR CHRONIC INSULIN DEFICIENCY IN LEAN NIDDM UNDER LOW-CALORIE AND HIGH-CARBOHYDRATE

H.KOH, M.TSUSHIMA AND T.MATSUYAMA Division of Atherosclerosis and Metabolism, Department of Interal Medicine, National Cardiovascular Center, Osaka, JAPAN

The aim of this study was to find a role of T_3 for lean NIDDM since T_3 was reported to induce GLUT4. **Methods**:10 lean NIDDM (51yr,BMI:21.8 kg/m^2) were included in a **Diet Crossover Study**: First, they were given control diet(C)(2,012 kcal/d;CHO 299g) for more than 3 days and then C was substituted by low-calorie and low-CHO diet(L-CHO)(1,156 kcal/d: CHO 139g) for 2 wk. L-CHO was subsitituted by low-calorie and high-CHO diet (H-CHO) (1,154 kcal/d: CHO 176g) for 2 wk and H-CHO was subsitituted by 2nd L-CHO for 2 wk. Statistical analysis was performed by ANOVA and Fisher's test. **Results**: **1**) Under C, glucose intolerance, impaired IRI- and impaired T_3-response (ΣdT_3) were found. **2**) Effects of **CROSSOVER** upon 75gOGTT parameters: (1) ΣGlucose (mmol/l) decreased from 134.7±8.7(C) to 95.9±6.3 after L-CHO and it reached the lowest level (83.1±7.3) after H-CHO but it increased to 84.7±7.4 after 2nd L-CHO ($F=10.40, p<0.0001$). (2) ΣIRI(pmol/l) remained unchanged($F=0.99$,NS). (3) ΣdT_3(nmol/l) increased from -0.18±0.16(C) to 0.12±0.21 after L-CHO and it reached the highest level (0.92±0.19) after H-CHO but it decreased to 0.36±0.21 after 2nd L-CHO ($F=5.92$, $p<0.002$). T_3 played a compensatory role for chronic insulin deficiency in lean NIDDM under high-carbohydrate.

1533

PHYSIOLOGICAL AND PSYCHOLOGICAL EFFECTS OF ACUTE CAFFEINE WITHDRAWAL.

Watson J, Lunt M, Murphy J, Jenkins E and Kerr D. Metabolism Unit, Royal Bournemouth Hospital, Bournemouth, UK.

Acute ingestion of caffeine can augment both the perception of and physiological responses to hypoglycaemia in healthy volunteers and patients with IDDM. These effects of caffeine relate to direct actions on blood glucose supply (cerebral blood flow) and glucose utilisation by the brain. The aim of this study was to investigate the effect of acute caffeine withdrawal on aspects of brain and peripheral function. 12 healthy volunteers (9 female, aged 20-50years) who regularly consumed caffeine (145-790mg/day)were studied. On their normal diets, baseline measurements were made of cognitive function (4-choice reaction time), middle cerebral artery velocity (MCAV- an index of cerebral blood flow), blood pressure and heart rate, and mood (UWIST mood adjective checklist). Following this, measurements were repeated 28 and 52 hours after complete caffeine abstention and 2 hours after re-introduction of caffeine (250 mg). Measurements were also made 72 hours after re-commencing their normal caffeine diet. Acute caffeine withdrawal was associated with a rise in MCAV (+7% [3.6-9.6]%, mean [95% CI], $p<0.02$), and a fall in diastolic pressure (-3%[1-6%], $p<0.005$). Heart rate was unchanged. 2 hrs after acute caffeine ingestion, MCAV fell 14 % ([-7to-21%], $p<0.001$) below the level seen during the withdrawal period, associated with a rise in diastolic pressure (+6% [2-11%], $p<0.002$). 72 hours after returning to their normal caffeine intake, MCAV and diastolic pressure were indistinguishable from baseline. Feelings of energy fell markedly during caffeine withdrawal (-7 [4-10], $p<0.005$ vs baseline), without any change in reaction time. Following re-introduction of caffeine, this mood change was reversed (+10[7-13], $p<0.005$) and was associated with positive feelings of hedonism (+6[2-10],$p<0.02$).In conclusion, acute caffeine withdrawal is associated with a rise in brain blood flow, a fall in blood pressure and negative mood changes. On restarting caffeine, the results show that this substance has a stimulant effect on mood but not cognitive performance.

1534

PROTEIN RESTRICTION AND MICROALBUMINURIA IN NIDDM

LTJ Pijls[1], H de Vries[1], AJM Donker[2] and JTM van Eijk[1]. [1]EMGO-Institute, [2]Department of Internal Medicine, Vrije Universiteit Amsterdam

Protein restriction preserves renal function in nondiabetic renal disease and in patients with IDDM; is it feasible and effective in NIDDM? NIDDM patients (n=90) were selected with: a. albuminuria > 6.5 $mg.l^{-1}$ (=detection level) in two 24hr urines or albuminuria (ALB) >20 $mg.24hr^{-1}$ in at least one, but mean ALB $\leq$300$mg.24h^{-1}$, or b. diabetes duration $\geq$5y. Only patients were included with protein intake >0.80 $g.kg^{-1}$ according to urinary urea and without leucocyturia or nitrite-positive urine. All subjects received dietary guidance for 12 months on fat intake, a randomly selected subgroup (E) also on protein restriction. Baseline data for E (32♂, 13♀) and control group (C) (25♂, 20♀), respectively, are (means): age 66 and 64 y, diastolic blood pressure (DBP) 80 and 79 mmHg, systolic (SBP) 140 and 138 mmHg, HbA1c 7.6 and 7.6 %, protein intake 1.16 and 1.11 $g.kg^{-1}$, (medians:) ALB 16.6 and 18.7 $mg.24hr^{-1}$, albumin-creatinine ratio (ACR) 1.39 and 1.46 $mg.mmol^{-1}$, fractional albumin clearance (FAC) 3.0 and 3.9 $.10^{-6}$, and creatinine clearance (mean, while blocking renal-tubular creatinine secretion by cimitedine, CrCl) 80 and 80 ml $min^{-1}.1.73m^{-2}$. The following *changes* in E and C, respectively, were observed (means): protein intake -0.06 and +0.01 $g.kg^{-1}$ ($p<0.10$), DBP -4 and -1 mmHg (NS), SBP -6 and -2 mmHg (NS), CrCl -6 and +2 $ml.min^{-1}.1.73m^{-2}$ ($p<0.10$), body weight -0.7 and +1.0 kg ($p\leq0.005$)and (medians:), ALB -1.84 and +0.18 $mg.24hr^{-1}$ (NS), ACR -0.03 and 0.02 $mg.mmol^{-1}$ (NS), and FAC -0.16 and +0.26 $.10^{-6}$ (NS). When combining both study groups, no significant correlations between individual protein intake and change in albuminuria were found. From the only small contrast so far in our population we conclude that protein restriction is difficult to put into practice, the effect of a more substantial restriction to be assessed by intention-to-treat analysis remaining largely unknown. The dose-response analysis, however, based on non-randomly selected subgroups, does not suggest an effect of protein restriction.

1535

THE SEVERITY OF PARBOILING INFLUENCES THE GLYCAEMIC RESPONSE TO RICE IN NIDDM SUBJECTS.

H.N. Larsen[1,4], S. Parvin[2], S K. Biswas[3], F. Pathan[2], L. Ali[2], I. Tetens[1], S.H. Thilsted[1] and K. Hermansen[4]. [1]Royal Veterinary and Agricultural University, Frederiksberg, Denmark. [2]BIRDEM, Dhaka, Bangladesh [3]Bangladesh Rice Research Institute, Gazipur, Bangladesh [4]Aarhus University Hospital, Aarhus, Denmark.

Rice is the staple food for almost half of the world's population, and approx. 20% of the rice is parboiled. Conflicting results have been found regarding the influence of parboiling on the glycaemic and insulinaemic responses to rice. We hypothesize that the discrepant findings are related to the use of different parboiling methods. *Aims:* to investigate the influence of parboiling and the severity of the parboiling method on the glycaemic and insulinaemic responses to rice in NIDDM patients. *Study design:* twelve Bangladeshi NIDDM patients participated (6M, 6F): age: 52±2 years (mean±SEM); BMI. 23.4±0.9 kg/m^2; HbA_{1c} 7.4±0 3% The subjects ingested 4 test meals: white bread (*a*) and 3 meals of cooked, polished rice of the same variety being non-parboiled (*b*), mildly parboiled by the method traditionally used in Asia (*c*) and pressure parboiled as used in industrialized countries (*d*). All test meals contained 50 g available carbohydrates The rice meals were cooked to the same degree of gelatinization. Plasma glucose and serum insulin concentrations (ELISA method, C.V.:1.7%) were measured fasting and during 180 minutes after ingestion of the meal. Repeated measurements, a multivariate-analysis of variance, followed by paired t-tests were used for statistical analyses. *Results.* All rice samples gave lower glycaemic responses (*b*.417±39; *c*:426±56; *d*:300±29 mmol/L*180 min) compared to white bread (*a*:631±42 mmol/L*180 min; $p<0.001$). Within the rice samples, the pressure parboiled (*d*) gave lower glycaemic response than *b* and *c* ($p<0.03$). The glycaemic indices for *b*,*c* and *d* were 67±6, 69±9 and 49±5, respectively. The insulin responses reflected the observed glycaemic responses. *Conclusions*: in NIDDM the influence of parboiling on the glycaemic and insulinaemic responses to rice depended on the severity of the parboiling method All rice samples studied were low-glycaemic - the pressure parboiled sample being most pronounced - and may be considered useful in a low-glycaemic diet.

1536

DIETARY-HABITS IN DIABETICS WITH CENTRAL DISTRIBUTION OF BODY FAT

M. Pavcic, M. Bohnec and M. Šporar-Tomazin, University Clinical Centre Ljubljana, Ljubljana, Slovenia

Central distribution of body fat characterised by waist-to-hip ratio (WHR) above 0.8 for women and 0.95 for men is linked to a greater risk of NIDDM and complications of diabetes. The aim of this study was to analyse dietary habits of newly diagnosed diabetics, to relate them to WHR, and to determine necessary dietary interventions. On the first visit in the outpatient clinic 55 diabetics (33 m, 22 f) completed the questionnaire about dietary history and food frequency for 38 items, characterising all food and beverage groups. According to WHR the patients were classified into "Normal WHR Group" (NWHR) (16 p, 12 m, 4 f) or "Increased WHR Group" (IWHR) (39 p, 21m, 18 f). The IWHR, though significantly heavier (91.3 ± 17.5 kg vs. 80.6 ± 13.4 respectively), consumed significantly less meals (3.23 ± 0.84 vs. 4.06 ± 0.77 respectively). It was due to skipped breakfast (35.9% patients) and supper (20.5% patients) which resulted in significantly longer time between evening and morning meal (14.34 ± 2.78 vs. 12.59 ± 2.18 hours). Some food frequencies expressed by Food use score (FUS) differed. The IWHR preferred whole to semi-skimmed milk, white to brown and wholemeal bread, hogs grease and butter to oil, butter to margarine, beef to fish. The consumption of other meats, meat products, offal, pasta, rice, legumes, fatty sweets, chocolate, biscuits, fruit and vegetables were similar. In contrast to NWHR which preferred mineral water, IWHR drank more carbonated soft drinks, pulpy juices, (sweetened) tea and compotes. Wrong eating patterns, selection of greasy, hidden sugar rich and dietary fibre depleted food and excessive weight in individuals with increased WHR ratio show that these patients need nutritional intervention, highlighting the most important mistakes in their diets and recommending the way of reducing their weight. For prevention of diabetes associated with central distribution of body fat, National nutritional guidelines and education programmes based on Healthy nutrition recommendations could be useful.

1537

SETTING DIABETES DIETARY STANDARDS -IS IT WORTH THE EFFORT?

E. Jenkins, J. Knott, L. Scott, and D.Kerr. Metabolism Unit, Royal Bournemouth Hospital, Bournemouth, U.K.

Diet is the 'cornerstone' of diabetes management. In 1992 The British Diabetic Association (BDA) set standards for the dietary intake of people with diabetes. The question is, are they achievable and what measurable outcomes can be evaluated against them? In Bournemouth, patients with newly diagnosed NIDDM attend a series of education sessions including staged dietary instuction. Basic advice is given at diagnosis followed by group education and then individual counselling by a specialist diabetes dietitian and diabetes nurse specialist. Patients are managed for the first 3 months according to pre-determind protocols without formal 'medical' input. This study aims to determine whether patients can achieve dietary standards and, if so, do they lead to positive clinical outcomes.

Method: 36 consecutive patients with NIDDM completed 7 day food and drink diaries at diagnosis and after individual counselling. The results of analysis were compared with BDA standards.

Mean % Energy Contribution

	Standard	Before Education	After Education
Fat	30-35	31.7	28.2 ***
Protein	15	18.8	19.5*
Carbohydrate	50-55	44.1	50.6***
Added Sucrose:	<25g	-	12.1g
Salt:	<6g	-	5.9g

[* p<0.05, ** p<0.01, *** p<0.001]

After 3 months, 70% (n=25) of patients remained on diet alone. Of those on diet alone ; HbA1c had dropped from 11.7 to 7.9; -3.7 [-4.9 to -2.6]%, p<0.001 (mean difference [95%CI]) associated with weight loss of -3.4 [-5.2 to -1.7]Kg, p<0.001.

Conclusion: National diabetes dietary standards are achievable and can lead to improved diabetes control without the need for formal medical intervention; They are worthwhile!

1538

SHORT TERM VITAMIN E TREATMENT NORMALIZES LDL OXIDATIVE SUSCEPTIBILITY IN DIABETIC SUBJECTS.

A. Consoli, F. Costantini, E. Vitacolonna, F. Capani, A. Pandolfi, E. Pennese, G. Davi', C. Patrono, A. Mezzetti. Università d'Annunzio, Chieti, ITALY.

Increased LDL oxidability might contribute to accelerated atherosclerosis in diabetes. It has been shown that Vit E supplementation can reduce LDL susceptibility to oxidation in diabetic subjects. It is not known, however, whether Vit. E treatment is able to restore normal LDL oxidability in these subjects. Aim of this study was to observe whether short term Vit E treatment of diabetic subjects could reduce LDL peroxidation state and LDL susceptibility to oxidation to values observed in non diabetic control subjects. To this end we studied 9 non smoker subjects with NIDDM (M/F=4/5, age 56.4±3.1yrs, BMI 28.1±2.3.Kg/m2, duration of diabetes 12±3yrs, FBS 8.4±0.9mmol/L, HbA1C 8.7±0.7%) and 13 non-smoker non diabetic subjects matched for gender, age and BMI. Baseline blood samples were obtained in all subjects for determination of plasma Vit. E concentration and LDL Vit E content (HPLC), LDL susceptibility to oxidation (lag time before propagation of oxidation reaction with Cu++ [LAG]) and native LDL oxidative state (LDL content of Fluorescent Lipoperoxidation Products [FLP]). Diabetic subjects were then given a 600 mg/day Vit. E supplement for 3 weeks and measurements were repeated As compared to controls, at baseline diabetic subjects exhibited shorter LAG (59.5±3.8 vs 76.2±3.2 min, p< .0003) increased FLP (13.9±1.5 vs 7.4±0.6 urf/LDL-C, p< .0001), decreased plasma Vit. E (30.1±1.8 vs 40.9±3.1 µmol/l, p< .006) and no change in LDL Vit E content (4.1±0.4 vs 4.5±0.2 nmol/mg LDL-C). Vit. E supplementation determined an increase in LAG (84.0±6.6 min, p< .0007 vs baseline), a decrease in LDL-FLP, and an increase in plasma Vit E and LDL Vit E content (5.6±0.6 urf/LDL-C, 60.3±5.7 µmol/l and 6.2±0 6 nmol/mg LDL-C, p< .002, p<.0001 and p< .0004 vs basal values respectively) so that no difference between diabetics and controls was observed after Vit. E in any of the parameters evaluated. We conclude that in NIDDM subjects short term Vit. E treatment is able to normalize LDL susceptibility to oxidation and LDL oxidation state.

1539

DIETARY ASSESSMENT OF AN INDUSTRIAL POPULATION SAMPLE IN NORTH INDIA

A Dudha, N Singh, P Shah, M Joshi, SK Puri, and KS Reddy. All India Inst Med Sci, N. Delhi, India.

Background: High prevalence of diabetes and risk factors for coronary heart disease have been reported from an industrial population in North India. Proximate principals of diet are considered as an important modifiable risk factor.

Aim: to assess the consumption of proximate principals of diet in an industrial population, and to determine the proportion of these contributed by the subsidised industrial canteen.

Design: Cross sectional survey of a sample of industrial population (22 Females, 25 Males) for estimation of proximate principals of diet by a detailed 24 hour recall method. Estimates of consumption from the industrial canteen were made by dividing total consumption by number of consumers.

Results: Female (40 ± 4 years) and male (42 ± 5) employees consumed 1879 ± 39 and 2519 ± 72 kcal/day. This included 260 ± 52 and 378 ± 14 g of carbohydrates per day (69% and 72% of total calories); 69 ± 22 and 78 ± 23 g fat (33% and 28% of total calories); and, 53 ± 16 and 75 ± 24 g of protein per day. Employees of the industrial unit consume one major meal (of three) and one minor (of two) per day in the industrial canteen. This contributes 28% and 33% of total daily calories consumption and 12% and 11% of total daily fat consumption.

Conclusions: Coronary heart disease risk factor modification in this industrial population requires dietary intervention strategies targeting both home and (grossly subsidised) industrial canteen consumption patterns. It is proposed to extend this study to a larger sample and subsequently evaluate intervention strategies.

1540

METABOLIC RESPONSE TO MEALS VARYING IN CHO AND STARCH CONTENT IN SUBJECTS WITH NIDDM

M.C. Gannon, F.Q. Nuttall, S.A. Westphal, K.J. Sheridan, S. Fang, and N. Ercan-Fang, VA Medical Center, Minneapolis, MN. USA

A high carbohydrate (CHO)-high starch diet has been recommended for people with diabetes, and the population in general. Therefore, we decided to determine the metabolic response to three identical meals ingested at 0800, 1200, and 1700 hr, with a snack at 2100 hr, in six male subjects with untreated non-insulin-dependent diabetes mellitus (NIDDM). Three diets differing in type and content of CHO were tested. On separate occasions, subjects ingested meals composed of 55% CHO, 15% protein, 30% fat (high CHO-high starch); 40% CHO, 20% protein, 40% fat (usual CHO and starch content, typical American); and 43% CHO, 22% protein, 35% fat (usual CHO, low starch). They were ingested in random order. Total energy was ~ 2100 Kcal/day. Blood was obtained at 15 and 30 minutes after each meal, and hourly thereafter from 0800 on the day of the test until 0800 the following morning for determination of plasma glucose, insulin, C-peptide, glucagon, and triglycerides. The 24 hour integrated values above the initial overnight fasting values were determined. The plasma glucose area response was 31 mM·hr, 23 mM·hr, and 1 mM·hr, respectively for the three diets (high CHO-starch, usual CHO, low starch). The insulin area responses were ~6000 pM·hr, 6660 pM·hr, and 3570 pM·hr, respectively. The C-peptide data confirm the insulin data. The glucagon area responses were 336 ng·hr/l, 1243 ng·hr/l and 1178 ng·hr/l, respectively for the three diets (high CHO-starch, usual CHO, low starch). The triglyceride area responses were 15 mM·hr, 16 mM·hr and 22 mM·hr, respectively. **Conclusion**: A diet in which fruits, non-starch vegetables, and dairy products are emphasized results in a much smaller plasma glucose and insulin rise, but a modestly greater glucagon and triglyceride increase compared to a high CHO, high starch diet. A low-starch, moderate CHO diet could be useful for people with NIDDM.

1541

SOME IMPORTANT REVELATIONS IN A DIET SURVEY OF SOUTH INDIAN IDDM SUBJECTS WITH AND WITHOUT COMPLICATIONS.

Srivatsa A., Chellamariappan M., Vijayakumar G., Buchi Babu Reddy O., Ramesh Chandrasekaran, Mala Chettri, Jayalakshmi R., Ganesan A., Asha Bai P.V., and Krishnaswami C.V., VHS Diabetes Department, Chennai (Madras), India.

Self reported dietary intake was estimated by 24-hours-dietary recall questionnaire, completed by type-I diabetes subjects attending V.H.S. Diabetes Department. 51 Randomly selected patients had received individual diet counselling. They were classified for gender, economic status, physical activity, duration of diabetes and treatment. The macronutrients were assessed based on the National Institute of Nutrition (India), recommendations (Carbohydrate-60 to 70% : Protein - 10 to 12.5%: Fat - 18 to 25% of the total energy). Patients were grouped according to the proportion of energy from macronutrients. 33 (65%) subjects were taking optimal carbohydrate intake (270 gms per day), 24 (47%) were taking higher protein (62 gms per day) and 24 (47%) were taking higher fat (57 gms per day), in their diet. 75% of the subjects derived fat from vegetarian sources. Mean crude fibre intake at 3.5 gms per day was very low. Persons with low income and those with sedantary habits were consuming high carbohydrate. Intake of protein and fat increased with increased income and activity. Contrary to our long held belief, the prevalence of BGDR and ECG changes was found to be higher among people consuming low fat rather than high fat, more in the vegetarian than the non-vegetarian diet. Nephropathy was associated with higher protein intake; lower HbA1C levels were noted with higher carbohydrate in the diet. Preliminary analysis of the reasons for **higher microvascular complications associated with lower fat and vegetarian diet revealed that the type of oil used by these subjects could have a bearing on the vasculopathy.**

1542

ENERGY INTAKE DURING AN ISO-CALORIC LOW PROTEIN DIET IN IDDM PATIENTS WITH DIABETIC NEPHROPATHY (DN).

E. Tauber-Lassen, P. K. Christensen, A. Klausen and H. P. Hansen. Steno Diabetes Center, Copenhagen, Denmark.

The aim of our study was to measure compliance during a 4 weeks period of protein restriction with a recommended iso-caloric diet in IDDM patients with DN. In a 8 weeks prospective, randomized, controlled trial, we compared changes in energy-, carbohydrate-, fat- and alcohol intake during low protein diet (LPD, 0,6 g/kg/24 h) and normal protein diet (NPD, 1,0 g/kg/24 h) in 29 IDDM with DN. At baseline the patients were randomized to either NPD (n=15) or LPD (n=14) for 4 weeks. Between week 4 to 8, all patients received NPD. Energy and protein intake were measured by means of a three-days dietary record; at baseline, after 4 and 8 weeks. Patients randomized to LPD were advised by a dietitian in an isocaloric, low protein diet. All LPD food for lunch and dinner were supplied. At baseline patients in the LPD and the NPD groups were comparable regarding age, energy-, protein-, fat-, carbohydrate- and alcohol intake. Changes in protein (intake), weight, energy- and carbohydrate- (cho) intake from baseline to 4 weeks and from 4 to 8 weeks, were compared between the LPD and the NPD groups (median (range)):

	Baseline to 4 weeks			4 to 8 weeks		
Changes in	LPD	NPD	p	LPD	NPD	p
protein (g/kg/24 h)	- 0,6 (-1,3 to -0,1)	- 0,1 (-0,6 to 0,9)	<0,001	0,4 (-0,1 to 0,9)	-0,1 (-1,0 to 0,4)	<0,001
weight (kg)	-1,5 (-4,4 to 0,8)	-0,6 (-3,8 to 1,8)	<0,05	1,1 (-1,0 to 2,6)	0,3 (-1,3 to 3,2)	NS
energy (MJ)	-0,6 (-3,0 to 2,1)	0,2 (-2,3 to 5,4)	<0,05	0,2 (-7,3 to 3,5)	-0,3 (-3,8 to 1,7)	NS
cho (E%)	12 (-1 to 22)	2 (-5 to 11)	<0,005	-12 (-22 to 5)	-2 (-14 to 11)	<0,005

No changes in HbA_{1c}, fat- or alcohol intake were seen between the two groups. In conclusion LPD was associated with a decrease in energy intake, despite a recommended iso-caloric diet. Increased carbohydrate intake during LPD,did not affect metabolic control.

1543

HIGH PLASMA VALUES OF N6 FATTY ACIDS AND N6/N3 RATIO;A RISK FACTOR FOR NIDDM AND DYSLIPIDEMIAS IN URBAN ASIAN INDIANS.

B. S. Raheja, R. Taskar, M. B. Rao, R. B. Phatak and A. S. Bhoraskar. All India Institute of Diabetes, Mumbai, INDIA.

Increased susceptibility of urban Asian Indians to coronary heart disease is often associated with NIDDM and dyslipidemias such as high plasma triglycerides (TG), low HDL-cholesterol (HDL-c) and elevated total cholesterol (Tc) / HDL-c ratio. High values of plasma n6 fatty acids and n6/ n3 ratio resulting from increased consumption of n6 fat may be a common risk factor for the above metabolic disorders. To test this hypothesis, we measured various n6 and n3 fatty acids in plasma by gas liquid chromatography in 59 unselected diabetic subjects (D) with NIDDM (M=24, F=35) age 51.41 ± 7.9 yr. and compared with 32 controls (C) non diabetic subjects (M=10, F=22) age 50.32 ± 8.34 yr. Plasma lipid values (mg/dl) measured by enzymatic methods showed no difference between the D and C groups in Tc [192.4 (50.28) vs 184.67 (26.51), P:N.S.] but D had higher TG [176.15 (98.48) vs 110.5 (31.31), P < 0.0004], Tc/HDL-c [4.43 (1.29) vs 3.52 (0.78), P < 0.001] and lower HDL-c [44.89 (10.92) vs 53.95 (9.72), P < 0.0002]. D also had higher values (mg/dl) than C of linoleic acid [97.91 (45.33) vs 75.5 (28.89), P < 0.02],arachidonic acid [24.73 (13.48) vs 17.21 (4.22), P < 0.002], total n6 [122.66 (52.73) vs 92.71 (29.04), P < 0.004] and n6/n3 ratio [100.38 (45.96) vs 78.38 (45.75), P < 0.03] but lower values of alpha linolenic acid [0.54 (0.37) vs 0.78 (0.49), P < 0.01]. Regular intake of fish oil by > 50% of D was reflected in improved values in D of eicosapentaenoic acid [0.43 (0.17) vs 0.34 (0.25), P : NS], docosahexaenoic acid [0.35 (0.21) vs 0.35 (0.25), P : NS] and total n3 fatty acid [1.31 (0.5) vs 1.46 (0.65), P : NS]. Results suggest adverse impact of high plasma n6 fatty acids and markedly elevated n6/n3 ratio may not be corrected by fish oil supplements alone and imply that increased consumption of n6 fat may be a common risk factor for above disorders in Asian Indians.

EATING ATTITUDES IN PATIENTS WITH NIDDM.

E. Mannucci, G. Bardini, V. Ricca, Tesi F. and C.M. Rotella. *Section of Metabolic Diseases, Division of Endocrinology, University of Florence, Italy.*

The present study is aimed at the identification of clinical and psychopathological features related to eating attitudes and behavior in NIDDM. A consecutive series of 450 patients (223 F, 227 M) with NIDDM aged 30-70 years (m±sd 58.4±8.7), with a duration of NIDDM of 10.0±8.2 yrs, a Body Mass Index (BMI) of 27.8±4.6 kg/m^2, and a HbA_1c of 7.4±1.7%, was studied; 84 were treated with diet only, 237 with oral hypoglycemic agents, 76 with insulin, and 53 with combinations of insulin and oral hypoglycemic agents. A structured psychiatric interview (SCID) was performed, using DSM-IV criteria for the diagnosis of eating disorders. Eating attitudes were further examined with the BITE questionnaire. Anxiety (STAI), depression (Ham-D), and diabetes-related quality of life were also applied. 26 of the patients (20 F, 9.0%; 6 M, 2.6%) were found to be affected by Binge Eating Disorder, and 55 (40 F, 17.9%; 15 M, 6.6%) showed subclinical alterations of eating behavior. BITE scores were found to correlate significantly with BMI (r=0.29, p<0.01), HbA_1c (r=0.27, p<0.01), DQOL scores (r=0.40, p<0.01), STAI-1 (state anxiety) scores (r=0.33, p<0.01), STAI-2 (trait anxiety) scores (r=0.32, p<0.01), and Ham-D scores (r=0.38, p<0.01), but not with age and duration of diabetes. These results were confirmed at multivariate analysis. No significant difference was observed between the different groups of treatment. In conclusion, disturbances of eating behavior are common among NIDDM females, and interfere significantly with metabolic control and quality of life. For this reason, eating attitudes should always be evaluated, at least in overweight NIDDM patients. Eating disorders in NIDDM are associated with high levels of anxiety and depression.

Endothelial Function in Vitro and in Vivo

1545

MONITORING OF THROMBOMODULIN LEVEL AND RENAL FUNCTION IN DIABETIC PATIENTS DURING AFTER ANTIPLATELETS ADMINISTRATION

T. Yonemoto, A. Shouzu, H. Shimizu, Y. Miyake, T. Hayakawa, S. Tabata, M. Nishikawa, and M. Inada. Kansai Medical University, Osaka, Japan

In order to evaluate the effect of antiplatelets (AP), we examined the correlation between serum thrombomodulin (TM) levels and renal function in diabetic patients during one year administration of AP. TM levels were determined in 34 patients. They were divided into group A who received AP (n=14) and group B who did not received AP (n=20). 14 patients in group A were further divided into group A-I who received veraprost (n=8), and group A-II who received cilostazol (n=6). There was a significant increase of the TM levels in group B after the follow-up (4.0±2.1FU/ml) compared with those before the follow-up (3.7±1.8) (P<0.01) without affecting renal functions. A significant decrease was noted in group A from the pre-treatment (5.9 ±2.4) to one month (5.4±2.2) and three months (5.0±2.1) after the AP administration. Though there was a slight decrease of TM levels (5.6 ±2.5) in group A, serum creatinine (Cr) values increased from the pre-treatment (142±62) to the post-treatment (186±177 μ mol/L). We noted a significant positive correlation (r=0.75, p<0.01) between the TM levels and Cr values before the AP administration. TM levels in the group A-I (6.9±2.7) and group A-II (4.6±1.0) decreased to (6.7±2.7) and (4.1±1.3), after AP administration respectively, although the Cr values showed a slight increase in group A-I. These results suggest that AP administration is beneficial for inhibiting the progression of vascular endothelial cell injuries in DM when they do not show the worsening of renal dysfunction.

1546

MATERNAL DIABETES TOGETHER WITH A HIGH SATURATED FAT DIET AFFECTS VASCULAR FUNCTION OF MOTHER AND OFFSPRING

E. Koukkou[a], L. Poston[b], C. Lowy[a].
Department of Endocrinology and Diabetes[a] and Department of Obstetrics and Gynaecology, Fetal Health Research Lab[b], St Thomas' Hospital, UMDS, London, UK.

Maternal nutrition and diabetes may affect cardiovascular development in the offspring. Vascular function was determined in maternal and offspring arteries from STZ diabetic rats fed a breeding or a high saturated fat diet (30% w/w, 10 days before mating to 16 days post partum). Maternal (day 16 post partum) mesenteric arteries and offspring (15 days) femoral arteries were mounted on a small vessel myograph.

Maximum constrictor responses to noradrenaline were increased in maternal and offspring arteries from high fat fed diabetic rats (DF) (mothers: 147±40 % of K-induced contraction, n=4 v diabetics on breeding diet (DC) 102±3%, n=9, p<0.05; offspring: 122 ±14% v 76 ±6%, p<0.01) Neither diabetes alone nor the high fat diet alone was associated with a constrictor defect. Similarly, endothelium-dependent relaxation to acetylcholine was impaired in the DF animals (mothers: 70±7% reduction of NA-induced constriction v DC 94±2%, p<0.001; offspring: 41 ±10% v 83 ±4%, p<0.001). Endothelium dependent relaxation was also impaired in the offspring of non-diabetic mothers fed a high fat diet.

We conclude that a high saturated fat diet in the presence of diabetes has a deleterious effect on vascular function in mother and offspring.

1547

The Relationship between Serum sVCAM-1 and Plasma von Willebrand Factor (vWF) or Thrombomodulin (TM) in Diabetics

MIYAKO YOSHIZAWA, YUKIHIRO NAGAI, AZUSA HISADA, HARUHISA YAMASHITA, MASAYOSHI OHTA, KEN-ICHI KOBAYASHI. 1st Dept of Internal Medicine, School of medicine, Kanazawa univ, KANAZAWA, JAPAN.

We have previously demonstrated that circulating soluble vascular cell adhesion molecule-1 (sVCAM-1) levels are increased in diabetics compared with healthy volunteers (in 3rd IDF-WPRC, Hong Kong). However, the mechanisms of increased serum sVCAM-1 levels in diabetics are unknown. There are several possible mechanisms, including endothlial activation or dysfunction. To investigate whether elevated serum sVCAM-1 levels in diabetics may simply reflect endothlial dysfunction, we evaluated the relationship serum sVCAM-1 levels and the markers of endothelial damage (vWF and TM).Fourteen diabetic patients without hypertension, hyperlipidemia, and any diabetic vascular complications were selected, and serum sVCAM-1 levels were measured by sVCAM-1 ELISA Kit (R&D Systems,Ltd). Although serum sVCAM-1 levels (mean± SE) were elevated in diabetics compared to healthy volunteers (1085.7± 74.9 vs 632.1 ± 118.6 ng/ml, p < 0.01), plasma levels of both vWF and TM in diabetics were within normal limits (vWF;70-140%,TM; 1.3-2.1FU/ml). Serum sVCAM-1 levels neither correlated to plasma vWF nor TM levels (sVCAM-1 vs vWF : r=0.24, p=0.41 ; sVCAM-1 vs TM : r=0.31, p=0.28). These results suggests elevated circulating sVCAM-1 may not simply be derived from endothelial damage.

1548

Effects of Shear Stress on Glucose Transport in Vascular Endothelial Cells

T. ARISAKA, M. KAWASUMI, S. SHIMADA, T. TOHJIMA, T. ONUMA, Y. YOSHIDA and R. KAWAMORI. Dept.of Medicine, Juntendo University, Tokyo, Japan

(Purpose) Hemodynamic shear stress plays an important role in atherogenesis. It was postulated that vascular endothelium sheared in vitro closely mimic those in vivo. Hyperglycemia has been implicated in the pathogenesis of vascular complications in diabetes. In this study, the effect of shear stress on glucose transport was examined in cultured endothelial cell (EC). **(Flow experiments)** Porcine ECs were seeded on a polyester sheet and cultured until cells reached confluence. Flow experiments were performed by the methods of Levesque et al. A confluent monolayer of EC on the polyester sheet was placed in a parallel plate flow chamber and subjected to steady shear stress of 30 dyn/cm^2 for 24 h. Control cells were grown on polyester sheets in the same experimental medium (DMEM+10%FCS+5.5mM glucose)and maintained in the incubator. **(2DG uptake)** Immediately after exposure to shear stress, the cells on polyester sheets were placed in plastic dishes. For the uptake studies, the cells were rinsed 5 times with PBS and incubated for 5 min with 10 ml of PBS containing 5-10 μCi[^{3}H] 2DG. Cell-associated radioactivity was measured after extensive washes and solubilization of cells. **(Results)** A comparison of transport activity in the two types of endothelial cells at 5.5mM glucose concentration showed that the transport rate in sheared cell was about 1.5 fold higher than that of control cell. (cont. us sheared:19.50±1.20 us 29.78±4.51 dpm/μg protein , P<0.05)**(Conclusion)**It was postulated that shear stress increased glucose transport in cultured EC.

1549

PLASMA vWF LEVELS CORRELATE WITH SOLUBLE INTERLEUKIN-2 RECEPTOR (sIL-2R) LEVELS IN TYPE 2 DIABETICS WITH RETINOPATHY.

Ü. Karayalçın, A. Timurağaoğlu, M. K. Balcı, İ. Karadoğan, H. Altunbaş and L. Ündar. Medical School of Akdeniz University, Antalya, TURKEY.

The endothelial injury and/or dysfunction in diabetes may be associated with activation of monocyte-macrophage system and T lymphocytes. Plasma sIL-2R level reflects mononuclear cell activation. The aim of this study was to investigate the possible relationship between sIL-2R and vWF levels, since the latter has been reported to reflect endothelial injury/dysfunction in diabetic patients with microvascular complications. Twenty-four type 2 diabetic patients [14 females and 10 males, median age 56 years (range 29-68), median duration of diabetes 5 years (range 0-18)] were included. Nine patients had background retinopathy (R+), while 15 had no retinopathy (R-). Eighteen healthy subjects [7 females and 11 males, median age 43 (range 27-64)] were also included for comparison. Plasma levels of sIL-2R and vWF were measured by EIA. Both median sIL-2R [57 pM (12-101) vs 42 pM (0-109)] and median vWF levels [118% (96-149) vs 107%(62-140)] were comparable in R+ and R- groups. R+ patients had higher vWF levels than healthy controls [104% (59-140)] (p=0.027). No significant differences were found in sIL-2R levels of patients and controls [62 pM (11-168)]. vWF levels correlated positively with sIL-2R levels only in the R+ group (r= 0.8, p=0.008). These findings suggest that mononuclear cells might be involved in the pathogenesis of microvascular injury in diabetic retinopathy. Further studies are needed to clarify the reason why sIL-2R levels do not show any significant difference in our R+ and R- diabetic patients.

1550

THE EFFECT OF IMPAIRED GLUCOSE TOLERANCE AND NIDDM ON THE FOREARM MICROCIRCULATION

A.E. Caballero, S. Arora, R. Saouaf, G.L. King, F.W. LoGerfo, E.S. Horton and A. Veves. Harvard Medical School, Boston, USA.

The natural history of the endothelial dysfunction in diabetes is not known. We have examined the effect of impaired glucose tolerance (IGT) and recently diagnosed NIDDM on the microcirculation. We studied three groups matched for age and sex: 14 healthy controls (C) (3 males, mean age 45 years), 13 subjects with IGT (4 M, age 48) and 11 recently diagnosed NIDDM patients (DM) (7 M, age 53, mean DM duration 2.3 years). Significant differences existed in the body mass index [DM 32.4 ± 4.8 (mean ± sd), IGT 36. 9 ± 7.9, C 26.4 ± 4.6, p < 0.001], the fasting plasma glucose levels [DM 174 ± 69 mg/dl, IGT 108 ± 10, C 96 ± 7, p<0.001, ANOVA test], the HbA1c levels [DM 8.2 ± 2.0%, IGT 5.6 ± 0.4, C 5.7 ± 0.4, p<0.001], and the fasting insulin levels [DM 15.8 ± 9. 3μU/ml, IGT 21.0 ± 12.5, C 5.4 ± 1.4,p <0.01]. All subjects had total cholesterol <300 mg/dl, triglycerides< 300 mg/dl, were non-smokers and normotensive or mildly hypertensive (HTN) without anti-HTN medications. Microalbuminuria and retinopathy were present in 3 (27%) DM subjects, and neuropathy in none. We employed single point laser Doppler and laser Doppler imaging scanner to measure vasodilatation at the forearm in response to heating to 44 °C, and to iontophoresis of 1% acetylcholine (endothelium-dependent) and 1% sodium nitroprusside (endothelium-independent). The response to heat was reduced in the DM (825 ± 390, % of increase over the baseline) compared to IGT (1368 ± 671), and C (1561 ±, 695), (p <0.05). Using the laser scanner, the response to acetylcholine, which stimulates the production of Nitric Oxide (NO), was different among the three groups [DM (64 ± 33 % of increase over the baseline), IGT (98 ± 54), C (118 ± 57), p <0.05]. The response to sodium nitroprusside (a NO donor) showed a similar trend [DM (64 ± 29), IGT (80 ± 34), C (96 ± 41)], but failed to reach statistical significance (p = 0.09). The above data indicate that endothelial dysfunction is present in early stages of NIDDM and may even precede its development during the IGT phase.

1551

Modulation by High Glucose of Thrombin Stimulated Protein Kinase C in Cultured Human Endothelial Cells

G. Reining, S. Baumgartner-Parzer and W. Waldhäusl
Department of Internal Medicine III, Division of Endocrinology and Metabolism, University of Vienna, Vienna, Austria

Hyperglycemia is a major factor in the development of cardiovascular complications in diabetic patients and has been reported to activate Protein Kinase C in cells derived from vascular tissue. This study was consequently designed to evaluate the effect of long term incubation (16±1 days) in 30mM vs 5mM glucose on ligand induced activation of PKC in paired cultures of individual isolates of human umbilical vein endothelial cells (HUVECs). Cells from these isolates were stimulated with increasing concentrations of thrombin for 30 seconds and analyzed by immunoblotting for PKC-isoforms α, β_{II}, and ε. An increase in intensity of the isoform specific band in the membrane fraction was assumed to reflect PKC activation. Thereby, longterm incubation with 30mM vs 5mM glucose caused no change of total and membrane bound PKCα, PKCε, or $PKC\beta_{II}$. Interestingly, $PKC\beta_{II}$, was only found in the membrane fraction, even in resting cells. Stimulation by thrombin (0.01, 0.1, 1, 10 and 100nM) of confluent cultures displayed a concentration dependent rise in membrane bound PKCα and ε. In that context thrombin induced activation of PKCα remained unaffected by high ambient glucose, while translocation of PKCε in cells grown in 30mM glucose was reduced at high thrombin concentrations (AUC: 90.4±7% of control cells; p < 0.008; n=6) versus control cultures kept in 5mM glucose. Cells cultured in 30mM mannitol did not show reduced translocation of PKCε. These data suggest modulation by 30mM glucose of ligand induced PKC activation in an isoform specific manner, whereas basal expression of PKC isoforms remained unaffected suggesting interference by hyperglycemia with dynamic endothelial function.

1552

EFFECT OF C-PEPTIDE ON FOREARM BLOOD FLOW IN IDDM PATIENTS SEEM NOT TO BE ENDOTHELIUM - MEDIATED

B-L. Johansson, M. Eriksson, E.Fernqvist-Forbes and J.Wahren. Dept of Clinical Physiology, Karolinska Hospital, Stockholm, Sweden.

Recent studies suggest that C-peptide increases blood flow in both exercising and resting forearm skeletal muscle in patients with IDDM. To find out whether this effect is dependent on endothelial function non-invasive measurements of endothelium-mediated arterial response were undertaken using a high-resolution ultrasound doppler technique. Ten IDDM patients, age 30±2 yrs with a diabetes duration of 17±2 yrs, were studied twice within one week. They were treated with insulin s.c. four times per day. Their mean insulin dosage and HbA1c were 0.70±0.05 U/kg/24 hrs and 7.6±0.3%, respectively, prior to the study. No clinical sign of neuropathy, nephropathy and retinopathy were found. They recived i.v. insulin the night before and during the study so regulated that euglycemia (5-6mmol/l) was achieved. Blood flow and the diameter of the brachial artery were measured in basal state, one min after reactive hyperemia (4 min distal arterial occlusion) and 10 min later. Subsequently, C-peptide (6 pmol/kg/min) or saline was given i.v. in a randomized double blind order. Repeated measurements were performed during 60 min of infusion as well as after administration of sublingual glyceryl trinitrate. Close to the blood flow measurements both before and during the infusion period left ventricular function was measured by echocardiography. All patients showed a blunted brachial arterial dilatation (2.0±0.5%) after reactive hyperemia in comparison to healthy controls (9.3±0.3%), indicating a disturbed endothelial function. C-peptide infusion compared to saline resulted in increasead basal blood flow (+36±8%,p<0.001) and augmented left ventricular ejection fraction (+5±2%, p<0.05) and a tendency to increased dilatation (+3±1%,ns) of the brachial-artery. However, the vascular response to reactive hyperemia (endothelium-mediated) and glyceryl trinitrate did not differ between the periods. It is concluded that C-peptide at physiological levels (1.5 nmol/l) increases resting forearm blood flow in IDDM patients, but the effect is probably not endothelium-mediated.

1553

GLYCATION OF LOW DENSITY LIPOPROTEINS DISTURBS THE PRODUCTION OF FIBRINOLYTIC REGULATORS IN VASCULAR ENDOTHELIAL CELLS

J.Y. Zhang, A. Angel and G.X. Shen. University of Manitoba, Winnipeg, Canada

Attenuated fibrinolytic activity and increased incidence of intravascular thrombosis are found in diabetic patients. The present study investigated the effect of glycated low density lipoproteins (LDL) on the production of plasminogen activator inhibitor-1 (PAI-1) and tissue plasminogen activator (tPA) in human umbilical vein endothelial cells (HUVEC). Native LDL moderately increased the production of PAI-1 and reduced the generation of tPA in HUVEC. Glycation further increased the production of PAI-1 induced by LDL at both mRNA and protein levels. The synthesis and secretion of tPA from the cells treated with glycated LDL were significantly lower than that from native LDL-treated cultures. The production of PAI-1 and tPA was not affected by glycated albumin modified at the equivalent condition. Aminoguanidine, an inhibitor of the formation of advanced glycation end products (AGEs), effectively inhibited the glycation of LDL. Aminoguanidine treatments of LDL during the glycation inhibited glycated LDL-induced overproduction of PAI-1 and the reduction in tPA synthesis in HUVEC. The results indicate that glycation enhances LDL-induced imbalance of the production of PAI-1 and tPA in HUVEC. AGEs may be involved in the disturbed production of fibrinolytic regulators in vascular endothelial cells induced by glycated LDL, that may contribute to the reduction of fibrinolytic activity and the increase in thrombotic vascular complications in diabetic patients (supported by grant provided by Canadian Diabetes Association in memory of the late Archibald Mitchell).

1554

ARTERIAL NOREPINEPHRINE IS DECREASED IN NON-COMPLICATED IDDM

G.Vervoort, J.Wetzels, J.Lutterman, J.Lenders and P.Smits. University Hospital St. Radboud, Nijmegen, The Netherlands.

Microangiopathy in IDDM is preceded by a state of generalized capillary hyperperfusion. These observations have led to the hypothesis that changes in regional haemodynamics contribute to microvascular complications. Up to now the pathogenesis of the increased blood flow is not completely understood. Studies using microneurography showed reduced sympathetic nerve activity (SNA) in non-complicated IDDM. A decrease in SNA is accompanied by a decrease in basal vascular tone. Therefore we performed a study in which we investigated basal forearm blood flow (FBF) and arterial norepinephrine (NE) concentration reflecting total body sympathetic activity in 50 non-complicated type I diabetic patients (DP) and 50 healthy controls (C). Forearm blood flow was measured by plethysmography. Arterial blood samples for NE and epinephrine (E) were drawn 45 minutes after cannulation of the brachial artery in the supine position. Blood pressure (BP) was measured intra-arterially. All subjects were in a fasting state. Plasma glucose concentration was not corrected to avoid confounding by the vasodilator effect of insulin. Data were analyzed by unpaired Student-*t*-test. Results are expressed as means$\pm$SE. Basal FBF was increased in DP compared to C (2.9 ± 0.1 and 2.0 ± 0.1 ml/dl/min, $p<0.01$). Arterial NE concentration was decreased in DP (NE concentration 0.58 ± 0.03 in DP and 0.81 ± 0.05 nmol/l in C, $P<0.01$). Epinephrine concentrations did not differ between groups (E concentration 0.21 ± 0.03 in DP and 0.21 ± 0.02 nmol/l in C, NS). Systolic / diastolic blood pressure was 116.2 ± 1.2 / 61.7 ± 0.8 in DP and 115.6 ± 1.2 / 63.2 ± 0.9 mmHg in C. Heart rate was not statistically different in both groups (66.5 ± 1.3 in DP and 63.3 ± 1.7 b/min in C, NS). It is concluded that forearm blood flow is increased in non-complicated IDDM. Arterial NE concentrations are decreased in non-complicated IDDM reflecting a decrease in sympathetic activity. A decrease in SNA could probably play a role in the pathophysiology of the hyperperfusion in non-complicated IDDM.

OXIDATIVE STRESS AND ACE ACTIVITY IN IDDM PATIENTS

G.Marra, S.A.Santini, A.Manto, P.Cotroneo, L.Todaro, D.Pitocco, Mordente and G.Ghirlanda. Dept Int Med and Geriatry, Dept of Biochemistry. Rome, Italy.

Angiotensin converting-enzyme (ACE) is synthesized by endothelial cells and play a role in vascular tone, modulating anion superoxide and vasodilating kinins production. Elevated plasma levels of ACE have been demonstrated in IDDM patients with microangiopathy. In addition, oxidative stress is increased in IDDM patients and correlates with vascular diseases. We evaluated the relationship between ACE plasma activity and markers of oxidative stress such as lipid hydroperoxides (ROOHs), conjugated dienes (CD) and plasma anti-oxidant capacity. 70 IDDM patients (mean age 34±9 yrs; duration of disease 13.5±8.8 yrs; mean HbA1c 7.4), without microvascular complications, and 30 controls matched for age and sex were studied. Plasma antioxidant capacity was evaluated by total peroxyl radical-trapping capacity (TRAP), ROOHs by colorimetric assay, CD in *cis-trans* and in *trans-trans* conformation, by second derivative spectroscopy and ACE activity by spectrophotometric assay. TRAP was significantly reduced(663±131 vs 951±105 µmol/L;p<0,0001), while ROOHs (7.2±2.0 vs 2.1±0.7 µmol/L;p<0,0001) and total CD (0,0368±0,0027 vs 0.0328±0.0028 AU; p<0,0001) were significantly augmented in IDDM. CD in *trans-trans* conformation were significantly elevated (0.0340±0.0025 vs 0.0259± 0.0035 µmol/L;p<0,0001), the ratio of *cis-trans/trans-trans* CD isomers (0.088±0.038 vs 0.310±0.148;p<0,0001), a marker of altered plasma redox status, was significantly reduced in IDDM. ACE activity was significantly augmented in IDDM (28±6 vs 20±5 UI/L;p<0,05). Significant direct correlations were found in IDDM between ACE activity with total CD(r^2=0.127;p<0,002) and with *trans-trans* C D isomers(r^2=0.138; p<0,002). Neither markers of oxidative stress nor ACE activity were correlated with metabolic control or diabetes duration. Increased plasma ACE activity, possibly due to an elevated oxidative stress, as evidenced by augmented plasma CD, may represents an early marker of vascular injury in IDDM, without complications. The lack of correlation of these markers with metabolic control and the duration of disease may suggest that diabetes per sè is a condition of altered redox status and endothelial damage.

CAPILLARY PERMEABILITY TO ALBUMIN AND ERYTHROCYTE DEFORMABILITY ABNORMALITIES IN DIABETIC NEUROPATHY.

P. Valensi, A. Behar, F. Cohen-Boulakia, J. Sibony-Prat, J. Pariès, J. Valensi and J.R Attali. Endocrinology-Diabetology-Nutrition, Jean Verdier Hospital, Bondy ; Nuclear Medicine, Hôtel-Dieu, Paris, France.

Capillary permeability to albumin (CPA) is often higher in diabetic subjects, particularly in those with peripheral neuropathy. An abnormality in the microcirculation could contribute to an increase in CPA. The aim here was to study how erythrocyte deformability affects the increase in CPA in diabetic subjects with peripheral neuropathy. Thirty-eight IDD's and NIDD's with peripheral neuropathy confirmed by electrophysiology were included in the study. An isotopic CPA test, according to the Landis method, was performed, consisting of an IV of 99m-technetium-labelled albumin, venous compression applied to an arm for 12 minutes, and the analysis of the decrease in radioactivity after withdrawal of venous compression. Interstitial albumin retention was measured 10 minutes after compression withdrawal. A lymphatic index (LF/HF) was obtained by analysing the decreasing radioactivity curve by Fast Fourier Transform. The erythrocyte rigidity index was determined by the Hanss hemorheometer. Excessive albumin retention ($\geq$ 8%) and an abnormality in the lymphatic function of interstitial albumin recuperation (LF/HF $\geq$ 1%) were found in 18 and 17 patients respectively. The erythrocyte rigidity index correlated positively with the LF/HF index (r = 0.442, p = 0.005). This study confirms the frequency of an abnormality in capillary permeability to albumin in diabetic patients with peripheral neuropathy and suggests that the increase in capillary pressure linked to a rheologic abnormality may contribute to albumin hyperfiltration and saturation of the lymphatic function.

1557

HIGH GLUCOSE INDUCED GROWTH FACTOR RESISTANCE IN HUMAN FIBROBLASTS CAN BE REVERSED BY ANTIOXIDANTS AND PROTEIN KINASE C INHIBITORS

K. Hehenberger and A. Hansson.
Department of Molecular Medicine, The Endocrine and Diabetes Unit, Karolinska Hospital, Stockholm, Sweden

Insulin resistance is clinically significant both in insulin - and non-insulin-dependent diabetes mellitus. Hyperglycemia on its own induces insulin resistance by decreasing the numbers of glucose transporters, but also by affecting the insulin receptor. Hyperglycemia is correlated with a decreased kinase activity in the insulin receptor due to a phosporylation of the insulin receptor by protein kinase C (PKC) and / or an increased activity of cytosolic protein tyrosine phosphatase (PTPase). Chronic diabetic foot ulcers show deficient granulation and epithelisation. We have shown previously that fibroblasts from chronic diabetic and non-diabetic wounds have decreased proliferation compared to those from uninjured skin. The aim of this study was to investigate the effects of high glucose on human fibroblast proliferation, influence of growth factors, and the effects of antioxidants, PKC inhibitors and troglitazone. Normal human dermal fibroblasts were obtained from biopsies taken from five patients undergoing mammary reduction plastic surgery. Fibroblasts in 12-well plates were serum starved for 24 hours, whereafter experiments were conducted. 1. D- and L-glucose in various concentrations were added to the cells. 2. Serum free medium, newborn calf serum, insulin, IGF-I, EGF in high (25.5 mM) and low (11.5 mM) D-glucose. 3. Ascorbic acid, selenite, alpha-tokopherol, Q10, N,N-dimethyltiourea, beta-carotene, troglitazone, H-7, isoH-7 and bisindolylmaleimide IX were added to high and low D-glucose. DNA measurement with a fluorometric method was performed 48 hours after the addition of glucose in all three experiments. D-glucose but not L-glucose in a concentration >15.5 mM inhibited fibroblast proliferation ($p<0,05$). The cells showed resistance against growth factors and insulin in high glucose. Antioxidants, PKC inhibitors and troglitazone could reverse the high glucose induced inhibition of fibroblast proliferation. We postulate that these findings may be of importance for the understanding and future treatment of chronic diabetic foot ulcers.

EFFECTS OF CYCLOOXYGENASE INHIBITION ON THE ENDOTHELIUM DEPENDENT RELAXATION IN DIABETIC FEMORAL AND CORONARY ARTERIES.

G. Pogátsa, E. Kocsis, M.Z. Koltai and I. Pósa. National Institute of Cardiology, Budapest, Hungary

Interaction between arachidonic acid metabolism and endothelium dependent relaxation in the femoral and coronary arterial bed in diabetes was studied. Healthy (n=10) and alloxan-diabetic (560µmol/kg alloxan-tetrahydrate iv., Sigma, n=10) young mongrel dogs of both sexes, weighing 19-25 kg were used. Femoral (n=5-5) and left anterior descending (LAD) coronary (n=5-5) arteries were dissected under pentobarbital anaesthesia (133µmol/kg Nembutal, Ceva), freed from fat and connective tissues, cut into 3-4 mm rings and suspended in organ chambers containing 5 ml Krebs buffer (pH 7.4, 37°C) areated constantly with a mixture of 95% O_2 and 5% CO_2. Changes in isometric tension were registered by a microdynamometer (F-30, Hugo Sachs). Relaxation elicited by acetylcholine (Ach, 3nmol/l-10µmol/l, added in a cumulative manner) - compared to the effect of 1 µmol/l sodium nitroprusside as 100% - was studied in vascular rings precontracted with $PGF_{2\alpha}$. Ach induced relaxation did not differ significantly between diabetic and healthy femoral vascular rings, characterized by the maximal relaxing effect of Ach and Ach sensitivity (pIC_{50}), after incubation in Krebs buffer containing 3µmol/l indomethacin (INDO) either. In LAD rings the maximal relaxing effect of Ach and Ach sensitivity was lower ($p<0.05$) in the diabetic (86±2%, 6.53±0.07) than in the healthy group (92±2%, 6.80±0.14), respectively. After INDO incubation pIC_{50} decreased in both groups, but the maximal relaxing effect of Ach decreased ($p<0.05$) in the diabetic group (75±5%) only, and Ach sensitivity of the diabetic coronary arteries (6.25±0.11) was lower ($p<0.05$) than that of healthy vessels (6.54±0.10). These results suggest that arachidonic acid metabolism is involved in the alteration of the vascular reactivity in diabetes. In coronary arteries the impaired endothelium dependent relaxation is worsened by the inhibition of the synthesis of vasodilator prostanoids.

CYTOCHROME P450 2E1 ACTIVITY IN DIABETIC AND OBESE PATIENTS

D. LUCAS, C. FAREZ, J.R. ATTALI, J.F. MENEZ AND P. VALENSI. Laboratory of Biochemistry-Nutrition, Brest ; Department of Endocrinology, Diabetology and Nutrition, Jean Verdier Hospital, Bondy, France.

Cytochrome P450 2E1 (CYP2E1) is a key-enzyme for detoxification, induced in particular after chronic alcohol consumption. It is also involved in carcinogen activation (benzene, N-nitrosamines...) and the production of highly reactive free radicals. Obesity and diabetes seem also to be induction factors for CYP2EE1 in the rat. The aim of this study was to measure CYP2E1 activity in nonalcoholic subjects : 19 patients with NIDDM and 7 with IDDM, with poor glycemic control (HbA1c = 9.1 ± 0.6 %, fructosamine = 385 ± 20 mol/l), 19 obese patients (BMI > 29 kg/m^2) and 42 controls, by measuring the level of 6-hydroxylation of chlorzoxazone, a myorelaxing drug, according to a method we have previously described. CYP2E1 did not differ significantly in the diabetic patients and controls (0.30 ± 0.02 vs 0.29 ± 0.02) and was slightly higher in the patients with NIDDM than in those with IDDM (0.33 ± 0.03 vs 0.21 ± 0.03, $p < 0.05$). In the obese patients CYP2E1 activity was increased by 30 % compared to the controls (0.38 ± 0.04, $p < 0.05$). These results show that CYP2E1 induction by diabetes or obesity is relatively weak in man unlike that in rats with experimentally-induced diabetes (level 3 to 8 times higher) and that in chronic alcoholism in man (level 2 to 5 times higher). This suggests that CYP2E1 does not play an important part in the complications of diabetes or obesity.

This study was carried out thanks to a PHRC grant (Brest, 1994).

ALTERED ENDOTHELIAL FUNCTION IN DIABETIC CORONARY ARTERIES

MZ Koltai, E Kocsis, I Posa, P Rösen and G Pogátsa. National Institute of Cardiology, Budapest, Hungary and Diabetes Research Institute, Düsseldorf, Germany.

Diabetic basal coronary blood flow is known by our previous data not to be different from that of the healthy. However, its sensitivity to exogenous and endogenous vasodilators is markedly diminished.To study the mechanisms underlying the impaired endothelial dependent relaxation (EDR), effect of acethylcholine (Ach) (2.25-4.5-9-18-36 pmol/kg) was measured on coronary blood flow in 6 metabolically healthy and 6 alloxan-diabetic dogs. Additionally the influence of Ach (0.1-1-10 µmol/l) and L-arginine (A:1 mmol/l) on the release of cGMP by isolated coronary rings as parameter for the generation of NO was determined. The increase of coronary blood flow due to Ach was significantly ($b_o \neq b_\bullet$; $t=4.68$; $p<0.01$) depressed in diabetes. The basal release of cGMP by diabetic coronaries was also less (1.3±0.3 fmol/mg) than by healthy ones (2.2±0.4 fmol/mg). Ach stimulated the release of cGMP dose-dependently, however the amount of cGMP maximally released was reduced ($p<0.05$) in diabetes (C: 3.54±0.5 ; D:1.86±0.2 fmol/mg) . Accordingly, the effect of acethylcholine inducing cGMP release is higher ($p<0.05$) in healthy vessels ($y=0.05 \log x+3.21$; $r=0.9245$) then in the diabetic coronaries ($y=0.015\log x+1.69$; $r=0.8990$). L-arginine induced cGMP elevation only in the controls (179±10%), without any effect ($p<0.05$) in the diabetic arteries (97±40%). These results are suggesting the diminished vasodilation in diabetes to be developing due to the insufficiency of endothelial nitric oxide production.

ARE SOLUBLE ADHESION GLYCOPROTEINS A MARKER FOR CORONARY LESIONS IN THE DIABETIC PATIENT ?

J.P. ALBERTINI, P. VALENSI, B. LORMEAU, F. FERRIERE, J.R. ATTALI, L. GATTEGNO. Laboratoire de Biochimie, Hôpital Avicenne ; Service d'Endocrinologie-Diabétologie-Nutrition, Hôpital Jean Verdier, Bondy, France.

The circulating level of certain soluble adhesion glycoproteins has been found to be high in diabetic patients and could be involved in atherogenesis. The aim here was to compare the level of 5 soluble adhesion glycoproteins : Intercellular Adhesion Molecule-1 (ICAM-1), Vascular Cell Adhesion Molecule-1 (VCAM-1), selectins (Sel) E, P and L in NIDD's with no inflammatory disease, but with a symptomatic coronary disease (group 1, n = 11), silent myocardial ischemia with significant coronary stenoses on angiography (group 2, n = 11), or who were free from ischemic heart disease after an exercise test, a thallium dipyridamole myocardial scintigraphy and a continuous 48-hour ECG (group 3, n = 11). Group 4 was made up of 16 poorly controlled NIDD's receiving a maximal oral antidiabetic treatment. Results were compared with a group of 23 controls ICAM-1 and Sel P were not different between the diabetic patients and the controls or between the groups of diabetics. In the 4 diabetic groups VCAM-1 was significantly higher than in the controls but without a significant difference between the 4 groups. In group 4, Sel E was significantly higher than in the controls ($p < 0.01$), and after 14 days of continuous subcutaneous insulin treatment sel E and VCAM-1 decreased significantly. Sel L was lower in groups 1 and 2 than in group 3 ($p = 0.01$ and $p = 0.07$) and the controls ($p = 0.003$ and $p = 0.01$). If only the poorly controlled diabetic patients were compared (HbA1c > 8 %), sel L was still significantly lower in groups 1 and 2 than in group 3 ($p = 0.03$ and $p = 0.01$). These findings suggest that in NIDD's without inflammatory disease 1) the high level of VCAM-1 and Sel E is related to poor glycemic control ; 2) the low level of Sel L, linked to a reduction in its release which could favour leukocyte aggregation and accumulation, could be a marker for coronary disease.

1562

ABNORMALITIES IN CORONARY VASOMOTRICITY IN DIABETIC PATIENTS AND SUPEROXIDE RADICALS.

P. Valensi, S. Ledoux, J.R Attali, and A. Nitenberg. Endocrinology-Diabetology-Nutrition, Jean Verdier Hospital, Paris-Nord University, Bondy ; INSERM U 426, Louis Mourier Hospital, Colombes, France.

We have already shown than an intracoronary injection of acetylcholine induces coronary vasoconstriction in diabetics, which suggests that coronary dilatation mediated by the EDRF is abnormal. In order to determine the mechanism for this abnormal response, we studied the flow-dependent and cold pressor test responses in 15 normotensive diabetic patients with no hypercholesterolemia and with normal coronary arteries on angiography. In 7 patients the measurements were carried out before and after an i.v perfusion of L-arginine (L-arg), a precursor of EDRF, and in the other 8 patients before and after an i.v. perfusion of deferoxamine (DF), an agent preventing the formation of superoxide radicals. Quantitative angiography was used to determine the size of the proximal interventricular artery (pIVA) at the basal state, at the end of the cold pressor test and after an injection of 10 mg papaverine (PAP) in the distal IVA given in order to increase coronary flow in the pIVA. At the basal state the diameter of the pIVA decreased during the cold pressor test ($p < 0.01$) and did not change after PAP. Administration of L-arg did not change the response to these two tests. After administering DF the pIVA dilated significantly during the cold pressor test ($p < 0.01$) and after the PAP injection ($p < 0.001$). The isosorbide dinitrate injection induced a comparable coronary dilatation in both groups. In conclusion 1) the blood-flow-dependent and cold-induced coronary dilatation is abnormal in diabetic patients ; 2) the absence of an L-arg effect on these abnormal responses suggests that there is no deficit in the substrates necessary for EDRF synthesis ; 3) the improvement in the responses to the two stimuli by deferoxamine suggests that inactivation of nitrogen monoxide by superoxide radicals could be responsible for the subclinical abnormalities in coronary vasomotricity observed in diabetic patients.

1563

ADRENOMEDULLIN PLASMA LEVELS IN PATIENTS WITH INSULIN DEPENDENT DIABETES MELLITUS (IDDM)

J.A. Amado, M.T. García-Unzueta, C. Pesquera, C. Montalbán, F. Mateos, F. Pazos and J.R. Berrazueta. H.U. Marqués de Valdecilla. Santander. Spain

Adrenomedullin (AM) is a new vasodilatador and hypotensive peptide, originally isolated from human pheocromocitoma. AM is widely distributed in peripheral tissues including vascular endothelial cells. AM may have an important role in the regulation of cardiovascular system. We measured plasma levels of AM by radioimmunoassay (Peninsula Laboratories kit, after Sep Pack C18 extraction) in 135 patients with IDDM classified according to the presence of complications (91 patients without nephropathy -A-; 28 with microalbuminuria and serum creatinine concentration <1,3 mg/dl -B-; and 16 with serum creatinine concentration >1,3 mg/dl -C-), and 54 healthy subjects. Results are shown as mean±SD. Kruskal-Wallis and Mann-Whitney tests were used for comparisons between groups. Spearman test was used to study correlation.

	CONTROL	A	B	C
Adrenomedullin (pg/tube)	7,4±3,8	8,1±3,3	8,8±3,6	30,1±32,6

AM was not significantly higher when we compared all patients (A+B+C) with controls (p=0,053); AM was higher in C group than in other groups. There were not differences between A, B, and control groups. AM concentration was also higher in the patients with hypertension (15±7,8) than in the patients with normal levels of arterial pressure (10,8±14,5). AM levels correlated significantly with serum creatinine and HbA1c levels, and with duration of the disease. These data suggest that AM may be released from damaged vascular tissue as a compensatory mechanism.

1564

AUTOANTIBODY AGAINST OXIDIZED LDL AND PARTICLE SIZE: ASSOCIATIONS TO CORONARY REACTIVITY IN YOUNG MEN.

O-P.Pitkänen, O.T. Raitakari, T. Lehtimäki, S. Lahdenperä, S. Ylä-Herttuala, J. Luoma, M-R. Taskinen, T. Nikkari, J.S.A. Viikari, and J. Knuuti. Universities of Turku, Tampere, Helsinki and Kuopio, Finland.

Endothelial dysfunction is an early event in coronary atherosclerosis, and it leads to lowered coronary flow reserve (defined as the ratio of maximal to basal coronary blood flow). According to experimental studies oxidized LDL particles are injurious to endothelium impairing its normal vasodilator function. Small dense LDL particles may be especially susceptible to oxidative modification. We studied the importance of oxidized LDL and LDL particle size to coronary reactivity in healthy men (age 34±3 years). Coronary flow reserve was assessed with positron emission tomography imaging and oxygen-15-labelled water with intravenous dipyridamole infusion. Autoantibodies against oxidatively modified lipoproteins were measured with ELISA method using native LDL and copper-oxidized LDL as antigens. The antibody titer was calculated as the ratio of antibodies to native LDL against modified LDL. LDL particle size distribution was determined by nondenaturing polyacrylamide gradient gel electrophoresis. Mean myocardial blood flow was 0.8 $mL \cdot g^{-1} \cdot min^{-1}$ at rest, and 4.1 $mL \cdot g^{-1} \cdot min^{-1}$ after dipyridamole infusion. The mean coronary flow reserve was 4.9 (range 1.3 to 8.4). The titer of autoantibodies to oxidized LDL was inversely correlated with coronary flow reserve ($r=-0.42$, $P=0.02$). LDL particle diameter was not significantly correlated with coronary flow reserve ($r=0.16$, $P=0.40$) or with the titer of autoantibodies to oxidized LDL ($r=-0.08$, $P=0.83$). In conclusion, these data provide evidence for the role of oxidatively modified LDL in affecting coronary vasoreactivity in vivo.

1565

Effects of AGE on Glycosaminoglycan synthesis in Sheared Endothelial Cells.

M. KAWASUMI, T. ARISAKA, K. MOCHIZUKI,T. TOHJIMA,T. ONUMA, Y. YOSHIDA , and R. KAWAMORI. Dept. of Medicine , Juntendo University , Tokyo , Japan

(**Purpose**)Glycosaminoglycans(GAGs) present on the surface of endothelial cells (ECs) has long been known to be function as a inhibitors for blood coagulation.It was postulated that vascular endothelium sheared in vitro closely mimic those in vivo. In this study, the effect of advanced glycosylation end product (AGE) on GAGs synthesis was examined in sheared or static ECs. (**Methods**) A confluent monolayer of ECs on the polyester sheet was placed in a parallel plate flow chamber and subjected to steady shear stress of 30 dyn/cm^2 for 24 h. Control cells were grown on polyester sheets in the same experimental medium and maintained in the incubator. Each cells were exposed with bovine serum albumin(BSA) or AGE which was prepared with BSA. DNA synthesis was measured with [^{3}H] thymidine and GAG synthesis was measured [^{35}S] sulfate.(**Results**)In the static condition with AGE, the amounts of newly synthesized GAGs was significantly decreased with dose dependent manner.Furthermore,this decrease was in proportion to that of DNA synthesis with time dependent manner.In the sheared condition,these effect by AGE has not been seen.(**Conclusion**)These protective effects of relative high shear stress on GAGs synthesized by ECs under the influence of AGE may be function as an antiatherogenic factors in vascular wall.

1566

ENDOTHELIAL FUNCTION IN COMPETITIVE ATHLETES: RELATIONSHIP TO ANTIOXIDANT STATUS AND LDL CONCENTRATION, SIZE AND OXIDABILITY

Robert Bergholm, Ming-Lin Liu, Sari Mäkimattila, Sanni Lahdenperä, Miia Valkonen, Jukka Luoma*, Seppo Ylä-Herttuala*, Marja-Riitta Taskinen and Hannele Yki-Järvinen. Universities of Helsinki and Kuopio*, Finland

Physical exercise induced increases in oxygen uptake is accompanied by increased free radical generation, which may exceed the capacity of antioxidant defenses. The functional consequences of such changes are unknown. We determined forearm vasodilatory responses to intra-arterial infusions of endothelium-dependent (acetylcholine, ACh) and -independent (sodium nitroprusside, SNP) vasodilatators, and levels of antioxidants, lipoproteins, LDL size and oxidation (diene formation, antibodies) in 8 competitive athletes (VO_2max 69±2 ml/kg·min, age 24±2 yrs; BMI 21±1 kg/m^2, n=8) and 13 normal men (50±2 ml/kg·min, p<0.001; 26±1 yrs; 22±1 kg/m^2, n=13). Athletes had lower plasma protein thiol (SH-group) (307±31 vs 368±14 mmol/l, p<0.05) but not ascorbate or uric acid concentrations. Thiol correlated with total plasma radical trapping capacity (r=0.49, p=0.025). Athletes had higher serum apoAI (141±12 vs 123±3 mg/dl, p<0.05) and HDL (1.6±0.1 vs 1.3±0.04 mmol/l), p<0.05), while LDL cholesterol (2.5±0.3 vs 2.6±0.1 mmol/l), autoantibodies against oxidized/native LDL (1.2±0.2 vs 1.0±0.1), LDL size (27.0±0.2 vs 26.8±0.2 nm) and oxidized LDL lag time (149±8 vs 158±10 min) were comparable. VO_2max was inversely related to endothelium-dependent/-independent vasodilatation (r=-0.45, p<0.05). In multiple linear regression analysis (multiple r=0.61, p<0.02), both VO_2max (p=0.008) and LDL cholesterol (p=0.043) were independently associated with impaired endothelium-dependent vasodilatation. We conclude that a high aerobic capacity in competitive athletes may impair endothelial function, possibly by impairing antioxidant defenses.

1567

ENDOTHELIAL INTERLEUKIN 6 SECRETION IS DOWN-REGULATED BY SHEAR STRESS AND POSITIVELY DEVIATED BY GLUCOSE

H. Kato, M. Morohoshi, I. Uchimura and F. Numano. The 3rd Dept. of Internal Medicine, Tokyo Medical and Dental University, Tokyo, Japan

We investigated the effect of shear stress and glucose concentration on interleukin 6 (IL6) secretion in cultured human umbilical vein endothelial cells (HUVEC) to clarify the mechanism of elevated plasma fibrinogen and IL6 concentration in diabetic patients. HUVEC at 3rd passage were subjected to laminar shear stress up to 7.3dynes/cm^2 loaded by static parallel plate flow chambers of 40cm^2 in cell attaching area with MCDB131 media containing 5mmol/l or 20mmol/l glucose in humidified 37℃ 5% CO_2 95% air. IL6 concentration of media samples obtained before and after 24h stress load was measured with ELISA. The rate of IL6 secretion by HUVEC was then calculated. Statically incubated HUVEC and media were used as control. The rate of IL6 secretion by HUVEC was reduced in accordance with increase of shear stress in media containing 5mmol/l glucose (18.8 pg/cm^2/24h in statical incubation vs 12.2pg/cm^2/24h in 7.3dynes /cm^2). The rate was elevated as 28.8pg/cm^2/24h in HUVEC statically incubated in media containing 20mmol/l glucose.

These results indicate that endothelial IL6 secretion is down-regulated by shear stress and positively deviated by glucose. We have reported previously that IL6 secretion is increased and IL6 mRNA levels are elevated also in human monocytes incubated in high glucose concentration media. Thus we suspect: 1)the negative feed back regulation system of plasma fibrinogen concentration through IL6 secretion by vascular endothelial cells, 2)the positive deviation by glucose concentration in this system. This deviation may be relevant to the development of vascular complications in diabetes.

1568

HIGH ICAM-1 IN CHILDREN WITH DIABETES MELLITUS: A POSSIBLE ROLE OF WHITE CELLS IN ENDOTHELIAL DYSFUNCTION IN DIABETES?

T.A. Elhadd, G. Kirk, M. McLaren, S.A. Greene and J.J.F. Belch. Ninewells Hospital & Medical School, Dundee, United Kingdom.

Endothelial dysfunction was recognised recently to represent at early stage of diabetic angiopathy. Children and adolescents with diabetes generally do not show clinical evidence of such complications, and this is usually delayed to late adolescence or early adulthood. Hyperglycaemica and advanced glycation endproducts can cause endothelial dysfunction and this might trigger expression of cell adhesion molecules (CAM) via the cytokines tumour necrosis factor alpha (TNFα) and interleukin-1 (IL-1). Of CAMs, ICAM-1 represents a marker of endothelium/white cell interaction and trans-endothelial migration of white cells. We have found high levels of ICAM in 51 children, adolescents and young adults with insulin dependent diabetics (22 males and 29 females), mean age ± SD 14.7 ± 3.4 years, duration of diabetes 6.6 ± 4.6 years, and HbA1c of 8.6 ± 1.5% (normal < 5.8%), compared with 22 healthy age and sex matched normal controls (9 males and 13 females) age 15.6 ± 4.1 years. None of the diabetic patients had any clinical evidence of microvascular disease and all had urinary microalbumin within the normal range. The levels of ICAM-1 in the diabetic cohort were 286.5 ± 56.78 ng/ml vs 247.65 ± 71.38 ng/ml in the controls, reaching statistical significance of p < 0.02 ANOVA. ICAM-1 didn't correlated with duration of diabetes of glycated haemoglobin. These results support the hypothesis that microvascular disease starts early in the course of childhood diabetes. Furthermore elevated ICAM-1 delineates possible contribution of white cells in the pathogenesis of endothelial dysfunction in diabetes.

HIGH GLUCOSE-INDUCED COLLAGEN IV UPREGULATION IS MODULATED BY ANTISENSE OLIGONUCLEOTIDES

S. Roy, T. Roth, and K. Zhang. Schepens Eye Research Institute, Harvard Medical School, Boston, USA

Increased synthesis of collagen IV is associated with the development of basement membrane thickening--a characteristic lesion of diabetic microangiopathy. Because antisense technology offers a unique opportunity to down regulate specific gene expression, we investigated the effect of antisense phosphorothioate oligonucleotides (PS oligos) directed against collagen IV mRNA on collagen IV synthesis and proliferation in a cell line derived from rat microvascular endothelium and cultured in high (30mM) glucose. The rat endothelial cells grown in high glucose for 5.6±1.3 days exhibited increased cell proliferation compared to control cells grown in 5mM glucose (169% of control, P=0.038). Collagen IV mRNA level (determined by Reverse Transcription-Polymerase Chain Reaction) was increased to 172% of control. However, when cells grown in high glucose were transfected with 0.4 μM collagen IV-antisense PS oligos in the presence of cationic liposomes, the cell number and collagen IV mRNA level decreased compared to cells grown in high glucose to 61% and 115% of control, respectively. Actin expression, used as control, was not affected by PS oligos. This study indicates that antisense PS oligos directed against collagen IV mRNA specifically reduce collagen IV mRNA in rat endothelial cells and decrease proliferative effects of high glucose. Since vascular endothelial cells overexpress collagen IV in diabetes such an intervention may provide a means to arrest collagen IV overexpression and clarify its role in the pathogenesis of diabetic microangiopathy.

THE EXPRESSION OF ENDOTHELIAL NITRIC OXIDE SYNTHETASE IS REDUCED IN DIABETIC PATIENTS WITH PERIPHERAL NEUROPATHY

A. Veves, J. Primavera, C.M. Akbari, V.M. Donaghue, D. Zacharoulis, J.S. Chrzan, U. DeGirolami, F.W. LoGerfo and R. Freeman. Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, USA.

Reduced production of nitric oxide has been proposed as an important factor in the development of peripheral diabetic neuropathy. We have studied the expression of nitric oxide synthetase activity in the skin of diabetic neuropathic patients and healthy subjects. Five control (2/3 M/F) and 5 diabetic subjects [3/2 M/F, 2 IDDM, DM duration 17 (range 6-33) years] matched for age [53 (26-76) (mean, range) years vs 58 (48-71), sex and body mass index [31.1 ± 5.0 (mean± sd) vs 28.6 ± 7.6] were included. Nerve function measurements were impaired in the diabetic group, including Neuropathy Disability Score (0 ± 0 vs 21.8 ± 5.5, $p < 0.001$), Vibration Perception Threshold (15 ± 10 Volts vs 50 ± 1.3, $p < 0.001$) and peroneal motor conduction velocity which was measurable in 1 patient. The transcutaneous oxygen tension was similar in both groups (69 ± 7 mmHg vs 58 ± 17, p=NS) and clinical peripheral vascular disease was not present in any participant. Full thickness skin biopsies from the dorsum of the foot were obtained and were immunostained with antiserum to human endothelial nitric oxide synthetase, glucose transporter I (GLUT I) and von Willebrand factor, an anatomical marker of the endothelium. The staining intensity was evaluated by a pathologist, who was blinded to the diabetes status of each subject, as normal or reduced. No differences were found between the two groups in the staining intensity of von Willebrand factor [reduced in 1 (20%) control vs 2 (40%) diabetic patients (p=NS)] and GLUT I [reduced in 1 control (20%) vs none (0%) diabetic patients p=NS]. In contrast, the staining intensity of nitric oxide synthetase was reduced in 1 (20%) control and in all 5 (100%) diabetic patients ($p < 0.01$). We conclude that in diabetic neuropathic patients the endothelial nitric oxide synthetase activity is reduced despite the fact that the endothelium is anatomically present indicating that endothelial functional changes may be related to the development of neuropathy.

1571

ORGANS' VASCULARISATION IN OFFSPRING OF PREGNANT RATS FED AN ISOCALORIC PROTEIN RESTRICTED DIET

B. Reusens, V. Iglesias-Barreira, N. Bennis-Taleb, C. Remacle and J.J. Hoet. Catholic University of Louvain, B-1348 Louvain-la-Neuve, Belgium

Functional and structural changes are induced in the fetal endocrine pancreas by derangements in maternal metabolism or nutrition such as in low protein diet. Brain and kidney manifest also alterations which may remain till adulthood. Vascularisation of organs have not been analyzed and may also be affected. The aim of the study is to investigate the blood vessel density (BVD) by morphometric analysis and blood flow (BF) by non radioactive microspheres injection in organs of offspring receiving 20 % protein (C) or 8 % protein (LP) during fetal life till adulthood. A recuperation group (R) received 8 % protein only during fetal life and a normal diet after birth. BVD of the islets was analysed on semithin sections. BVD of the brain and the duodenum was analysed on 30 μm sections in animals injected with nuclear track emulsion. Islet BVD decreased from 7.74 ± 0.47% in C to 2.79 ± 0.34% in LP newborns ($P<0.01$) and from 3.34 ± 0.28 % in C to 1.96 ± 0.11% in LP adults ($P<0.01$). Islet BF is reduced from 29 ± 5 μl/min/g in C to 10.3 ± 1.9 μl/min/g in LP adults ($P<0.05$). Islet BVD and BF were normalized in R adults. In the duodenum, BVD was decreased by 24 % ($P<0.05$) in LP while it was normal in R adults. In the latter BF was increased by 60 % ($P<0.05$). In contrast, BVD in brain of LP newborns showed a reduction of 70% ($P<0,01$). At adulthood, it remained decreased respectively by 35% and 30% in LP and R group. These results show that in the neonates, islet and brain vascularisation is decreased when a LP diet is given during fetal life. With a low protein diet given after birth till adulthood, the reduction of the vascularisation of the endocrine pancreas, the duodenum and the brain remains. With a normal diet given after birth, vascularisation in the adult duodenum and islet is recovered but reduced brain vascularisation still prevails.

1572

ENDOTHELIUM-INDEPENDENT CYCLIC GMP FORMATION IN CAROTID ARTERIES OF DIABETIC RATS

F.R.L. Crijns, B.H.R. Wolffenbuttel, D.S. van Ingen Schenau, H.A.J. Struijker Boudier* and J.G.R. De Mey*. Depts. of Endocrinology and *Pharmacology, CARIM, University Maastricht, The Netherlands.

The development of vascular complications in diabetes mellitus is often associated with endothelial dysfunction. Previously, we showed that cyclic 3'-5'-guanosine monophosphate (cGMP) production was reduced in denuded carotid artery segments of diabetic rats, compared to denuded segments of control rats, during stimulation with the NO-donor sodium-nitroprusside (SNP, 10^{-6} M).The present study was performed to investigate whether this reduced cGMP production was due to a decrease in sensitivity, or whether the maximal response was reduced. Furthermore, another NO-donor, S-nitroso-N-acetyl-penicillamine (SNAP), was examined. Diabetes was induced in Wistar Rp rats by streptozotocin (70 mg/kg, D). Control rats (C) received vehicle only. After 3 months, carotid arteries were isolated, mechanically denuded of endothelium and divided into 6 segments. Segments were pre-incubated for 60 min in Krebs-Henseleit buffer (glucose 7 mM for C and 20 mM for D), and then exposed for 10 min to 3-isobutyl-1-methylxanthine with addition of SNP (n=8-10) or SNAP (n=3) in 3 concentrations (10^{-6}, 10^{-5} and 10^{-4}M) during the last 2 min. cGMP was determined by RIA. SNP-stimulated cGMP levels (fmol/mm vessel ± SEM) were significantly lower in diabetic arteries than in control vessels (10^{-6}M: 2117 ±302 vs 3491 ±571; 10^{-5} M: 2480 ±438 vs 4734±611; 10^{-4} M: 3207± 474 vs 4828 ±590 fmol/mm, $P<0.05$). SNAP-induced cGMP production was comparable in arteries of diabetic and control rats (10^{-6} M: 2545±381 vs 4161± 755; 10^{-5} M: 3784±652 vs 3923±531; 10^{-4} M: 4390± 860 vs 4525±214 fmol/ mm). We conclude that in de-endothelialized carotid arteries of diabetic rats the maximal stimulation of cGMP production that can be induced by SNP, is reduced. There seems to be no general defect in endothelium-independent stimulation of cGMP since preliminary results indicate that SNAP-induced cGMP production is normal.

MORPHOHISTOMETRIC INVESTIGATIONS OF PLACENTAS OF DIABETIC PATIENTS, USING A DIGITAL ANALYSER

Michał Krekora, Jan Wilczyński, Lech Podciechowski, Katarzyna Cypryk, Krzysztof Zieliński, Krzysztof Trojanowski. SDM Group-Łódź, Polish Mother's Memorial Hospital, Łódź, Poland.

OBJECTIVE: We performed histomorphologic evaluation of placentas from pregnant women with diabetes mellitus and compared them with placentas from normal women.
STUDY DESIGN: 53 pregnant women with diabetes participated in the study treated according to SDM Program, 42 patients with with diabetes prior to pregnancy (PGDM) and divided into classes acc. to White, and 11 patients with gestational diabetes (GDM), 16 women with physiological pregnancy (N), after 37th week of gestation were used as a control. For digital image analysis an IBAS 2000 analyser (Kontron) was used with a Chalnicon B/W camera and a custom-made image analysing program. In each analysed field the program computed the following histomorphological parameters of selected vascular profiles:
- total area of selected profiles [FAREA],
- total circumference of the selected profiles [FPERIM],
- in dividual area of each profile [AREA],
- individual circumference of each profile [PERIM],
- diameter of the circle inscribed in each profile [DMIN],
- the number of complete vascular profiles in the microscopic field [COUNT].

RESULTS: **1.** Statistically significant differences were found in the diameters of vascular profiles [DMIN] between normal placentas and placentas of diabetic mothers. **2.** Placental vessels of diabetic mothers are wider than those of normal placentas, except RF diabetes, acc. to White. **3.** A significantly lager total area of selected profiles [FAREA] was found in the placentas of diabetic patients vs. normal pregnancy.
CONCLUSIONS: Statistically significance results was found between histometric parameters (AREA, PERIM, DMIN), in studied groups [acc. to White (B, C, D)] compared to a normal group.

1574

ABNORMAL RESPONSE OF NITRIC OXIDE METABOLITIES TO ACUTE HYPERGLYCEMIA AND IV FUROSEMIDE IN IDDM PATIENTS.

J. Křížová, T. Pelikánová and L. Kazdová. Institute for Clinical and Experimental Medicine and Postgraduate Medical School, Prague, Czech Republic.

Nitric oxide (NO) plays an important role in kidney function control influencing the renal vascular tone and sodium handling. The aim of the study was to evaluate the urinary NO_2^- /NO_3^- (NO_x) a) under basal conditions and after stimulation with iv furosemide (0.5 $mg.kg^{-1}$) and b) during glycemic clamp-induced normo- and hyperglycemia (5 and 12 mmol/l) in 19 patients with insulin-dependent diabetes mellitus (IDDM) without microalbuminuria compared to 12 weight-, age- and sex-matched healthy controls. Sodium excretion and renal hemodynamics using the clearances of inulin (C_{in}) and para-amino-hippuric acid (C_{PAH}) were measured during examinations in both groups. Despite comparable baseline urinary NO_x excretion in diabetics and controls, the different response of NO_x was found after furosemide administration: no changes in diabetics (228±50 vs 146±38 $nmol.min^{-1}$) and increase NO_x excretion in controls (196±54 vs 681±146$nmol.min^{-1}$; $p<0.001$), although the furosemide-induced increases in natriuresis were comparable. During clamp-induced euglycemia, NO_x excretion was comparable in diabetic and control subjects and significantly increased during hyperglycemia in controls (425±57 vs 560±57 $nmol.min^{-1}$; $p<0.01$), while it did not change in diabetics (352±56 vs 323±39 $nmol.min^{-1}$). Fractional excretion of sodium (FE_{Na}) was comparable and declined significantly during hyperglycemia in both groups ($p<0.05$). There were no significant relationships between NO_x excretion and FE_{Na} or renal hemodynamics. We conclude that 1) IDDM without alterations in renal hemodynamics is associated with blunted renal generation of NO in response to hyperglycemia and furosemide administration, and 2) the antinatriuretic effect of hyperglycemia is not mediated by increased renal NO production.

1575

SERUM VASCULAR ENDOTHELIAL GROWTH FACTOR LEVELS ARE ELEVATED IN DIABETIC PATIENTS WITH HYPERGLYCEMIA

S.Yatoh, Y.Okuda, M.Asano, H.Sone, Y. Asakura, S.Suzuki, Y.Kawakami, H. Suzuki* and K. Yamashita. University of Tsukuba, Tsukuba Res. Toagosei Co.*, Tsukuba, Japan.

Diabetic complications (ex.proliferative retinopathy) are often angiogenic, so we studied the relation between vascular endothelial growth factor (VEGF) levels and plasma glucose (PG) levels in diabetic patients. We already reported VEGF level in aqueous humor of diabetic patients with rubeotic glaucoma is markedly elevated (Diabetes Care 19: 1996). We enrolled 108 diabetic patients (age was 59±12 years, man/woman rate was 67:41) and measured serum VEGF, PG and HbA1c. Serum VEGF levels were measured by our newly developed sensitive ELISA using the rabbit anti-human VEGF polyclonal antibody. We checked age, sex, type of DM and the degree of diabetic retinopathy, nephropathy and neuropathy. We divided patients into 4 groups with PG (A: PG<200, B: 200≤PG<250, C: 250≤PG<300, D: PG≥300 (mg/dl)) and into 4 groups with HbA1c (a: HbA1c<10, b: 10≤HbA1c<11, c: 11≤HbA1c<12, d: HbA1c≥12 (%)). In 108 patients, their mean VEGF was 67.2±48.0 (mean±SD) pg/ml, PG was 178±81 mg/dl, HbA1c was 8.9±2.1%, respectively. In group A (n=71)/ B (20)/ C (7)/ D (10), their VEGF levels were 58.8±37.8/ 76.9±45.8/ 63.9±35.1/ 110.6±90.2, respectively. VEGF level in group D was significantly higher than in group A (p=0.014). In group a (n=80)/ b (13)/ c (9)/ d (6), their VEGF levels were 60.6±39.3/ 58.5±40.4/ 88.8±38.8/ 142.3±100.9, respectively. VEGF level in group d was significantly higher than in group a (p=0.0006) and in group b (p=0.003). These results suggest that hyperglycemia (PG ≥ 300 mg/dl or HbA1c ≥ 12%) may up-regulate VEGF levels in vivo and influence diabetic complications.

1576

ENDOTHELIAL DYSFUNCTION IN IDDM IS ASSOCIATED WITH LOW CONCENTRATION OF ACTIVE TRANSFORMING GROWTH FACTOR-β.

D.R. Meeking[a], M.H. Cummings[a], J.R. Crook[b], S. Thorne[c], A. Donald[c], P. Clarkson[c], J.E. Deanfield[c], G.F. Watts[d], K.M. Shaw[a]. [a]Department of Diabetes, Queen Alexandra Hospital, Portsmouth,UK., [b]Coronary Artery Disease Research Group, St George's Hospital, London, UK., [c]Cardiothoracic Unit, Great Ormond Street Hospital for Children, London, UK. and [d]Department of Medicine, University of Western Australia, Perth, Western Australia.

Low levels of active transforming growth factor-β (active TGF-β) have been observed in non-diabetic patients with advanced atherosclerosis and it has been proposed that active TGF-β might be a key inhibitor of atherogenesis. Since endothelial dysfunction is an early event in atherosclerosis, we hypothesised that low levels of active TGF-β might be associated with increased endothelial dysfunction in patients with IDDM. To test this hypothesis, we measured responses of the brachial artery to flow-mediated dilation (FMD) and to 400 µg sublingual glyceryl trinitrate (causing endothelium-dependent and endothelium-independent dilation respectively) using a high-resolution ultrasound technique in 31 patients [17 males, 14 females; age 38.5 ± 2.1 yr (mean ± SEM); duration of diabetes 27.6 ± 1.5 yr; HbA1 10.1 ± 0.4 %; total cholesterol 5.3 ± 0.2 mmol l^{-1}; triglyceride 1.8 ± 0.2 mmol l^{-1}; HDL-cholesterol 1.3 ± 0.1 mmol l^{-1}, urine albumin/creatinine ratio 25.5 ± 7.0 µmol l^{-1}. Active TGF-β was measured by ELISA. FMD response was 103 ± 0.6 %, GTN response was 116.8 ± 1.8 %. Active TGF-β concentration was 4.61 ± 0.53 $ng.ml^{-1}$ There was a positive correlation between active TGF-β concentration and endothelium-dependent flow-mediated dilation (FMD = 101 + 0.417.TGF-β, $r = 0.36$, $p < 0.05$) but not endothelium-independent dilation ($p = 0.27$) nor other biochemical parameters. In conclusion, these preliminary data suggest that low levels of active TGF-β are associated with impaired endothelial response in Type 1 diabetes.

1577

STUDIES OF PLASMA ECMR-III(CD44) AND PECAM-1(CD31) LEVELS IN DIABETIC PATIENTS

T. Saika and N. Aoki.
Department of Medicine, Kinki University School of Medicine, Osaka, Japan.

In cases of chronic diabetic complication, highly organ-specific lesions involving endothelial cells are frequently formed. It has been demonstrated that vascular endothelium has various function as shown by the participation in the blood coagulation-fibrinolysis system, lipid metabolism, vasodilation, vasoconstriction and the immune system. As the cause of diabetic microangiopathy, adhesion molecules derived from vascular endothelial cells is drawing attention. In this study, plasma ECMR-III (CD44) and PECAM-1 (CD31) levels in diabetic patients were measured using ELISA kits, and the relation of these factors with microangiopathy was examined. Plasma CD44 level (Mean±SD, ng/ml) in 69 diabetic patients was 1.92±0.72 which was significantly higher than 1.22±0.18 in healthy subjects ($P<0.05$). Plasma CD31 level in diabetic patients was 6.04±1.73, which was not significantly different from 6.80±1.02 in healthy subjects. Plasma CD44 level in the microangiopathy group of diadetics was 1.92± 0.66. It was 1.84±0.76 in diabetics without microangiopathy. There was no significant difference between these two groups. However, plasma CD44 level in the macroalbuminuria group was 2.34±0.96, which was significantly elevated when compared with 1.70±0.31 in the normoalbuminuria group ($P<0.001$) and 1.80±0.33 in the microalbuminuria group ($P<0.05$). Plasma CD44 level in diabetic patients did not show any significant difference with the states of diabetic control and therapeutic methods. The level did not correlate with any of BMI, total cholesterol, HDL-C, Lp(a), and RLP-C. Involvement of CD44 in the development and progress of microangiopathy in diabetic patients was suggested.

1578

EVIDENCE FOR A DIRECT IN VIVO EFFECT OF INSULIN ON ENDOTHELIAL CONSTITUTIVE NITRIC OXIDE-SYNTHASE

T. Monauni, L. Bertolini, A. Cretti, V. Cacciatori, M. Muggeo, E. Bonora and R.C. Bonadonna. Division of Endocrinology and Metabolism, Verona, Italy.

Insulin (I) augments endothelium(E)-dependent vasodilation induced by muscarinic (M) agonists, a finding interpreted as a proof that I stimulates endothelial constitutive nitric oxide (NO)-synthase (cNOS). However, I could do so also by acting at some point in the M-receptor-signal transduction pathway upstream to cNOS. We studied 7 (6 males, 1 female) young, healthy subjects with the forearm (F) perfusion technique and assessed the F blood flow (FBF, measured by Cardio-Green dilution) responses to graded intra-arterial (i.a.) doses of the M-agonist acetylcholine (ACH, 3, 9 and 30 µg/min/kg of F), of bradykinin (BK, 40, 120 and 400 ng/min/kg of F), which activates endothelial cNOS through a receptor and a transduction pathway completely independent of ACH, and of sodium nitroprusside (SNP, 1, 3, and 10 µg/min/kg of F), an NO donor, during the i.a. infusion of both saline (SLN) and I, the latter at a dose designed to raise local I concentrations to ~500 pmol/l with no systemic effects. Hyperinsulinemia enhanced both ACH (63.9±8.3, 115±19, 192±33 vs 52±11, 81.2±13, 171±21 ml/min/kg of F, $p<0.01$ by ANOVA, I vs SLN dose-response) and BK (81.3±14, 118±19, 159±13 vs 50±11, 99±20, 136±27 ml/min/kg of F, $p<0.05$ by ANOVA, I vs SLN dose-response), but not SNP (45.6±5.5, 65.9±5.5, 107±11 vs 42.9±7, 64.2±11, 93.6±10 ml/min/kg of F, p=n.s. by ANOVA, I vs SLN dose-response) effects on FBF. Identical patterns were observed when the dose-responses of FBF, expressed as % increases over baseline, and of F vascular resistance were examined. CONCLUSION: Since I improves the vasodilatory effects of both ACH and BK, which converge on endothelial cNOS through two completely independent transduction pathways, but not of SNP, which directly releases NO, these data are most consistent with a direct in vivo effect of I on endothelial cNOS.

1579

GLUCOSE-DEPENDENT RESPONSE OF RETINAL ENDOTHELIAL CELLS TO GROWTH FACTORS RM Knott, M Robertson, E Muckersie and JV Forrester. Department of Ophthalmology, University Medical Buildings, Foresterhill, Aberdeen, AB9 2ZD

Clinical studies have demonstrated that the onset and progression of diabetic retinopathy (DR) is influenced by the glucose control of the patient. DR is characterised by the co-existence of impaired cell growth and excessive cell proliferation and we wished to determine the effect that glucose has upon these parameters. Bovine retinal endothelial cells (BREC) were exposed to a range of glucose concentrations from 0 - 25 mmol/l. The level of DNA synthesis and cell number was then determined using pulse labelling with tritiated thymidine and a Coomasie blue dye based assay respectively. The level of DNA synthesis declined significantly as the concentration of glucose increased. This effect was shown to be dependent upon the presence of TGF-β and was mediated by a PKC dependent pathway. Furthermore, in the presence of glucose (5mmol/l), insulin failed to increase DNA synthesis in BREC while in its absence, insulin readily induced DNA synthesis. A similar loss of IGF-1 mediated DNA synthesis was observed in the presence of 5 mmol/l glucose. Thus, glucose impairs DNA synthesis via a TGF-β mediated mechanism and also renders BREC less responsive to the growth factors IGF-1 and insulin. This suggests that antagonistic effects of TGF-β and insulin/IGF-1 can be induced in BREC which is dependent upon the concentration of glucose that the cells are exposed to.

IMPAIRED ENDOTHELIUM DEPENDENT DILATATION IN AFRICAN AMERICAN SUBJECTS MAY CONTRIBUTE TO INSULIN RESISTANCE

D. Perregaux, S. Rao, A. Chaudhuri, A. Airen, B.H. Sung, M.F. Wilson and P. Dandona. State University of New York at Buffalo, Buffalo, New York.

Impairment of endothelium dependent NO mediated dilatation has been shown in insulin resistant states. It has been postulated that this defect might contribute to the decreased insulin sensitivity by altering the supply of insulin and substrate to the tissues. As the incidence of insulin resistance is high in the African American we have studied the dilatory response of the brachial artery following forearm ischemia, a response that is endothelium dependent and NO mediated, in a healthy subset of this population. Sixteen normotensive African Americans, age 20-47 years, with fasting blood glucose of 77 ± 10 mg/dl, total cholesterol 120.1 ± 31 mg/dl and twenty two age matched Caucasians were investigated. Ischemia was induced by inflating a cuff over the arm to a pressure of 40 mm of Hg over systolic for 5 minutes. Doppler ultrasonography (using Acuson 128XP10 ultrasonograph with 7.5 Mhz linear array transducer) was used to measure brachial artery diameter and blood flow velocity at 15 seconds and 45-60 seconds following deflation. Dilatation and hyperemia were defined as the percentage increase over basal diameter and percentage of basal flow respectively. Postischemic median dilatation was 0% (range 0-3.14%) in African Americans and 4.42% (range 4.42-8.70%) in Caucasians ($p<0.05$). Six out of 16 African Americans as compared to 4 out of 22 Caucasians did not dilate following ischemia (0%) ($x^2=4.39$, $p<0.04$). Hyperemic response was less than 300% in 5 out of 16 African Americans as compared to 1 out of the 22 Caucasians ($p<0.05$). We conclude that vasodilatation and hyperemic response to ischemia is decreased in a significant number of African Americans who are also likely to be more insulin resistant. An impairment in endothelium dependent NO generation may contribute to the insulin resistance, hypertension and vascular disease in this population.

1581

TROGLITAZONE INHIBITS PROLIFERATION OF MICROVASCULAR ENDOTHELIAL CELLS: IMPLICATIONS FOR DIABETIC RETINOPATHY

S. Danehower, A. Proia, B. Gordon, J. Barnard, S. Witherspoon and L. Ross.
GlaxoWellcome, Inc., Research Triangle Park, USA

We examined the effects of troglitazone, a novel member of the thiazolidinedione class of oral antidiabetic drugs, on microvascular endothelial cells from human and murine tissues. Thiazolidinediones have been shown in adipocytes to activate peroxisome proliferator-activated receptor γ (PPAR γ), a member of the nuclear receptor superfamily of ligand activated transcription factors believed to play a role in the regulation of lipid metabolism. Adipose tissue, one of the target tissues of troglitazone, is highly vascularized but endothelial cell sensitivity has not been examined previously. We discovered that PPAR γ is constitutively expressed in human and murine microvascular endothelial cells (MVEC), and that 20 μM troglitazone will upregulate the expression of PPAR γ. We sought to determine if there was a corresponding phenotypic change. Human MVEC treated with troglitazone *in vitro* were growth inhibited by 29.2-36.8% at 1 μM and 48.7-59% at 20 μM twenty four hours post treatment. By contrast, large vein human umbilical vein endothelial cells (HUVECs) and murine MVECs were not significantly growth inhibited with 1 μM troglitazone. There was, however, significant inhibition at higher concentrations (37% and 34% at 10 μM respectively). There was no decrease in cell viability at concentrations up to 20 μM, the highest dose tested. Based on the *in vitro* results, we performed experiments to determine if troglitazone would inhibit angiogenesis in a rat corneal angiogenesis wounding model. There was no significant change in angiogenesis at the doses tested (150 mg/kg and 500 mg/kg) in this rat model, but based on the proliferation results this model may not be predictive of effects on human vasculature. Troglitazone has a direct effect on human microvascular endothelial cells, both upregulating PPAR γ mRNA and inhibiting cell growth *in vitro*. These effects may possibly result in a decrease of pathological angiogenesis and a delay in the onset of proliferative retinopathy in diabetic patients.

1582

INSULIN-MEDIATED GLUCOSE UPTAKE IN NIDDM: METABOLIC PARAMETERS AND ENDOTHELIAL FUNCTION.

M. Sambataro, E. Brocco, A. Carraro, M. Trevisan, A. Sfriso, M. Maioli, G. Tonolo, P. Fioretto, G. Pacini, G.Crepaldi, and R. Nosadini. CAD Portoviro (RO) Italy, University of Padua, University of Sassari, Institute of Systems Science and Biomedical Engineering (LADSEB-CNR), Padua, Italy.

Introduction. It is well known that insulin resistance is a typical feature of non insulin-dependent diabetes mellitus (NIDDM). Insulin resistance is worsened in microalbuminuric (>30μg/min) hypertensive (AER+) with respect to normoalbuminuric normotensive (AER-) NIDDM patients. However, if this phoenomenon is due to an endothelial dysfunction, i.e. an altered insulin transcapillary passage from the blood flow to the interstitial space, or to an impaired intracellular insulin action is not known. Aim and Subjects (i) to quantify insulin resistance parameters in 11 AER+ and 23 AER- well matched NIDDM patients (age 59±2 vs. 59±1yr; BMI 29±2 vs. 29±1 kg/m^2); (ii) to correlate insulin resistance with endothelial function evaluated by von Willebrandt factor (vWF). Methods. Insulin sensitivity (SI) was obtained by the minimal model method after an i.v. glucose test, and vWF by ELISA. Disposition index (DI) was calculated as the product between SI and the suprabasal area under the insulin curve during first 10 min. Results Basal insulin (Ib) was 66±12(SE) pM in AER- and 102±12 in AER+ ($p<0.02$). Basal glucose (Gb) was 7.4±0.7 mM in AER- and 11.8±0.9 in AER+ ($p<0.005$). SI was 0.25±0.07 10^{-4}min^{-1}/pM in AER- and 0.08±0.02 in AER+ ($p<0.032$). DI was 0.22±0.006 in AER- and 0.01±0.002 in AER+ ($p<0.04$). vWF was unchanged in the two groups (140±9 vs. 169±13%) and did not correlate with SI or DI ($p>0.2$). Conclusions (i) SI is impaired in all diabetic patients, and this impairment is more enhanced in AER+; (ii) the variability of endothelial status, in basal conditions, does not suggest that reduced insulin-mediated uptake of glucose is due to an impaired capillary permeability to insulin; (iii) a metabolic intracellular defect, more evident in AER+ than in AER-, can alternatively explain some components of insulin resistance in NIDDM.

EFFECTS OF TROGLITAZONE ON EXPRESSION OF PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR γ IN ENDOTHELIAL CELLS

L. Ross, S. Witherspoon, J. Barnard and S. Danehower
Glaxo Wellcome Inc., Research Triangle Park, USA

We have examined the *in vitro* effects of troglitazone, a member of the thiazolidinedione class of oral antidiabetic drugs, on growth and gene expression in human and murine microvascular endothelial cells (HMVEC and MMVEC), human large vein umbilical endothelial cells (HUVEC) and murine heart endothelial cells (MHEC) to explore possible beneficial effects of troglitazone in microvascular complications of non-insulin-dependent diabetes mellitus (NIDDM). Troglitazone is being developed as a treatment for NIDDM, as it improves sensitivity to insulin and reduces plasma glucose and lipid levels. The antidiabetic effects of troglitazone correlate with effects upon the peroxisome proliferator-activated receptor γ (PPARγ), a member of the steroid/ retinoid/ thyroid hormone receptor family of ligand-activated transcription factors. We have obtained and characterized HMVEC, MMVEC, HUVEC and murine MHEC. Administration of 20 μM troglitazone for eight days results in a 2.1 +/- 0.3 fold induction of PPARγ mRNA in HMVEC (n=5), a 1.4 fold induction in MMVE cells, and a 3.7 fold induction in MHEC, but does not upregulate PPARγ expression in HUVEC. Induction of adipocyte binding protein 2 (aP2) mRNA, an intracellular lipid binding protein, was also examined, since it has been shown by other investigators that transcription of aP2 can be regulated by the PPARγ gene in adipocytes and fibroblasts. Following eight days of treatment with 20 μM troglitazone, aP2 is induced 5.8+/-2.5 fold in HMVEC and 4.9 fold in MHEC while no induction is observed in HUVEC or in MMVEC. Induction of aP2 mRNA is not observed in all endothelial cell types in which PPARγ mRNA is induced by troglitazone treatment, suggesting that transcriptional regulation of aP2 by PPARγ may be cell type specific, or that other factors influence expression of aP2. There may also be organ or tissue specific endothelial cell differences to the effects of troglitazone, since HMVEC and MMVEC both upregulate PPARγ, while HUVEC are not responsive.

1584

ACUTE HYPERGLYCEMIA REDUCES NITRIC OXIDE AVAILABILITY IN MAN.

R. Marfella, L. Coppola, C. La Marca, F. Turano, F. Saccomanno, F. D'Onofrio and D. Giugliano. Department of Geriatrics, Second University of Naples, Naples, Italy

The aim of this study was to investigate whether the increase in vascular tone induced by acute hyperglycemia in man is related to reduced nitric oxide (NO) availability. Acute hyperglycemia (15 mmol/L) was induced in 12 healthy subjects. Systolic (8±3 mmHg, mean±SE) and diastolic (5±2 mmHg) blood pressure and heart rate (6±3 beats/min) showed significant ($p<0.05$-0.001) increments starting from 30 min of hyperglycemia; leg blood flow in the femoral artery decreased at 60 and 90 min (-91±23 ml/min, $p<0.05$). Platelet aggregation response to ADP (9±3%) and blood viscosity (0.7±0.2 centipois) also showed significant increments during acute hyperglycemia ($p<0.05$). The infusion of L-arginine (1 g/min), the natural precursor of NO, in the last 30 min of the hyperglycemic clamp completely reversed all hemodynamic and rheologic changes brought about by hyperglycemia. Neither the infusion of D-arginine (1 g/min), which is not used as substrate for nitric oxide synthase, nor L-lysine (1 g/min), which uses the same amino acid transport system as L-arginine does, changed the vascular responses to hyperglycemia. Acute hyperglycemia in man causes significant vascular changes which are reversed by L-arginine, but not D-arginine or L-lysine. Acute Hyperglycemia may reduce NO availability in man.

1585

PROTECTION OF ENDOTHELIUM BY BIMOCLOMOL (INCREASED EXPRESSION OF HEAT SHOCK, HSP-72 GENE)

A. Jednákovits, I. Kurucz, E. Hegedűs and L. Korányi. BIOREX Research & Development Co., Veszprém, Hungary.

Bimoclomol (BRLP-42) is a vasoprotective agent under development by Biorex (Hungary) for the treatment of diabetic micro- and macroangiopathy (Phase II clinical trials). In the present study the effects of chronic Bimoclomol treatment on function and structural properties of the arterial wall and on the expression of heat shock protein (HSP-72) gene were investigated in insulin resistant rats. 3-month-old male spontaneously hypertensive rats (SHR) were treated with BRLP-42 (20 mg/kg/p.o.) for 1,2 and 3 months. The endothelium-dependent relaxation by Ach showed an age dependent decrease in preparations from SHRs. The maximal relaxing effect achieved with 10μM Ach in rings from 4-, 5- and 6-month-old SHR untreated animals were: 56,5±9,3; 42,9±10,4; 32,9±4,4%, resp. In contrast vasodilator responses were significantly improved in aortic rings of BRLP-42 treated rats (max. relaxation: 87,3±6,2; 79,9±4,6; 65,6±3,7%, $p<0.05$ for all). The endothelium of SHR aortas was severely damaged, some of the cells were necrotized or ulcerized. After BRLP-42 treatment the structure of the endothelium was intact, cells grew over the discontinuities. With ageing and deterioration of carbohydrate metabolism not only the endothelial dysfunction became more pronounced but also the expression of HSP-72 was less intensive. BRLP-42 treatment preserved the expression rate of HSP-72 gene ($p<0.05$) and restored the function and morphology of aortic endothelium.

1586

ENDOTHELIAL DYSFUNCTION IN NIDDM: ASSESSMENT BY L-ARGININE AND REVERSAL BY ANTIOXIDANTS.

R. Marfella, F. Acampora, M. Marfella, R. Giunta, F. D'Onofrio, and D. Giugliano. Department of Geriatrics, Second University of Naples, Naples, Italy.

L-arginine (L-AR) is the natural precursor of nitric oxide (NO). In 20 healthy subjects (age range 20 to 37 yrs), mean blood pressure (MBP) fall to graded iv bolus (1 to 5 g) of L-AR was maximal with the 3 g dose (7.6±1.3 mmHg, m±SD). D-arginine, which is not used as substrate for NO synthase, did not change MBP or platelet activity; L-NMMA (6 mg/min), an inhibitor of NO synthase, reduced by 70% the MBP fall and the antiplatelt effect seen after L-AR. In the whole population of healthy subjects (n=52, 20 to 89 yrs), there was an inverse relation between age and MBP ($r=-0.88$) or platelet aggregation ($r=-0.69$, $p<0.001$) changes after L-AR. The MBP decrease after L-AR was lower in 20 NIDDM patients (47±7 yrs) than in 20 matched controls (-2.2±1.8 vs -4.8±1.2 mmHg, $p<0.01$). There was an inverse relation between hemoglobin A1c and both the MBP fall ($r=-0.40$) and the platelet aggregation response ($r=-0.52$, $p<0.01$) to L-AR. Treatment with vitamin E (600 mg/day per os) or glutathione (1200 mg/day im) for one month ameliorated the endothelial dysfunction seen in NIDDM patients. L-arginine test (3 g iv bolus) may be a simple tool to assess both the endothelial control of systemic vasodilation and platelet activity in human diabetes and the effect of interventions.

EFFECTS OF GLUCAGON ADMINISTRATION ON MICROCIRCULATION IN DIABETES

R. KOMATSU, N. TSUSHIMA and T. MATSUYAMA
Department of Internal Medicine, National Cardiovascular Center Hospital, Osaka, JAPAN

Microcirculation is very important for metabolism and gas exchange in tissue, and microvascular diseases are characteristic complications in patients with diabetes mellitus. It has been reported that some rheologic abnormalities are associated with diabetes. However it is difficult to realize the condition of microcirculation in men. We developed an intravital video-microscopic system (IVVMS) to observe microcirculation directly on the bulbar conjunctiva. Using this system, we investigated the effect of intravenous glucagon administration on microcirculatory parameters such as the internal diameter of venules, flow velocity and flow volumes in diabetic patients. Blood viscosity and rheology factors were also examined before and after glucagon administration. Plasma glucose, insulin, C-peptide and cyclic-AMP were increased after glucagon administration. The time required for erythrocytes to pass through pores of 5 μm diameter, as well as whole blood and plasma viscosity were decreased significantly after glucagon administration. Flow volumes of venules were increased significantly by glucagon. Leukocyte counts, platelet counts and fibrinogen did not change after glucagon administration. Changes of blood factors, such as improvement of deformability of red blood cell or decreased viscosity, were considered to cause increase in the blood flow. In conclusion, glucagon administration improved blood fluidity and modified the microcirculation in patients with diabetes mellitus.

Insulin and Vasopressin Induce Vascular Endothelial Growth Factor on Human Vascular Smooth Muscle Cells

Y. OKUDA, K. TSURUMARU, M. ASANO, Y. ASAKURA, S. YATOH, H. SONE, S. SUZUKI, Y. KAWAKAMI, H. SUZUKI*, K. YAMASHITA,
Inst. of Clin. Med., Univ. of Tsukuba. *Tsukuba Res Toagosei Co., Tsukuba, JAPAN

Vascular endothelial growth factor (VEGF) is a secreted mitogen for vascular endothelial cells, and it promotes neovascularization. We investigated how low oxygentension, pancreatic hormones and vasoactivators could modulate the expression and production of VEGF in human aortic vascular smooth muscle cells (SMC). Human SMC were established from a piece of aorta obtained from non-atherogenic adult human. Hypoxic conditions were induced using the BBL Gas Pak Plus system at 37℃. RNAs were prepared by guanidine isothiocyanate solubilization and centrifugation over aCsCl cushion. Ten μg of total RNA was subjected to Northern blot analysis. Medium VEGF levels were measured by our newly developed high sensitive enzyme-linked immunosorbent assay (ELISA). Using rabbit anit-human VEGF/VPF polyclonal antibody for both capture (solid) and secondary (enzyme-labeled) antibodies. Hypoxia (0%O_2) and Cobalt (10^{-4}M) resulted in substantial induction of VEGF transcripts at 24 hr (each, × 2.4 fold). The VEGF production was significantly ($P< 0.05$) elevated (496±18~767±5 pg/ml) by 24h-exposure to insulin (10^{-6}M). But glucagon (10^{-6}M) did not elevate VEGF production. In addition, vasopressin (AVP) significantly stimulated the production of VEGF in a concentration- dependent manner (10^{-6}~10^{-10}M).

Our findings suggest that insulin and AVP may play a important role for vascular remodelling by up-regulating VEGF levels of SMC.

1589

Aortic supersensitivity to vasoconstrictor action of phenylephrine in Zucker diabetic fatty (ZDF) rats.

L. Caputo, T.N. Luong, F. Contard and D. Guerrier. LIPHA CRD, Lyon, France.

The Zucker diabetic fatty (ZDF) male rat is a rodent model of NIDDM, which is characterized by early spontaneous development of hyperglycaemia, hyperinsulinemia and insulin resistance. In the present work, we studied the relationship between lipid profile, glucose level, microscopal vascular morphology and arterial reactivity in male ZDF rats and their lean normal male littermates at age 12 weeks. Arterial responsiveness to vasoactive agents was tested on isolated thoracic aortic ring segments. The ZDF rats were significantly obese at 12 wks of age and weighted 12% more than the lean control animals. The obese ZDF rats were also hyperglycaemic (33.03±1.2 vs 10.09±0.14 mM, $p<0.001$) and hyperlipidemic (triglycerides, 6.52±0.68 vs 1.38±0.09 mM, $p<0.001$; cholesterol, 4.65±0.08 vs 2.28±0.03 mM, $p<0.001$; HDL, 3.11±0.09 vs 1.71±0.06 mM, $p<0.001$; free fatty acids, 0.67±0.04 vs 0.4±0.02 mM, $p<0.001$, in ZDF and lean rats, respectively). No morphological alteration of the aortic wall in both lean and ZDF rats was observed. In isolated aortic rings, there was no difference in the acetylcholine induced endothelium-dependent vasodilation between ZDF and lean control rats. In contrast, the contractile capacity of the aorta in response to phenylephrine (PE) was increased: the concentration response curve was shifted to the left in diabetic animals (ED50: lean rats, 0.26 μM, n=6 versus ZDF rats 0.02 μM, n=7, $p<0.001$). The maximum response to PE was also enhanced in aortic rings from ZDF rats (28%±8.54, $p<0.001$). The overall results indicate that prolonged hyperglycaemia in insulin-resistant 12 wks old rats does not impair aortic endothelial-dependent dilation, but enhances vasoconstrictor responses to PE, exhibiting a change in both sensitivity (decrease in ED50) and responsiveness (increase in maximum response). The aortic supersensitivity to PE could precede endothelial dysfonction and vascular morphological alterations described in type 2 diabetes with macrovascular complications.

MICROCIRCULATORY EFFECTS OF HYPERGLYCEMIC SPIKE IN HEALTHY SUBJECTS AND DIABETIC PATIENTS.

C. LE DEVEHAT[1]; T. KHODABANDEHLOU[2]; H. ZHAO[3], M. VIMEUX[1]
[1]Service de Diabétologie,Endocrinologie,Nutrition, Centre Hospitalier 58000 NEVERS France - [2]Unité de Recherches d'Hémorhéologie Clinique, Centre Hospitalier 58000 NEVERS France

The present work aimed to assess the direct and immediate effects of acute hyperglycemia on cutaneous blood flux and tissue oxygenation in 10 insulin dependent diabetic (IDDM) patients and 5 healthy control subjects. Investigations were performed by means of GCIIS Biostator allowing the control of blood glucose level. In fact, blood glucose level was first normalized (<1 10 g/l), then increased to a value within 2.5 g/l and 3.0 g/l and maintained at this value during 1 hour. Microcirculatory cutaneous blood flux and vasomotion amplitude and frequency were measured by a laser doppler fluxmeter (PF4 Perimed, Sweden) on the dorsum of the big toe at skin temperature before, during and after an arterial occlusion (200 mmHg during 3 minutes), during both normoglycemia and hyperglycemia. The transcutaneous oxygen pressure (TcPO2) was measured at the same time by an Oxymonitor SM 361 (Hellige, France) on the first intermetatarsal space on the dorsum of the foot heated at 44°C Acute hyperglycemia resulted in an increase in microcirculatory basal flux and vasomotion in IDD patients. The increase persisted despite normalization of the glycemia No change was observed in control subjects.

At normoglycemia, IDDM patients showed an increased duration of reactive hyperaemia, which was further increased as a result of the acute hyperglycemia. Furthermore, acute hyperglycemia was accompanied by a decrease in TcPO2 in IDDM patients. It is concluded that the acute hyperglycemia leads to functional microcirculatory alterations in IDDM patients.

1591

PREGNANCY INDUCED IMPROVEMENT IN VASCULAR FUNCTION PERSISTS POSTPARTUM BUT IS REVERSED BY A HIGH FAT DIET

E. Koukkou[a], R. Gerber[b], L. Poston[b], C. Lowy[a].
Department of Endocrinology and Diabetes[a] and Department of Obstetrics and Gynaecology, Fetal Health Research Lab[b], St Thomas' Hospital, UMDS, London, UK.

Diabetes and dyslipidaemia are both associated with vascular endothelial dysfunction while female sex hormones, particularly oestradiol, are considered protective of the endothelium. We have recently shown that pregnancy protects against vascular endothelial dysfunction in diabetic rats. We have now determined whether pregnancy induced changes persist in the puerperium and if they are compromised by a high saturated fat diet. Mesenteric small arteries were mounted on a small vessel myograph from the following five groups: control, STZ diabetics fed breeding diet and STZ diabetic rats fed high saturated fat diet (16 days post partum) and virgin diabetic or virgin control rats. Endothelial function, assessed by acetylcholine (Ach) induced relaxation, was abnormal in virgin diabetic rats compared with virgin controls (77±5% reduction of noradrenaline-induced constriction, n=6 v 90±3% n=13, $p<0.01$). In the diabetic rats on breeding diet postpartum the ACh induced relaxation (94±6%, n=7) was similar to both post partum controls (92±3%, n=12) and to virgin controls. However post partum diabetic on a high fat diet had similar ACh responses to virgin diabetic rats (70±7%, n=4). Thus, the protective effect of pregnancy persists post partum, but is abolished in animals on high fat diet.

PLASMINOGEN ACTIVATOR INHIBITOR-1 ACTIVITY AND INSULIN RESISTANCE IN 70-YEAR OLD MEN

L. Byberg, A. Siegbahn*, R. Reneland, H. Lithell. Departments of Geriatrics and Clinical Chemistry*, Uppsala University, Uppsala, Sweden.

Increased levels of plasminogen activator inhibitor-1 (PAI-1) has been discussed as a part of the insulin resistance syndrome and has been suggested to be the link between insulin resistance and cardiovascular disease. It is however not clear whether the relationship between PAI-1 and insulin resistance is independent or mediated by increased triglycerides levels. The aim of this study was to investigate if PAI-1 activity is associated with insulin sensitivity independent of serum triglycerides (sTG) and of potential confounders. 871 men aged around 70, participants of a cohort study undergoing extensive metabolic investigations, had blood samples taken for determination of PAI-1 activity. Insulin sensitivity was determined by the euglycemic hyperinsulinemic clamp procedure. In multivariate correlation and regression analyses, insulin sensitivity was a statistically significant determinant of PAI-1 activity (partial r=-0.14; p<0.001), independent of sTG, BMI, waist-hip ratio (WHR), systolic and diastolic blood pressure (BP), and treatment with lipid- and BP-lowering drugs. Levels of sTG was also independently related to PAI-1 activity (partial r=0.17; p<0.001). The relationships between PAI-1 and insulin sensitivity and sTG were not changed by fasting glucose levels. Men with IGT and NIDDM (prevalence: 13 and 15%, respectively) had higher PAI-1 activity than men with NGT, also after adjustment for insulin sensitivity, sTG, BMI, WHR, blood pressure, medications, and fasting glucose. Increasing number of risk factors associated with the insulin resistance syndrome increased the activity of PAI-1 in men with NGT. The odds ratio for having angina pectoris (prevalence: 14%) was 1.42 (p<0.001) for each increase of one standard deviation in PAI-1 activity. We conclude that PAI-1 activity is related to insulin sensitivity and serum triglycerides, independent of each other and of other potential confounders, and that incresed levels of PAI-1 should be regarded as a component of the insulin resistance syndrome.

1593

EVALUATION OF HYPERCOAGULABLE STATE IN DIABETIC SUBJECTS WITH AND WITHOUT RETINOPATHY

A. Sobol, Laboratory of Haemostatic Disorders, Diagnostics Dept., Medical University of Łódź, Łódź, Poland.

The significance of haemostatic abnormalities in the pathogenesis of diabetic retinopathy is not clear. The aim of this study was to evaluate the potential hallmarks of hypercoagulable state in insulin dependent (IDDM) diabetics. The study was carried out in 50 well-controlled diabetics (aged 33.3±9.4 yrs) divided into: group A (22 patients with retinopathy; 12 M and 10 F; mean duration of diabetes 13.6±7.0 yrs) and group B (28 patients without any diabetic complications, 16 M and 12 F, mean duration of diabetes 5.4±1.3 yrs). Apart from that, a randomized group of 25 IDDM patients have been examined as a group C (aged 35.8±7.5, 7 M and 18 F, mean duration of diabetes 9.9 ± 5.0 yrs). The control group consisted of 22 well-matched healthy individuals (aged 32.3±5.2 yrs). All the subjects had the platelet count, activated partial thromboplastin time (APTT), prothrombin time, fibrinogen, euglobulin clot lysis time before and after venous occlusion, activity of antithrombin III (ATIII), the level of thrombin-antithrombin III complexes (TAT), D-dimers, fibrin(ogen) degradation products (FDP) plasma concentrations assessed. Results: There was no significant difference between the patients from group A or B. All diabetic patients (group A+B) showed significantly increased platelet count (353,800±112,100 vs 253,000±44,000/mm^3 in controls; p<0.001), poor fibrinolytic response to venous occlusion (114.3±60.5 vs 43.0±18.0 min in controls; p<0.001). Other haemostatic parameters in diabetic patients did not differ significantly from the controls. Patients from group C revealed significant elevation in plasma fibrinogen concentration compared to groups A and B, and the controls (333.4±103.4 vs 253.2±65.0 in groups A and B, and vs 263.0±32.0 mg/dl in controls; p<0.01). In conclusion, patients with well-controlled IDDM showed no symptoms of hypercoagulability, whether they had retinopathy or not. Therefore, it is possible that diabetic retinopathy is not always associated with hypercoagulable state. The results may encourage the revision of the views on the pathogenesis and treatment of diabetic retinopathy.

1594

NO IMPROVEMENT IN FIBRINOLYSIS AFTER STARTING INSULIN TREATMENT IN NIDDM PATIENTS WITH INSUFFICIENT GLYCAEMIC CONTROL.

J.W. van der Beek-Boter, P.H.E.M. de Meijer, C. Kluft*, A.E. Meinders. Department of General Internal Medicine, Leiden University Hospital and *Gaubius Laboratory TNO-PG, Leiden, The Netherlands.

Fibrinolytic activity is reduced in non-insulin-dependent diabetes mellitus (NIDDM). Since disturbances in fibrinolysis are important in the pathogenesis of cardiovascular disease, this reduction might be responsible for the increased cardiovascular risk in NIDDM patients. The aim of our study was to assess fibrinolysis in NIDDM patients with poor glycaemic control and to investigate if a relation with improved control during insulin could be found. Seventeen NIDDM patients (10 F, 7 M, age 60.0 ± 11.2 y, diabetes duration 10.6 ± 6.6 y) with insufficient control during maximum sulphonylurea were treated with insulin. Variables of glycaemic control (HbA1c and fasting blood glucose) were collected before and after six months of insulin treatment, as were variables of fibrinolysis (plasminogen activator inhibitor 1 (PAI-1), tissue type plasminogen activator (t-PA) antigen, t-PA activity and Von Willebrand factor (VWF)). Fasting blood glucose decreased from 13.7 ± 2.0 (SEM) to 9.9 ± 0.8 mmol/l (p=0.001), HbA1c from 10.3 ± 0.3 to 8.6 ± 0.2% (p<0.0001). Body weight increased from 77.6 ± 4.6 to 82.0 ± 4.9 kg (p<0.0001), body mass index (BMI) from 27.4 ± 1.4 to 29.4 ± 1.4 kg/m^2 (p<0.0001). At baseline PAI-1 was positively correlated with body weight (r=0.39, p=0.04) and BMI (r=0.41, p=0.03); changes in these variables were not correlated with changes in PAI-1. PAI-1 was negatively correlated with tPA-activity at baseline (r=-0.71, p<0.0001) and after insulin (r=-0.75, p<0.001) and positively with t-PA antigen (r=0.46, p=0.01 and r= 0.57, p=0.02, respectively). Fibrinolysis variables did not improve: PAI-1 65.7 ± 9.4 to 55.7 ± 9.7 ng/ml, t-PA antigen 13.5 ± 1.4 to 13.1 ± 1.4 ng/ml and t-PA activity 0.58 ± 0.11 to 0.75 ± 0.12 IU/ml (all NS). VWF, however, increased from 148.2 ± 10.9 to 161.9 ± 13.4% (p=0.005).

Conclusion: Our results did not show an improvement in fibrinolysis during insulin treatment, despite a significant improvement in glycaemic control.

1595

FIBRINOGEN IN TYPE II DIABETES: CORRELATION WITH METABOLIC CONTROL. EFFECT OF BEZAFIBRATE.

J. Libman, M. Polenta, G. Bessone and A. M. Libman. University of Rosario, Rosario, Argentina.

Different studies have shown a strong and independent relation between fibrinogen (F) levels and the incidence of arterial disease (AD), that is more severe and frequent in DM. This study was performed in order to measure F (immunoturbidimetric method) in patients with NIDDM (N = 104, AGE 54±8, 45 M and 59 F) and in controls (C) (N = 82, AGE 57±7, 35 M and 47 F), assess its relationship with metabolic control (MC) and other risk factors and the effect of Bezafibrate (BZ). ANOVA and multiple regression were used for statistical analysis. Significant differences were observed between C and NIDDM with and without AD (249.8 ± 39.5 vs. 319.4 ± 41.6 vs 285.7 ± 46.2 mgs/dl, p<0.01). Multivariate analysis with F as dependent variable showed that age, BMI, fructosamine, HbA1, LDL and TGC contributed to the regression, with a stronger relation for the group with AD (R^2 = 0.41) than without AD (R^2 = 0.27). BZ (N = 24) lowered F from 301.5 ± 37.8 to 255.4 ± 30.6 mgs (p<0.01) It is concluded that F increases in NIDDM, even more in the presence of AD, that it is influenced by MC and may decrease with BZ.

1596

INTERCELLULAR ADHESION MOLECULE -1 AS A PREDICTOR OF VASCULAR COMPLICATIONS IN DIABETES MELLITUS

[a]EB Jude, [a]MJ Young, [a]CA Abbott, [b]J Bennett, [b]R Aboygunratne, [b]JT Douglas, [a]AJM Boulton
[a]Department of Medicine/Diabetes and [b]Department of Vascular Biology, Manchester Royal Infirmary, Oxford Road, Manchester, U.K.

Diabetes mellitus has been described as a metabolic syndrome with vascular atherothrombosis being an important complication. Increased levels of soluble intercellular adhesion molecule - 1 (sICAM-1) have been described in diabetes mellitus (DM). We compared sICAM-1 levels in 36 patients (17 IDDM, 19 NIDDM; 20 males, 16 females) with 24 age matched controls (C). All diabetic patients were then followed up over a five year period for development of vascular complications (coronary, cerebral and peripheral) which occurred in 11 patients (B) (6 coronary, 3 cerebral, 2 peripheral vacular disease). sICAM-1 levels at baseline were significantly elevated in patients who later developed atherothrombosis (299 $\pm$ 32.9 ng/ml) compared to patients without manifest vacular disease (A) (243 $\pm$ 58.2 ng/ml) ($p<0.005$). sICAM-1 levels in A vs C was not significant. At 5 year follow-up the sICAM-1 levels were still significantly elevated in A vs B (361 $\pm$ 88.2 ng/ml vs 435 $\pm$ 92.7 ng/ml; $p=0.001$).There was no difference between diabetic groups for HbA1c and cholesterol and sICAM-1 levels between C and IDDM and NIDDM at baseline. . This study thus shows that diabetic patients with elevated sICAM-1 levels are more prone to develop vascular complications and possible future therapy could be targetted against sICAM-1.

1597

INCREASED FIBRINOGEN SYNTHESIS IN TYPE 2 DIABETES MELLITUS WITHOUT VASCULAR COMPLICATIONS.

R. Barazzoni, M. Zanetti, G. Davanzo, M. Vettore, E. Kiwanuka, P. Carraro*, A. Tiengo, and P. Tessari. *Dept. of Metabolic Diseases and *Dept. of Laboratory Medicine, University of Padova, Italy.*

Whether fibrinogen synthesis is increased in non insulin-dependent diabetes (NIDDM), even without micro- and macrovascular complications, is not known. Therefore, we have measured fibrinogen fractional (FSR) and absolute (ASR) synthetic rates in 6 male NIDDM patients (age: 45 ± 5 yrs [mean $\pm$ SE]; duration of disease: 11 ± 3 yrs; HbA_1c: $10.1 \pm 1\%$) under spontaneous hyperglycemia after the overnight fast, and in 7 controls (C, 6M/1F), matched for age, physical activity, alcohol and smoking habits (all subjects non-smokers). FSR was determined using a precursor-product model with i.v. radioactive leucine infusion. ASR was calculated from FSR, measured plasma fibrinogen concentration and estimated plasma volume. Absence of micro- and macrovascular complications was assessed with clinical, instrumental and laboratory data. NIDDM subjects had slightly increased BMI, mean blood pressure (MBP) and triglycerides (TG) (BMI: 28.4 ± 2.2 vs 23.1 ± 0.4 kg/m^2, $p=0.03$; MBP: 105 ± 3 vs 97 ± 2 mm Hg, $p=0.04$; TG: 165 ± 31 vs 90 ± 14 mg/dl, $p=0.04$ vs C). Plasma glucose (10.3 ± 1.1 vs 5 ± 0.2 mM/liter, $p<0.01$), insulin (15 ± 2 vs 8 ± 1 μU/ml, $p<0.05$) and C-peptide (1.8 ± 0.3 vs 1.2 ± 0.1 ng/ml, $p<0.05$) were higher in NIDDM. Fibrinogen concentration was $\approx 40\%$ greater in NIDDM (270 ± 28 vs 197 ± 14 mg/dl, $p=0.034$), while FSR was comparable in the two groups (21.9 ± 3.6 vs $18.2 \pm 2.6\%$ per day, NS). In contrast, fibrinogen ASR was markedly increased in NIDDM, by $\approx 80\%$ (1847 ± 362 vs 1020 ± 153 mg per day, $p=0.048$). In summary, NIDDM patients without vascular complications have increased plasma fibrinogen levels and synthetic rates, in spite of normal FSR, suggesting that plasma levels may not accurately reflect the extent of fibrinogen altered turnover in NIDDM.

1598

LIPID PEROXIDATION OF LDL MODULATES PLATELET ADHESION AND PLATELET RELEASE REACTION IN TYPE 2 DIABETIC PATIENTS

Watala C[1], Boncler MA[1], Trojanowski Z[2], Gwoździński K[3] and Baj Z[4] [1]*Laboratory of Haemostatic Disorders,* [2]*2nd Clinic of Internal Diseases and* [4]*Department of Pathophysiology, WAM Łódź, and* [3]*Department of Molecular Biophysics, University of Łódź, Poland*

Nonenzymatic glycosylation of platelet membrane proteins and the interactions of platelets with nonenzymatically modified lipoproteins have been suggested to underlie the altered expression of platelet membrane receptors and platelet hypersensitivity in diabetic subjects. We monitored the associations between the expression of selected platelet membrane glycoproteins and the formation of reactive oxygen species in platelet membranes, the content of lipid peroxides in plasma LDL, membrane fluidity and the glycation of LDL and membrane proteins. We revealed that: 1/ the expressions of GPIIb-IIIa and GMP-140 were significantly enhanced in circulating platelets (resp., $p<0.035$ and $p< 0.01$ *vs.* platelets of control subjects), whereas that of GPIb was depressed (by 23%) in diabetic patients, 2/ these changes were paralleled by the significant increases of platelet aggregates and microparticles in diabetic individuals ($p< 0.025$ or less). Platelet membrane fluidity was reduced ($p< 0.02$), whereas the glycation of membrane proteins, and LDL apo-B, and the content of LDL lipid peroxides increased in diabetics ($p< 0.035$ *or less*). The generation of reactive oxygen species was increased in diabetic platelets ($p< 0.04$), especially in platelets treated with phorbol myristate acetate under *in vitro* conditions ($p< 0.005$). When control platelets were incubated in serologically-matched diabetic plasmas the expressions of platelet membrane receptors changed according to the impairments observed in diabetic circulating platelets, and such an activation of control platelets following their incubation in diabetic plasma was accompanied by their reduced membrane lipid fluidity ($p< 0.02$). The generation of reactive oxygen species in the incubated control platelets was slightly enhanced on average, and correlated with LDL peroxidation in diabetic plasma. We conclude that the glycation of membrane proteins and the interactions of plasma lipoproteins with blood platelets may coincide in affecting platelet function in diabetic patients. The altered structure of platelet membrane-associated components might result in the impaired metabolism of platelet arachidonate and lead to the augmented formation of reactive oxygen species in platelet membranes. Overall, the resulting augmented platelet activation and the accelerated release of platelet membrane microvesicles might underlie the reduced membrane lipid fluidity, and consequently the altered expression of platelet membrane receptors in diabetes mellitus.

1599

EFFECTS OF METABOLIC CONTROL ON FASTING AND POST-MEAL FIBRINOGEN FRACTIONAL SECRETION RATE (FSR) IN IDDM.

P. Tessari, M. Zanetti, M. Vettore, E. Iori, D. Bruttomesso, R. Barazzoni. *Dept. of Metabolic Diseases, University of Padova, Italy.*

Fibrinogen, a liver-synthetized, acute-phase protein which plays a key role in thrombus formation, is often increased in poorly controlled diabetes. Recently, isotope-determined fibrinogen FSR was found to be stimulated by acute insulin-deficiency in IDDM subjects, while it was decreased by insulin infusion in both IDDM and normal subjects. However, whether a good glycemic control can normalize fibrinogen FSR in IDDM also following a meal, is unknown. Therefore, we have studied fibrinogen FSR in five IDDM patients (age: 35 ± 6 yrs; BMI: 23 ± 1 Kg/m^2; sex: 4M/1F) infused overnight with insulin to maintain blood glucose at $\approx$euglycemic values (≈ 120 mg/dl) and in 6-10 controls (age: 32 ± 4; BMI: 24 ± 1 Kg/m^2; sex: 8M/2F). All subjects were free of clinical and laboratory signs of either micro- or marco-angiopathy, and were not smokers. The subjects were studied both in the postabsorptive state and following the continuous administration of a mixed meal (≈ 11 Kcal/Kg over ≈ 4 hours). FSR was calculated at steady-state using precursor-product relationships with i.v. radioactive phenylalanine tracers, and estimated intrahepatic phenylalanine SA as precursor pool. In the fasting state, fibrinogen FSR was comparable in IDDM (18.2 ± 1.2 percent per day) and controls ($n=10$) (18.4 ± 3.9). During the meal, the IDDM subjects were infused with stepwise i.v. insulin to maintain blood glucose below ≈ 170 mg/dl. Post-prandial fibrinogen FSR tended to increase in both groups ($p<0.05$ by ANOVA), but it was not different between IDDM (25.3 ± 4.5 percent per day) and controls ($n=5$) (36 ± 8.6). In conclusion, a near normal glycemic control achieved by i.v. insulin is capable to normalize fasting fibrinogen FSR in IDDM. Meal ingestion may be associated with increased fibrinogen FSR, which is maintained at normal values in IDDM by physiologic insulin infusion.

INCREASED BLOOD LEVELS OF PLATELET-ACTIVATING FACTOR IN INSULIN-DEPENDENT DIABETIC PATIENTS WITH MICROALBUMINURIA.

Gruden G, Olivetti C, Montrucchio G, Lupia.E, Camussi G, Cavallo-Perin P.

Platelet-activating factor (PAF) has potent vaso- and glomerular permeability properties, in experimental animals. In the present study we evaluated the intravascular levels of PAF and of its main catabolic enzyme, the PAF-specific plasma acetyl-hydrolase, in basal conditions and after exercise in normo- or microalbuminuric insulin-dependent diabetic (IDD) patients and in normal subjects. In addition, we studied the responsiveness of platelets in platelet-rich plasma to PAF and ADP. The results indicate that the concentration of PAF in whole blood was significantly increased in basal conditions, during and after the exercise in microalbuminuric, but not in normoalbuminuric IDD patients or in controls ($p=<0.05$). In microalbuminuric IDD patients, the levels of PAF correlated with the albumin excretion rate (pre-exercise $r=0.71$ $p=0.000$, exercise $r=0.64$ $p=0.001$, post-exercise $r=0.55$ $p=0.007$). The exercise induced an hyper-responsiveness of platelets to PAF and ADP in both normoalbuminuric IDD patients and controls. The hyper-responsiveness of platelets to ADP was abrogated by a PAF receptor antagonist, suggesting an endogenous synthesis of PAF within platelets. In contrast, an hypo-responsiveness of platelets to PAF was found in microalbuminuric IDD patients undergoing exercise, suggesting an "in vivo" desensitization of platelets to PAF. These results indicate that the increased production of PAF is associated with an enhanced glomerular permeability in microalbuminuric IDD patients.

1601

DETERMINANTS OF SERUM FIBRINOGEN LEVELS IN MALTESE PATIENTS WITH NIDDM

A. Schranz, J. Tuomilehto, A. Laine and M. Karvonen
St. Luke's Hospital G'Mangia, National Public Health Institute, Helsinki

Serum fibrinogen (FIB) is an independent cardiovascular (CVD) risk factor, and high FIB levels have been reported in NIDDM. The aim of the present study was to determine the FIB levels in 431 Maltese NIDDM patients, and the effect of the age-at-onset (ONS), the duration (DUR) of NIDDM and the glycaemic control (GLY) on FIB. Moreover, we wanted to find out the extent to which the variation in FIB levels in NIDDM patients are related to other CVD risk factors. The mean FIB was 363 µmol/l, the 90th percentile 470, and no sex difference in FIB was found. Overall, the following parameters contributed significantly to the variation in FIB: Age, total cholesterol (CHOL), DUR and waist circumference. In separate models by sex, CHOL was significant in women, and DUR in men. In patients with DUR<6 years only CHOL and serum uric acid were related to FIB, while in patients with ONS<40 years and in normotensive patients age and BMI were related to FIB. In hypertensive NIDDM patients treated with antihypertensives DUR, smoking and CHOL were the strongest predictors of FIB. In obese (BMI≤30) and well-controlled (usual blood glucose <8.2) patients DUR was the most important predictor of FIB. In conclusion, DUR is a major determinant of FIB in NIDDM. Obesity and CHOL are other important predictors, but there seems to be a marked variation in the relationship between FIB and CVD risk factors among various subgroups of NIDDM. These results also suggest that it might be possible keep FIB levels in NIDDM low by healthy life style.

1602

POSSIBLE INVOLVEMENT OF GENETIC FACTOR IN PLATELET RESPONSE ALTERATIONS IN PATIENTS WITH IDDM

[1]H.W.Witas,[1]D.Cedzyńska,[1]M.Różalski,[1]E.Brzezińska,[1]W.Młynarski,
[1]K.Jędrychowska-Dańska,[2]C.Watała and [1]J.Bodalski
[1]Molecular Biology Unit, 2nd Clinic of Children Diseases, Institute of Pediatrics, Medical University of Lodz, Lodz, Poland and [2]Laboratory for Coagulation Disorders, Dept. of Medical Analytics, Medical University of Lodz, Lodz,Poland

Flow cytomertic assay using anti CD41-PE, anti CD61-FITC and anti CD62-PE antibodies (*Becton Dickinson Procedure*) was applied to analyze the value of platelet parameters in 36 IDDM families (45 patients, aged: 13.8±0.6; 65 parents, aged: 41.4±0.8; 17 healthy siblings, aged: 15.5±1.0) and 50 unrelated controls, aged: 10.7±1.0. The following platelet parameters were investigated: %activated platelets, %aggregates, %microparticles, medians of fluorescence intensity of anti CD41-PE, anti CD61-FITC and anti CD62-PE (before and after thrombin activation). We found the activation of platelets in IDDM patients to be elevated comparing to other studied groups. The %activated platelets were as follows: 7.535±2.314 in diabetics; 1.476±0.152 in parents; 1.297±0.204 in siblings and 1.349±0.145 in control subjects. We carried out stepwise discriminant analysis of obtained results. The highest discrepancy was found between IDDM patients and controls ($p=0.000001$) in comparison to IDDM children and their siblings ($p=0.001016$) as well as IDDM patients and their parents ($p=0.008479$). There was no difference between parents and siblings ($p=0.169830$). A control group representing unrelated subjects is particularly well separated from other groups what implies involvement of genetic factor(s) modifying platelet response. For further investigation of putative influence of hereditary factors on platelet features, 16 families with at least one affected and one not affected child (control group was excluded) were chosen for discriminant analysis. Obtained results showed highly marked similarity between IDDM children and parents ($p=0.657803$) while statistically significant separation ($p=0.015581$) between IDDM children and healthy siblings was found. It seems to suggest that similarities observed between IDDM children and their parents result from non-genetic factors (both parents and children as well as siblings share half genes) In conclusion, the data presented above suggest genetic factor(s) contribution in determinig some platelet properties. Age of patient could be the additional factor which strongly affect platelet features.

PLASMA FIBRINOGEN IN A SAMPLE OF INDUSTRIAL POPULATION OF NORTH INDIA

R Lakshmy, P Shah, KS Reddy, All India Inst Med Sci ,New Delhi, India.

Diabetes mellitus is an established risk factor for cardiovascular diseases and part of the increased risk in diabetic patients could be related to enhanced thrombogenic factors like fibrinogen. The aim of the present study was to compare the fibrinogen levels between diabetics and nondiabetics in a nested case control design from an industrial population survey. A total number of 92 subjects were sceened (47 diabetic and 45 non diabetic).

RESULTS: Mean fibrinogen levels was not significantly different in diabetics as compared to non diabetics (2.96 ± 0.463 g/l vs 2.86 ± 0.479g/l). A highly significant positive correlation was observed between fibrinogen and HBA1c levels (r = 0.35, 95% confidence limits : 0.16 < R < 0.52) though no correlation was found between fibrinogen and fasting and postload plasma glucose levels. None of the other variables studied correlated with fibrinogen levels. We did observe a higher fibrinogen levels in current smokers as against exsmokers (2.98 ± 0.48 vs 2.68 ± 0.36 g/l).

CONCLUSION : Plasma fibrinogen levels in an industrial population were studied; there was no difference between diabetic and non-diabetic samples. Fibrinogen levels correlated with HbA1, it did not correlate with the other risk factors for coronary heart disease.

1604

REVERSAL OF ERYTHROCYTE OSMOTIC FRAGILITY WITH VITAMIN E SUPPLEMENTATION IN DIABETICS WITH MICROANGIOPATHY

N. Başçıl, M. Bayraktar, B. Pehlivanoğlu and O. Gedik Department of Endocrinology and Department of Physiology, Hacettepe University Faculty of Medicine, Ankara, TURKEY.

Free radical mechanisms are increasingly being implicated in the pathogenesis of tissue damage in diabetes. Various sources of free radicals may modulate oxidative stress in diabetes, including nonenzymatic glycosylation of proteins and monosaccharide autooxidation, polyol pathway,indirect production of free radicals through cell damage from other causes and reduced antioxidant reserve. The present study was designed to examine the effect of antioxidant vitamin E on osmotic fragility in human diabetic red blood cells. Two groups of noninsulin dependent diabetic patients matched for duration of disease and metabolic control, received daily vitamin E supplementation of 900 mg and placebo, respectively, for 6 months. Fasting plasma glucose and hemoglobin A_1 (Hb A_1), postprandial plasma glucose and erythrocyte fragility tests in the basal state and after 6 months of treatment were measured. In the basal state diabetic patients without microangiopathic complications (n= 8) and control group consisting of healthy people (n= 8) showed no difference in the red blood cell osmotic fragility indices ($p > 0.05$). On the other hand diabetic group with microvascular complications (n= 21) displayed significantly higher ratios ($p < 0.05$) of osmotic fragility indices compared to the uncomplicated diabetics and healthy subjects. Glycemic indices did not show any significant changes during study, whereas erythrocyte osmotic fragility decreased significantly after 6 months in patients on vitamin E supplementation. The decline in osmotic fragility indices were especially prominent at sodium chloride concentrations greater than 0.03 % (p=0.001). This study shows that red blood cell osmotic fragility is increased in diabetic people with microangiopoathic complications and is reversible by antioxidant therapy with vitamin E.

1605

Effect of glycemic control on fibrinogen plasma levels in diabetic subjects. Relationship with β fibrinogen genotype.

F. Mercuri, D. Fabbro, R. Giacomello, G. Stel, C. Taboga, L. Tonutti, G. Damante and A. Ceriello. University of Udine and Udine General Hospital, Udine, Italy.

Recent studies demonstrate that in diabetic subjects an increase of plasma fibrinogen level is associated with a high risk of cardiovascular complications. Either environmental and genetic factors contribute to the plasma fibrinogen level. Several studies indicate a relationship between the polymorphism in the 5' region of the b fibrinogen gene and plasma protein levels. In this study, such kind of relationship was investigated in 25 NIDDM diabetic patients before and after three months of intensive insulin therapy. Hind III polymorphism was evaluated by a PCR-based technique. On the basis of the observed allelic combination, the patients were divided into three groups ($\alpha1\alpha1$: 11, $\alpha1\alpha2$: 9, $\alpha2\alpha2$: 5). After insulin therapy, the improvement of glicemic control was equivalent, in terms of HbA1c, in all the three groups ($\alpha1\alpha1$: from 8.7±0.5 to 6.3±0.4%; $\alpha1\alpha2$: from 9±0.4 to 6.6±0.3%; $\alpha2\alpha2$: from 9.2±0.5 to 6.4±0.3%; M±SD). In all the three groups a fibrinogen reduction was observed. However, this decrease was low in $\alpha1\alpha1$ group (from 327±25.4 to 293.6±21.4 mg/dl, -11%), intermediate in $\alpha1\alpha2$ group (from 377.2±22.4 to 315.2±15.2 mg/dl, -17%), and very evident in the $\alpha2\alpha2$ group (569.6±31.2 to 412.5±22.3 mg/dl, -28%; $p<0.01$ between groups). These results underline a strong relationship between fibrinogen genotypes and glycemic control in determining plasma fibrinogen levels in diabetic patients.

1606

VASCULAR COMPLICATIONS OF DIABETES MELLITUS: ROLE OF ANTIPHOSPHOLIPID ANTIBODIES ?

F. Galtier-Dereure, C. Biron, M. Vies, V. Bourgeois, J.F. Schved and J. Bringer. University Hospital, Montpellier, France.

Risk factors for micro and macro vascular disease in diabetes remain uncompletely elucidated. Antiphospholipid antibodies (APA) are thrombogenic and arterial thrombosis and microangiopathy are described in the APA syndrome. The purpose of this study was to determine the frequency of APA prevalence in diabetic patients according to the presence of micro or macro vascular complications. We studied 141 diabetic patients classified into 3 groups: group I: 53 uncomplicated diabetic patients, type 1 (n=32) or type 2 (n=21); group II: 37 diabetic patients with severe macroangiopathy (n=37); group III: 51 diabetic patients with microangiopathy, either isolated proliferative retinopathy (n=23) or clinical nephropathy (n=28); 22 non diabetic patients served as control. APA were considered present either if lupus anticoagulant was positive (PTTLA and Staclot LA, Diagnostica Stago, Asnieres, France), or if anticardiolipin antibodies IgG or IgM titers were above 15 or 12.5 units/ml respectively (ELISA, quantalite ACA, Inova Diagnostics, San Diego, USA). In group I, the prevalence of APA was comparable to that of control patients (type I diabetes: 9.4%; type 2 diabetes: 9.5%; control group: 4.6%; p=0.76). In group II, the prevalence of APA was significantly higher (32.4%, p=0.006 vs group I). In group III, the prevalence of APA was increased only in patients with clinical nephropathy (32.1%, p=0.015 vs group I), while patients with isolated retinopathy were comparable with group I (4.3%, p=0.66). In a logistic regression analysis, independant risk factor for macroangiopathy were age, HDL cholesterol, Lp(a) and presence of APA. We conclude that uncomplicated diabetes does not appear to be linked with a higher prevalence of APA. However, our results suggest that APA could play a role in the patients'susceptibility to complications and promote the occurence of diabetic macroangiopathy and/or nephropathy.

1607

The relationship of arterial blood pressure values with body mass index , viscosity, fibrinogen and microalbuminuria in children with IDDM.

K.Püşüroğlu, A.Aydın, C.Fıçıcıoğlu, M. Ercan,E.Adal,F.Koca .University of İstanbul,Cerrahpaşa Medical Faculty, Dept. of Pediatrics, İstanbul ,Turkey.

Arterial diastolic and systolic pressures were measured in a group of 46 type 1 diabetic patients -27 females, 19 males- whose mean age was 12±2.8 years (range:6-16 years), duration of diabetes 4±3 years (range:0.2-2years) , and glycosylated haemoglobin value was 7.35±1.4% .The results were compared to those of two groups comprised of 29 healthy children and 32 healthy obese children . Furthermore , the relationship of systolic and diastolic blood pressure levels in diabetic children with biochemical factors (blood , plasma and serum viscosities; total protein, albumin globulin, fibrinogen , haptoglobulin, triglyceride ,HDL,LDL,VLDL values) , urinary albumin excretion and body mass index (BMI) was studied.

1. In diabetic children , despite short duration of illness and good metabolic control , systolic (109±13 mmHg) and diastolic (74.3±9.5 mmHg) pressures of diabetic children were higher than systolic (97.9±10.3 mmHg) and diastolic (66±5.6 mmHg) pressures of healthy children irrespective of age , sex and disease duration ($p<0.05$ and $p<0.01$, respectively).
2. No significant difference was seen between the systolic and diastolic pressure values of diabetic and obese children.
3. In the diabetic group , a positive correlation was found between BMI , viscosity (blood , plasma and serum), total protein, albumin , and fibrinogen values and the systolic and diastolic blood pressures, while no such correlation was present in microalbuminuric levels.

In multiple regression analysis , increase in systolic and diastolic blood pressure levels was found to be most closely associated with BMI , plasma viscosity and fibrinogen.

Conclusion: The mechanism of hypertension in type 1 diabetic patients and obese children may be the same. High BMI , plasma viscosity and fibrinogen levels may be forewarning signs of developing hypertension in type 1 diabetic children.

1608

ANTITHROMBIN III ACTIVITY AND LEVEL OF THROMBINOGENESIS MARKERS WITH RESPECT TO THE DIABETIC RETINOPATHY

E. Kozek, B. Mirkiewicz-Sieradzka* and J. Sieradzki, Depts of Metabolic Diseases & *Ophthalmology, Jagiellonian University, Kraków, Poland

The aim of the study was to measure the activity of antithrombin III (AT III) and concentrations of prothrombin fragments (F1+2), thrombin-antithrombin III complex (TAT) and D-Dimer in patients with IDDM and NIDDM, and varying severity of diabetic retinopathy (R). The study population consisted of 89 patients (47 IDDM, 27 NIDDM, 15 controls) AT III was determined by using Chromo Time System, whereas F1+2 and D-Dimer with the ELISA method. Ophthalmoscopy with a photograph of the eye fundus was performed, and classification of retinal changes was based upon angiography. In IDDM a significantly decreased AT III was seen in nonproliferative mild R as compared with preproliferative R (mean 101.19, SE 5.46% and mean 136.96, SE 8.10%; p<0 05). D-Dimer was significantly increased in preproliferative R as compared with nonproliferative R (mean 11.84, SE 1.06 ug/l and mean 10.65, SE 0.31 ug/l; p<0.05) and patients without retinopathy (mean 11.18, SE 0.54 ug/l; p<0.05). In NIDDM a significant increase was observed in F1+2 in proliferative R as compared with nonproliferative R (mean 3.41, SE 0.86 nmol/l and mean 1 18, SE 0.35 nmol/l; p<0.05). TAT was significantly increased in proliferative R as compared with nonproliferative R (mean 31 05, SE 16.28 ug/l and mean 6.17, SE 3.12 ug/l; p<0.05) and patients without retinopathy (mean 8.91, SE 6.42 ug/l, p<0.05). The present study demonstrates differences in the thrombophilia pattern in IDDM vs. NIDDM. In IDDM with nonproliferative R the decreased AT III may indicate thrombophilia as well as increased D-Dimer in IDDM with proliferative R. In NIDDM the markers of thrombophilia may be: increased F 1+2 and TAT.

1609

HAEMORHEOLOGIC DETERMINANTS OF BLOOD PRESSURE REGULATION IN OBESE NIDDM WITH HYPERINSULINAEMIA.

M.Fioravanti,N.Cerutti,S.Severgnini,M.Locatelli,N.Schifino, E.Ferrari and S.B.Solerte ,Department of Internal Medicine University of Pavia,Piazza Borromeo 2,27100 Pavia(Italy)

Hyperinsulinaemia may be related to hypertension and obesity in NIDDM and might alter arterial blood pressure regulation by means of several haemorheological modifications. In 59 obese NIDDM(BMI>30 kg/m^2),systolic(SBP)and diastolic(DBP) blood pressure levels were determined together with fasting and post-prandial serum insulin(FSI and PPSI:RIA procedure), erythrocyte deformability(ED:filtration),blood viscosity(BV at 1,200,1/200 shear-rate x1/s,HAAKE Rotovisco CV100),fibrinogen(FG:nephelometry)and urinary albumin(UAER:nephelometry). Higher FSI(mean±SD:251±67 pmol/L),PPSI(1106±202 pmol/L),BV (19.7±2 mPas at SR 1x1/s and 4.38±0.15 mPas at 200x1/s)and FG(459±68 mg/dL),and lower ED(1.87± 1.21 mL/min)were found in obese NIDDM than in non-obese NIDDM(p<0.001)and in healthy subjects(p<0.001).Significant correlations among FSI, PPSI and haemorheologic parameters(p<0.01 vs BV,p<0.001 vs ED)were found in these patients.Moreover,increased BV and FG levels and reduced ED significantly correlated with DBP. A significant increase of UAER was found in obese NIDDM with blood rheology alterations(145±33 ug/min),in comparison with non-obese NIDDM(39±11 ug/min,p<0.001)and healthy subjects (6.5±3 ug/min,p<0.001). Hyperinsulinaemia may determine haemorheological disturbances linked to blood pressure alterations in obese NIDDM.The haemorheologic mechanism of hypertension in NIDDM obese can represent a high risk factor.

1610

A PROTHROMBOTIC STATE AS A RISK FACTOR PROMOTING VASCULAR DISEASE IN IDDM AND NIDDM PATIENTS.

B. Telejko, A. Zonenberg, I. Borejszo and I. Kinalska. Department of Endocrinology, Medical School Białystok, Poland.

A disturbed balance between coagulation and fibrynolysis is a proposed risk factor for accelerated atherosclerosis and vascular complications in NIDDM patients. Its role in type I diabetes remains unclear. Therefore the aim of the study was to estimate selected parameters of hemostasis and fibrinolysis in both types of diabetes. The investigation was carried out in 23 IDDM patients aged 33.7 ± 11.5 ys, in 25 NIDDM patients aged 55.4 ± 8.3 ys and in 38 healthy subjects: 16 „young" - aged 32.5 ± 13.2 ys and 22 „old" - aged 56.2 ± 9.4 ys. In all persons fibrinogen, plasminogen activator inhibitor (PAI-1) activity, glycemia, HbA1c and microalbuminuria were determined. Plasma fibrinogen concentration was elevated in NIDDM subjects (390.33 ± 109.03 mg/100ml vs 331.04 ± 91.73 mg/100ml in „old" controls), and the highest levels were noted in overweight persons (BMI > 28 kg/m^2) - 403.06 ± 105.59 mg/100ml and in the group with diabetic neuropathy, retinopathy or arterial hypertension (435.92 ± 116.89 mg/100ml vs 336.45 ± 71.07 mg/100ml, p<0.05). Surprisingly, similar levels were found in IDDM subjects with nephropathy (412.0 ± 82.09 mg/100 ml, p<0.05) and coronary vascular disease (CVD) - 401.6 ± 130.79 mg/100ml vs 307.88 ± 69.19 mg/100ml, p<0.05. There were also positive correlations between fibrinogen level and systolic blood pressure (r=0.3413, p<0.02), diastolic blood pressure (r=0.3809, p<0.002) and microalbuminuria (r=0.3552, p<0.05). PAI-1 activity was slightly higher in IDDM patients than in the other groups (19.28 ± 11.9 Au/ml in IDDM and 17.34 ± 11.77 Au/ml in NIDDM vs 14.62 ± 13.2 Au/ml in „young" and 17.53 ± 13.46 Au/ml in „old" healthy population). This increase was mostly pronounced in patients with type I diabetes complicated with neuropathy (25.95 ± 7.21 Au/ml), nephropathy (32.5 ± 3.87 Au/ml, p<0.02) and CVD (26.0 ± 7.0 Au/ml). These changes were not so evident in NIDDM subjects. Surprisingly, the highest activity of PAI-1 was found in overweight controls (28.87 ± 6.24 Au/ml, p<0.002). It would seem that obesity and insulin dependent diabetes are the factors also connected with the risk of a prothrombotic state - accelerating atherosclerosis and triggering vascular complications.

1611

NID DIABETES ASSOCIATED TO HYPERTENSION DETERMINES THE RELATIONSHIP BETWEEN PAI-1 AND Lp(a) PLASMA LEVELS

[1]R. Testa, [1]A.R. Bonfigli, [2]C. Pieri, [2]M. Marra, [3]C. Sirolla, [4]R. Antonicelli, [5]S. Manfrini and [5]I. Testa. [1]Centres of Biochemistry and [2]Cytology, Gerontological Research Dept. [3]Dept. of demographic and statistical studies, [4]Cardiology Dept., INRCA Ancona [5]Institute of Internal Medicine, University of Ancona, Italy.

A reduced fibrinolytic activity has been found in diabetes mellitus and hypertension. In a previous work we demonstrated a negative correlation between two fibrinolytic inhibitors, plasminogen activator inhibitor-1 (PAI-1) and lipoprotein(a) (Lp(a)) plasma levels in a NIDDM population. Present work was aimed to investigate whether other risk factors, such as hypertension, obesity, dislipidemia and oxidative stress, may influence the observed correlation between PAI-1 and Lp(a). 108 NIDDM patients (age 65.1±9.5 yr.) and 49 non diabetic subjects (age 66.7±8.3 yr.) were studied. Blood concentrations of Lp(a), PAI-1 antigen and activity and the main parameters of lipo and glycometabolic balance were determined. Antioxidant defense was assayed as oxygen radical absorbance capacity ($ORAC_{OH}$). The subjects were divided into 4 groups based on the presence or absence of diabetes and essential hypertension. No statistical differences among groups were found as regards BMI and cholesterol, while, as expected, significant statistical differences between diabetic and non diabetic subjects were found as far as triglycerides and $ORAC_{OH}$ are concerned (p<0.01). Covariance analysis was performed in order to evaluate the entity of the relationship between PAI-1 and Lp(a) in the four groups, considering triglycerides and $ORAC_{OH}$ as confounding variables. We found the F test statistically significant in evaluating the Log PAI-1/Lp(a) plasma levels relationship among the four groups (p<0.02), while $ORAC_{OH}$ and triglycerides do not influence the above relationship. Regression analysis of Log PAI-1/Lp(a) showed a strong correlation only in hypertensive diabetic patients (r=-0.76, p=0.00001). These results suggest a close association between NID diabetes and hypertension in determining PAI-1 and Lp(a) relationship.

1612

COAGULATION PARAMETERS IN IDDM AND NIDDM PATIENTS WITH AND WITHOUT LATE COMPLICATIONS.

P.Born,P.Olbert,P.Wallisch,P.Bottermann,R.Lorenz.
II.Med.Klinik,Klinikum r.d.Isar; Technical University of Munich, Munich, Germany.

Introduction: The role of coagulation factors in diabetes and specially in the pathogenesis of late comlications is still unclear. Therefore we measured fibrinogen,F XIII, F VIII,vWF,TAT,AT III,PAI-1,a2 Plasmin-Inhibitor in IDDM and NIDDM patients with and without late complications.
Subjects and methods: We investigated 11 IDDM patients without complications (8m,3f;27+/-6 years), 9 IDDM patients with diabetic microangiopathy (6m,3f;39+/-16), 47 IDDM adulescents (29m,18f;13+/-3) and 113 age matched controls (44m,69f;44+/-18) and 21 NIDDM with peripheral arterial occlusive disease (PAOD) stage IIb-IV (14m,7f; 72+/-6),10 NIDDM with microangiopathy (6m,4f;67+/-8), 9 NIDDM without complications (5m,4f;57+/-14), 62 ageadapted controls (20m,42f;62+/-8) and 9 non-diabetics with PAOD (7m,2f;62+/-7) using commercially available kits.
Results: There was a significant ($p<0.05$) elevation of fibrinogen and vWF in all patient groups, but independent from diabetes and complications. TAT was elevated only in the IDDM groups. In IDDM correlations between HbAlc and vWF ($r=0.27$; $p<0.03$) and a2-PI ($r=0.29$,$p<0.02$) were seen.
Conclusion: The role of coagulation parameters in diabetes and its complications remains unclear. The constant elevation of vWF and fibrinogen seen already at an early stage may indicate alterations (at the endothelial level?) long before of the clinical manifestation of complications.

1613

THE EFFECT OF ALPHA-LINOLENIC ACID ON COAGULATION IN JAPANESE PATIENTS WITH NON-INSULIN-DEPENDENT DIABETES MELLITUS

N. Tohgi, K. Koga, S. Sumita, T. Ueshima, M. Koba and S. Kikuchi. Saisei-kai Ohmuta Hospital, Ohmuta, Japan.

We investigated the effects of supplemental dietary linseed oil, containing the omega-3 fatty acid, alpha-linolenic acid, on coagulation and fibrinolysis in 12 Japanese patients with non-insulin-dependent diabetes mellitus. Five grams of linseed oil per day containing 58% alpha-linolenic acid was administered to each patient for 2-4 weeks. Plasmin • $\alpha_2$plasmin inhibitor complex (PPI), plasminogen activator inhibitor-1 (PAI-1) and thrombin • antithrombin III (TAT) were measured before and after the supplementation period. PPI showed a significant decrease (0.62±0.18 vs. 0.48±0.1 μg/ml, $p<0.01$), while PAI-1 showed a decreasing trend (59.5±34.8 vs. 35.3±20.3 μg/ml, $p=0.059$). There was no significant change in TAT. These findings suggest that the change in the omega-3/omega-6 fatty acid ratio caused by supplementation with linseed oil affects on coagulation and fibrinolysis.

1614

REGIONAL ADIPOSITY AND HAEMOSTATIC PROFILE IN DIABETIC WOMEN AND WOMEN WITH NORMAL GLUCOSE TOLERANCE

RM Stoney, JD Best, KZ Walker and K O'Dea. Deakin University, Melbourne, Australia.

Women with non-insulin-dependent diabetes (NIDDM) have a greatly elevated risk of coronary heart disease (CHD), possibly through increased formation of occlusive thrombi. Android obesity in women appears to be an important determinant of increased CHD risk. We therefore examined the relationship between regional adiposity and haemostatic profile in women with well-controlled NIDDM (HbA_{1c} 7.3 ± 0.3%) compared to a group of normoglycaemic women matched for age and BMI. Body composition was assessed by dual-energy X-ray absorptiometry. Two regions of interest were delineated to depict body fat distribution: an android waist (AW) region and a gynoid leg (GL) region. Although there were no differences between women with NIDDM and controls in either total fat mass (30.9 ± 1.5 and 32.8 ± 1.5 kg, respectively) or lean tissue mass (39.5 ± 0.86 and 38.3 ± 0.63 kg, respectively), differences in regional adiposity were evident. (Data: mean ± SEM, PAI-1: geometric mean ± SEM)

	NIDDM (n=45)	**Control** (n=40)	***p* value** (*t* test)
age (years)	64 ± 1	62 ± 1	-
BMI (kg/m^2)	29 ± 1	29 ± 1	-
AW/GL fat ratio	1.07 ± 0.04	0.75 ± 0.03	< 0.001
PAI-1 antigen (ng/ml)	26.3 ± 1.2	12.7 ± 1.2	< 0.005
factor VII (% activity)	115 ± 3	110 ± 4	n.s.
fibrinogen (g/l)	2.92 ± 0.07	2.88 ± 0.07	n.s.

Women with NIDDM had more fat mass in the AW region and less fat mass in the GL region, thus giving a significantly higher AW/GL fat ratio. They also had higher levels of plasminogen activator inhibitor-1 (PAI-1) antigen, suggestive of reduced fibrinolytic activity. Elevations in fibrinogen or factor VII were not observed in NIDDM. A significant relationship ($r = 0.37$, $p = 0.001$, Pearson's correlation) was evident between PAI-1 antigen levels and the AW/GL fat ratio. Upper body obesity in women with NIDDM may contribute to increased CHD risk through impaired fibrinolysis, rather than increased tendency for thrombosis.

1615

THE EFFECT OF INSULIN AND PROINSULIN ON THE SECRETION OF PAI-1 BY INSOLIN-RESISTANT $HEPG_2$ CELL LINE

G. NING,C.G. LI and Y.W. PENG. Shanghai Inst of Endocrinol, RuiJin Hosp., Shanghai 2nd Medical University, Shanghai , China

Abstract: High plasma plasminogen activator inhibitor-1 (PAI-1) is associated with insulin resistance. The heptoma cell line $HEPG_2$ has been shown to synthesize PAI-1 in response to insulin and proinsulin. The secretion of PAI-1 by insulin-resistant HEPG2 cell were evaluated after insulin , proinsulin stimulation. The results showed that:① PAI-1 secretion levels from insulin-resistant $HEPG_2$ cells were not significantly different from those observed with control cells . ② The levels of PAI-1 by insulin-resistant $HEPG_2$ cells is higher than by control $HEPG_2$ cells after stimulation of insulin or proinsulin. In the present of 10^{-4}M metformin the over stimulation effect of insulin and proinsulin on insulin-resistant $HEPG_2$ cells were abolished. The results indicated that: In insulin-resistant $HEPG_2$ cells,PAI-1 plasma levels are largely increased after stimulation of insulin or proinsulin. Metformin inhibites the insulin and proinsulin mediated PAI-1 over synthesis.

1616

EFFECT OF TROGLITAZONE ON PLASMINOGEN ACTIVATOR INHIBITOR ON (PAI-1)

V Fonseca, T Reynolds, D Hemphill, C Randolph,T Valiquett, J Graveline, and L Fink. Univ of AR for Med Sciences, Little Rock, AR, USA, Parke-Davis USA and Sankyo USA.

NIDDM is associated with impaired fibrinolysis which may contribute to the increased incidence of cardiovascular disease. Plasma concentrations of plasminogen activator inhibitor (PAI-1) are elevated in patients with NIDDM and correlate with hyperinsulinemia and insulin resistance. We measured plasma PAI-1 antigen concentrations in two groups of patients participating in two clinical trials with the "insulin sensitizer" Troglitazone in doses of 200 to 600 mg daily. In one trial patients were treated with Troglitazone alone and in the other Troglitazone was added to previous treatment with insulin. In 8 patients on placebo (4 in each trial) the mean ± SD plasma PAI-1 was of 72.6 ± 39.3 ng/ml at the beginning of the study and did not change significantly by the end of the trial (54.9 ± 30.8 ng/ml, ns). In contrast, in 18 patients treated with Troglitazone (8 monotherapy, 10 with insulin) PAI-1 levels fell significantly from 68.8 ± 32.3 ng/ml to 40.4 ± 20.4 ng/ml ($p < 0.01$). The change in PAI-1 levels did not correlate with changes in glycemic control. We conclude that Troglitazone has a direct beneficial effect on the impaired fibrinolysis associated with NIDDM and may, therefore, protect patients from cardiovascular disease.

1617

BOTH ACUTE AND CHRONIC HYPERGLYCEMIA DECREASE PLASMA FIBRINOLYTIC ACTIVITY IN THE RAT

A. Pandolfi, A. Giaccari*, L. Morviducci*, L. Pastore*, E. Vitacolonna, F. Capani and A. Consoli. Universita' D'Annunzio, Chieti and *Universita' Cattolica, Roma, Italy

Decreased plasma fibrinolytic activity has been observed in diabetes and this might contribute to accelerated atherothrombosis in this disease. It is unclear, however, whether hyperglycemia per se is directly responsible for this finding or whether hypofibrinolysis is a result more than a cause of diabetic vascular complications. Aim of this study was to determine the effect of both chronic and acute hyperglycemia on plasma fibrinolysis in the rat. To this end, we compared plasma fibrinolytic activity (lysis of fibrin plates) in 9 Sprague Dowley rats who had undergone a 90% pancreatectomy 5 weeks before (weight 235±14 g., blood glucose 301±9 mg/dl) and in 8 control rats (weight 208±5 g., blood glucose 119±4 mg/dl). In separate experiments we compared rat plasma fibrinolitic activity after 4 hrs of saline infusion (n=9, weight 285±4 g., blood glucose after saline infusion 106±4 mg/dl) or after a 4 hrs hyperglycemic clamp (n=6, weight 281±8 g., blood glucose clamped at 291±12 mg/dl while insulin concentration was kept constant by infusion of octareotide 100 ng/Kg/min and insulin 0.5mU/Kg/min). Plasma fibrinolytic activity was significantly reduced both in the pancreatectomized as compared to control animals (mean lysis areas on the fibrin plate = 163±23 vs 308±21 mm^2, $p< 0.001$) and after the hyperglycemic clamp as compared to saline infusion (mean lysis areas on the fibrin plate = 105±16 vs 373±40 mm^2, $p< 0.001$). This data show that both chronic and acute hyperglycemia can decrease plasma fibrinolytic activity and suggest that hyperglycemia could be the primary culprit of impaired fibrinolysis in patients with diabetes mellitus.

1618

CAN IDDM CAUSE ATHEROSCLEROSIS BY GENERATING ALTERATIONS IN A SET OF PLASMA PARAMETERS?

H.W.Witas,W.Młynarski,M.Różalski,K.Jędrychowska-Dańska,D.Cedzyńska, E.Brzeziańska and J.Bodalski

Molecular Biology Unit, 2nd Clinic of Children Diseases, Institute of Pediatrics, Medical University of Lodz, Lodz, Poland

The studies were performed to elucidate an impact of IDDM on fibrinolytic markers (t-PA, PAI-1, active PAI-1), thrombin/antithrombin III complex and blood lipids distribution (TG, LDL, HDL, total cholesterol) and lipoprotein (a). 35 families were studied including: 45 IDDM patients (aged 13.8±0.6), their parents (n=65, aged 41.4±0.8) and non-diabetic siblings (n=17, aged 15.5±1.0), as well as 50 unrelated controls (aged 10.7±1.0) without clinical symptoms of IDDM and no family history of the disease. Stepwise discriminant analysis and Tuckey honest significant differences test for unequal N were applied to assess the differences between groups of subjects. Obtained results did not reveal any statistically significant differences in concentration of fibrinolytic markers. However, decreasing tendency of the level of both inhibitors and activators of fibrinolysis in IDDM subjects was found. Elevated concentration of thrombin/antithrombin III complex in parents group (mean 4.2 mg/L) and IDDM children (mean 4.07 mg/L) was not statisical significant comparing to controls (mean 3.45 mg/L). We did not find any influence of IDDM onset age and values of HbA_{1c} as well as fructosamine concetration on the value of studied parameters in IDDM patients. Discriminant analysis showed altered distances between parents v. IDDM (p=0.0036), v. siblings (p=0.0091) and v. controls (p=0.000034). HDL (p=0.027) and total cholesterol (p=0.035) were found to strongly discriminate studied groups. Means of total cholesterol concentration in parents, IDDM children, siblings and controls were as follows: 209.9, 173.6, 174.0 and 168.1 mg/dL, respectively and means of HDL cholesterol: 49.1, 47.6, 53.9 and 39.0 mg/dL, respectively. Average values of lipoprotein (a) concentration in studied groups were as follows: 199.2, 209.3, 136.0 and 205.4 mg/dL, respectively, without any significant differences. Our observations enable us to suggest the similarity between IDDM children and their parents in recpect to plasma parameters distribution. It indicates that the age caused atherogenic changes in blood can be accelerated by hyperglycaemic state in IDDM.

OXIDATIVE STRESS AND FIBRINOLYSIS IN PATIENTS WITH INSULIN-DEPENDENT DIABETES MELLITUS.

JH Assink [1], RP Stolk [2], DE Grobbee[1,2], HGT Nijš, AF Casparie and HJG 1Bilo [3], 1) Erasmus University Rotterdam, 2) Utrecht University, 3) De Weezenlanden Hospital Zwolle, The Netherlands.

The development of diabetic complications may be related to diminished fibrinolytic activity, which could be associated with oxidative stress. We studied the relationship between oxidative stress measured by malondialdehyde levels (MDA) and plasma concentrations of Plasminogen Activator Inhibitor-1, antigen and activity (PAI-ag resp. PAI-ac), tissue type Plasminogen Activator, antigen and activity (t-PA-ag resp t-PA-ac). The study was conducted in 278 consecutive IDDM patients (153 men, 125 women; mean age 38.1 years (SD12.0), duration of diabetes 17.2 years (SD 10.2), HbA1c 8.2 % (SD 1.89)).

A significant correlation was found between age and respectively MDA-levels (r= 0.12), t-PA-ag (r= 0.13) and t-PA-ac (r= 0.40).

Duration of disease was related with PAI-ag (r= -0.14), PAI-ac (r= -0.14), and t-PA-ac (r=0 .21), but not with MDA-concentrations or t-PA-ag. Metabolic control, as assesses by HbA1c-levels, did not correlate with MDA-concentration nor with the parameters of fibrinolysis. No relationship could be found between oxidative stress and the fibrinolysis parameters.

These results suggest that oxidative stress, as measured by malondialdehyde concentrations, is not related with parameters of fibrinolysis, which does not support a role of oxdative stress in diminishing fibrinolysis.

1620

DAYTIME FLUCTUATIONS OF PLASMINOGEN ACTIVATOR INHIBITOR-1: IMPAIREMENTS IN NIDDM PATIENTS WITH CORONARY HEART DISEASE

K.Lalić, P.B.Djordjević, N.M.Lalić, D.Bošković, M.Zamaklar, V.Dimitrijević, A. Jotić and M.Ilić, Institute for Endocrinology, Belgrade,Yugoslavia

It has been previously shown that increased plasminogen activator inhibitor-1 (PAI-1) levels could be an important risk factor for coronary heart disease (CHD). Also, diurnal fluctuations in PAI-1 levels have been demonstrated in healthy subjects with the highest value in the morning and the nadir in the late afternoon. However, the relations between the daytime fluctuation pattern of PAI-1 levels and the appearance of CHD in NIDDM patients have not yet been clarified. The aim of this study was to analyse the pattern of diurnal changes in PAI-1 levels in 38 NIDDM patients with arteriographically documented CHD (group A), in 20 NIDDM patients without CHD (group B), and in 15 age-matched healthy controls (group C). The PAI-1 levels were determined at 08.00, 10.00, 13.00, 15.00 and 18.00h by using a plasminogen/chromogenic plasmin substrate assay (Table 1). In group A, PAI-1 levels did not show a significant decrease between 08.00 and 18.00h (6.2+/-2.9%). In contrast, in group B, PAI-1 levels decreased during the same interval (26.7+/-12.7%). In group C, we detected a more profound decrease in PAI-1 levels (88.6+/-5.6%), which was significantly higher than in group B ($p<0.01$). Also, both at 08.00 and 18.00h, the PAI-1 levels were higher in group A than in group B ($p<0.01$;respectively) and in both groups the levels were higher than in group C ($p<0.005$; respectively).

Table 1. Diurnal fluctuations of PAI-1 levels (U/ml)

	08.00h	10.00h	13.00h	15.00h	18.00h
Group A	6.3+/-0.4	6.4+/-0.4	6.2+/-0.5	6.1+/-0.3	6.0+/-0.4
Group B	4.8+/-0.5	4.6+/-0.4	4.3+/-0.2	4.2+/-0.2	3.9+/-0.4
Group C	2.8+/-0.2	2.6+/-0.2	2.2+/-0.3	1.7+/-0.1*	0.6+/-0.1**

Means+/-SEM * $p<0.05$ and ** $p<0.01$ (vs 08.00h in group C)

Conclusions: our results have shown the absence of diurnal fluctuations of PAI-1 in NIDDM patients with CHD, in contrast to the NIDDM patients without CHD and healthy controls. The results imply that prolonged exposure to increased PAI-1 levels might be an important determinant influencing the pathogenesis of CHD in NIDDM.

1621

PROGNOSTIC MARKERS OF VASCULAR DISEASE IN JUVENILE PATIENTS WITH NEWLY ACQUIRED DIABETES - RELEVANCE TO GENETIC MARKERS OF TYPE 1 DIABETES

Watala C.[1], Pietrucha T.[2], Greger J.[2], Dziatkowiak H.[4], Brylska U.[4], Wąsik R.[5], Szalewski M.[6], Witas H.[3], Bodalski J.[3] [1]*Laboratory of Haemostatic Disorders,* [2]*Department of Biochemistry and* [3]*Institute of Paediatrics, Medical University of Łódź,* [4]*Department of Endocrinology of Children and Juveniles, Polish-American Institute of Paediatrics, Kraków,* [5]*Department of Endocrinology of Children and Adolescents, Medical University of Wrocław,* [6]*Children's Hospital, Kielce, Poland*

The alterations in fibrinolytic system, are believed to play an essential role in the pathogenesis of diabetic vascular complications. We monitored fibrinolytic disorders in 76 juvenile type 1 diabetics (aged 5-17 yr) with a newly acquired and diagnosed type 1 diabetes mellitus. When analysing the heterogeneous group of all diabetic juveniles, the mean antigen levels of plasma plasminogen activator inhibitor (PAI-1), tissue-type plasminogen activator (t-PA) and lipoprotein (a) (Lp(a)) remained within physiological ranges and were not different from those noted for control group. However, in selected patients (13%), who were excluded in so called 'high-risk vascular disease' group, PAI-1 and Lp(a) were drastically increased and greatly exceeded the relevant mean values observed in 'low-risk vascular disease' group (respectively 5-fold, 66.5±31.0 *vs.* 8.1±5.3 ng/ml, and 8-fold, 560±295 *vs.* 72±44.5 μg/ml). The correlation between these most profound alterations in PAI-1 and Lp(a) was insignificant, however these drastic enhancements significantly contributed to the highly significant discrimination of two groups of diabetics. The occurrence of two susceptibility markers predisposing to acquire type 1 diabetes, HLA-DQα52Arg(+) (67% of which 46.5% were homozygotes) coincided in 25.6% of the examined patients, although there was no apparent relation between HLA-DQ haplotypes and the alterations in fibrinolytic parameters. We conclude that high PAI-1 level in the 'high-risk' group might be interpreted as the result of either single or combined effect of endothelium damage and/or platelet release reaction. Further, the impairments in fibrinolytic system observed in selected type 1 diabetic juveniles might result from their proneness to develop haemostatic disorders and not necessarily merely from the direct consequences of metabolic disorders encountered in type 1 diabetes.

1622

Abnormality of fibrinolytic system in patients with NIDDM

H Watanabe,M Kuriki,M Iwamoto,S Niimura and S Shigetomi. Fukushima Medical College, Fukushima city, Japan.

The influence of the fibrinolytic system on diabetic complications was investigated. Tissue-plasminogen activator-plasminogen activator inhibitor-1 complex (T-PAI-C) is a new marker of fibrinolysis. T-PAI-C was determined in patients with NIDDM(n=50) and normal subjects(n=9). T-PAI-C level were higher in NIDDM(15.3±4.0 ng/ml) than normal subjects (7.8±3.5 ng/ml). With increasing LDL,VLDL and ApoB levels, higher prevalences of nephropathy were observed. LDL,VLDL and ApoB were associated with raised t-PAI-C level. But t-PAI-C level were no significantly different between NIDDM patients with normoalbuminuria(n=16, 14.8±5.9 ng/ml), micro-albuminuria (n=16, 15.3±4.1 ng/ml) and overt proteinuria(n=18, 16.3±4.4 ng/ml). With increasing t-PAI-C levels, higher prevalences of retinopathy were not observed. Glucose, HbA_{1c} and proteinuria were not associated with raised t-PAI-C level. This results indicate that fibrinolysis is accelerated in NIDDM patients with and without diabetic complications. Increase of t-PAI-C could be a primary factor of common genetic background in NIDDM.

STUDY ON SUSCEPTIBILITY OF SERUM TO COPPER INDUCED OXISTRESS IN DIABETIC PATIENTS

M.Kibata,Y.Mishima,A.Kuyama,M.Ando and M.Takeyama
Nat'l Sanatorium Minamiokayama Hospital, Japan

Oxidative changes of serum added 500μM $CuSO_4$ and incubated at 37°C for 24 hrs (Stage 3) were compared with of serum kept at 4°C (Stage 1) in following components, that is, uric acid, total bilirubin, total protein, albumin, lipids, apo-lipoproteins, total fatty acid fractionation, vitamin E, TBARS and PAG electrophoresis. Serum were obtained from 14 normal controls and various state of 24 NIDDM patients(DM).

The rate of changes (difference between the value of Stage 3 was divided by the value of Stage 1) were shown to be significantly high in uric acid, vitamin E, apolipoproteins and PUFA of DM.

Furthermore, in 15 DM of whom immunologically determined anti AGE antibody levels were signi-ficantly increased in Stage 3 compared with Stage 1.

These data are likely to tell us that diabetic serum are highly susceptible to oxistress.

1624

THE DETECTION OF APO CIII PROMOTER T→C -455 POLYMORPHISM IN INSULIN RESPONSE ELEMENT

S.Anisimov, M.Volkova and E..Schwartz, St.-Petersburg Institute of Nuclear Physics RAS, St.-Petersburg, Russia.

One of the most important problems in diabetes is investigation of molecular bases of high level of triglycerides. W.Li et al.(J.Clin.Invest.1995,96:2601-2605) showed the strong influence of the T→C -455 polymorphism of insulin response element of apo CIII promoter to the triglyceride level. The main aim of our work was to create a simple method for detection of that polymorphism. For that purpose two oligonucleotid primers were sintezed. The downstream primer was 25-mer 5' - ATC TCA GCC TTT CAC ACT GGA ATT T - 3', as upstream primer we used 25-mer 5' - GTC TTC TGT GCC TTT ACT CCA AAG A - 3', ends up one nucleotide short of the polymorphism site, and contains, as the 3'-penultimate nucleotide, a G rather than the native C residue. Thus, elongation of this primer must lead through a site-directed mutagenesis (C→G in the coding strand) to the MboI site GATC formation in case of the T at position 455 (CATC→GATC), but not in case of the C at the same position (CACC→GACC). Genomic DNA was PCR amplified with two described primers, cycling conditions were: initial cycle: 93°C 1.5 min., 52°C 1 min., 72°C 1 min., 29 cycles 93°C 1 min., 56°C 1 min., 72°C 1 min., final extension 72°C 5 min. Restriction products were electrophoresed in 10% polyacrilamide gel. Possible patterns were 154 bp (no restriction, C in 455 position), 131 bp, and 23 bp long(in the case there was T in 455 position). Using this approach, we analyzed 61 children from three schools of Saint-Petersburg. The frequencies of T and C alleles were 55.7% and 44.3% respectively.

1625

LIPID PEROXIDATION IN DIABETIC PATIENTS: RELATIONS TO HYPERTRIGLYCERIDAEMIA, OBESITY AND HYPERGLYCAEMIA

V. Peltola, T. Vasankari, J. Viikari and M. Ahotupa. Departments of Physiology and Medicine, University of Turku, Turku, Finland.

The relations of hypertriglyceridaemia, obesity (body mass index, BMI) and hyperglycaemia (HbA1C levels) to LDL oxidation were studied in 62 diabetic patients. The patients having an additional disease to diabetes, such as a systemic infection, or using immunosuppressive drugs were excluded from the study. Diene conjugates (DC) were measured in LDL and serum samples to estimate the level of lipid peroxidation. In NIDDM patients (n=43) serum triglyceride levels correlated positively with the total amount of oxidized LDL (LDL-DC; r=0.58, p<0.001), with the proportion of oxidized form in LDL (LDL-DC/LDL; r=0.72, p<0.001), and with the serum level of diene conjugates (S-DC; r=0.74, p<0.001). BMI of NIDDM patients correlated positively with LDL-DC (r=0.36, p<0.05), and in the analysis of the patients with serum LDL-cholesterol less than 6.0 mmol/l (n=25), also with LDL-DC/LDL (r=0.44, p<0.05) and S-DC (r=0.68, p<0.001). Serum triglyceride levels of IDDM patients (n=19) correlated with S-DC (r=0.88, p<0.001). The HbA1C values of the IDDM patients with serum LDL-cholesterol less than 6.0 mmol/l (n=15) correlated positively with LDL-DC (r=0.60, p<0.05) and LDL-DC/LDL (r=0.56, p<0.05). The present study demonstrates connections between hypertriglyceridaemia and LDL oxidation, as well as obesity and LDL oxidation in NIDDM patients. A weak association was found between HBA1C levels and LDL oxidation in IDDM patients with LDL-cholesterol less than 6.0 mmol/l. The present results suggest that in hypertriglyceridaemic and obese NIDDM patients, LDL oxidation may be an important risk factor of atherosclerosis.

1626

EFFECT OF CHRONIC INTRAPERITONEAL VS SUBCUTANEOUS INSULIN DELIVERY ON TRIGLYCERIDE SECRETION RATE IN STZ-DIABETIC RATS.

A. Giacca, T. Mason, B. Chan, Z.Q. Shi and G. Steiner. University of Toronto, Toronto, Canada.

The effect of chronic insulin treatment by continuous delivery from an implant via the intraperitoneal (IP) vs the subcutaneous (SC) route ($3U \cdot day^{-1}$ x 21 days) on hepatic triglyceride secretion rate (TGSR) was examined in streptozotocin (STZ) diabetic rats. Two control groups were used: untreated STZ-diabetic (UD) rats, and nondiabetic (N) rats. All groups were allowed ad lib access to standard Purina chow and to drinking water. TGSR was calculated from the linear increase in plasma triglyceride levels following lipase inhibition by Triton WR-1339. Untreated STZ-diabetic rats had lower insulin, higher glucose and TG levels, and lower body weight (BW) than nondiabetic rats. However, their FFA levels were similar to controls perhaps because their fat stores were depleted. Insulin treatment (either IP or SC) restored fasting plasma glucose, TG, and BW to normal independent of the route of insulin administration and did not significantly alter FFA levels. Both insulin-treated groups were hyperinsulinemic. Peripheral insulin levels were greater in the SC treated group (SC 273 ± 46 $\mu U \cdot ml^{-1}$; IP 98 ± 25; N 70 ± 19; SC vs IP or N, $p < 0.001$). Portal insulin levels were greatest in the IP treated group (IP 474 ± 91 $\mu U \cdot ml^{-1}$; SC 217 ± 51; N 260 ± 86; IP vs SC or N, $p < 0.05$). Despite elevated TG levels, TGSR was reduced in the untreated STZ-diabetic rats (UD 0.44 ± 0.06 mg/min; N 0.68 ± 0.05; $p < 0.05$). TGSR was restored to normal following insulin administration, regardless of route (SC 0.67 ± 0.08 mg/min; IP 0.67 ± 0.09). This occurred despite the 2-fold increase in portal insulin levels of the IP group compared to the SC group. CONCLUSIONS: **1)** In STZ-diabetes, TGSR is decreased, probably due to insulin deficiency. **2)** As the increase in TG levels in STZ-diabetes is not due to increased TGSR, it may result from defective TG clearance. **3)** Chronic hyperinsulinemia in STZ-induced diabetes normalizes TGSR. **4)** The route of insulin delivery does not affect TGSR in these rats.

1627

MEMBRANE FLUIDITY IS IMPROVED BY GLUCOSE CONTROL IN DIABETIC PATIENTS

I. Tauveron, S. Hors, A. Fabricio, F. Conan*, Ph. Thieblot, C. Motta*. Services d'Endocrinologie et Biochimie Hôtel-Dieu*, CHU, B.P. 69, F 63003 Clermont-Ferrand, France.

Diabetes is associated with a reduction in membrane fluidity which could be implicated in the pathogenesis of diabetic vascular disease. Yet, the role of glucose control on membrane fluidity remains debated. Thus we analyzed in 7 type 1 and type 2 diabetics the incidence of near normoglycaemia induced by continuous intravenous (Day 1 to D 10) or subcutaneous (D 10 to D 20) insulin infusion on the behaviour of the membrane phospholipids by physicochemical changes on the lipidic dynamics of erythrocytes and lymphocytes membranes. Fluorescence polarization (FP) and electron spin resonance (ESR) were used to respectively measure the FP anisotropy (r) of diphenylhexatriene (DPH) in lymphocytes membranes, the correlation relaxation time (τ c) of a 16 nitroxyde stearic acid (16 NS) probe and the degree of order (S) with 5 NS probe embedded in the membranes of intact erythrocytes. These parameters are directly related to the membrane fluidity (η) at the molecular level of resolution. Throughout the study, in conjunction with the reduction of HbA1c and fructosamine, the seven patients exhibit a progressive increase of the membrane fluidity, associated to a decrease of the degree of order. Every patient exhibits a constant trend to a progressive change of both fluidity and order, from D10 to D 20 when compared to basal value, reaching a mean range from 2 to 20% at D 20.

These preliminary results indicate that glucose control in diabetic patients can improve membranes properties and may presumably restore an optimum fluidity related to the membrane physiological roles.

1628

Lipid metabolism in the hepatocellular nuclei of the diabetic rats.

M. Górska*, M. Żendzian-Piotrowska, R. Bucki and J. Górski.
Departments of Physiology and *Endocrinology, Medical Academy of Białystok, Poland.

The nuclei contain different lipids. However, regulation of metabolism of that lipid pool remains almost unexplored. The aim of the present study was to examine effect of insulin deficiency on incorporation of the blood-borne 14C-Palmitic Acid into different lipid classes and on the content of different fractions of phospholipid in the nuclei isolated from the liver of control, 2 and 7 day streptozotocin-diabetic rats. The rats were not treated with insulin. Incorporation of the label into the fraction of phospholipids and 1,2-diacylglycerols increased considerably already in 2 days after administration of streptozotocin and remained further unchanged in 7 days. Radioactivity of the fraction of triacylglycerols decreased in 2 days and also remained further unchanged. Incorporation of the label into the fraction of free fatty acids, monoacylglycerols and cholesterol esters was unchanged in 2 days and decreased in 7 days after administration of streptozotocin. The content of total phospholipids was markedly reduced in 7 day diabetic rats and it was accounted for by a reduction in each fraction (sphingomyelin, phosphatidylcholine, phosphatidylethanolamine, phosphatidylinositol, phosphatidylserine and cardiolipin). Specific activity of each phospholipid fraction increased significantly though not uniformly. The largest increase was noted in the fraction of phosphadidylcholine (8 fold) and the smallest in the fraction of phosphatidylethanolamine (50% increase). It is concluded that diabetes profoundly deteriorates lipid metabolism in the hepatocellular nuclei and that, in this way, it can effect certain nuclear functions.

1629

A RELIABLE FLOW CYTOMETRIC ASSAY FOR FUNCTIONAL LOW DENSITY LIPOPROTEIN RECEPTORS IN HUMAN LYMPHOCYTES.

H. Hattori, N. Nagano, T. Egashira, *T. Okada. R & D Center, BML, Inc., Saitama, Japan, *Dept. of Pediatr., Nihon Univ. Sch. of Med., Tokyo, Japan.

A simple, specific flow cytometric method has been developed for the diagnosis of familial hypercholesterolemia (FH) caused by mutation of the low density lipoprotein receptor (LDLR) gene. Using this method, the LDLR activity in 45 patients from 18 Japanese FH families was analyzed. In 43 of 45 FH patients, LDLR activity was 55±18% (mean±SD) compared to that of control subjects (100.9±10.6%). In 2 of 45, showed normal activity of 84% and 123%, respectively. Subsequently, PCR products of the LDLR gene were screened by DGGE. Abnormal band patterns were observed in PCR products of exon 4, 7, 9, 12 and 17. PCR products in patients with ab-normal band pattern were subcloned and sequenced by an automated DNA sequencer. Four known mutations of a 21 bp insertion in codon 200-206 of exon 4, C317S in exon 7, intron 12+2 T to C and K790X in exon 17 were identi-fied. Furthermore, three new mutations were identified: a insertion of C at 390nt in codon 109 of exon 4 and a 7 bp deletion of GGGAAGT in codon 98-100 of exon 4, which caused a frameshift, resulting in the introduction of a stop codon 50 and 85 amino acids (aa) further downstream, respectively. Also, 5 bp inser-tion of GGACC at 1247nt in codon 416 of exon 9 causes a frameshift, creating a stop codon 13 aa further downstream. It is suggested that these mutations introducing a stop codon resulted in a premature termination of the LDLR protein expressed as the class 1 of receptor-negative mutations. Detection of each mutation in their family members showed that mutations were causa-tive for FH. The patients with these known and new mutations showed about half the activity of normal controls but 2 of 6 patients with K790X showed normal activity. These studies suggested that a flow cytometric pro-cedure of the LDLR activity might be specific and reliable for the diagnosis of FH and a useful tool to distinguish from other hypercholesterolemia.

INFLUENCE OF INSULIN AND DIABETES ON THE SECRETION OF CHOLESTERYL ESTER TRANSFER PROTEIN (CETP) FROM HAMSTER ADIPOSE TISSUE

G.X. Shen and A. Angel. University of Manitoba, Winnipeg, Canada

Cholesteryl ester transfer protein (CETP) promotes the exchange of cholesteryl ester and triglycerides between HDL and triglyceride-rich lipoproteins. Increased CETP activity may explain the low HDL in diabetes. The present study demonstrates that plasma CETP activity was increased in streptozotocin-induced diabetic Syrian hamsters. Incubation of adipose fragments from these animals resulted in increased secretion of CETP activity into the medium and a reciprocal decrease in CETP activity in tissue homogenates. In normal animals, intraperitoneal administration of regular insulin (2 U/100 g body weight) reduced the levels of plasma CETP activity within 1-2 h and that was associated with a reduction of CETP activity released from adipose tissue. Chronic administration of insulin increased plasma CETP activity due to increased plasma triglycerides without a significant alteration in the release of CETP activity from adipose tissue in vitro. The results of the present study suggest that the levels of CETP activity generated from adipose tissue and that in plasma are augmented in insulin-deficient hamsters. Acute administration of insulin reduces the release of CETP activity from adipose tissue which may be partially responsible for the reduction in circulating CETP. Thus, insulin appears to be a negative regulator of CETP secretion in adipose tissue, which may explain insulin's positive effect on plasma HDL (This study is supported by Canadian Diabetes Association and Heart and Stroke Foundation of Canada).

LPL MASS IS DECREASED BY ENDOTHELIAL CELL DAMAGE IN NIDDM PATIENTS WITH NEPHROPATHY

K. Kashiwazaki, T. Hirano, Y. Moritomo, H. Naito, S. Nagano, M. Adachi and G. Yoshino. Showa University and Toho University, Tokyo, Japan

We examined relationship between heparin-releasable lipoprotein lipase (LPL) mass and von Willebrand factor (vWF), an indicator of endothelial cell damage , to elucidate the mechanism for hypertriglyceridemia (HTG) in NIDDM with nephropathy. NIDDMs (n=65) with normo-, micro-, and overt- albuminuria (AU) and non-diabetic controls with normo AU (n=29) were studied. LPL mass was measured in postheparin plasma by Sandwich EIA, and vWF by ELISA. Dietary TG response was determined in plasmas before and 3,6, 9 h after ingestion of milk fat. Age, BMI and HbA1c were comparable between the three NIDDM groups. Both fasting TG and dietary TG response were significantly increased in micro-AU and further increased in overt-AU compared to those in NIDDM with normo-AU or controls. LPL was decreased and vWF was increased with the pregression of nephropathy. Reduction in LPL was markedly correlated with vWF ($r=-0.694$, $p<0.0001$) in total NIDDMs. These results suggest that functional LPL attached to heparan sulfate proteoglycan is decreased by widespread endothelial cell damage in NIDDM with nephropathy. We propose this as a new mechanism for HTG in NIDDM with nephropathy.

THE EFFECT OF JTT-501 ON SERUM TRIGLYCERIDES IN OBESE ZUCKER FATTY RATS

Y. Yamazaki[1], T. Murakami[1], T. Osaka[2], S. Iino[1], Y. Mizushima[1] and S. Inoue[2]
Institute of Medical Sciences, St. Marianna University School of Medicine[1], National Institute of Health and Nutrition[2], Japan.

Purpose: JTT-501 is a new oral hypoglycemic agent which improves blood glucose control through improving insulin resistance. It was also found that this agent decreases triglycerides (TG) in the blood. The aim of the present study was to clarify the mechanism of decreased TG in obese Zucker fatty rats after the treatment of JTT-501. Methods: After an oral administration of JTT-501 (100 mg/kg, once per day) to obese Zucker fatty female rats, which shows insulin resistance with impaired glucose tolerance and hypertriglyceridemia, and SD female rats for 7 days. Serum TG, glucose, insulin, post-heparin plasma lipoprotein lipase (LPL) and TG secretion rate (TGSR) using Triton 1229 were determind after overnight fast. Results: In obese Zucker fatty rats, serum TG (392.5±145.4 vs 1331.6±438.1 mg/dl, $p<0.0001$) and glucose (86.0±25.6 vs 145.1±66.2 mg/dl, $p<0.01$) were significantly decreased after the treatment. On the other hand LPL (195.9±47.9 vs 59.2±60.7 ng/ml, $p<0.002$) were significantly increased. Serum insulin level and TGSR did not change. In normal SD rats, plasma LPL (250.3±26.9 vs 189.0±16.5ng/ml, $p=0.0005$) was significantly increased and serum insulin (6.8±1.9 vs 13.2±8.4 μU/ml, $p<0.02$) was significantly decreased after the treatment. Conclusion: The decreased serum TG levels were closely associated with increased LPL but not with TGSR in obese Zucker fatty rats. The improvement of insulin resistance may contributed to the increased plasma LPL, resulting in decreased TG. The results of normal SD rats also suggest that this agent has the potential to increase plasma LPL.

1633

AUTOANTIBODIES AGAINST OXIDIZED LDL ARE INCREASED IN IDDM

S. Mäkimattila, J. Luoma, S. Ylä-Herttuala, R. Bergholm, T. Utriainen, M. Mäntysaari, P. Summanen and H. Yki-Järvinen. Universities of Helsinki and Kuopio, Finland.

Plasma lipid and lipoprotein concentrations do not generally differ between patients with IDDM and normal subjects, although the risk of macrovascular disease is markedly increased in IDDM. We determined the concentration of autoantibodies against oxidized LDL (ratio between antibodies to native vs oxidized antibodies, oxLDLab) in 38 patients with IDDM (HbA_{1c} 8.4±0.2 %, S-LDL cholesterol 2.9±0.1, S-HDL cholesterol 1.3±0.1, S-triglycerides 1.1±0.1 mmol/l) and 33 normal subjects (HbA_{1c} 5.1±0.1 %, $p<0.001$, 2.8±0.1, 1.3±0.1, and 0.9±0.1 mmol/l, NS for all lipids, respectively). OxLDLab were 1.5-fold higher in the IDDM (1.81± 0.15) than in the normal subjects (1.23±0.07, $p<0.001$). None of the IDDM patients had evidence of macrovascular disease. When the IDDM patients were divided according to their mean oxLDLab level (1.8), patients with high oxLDLab (2.87±0.22, n=13) did not differ from those with low oxLDLab (1.26±0.06, n=25) with respect to age (37±2 vs 38±2 yrs), duration of IDDM (21±2 vs 25±2 yrs), LDL cholesterol (2.8±0.2 vs 3.0±0.1 mmol/l), HbA_{1c} (8.6±0.3 vs 8.3±0.2 %), body mass index (24.2±0.9 vs 24.8±0.6 kg/m^2), S-creatinine (108±8 vs 99±5 μmol/l), urinary albumin excretion rate (377±102 vs 349±212 μg/min) or degree of retinopathy. The patients with IDDM and high oxLDLab:s had, however, signs of more severe autonomic neuropathy than those without (E/I ratio 1.1±0.02 vs 1.3±0.04, $p<0.001$; Valsalva ratio 1.3±0.04 vs 1.6±0.07, $p<0.001$; orthostatic test -18.1±6.2 vs -3.8±2.9 mmHg, $p<0.05$; reflex vaso-constriction to cold -24±6 vs -42±4 %, $p<0.02$). These data provide the first evidence of increased oxLDLab concentrations in patients with IDDM. Unexpextedly, high levels were significantly associated with the presence of autonomic neuropathy but not with other microvascular complications.

Lipids and Lipoproteins – Epidemiology and Clinical Studies

1635

INCREASED CHOLESTERYL ESTER TRANSFER PROTEIN (CETP) SPECIFIC ACTIVITY IN A POPULATION OF 126 NIDDM PATIENTS.

B. Vergès, L.Lagrost, G.Vaillant, JM.Petit, P.Gambert and JM.Brun. University Hospital and INSERM-CJF 93-10, Dijon, France.

Cholesteryl Ester Transfer Protein (CETP), responsible for the transfer of cholesterol esters (CE) and triglycerides (TG) between lipoproteins, plays a determinant role in lipid metabolism. So far, the few studies on CETP activity in NIDDM have been performed in a very small number of patients and have given controversial results. The aim of our study was to evaluate plasma CETP activity and its main determinants in a large population of NIDDM patients, using normal HDL particles as CE donor. One hundred and twenty six NIDDM patients (66 men, 60 women) were studied. These patients were treated by diet ± oral hypoglycemic drugs. CETP activity was measured as the capacity of the plasma to promote the transfer of radiolabeled CE from HDL_3 to the endogenous apoB-containing fraction of the native plasma. CETP mass concentration was measured by ELISA. Specific activity of CETP, calculated as the ratio of plasma CETP activity to CETP mass was significantly higher in NIDDM patients than in controls (125 ± 67 vs 62 ± 15 %/h/μg). In the whole diabetic population, plasma CETP activity was positively correlated with (VLDL+LDL) cholesterol (r=0.36;p<0.0001), BMI (r=0.24; p=0.006) and negatively with HDL cholesterol (r= -0.25;p=0.004). However, the correlations were different in the normotriglyceridemic NIDDM (TG<150 mg/dl; n=68) and in the hypertriglyceridemic NIDDM (TG≥ 150 mg/dl; n=58) patients. In both groups, a correlation with (VLDL+LDL)chol was found. Triglycerides (r=0.35;p=0.003), BMI (r=0.32; p=0.006) and HDLchol. (r= -0.36; p=0.002) were correlated with CETP activity only in the normoTG group, and HbA1c (r= 0.26; p=0.04) only in the hyperTG group. In the multivariate analysis, (VLDL+LDL)chol. was the only significant determinant of CETP activity in the whole diabetic population (t=3.02;p=0.003) and in the hyperTG group (t=5.4; p<0.0001) when, in the normoTG group, both (VLDL+LDL)chol. (t=2.71;p=0.008) and HDLchol. (t=-2.36; p=0.02) were significant determinants. **In conclusion**: 1) CETP specific activity is significantly increased in NIDDM. This is likely to promote the generation of atherogenic modified lipoproteins in NIDDM. 2) (VLDL+LDL) chol. level is the main determinant of CETP activity in NIDDM; HDL chol. is a significant determinant only in normotriglyceridemic NIDDM patients.

1636

TRIGLYCERIDE INDUCED DIABETES MELLITUS DUE TO LIPOPROTEIN LIPASE GENE POLYMORPHISM. F.L.Henriksen, [‡]G.Mingrone, L.N.Krogh, M.Hørder. [‡]G.Gasbarrini and H.Beck-Nielsen. Odense University Hospital, Odense, Denmark and [‡]University Cattolica S. Cuore, Rome, Italy.

Two sisters (sib1: 18 and sib2: 15 years old) developed hyperchylomicronemia 14 years old. Diffuse eruptive xanthomas and recurrent attacks of acute pancreatitis ensued. Both developed an insulin-resistant diabetes mellitus (NIDDM). which were intractable on peroral antidiabetics and insulin. A modified biliopancreatic diversion was employed in both sisters. After the operation triglycerides decreased to nearly normal and the eruptive xanthomas, pancreatitis and NIDDM disappeared. The lipolytic enzyme lipoprotein lipase (LPL) has a cental role in the metabolism of triglyceride rich chylomicrons and very low density lipoproteins (VLDL). Decreased LPL activity caused by LPL gene polymorphism or mutations are possible reasons for this triglyceride induced diabetes mellitus. After a 14-h overnight fast Heparin 100 IU/kg is injected intravenously, 15 minutes later post-heparin blood were collected and catalytic LPL activity measured. GC-clamped PCR-amplified DNA from the promotor region and exon 1 through 10 of the LPL gene were screened for nucleotide substitution by denaturing gradient gel electrophoresis (DGGE). Exons with abnormal DGGE pattern (4 band pattern) were sequenced by an automated laser fluorescence sequencer. HDL, HDL_2, HDL_3 cholesterol were quantified by a polyethylene glycol precipitation kit Quantolip, Immuno. Postheparin plasma LPL activity were low in the whole family 76.0 mU/ml in sib1, 117.1 in sib2, 205.7 in a healthy younger sib3, 101.7 in the mother and 145.0 mU/ml in the father. The most of the family presented extremely low HDL cholesterol concentrations (HDL, HDL_2, HDL_3), (0.51 mM, 0.17 mM, 0.34 mM) in sib1, (0.63, 0.19, 0.44) in sib2, (1.12, 0.32, 0.80) in sib3, (1.24 , 0.38, 0.86) in the mother, (0.58, 0.14, 0.44) in the father. Two polymorphies were found in the LPL gene, in exon 4 (GAG to GAA) coding for the same aminoacid Glu^{118} segregating in both the father, sib1, sib2, sib3; in exon 8 (ACC to ACA) coding for the same aminoacid Thr^{361} segregating in both the mother, sib1, sib2; and a stop mutation was detected in exon 9 (TCA to TGA) coding for the change of Ser^{447} to termination segregating in both the mother and sib3. Extremely low LPL activity. HDL cholesterol and the same two LPL gene polymorphisms in sib1 and sib2 support the hypothesis about genetically decreased LPL activity, hypertriglyceridemia and NIDDM.

1637

DYSLIPIDEMIA IN NON-DIABETIC SUBJECTS FROM FAMILIES WITH TYPE 2 DIABETES

Z. Čaparević, D.Simić, S.Jelić, N.Kostić,V. Diligenski, G. Bojković. Clinical Hospital "Dr Dragiša Mišović" Dedinje, Department of Endocrinology, Belgrade, Yugoslavia.

Non-diabetic subjects from families with type 2 diabetes have a prevalence of dyslipidemia similar to that observed in type 2 diabetic patients. In order to establish the type of dyslipidemia we have examined lipoprotein abnormalities in 20 non-diabetic subjects with family history of type 2 diabetes. The obtained results were compared to the results of the control group (20 type 2 diabetic patients of the same age and in a good glycaemic control). All tested subjects were non-obese but hypertensive. In all subjects measurements of total cholesterol (TC), LDL-cholesterol (LDL-C), HDL cholesterol (HDL-C), triglycerides (TG), apo A, apo B and lipoprotein (a) in the serum were performed. According to obtained results TG levels were elevated in both groups but significantly higher in the type 2 diabetic group (p=0,01), while levels of HDL-C were significantly lower in the both groups. We also found that lipoprotein (a) levels were normal to low in the both groups. Hypertriglyceridemia, which is a frequent trait in type 2 diabetic patients may explain the variability of lipoprotein (a) levels. Other observed parameters were normal.

In conclusion we consider that according to similarities in dyslipidemia to type 2 diabetic patients non-diabetic subjects with family history of type 2 diabetes have to be under careful medical control for prevention of cardiovascular complications.

1638

LPL MASSES ARE MAJOR DETERMINANTS OF CHOLESTERYL ESTER (CE) TRANSFER AND LIPOPROTEIN CORE WEIGHT RATIO (CWR) IN TYPE II DIABETIC PATIENTS

T Murakami, S Miyamochi, T Yoshida, A Yamashita, E Miyazaki, Y Oka, S Iino, Y Yamazaki, C R Sirtori (*), G Franceschini (*). St. Marianna University School of Medicine, Kawasaki, Japan. University of Milan, Milan, Italy (*).

The aim of our study was to evaluate the role of LPL on CE transfer rate (CETR) and plasma lipoprotein CWR (TG/TG+CE) in diabetic patients. Subjects were 30 type II diabetics treated by diet alone and compared to the 30 age-, sex-, body mass index-matched controls. Post heparin LPL masses were measured by monoclonal antibody. CETR was evaluated by the method of substrate dependent. Plasma CETP concentration was measured by anti-peptide antibody. Plasma total cholesterol (TC) and TG levels were comparable between the two groups. CETR was significantly lower in the type II diabetics compared to controls (42±21 vs 70±30 nmol/ml/h, $p<0.01$). CETP masses were not different between the two groups (1.52±0.45 vs 1.50±0.39 μg/ml). VLDL and HDL CWR were significantly higher in the type II diabetics (0.921± 0.040 vs 0.780±0.051, $p<0.01$, 0.325±0.142 vs 0.214±0.091, $p<0.01$, respectively). In type II diabetics, CETR correlated positively with plasma VLDL-TC ($r=0.476$, $p<0.01$) and apo B ($r=0.446$, $p<0.02$), inversely with HDL-TC/TG ratio ($r=-0.461$, $p<0.02$), apo AI/AII ratio ($r=-0.651$, $p<0.001$) and LPL masses ($r=-0.448$, $p<0.02$). Furthermore LPL masses were inversely correlated with HDL-CWR ($r=-0.476$, $p<0.01$) and the 24/h urinary C-peptide excretion ($r=-0.425$, $p<0.02$). In conclusion, plasma LPL concentration was closely associated with the net mass transfer of CE, lipid compositions of acceptor or donor lipoprotein and endogenous insulin secretion in the plasma of type II diabetic patients.

1639

HYPERTRIGLYCERIDEMIA AND LOW HDL CHOLESTEROL IN JAPANESE PATIENTS WITH NIDDM

K. MORIDERA, M. KAJIKAWA, H. KOBAYASHI, T. ISHIHARA and H. KURAHATI. Department of Internal Medicine, Kobe City General Hospital, Kobe, Japan.

The abnormalities in serum lipids commonly observed in diabetic patients are possible risk factors for cardiovascular disease. So we investigated the frequency of hypertriglyceridemia (h-TG) and low HDL-cholesterol (HDL-C) level, and the relation between these dislipidemia, BMI and blood glucose control in Japanese NIDDM patients, and then the influence of strict diet therapy for 2 weeks on these dislipidemia. 511 patients with NIDDM (259 male, 252 female ; 29-89 years of age) were studied. The prevalence of h-TG (> 1.69mmol/l) was 32.5% (83 of 257) in male and 24.2% (61 of 252) in female. The frequency of h-TG increased paralleling an increase of BMI in both male and female. On the other hand the prevalence of low HDL-C (< 0.91mmol/l) was 39.7% in male and 27.2% in female, there was no correlation between frequency of low HDL-C and BMI in male and female. The frequency of h-TG in poorly controled (FBS 180mg/dl and HbA1c > 8.0) obese (BMI > 24.2) patients was 7.1 fold higher than that in good controled (FBS < 140mg/dl and HbA1c < 7.0) non-obese (BMI < 24.2) patients in male, 5.4 fold in female, but frequency of low HDL-C was 1.9 fold higher in male and 2.5 fold in female (see table).

The percentage of diabetic patients with h-TG and low HDL-C

			TG		HDL-C	
			male	female	male	female
non-obese	good	control	8.5 (%)	10.3	26.0	20.7
	poor	control	42.8	23.8	47.8	38.1
obese	good	control	46.3	20.7	41.0	24.1
	poor	control	60.0	56.0	50.0	52.0

Strict diet therapy significantly reduced serum TG (from 2.21 ± 0.45 to 1.53 ± 0.29), but HDL-C did not change significantly (from 0.95 ± 0.17 to 1.02 ± 0.16). Conclusion. The frequency of h-TG in NIDDM was strongly correlate to BMI and blood glucose control, but that of low HDL-C was not correlate to BMI and weekly association to blood glucose control.

1640

Lp(a) IS A RISK FACTOR OF MACROANGIOPATHY, BUT INDEPENDENT FROM DIABETES

P.Born,P.Olbert,P.Wallisch,R.Lorenz,P.Bottermann. II.Med.Klinik,Klinikum r.d.Isar; Technical University of Munich, Munich, Germany.

Introduction: Lp(a) is an accepted risk factor of coronary heart diesease (CHD) and seems also to play an important role in the pathogenesis of peripheral arterial occlusive disease (PAOD). The influence of diabetes on Lp(a) levels is controversly discussed.

Subjects and methods: Therefore we measured Lp(a) in 11 IDDM patients without late complications (group A: 8m, 3f;27+/-6 years), in 9 IDDM patients with diabetic microangiopathy (B:6m,3f;39+/-16),47 IDDM adulescents (C:29m, 18f;13+/-3) and 113 age adapted controls (D:44m,69f;44+/-18) as well as in 9 non-diabetics with PAOD stage IIb-IV (E:7m,2f;62+/-7),in 21 NIDDM with PAOD (F:14m,7f;72+/-6), in 10 NIDDM with microangiopathy (G:6m,4f; 67+/-8),in 9 NIDDM without microangiopathy (H:5m,4f;57+/-14) and also 62 age adapted controls (I:20m,42f;62+/-8). The determination was performed by enzyme immuno assay (Immuno,Germany)

Results: The levels of Lp(a) were: A:24+/-25 (HbAlc:8.7) B:17+/-20 (10.6), C:20+/-4 (8.6), D:18+/-22 (5.2), E:46+/-26 (5.3), F:35+/-34 (7.9), G:19+/-39 (8.8),H:18+/-19 (8.2) I: 23+/-29 (5.4). A significant ($p<0.05$) elevation was only seen in patients with PAOD independent from diabetes. There was no correlation with HbAlc.

Conclusion: In accordance with other studies we show that Lp(a) is beside CHD also a risk factor of PAOD. Diabetes, its duration and the metabolic control have no influence.

1641

LIPIDS AND OTHERS CARDIOVASCULAR RISK FACTORS IN ABORIGIN POPULATION FROM CHILE

Carrasco E (1), Pérez-Bravo F (2), Santos Jl (2), Larenas G (3), Calvillán M (1), Montalvo D (4), Montalvo MT (4), Pérez N (4)
(1) Faculty of Medicine, Diabetes Unit. Hosp. SJ de Dios. (2) Molecular Biology and Epidemiology Department. INTA. U. de Chile. (3) Faculty of Medicine. U. de la Frontera. (4) Health Dept. U. de Tarapacá. (Supported by grant Fondecyt 1960395)

Cardiovascular disease (CVD) remains as the primary cost in terms of mortality and morbidity in industrialized nations. The relationship between lipoprotein disorders and atherosclerosis, specially of the coronary arteries, has received special attention in the last decade. In the different ethnic groups in the world, there are a great variability in the prevalence of CVD and in the lipoprotein profile. OBJECTIVE: Determine the lipid profile in two aborigin populations from Chile. METHODOLOGY: Two populations were analyzed: Mapuches (n = 64) from the south of Chile and Aymaras (n = 56) from the north of the country. We determine: anthropometric measures (BMI), plasma total cholesterol (TC) and HDL, triglicerides (TG) and blood pressure (BP). Data are expressed as mean ± standard deviation (DE) or percentages. Statistical analysis was performed by t-test and. RESULTS: Means and DE from The Mapuche group comparing to Aymara group yielded the following figures: TC: 191 ± 43 mg/dl vs 172 ± 53 ($p<0.05$); HDL: 62 ± 21 vs 45 ± 18 ($p<0.001$); BMI: 28 ± 5 vs 25 ± 5 (Kg/m^2) ($p<0.01$); BP: 139/86 vs 123/76 mmHg ($p<0.01$); TG:156 vs 143 mg/dl (NS). In the Mapuche group, 34% of the sample showed TC levels over 200 mg/dl while this characteristic was seen in 16% of Aymaras ($p<0.05$), TG concentration over 150 mg/dl was 30% in Mapuche group and 32% inAymara group(NS). BMI>30: 25% in Mapuche group and 13% in Aymara group($p<0.01$).
CONCLUSION: Mapuche population shows higher levels of TC and BP than Aymara population, although the latter presents higher concentration of HDL compared to the Mapuche group.

FAMILY CLUSTERING OF ELEVATED PLASMA LP(a) IN IDDM.

R. Ghelardi, G. Zerbini, F. Ciralli, E. Bognetti, M.R. Pastore, R. Del Giudice, G. Meregalli, C. Tettamanti, G. Ruotolo, R. Mangili and G. Pozza. Istituto Scientifico San Raffaele, Milan, Italy.

The blood concentration of apolipoprotein(a) [LP(a)] is a quantitative genetic trait in the general population, and elevated levels associate with increased cardiovascular risk. Poor glycaemic control has been suggested to increase LP(a) levels in IDDM, but whether this can confound the parental component in LP(a) levels is unclear. We measured LP(a) in 95 patients (42 M, 53 F) with duration of IDDM ranging between 1 and 31 years (median = 7) and all their parents. Albumin excretion was higher than 20 µg/min in 8 patients. The distribution of LP(a) concentration was independent of sex in the parents (5.9±0.8 and 6.6±0.9 mg/dl, p=ns) and was similar in the patients (6.8±0.8 mg/dl, mean±SEM). Glycated haemoglobin levels ranged between 5.1 and 15.3% (median = 8.0) but were unrelated with LP(a) levels. Likewise, no correlations were found with blood glucose, age, duration of diabetes, urinary albumin excretion and BMI, but also total cholesterol and triglycerides. There was no correlation in LP(a) concentrations between spouses ($r^2=0.02$, p=ns), but there was a strong relationship between midparental and offspring levels ($r^2=0.25$, $p<0.0001$) that was independent of glycaemic control. A similar pattern of relationships was observed for major blood lipids. We suggest that the presence of IDDM and poor glycaemic control may not confound the parental, perhaps inherited component of LP(a) levels. Whether raised LP(a) may predict cardiovascular events also in IDDM remains to be determined by prospective studies.

DYSLIPIDEMIA AMONG DIABETICS IN AN URBAN POPULATION IN INDONESIA. Sarwono Waspadji, Pradana Soewondo, Imam Soebekti, Maryantoro Oemardi and Sidartawan Soegondo, Div. of Endocrinology and Metabolism, Dept. of Med., Fac. of Med., Univ. of Indonesia, Salemba 6, Jakarta 10430, Indonesia.

Among diabetics, dyslipidemia is one of the important factors for the development of premature coronary artery disease. Data on lipid profile among diabetics are often conflicting. Population studies on lipid profile among diabetics are rarely conducted in Indonesia. The aims of this study were to determine lipid profile among diabetics, to compare the results with lipid profile among diabetics found in our previous epidemiological study conducted 10 years earlier, and also to compare with lipid profile among diabetic clinic attendees. A survey was conducted in an urban subdistrict in Jakarta with a total population of 34,645. Adult members of the family (age >15 years) who were randomly recruited (5 %, stratified cluster random) to join this survey. Diabetes mellitus was determined using WHOcriteria. Lipid profiles were measured using commercial kit (enzymatic methods). Altogether there were 58 diabetics (5.7%)among 1019 eligible respondents. The peak prevalence of diabetes mellitus was found in the 4th-6th decades. High TC (> 240 mg/dl) was found in 24.1 % and high TG (> 200 mg/dl) in 29.3 % of the diabetics. The mean TC and TG levels among diabetics were 211±52 mg/dl and 202±173 mg/dl respectively. In our previous survey done 10 years earlier in an urban population adjacent to the present study site using similar methods and criteria, we found 44 diabetics among 2704 respondents. The peak prevalence of diabetes mellitus was also found in the 4th-6th decade's group. The mean TC and TG in this diabetic population were 241±52 mg/dl and 183±95 mg/dl respectively. Data on lipid profile compiled from diabetic clinic Cipto Mangunkusumo hospitals' attendees in 1995 showed the prevalence of high TC and high TG to be 25% and 17.8 % respectively, while the mean TC and TG were 234±64.6 mg/dl and 186±104.9 mg/dl. We concluded that although the prevalence of diabetes mellitus increases, the pattern of dyslipidemia among diabetics remains similar.This means that the prevailing abnormal lipid profile among diabetics is caused by diabetic condition, not due to the changing dietary pattern of the population.

1644

OVERESTIMATION OF LOW-DENSITY CHOLESTEROL BY THE FRIEDEWALD FORMULA DUE TO Lp (a) IN DIABETIC PATIENTS.

C. Hernández, R. Simó, L. García-Pascual[1], R. Burgos. P. Chacón[2] and J. Mesa. Diabetes Unit and [2]Biochemistry Department. Hospital Vall d'Hebron. [1]Hospital Mutua de Terrassa. Barcelona. Spain.

Serum low-density liporotein cholesterol (LDL-C) and lipoprotein (a) [Lp(a)] have been considered independent cardiovascular risk factors; however the calculation of serum LDL-C by the Friedewald formula includes the cholesterol associated with Lp(a). Therefore, serum Lp(a) levels might act as a confounding factor in epidemiological as well as interventional studies. The main aim of the present study was to evaluate whether the overestimation of LDL-C by the Friedewald formula could be relevant in diabetic patients. For this purpose we included 118 consecutive diabetic patients (46 type 1 and 72 type 2) with serum triglycerides lower than 400 mg/dl. Total cholesterol and total triglycerides were tested on unfrozen samples by an automated enzymatic method. HDL-C was determined by assaying the cholesterol concentration in the supernatant obtained after precipitating lipoproteins with density lower than HDL by a mixture of phosphotungsting acid and magnesium chloride. Lp(a) was measured by ELISA. Diabetic patiens were classified according Lp(a) serum concentrations (mg/dl) as follows : 0-15, group A (n=73); 15-30 group B (n=33) ; 30-45 group C (n=8) and >45 group D (n=4). LDL-C was calculated following the Friedewald formula. Corrected LDL-C was obtained by subtracting the cholesterol portion of Lp(a) [estimated as 0.3 x Lp(a) mass] from the levels of cholesterol calculated by the Friedewald formula. Results : a linear correlation was observed between Lp(a) and both, uncorrected and corrected LDL-C ($r=0.30, p<0.001$ and $r=0.23, p<0.01$; repectively). The overestimation of serum LDL-C levels (mg/dl) using the Friedewald formula for the diferent groups of patients were : 1.5±1 for group A, 6.3±1.3 for group B, 10.6±1.3 for group C and 21.6±3.8 for group D. Our results suggest that overestimation of LDL-C by the Friedewald formula is not negligible in diabetic patients with high serum levels of Lp(a) .

1645

DYSLIPIDEMIA AND CORONARY HEART DISEASE IN NATIVE ASIAN INDIANS WITH NIDDM.

A.Sharda, GS.Narayan, MG.Mamatha, AS.Vinaya, BS.Sudha, DV.Rama, S.Krishnamurthi, J.Srikanth, S.Nagabushan, P.Hegde, N.Nagesh, and SS.Srikanta. Samatvam: Endocrinology Diabetes Center, Bangalore, India.

Genetic and environmental factors contribute to the higher prevalence of NIDDM, insulin resistance syndrome (X), and coronary heart disease (CHD) in both native and migrant Indians,. Total cholesterol (TC), HDL-cholesterol (HDLC), triglycerides (TG) and LDL-cholesterol (LDLC) were quantitated (mg/dl) in 231 consecutive NIDDM subjects, and results correlated with other clinical and biochemical parameters, including urine albumin excretion (UAE: mg/24h; immunoturbidometry). The most striking abnormality was the very high prevalence of low ("high risk") HDL-C (19% and 43% in males and females respectively); central obesity, inactive life style, premature menopause and infrequent estrogen replacement therapy, besides possible genetic factors may be contributory. The overall prevalence of incipient (IDN) and overt (ODN) diabetic nephropathy were 68% and 11% respectively. In patients with all CHD (22%) and major CHD (5%; myocardial infarction, heart failure, coronary revascularisation), there was a clustering of risk factors including higher LDLC, diabetes duration, systolic BP and UAE. UAE demonstrated a striking positive correlation with LDLC, reflecting association of atherogenic lipid profiles with DN. Conclusion: Dyslipidemia, including low HDLC, is highly prevalent in Asian Indians (especially females) with NIDDM; DN and other coronary risk factors (hyperinsulinemia, hypertension, hyperglycemia etc.), likely account for the very high burden of CHD and mortality.

LIPID RISK % PREVALENCE (URINE ALBUMIN EXCRETION : mg/24h)

TYPE	N	DESIRABLE	BORDERLINE RISK	HIGH RISK
L DLC	201	68 (174)	24 (189)	8 (411)
TG	231	57 (213)	30 (164)	13 (129)
HDLC(M)	143	28 (275)	53 (246)	19 (135)
HDLC(F)	88	21 (63)	36 (76)	43 (94)

1646

LIPOPROTEIN(a)[Lp(a)] AND PROGRESSION OF ALBUMINURIA IN TYPE 2 DIABETES - RELATIONSHIP TO FIBRINOGEN LEVEL

T.Inokuchi, Y. Tojyo, M. Sasamoto, K. Mogami, M. Kameyama, C. Nishimura and S. Isogai, Toho University School of Medicine, Tokyo, Japan

To determine the potential role of Lp(a) for the development of albuminuria and to investigate the link between Lp(a) and fibrinogen(Fbg) levels in a 4.5-year follow-up study in patients with non-insulin-dependent diabetes(NIDDM). Sixty-nine patients with NIDDM were selected by the following criteria: age less than 70 years, urinary albumin excretion index(UAEI) less than 300 mg/g·creatinine(Cr) on 3 separate occasions over a 3-month period and regular attendance in our outpatient clinic. The mean values obtained in the initial and last 3 months in the follow-up were calculated as the values of baseline and end point, respectively, and the mean values(m) of the variables and the change(△) from baseline throughout the follow-up were also used for data analysis. The patients were divided into the following two groups: patients with baseline Lp(a)≧25 mg/dl(group H, n=24) and those with Lp(a)<25 mg/dl(group N, n=45). No differences in age, sex, BMI, duration of diabetes, and the proportion of smokers, hypertension and diabetic retinopathy were found between the groups. With regard to intragroup differences, only log UAEI significantly($p<0.05$) increased in the H group at follow-up. Comparing the two groups, Fbg at baseline and follow-up or mFbg in the H group were significantly($p<0.05$) higher than those in the N group. The values of both m and △log UAEI in the H group were signuficantly($p<0.01$) greater than those in the N group. Multiple regression analysis revealed that systolic blood pressure, Lp(a) and total cholesterol at baseline, and △ of HbA1c, HDL-c, Fbg and 1/Cr were significant independent variables for △log UAEI ($p<0.05$). Logistic analysis demonstrated only baseline Fbg concentrations($p=0.038$) as a predictor of high Lp(a) values. These results indicate that raised Lp(a) value is a significant risk marker for the progression of albuminuria in NIDDM, independent of the other risk factors examined, and that baseline Fbg level is a strong predictor of high Lp(a) level.

1647

RISE IN PLASMA TRIGLYCERIDES : A SIMPLE EARLY INDICATOR OF OXIDATIVE STRESS IN URBAN ASIAN INDIANS.

A. S. Bhoraskar, S. V. Narang and B. S. Raheja. All India Institute of Diabetes, Mumbai, INDIA.

Presently urban Asian Indians are a high risk group for coronary heart disease (CHD), non-insulin dependent diabetes mellitus (NIDDM) and dyslipidemias such as raised plasma triglycerides (TG) low high density lipoprotein cholesterol (HDL-c) and raised total cholesterol (Tc) / HDL-c ratio. Above metabolic disorders are associated with insulin resistance and possibly have a common pathogenic mechanism. Oxidative stress is implicated in the pathogenesis of both CHD and NIDDM. The same may apply to dyslipidemias. However, rise in TG may appear much earlier than other metabolic defects. We studied 42 unselected subjects (M=23, F=19), age (47.84 ± 6.9 yr.) to see if dyslipidemias or rise in TG correlate with parameters of oxidative stress. Care was taken to see that none of the subjects had any antioxidant supplements. Lipids were measured by enzymatic methods and expressed as mg/dl while oxidative stress was assessed by measuring plasma reduced glutathione (GSH) by method of Beutler et al and expressed as μ moles / gmHb. The values with Mean (± SD) and correlation with lipids are as under :

	MALES	r	FEMALES	r
GSH	5.51 (2.07)		5.32 (2.40)	
Tc	176.70 (31.24)	- 0.38	218.89 (61.23)	- 0.34
TG	187.17 (187.81)	- 0.56	187.16 (169.64)	- 0.34
HDL-c	47.04 (10.53)	NS	51.31 (9.66)	NS
Tc/HDL-c	3.95 (1.14)	- 0.37	4.40 (1.54)	- 0.2

Results show significant correlation of GSH, a parameter of oxidative stress with values of TG, Tc and Tc / HDL-c. Since rise in TG appears much earlier this may be a simple early indicator of oxidative stress.

1648

SERUM LIPOPROTEINa AND DIABETIC MACROANGIOPATHY.

A. Yoshimura, R.Takeda and J.Koizumi* KKR-Hokuriku Hospi tal, Kanazawa University.*Kanazawa, 921 Japan

To investigate the possible role(s) of Lp(a) in diabetic macroangiopathy, the relationship between serum Lp(a) levels and echographycally assessed intima-media thickness (IMT) and plaque formation in the common carotid and femoral artery (CA & FA) was evaluated in 193 cases of DM and non-DM,aged 23 to 88 yr. Arterial morphology (IMT and plaques) was evaluated with a Hitachi EUB-555. Serum Lp(a) was determined by turbidimetry. The severity of arterial plaque formations was expressed according to the score of point 0: no plaque, 1: unilateral or 2: bilateral lesions.

Results and Conclusion ; 1) Serum Lp(a) levels showed a positive correlation to the IMT, in either CA or FA, but the statistic analysis did not reach a significant value. 2) In stepwise multi-variate regression analysis, IMT and plaque formations were significantly associated with age and smoking. 3) When the subjects were confined to non-smoker-NIDDM, aged 40 to 65 yr, serum Lp(a) levels showed a significant correlation to CA-IMT ($r=0.555$, $p< 0.02$). No significant correlation was found between serum Lp(a) and IMT in non-smoker-non-NIDDM.

1649

INDEPENDENT ASSOCIATIONS OF GLUCOSE-INTOLERANCE AND DYSLIPIDAEMIA WITH MORTALITY: THE HOORN STUDY

H.G. Ruhé, J.M. Dekker, F. de Vegt, C.D.A. Stehouwer, L.M. Bouter, and R.J. Heine. Institute for Research in Extramural Medicine, Vrije Universiteit, Amsterdam.

Glucose-intolerance and dyslipidaemia are related abnormalities, and both associated with increased mortality. The question is whether the combination of glucose-intolerance and dyslipidaemia is associated with higher mortality. We studied the association of glucose-intolerance, triglyceride-levels (TG) and HDL-cholesterol (HDL) with mortality in a population-based cohort study of 2484 men and women, aged 50 to 75 years, with a follow-up duration of six years. Causes of death of the deceased (n= 177) were retrieved by reviewing the medical records, and classified according to ICD-9. Relative Risks (RR) were estimated by Cox proportional hazards regression models. All models were adjusted for age and sex. Lipid categories were defined as 'favourable' (top HDL-tertile and lowest TG-tertile), 'unfavourable' (lowest HDL-tertile and top TG-tertile) or 'intermediate' (other combinations). In 168 out of 177 the cause of death could be retrieved. When glucose-intolerance and lipid categories were included in one model, dyslipidaemia and abnormal glucose-tolerance were found to be independent risk factors for mortality. Increased mortality could be attributed to ischaemic heart disease (IHD) and sudden death (SD). Of interest is that no significant interaction between lipids and glucose-tolerance was found.

	Relative Risk (95% CI) compared to NGT and 'intermediate' lipid group				
	IGT	NDM¶	Known DM	Favourable	Unfavourable
Mortalty	(254)	(118)	(87)	(464)	(435)
Total (n= 175)	1.1 (0.7-1.8)	1.7 (1.0-2.9)	3.1 (1.9-5.1)	0.7 (0.4-1.1)	1.3 (0.9-3.8)
IHD+SD* (n= 49)	1.5 (0.6-3.5)	3.0 (1.3-7.1)	4.7 (2.0-11.0)	0.8 (0.3-2.0)	1.4 (0.7-2.7)

¶ Newly diagnosed DM at baseline. * ICD-9 codes 410-414, 427.4, 427.5, 798.

CONCLUSION: In a general caucasian population, abnormal glucose-tolerance and dyslipidaemia (high TG and low HDL) are independent predictors of mortality due to ischaemic heart disease and sudden death.

1650

Lipoprotein (a) levels in diabetic subjects with and without ictus cerebri.

M Malaguarnera, M.Rizzo, M.P. Panebianco, P.Ruello, I.Giugno, S.Restuccia.

Institute of Internal Medicine and Geriatrics - University of Catania - Catania - ITALY

Non Insulin Dependent Diabetes Mellitus (NIDDM) is associated with a much higher prevalence (about 2-4 folds) of coronary heart disease and ictus cerebri, compared with health subjects. In elderly people affected by NIDDM, duration of the disease and glucose serum levels are the main predictive factors for cerebro-cardiovascular disease. We studied the influence of lipoprotein (a) [Lp(a)], an indipendent risk factor for vascular disease, in NIDDM patients either affected or not affected by ictus cerebri. Seventy NIDDM patients (34 males and 36 females; mean age 72 4 ± 8.78 years) have been assessed and divided into two groups: group A included 36 NIDDM subjects (20 males, 16 females; mean age 72.44 ± 3.63 years; mean duration of the disease 8.66 ± 7.34 years), while group B was composed of 34 NIDDM (14 males and 20 females; mean age 72.5 ± 12.14 years; mean duration of the disease 20.29 ± 9.95 years) affected by ictus cerebri. The following parameters have been evaluated in all subjects: glycaemia, total and HDL cholesterol levels, trygliceride values, glycosilate hemoglobin levels. Statistical analysis was performed using Student's t test. Trygliceride and Lp(a) serum values were analyzed by Wilcoxon's non parametric test. Bivariate regression analysis was applied to the extrapolated data. Patients included in the group B presented higher glycaemia and glycosylated hemoglobin serum levels and more altered lipid pattern than group A subjects. No significant differences in Lp(a) serum levels were observed between these two groups. However, there was a significant positive correlation of Lp(a) levels with glycosilate hemoglobin in the group B. On the basis of this finding we postulated that glycosilation of Lp(a) may enhance its atehrogenic potential.

1651

Relationship between postprandial triglyceride (TG) response and metabolic vascular risk factors in healthy subjects.

H. Cintora, C. Gonzalez, M. Machain, E. Cavallero.
Instituto de Enfermedades Metabolicas, Junin; Dpto de Farmacologia de la Universidad de Buenos Aires and Div. Endocrinologia Hospital R. Mejia. ARGENTINA.

The postprandial (PP) TG response has been shown to be increased in coronary artery disease patients and in type II diabetics. A higher PP TG response could be related to a complex metabolic disorder including insulin resistance. We studied 50 normolipemic subjects (TC levels < 240 and TG < 200 mg/dl) aged 20-60 (31 w and 19 m) without any history of diabetes, hypertension or vascular disease, before, and 2, 5, and 8 hours after a standardized mixed meal (1145 kcal, 53 g/lipids). Subjects in the highest quartile of the PPTG response (calculated as incremental PP area), showed a trend to higher age, BMI, glycemia and TC/HDL-C ratio as well as a lower glycemia/insulin ratio, when compared with subjects in the other 3 quartiles, but only differences in age were statistically significant ($p = 0.002$). When analyzing the quartiles of the fasting TG distribution the same not significant trends were observed. In contrast, subjects in the highest quartile of the 8th hour postprandial TG value had significantly lower HDL-C ($p = 0.01$) and higher TC/HDL-C ratio ($p = 0.001$). Also, these subjects showed abnormal mean fasting insulin levels and glucose/insulin ratio (20.6 mUI/L and 4.66 respectively). Median Q1-Q3 8th h PP TG values were respectively 98, 72 and 147 mg/dl. A low late postprandial TG value may indicate both normal TG rich lipoprotein production and clearance. In contrast, we suggest that a high value could, better than the fasting TG, discriminate subjects with metabolic abnormalities that increase the vascular risk. Glucose tolerance and fibrinolytic capacity in these groups is currently under analysis.

1652

LIPOPRROTEIN (a) LEVELS AND GLYCEMIC CONTROL IN NIDDM SUBJECTS.

M.Yamamoto, K.Tsukiyama, H.Ishizaki and T.Yokoi. Anjo Kosei Hospital. Anjo, Aichi, JAPAN

We examined the effects of 6 and 12-months improved glycemic control on Lp(a) concentrations in 32 poorly controlled NIDDM subjects. 6 subjects were treated by α-glucosidase inhibitor, 8 by insulin and 18 by sulfonyl urea. LP(a) was measured by monoclonal anti-LP(a) antibody technique, HbA1c by HPLC and Fructosamine by calorimetric method Results are shown by mean±SE.

※<0.01, ※※<0.05 compared with pre-treatment values.

		Before	6 months	12 months
FPG	(mg/dl)	241±17	139±5※	139±6※
HbA1c	(%)	10.3±0.4	6.8±0.3※	6.9±0.2※
FRA	(mM/L)	381±14	287±10※	304±12※
Lp(a)	(mg/dl)	28.9±3.2	20.5±2.7※	18.4±1.9※
T-chol	(mg/dl)	211±8	193±7※※	199±8
HDL-chol	(mg/dl)	50±4	50±4	47±4
TG	(mg/dl)	128±13	107±10	130±12
Apo A1	(mg/dl)	116±4	127±5	138±5
B	(mg/dl)	100±5	93±5	106±7
E	(mg/dl)	5.1±0.3	4.7±0.3	5.9±0.4※※

LP(a) concentrations did not differ among subjects treated by α-glucosidase inhibitor, insulin and sulfonyl urea. We conclude that in NIDDM subjects, LP(a) concentrations are related to the degree of glycemic control.

1653

PREVALENCE OF LARGE VESSEL DISEASES AMONG ADULT DIABETICS IN SOUTHERN TAIWAN-POPULATION BASED STUDY

C.J. CHANG, Y.C. YANG, F.H. LU, J.S. WU, J.H. WU, T.J. WU and J.T. KAO*
National Cheng Kung University Hospital, Tainan, Taiwan.
National Taiwan University*, Taipei, Taiwan

In a population-based study in Southern Taiwan during the years 1995-1996, 1200 subjects aged 20 years or older were screened for diabetes mellitus. Response rate was 80%. The prevalence of diabetes melllitus was 9.9%. Diabetics had higher prevalence of large vessel diseases than nondiabetics. ($P<0.05$) Prevalence of ischemic heart disease (IHD), leg vessel disease (Leg VD) and stroke were 22.8, 2.0 and 5.1% for diabetics, and 11.8, 1.6 and 1.5% for non-diabetics, respectively. Selected cardiovascular variables in diabetics (non-diabetics) were systolic blood pressure (SBP) 138.2±26.3 (114.8±23.4) mmHg, diastolic blood pressure (DBP) 78.5±10.8 (60.0±13.1) mmHg, body mass index (BMI) 26.1±3.5 (23.3±3.5) kg/m^2 and high density lipoprotein cholesterol (HDL-C) 44.9±13.8(50.6±13.4) mg/dl. Diabetics had higher SBP, DBP, BMI but lower HDL-C concentrations than non-diabetics. ($P<0.05$) Conclusions: 1. Compared with western NIDDM, the prevalence of large vessel disease were lower among our patients. 2. Diabetics had higher prevalence of large vessel disease than non-diabetics. 3. Diabetics had high blood pressure, body mass index but lower HDL-C levels than non-diabetics.

1654

PROSPECTIVE STUDY OF LIPOPROTEIN(a) AND THE RISK OF MYOCARDIAL INFARCTION IN NIDDM WITHOUT VASCULAR COMPLICATIONS

T.Ishida, Y.Sugimoto, T.Tada, T.Kajikawa, N.Uemura, K.Kawanishi and J.Takahara. Kagawa Medical University, Kagawa, Japan.

To assess whether lipoprotein(a) [Lp(a)] is a risk factor for macroangiopathy in non-insulin dependent diabetic patients (NIDDM) without any diabetic complications and they had neither history nor sings or symptoms of cardiovascular and cerebrovascular disease. We studied 56 NIDDM without diabetic complications who were followed for 5~6 years. The serum Lp(a) levels were measured by ELISA. The distributions of Lp(a) in the subjects were identical to that of controls, while the median Lp(a) levels in the subjects were significantly higher than that of control(23.6mg/dl vs 13.0mg/dl; $p<0.05$). The subjects were divided two groups, one(N=36) had low Lp(a) levels(below 20mg/dl) and other(N=30) had high Lp(a) levels (above 20mg/dl). There were no significant differences between the two groups with respect to age, HbA1c, BMI, cholesterol and uric acid. Of the 30 patients with high Lp(a), 4 experienced a myocardial infarction(MI), while 2 of 36 patients with low Lp(a) had same episode. There were no significant differences in HbA1c, cholesterol, triglyceride values between NIDDM who developed incident MI events compared with who did not. Of the 30 patients with high Lp(a), 2 experienced a cerebral infarction(CI), while 4 of 36 patients with low Lp(a) had same episode. There were no significant differences in HbA1c, cholesterol, triglyceride values except blood pressure between NIDDM who developed incident CI compared with who did not. We founded Lp(a) is a significant risk factor for cardiovascular disease but is not a risk factor for cerebrovascular disease.

1655

HYPERLIPIDEMIA AND OBESITY AMONG DIABETICS AT JUBAIL MILITARY HOSPITAL

Dr. Khalid Saad Alghamdi. Armed forces hospital, Jubail, Saudi Arabia.

OBJECTIVE Evaluate the pattern of dyslipidemia among diabetics, attending the Primary care clinic.
DESIGN: Retrospective study.
SETTING: Primary health care department of the Armed forces hospital at King Abdul Aziz Naval Base, Jubail, Eastern Saudi Arabia.
SUBJECTS: All diabetics registered and followed up at the Primary Care clinic.
METHODS: 282 diabetics were registered in this clinic and interviewed by Primary care doctors. Weight and height were recorded, fasting blood glucose level and cholesterol level were measured after 12 h fasting.
RESULTS: The study revealed that among 90% NIDDM and 10% IDDM. 22.7% were having a normal Body Mass Index (BMI) 40% overweight, and 36.5% obese. Females had a significantly higher BMI than males (P< 0.005).Total cholesterol was more than normal in 26%, LDL in 27% and Triglyceride in 11% but HDL lower than normal in 38 %.. However mixed hyperlipidemia was seen in (5%) of the study population.
CONCLUSION: Obesity was high among diabetic patients and require special attention as well as dyslipidemia.

1656

ASSOCIATION OF APOPROTEIN E POLYMORPHISM ON LIPOPROTEIN (a) LEVELS IN TYPE 2 DIABETIC PATIENTS.

A. Durlach[1],C. Clavel[2],V. Durlach[2], P.Birembaut[2],M.Leutenegger[1].
[1]Pol Bouin Institute, [2]Medical Clinic, Reims, France.

Apolipoprotein E (apoE) polymorphism is known to modulate cholesterol and triglycerides serum levels in diabetic as well as in non diabetic subjects. However little is known concerning its possible influence on Lp(a). In a groupe of 406 NIDDM patients aged 59.48 ± 10.78 years, with a BMI of 28.89 ± 5.34 kg/m2 and HbA1c=8.23 ± 1.88%, Lp(a)=21.19 ± 32.0 mg/dl with a median value of 81 mg/l, we determined 6 apoE genotypes. Patients were separated in 3 groups (A:2/2 and 2/3), (B:3/3), and (C:3/4 and 4/4) with 231 males (respectively A=37, B=136, C=57) and 175 females (A=30, B=113, C=29) and compared according to their Lp(a) serum levels assayed by immunonephelometry. Increasing significant differences were found between A and B (8.8 ± 15.3 vs 19.6 ± 26.0mg/dl, p<0.01), A and C (8.8 ± 15.3 vs 20.6 ± 27.0, p<0.02) in males, in females differences were found between A and C (14.5 ± 16.2 vs 50.6 ± 71.6mg/dl, p<0.05). These data were confirmed after logarithmic transformation of Lp(a). Thus apoE polymorphism seems to be responsible for a significant modulation of Lp(a) plasma levels although differently in male and female diabetic patients. This phenomon could be of interest in the understanding of Lp(a) catabolism and may be of importance in the comprehension of macroangiopathic complications.

INSULIN RESISTANCE AND DYSLIPIDEMIA IN HEMODIALYSIS PATIENTS

Z.Rašić,G.Peruničić,S.Plješa and Lj. Bokan
University hospital Zemun/Beograd,Beograd,Yugoslavia

Dyslipidemia and insulin resistance are commom among patients with end-stane renal failure. The aim of this study was to evaluate lipid and lipoprotein profile, decreased tissue insulin sensitivity /expressed as fasting plasma insulin>18 mU/L/, and to investigate the role of insulin resistance on lipid levels in hemodialysis patients. We studied 39 patients /24F,15M/, 20 with decreased tissue insulin sensitivity /fasting insulin 29+8,2 mU/L/ and 19 with better tissue insulin sensitivity /fasting insulin 9,7± 4,6/, with similar age and duration ofhemodialysis. First group of patients had higher fasting glucose levels /5,4± 0,7 vs 5,1±0,6 mmol/L,p=0.05/, fasting triglyceride levels /2,7±1,6 vs 2,1±1,0,p<0,05/. Fasting apolipoprotein AI was lower in the first group /1,3+0,2 vs 1,7+0,3,p< 0,05/, but there were no differences in fasting apolipoprotein B100,HDL-ch,LDL-ch,Lp/a/, between two groups. There were significant positiv correlation between fasting insulin and triglyceride levels /r=0.580,p<0,05/,significant negativ correlation between insulin and HDL-ch /r=-0.489, p<0,05/ and fasting insulin and Apo A1 /r=-0.410,p<0.05/, in the first group only. In the second group there was significant negativ correlation between triglyceride and HDL-ch/r=-0,391,p<0,05/ only. We concluded thatdecreased tissue insulin sensitivity is associated with hipertriglyceridemia and lower Apo A1 and HDL-ch, in our hemodialysis patients, as in other insulin resistant statments.

1658

INDEPENDENT CORRELATION BETWEEN LIPOPROTEIN (a) AND ANGIOGRAPHIC CORONARY ARTERY DISEASE IN NIDDM.

A. Melidonis, S. Hraklianou, A. Stefanidis,G. Garoufalis, E. Bilianou, S. Foussas.
Diabetic Unit & Cardiology Dept., Tzanio Hospital, Piraeus-GREECE.

Lipoprotein (a) (Lpa) is an established risk factor for Coronary Artery disease (CAD) in non-diabetic subjects. The correlation between serum levels of Lpa in NIDDM patients with CAD is not yet clearly established. One of the best methods for the assessment of the severity and extension of CAD is coronary angiography (CA). We examined the correlation between serum levels of Lpa and CAD in NIDDM. 43 patients with NIDDM with CAD participated in this study. Mean age 59.7±5.7, Mean BMI 27.789±3.41, 60% suffered from hypertension (A.H.) and 75% were smokers.
Patients under lipid lowering therapy and patients with albuminuria were excluded. The estimation of the degree of stenosis and obstruction in the 11 segments of coronary artery tree (in CA) was made according to the Gensini Score (G.S.). We also measured the ejection fraction (E.F.), total serum levels of cholesterol, triglycerides, fractions of cholesterol, apolipoproteins A and B, Lp(a) [Lp(a) was measured with the immunoturbidimetric method], HBA_{1C} and fibrinogen.
The mean value of Lpa was 37.69±29.74 mg/dl (range 9-132), mean GS 55.72±41.88 (range 4-168). The bottom tertile of GS (range 4-18) had Lp(a) 18.18±7.77 and the upper tertile of GS (range 80-168) had Lpa 51±49.05
The multifactorial analyses between G.S. and all the other parameters indicated statistically significant correlation between GS and Lp(a) (r=0.374, p<0.01), serum level of fibrinogen and GS (r=0.425, p<0.005), serum level of LDL cholesterol and GS (r=0.291, p<0.05).
There was also statistically significant correlation between E.F. and Lp(a) (r=-0.339, p<0.025) and E.F. and fibrinogen (r=-0.345, p<0.02).We concluded that there is significant and independent correlation between serum levels of Lp(a) and the severity and extention of C.A.D. in patients with NIDDM.

1659

INSULIN INSENSITIVITY, MINIMAL MODELLING AND HEPATIC LIPASE ACTIVITY IN THE DYSLIPIDAEMIA OF TYPE 2 DIABETES

C. Kong, L. Nimmo, V.N. Anyaoku, A. McColl, W Richmond, D.G. Johnston. S. Robinson and R.S. Elkeles. *Unit of Metabolic Medicine, Imperial College School of Medicine at St Mary's, London, UK.*

NIDDM is commonly associated with insulin resistance and dyslipidaemia characterised by hypertriglyceridaemia and low HDL. Previous studies of insulin insensitivity have employed insulin measurements by conventional radioimmunoassay. We investigated insulin action and secretion in relation to hepatic lipase activity in 23 NIDDM subjects (median age 58 (IQR 46-65) years, BMI 25.0 (24.1-29.0) kg $\cdot m^{-2}$) using an insulin-modified frequently sampled intravenous glucose tolerance test. Specific insulin was measured by ELISA , minimal modelling was used to measure insulin sensitivity (Si) and glucose effectiveness (Sg). Hepatic lipase (HL) activity was measured in postheparin plasma. Si correlated negatively with BMI (r=–0.46, p<0.05), Sg (r=–0 52, p<0.05) and with fasting triglyceride (r=–0.71, p<0.001) but not with total cholesterol nor HDL-cholesterol HL correlated positively with triglyceride (r=0.43, p<0.05) and negatively with HDL-cholesterol (r=–0.46, p<0.05) and glucose tolerance (r=–0.42, p<0.05) but not with fasting glucose, Si or Sg. There was a negative corelation between HL and glucose tolerance (r=–0.42, p<0.05). Fasting triglyceride was positively correlated with fasting insulin (r=0.50, p<0.05) and first phase insulin secretion (r=0.46, p<0.05). Using a specific insulin assay, we have shown that hypertriglyceridaemia is closely associated with insulin insensitivity and increased hepatic lipase activity which may in turn lower HDL-cholesterol.

1660

LIPOPROTEIN(a) LEVEL AND VASCULAR COMPLICATIONS IN NON-INSULIN DEPENDENT DIABETES MELLITUS

M.Y.Chung, J.Y.Kim, S.W.Yang, D.J.Chung, and T.H.Lee. Division of Endocrinology and Metabolism, Department of Internal Medicine, Chonnam National University Medical School, Kwangju City, Korea

Lp(a) has been shown to be an independent risk factor for atherosclerotic vascular disease in subjects without diabetes. But, in patients with NIDDM, Lp(a) levels have been reported to be normal or increased. In this study, we examine the following issues : the relationship between Lp(a) levels and development of micro- and macrovascular complications and the relationship between Lp(a) and other risk factors of vascular complications in patients with NIDDM. For determination of Lp(a), $ApoA_1$, $ApoB_{100}$, triglyceride, total- and HDL-cholesterol, blood samples were collected after an overnight fast from ninety-five patients with NIDDM (41 women and 54 men). Lp(a) levels in patients with diabetic retinopathy (n=41) were significantly higher (53.6±7.9 vs 27.5±5.3mg/dL, p=0.008) than those in patients without retinopathy (n=33). And also Lp(a) levels in patients with macrovascular complication(s) (n=21) were significantly higher (52.3±11.0 vs 32.2±4.3mg/dL, p=0.047) than those in patients without macrovascular complication(s) (n=71). $ApoB_{100}/ApoA_1$ ratio in patients with Lp(a) level≥30mg/dL (n=34) were significantly higher (1.20±0.09 vs 0.86±0.04, p=0.002) than that in patients with Lp(a) level<30mg/dL (n=59). LDL-cholesterol levels in patients with Lp(a) level≥30mg/dL (n=34) were significantly higher (131.5±9.37 vs 108.1 ±5.24mg/dL, p=0.020) than those in patients with Lp(a) level<30mg/dL (n=59). And Lp(a) levels were not related with sex, age, body mass index, HbA_1c, smoking history and 24-hour urine protein amount. These results suggest that Lp(a) levels seem to be associated with microvascular and macrovascular complications in patients with NIDDM.

1661

RELATIONSHIP BETWEEN INSULIN RESISTANCE AND ABNORMAL LIPID PROFILE IN GREEK OBESE ADOLESCENTS

D. Damianaki, A. Melidonis, A. Tsoutsinos, J. Zika and E. Konstantelou
Paediatric Endocrinology Unit, Diabetic Unit, Tzanio Hospital, Piraeus - Greece

The present investigation was undertaken to identily metabolic variables in childhood which may reflect independent atherogenic risk factor in obese pediatric population. Anthropometric data reflecting overweight, fat distribution were evaluated in 41 obese adolescents and concentrations of apolipoproteins and lipids, IGF-1, C-peptide were selected. Insulin resistance was assessed by fasting insulin level and sum of the insulin values during 2 hours, after an O.G.T.T. in all subjects and compared with 27 lean age-matched normal children. Insuline level was determined by RIA. Results from the two groups were ajusted for puberty, age and sex and were correlated with multivariate analysis, Lipids and lipoprotein evaluated used z=x-x´/SD. In obese vs non-obese mean value/SD for age (11.78 vs 10.95), Bone age (11,98 vs 9,18) BMI (31,40 vs 18,76 kg/m^2) W/h (0,80 vs 0,77) Results: In obese vs nonobese mean value HDL (42,6±15,84 vs 44,02±15,3) LDL (98,57±27,34 vs 95.89±40,04), CHOL (166,69±24,39 vs 152,84±40,04), TRYG (106,35±45,14 vs 76,56±41,4), Lpa (31,6±36.77 vs 29,92±37,0), IGF1 (389,85±227,26 vs 269,52±175,97). The obese had significant higher values IGF1 P<0,011, Tryg, P<0.04, APO-B, P<0,027 and T-CHOL, P<0,05. Mean fasting-insuline-value (29,54 IU/L±SD 13,89 vs noobese (10,11 IU/L±SD 7,73, P<0.01) and sum insulin 489,3 IU/L±SD 296,6 vs 208,55 IU/L±SD 178,1, P<0,01). Fasting-insulin-levels indepentendly of age and BMI were significantly correlated with CHOL (r=0,53, P<0,0005) Lpa (r=0,498, P<0,008) and 2h insulin with LDL (r=0,35, P<0,028) and TRYG (r=0,457, P<0,009). There was a significant difference between obese and nonobese boys and girls regarding HDL and insulinaemia. HDL was positively correlated to fasting and 2-h ins: in nonobese boys. (r_z=0,41, P<0,053, r_z=0,35, P<0,053) and girls (r_z=0.5, P<0,028, 2h r_z=0,39, P<0,07) and negatively related to obese boys (r_z=-0,53, P<0,35, 2h r_z=-0,49, P<0,043) and girls (r_z=-0,46, P<0,06 and 2h r_z=-0,37, P<0,092). **CONCLUSION:** Insulin resistance in obese Greek young subjects is the key of atherogenic metabolic abnormality.

1662

LP(a) PHENOTYPES IN JAPANESE NIDDM

T.Naito#1 and S.Oikawa#2. Saka General Hospital#1 and Third Depertments of Internal Medicine, Tohoku uniyersity School of Medicine #2, Shiogama#1 and Sendai#2, Japan.

In this study, we determined Lp(a) concentrations and phenotypes in group of 121 randomized NIDDM patients under 65 y.o. and 200 controls to investigate differences of apo(a) isoform between patients and controls, and relationship between apo(a) isoform and diabetic nephropathy. Lp(a) phenotyping was performed by using SDS PAGE and classified according to Utermann's classification. Serum Lp(a) concentrations were 18.4±1.4 mg/dl (mean± SE) in the patients and 14.7±1.2 mg/dl in controls (p<0.05,t-test). Lp(a) phenotype frequencies in the patients and controls were significantly different (p<0.0001,x^2-test). F:0 (0)%, B:0 (0.5)%, S1:0.8 (2.5)%, S2:4.1 (4.5)%, S3:43.0 (28.5)%, S4:12.4 (40.5)%, O:3.3 (5.5)%, F/S4:0 (0.5)%, B/S3:0.8 (0.5)%, S1/S3:4.1 (1.0)%, S1/S4:1.7 (1.5)% S2/S3:9.9 (4.5)%, S2/S4:3.3 (5.0)%, S3/S4:16.5 (5.0)% ;[patients (controls)]. We classified NIDDM patients to 3 groups by qualitative urinary protein (group A:(-) n=91, group B:(±)and(+) n=22, and group C:(2+)and(3+) n=8). Each serum Lp(a) concentrations were 17.0±1.6, 19.4±2.7, and 31.6±8.8 mg/dl (p<0.05:group A vs. Group C). Lp(a) phenotype frequency of group C was S3:n=5, S2:n=1, S1/S3:n=1,and B/S3:n=1. That frequency was significantly different to group A (p<0.05,x^2-test). These data suggest that NIDDM patiens have another apo(a) isoform frequency than non-diabetics, and apo(a) isoform relate with aggravation of diabetic nephropathy.

1663

ROLE OF BODY WEIGHT AND GLYCAEMIC CONTROL IN THE DYSLIPIDAEMIA OF NON-INSULIN DEPENDENT DIABETES MELLITUS.

L.Davies, G.Fulcher, P.Clifton-Bligh, E.Hibbert, A.McElduff, B.Robinson, S.Twigg and E.Wilmshurst. Royal North Shore Hospital, St Leonards, Australia.

Dyslipidaemia, in particular raised serum triglyceride and low HDL cholesterol, is characteristic of patients with non-insulin-dependent diabetes mellitus (NIDDM). Controlled clinical trials under strict laboratory conditions have demonstrated that improved glycaemic control can also improve lipid values. In fact, the National Cholesterol Education Panel has stated that control of hyperglycaemia is the key to improving the lipoprotein pattern in diabetes. In this study we aimed to determine whether improved glycaemic control under routine clinical conditions significantly impacted on lipid values in a diabetic out-patient population.

260 patients with NIDDM (151M, 109F, age 63 ± 11 yr), who were not taking lipid-lowering therapy were followed for 12 months with measures of fasting serum lipids, glycaemic control and body weight. During this time, 21 patients were commenced on lipid-lowering therapy leaving 239 patients who formed the study group. Overall there was no change of total cholesterol (5.64 ± 1.25 vs 5.59 ± 1.12mM), triglyceride (2.37 ± 2.70 vs 2.22 ± 1.74mM), serum glucose (9.6 ± 3.3 vs 9.4 ± 3.1mM) or HbA1c (7.3 ± 1.75 vs 7.16 ± 1.52mM). Patients whose HBA1c improved (8.39 ± 1.99 vs 6.60 ± 1.37%:P<0.001) had a significant albeit small decrease of total cholesterol (5.83 ± 1.48 vs 5.54 ± 1.23mM, p<0.01), with no change in HDL cholesterol or serum triglyceride. Conversely subjects whose BMI was significantly lower at follow up (28.9 ± 5.1 vs 27.5 ± 4.8kg/m2) had a significant decrease of serum triglyceride (2.53 ± 2.28 vs 2.09 ± 1.64mM; p <0.01), and increase of HDL cholesterol (1.10 ± 0.28 vs 1.17 ± 0.33mM, p<0.01). The major factor determining change of triglyceride and HDL cholesterol was the change of body weight (p< 0.001 and p<0.01 respectively), while the change of fasting glucose levels predicted the change of serum cholesterol (p< 0.01). We conclude that improved glycaemic control in the absence of weight reduction is insufficient to produce a major change of the abnormal lipoprotein pattern of NIDDM. Consideration should therefore be given to the early introduction of lipid-lowering therapy in patients with NIDDM, even those whose glycaemic control is suboptimal.

1664

LP(a) AND OTHER CARDIOVASCULAR RISK FACTORS IN CHINESE NIDDM PATIENTS WITH AND WITHOUT ALBUMINURIA

V.T.F. Yeung, G.T.C. Ko, C.K. Cheung[1], W.Y. So, R.S.Y. Chan, K.Y. Li, C.C. Chow, J.C.N Chan, and C.S. Cockram. Diabetes and Endocrine Centre and Department of Chemical Pathology[1], Prince of Wales Hospital, Shatin, Hong Kong.

Lp(a) is a recognized risk factor for cardiovascular diseases. Its concentrations are increased in IDDM patients with proteinuria. However, it remains unresolved whether levels are elevated in NIDDM. To address this issue and other cardiovascular risk factors in these patients, we have evaluated 164 Chinese NIDDM newly referred to the Diabetes Specialist Clinic, which serves as a tertiary referral centre to the region. Data are expressed as mean ± SEM, with the exception of Lp(a) and triglyceride which have a skewed distribution and are thus expressed as geometric mean x/÷ antilog SEM. Diabetic patients had Lp(a) concentrations comparable to 132 normal controls (164.7 x/÷ 1.1 mg/L Vs 148.4 x/÷ 1.1 mg /L). Among diabetics, 43 % had abnormal albuminuria as defined by albumin:creatinine ratio of ≥3.5 mg/mmol.. There was no significant difference in the Lp(a) values between the albuminuric and normoalbuminuric group (165.9 x/÷ 1.1 mg/L Vs 175.9. x/÷ 1.1 mg/L). Albuminuric patients had significantly higher fasting glucose (10.9 ± 0.6 mmol/L Vs 9.1 ± 0.4 mmol/L, p<0.01) and HbA1c (9.2 ± 0.3 % Vs 7.8 ± 0.3 %, p=0.001) than normoalbuminuric patients. They also had higher systolic BP (145 ± 4 mmHg Vs 133 ± 4 mmHg, p<0.05) and mean BP (123 ± 3 mmHg Vs 113 ± 3 mmHg, p<0.05). The prevalence of hypertension (systolic BP≥140 mmHg or diastolic BP ≥90 mmHg) was also significantly greater in the albuminuric group (68% Vs 27 %, p=0.001). Albuminuric and normoalbuminuric patients, however, had comparable BMI (24.5 ± 1.4 Kg/m^2 Vs 24.9 ± 0.6 Kg/m^2), waist:hip ratio (0.93 ± 0.01 Vs 0.92 ± 0.02), total cholesterol (5.83 ± 0.17 mmol/L Vs 5.67 ± 0.15 mmo/L), LDL-C (3.70 ± 0.15 mmol/L Vs 3.63 ± 0.12 mmol/L), HDL-C (1.27 ± 0.05 mmol/L Vs 1.33 ± 0.05 mmol/L) and triglyceride (1.62 x/÷ 1.1 mmol/L Vs 1.43 x/÷ 1.1 mmol/L). In conclusion, neither NIDDM nor development of diabetic nephropathy significantly effects Lp(a) concentrations in these Chinese subjects. In line with previous studies, albuminuric patients are at greater risk of cardiovascular disease as evidenced by their poorer glycaemic control and elevated blood pressure.

1665

INFLUENCE OF BODY FAT AND ITS REGIONAL DISTRIBUTION ON PLASMA LIPIDS AND GLYCAEMIC CONTROL IN NIDDM.

M. Alberiche, G. Targher, F. Saggiani, V. Cacciatori, G. Formentini, F. Calcaterra, F. Marini, L. Zenari, A. Raffaelli, M. Poli, S. Perbellini, L. Santi, M. Muggeo and E. Bonora. Division of Endocrinology and Metabolic Diseases, University of Verona, Verona, Italy.

Aim of the present study was to evaluate whether the presence of obesity and a central pattern of fat distribution are significantly associated with plasma lipid profile and glycemic control in patients with NIDDM. We have examined 1,639 noninsulin-treated patients with NIDDM (aged 31-91 yrs), randomly selected from those attending the Diabetes Centers of Verona and sorroundings. Patients were grouped in quintiles of either body mass index (BMI) or waist/hip ratio (WHR). Plasma levels of triglycerides, total and LDL-cholesterol significantly increased across the quintiles of BMI (p<0.001), while HDL-cholesterol significantly decreased (p<0.001). However, when allowance was made for sex, age, WHR, fasting insulin concentration, diabetes duration, treatment (diet vs oral agents), and inverse of creatinine, only total cholesterol (p=0.02) and LDL-cholesterol (p<0.01) levels retained a significant trend to increase with the increase of BMI. Plasma levels of triglycerides (p<0.001) increased, and HDL cholesterol (p<0.05) decreased across the quintiles of WHR, but these trends were no longer statistically significant after adjusting for BMI and all other potential confounders. Glycated hemoglobin (HbA_{1c}) did not change significantly with the increase of either BMI or WHR. These results suggest that in noninsulin-treated patients with NIDDM, an excess of body fat, irrespective of its regional distribution, is independently associated with a more atherogenic plasma lipid profile. On the contrary, neither an excess of body fat nor a central pattern of fat distribution are independently associated with a worse glycaemic control.

1666

LIPOPROTEIN (a) IN URBAN SOUTH INDIAN NIDDM PATIENTS WITH ISCHAEMIC HEART DISEASE

Deepa R, Mohan V, Premalatha G, Sastri NG, and Karkuzhali K, M.V.Diabetes Specialities Centre and Madras Diabetes Research Foundation, Madras, India.

High rates of ischaemic heart disease (IHD) occuring at a younger age have been well documented in several migrant Asian Indian populations. Recently elevated Lipoprotein (a) (Lp-a) levels have been shown to be associated with IHD in Asian Indians. However there is no data on Lp (a) levels within the Indian subcontinent. We compared the levels of Lp(a) in NIDDM patients with and without IHD and non-diabetic control subjects without IHD (n=16 in each group). The mean Lp(a) levels were significantly higher (P<0.001) in NIDDM with IHD (55.4 ± 34.1 mg/dl) compared to NIDDM without IHD (24.2 ± 23.9 mg/dl) and control subjects (24.4 ± 19.5 mg/dl). Thirteen of the 16 NIDDM with IHD (81.3%) compared to 4/16 (25%) of NIDDM without IHD and 5/16 (31.3%) of the control group had Lp(a) values above 30 mg/dl. Lp(a) levels showed a much stronger correlation with IHD than conventional lipid markers like total cholesterol, LDL, VLDL, and HDL cholesterol and serum triglyceride. Lp(a) appears to be a very good marker of IHD in South Indian NIDDM patients.

1667

OVERWEIGHT AND OBESITY. 1985- 1995. PATHOLOGIC ENTITIES ASSOCIATED

M. Pérez, C. Orellana and J. Robalino. Diabetes Ecuadorian Foundation (FED). Quito-Ecuador.

We wanted to establish the frequency of association between lipid disorders, arterial hypertension, diabetes mellitus and impaired oral glucosa test in a group of patients with overweight and obesity. We realized a descriptive study with the information of 604 patients above 19 years old with different degrees of obesity. Variables of study were: arterial hypertension (values ≥ 140/90), lipid disorder (cholesterol and tryglicerids ≥ 200 mg/dL), diabetes mellitus (basal glucemia ≥ 140 mg/dL or ≥ 200 mg/dL at any time of the day and two hours later of realizing glucose oral tolerance test) and impaired oral glucose test (values between 140 and 199 mg/dL two hours later of the test). We used univariate analysis and Epi-Info software. We found lipid disorders in 96.96% of the total group, 96.32% in women and 100% in men (p NS). Arterial hypertension was observed in 39.36% of total group, 37.02% in women and 53.65% in men (p < 0.01). Diabetes mellitus was present in 42.69% of total group, with 39.52% in women and 63% in men (p < 0.01). Finally, we observed an impaired oral glucose test in 22.28%, 22.97% in women and 16.66% in men (p NS). Data collected corroborate the enormous impact of this group of pathologies in morbimortality of patients with overweight and obesity, inside the concept of plurimetabolic syndrome. It is necessary to realize analytical studies to determine the factors that explain the differences observed.

1668

RELATION OF LIPOPROTEIN(A) AND DEVELOPMENT OF DIABETIC MICROANGIOPATHY

M.Matsumoto, I.Hayaki, and T. Yamauchi. Kitakyushu Municipal Hospital, Kitakyushu, Japan

Lipoprotein(a)(Lp(a)) has been reported to be related to atherosclerotic vasucular diseases. Many studies have indicated that the serum levels of Lp(a) in diabetic patients are elevated to be associated with higher incidence of macroangiopathy such as ishemic heart diseases. In this study we investigated the relation between Lp(a) and development of microangiopathy in 120 NIDDM patients(69.4 ± 0.7 y.o.:M ± SE)followed for more than 10 years. In 79 patients without retinopaty at the beginning of the observation , 45 patients remained unchanged in no-retinopathy(NDR) but 26 patients finally worsened to simple retinopathy(SDR) and 8 patients to pre-or proliferative retinopathy(PDR) .Though 74 out of 109 patients without proteinuria at the start of follow－up showed normoalbminuria(NOR) in the end, 37 and 8 patients were developed to microalbuminuria (30 ～ 300mg/gcr.)(MIC)and macroalbuminuria(MAC) , respectively. Lp(a) levels were 25.2±3.0mg/dl in NDR, 22.3±3.4 mg/dl in SDR , 29.8±7.4 mg/dl in PDR. There were no significant differences of Lp(a) levels among three different diabetic retinopathy stages. On the other hand , the serum levels of Lp(a) were 23.0±2.4 mg/dl in NOR , 27.9± 3.8mg/dl in MIC, 46.3± 14.2mg/dl in MAC. There existed significant differnces in serum Lp(a) concentrations among three stages of diabetic nephropathy. In conclusion the risk of macroangiopathy must be much more taken into consideration because of elevated serum Lp(a) levels in diabetic nephropathy.

1669

CLINICAL SIGNIFICANCE OF ACCUMULATED VISCERAL FAT IN PATIENTS WITH NON-INSULIN DEPENDENT DIABETES MELLITUS.

K.Tayama, T.Inukai, Y.Fujiwara, Y.Aso, K.Ogino and Y.Takemura.
Koshigaya Hospital, Dokkyo University School of Medicine, Koshigaya, Japan

It is generally recognized that the accumualtion of visceral fat is closely associated with hypertension, lipid metabolism disorder and impaired glucose tolerance, and also it is one of important factors to develop the atherosclerosis. We challenged to elucidate whether the accumulation of visceral fat would be involved in diabetic complications in patients with non-insulin dependent diabetes mellitus (NIDDM) or not. Studies were performed in 60 NIDDM patients (31 men, 29 women, 54.1 ± 2.1 (mean ± SE) y-o) and 490 healthy subjects. The thicknesses of the preperitoneal fat layer (P-fat) as visceral fat and subcutaneous fat layer (S-fat) were measured using ultrasonography method by Sizuki et al. and then the relationships between those fats and the metabolic markers or the grade of diabetic complications were analysed. S-fat in female remarkably increased that in male in all subjects. P-fat in NIDDM patients significantly increased compared to that in healthy subjects. P-fat in patients treated with insulin were significantly reduced compared to that with diet alone. No significant relathionship was found between both fats and metabolic markers such as FPG and HbA_{1c}. A significantly positive correlation was shown P-fat with MNCV in male, and also P-fat in female showed similar results with SNCV and R-R time interval variation. The tendency of negative correlations were obtained between both fats and urinary albumin excretion. P-fat in NIDDM patients with proliferative retinopathy was markedly reduced compared to that in those in no retinopathy. Daily urinary CPR values revealed a significantly positive correlation with P-fat.

Conclusions: The present data suggest that visceral fat would be a negative modulator against diabetic complications derived from microangiopathy and it might be regulated by the amount of insulin secretion from the pancreas.

HAND AND SHOULDER ABNORMALITIES IN DIABETIC PATIENTS: ASSOCIATION WITH SERUM LIPIDS

PET Arkkila, IM Kantola, T Rönnemaa and JSA Viikari
Turku University Central Hospital, Turku, Finland

Hand and shoulder abnormalities have been shown to be common in conditions like diabetes and coronary heart disease, which are related to the lipid abnormalities. The aim of our study was to evaluate whether limited joint mobility (LJM), Dupuytren's disease (DD) and shoulder capsulitis (SC) are associated with lipid abnormalities in diabetic patients. We examined 291 type 1 (age±SD 33.2±10.0 years) and 139 type 2 (61.3±12.3 years) diabetic patients in terms of LJM, DD, SC, serum total cholesterol (TC), high density lipoprotein-cholesterol (HDL-C) and triglycerides (TG). Differences were regarded significant at p-level <0.05. Prevalence of LJM, DD and SC were 58, 14 and 10% in type 1 and 60, 14 and 22% in type 2 diabetic patients, respectively. The mean TC concentrations were higher in type 1 diabetic subjects with moderate (5.5±1.4 mmol/L) and severe LJM (5.2±0.6 mmol/L) than in those without LJM (4.7±1.1 mmol/L). In type 2 patients HDL-C values were higher in subjects without LJM (1.3±0.4 mmol/L) than in subjects with moderate (0.9±0.3 mmol/L) or severe LJM (0.9±0.3 mmol/L). No significant association between LJM and serum TG concentration was found in type 1 or 2 patients. TC (5.4±1.4 vs. 4.8±1.1 mmol/L) and TG (1.5±1.2 vs. 1.0 ±0.6 mmol/L) concentrations were higher in type 1 diabetic subjects with than in those without DD, whereas no associations were found in type 2 diabetic subjects. No significant association between DD and HDL-C was found in type 1 or 2 diabetic subjects. The mean TC concentration was higher (5.5±0.7 vs. 4.8±1.2 mmol/L) in type 1 patients with SC than in those without, whereas no association was found in type 2 patients. No significant associations between SC and mean HDL-C or TG concentrations were found in type 1 or 2 diabetic subjects.

Conclusions: High TC and TG are associated with hand and shoulder abnormalities in type 1 diabetic subjects, whereas only LJM was associated with HDL-C in type 2 diabetic subjects.

1671

ATHEROGENIC SERUM FATTY ACID PROFILE IN TYPE 2 DIABETICS WITH HYPERTRIGLYCERIDEMIA

P. Bohov, I. Klimeš, V. Baláž[1] and E. Šeböková. Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava and [1]Research Institute of Gerontology, Malacky, Slovak Republic

Hypertriglyceridemia significantly accelerates the atherogenic risk in diabetics, especially in non-insulin dependent diabetes mellitus (NIDDM). There is growing evidence that beside serum lipids the process of atherogenesis is seriously influenced also by the abnormal serum and tissue fatty acids (FA) composition. The aim of the study was therefore to assess the changes in serum FA composition in NIDDM patients with diverse types of hyperlipidemia (HLP). The groups of NIDDM patients, treated with oral antidiabetic drugs, consisted of 21 subjects (10 men) with normal serum lipids (DM-NLP), 11 cases (4 men) with hypercholesterolemia (DM-CH), 43 (14 men) with hypertriglyceridemia (DM-TG) and 39 patients (16 men) with combined hypercholesterolemia and hypertriglyceridemia (DM-HLP). 21 (10 men) age-matched healthy control (C) subjects were also investigated. Serum lipid levels and glycemia were determined with the aid of an automatic biochemical analyzer. Fatty acid analysis of total serum lipids was carried out by gas chromatography using a capillary column with a highly polar stationary phase. The statistical significance of differences among the groups were evaluated with the ANOVA test. There were no differences between the groups in the age of subjects (mean±SEM 63.4±0.7 yrs) and in the duration of diabetes (10.1±0.43 yrs). The significantly different serum FA composition was found in DM-TG and DM-HLP groups compared to others. In particular, the proportion (wt%) of total saturated FA increased compared to that of the C (C: 30.48±0.49 vs DM-TG: 32.60±0.34, DM-HLP: 32.74±0.34; P<0.01). They had also a higher content of total monounsaturated FA in comparison to other groups (C: 27.67±0.44, DM-NLP: 27.67±0.76, DM-CH: 27.53±1.09 vs DM-TG: 30.80±0.44, DM-HLP: 31.84±0.59; P<0.01), and lower content of total polyunsaturated FA of the omega-6 series (C: 37.90±0.58, DM-NLP: 37.23±1.07, DM-CH: 37.72±1.04 vs DM-TG: 32.49±0.52, DM-HLP: 31.56± 0.72; P<0.01). The latter was mainly due to a decreased content of C18:2n-6 in these groups (C: 27.71±0.34, DM-NLP: 27.19±0.94, DM-CH: 27.12±1.16 vs DM-TG: 23.05±0.45, DM-HLP: 23.07± 0.52; P<0.01). From the long chained omega-6 FA, a lower content of C20:3n-6 and C20:4n-6 in the DM-HLP group in comparison to normolipidemics was noted. The data on n-3 polyunsaturated FA revealed only a lower content of C18:3n-3 in diabetics when compared to controls. In conclusion, the increase of serum saturated FA level at the cost of polyunsaturated FA, especially those of n-6 serie, may together with higher level of serum triglycerides significantly contribute to the increased atherogenic risk commonly found in hypertriglyceridemic NIDDM patients.

1672

NON-DIETARY DETERMINANTS OF POSTPRANDIAL TRIGLYCERIDE VALUES IN NORMOTRIGLYCERIDEMIC TYPE II DIABETICS.

S.J.L. Bakker[1], S. Casteleijn[1], A. Hattemer[2], P.G. Scheffer[1], T. Teerlink[1] and R.J. Heine[1]. Research Institute for endocrinology, reproduction and metabolism[1], Academic Hospital Vrije Universiteit, Amsterdam, The Netherlands and Dept. of Diagnostics[2], Boehringer Mannheim, Mannheim, Germany.

In Type II diabetes, fasting hypertriglyceridemia has been shown to be a risk factor for cardiovascular disease. The aims of this study were to assess the determinants of postprandial triglyceride (TG) levels and the association between fasting TG levels and postprandial TG levels in normotriglyceridemic (fasting TG ≤ 2.2 mmol/l) subjects with Type II diabetes. We included 23 (11m/12f) euthyroid, diet or tablet-treated subjects, aged 61±7.9 years and with a BMI of 30.4±5.3 kg/m^2. The HbA1c was 6.0±1.3% and mean fasting TG levels ranged from 0.6 to 2.2 mmol/l with a median value of 1.5 mmol/l. All subjects performed self-monitoring of their TG values with an Accutrend GCT (Boehringer Mannheim, Mannheim, Germany). The following values were computed from their self-monitored TG (STG) data: A mean fasting (F-STG), mean bedtime (BT-STG) and a mean incremental area under the curve (A-STG). The laboratory measured fasting TG level correlated significantly with the F-STG (r =0.65, p=0.001) and with the BT-STG (r =0.54, p=0.011), but not with the A-STG. Waist-to-hip ratio (WHR) correlated significantly with BT-STG (r =0.55, p=0.01), but not with fasting TG, F-STG or A-STG. Thyroid stimulating hormone (TSH) correlated significantly with BT-STG (r =0.55, p=0.01) and A-STG (r =0.55, p=0.009), but not with fasting TG or F-STG. In conclusion, in normotriglyceridemic subjects with Type II diabetes the fasting TG levels correlate strongly with self-monitored fasting and bedtime TG values, but not with the incremental area under the curve. Body fat distribution (WHR) and TSH levels, even in these euthyroid subjects, were important determinants of postprandial TG levels. The clinical significance of these findings remains to be demonstrated.

1673

GENDER INFLUENCE ON LDL SUBFRACTION DISTRIBUTION IN TYPE II (NIDDM) DIABETIC PATIENTS.

A.Caixàs, A.Pérez, A.Payés*, JL.Sánchez*, J.Ordóñez-Llanos*, A.Caballero, A.de Leiva. Endocrinology & *Biochemistry Dpts. H.Sant Pau. UAB. Barcelona. Spain.

Predominance of small and dense LDL (phenotype B) is considered a risk factor for cardiovascular disease. We evaluated the influence of gender on LDL subfraction distribution in NIDDM patients before (HbA1c 9.8±2.0%) and after (HbA1c 5.9±1.0%) the optimization of glycemic control with insulin therapy. Thirty-three NIDDM (19 males, age 56.4±7.0 years, Body mass index (BMI) 26.4±3.5 kg/m^2; 14 postmenopausal females, age 63.9±11.4 years, BMI 25.2±3.5 Kg/m^2) and 25 age-sex-BMI matched control subjects were studied. Six LDL subfractions were isolated by density gradient ultracentrifugation and classified as the quotient LDL_1-LDL_3/LDL_4-LDL_6 (phenotype A >1.8, AB 1.1-1.8, B < 1.1). Differences were assessed by Mann-Whitney test. In NIDDM patients, during both stages of glycemic control, no differences between men and women were observed in the percentage of LDL subfractions and the phenotype. However, compared with non-diabetic women, NIDDM women showed a lower percentage of LDL_2 (31.0±3.6 vs 24.4±8.7%, p<0.05) and a higher percentage of LDL_5 (6.3±1.5 vs 10.0±4.8%, p<0.05) and LDL_6 (4.2±0.8 vs 6.1±2.3%, p<0.05) that resulted in a lower phenotype ratio (3.4±1.1 vs 2.4±1.7, p<0.05). No differences were observed between non-diabetic and NIDDM men during both stages of glycemic control. In conclusion, these findings may contribute to explain the loss of protection for cardiovascular disease in diabetic women.

1674

DIABETIC MICRO- AND MACROANGIOPATHY. HOMOCYSTEINE AND LDL-TRIGLYCERIDES COMPARED TO OTHER LIPOPROTEIN-RELATED RISK FACTORS

W. März, E. Bissé, M. Nauck, N. Weickmann, and H. Wieland
Department of Medicine, Division of Clinical Chemistry, University of Freiburg, Germany

We analysed lipids, lipoproteins and homocysteine in 200 female and male patients with type I and type II diabetes mellitus and in age-matched healthy controls. Blood samples were drawn after an overnight fasting period. In contrast to healthy controls, diabetic patients had higher HbA1c values and type II diabetics were overweighted. In female type II diabetics, serum triglycerides were significantly higher than in female controls (2.47 vs 1.58 mmol/L, $p < 0.05$); in contrast, the increase in triglycrides in male type II diabetics was not significant (2.79 vs 1.96 mmol/L). In both, female (f) and male (m) diabetic patients, HDL-cholesterol was significantly reduced compared to controls. In type II diabetic patients serum triglycerides as well as HDL-cholesterol correlated with the severity of the diabetic macroangiopathy. None of the standard serum lipid measurements correlated with microangiopathic lesions. However, LDL-triglycerides were significantly elevated in female and male diabetic patients with severe macroangiopathic (f: 0.49 vs 0.39; m: 0.42 vs 0.35 mmol/L) and microangiopathic lesions (f: 0.48 vs 0.41; m: 0,41 vs 0.33 mmol/L). Moderately elevated homocysteine levels were reported as a risk factor for peripheral vascular and premature coronary artery disease. In this study, however, diabetic patients showed significantly decreased homocysteine concentrations compared to healthy controls (f: 12 vs 15; m: 13 vs 17 μmol/L). In the group of diabetes patients, severity of macroangiopathic lesions correlated with increasing homocysteine levels (f: 15 vs 11; m: 15 vs 12 μmol/L); there was no correlation between homocysteine and microangiopathic lesions. We conclude that, in contrast to conventional lipid-related risk indicators, LDL-triglycerides could become a powerful predictor for microangiopathy in diabetic patients. The finding that homocysteine is generally lower in patients with impaired glucose tolerance should be accounted for if homocysteine is used to assess an individual's risk for atherosclerosis.

1675

CHANGES IN LDL_A AND LDL_B IN POORLY CONTROLLED PATIENTS WITH NON-INSULIN DEPENDENT DIABETES MELLITUS

A.Kiriakov, J.Dimova, J.Kavrakova, S.Zlateva, M.Nenova and V.Christov.
Medical University, Sofia, Bulgaria.

This study attempted to reveal atherogenesis specificity in NIDDM patients considering lipoprotein heterogenity and the strong evidence for direct involvement of LDL subpopulations in particular LDL_B subfraction's potential for involvement in atherosclerosis.
36 poorly controlled NIDDM patients (HbA_{1c} > 10%) were compared with 36 sex and age matched healthy control subjects. LDL subclasses were separated by sequential ultracentrifugation. ApoAI and ApoB were assayed using immunoturbidimetric tests, cholesterol (Chol) and triglyceride (TG) concentrations in plasma, lipoprotein-classes and LDL-subclasses using enzymatic methods. The comparative analysis applied between poorly controlled NIDDM patients and controls reveals: decrease in Chol-contents in LDL_A ($\Delta\%LDL_A$-Chol=-16.9, $p<0.05$) whereas in LDL_B was observed increase ($\Delta\%LDL_B$-Chol= 20.0, $p<0.05$); the increase in TG-contents was different for LDL_A ($\Delta\%LDL_A$-TG = 105.0, $p<0.001$) and LDL_B ($\Delta\%LDL_B$-TG = 56.2, $p<0.001$); the decrease in ApoB-contents is also different for LDL_A ($\Delta\%LDL_A$-ApoB = -47.8, $p<0.001$) and LDL_B ($\Delta\%LDL_B$-ApoB= -22.8, $p>0.05$). Significant changes in plasma TG, total Chol, HDL-Chol ApoAI and ApoB were also observed.
Conclusion: in poorly controlled NIDDM patients were found differences both in the size and Chol- and TG-contents of LDL_A- and LDL_B-subclasses.

1676

ATHEROGENIC LIPIDS AND LIPOPROTEINS ABNORMALITIES IN IDDM COMPLICATED BY EARLY AND LATE NEPHROPATHY.

J.Walewski, J.Tatoń, J.Leowski, and A.Czech, Department of Internal Medicine and Diabetology, Warsaw Medical School, Poland.

Assumption: Accordingly to epidemiological study in Warsaw (1995) nephropathy increases 9 - folds the risk of cardiovascular death in IDDM. This is much more than it could be explained by traditionally studied risk factors. The specific for diabetic nephropathy, quantitative and qualitative lipids and lipoproteins abnormalities could be considered as the possible explanation for this additional atherogenic risk. **The research aims were:** 1. to evaluate the plasma lipids composition - total cholesterol, VLDL - cholesterol, HDL - cholesterol, LDL - cholesterol, total triglycerides, triglycerides in VLDL, triglycerides in LDL, protein content of LDL; 2. to determine the oxidizability of isolated LDL (oxidation test in vitro). **3 groups of the IDDM were studied**: a. 20 patients with overt nephropathy; b. 15 patients with microalbuminuria; c. 20 patients without nephropathy (as control group). All patients were hospitalised for the study. **Results:** I. Statistically significant differences in plasma lipids were found: 1. in microalbuminurics vs controls - LDL cholesterol; 2. in proteinurics vs controls a) total cholesterol, b) LDL cholesterol, c) total triglycerides, d) triglycerides in VLDL; 3. in proteinurics vs microalbuminurics a) total cholesterol , b) total triglycerides, c) triglycerides in VLDL. II. Statistically significant differences in LDL oxidizability in vitro were found: 1. in proteinurics vs controls a) lag phase, 2. in all three groups - maximal rate of LDL oxidation. **Conclusion**: In microalbuminurics (pre-clinical nephropathy) and proteinurics (overt nephropathy) IDDM subjects similar atherogenic abnormalities of lipids and lipoproteins composition and oxidizability were found. This suggests, that atherogenic risk in diabetic nephropathy occurs very early and is not simply related to the degree of proteinuria.

1677

LDL oxidation in type 2 diabetic patients with microalbuminuria.

E. Moro, C. Zambon, S. Pianetti, G. Cazzolato, P. Alessandrini, M. Pais, G. Bittolo Bon. Diabetes Clinic, Regional General Hospital, Venice, Italy.

The aim of this study was to evaluate if there is a relationship between LDL oxidation and microalbuminuria, that is considered an early marker of vascular involvement in type 2 diabetes. Twenty-four type 2 diabetics, 12 out of them microalbuminuric (MA+) and 12 normoalbuminuric (MA-), and 12 control subjects were selected. Microalbuminuria was defined as an urinary albumin excretion rate of 30-300 mg/24h. There was no difference in the three groups for age, gender, and blood pressure values. As index of in vivo LDL oxidation, we measured the percentage of LDL^- by ion-exchange HPLC. In vitro susceptibility to oxidation of LDL was evaluated following the kinetic of coniugated diene formation in presence of Cu++ ions (lag time). Metabolic control was significantly worse in diabetics MA+ in comparison with diabetics MA- (fructosamine 341±71 vs 279±53 mM/L; $p<0.02$). Diabetics MA+ had triglyceride level significantly higher in comparison with diabetics MA- (2.21± 1.01 vs 1.15± 0.39 mmoli/L, $p<0.01$) and controls (2.21± 1.01 vs 1.18± 0.61 mmoli/L, $p<0.01$). Diabetics MA+ had significantly higher percentage of LDL^- in comparison with diabetics MA- (5.2±1.7 % vs 3.1±1.2 %; $p<0.01$) and controls (5.2±1.7 % vs 2.34±1.03 %; $p<0.001$). LDL isolated from diabetics MA+ had a significantly shorter lag time in comparison with diabetics MA- (79±11 vs 97±9 minutes; $p<0.05$), and controls (79±11 vs 120±24.5 minutes; $p<0.001$). A significant linear correlation was observed between LDL^- and some parameters of metabolic control such as fructosamine ($r=0.45$, $p<0.05$) and triglycerides ($r=0.65$, $p<0.001$). An inverse correlation was found between lag phase and fructosamine ($r=-0.50$, $p<0.01$) and triglyceride ($r=-0.69$, $p<0.001$). These data show that type 2 diabetics with microalbuminuria have evidence of an increase oxidation in vivo and oxidability in vitro of LDL in association with a poor metabolic control. We propose that an increased lipoprotein oxidation could promote endothelial lesions in type 2 diabetics with microalbuminuria.

1678

RELATIONSHIP BETWEEN SEQUENTIAL CHANGES OF MICROPROTEINURIA AND SERUM LIPIDS IN NIDDM

Katsuhiko Hoshi, Akinori Sasaki, Yasushi Ishigaki, Susumu Hara, Akihiro Sekikawa, Hiroshi Midorikawa, Kyoko Hayasaka, Hidetoshi Kotake, Shinichi Oikawa and Takayoshi Toyota The Third Department of Internal Medicine, Tohoku University School of Medicine, Sendai, Japan

There are many risk factors to deteriorate diabetic nephropathy. To determine these factors, we compared sequential changes of microproteinuria with clinical backgrounds in NIDDM. We studied the levels of microproteinuria (microalbuminuria by immunoturbidity method and transferrinuria by latex agglutination method) in 204 diabetic patients. We divided them into three groups by the levels of microproteinuria; Normal group (N, n=77): normoalbuminuria (<20mg/g Creatinine) and normotransferrinuria (<1.0mg/g Creatinine), Mild group (M, n=43): normoalbuminuria and high transferrinuria, High group (H, n=84): high albuminuria and high transferrinuria. After 3-year observation, they were divided into three groups according to sequential changes of microproteinuria; (1) Deteriorated group: 23 cases (N→M, N→H, M→H), (2) Unchanged group: 78 cases (N→N, M →M), (c) Improved group: 48 cases (H→M, H→N, M→N). Among these three groups, we compared clinical backgrounds (Age, Duration, Blood pressure, Body mass index, FPG, HbA1c, Total-cholesterol, Triglyceride, HDL-cholesterol, BUN and Creatinine). In the deteriorated group, triglyceride ($P<0.01$) and body mass index ($P<0.05$) were significantly increased and HDL-cholesterol ($P<0.05$) was significantly decreased compared with other two groups. We conclude that the deterioration of microproteinuria in NIDDM will be associated with lipids metabolism.

1679

RELATIONSHIP BETWEEN LDL PARTICLE SIZE AND ATHEROSCLEROSIS IN THE PATIENTS WITH NIDDM.

N.Nagase, R.Kawahara, M.Yoshino, Y.Omori, K.Kondo #, H.Itakura#.
Diabetes Center, Tokyo Women's Medical College.
#The National Institue of Nutrition, Tokyo Japan

This study was conducted to determine the relationship between atherosclerotic diseases and LDL particle size in NIDDM. Method: Included in the present study were 125 NIDDM patients treated in this diabetes center, 102 male and 23 females aged 60.1±7.7 years with BMI of 23.7± 3.6. They were divided into 4 groups: 62 with ischemic heart disease (CHD), 17 with cerebral infarction (CVD), 20 with arteriosclerosis obliterans in the lower limbs (ASO), and 26 with no sclerotic disease(C). The healthy volunteers were used as control(N). Plasma lipid and lipoprotein levels and LDL particle size (Kraus & Bruke method) were determined using over nigt fasting blood samples. Results:The LDL particle size was 25.4±0.9, 25.4 ± 0.6, 25.4 ± 0.8, 25.2 ± 0.7, and 26.1 ± 0.7nm respectively, in Groups CHD, CVD, ASO, C and N. It was smaller in all 4 NIDDM groups than in Group N. The percentage of Pattern B was statistically significantly higher in all 4 NIDDM groups than in Group N. The plasma lipid and lipoprotein profile showed a TG-rich tendency in the NIDDM groups compared to Group N. In conclusion, LDL particles were small in NIDDM patients regardless of the presence or absence and the type of atherosclerotic diseases. This seemed to be related to the fact that lipoprotein profile was TG-rich.

1680

LIPIDE STATUS OF POORLY REGULATED DIABETES : OBESE TYPE 2 WITH AND WITHOUT MACROANGIOPATHY , TYPE 1 AND TYPE 1 WITH NEPHROPATHY

D.Banovic, M.Dragasevic, S.Popovic, Lj.Popovic, M.Dragasevic and P.Dodevic
Institute of Endocrinology, Diabetes Center , Belgrade, Yugoslavia

Determinants of hyperlipidaemia in diabetes mellitus are numerous: age, obesity, glycaemic control, nephropathy etc. According to PROCAM study results, different dislypidemias have disproportional grades of risks for macroangiopathy. Group of 20 obese(BMI=30,4=/-4,9) type 2 Diabetics without Macroangiopathy (OD2-M), 20 obese (BMI=32+/-5,1) type 2 Diabetics with Macroangiopathy(OD2+M), 20 nonobese type 1 Diabetics (D1) and 10 nonobese type1Diabetics with Nephropathy (D1+N) were compared according to first level lipidogram. Patients were not smokers, and except D1+N group were normotensive. Duration of diabetes was 6,4+/-2,5 y. for OD2-M; 6,1+/-3,2 y. for OD2+M ; 8,2+/-3,1 y. for D1 and l3+/-4,4 y for DI+N group. HbAlc was high and not significantly different: OD2-M =10,5+/-2,56%,OD2+M =9,83+/-4,3%, D1 =11,23+/-2,7% and D1+N=10,2+/-2,6%(p>0,05).Values for triglicerides / cholesterol/ LDL/HDL were: OD2-M 1,7/5,62/3,62/1,31 mmol/l; OD2+M 3,94/6,36/3,91/1,19 mmol/l; D1 1,88/6,68/3,95/1,33 mmol/l; D1+N 3,28/9,26/6,49/1,12 mmol/l (without SD here). Basal C-peptide levels were significantly higher in DM2+M group than in DM2-M (1,73+/-0,29 vs 1,21+/-0,23 nmol/l , p<0,01) . Conclusive differences were found between significantly higher level of triglicerides in DM2+M than in DM2-M,positively correlated with higher C-peptide levels(p<0,01); significantly (but less) higher cholesterol as well as LDL level in D1 than in DM2-M(p<0,05) but not DM2+M group(p>0,05); significantly higher triglicerides,holesterol and LDL in D1N group comparing to all other groups (p<0,01). HDL cholesterol was not found significantly different between groups (p>0,05). It was concluded that in chronically hyperglycemic patients hypertrigliceridaemia with higher insulin (resistance) is risk factor of macroangiopathy in OD2 patients, moderate hypercholesterolaemia in D1 patients ,and frank hypercholesterolemia and hypertrigliceridemia in D1+N.

1681

SMALL, DENSE LDL AND EARLY STAGE OF DIABETIC NEPHROPATHY

G.Yoshino, T.Hirano, H.Naito, T.Mori, T.Kazumi and T. Urayama. Toho University, Tokyo, Japan

We have previously reported the decrease in LDL particle size in NIDDMs with microalbuminuria compared to that in those with normoalbuminuria. Therefore, the present study was conducted to examine the influence of LDL size on the development of early diabetic nephropathy monitoring urine FDP(fibrin/fibrinogen drgradation products),a new candidate for earlier marker for the nephropathy. We examined 144 NIDDMs without hypertension and 142 non-diabetic healthy volunteers (N). Urine (early morning) FDP was measured by chemiluminescent enzyme-linked immunoassay with dioxetane derivative substrate for the labelled alkaline phosphatase. The detection limit is lng/ml, which is approximately 1/100 of conventional turbidimetric method. Abnormally high level of urine FDP (above mean+2SD of group N) was found in 68% (45/66) of NIDDMs with normoalbuminuria. Furthermore, 90% (30/33) of those with micro- or macroalbuminuria had elevated urine FDP. When NIDDMs with normoalbuminuria were divided into two groups according to thier urine FDP levels, there were no significant differences in either mean age, BMI, duration of diabetes, smoking rate, blood pressure, HbAlc, FBG or plasma lipids. The only one discriminater was LDL size ; the group with abnormally high urine FDP levels (n=23) had smaller LDL compared to that with normal urine FDP levels (n=22) (25.4±1.3 vs 26.3±1.2 nm, p<0.05). Together with our previous observation it is concluded here that small sized LDL is deeply involved in the development of early diabetic nephropathy.

1682

APOLIPOPROTEIN E (APO E) GENE POLYMORPHISM IN SARDINIAN NON INSULIN DEPENDENT DIABETIC PATIENTS (NIDDM)

M.G..Melis,G.Tonolo,G. Secchi,M. M. Atzeni, M. Ciccarese,M. Maioli, M.F.Angius, P. Brizzi, L Puddu, *G. Pala,**A. Massidda, ***M..Manai,***R.M.Pilosu and M. Maioli
Clinica Medica,Sassari, and Diabetologia, *Nuoro, ** Lanusei, *** Cagliari-Italy.
For The Sardinian Diabetes Genetic Study Group (SDGSG)

The preliminary aim of our study was to compare the frequency of apo E alleles between the homogeneous Sardinian population and what is reported for the rest of Italians in the mainland (James RW, Arterioscl Thromb 1993). Additionally we compared the Centre (the most archaic area)with the rest of Sardinia, as we found a difference in the frequency of the Gly40Ser amino-acid variant of the glucagon receptor gene between these Sardinian regions(Tonolo et al, Diabetologia 1997 in press). All subjects were of Sardinian ancestry for more than two generations. In multiplex NIDDM families at least two affected siblings and, if available, unaffected siblings were included. Additionally unrelated NIDDM and non diabetics subjects were also enrolled. All are currently characterised for BMI, diabetic complications (retinopathy, nephropathy, ischemic heart disease) and hypertension. Blood for DNA, apoA1, apoB, serum total and HDL cholesterol, triglycerides, HbA1c, and urinary albumin excretions rate were also obtained. So far a total of 950 subjects were enrolled. We report here the preliminary data on the first 517 subjects in whom apoE alleles were determined. No apparent allele distribution differences were evident so far between NIDDM and non NIDDM, and data (presented as % and analysed with χ^2)are cumulated.

Apo E	All	North	Centre	South	*=p<0.01vs Mainland
ε2	3.6 *	5.0	1.9	0.9	§=p<0.05 North vs
ε3	89.2 *	87.3 §	94.8	89.8	Centre; #=p<0.05
ε4	7.3	7.7	3.3 #	9.3	South vs Centre

Total cholesterol as well LDL cholesterol and apolipoprotein B were lower, but not significantly, in subjects with the ε2 allele. Our preliminary data indicate: 1)ApoE alleles frequency in Sardinia are different from the mainland, 2)the Centre of Sardinia is different from the North and the South, holding one of the lowest prevalence of ε4 in the world, 3) dietetic therapy in NIDDM may mask the effects of apoE polymorphism on lipid metabolism, 4)we are in a good position to analyse the relations between apo E alleles and cardiovascular disease in Sardinian NIDDM.

1683

APOLIPOPROTEIN E GENOTYPE AND CHOLESTEROL SYNTHESIS IN NORMOLIPIDEMIC TYPE II DIABETIC PATIENTS

A. Scoppola, A. Mancini*, C. Motti°, P. Rampa°, G. Testa*, C. Cortese° and A. Lala.
Endocrinology and °Clinical Biochemistry, University of Rome "Tor Vergata" - *S. Camillo Hospital, Rome - Italy

The polymorphism of the apolipoprotein (apo) E gene locus influences up to the 16% of the variance of total serum cholesterol in the normal population. Subjects carrying the E4 allele show decreased cholesterol synthesis and LDL receptor activity than those carrying the E3 allele. So far, the effect of apo E polymorphism on cholesterol synthesis in diabetic patients is unknown. We studied 14 type II non-obese diabetic patients in good metabolic control, with normal renal function and treated with diet and oral hypoglycemic agents. The patients were divided in two groups according to their Apo E genotype. Apo E 3/3 group: 4 males and 4 postmenopausal females aged 60±8 years, BMI 27±1.7 Kg/m^2, HbA1c 6.3±1%, Tot. Chol. 199±19 mg/dl, HDL Chol. 51±11 mg/dl, Tg. 140±54 mg/dl. Apo E 4/3 group: 3 males and 3 postmenopausal females aged 63±3.5 years, BMI 27±2 Kg/m^2, HbA1c 6.9±0.3%, Tot. Chol. 203±17 mg/dl, HDL Chol. 51±16 mg/dl, Tg. 157±49 mg/dl. Apo E genotype was determined on DNA extracts by restriction isotyping of PCR products. The 24/h urinary mevalonate excretion, an index of whole body cholesterol synthesis, was evaluated by GC(CI^-)MS after exctraction by CH_2Cl_2:PrOH (9:1). The mean mevalonate excretion was 1.43±0.18 µmol/24h in the Apo E 3/3 group and 1.20±0.13 µmol/24h in the Apo E 4/3 group (n.s.). In conclusion our preliminary data demonstrate no differences of cholesterogenesis between the two most common Apo E genotypes in a selected group of non-obese, normolipidemic type II diabetic patients under optimized metabolic control.

Lipids and Lipoproteins – Treatment

1684

EFFECT OF INSULIN ON LOW-DENSITY LIPOPROTEIN OXIDABILITY IN NIDDM PATIENTS .

T. Pelikánová, L. Kazdová, A. Žák and Z. Vlasáková. Institute for Clinical and Experimental Medicine, Postgraduate Medical School and 1st Medical Faculty of Charles University, Prague, Czech Republic.

Hyperinsulinemia and increased oxidative modification of low-density lipoproteins (LDL) have been implicated as independent risk factors for atherosclerosis, the most common cause of mortality and morbidity of patients with non-insulin-dependent diabetes mellitus (NIDDM). The aim of our study was to evaluate the effect of acutely induced hyperinsulinemia on LDL susceptibility to in vitro Cu^{2+} induced oxidative modification in 15 NIDDM patients and 11 healthy control subjects. A 10-hour isoglycemic hyperinsulinemic clamp (75 µU/ml) and a time-controlled study with saline infusion were performed in all subjects. Compared to healthy subjects NIDDM patients showed a shorter lag time of diene production (67±19 vs 74±10 min; $p<0.05$), increased oxidative modification of protein moiety measured by emission fluorescence spectra at 430 nm with excitation at 355 nm (EFS) (402±130 vs 281±115; $p<0.02$), although the differences in thiobarbituric acid reactive substances (TBARS) (50 0±26 vs 45.5±26 nmol/mg of LDL protein) did not reach statistical significance. While acute hyperinsulinemia resulted in a decrease in lag time (-18%; $p<0.01$), an increase in TBARS (+ 46%; $p<0.001$), and a rise in EFS (+51%; $p<0.01$) in controls, the LDL oxidability-enhancing effect of insulin was not significant in diabetics. We conclude that NIDDM is associated with increased LDL susceptibility to oxidative modification. While acutely induced hyperinsulinemia enhances LDL oxidability in healthy subjects it does not aggravate LDL oxidability in NIDDM patients, suggesting factors other than insulin play a role in diabetes.

1685

INSULIN THERAPY IN TYPE 2 DIABETES.

A. AMETOV, V. TOPCHIASHVILI. International Diabetes Program, Moscow, Russia.

The aim of our open randomized controlled study was to assess the influence of intensive and combined insulin therapy on insulin and lipid profile in NIDDM patients with secondary failure (SF) to sulphonylureas (SU). The study involved 32 patients: (10m, 22f., mean age 58,9± 0,9 y., BMI - 21,8±1,04 kg/m^2). Patients were divided into 2 groups: 1.basal-bolus insulin regimen (Actrapid® HM + Monotard® HM), (n=18); 2.combined basal insulin/glibenclamide therapy (Monotard® HM as basal insulin) (n=14). Lipid metabolism and pancreatic function assessment was conducted at baseline state, and at the end of 4 and 12 week period. Marked fall in basal and postprandial glycaemia was achieved after 4 week period in both groups. Basal free insulin level didn't change in patients of the 1st group, but significantly increased in the 2-nd group. Both regimes caused marked postload hyperinsulinaemia. Plasma levels of Cholesterol (Chol.), Tryglycerides (Tg.) and LDL-chol. were elevated in all patients. At the end of the 12 week period Tg and VLDL chol. levels decreased significantly till normal levels in both groups. Chol. level significantly decreased at the expense of LDL and VLDL fractions and reached normal level only in the 1-st group. Tg and VLDL chol. levels decreased in these patients at the end of 4 week period, while at the end of the study these atherogenic parameters were lower, than in control group. In the 2-nd group Tg and VLDL chol. levels decreased till normal ranges only at the end of 12 week period, while total and LDL chol. levels at the same study point were higher than those in control group. Marked fall in apoB/apoA1 ratio was observed at the end of the study in the 1-st group, while in combined regime, decreasing after 4 week period this parameter reached initial values at the end of the study. Phosfolipid content of HDL was improved after 12 week period in both groups. Lp(a) level was constant in both groups, irrespective of treatment mode. Finally, intensive insulin therapy during 12 weeks caused optimal antiatherogenic changes in lipid profile of NIDDM patients with SF, in spite of marked persisting hyperinsulinaemia.

1686

THE EFFECT OF INTENSIVE INSULIN THERAPY ON THE SERUM LIPID PROFILE IN DIABETIC PREGNANT WOMEN.

G.Sygitowicz, E.Jóźwicka, A.Minor, J.Krzymień, J.Pachecka and A.Czyżyk. University School of Medicine, Warsaw, Poland.

Intensive insulin therapy has improved the course of pregnancy and delivery in women with diabetes. Additional evidence shows that hyperinsulinemia exert effect on lipid metabolism, which undergoes specific modifications in these patients. The present study assessed the serum lipid profile in 54 pregnant women and 35 non-diabetic pregnant women with respect to the following parameters: triglycerides (TG), total cholesterol (TCh), HDL-cholesterol (HDL-Ch), LDL-cholesterol (LDL-Ch), apolipoprotein A1 (apo A1), apolipoprotein B (apo B). The metabolic control was determined by serum fructosamine concentration. Serum lipid profiles in women at the end of I and III trimester (TR) of pregnancy is shown in table:

	Non-	diabetic	Insulin	treated
	I TR	III TR	I TR	III TR
Fructosamine (mM)	2.18	1.93	2.89	2.73
TG (mM)	1.48	3.85	1.09	2.55**
TCh (mM)	6.30	8.87	4.65*	7.96
HDL - Ch (mM)	2.03	3.33	1.26*	1.57***
apo A1 (mg/dl)	209.1	234.8	158.8**	168.0***
apo B (mg/dl)	113.2	167.9	95.6	164.5

* $p < 0.05$ ** $p < 0.01$ *** $p < 0.001$

In diabetic pregnant women serum levels of TG, TCh, HDL-Ch, apo A1 and apo B were lower than those in non-diabetic pregnant patients. The reduced TG level may result from inhibition of lipoprotein lipase due to large doses of insulin. The decreased in HDL-Ch and apo A1 does not seem so clear. However, it may be caused by resistance of hepatic lipase to insulin, or to down regulation mechanism occurring in states of hyperinsulinemia.

1687

BEZAFIBRATE AND SIMVASTATIN COMBINATION THERAPY FOR DIABETIC DYSLIPIDEMIA. EFFICACY AND SAFETY

A. Rubinstein, M.Weintraub, D. Gavish. Tel-Aviv medical centre Tel-Aviv Israel

Diabetic dyslipidemia is a principal cause of cardiovascualr morbidity and mortality. Hypolipidemic drugs.- fibrates and statins, have been shown to correct diabetic dyslipidemia and reduce cardiovascular morbidity. In this study 142 patients (age 35-73) diagnosed as suffering from NIDDM (Hg A_1C above normal levels) on diet or oral hypoglycemic therapy with diabetic dyslipidemia which persisted in spite of glycemic control were assigned to simvastatin 20 mg/day for 3 months, followed by a combination therapy of 400 mg Bezafibrate + 20 mg Simvastatin per day for a period of 6 months. On statin alone, LDL-C decreased by 29% triglycerides by 16% HDL-C increased by 4.2% and no significant change was seen in Lp(a) and Fibrinogen levels. Combination therapy decreased LDL-C by 28% ($p<0.001$), triglycerides decreased by 40% ($P<0.0001$), HDL-C increased by 17.6% ($p<0.01$), Lp(a) decreased by 10% ($p<0.05$), Fibrinogen decreased by 10% ($p<0.05$), 11 patents had increased C.P.K. serum levels 3 patients stopped treatment due to C.P.K elevation and minor muscle pain. Adherence to therapy was 85% at 6 months on the combination regimen and 98% on statins monotherapy. Our results suggest that in diabetic dyslipidemia a combination therapy may be beneficial due to improved atherogenic and thrombogenic profile.

1688

LDL MODIFICATIONS IN WELL CONTROLLED DIABETIC PATIENTS: EFFECTS OF PHYSICAL TRAINING

A.Pérez, M.Rigla, J.L.Sánchez*, A.Caixàs, A.Payés*, R.Serra#, J.Ordóñez*, A.de Leiva. Endocrinology, Biochemistry* and Cardiology# Dpts. H.Sant Pau.UAB.Barcelona.Spain.

Our group previously reported that the atherogenic electronegative LDL subform (LDL-) is increased in diabetic patients and closely related to glycemic control in IDDM patients.We evaluated the effect of a 3 month physical training program (3-5 days/week, 1852±387 kcal/week)on LDL composition, the percentage of LDL - and LDL susceptibility to oxidation in fourteen type I (7 male, 7 female, age 25 ± 6 years, BMI 23.8±3 kg/m^2, HbA1c 6.6±0.8% (reference range 4.6-5.8%) and thirteen type II diabetic patients (9 male, 4 female, age 55±5 years, BMI 26±6 kg/m^2, HbA1c 7.3±1%). LDL was isolated by sequential ultracentrifugation and LDL - by anion exchange in a Fast Protein Liquid Chromatography device. LDL susceptibility to oxidation was measured by dienes formation induced by $CuSO_2$ (Lag phase). Differences were assessed by Wilcoxon test. After three months of physical training, cardiorespiratory capacity (VO_2 max and O_2 pulse) improved significatively ($p<0.05$), and no changes were observed in BMI and HbA1c. The percentage of LDL - decreased from 16.2± 7.4% to 14.04±5% ($p=0.06$). No changes in LDL components (total and free cholesterol, protein and phospholipid) and in Lag phase were observed (43.6±6.7 min to 43.3±7 min).In conclusion, physical training may contribute to reduce the atherogenic risk in diabetes by means of decreasing the proportion of electronegative LDL subform.

(FIS 95/1252).

1689

EFFECTS OF CILOSTAZOL ON SERUM LIPOPROTEIN PROFILES IN PATIENTS WITH NIDDM

Y.Mishima, M.Ando, A.Kuyama and M.Kibata
National Minamiokayama Hospital, Okayama, Japan

Recently, the lipid lowering effects of cilostazol in hyperlipidemic subjects has attracted attention. A study to evaluate the effects of cilostazol on lipoprotein metabolism of 12 NIDDM subjects with dyslipidemia was conducted. One hundred and fifty mg per day of cilostazol was administered orally for three 4-week periods. Serum lipid and apolipoprotein concentrations were measured during at the end of 4-week period. Cholesterol content in the remnant like particles (RLP-c) was measured by using monoclonal anti apo B-100 and anti apo A-1 immunoaffinity mixed gels. LDL particle size was analyzed based on a new parameter (LDL-migration index, LDL-MI) which was calculated by dividing the distance from the VLDL peak to the LDL peak by the distance from the VLDL peak to the HDL peak on a PAGE densitogram. Results: The triglyceride content in serum showed a significant decrease and the HDL-c content increased significantly. RLP-c decreased from 11.8 to 4.0 mg/dl. LDL-MI showed a significant decrease from 3.9 to 3.4. These data suggest that cilostazol may have some beneficial effects on lipoprotein metabolism by normalizing LDL particle size in NIDDM patients with dyslipoproteinemia.

1690

EFFECTS OF VOGLIBOSE AND ACARBOSE ON FASTING AND POSTPRANDIAL PLASMA LIPIDS IN NIDDM PATIENTS

W. März, M. Nauck, E. Stridde, P. Kleist and H. Wieland. University of Freiburg, Germany; Takeda Euro R & D Centre, Frankfurt, Germany

Both, impairment of glucose and lipid metabolism are components of the insulin resistance syndrome. The aim of this study was to investigate whether the α-glucosidase inhibitors voglibose and acarbose influence plasma lipids in diabetics. 170 hospitalized NIDDM patients were randomly allocated to six parallel groups and received 7 days treatment with either three times daily voglibose (0.5, 1, 2, 5 mg), acarbose (100 mg) or placebo. Blood samples were taken before and 2, 3 and 4 hours after a carbohydrate rich standard meal on day -1 and day 7 to analyse phospholipids (PL), triglycerides (TG), cholesterol (C) in the serum and in VLDL, LDL and HDL as well as apolipoproteins (apo) AI, AII, B (total, VLDL, and LDL), CIII, E, and Lp (a). The effects of the treatments were analysed by one-factorial analysis of variance of the difference (day 7 *minus* day -1). 157 patients (mean age 54 years; 135 male) could be analysed. *Fasting lipids*. Voglibose decreased fasting TG (-8 % and -16 % at 1 mg and 5 mg per day), VLDL-TG (-8 % and -12 %), VLDL-C and VLDL-PL; none of these changes, however, was significantly different from placebo. Acarbose had no effect on fasting TG. Voglibose (5 mg) decreased apo E (-13 %, $p < 0.05$) and apo CIII (-7 %, $p = 0.170$). There were no consistent changes in LDL-C, apo B and Lp(a). Voglibose did not change fasting HDL-C, but acarbose lowered HDL-C from 0.95 to 0.90 mmol/l (-6 %, $p < 0.05$). *Postprandial lipids*. On day -1, total TG increased in all groups by 12 % on average 2 hours after the test meal. The 2 hours postprandial TG were dose-dependently reduced by voglibose (from 2.1 to 1.6 mmol/l at 5 mg, $p = 0.02$). Consistent changes were obtained with 5 mg Voglibose for VLDL-TG (-16 %, $p < 0.05$), VLDL-C (21 %, $p = 0.07$), VLDL-PL (-22 %, $p < 0.05$), apo E (-13 %, $p < 0.01$) and apo CIII (-6 %, $p < 0.05$); there were only slight reductions in the acarbose group. We conclude that voglibose is more potent than acarbose in reducing fasting TG-rich lipoproteins and the postprandial TG response.

1691

THE EFFECTS OF CIPROFIBRATE ON PLASMA LIPIDS AND FIBRINOGEN

H.Makrygiannis, A.Mahler, Ch.Ellinas, M.Avlonitou, Th.Karabasis, B.Giannios and H.Kavakas. Diabetic Clinic, Sismanoglion General Hospital, Athens,Greece.

Increased levels of fibrinogen seems to be an independent risk factor for cardiovascular disease. The aim of the present study was to evaluate the effect of ciprofibrate on plasma lipids and fibrinogen in NIDDM dyslipidaemic patients.24 patients (mean age 65±6, gender 10 ♂/14♀).Their current antidiabetic therapy: 1 diet only, 14 diet+sulfonyluria(SU), 1SU+Metformin, 4SU+Insulin and 5Insulin. They, if after at least one month dietary treatment period, didn't normalize their lipidaemic profile(Total cholesterol (TC)>5.2mmol/L and or Trigycerides(Trg)>1.7mmol/L)start ciprofibrate treatment, 100mg daily for 6 months.Before and at the end of the 2nd,4th and 6th month, their body weight (BW),plasma,glucose,HBA_{1C},TC,HDL,Trg and also transaminases alkaline phospatase,γGT, creatinine, uric acid and CPK were measured.Statistical analysis was done by paired samples T-test.Results:(Mean±SD before(0) and at the end of 6th month(6) respectively and% change). Significantly reduced levels of a.Fibrinogen(10.79±2.6→8.99±2.17μmol/L, -16.6%, p<0.0001),b.T.C (7.23±2.4→5.57±0.65mmol/L,-23%, p<0.0001), c.LDL (5.03±2.38 3.70+0.69mmol/L, -26.3%, p<0.0001). d.Trg (2.02±0.97→1.13±0.38, - 44%, p<0.0001). HDL increased (1.14±0.26→1.39±0.36mmol/L, +17%, p=0.0015), plasma glucose reduced in a smaller degree(7.6±1.7→7.0±1.6mmol/L, -8%, p=0.02.BW and HbA_{1C} didn't change significantly.There was not elevetion of transaminases, creatinine and CPK.In conclusion: Ciprofibrate-100mg daily for 6 months-significantly improves lipidaemic profile of dyslipidaemic NIDDM patients. Also reduces fibrinogen levels without toxic effects on liver and muscles.

1692

LIPOPROTEIN CHANGES DURING SUBCUTANEOUS OR INTRAPERITONEAL INSULIN IN IDDM PATIENTS ON PERITONEAL DIALYSIS

P. Nevalainen[1], J. Lahtela[1,2], J. Mustonen[1,2], M-R Taskinen[3,4] and A. Pasternack[1,2] .
[1] Department of Medicine, University of Tampere, [2] Tampere University Hospital, Tampere, [3] Department of Medicine, University of Helsinki, [4] Helsinki University Hospital, Helsinki, Finland

Intraperitoneally administered insulin is regarded as the most physiological replacement therapy of insulin. Compared to subcutaneous insulin this leads to lower peripheral insulin concentration and equal or better glycemic control. The effects on serum lipids, a major risk factor of atherosclerosis, are conflicting. This study was undertaken to evaluate the effects of subcutaneous vs. intraperitoneal insulin on serum lipoproteins in type I diabetic patients on continuous ambulatory peritoneal dialysis (CAPD). Eleven patients participated in the study. Serum lipids, apoproteins A-I, A-II and B, and HDL subfractions were measured. While on CAPD all patients were first treated with subcutaneous and then with intraperitoneal insulin. The metabolic studies were repeated after three months on either treatment. Intraperitoneal insulin decreased HDL-cholesterol ($p<0.01$) and increased LDL/HDL ratio ($p<0.01$) significantly. HDL-cholesterol reduction was almost entirely seen in the HDL3 fraction ($p<0.05$) that consists of the smallest and densest particles. Apoprotein A-I, the major apoprotein of HDL, decreased during intraperitoneal insulin treatment ($p<0.05$), and the ratio of apo A-I/HDL increased ($p<0.05$). Apo B/apo A-I ($p=0.06$) and apo A-I/apo A-II ($p<0.01$) ratio diminished with the use of intraperitoneal insulin. Glucose control was better during intraperitoneal than during subcutaneous insulin (HbA_{1c} 8.13 ± 0.39 and 9.49 ± 0.43 %, respectively, $p<0.01$). Intraperitoneal insulin, while inducing lower peripheral insulin concentration and better glycaemic control than subcutaneous insulin had deleterious effects on the lipoprotein profile among CAPD patients. The significance of these changes in modifying the risk of atherosclerosis is unknown.

1693

EFFICACY AND SAFETY OF FLUVASTATIN TREATMENT IN KIDNEY TRANSPLANT, DIABETIC RECIPIENTS; 1-YEAR FOLLOW UP

L.Gerô, K. Földes, E. Makláry, P. Vargha, J. Járay and P. Perner. Semmelweis Medical University and National Institut for Cardiology, Budapest, Hungary.

Organ transplant recipients treated with steroid+cyclosporine often develop dyslipidemia which may significantly contribute to the increased cardiovascular mordity and mortality of these patients. Therefore, we studied the effect of fluvastatin treatment (Lescol, Sandoz, 20 mg/day) on serum lipid levels in 21 diabetic patients (13 men, 8 women, age range 31-63 years, BMI 25.9±4.5 kg/m2) who had underwent a successful kidney transplantation and had dominating hypercholesterolemia. Following an 8-week period of diet (daily cholesterol intake <250 mg) fluvastatin was applied subsequently for 1 year. Diet alone did not cause significant change in serum lipid levels. Fluvastatin reduced the total cholesterol, LDL-cholesterol and triglyceride levels from 7.70±0.87, 4.87±1.05 and 2.84±0.85 to 6.40±0.70, 3.52±0.69 and 2.64±0.86 mmol/L, $p<0.001$, <0.001 and <0.05, resp., while the level of HDL-cholesterol increased from 1.12±0.28 to 1.52±0.39 mmol/L, $p<0.001$. Lipoprotein-A1 increased from 1.52± 0.29 to 1.67±0.36, lipoprotein-B decreased from 1.27±0.20 to 1.14±0.15 mmol/L, $p<0.05$ and <0.01. These maximum improvements were achieved by the 12th week of fluvastatin therapy and no further significant changes were observed until the end of the study year. Serum concentration of Lp(a) remained unchanged throughout the study. Liver enzymes (ASAT, ALAT) did not increase. No side effects (myositis, myoglobinuria) was observed. Serum level of cyclosporine (using stable doses throughout the year) was 199±89 ng/ml at start and 206±28 ng/ml at the end of the year, i.e. no increase due to interference with fluvastatin was found. Thus, fluvastatin seems to be a very effective and safe drug for the treatmet of kidney transplant diabetic patints receiving steroid+cyclosporine immunosuppressive therapy.

1694

IMPROVEMENT OF HYPERVISCOSITY SYNDROME IN DIABETIC PATIENTS BY HEPARIN-INDUCED EXTRACORPOREAL LDL PRECIPITATION (HELP)

V. Mrzljak, V. Lipovac and Ž. Metelko, Vuk Vrhovac Institute, Medical Faculty, University of Zagreb, Dugi Dol 4a, 10000 Zagreb, Croatia

In contrast to other selective procedures for extracorporeal LDL precipitation, HELP can also effectively lower plasma fibrinogen and improve blood rheology. We compared the effectiveness of short-time HELP treatment, applied on a weekly basis in patients with: hyperlipoproteinaemia (A) and NIDDM with hyperlipoproteinaemia (B). Changes of metabolic and hemorheologic parameters during 5 consecutive HELP treatment were calculated as interval values (value after HELP and before next HELP divided by two) and expressed as percentage of the value before starting HELP($\bar{X}\pm SD$):

	A (Hyperlipoproteinaemia)	B (NIDDM+ hyperlipoproteinaemia)
LDL-C (mM/l)	-13% ± 7	-37% ± 6
TC (mM/l)	-28% ± 7	-34% ± 4
HDL-C (mM/l)	+2% ±11	-15% ± 5
TG (mM/l)	-43% ± 7	-28% ± 8
Fib (g/l)	-7% ± 6	-15% ± 6
ErcF (µl/sec)	+9% ± 7	+26% ± 5
PV (mPa.s)	-16% ± 1	-25% ± 3

Correlation between plasma viscosity and fibrinogen were r=0,758, p<0,01 and r=0,827, p<0,003 for A and B respectively. Our results demonstrate that HELP treatment immediately corrects hyperviscosity syndrom and hyperlipoproteinaemia as well, suggesting the usefulness of this method when a quick and drastic fluidification of blood is required.

1695

EFFICACY OF FENOFIBRATE TREATMENT IN POLYMETABOLIC SYNDROME (PMS) IS ASSOCIATED WITH SERUM INSULIN LEVELS

B Idzior-Waluś, J. Sieradzki, W. Rostworowski and A. Zdzienicka, Depts. of Metabolic Diseases & Biochemistry, Jagiellonian University, Kraków, Poland

Dyslipidemia, arterial hypertension (HT), central obesity (CO), impaired glucose tolerance (IGT), hyperinsulinemia and insulin resistance are the major features of the PMS. The aim of the study was to compare the effect of fenofibrate treatment in dyslipidemic patients with PMS divided 1) according to presence or absence of IGT and 2) according to insulin levels: above or below the third quartile of serum insulin distribution in the examined group. Material included 37 dyslipidemic males with PMS (at least two of the following: HT, CO or IGT), aged 20 - 70 years, with serum total cholesterol (TC) > 6.5 mmol/l, or triglycerides (TG)>3.0 mmol/l or HDL -cholesterol < 0.9 mmol/l, treated with micronised fenofibrate 200 mg daily. Serum lipids and glucose were evaluated enzymatically, insulin by RIA. After 12 weeks of therapy serum lipids changes were similar in both groups of patients:with normal glucose tolerance (NGT) and IGT: serum TC decreased by 12.5%, TG by 37.3%, and HDL-cholesterol increased by 10.0% of the baseline level in the IGT group and by 9 3%, 22 5% and 17.8% respectively in the NGT group. The fasting insulin and insulin area under the curve during the oral glucose tolerance test (OGTT) decreased in both IGT (by 30.2% and 16.1%) and NGT (by 18.5% and 6.4% respectively), while changes in fasting and area under the curve of glucose during OGTT were different (p<0.01): decrease was observed in the IGT group only. In the group with the fasting insulin values > 3rd quartile of insulin distribution serum TC decreased by 11.7% TG by 32.1% and HDL increased by 3.8%, while in the rest of the group the changes were 10.6%, 27.6% and 20.4% respectively. The difference in increase of HDL-cholesterol was significant (p<0.02). The results suggest that in dyslipidemic patients with PMS fenofibrate therapy 1) is associated with favourable changes in glucose profile in IGT patients and 2) the serum lipids response is associated with fasting insulin levels: the increase of cholesterol in antiatherogenic lipoprotein fraction HDL is significantly higher in patients with lower insulin levels.

1696

FEASIBILITY OF INTENSIVE LIPID LOWERING IN PATIENTS WITH DIABETES MELLITUS.

S.D.J.M. Kanters, A. Algra, T.W.A. de Bruin, D.W. Erkelens and J.D. Banga. University Hospital Utrecht, Utrecht, The Netherlands.

Macrovascular disease causes premature morbidity and mortality in diabetic patients. Agressive lipid lowering may prevent macro-angiopathy. The aim of our study was to investigate the feasibility of intensive lipid lowering in diabetic patients and to determine the effect of this therapy on the composition of plasma lipoproteins.Thirty-six IDDM and 59 NIDDM patients were included in an open study at the diabetes clinic. Target values for plasma lipids were: LDL-cholesterol < 2.6 mmol/l, triglycerides < 1.7 mmol/l and HDL-cholesterol > 0.9 mmol/l for men and > 1.1 mmol/l for women. After 6-12 weeks of diet, lipid lowering medication (statin / fibrate / acipimox) was prescribed and extended until all target levels were reached. Mean baseline lipid levels for IDDM and NIDDM were: total cholesterol 5.6 and 5.8 mmol/l, LDL-cholesterol 3.6 and 3.7 mmol, HDL-cholesterol for men 1.1 and 1.0 mmol/l, for women 1.4 and 1.2 mmol/l, and triglycerides 1.7 and 2.2 mmol/l, respectively. Target values were reached in 66% of the patients. Total cholesterol decreased by 1.3 mmol/l (95% CI 1.0 - 1.5) in IDDM and 1.7 mmol/l (95% CI 1.4 - 2.0) in NIDDM patients, LDL-cholesterol by 1.2 mmol/l (95% CI 0.8 - 1.5) and 1.3 mmol/l (95% CI 1.0 - 1.5) and triglycerides by 0.7 mmol/l (95% CI 0.3 - 1.0) and 1.1 mmol/l (95% CI 0.9 - 1.4), respectively. HDL-cholesterol increased only in men and women with IDDM: by 0.15 mmol/l (95% CI 0.01 - 0.28) and 0.34 mmol/l (95% CI 0.02 - 0.71), respectively. The cholesterol/triglycerides ratio decreased significantly in VLDL in IDDM and in IDL in NIDDM. The ratio increased significantly in HDL in NIDDM patients. In conclusion, these results show that intensive lipid lowering in diabetes mellitus is feasible and affects the composition of plasma lipoproteins, in agreement with improved lipoprotein metabolism and a less atherogenic lipid profile.

1697

EFFICACY AND SAFETY OF FLUVASTATIN IN PATIENTS WITH NON INSULIN DEPENDENT DIABETES ON INSULIN THERAPY AND DYSLIPIDEMIA.

K.P. Bouter, F.L.J. Visseren, R.J.A. Diepersloot, D.W. Erkelens, University Hospital, Utrecht, The Netherlands.

The incidence of dyslipidemia in patients with Non Insulin Dependent Diabetes (NIDDM) is high, as is cardiovascular morbidity and mortality. This double blind randomised placebo controlled study was initiated to evaluate the safety and efficacy of fluvastatin in NIDDM patients on insulin therapy and dyslipidemia (LDL>4.0mmol). Eighty-one NIDDM patients on insulin therapy entered the study (age 61±9 years, male/female=0,57). All patients started with 4 weeks of diet (ADA/EDA recommendation), then they were randomised between placebo and fluvastatin 40mg OD. The study groups were identic with respect to age, BMI, sex, cardiovascular history and laboratory evaluations. The following results were obtained:

	week 0	week 12		
	Baseline	placebo	fluvastatin	
HbA_{1c}	6.2 mmol/l	6.5	6.4	
TC cholesterol	6.6 mmol/l	+ 2.2%	-16,2%	(p<0.001)
triglyceriden	1.8 mmol/l	+ 8.6%	-4.9%	(p<0.05)
HDL cholesterol	1.2 mmol/l	- 1.9%	-1%	(ns)
LDL-cholesterol	5.0 mmol/l	+ 2.8%	-25.1%	(p<0.001)
Lp (A)	262 mmol/l	+ 10.6%	+2.6%	(ns)
$ApoA_1$	1.7	no changes		(ns)
ZUNG-scale	34	35	33	(ns)

In this double blind, randomised, placebo controlled study patients with NIDDM on insulin therapy and dyslipidemia were treated with fluvastatin 40mg OD. LDL-cholesterol and triglyceriden decreased significantly in the treatment group. We observed no change in patients mood (ZUNG scale). Adverse events were equally distributed between the two study groups. Conclusion: Fluvastatin treatment for dyslipidemia in NIDDM patients is effective and safe.

1698

EFFECT OF THE WEIGHT REDUCTION ON GENE EXPRESSION OF LIPOPROTEIN MODIFYING PROTEINS.

M. Rantala, Y. A. Kesäniemi, M. Kairaluoma, J. Palm and M. J. Savolainen.
University of Oulu and Biocenter of Oulu, Finland.

Low HDL-cholesterol concentration and hypertriglyceridemia are more prevalent in obese persons than in subjects with normal body weight. To study the regulation of serum HDL-cholesterol and triglyceride levels, we conducted a weight reduction trial among 33 obese, postmenopausal, middle-aged women. The intervention group (13 subjects) and control group (20 subjects) were comparable according to their age, body weights, serum lipid, plasma glucose and serum insulin concentrations. Conventional laboratory methods were used for analysis of lipids and lipoproteins. Cholesterol ester transfer protein (CETP) activity was measured. A quantitative RT-PCR method was established to measure the gene expression of CETP (biopsies from liver and adipose tissue obtained at the end of the weight reduction period) and lipoprotein lipase (LPL, adipose tissue only). The reduction of the body weight among the intervention subjects averaged 4.7±0.5 kg. Serum HDL-cholesterol concentration was reduced (–0.06±0.03 mmol/l, $p<0.01$), and triglyceride (–0.14±0.09 mmol/l) and total cholesterol concentrations (–0.14±0.12 mmol/l) tended to be reduced. Plasma CETP activity was not affected by the weight reduction, even though the CETP gene expression was lower both in liver (–29%) and adipose tissue (–25%) compared with controls. In the intervention group the LPL gene expression in the adipose tissue was 50% lower than in controls ($p<0.05$). After the weight reduction a highly significant negative correlation was noted between the serum HDL-cholesterol concentration and the amount of CETP mRNA in adipose tissue ($r= -0.76$, $p=0.01$), whereas a positive correlation between the serum triglyceride and CETP mRNA ($r=0.69$, $p<0.05$) was found. In conclusion, weight reduction affects lipid metabolism at the gene expression level, and adipose tissue itself seems to have a significant role in the altered lipid transfer.

Macrovascular Disease and Atherosclerosis – Experimental and Pathogenesis

1699

EFFECT OF GLYCATED FIBRONECTIN ON PROLIFERATION AND IGFBP4 SECRETION BY CULTURED HUMAN AORTIC SMOOTH MUSCLE CELLS (SMC)

MLC Correa, BL Wajchenberg, D LeRoith and D Giannella-Neto. Diabetes Branch, NIDDK, NIH, Bethesda, MD; Division of Endocrinology and Fundacao Hemocentro, University of Sao Paulo School of Medicine, Brazil.

The late products of nonenzymatic glycosylation, namely AGEs, contribute to several long-termed complications of diabetes, including vascular disease, where SMC proliferation plays an important role. PDGF has been considered a competence factor for this cell type and IGF-I can work as a progression factor for the mitogenic effect of PDGF. The objective of this study was to evaluate the effect of an AGE-modified matrix protein (fibronectin) on SMC proliferation as well as on IGF-I-IGFBP4 system after stimulation with PDGF-BB. Immortalized human aortic SMC (AALTR-16, provided by Dr. JK Dougall, Fred Hutchinson Cancer Res. Ctr. Seattle, WA) in culture were plated in three different substrata (plastic, fibronectin and AGE-fibronectin) and stimulated with 10 ng/mL of PDGF-BB for 24-h. Total RNA was extracted and analyzed by ribonuclease protection assay employing riboprobes complementary to IGF-I, IGF-IR and IGFBP4 mRNA. To study the secretion of IGFBP4, conditioned media of untreated and treated cells were submitted to Western Blot using antibody anti-IGFBP4 (UBI. Lake Placid, NY). To evaluate the effect of glycated fibronectin on SMC proliferation, the cells were seeded in 12-well plates coated with either fibronectin or AGE-fibronectin, grown in media supplemented with 2% FCS, PDGF-BB (10 ng/mL), IGF-I (20 ng/mL) and EGF (20 ng/mL) and counted after 4, 10 and 14 days. There was no significant differences in the amount of IGF-I, IGF-IR and IGFBP4 mRNA contents after stimulation with PDGF-BB in comparison to untreated conditions in any of the three substrata. On plastic and fibronectin substrata, the PDGF-BB elicited an increase of 63% and 40% respectively in IGFBP4, while on AGE-fibronectin substratum, PDGF-BB evoked a decrease of 28% in IGFBP4. SMC proliferation on AGE-fibronectin was significantly increased after 14 days in culture. Since IGFBP4 is known to inhibit the IGF-I action, the decrease of IGFBP4 secretion (probably by a post-transcriptional mechanism) induced by PDGF-BB when SMC are plated on AGE-fibronectin substratum can result in elevation of local free IGF-I. This increased availability of IGF-I may exert a role in SMC proliferation and therefore would be involved in the pathogenesis of atherosclerosis in conditions of chronic hyperglycemia. Supported by FAPESP grant 91/3617-8.

EFFECT OF PIOGLITAZONE ON THE FATTY STRIATED PORTION IN THE ARTERIAL WALL

K.Arai,J.Sato,G.Fukuda,H.Nishimura,A.Tanaka,M.Kanazawa, Y.Notoya and T.Hayashi.Tokyo Med.Coll.,Tokyo,Japan

<**Purpose**> We have previously reported that pioglitazone can inhibit fat deposition in the aortic wall. In the present study, we investigate the effect of pioglitazone on the compositions between macrophages (M ϕ) and smooth muscle cells(SMC) in the fatty striated portion. <**Methods**> Five male JW rabbits were assigned to group A, fed with a diet containing 0.5% cholesterol (C), and five to group B, fed with a diet containing C and 300 ppm pioglitazone (P). These diets were given at 200 g/day for 10 weeks. Blood was sampled at weeks 0 and 10 for the measurement of serum lipids and other parameters. The descending aorta was removed at week 10. The obtained aorta was sliced vertically to a long axis of the aorta from the site 0.5 cm above the diaphragm. These sections were also stained immunohistochemically (anti-M ϕ RAM11 antibody and anti-SMC Actin 1A4 antibody) for the measurement in the fatty striated portion by image analyzer (Olympus Co.). Moreover, we also measured the lipid deposition area (DL) on the tunica intima of the aorta from 2 to 6 cm above the diaphragm. <**Results**> Among serum lipids examined, T-CHO markedly increased after 10 weeks in both groups without significant intergroup difference, while the perioxide lipid level was significantly lower in group B than in group A. In the fatty striated portion, the number of macrophages was lower in group B than in group A. Use of M ϕ specific and SMC specific antibodies demonstrated that lesions from group B were significantly smaller and less cellular than were the lesions in group A. And DL was also significantly lower in group B (15%), compared with group A (57%). <**Conclusion**>From these results, it was thought that pioglitazone is a useful drug for the prevention and treatment of atherosclerosis through some mechanism, such as antioxidant action, other than enhancement of LPL activity, as previously reported.

1701

AGEs-LDL LEAD MACROPHAGES TO FOAM CELLS VIA MACROPHAGE SCAVENGER RECEPTOR IN VITRO

Y. Jinnouchi[1], R. Nagai[1], T. Higashi[1], K. Ikeda[1], H. Sano[1], K. Matsumoto[1], Y. Kawabe[2], T. Kodama[2], S. Horiuchi[1], [1]Department of Biochemistry, Kumamoto University School of Medicine, Kumamoto, JAPAN. [2]University of Tokyo, Tokyo, Japan

Recent studies showed that modification of LDL with AGEs (advanced glycation end products) leads to loss of its ligand activity for the LDL receptor, suggesting the possibility that the atherogenicity of AGEs-LDL in vivo could be explained by an increase in plasma LDL cholesterol level due to prolonged plasma clearance of AGEs-LDL. However AGEs-proteins are recognized by AGEs-receptors, in particular, by macrophage scavenger receptor (MSR) in macrophages or macrophage-derived cells. Therefore, it is also possible that AGEs-LDL are taken up by macrophages via MSR, which might contribute to the foam cell formation in the early atherosclerotic lesions. This possibility was tested in the present study. (i) modification of LDL with glycolaldehyde (GA) resulted in a time-dependent increase in its negative charge, fluorescent activity and immunochemical reactivity to anti-AGEs-antibodies. These physicochemical and immunological properties resemble those of AGEs-modified proteins. (ii) GA-LDL was actively taken up by mouse peritoneal macrophages, leading to intracellular accumulation of cholesteryl esters. (iii) CHO cells overexpressing MSR showed a high affinity binding not only to acetyl-LDL but also to GA-LDL. These data obtained from in vitro experiments suggest that AGEs-LDL may play a key role in pathogenesis of diabetic macro-angiopathy.

1702

EFFECT OF PIOGLITAZONE IN INHIBITING LIPID DEPOSITION STUDIES WITH THE INSULIN TOLERANCE TEST

G.Fukuda, J.Sato, T.Inamura K.Arai, Y.Kawasaki, M.Kanazawa, Y.Notoya and T.Hayashi. Tokyo Med.Coll.,Tokyo,Japan

<**Purpose**>Since the syndrome X was proposed as a risk factor for arteriosclerosis, insulin resistance has been considered to be a serious clinical problem in the treatment of diabetes. In the present study, we investigate the effect of pioglitazone on blood insulin and insulin sensitivity in the presence of hypercholesterolemia for the purpose of clarifying its effect on arteriosclerosis.<**Methods**> Male JW rabbits, weighing about 2.5 kg, were used at the age of 10 weeks. Five animals were assigned to group A, fed with 0.5% cholesterol-containing diet, and five to group B, fed with diet containing 0.5% cholesterol and 300 ppm pioglitazone. These diets were given at 200 g/day for 10 weeks. Blood glucose, serum insulin, and serum lipid levels were measured at the start of feeding (week 0) and at week 10. At the same time, the insulin tolerance test (ITT) was also performed. Moreover, the descending aorta was removed at week 10, and the lipid deposition area (DL) on the inner surface of the aorta was measured. <**Results**>Blood glucose and serum insulin levels remained unchanged at week 10, compared with week 0, and no significant intergroup differences were observed at week 10. Areas under the curves of changes in blood glucose levels (AUC) in ITT also remained unchanged at week 10, compared with week 0, and no significant intergroup difference was observed at week 10. However, DL at week 10 was 57% in group A, compared with 15% in group B, showing a significantly lower DL in group B than in group A.<**Conclusion**> It was revealed that pioglitazone had inhibited lipid deposition in the Aortic wall with hyper cholesterolemia. On the other hand, it could not be determined whether pioglitazone had the effect of improving insulin resistance in the presence of hypercholesterolemia because of the lack of significant intergroup difference in serum insulin or AUC measured in ITT. From these results, it was inferred that inhibition of lipid deposition in the arterial wall by pioglitazone was not achieved by the direct effect of this drug on insulin; however pioglitazone has some other effect on inhibition for lipid deposition.

1703

INVOLVEMENT OF POLYMORPHONUCLEAR LEUKOCYTES(PMN) IN THE OXIDATION OF LOW DENSITY LIPOPROTEIN.

H.Katoh, T.Taminato and T.Yoshimi. 2nd Dept. Medicine, Hamamatsu University School of Medicine,Shizuoka, Japan.

Oxidized LDL, which is increased in diabetics, has been thought to play central roles in the development of atherosclerosis. However, precise mechanisms of facilitated LDL peroxidation in diabetic state still remain unclear. To investigate the early events of oxidative modification of LDL, we tested the possible role of glycated-LDL(G-LDL) in stimulating leukocytes adhesion to endothelial cells(EC) and involvement of PMN in lipid peroxidation process.G-LDL was made by incubating native LDL(N-LDL) with 100 mM D-glucose for 70 hrs. Oxidatively modified LDL(GOX-LDL) was made by further incubation of G with 50 mM Fe-ADP. Circulating monocytes(M) and PMN were isolated from healthy donors, and incubated with LDLs at 37℃ for 30 min. The degree of lipid peroxidation was measured as TBARS and the superoxide(O^{2-}) was measured by MCLA-dependent chemi-luminescence and H2O2 by a scopoletin method. N-LDL and G-LDL stimulated adhesion of PMN, but not M, to EC. G-LDL caused 1.5 fold increase of O^{2-} generation by PMN pre-stimulated with phorbol 12-myristate 13-acetates (PMA). GOX-LDL caused greater increase O^{2-} generation from PMN than G-LDL. TBARS assay revealed that GOX-LDL received stronger oxidation of its own lipid by PMA-stimulated PMN than N-LDL did(5.72 ± 0.464 vs 2.65 ± 0.122, $p<0.001$). Results suggest that hyperglycemia increases the oxidation of G-LDL via the PMN activation including augmented cell-adhesion and free radical generation.

1704

EFFECT OF PIOGLITAZONE ON ATHEROSCLEROSIS

J.Sato, K.Arai, T.Inamura, M.Shizume, S.Shirabe, M.Kanazawa, Y.Notoya and T.Hayashi. Tokyo Med.Coll.,Tokyo,Japan

<**Purpose**>Insulin resistance is an etiologic factor for NIDDM and also a factor for the aggravation of NIDDM. In the present study, we investigated the effect of pioglitazone on atherosclerosis in the aspects of serum lipids, histology, lipid deposition, and blood pressure. <**Methods**>Five male JW rabbits were assigned to group A, fed with diet containing 0.5% cholesterol (C), and five to group B, fed with diet containing C and 300 ppm pioglitazone (P). These diets were given at 200g/day for 10 weeks. Blood was sampled before (week 0) and 10 weeks (week 10) after the start of feeding for measurement of serum lipids. At the same time, systolic and diastolic blood pressure was measured. The descending aorta was removed at week 10 to observe histological appearances (HE stain and immunohistochemical stain) and also to measure the lipid deposition area (DL) on the unfolded aorta using an image analyzer. <**Results**> As compared with serum lipid levels at week 0, T-CHO significantly increased in both groups, while HDL-C remained unchanged and T-G tended to decrease. There was no significant intergroup difference in T-CHO, HDL-C, or T-G at week 10. Although lipid peroxide(LPO) levels increased at week 10 in both groups, LPO at week 10 was significantly lower in group B than in group A. In histological observation, hypertrophy of the tunica intima was remarkable in group A, but slight in group B. Moreover, DL at week 10 was 57% in group A, compared with 15% in group B, showing a significantly lower DL in group B than in group A. Blood pressure at week 10 did not markedly alter in group A, as compared with week 0, whereas both systolic and diastolic blood pressure tended to slightly decrease at week 10 in group B, as compared with week 0. <**Conclusion**> Although pioglitazone had no effect on T-CHO, HDL-C, or T-G, this drug was confirmed to have inhibitory effects on lipid deposition and hypertrophy of the tunica intima. In addition to these results, the tendency toward decreases in LPO and blood pressure suggested that pioglitazone had inhibitory effects on atherosclerosis.

1705

INSULIN SIGNALING ACCELERATES ENDOCYTIC UPTAKE OF AGEs MEDIATED BY MACROPHAGE SCAVENGER RECEPTOR

H. Sano[1], T. Higashi[1], Y. Jinnouchi[1], K. Ikeda[1], Y. Ebina[2], H. Makino[3], S. Horiuchi[1] [1]Department of Biochemistry, Kumamoto University School of Medicine, Kumamoto, Japan [2]Department of Enzyme Genetics, Institute for Enzyme Research, the University of Tokushima, Tokushima, Japan [3]Department of Laboratory Medicine, Ehime University School of Medicine, Onsen County, Japan

Hyperglycemia is expected to accelerate the formation and accumulation of advanced glycation end products (AGEs) in plasma and tissues, which might be a causative factor for diabetic complications or vascular dysfunctions. Our recent studies showed that macrophage scavenger receptor (MSR) mediates endocytic uptake of AGEs-proteins by macrophages or macrophage-derived cells, implicating a possibility that the AGEs-receptor-mediated endocytic uptake of AGEs in circulation or AGEs deposited extracellularly may contribute to some extent to protect or reduce AGEs-accumulation in vivo. As an extension of this notion, the present study was undertaken to examine effects of insulin signaling on the MSR-mediated endocytic uptake of AGEs-proteins. Coexpression of human insulin receptor (IR) with MSR in Chinese hamster ovary (CHO) cells showed a 1.6-fold accelerating effect of insulin on the degradation of AGE-proteins compared with wild type CHO cells, whereas insulin had no effect on the cells coexpressing MSR with kinase-deficient insulin receptor or insulin receptor lacking binding site for insulin receptor substrate 1 (IRS-1). Furthermore, the insulin-induced endocytic activity for AGEs-proteins were inhibited by phosphatidylinositol-3-OH kinase (PI3 kinase) inhibitors such as wortmannin and LY294002. Thus, it is suggested that insulin might accelerate the MSR-mediated endocytic uptake of AGEs-proteins through a PI3 kinase pathway.

1706

Inhibitory Effect of TROGLITAZONE (CS-045) on Cytokines-Induced Monocyte Chemoattractant Protein-1 (MCP-1) Expression in Human Mesangial Cells.

Masayoshi Ohta, Yukihiro Nagai, Haruhisa Yamashita, Miyako Yoshizawa, Azusa Hisada and Kenichi Kobayashi First Department of Internal Medicine, School of Medicine, Kanazawa University, Kanazawa, JAPAN

Insulin resistance is one of the risk factors for progression of atherosclerosis. In diabetes, atherosclerosis and microvascular complications such as diabetic nephropathy may account for the disabilities and mortality rate of this disease. Recently, the new oral insulin sensitizing drug troglitazone (CS-045) is thought to be hopeful for the treatment of diabetes. Monocyte chemoattractant protein-1 (MCP-1) is a recently identified cytokine, which plays an important role in the pathogenesis of atherosclerosis, including glomerulosclerosis through the induction of monocyte migration. However, the direct effects of CS-045 on the progression of glomerulo -sclerosis have not been clarified yet. Thus, we investigated the effect of CS-045 on the expression of MCP-1 in human mesangial cells (HMCs). HMCs were treated with or without CS-045 (1-10mM) in the presence or absence of various concentrations of cytokines such as tumor necrosis factor-α (TNF-α) (50-500 ng/ml), interleukin-1β (IL-1β) (1-1000 pg/ml) and phorbol myristate acetate (PMA) (5-100 ng/ml), and then the amount of the MCP-1 released from HMCs was measured. Although the release of MCP-1 was increased by various cytokines (TNF-α to 55 fold, IL-1β to 2.7 fold and PMA to 4.9 fold vs control), CS-045 significantly inhibited the TNF-α-induced (49.3%), IL-1β-induced (35.0%) and PMA-induced (33.7%) MCP-1 production. Moreover, Northern blot analysis revealed that there was a decrease of the MCP-1 mRNA level in HMCs treated with CS-045. Our present studies indicated that CS-045 may prevent the progression of glomerulosclerosis by inhibition of MCP-1 expression in HMCs.

1707

MACROPHAGE SCAVENGER RECEPTOR MEDIATES GREATER PART OF THE ENDOCYTIC UPTAKE OF AGEs

S, Horiuchi[1], T, Higashi[1, 2], H, Suzuki[3, 4], T, Kodama[4], M, Shichiri[2] [1] Department of Biochemistry and [2] Metabolic Medicine, Kumamoto University School of Medicine, Japan [3] Chugai Pharmaceutical Co. Ltd., Shizuoka, Japan [4] Department of Molecular Biology and Medicine, Research Center for Advanced Science and Technology, The University of Tokyo, Japan

Cellular interaction of advanced glycation end products (AGEs) is mediated by the AGE-receptor. The AGE-receptors so far reported are RAGE, Galectin-3 and MSR (macrophage scavenger receptor). Macrophages or macrophge-derived cells are known to show the highest endocytic activity for AGEs-proteins. Our recent study using CHO (Chinese Hamster Ovary) cells overexpressed with MSR clearly showed that the endocytic uptake of AGE-proteins by macrophages are mediated by MSR (1). To strengthen this contention, the present study was undertaken to examine the interaction of AGE-proteins with peritoneal macrophages from MSR-deficient mice (MSR -/-). In experiments at 37°C, thioglycolate-induced peritoneal macrophages from MSR -/- showed a marked decrease (less than 10%) in the endocytic degradation capacity for ^{125}I-acetylated low density lipoprotein (acetyl-LDL). Under the parallel conditions, the degradation activity of ^{125}I-AGE-bovine serum albumin (BSA) by these MSR-deficient macrophages was less than 30% (2). The remaining endocytic capacity of ^{125}I-AGE-BSA by these MSR-deficient macrophages was not inhibited by acetyl-LDL, but inhibited significantly by AGE-BSA, AGE-hemoglobin or polyanions such as dextran sulfate and polyinosinic acid. These results indicate that approximately two thirds of endocytic uptake of AGE-proteins by macrophages is mediated by MSR, while the remaining part is mediated by other AGE-receptors.

1708

PROSTACYCLIN-STIMULATING FACTOR IS REGULATED BY PROTEIN KINASE C ACTIVATION INDUCED BY HIGH GLUCOSE LEVELS IN DIABETES MELLITUS.

M. Kunisaki, Y. Ono, N. Sekiguchi, T. Yamauchi, F. Umeda and H. Nawata. Kyushu University, Fukuoka, Japan.

Prostacyclin (PGI_2) synthesized by the vascular wall is a potent vasoactive prostanoid which regulates vascular tonus and inhibitoin of platelet aggregation. Reduced PGI_2 could play a key role in the development of macrovascular complications in diabetes mellitus. We have purified and cloned a newly identified PGI_2-stimulating factor (PSF) which regulates PGI_2 production by endothelial cells. The purified PSF is an acid-labile and anionic protein, with a molecular mass of 31 kDa on SDS/ PAGE. A cloned cDNA of PSF is 1124 bp which codes 282 amino acids from the putative first methionine with a potential N-glycosylation site at position 171. The expressions of PSF mRNA were decreased in the aorta from streptozotocin-induced diabetic rats (26±5%, n=6) and smooth muscle cells from diabetic patients (35±4%, n=5). The PSF protein expressions are decreased in the human coronary artery from diabetic patients (44±7%, n=5). As hyperglycemia has been shown to activate the protein kinase C (PKC) in the vascular tissues, we investigated the effects of glucose and PKC activation on the expression of PSF in aortic smooth muscle cells. The expression of PSF mRNA was reduced by increasing glucose levels from 5 to 22 mM. PKC agonist (PMA) and high glucose level (22 mM) reduced PSF mRNA expression to 38±8% (n=3) and 27±6% (n=5), respectively, as compared to low glucose level (5.5 mM). PKC inhibitor (GF109203X) abolished the effect of PMA and glucose-induced decrease of PSF mRNA levels. These findings suggest that PSF gene expression could be down-regulated by PKC activation which may be caused by high glucose levels, possibly resulting in the reduction of vascular PGI_2 synthesis in diabetes mellitus.

1709

THE RECEPTOR FOR ADVANCED GLYCATION END PRODUCTS MEDIATES THE CHEMOTAXIS OF SMOOTH MUSCLE CELLS

T. Higashi[1,2], H. Sano[1], T. Saishoji[1], K. Ikeda[1], Y. Jinnouchi[1], T. Kanzaki[3], N. Morisaki[3], H. Rauvala[4], M. Shichiri[2] and S. Horiuchi[1] [1]Department of Biochemistry and [2] Metabolic Medicine, Kumamoto University School of Medicine, Japan [3] Department of Internal Medicine, Chiba University School of Medicine, Japan [4] Institute of Biotechnology, University of Helsinki, Finland

Long-term incubation of proteins with glucose leads to advanced glycation end products (AGE). We recently demonstrated the intracellular AGE-accumulation in smooth muscle cell (SMC)-derived foam cells in the atherosclerotic lesions. To understand the mechanism of AGE-accumulation in SMC, we characterized the interaction of AGE-proteins with rabbit arterial SMC. In experiments at 4°C, ^{125}I-AGE-bovine serum albumin (AGE-BSA) showed a dose-dependent saturable binding to SMC. In experiments at 37°C, AGE-BSA underwent receptor-mediated endocytosis and lysosomal degradation. The endocytic uptake of ^{125}I-AGE-BSA was effectively inhibited by unlabeled AGE-proteins, but not by acetylated LDL and oxidized LDL, ligands for the macrophage scavenger receptor (MSR), and amphoterin, a ligand for one-type of the AGE-receptor (RAGE), and 2-(2-Furoyl)-4(5)-(2-furanyl)-1H-imidazole-hexanoic acid-BSA, a ligand for the other AGE-receptors, p60 and p90, indicating that the endocytic uptake of AGE-proteins is mediated by an AGE-receptor distinct either from MSR, RAGE, p60 or p90. To examine the functional role of this receptor, the migratory effects of AGE-BSA on SMC were tested. Incubation with AGE-BSA resulted in the dose-dependent cell migration. This phenomenon was chemotactic, and was significantly inhibited by an antibody against TGF-β, and the amount of TGF-β secreted into the culture medium from SMC was 7-fold higher than that of control, indicating that TGF-β is involved in the AGE- induced SMC chemotaxis. These data suggest that AGE may play a role in SMC migration in atherosclerotic lesions.

1710

THE TRANSCUTANEOUS IMPEDANCE MEASUREMENT FOR ASSESSMENT OF SOFT TISSUES ISCHAEMIA

I.I.Smirnov,V.V.Boiko,V.A.Prasol.Kharkov Research Institute of General and Urgent Surgery, Kharkov, Ukraine.

Macrovascular disease is a common complication of diabetes mellitus. Accordingly our data 24.3% of patients with foot problem due to blood vessels obstruction are diabetics. Objectiv assessment of the degree of ischaemia is not a solved problem now. At the same time the division ischaemic foot lesious from neuroischaemic is important because of influence clinical management. The measuring of transcutaneous oxygen pressure which is commonly used for mentioned purpose is enough expensive. We proposed the method of transcutaneous impedance measurement for assessment the degree of foot soft tissues ischaemia. It's based on the biological tissues electric resistance. The level of impedance in nondiabetic healthy people with normal major vessels blood flow is 49.1 +- 12.1 Om.30 patients with acute ischaemia and 30 patients with chronic ischaemia were studied. The results of clinical and morphological investigatious were assessed as well as impedance measuring. The localisation of obstruction was varied. Occlusia was caused by diabetic and nondiabetic atherosclerosis, thrombangitis or trauma of artery. It was established the results of the transcutaneous impedance measurement were not dependent on aetiology and localisation of obstruction. The severity of acute and chronic foot ischaemia was correlated to soft tissues electric resistance: I degree - 65.2 +- 0.6 Om; II degree - 66.7 +- 0.8 Om; III degree - 68.3 +- 0.7 Om; IV degree - 69.4 +- 0.3 Om. The level of impedance more then 69 Om was the sign of morphologically confirmed necessity of amputation. We consider described method of soft tissues ischaemia assessment as useful and costsaving test in clinical management of patients with diabetes.

1711

ELEVATION OF SUPEROXIDE DISMUTASE ACTIVITIES IN PATIENTS WITH NIDDM

T. Shiba, E. Maehata, and S. Suzuki. Mitsui Memorial Hospital and Shouwa University. Tokyo, Japan.

Hyperglycemia causes glycation of proteins and produce superoxide anion radicals(O_2^-), which has been postulated to develop diabetic angiopathy. To estimate the production of O_2^-, superoxide dismutases (SODs), O_2^--scavenging enzymes, were measured in 60 NIDDM patients and 50 healthy controls. The NIDDM patients were divided to two groups, the good control(GC; HbA1c≤6.9 %) and the poor control(PC; HbA1c≥7.0 %). The serum SOD activities were examined by electron spin resonance spectrometry using spin trapping method. The total SOD activities were measured and then, fractionated to Mn-SOD and Cu,Zn-SOD activities using CN^-. The total-, Mn- and Cu,Zn-SOD activites were positively correlated with HbA1c and glycated alubumin ($p<0.01$) measured by the automated HPLC analyzer, HA-8131 and GAA-2000 (Kyoto-Daiichi, Kyoto, Japan). Mn- and Cu,Zn-SOD activities were 1.98 ± 0.41 and 1.18 ± 0.55 U/ml in the control, 3.27 ± 1.30($p<0.001$ vs control) and 1.03 ± 0.79(NS vs control) U/ml in the GC, and 3.35 ± 1.55($p<0.001$ vs control) and 1.76 ± 1.20($p<0.05$ vs control) U/ml in the PC, respectively. Significant differences were found both between the control and the GC and between the control and the PC in Mn-SOD activities whereas in the Cu,Zn-SOD activities, significance was found only between the PC and the control.These data suggest that hyperglycemia causes the production of O_2^- and resultant increase in the SOD activities, but a different SOD is recruited depending on the glycemic control.

1712

The effect of n-3 fatty acids on the suppression of atherogenesis in the type 1 diabetic rats: Morphologic study.

C.Fıçıcıoğlu, İ.Okar, Ü.Zeybek and T.Altuğ. University of İstanbul,

Cerrahpaşa Medical Faculty, Dept. of Pediatrics, İstanbul ,Turkey

Thirty two male Wistar albino rats were included into the study with the purpose of investigating the effects of n-3 fatty acids on the development of atherosclerotic lesions in diabetic rats.Twenty rats were randomly selected and injected 60mg/kg/sc streptozotocin to make them diabetic. Of 20 rats with diabetes ,10 were given MaxEPA [Eikosapentonoik acid (EPA) + Dekosaheksanoik acid (DHA)] , 10 mg EPA and 7mg DHA per day)] .12 rats were taken into the control group. 6 rats chosen randomly were also on MaxEPA therapy. After 4 months their aorta examined with electronmicroscopy. In TEM findings of the aorta of the diabetic rats the luminal surface of endothelial cells was irregular , dilation of ER was noted, as well as decreased mitocondria number . The nuclei were pycnocytic. On the apical side of endothelial cytoplasm different sized vacuoles were found . At SEM level fibrin and cell wask substances were seen on the luminal surface. When N-3 fatty acids were administrated to diabetic rats TEM findings showed a much more regular surface when compared with the sole diabetic group. The vacuolar degeneration in endothelial cell was lesser . At SEM level a localised zone of degeneration was seen , evaluated as a crater developed after a treatment of N-3 fatty acid at the site of an aterom plaque. In the control group given N-3 fatty acids , TEM and SEM findings were similar with that of the control group which was not on N-3 fatty acids.

In the light of these findings , we can suggest that the use of n-3 fatty acids in order to prevent atherosclerosis in diabetes mellitus is effective and there is no side effects on the normal vessel structure.

1713

OXYDATIVE STRESS AND DIABETES CHRONIC COMPLICATIONS.
O.Pristupyuk. National Medical University, Kyiv, Ukraine.

Having as a purpouse research on correlation between diabetes chronic complications and conditions of lipid peroxidation studies were made on content of MDA in blood plasma, erythrocytes membranes and HDL. Positive correlation was determined between MDA content and diabetic angiopathys as well as neuropathys. MDA content had positive correlation with some degree of diabetic neuropathy (r=+0,63), angiopathy of legs (r=+0,53), periferic somatic polyneuropathy (r=+0,50), also vegetative cardiovascular, gastrointestinal and urogenital neuropathy (r=+0,47). Negative correlation was determined between MDA content and erythrocites deformability (r=-0,51). Sustainable and long time diabetes' compensation as well as entherosorption by carbon and natural fibrous sorpents are furthering factors of the lipid peroxidation. These sorpents re-activate the function of hepato-biliar system, further diabetes compensation and slow the lipid peroxidation, thus preventing development of diabetic angio- and neuropathies. Therefore, lipid peroxides are damaging factors for diabetic patients. Entherosorption by carbon and natural fibrous sorpents is a protective way in the progress of chronic vascular and neurologic diabetes complications.

1714

Effects of insulin and Tranilast on cytosolic free Ca^{2+} concentration and DNA synthesis of aortic smooth muscle cells

Y.Asakura,Y.Okuda, M. Asano ,Y.Tachi, S.Suzuki,Y.Kawakami and K. Yamashita

University of Tsukuba, Tsukuba , Japan.

In diabetic macroangiopathy, hyperinsulinemia induced by insulin resistance causes atherosclerosis. An essential event in atherogenesis is the proliferation and migration of vascular smooth muscle cells. The effects of insulin and tranilast(TRA), anti-allergic drug (N-(3,4-dimethoxycinnamoyl)anthranilic acid), on cytosolic free Ca^{2+} concentration ($[Ca^{2+}]i$) and DNA synthesis of cultured rat aortic smooth muscle cells (SMC) were investigated. SMC were isolated from fresh thoracic aortic media of 5-week-old male Wistar rats by enzyme dispersion methods and cultured in DMEM supplemented with 10% fetal calf serum (FCS). Cells at passages 5-10 were used in this study. Measurement of cytosolic free Ca^{2+} concentration ([Ca2+]i) was performed by the Ca^{2+} fura-2 fluorescence method. Insulin ($1X10^{-4}M$) significantly increased $[Ca^{2+}]i$ of SMC, from 20nM to 60nM. TRA ($1X10^{-4}M$) significantly inhibited the increase in $[Ca^{2+}]i$ of SMC induced by Insulin, from 40nM to 2nM. After SMC were incubated 48 h in medium without serum, SMC were incubated in media with or without various additions of insulin ($3X10^{-6}M$, $1X10^{-4}M$), TRA ($1X10^{-5}M$, $3X10^{-5}M$, $1X10^{-4}M$, $3X10^{-4}M$, $1X10^{-3}M$), and 0.5 μCi [methyl-^{3}H] for 18 hrs. The [^{3}H]-thymidine uptake was examined. Insulin ($3X10^{-6}M$,$1X10^{-4}M$) significantly increased [^{3}H]-thymidine uptake of SMC (150%,200%) in a concentration dependent manner. TRA inhibited the DNA synthesis of SMC induced by insulin ($3X10^{-6}M$) dosedependently. TRA ($3X10^{-4}M$, $1X10^{-3}M$) significantly inhibited the DNA synthesis of SMC induced by insulin, (40%,30%) respectively.

These findings suggest that Tranilast might inhibit the proliferation of vascular smooth muscle cells induced by hyperinsulinemia and ameliorate diabetic macroangiopathy and prevent atherosclerosis.

1715

OXIDATIVE STRESS IS PRODUCED DURING MEAL IN NIDDM PATIENTS.

A. Ceriello, C. Taboga, N. Bortolotti, L. Tonutti, A. Crescentini, E. Motz, A. Cavarape, M. Marra and C. Pieri, University of Udine, and Udine General Hospital, Udine, I.N.R.C.A., Ancona Italy

Free radical production has been reported to be increased in patients with diabetes mellitus. In this study a standard meal (600 Kcal, 49% as carbohydrates, 40% as fat, and 11% as protein, containing 100 mg vitamin C and 13 mg vitamin E) was aministered to 10 NIDDM patients (7 males and 3 females; age 54.1±3.5 years, mean±SD; duration of diabetes 10.2±3.2 years; BMI 25.9±2.1 Kg/m^2). Two h after meal, SH groups (484.5±58.4 vs 440.7±48.3 μmol/l, p<0.003), and uric acid (5.3±1.3 vs 4.9±1.1 mg.dl, p<0.001) were significantly decreased, vitamin C increased (3.34±0.9 vs 4.17±1.1 mg/l, p<0.01), while vitamin E unchanged. MDA (2.3±0.6 vs 3.2±0.6 μmol/l, p<0.001) significantly increased, while total plasma radical-trapping activity (TRAP), which evaluates plasma antioxidant capacity due to known and unknown antioxidants present in the plasma as well as their mutual cooperation, was reduced (542.4±71.7 vs 458.4 vs 47.9 μmol/l, p<0.001). LDL oxidizability significantly increased after meal (Lag time: 81.7±23.8 vs 71.5±14.8 min, p<0.03; peak time: 141.6±31.4 vs 127.8±23.7 min, p<0.01; rate: 9.6±1.3 vs 11.5±1.8 μmol/minxgr protein,p<0.001) This finding shows that in diabetic patients during meal an oxidative stress is produced.

1716

IMMUMOHISTOCHEMICAL STUDY OF MYOCARDIAL REMODELING IN DIABETIC RATS

S.Tohyo,T.Sunaga,N.Saito.St.Marianna University School of Medicine,Kawasaki,Japan.

<Aim>To clarify the effect of diabetes mellitus on remodeling after myocardial infarction,experimental myocardial infarction was induced in diabetic rats,and histological features of their heart tissues were determined by immunohistochemical staining as well as by computed image analysis.<Method&Materials>At six weeks of age male Wistar rats were divided into two groups;one was the diabetic group (85mg/Kg body weight)and the other the healthy control group. Ligation of right coronary artery was performed on rats of both group. Eight weeks after the ligation, the heart of each rat was removed and fixed. Specimens were stained by the Masson-trichrome stain.For evaluation of changes in the extracellular matrix,tissues were also stained by ABC method.Anti-rat antibodies raised in rabbits against fibronectin and collagens, of Type I,III,IV,V and VI were used for the immunohistochemical staining,respectively.For quantitative evaluation of the degree of fibrosis, 80 points were randomly selected in the anterior free wall of the non-injured left ventricles,and the percentage of fibrotic area was calculated by a computer analyzer.<Results>The degrees of deciduation and of regenerative fibrosis as well as the major molecular species of the extracellular matrix did not show any significant difference in areas of myocardial infarction between diabetic group and control one. In the diabetic group,however, the fibrotic pattern developed to a severer degree in areas without myocardial infarction than in the correesponding areas in the control group. Percentage of fibrosis in the areas without myocardial infarction was 2.39±0.39% in the diabetic group.The value was significantly (p<0.05)higher than the corresponding value of 1.58±0.24% in the control group.Immunohistochemical staining showed that the components of the fibrotic areas in the extracellular spaces were collagens of Types III and VI and fidronectin in the areas without myocardial infarction of the diabetic group.

1717

THE GLYCOXIDATION PRODUCT N^{ε}-(CARBOXYMETHYL) LYSINE IS INCREASED IN DIABETES AND AGING

E. D. Schleicher[1], E. Wagner[2] and A. G. Nerlich[3]
[1]Department for Internal Medicine, Endocrinology and Pathobiochemistry, Tübingen, Germany
[2]Institute for Diabetes Research, München, Germany
[3]Deptartment of Pathology, University of Munich, München, Germany

N^{ε}-(Carboxymethyl)lysine (CML) a major product of oxidative degradation of glycated proteins has been suggested to represent a general marker of oxidative stress and long-term damage to proteins in aging, atherosclerosis, and diabetes. It was our aim to study the occurrence and distribution of CML in these conditions. Therefore, we produced an antiserum which specifically recognizes protein-bound CML. In-vitro studies showed that the formation of CML was dependent on the presence of oxygen and on glycation of proteins. Furthermore, the oxidative formation of CML from glycated proteins was reduced by antioxidants e.g. lipoid acid and vitamin E. Immunolocalization of CML in human skin, lung, heart, kidney, intestine, intervertebral discs and particularly in arteries provided evidence for an age-dependent increase in CML accumulation in distinct locations, and acceleration of this process in diabetes. Intense staining of the arterial wall and particularly the elastic membrane was found. High levels of CML modification were observed within atherosclerotic plaques and in foam cells. The positively stained dermal connective tissue area was 3.1±0.9% in young adult, 22±1.5 in old adult and 56.5±11.3% in old diabetic patients. Corresponding values for arterial walls were 8.3±0.5%; 22.3±0.8% and 25.2±3.8%. The preferential location of CML immunoreactivity in lesions may indicate the contribution of glycoxidation to the processes occurring in diabetes and aging. Determination of CML-content in normal (25) and diabetic (37) sera revealed an increase in diabetes (7.3±2.9 vs. 11.6±4.1 pmol/mg protein). CML serum values correlated weakly to HbA1c (r=0.70). In summary, our observations, however, provide strong evidence for the enhanced formation of CML-modified proteins in aging and diabetes glycoxidation. Furthermore, CML may serve as an indicator for the efficiency of therapeutic approaches for limiting oxidative reactions in human subjects.

1718

MYOCARDIAL HYPERTROPHY IN THE NEWBORN GOTO KAKIZAKI RATS.

M. Garnier, D. Mésangeau, J. Pariès, F. Zkhiri and P. Valensi. Laboratory of Nutrition and Metabolic diseases, Paris-Nord University, Bondy and LIPHA Research Center, Chilly-Mazarin. France.

Left ventricle hypertrophy is frequent in diabetic patients and it is not always due to hypertension. In Goto Kakizaki (GK) rats, a model of non-obese genetically-determined diabetes, we have previously shown that a cardiac hypertrophy occurred without any significant increase in blood pressure, but that hemorheological disorders might be involved in cardiac hypertrophy . The aim of the present study was to examine the onset of cardiac hypertrophy and the myocardial chemical composition, using male Wistar rats as controls. After sacrifice of the animals, at 4 or 15 days, or 3, 6, 12, or 18 months, heart was weighed and several biochemical parameters were measured. In the GK rats cardiac weight and cardiac index were significantly higher than in control rats, by 4 days, and the difference was significant at each age. Heart proteins and triglycerides were significantly lower than in control rats. Heart sodium (at 3 months), potassium and magnesium (at 6 and 12 months) and calcium (at 6 months) were significantly lower in the GK rats. Fibronectin was determined in the heart of 6-months animals and was not significantly different in GK and control rats. In conclusion this study suggests that in the GK rats, 1) cardiac hypertrophy may be found very early and is constituted during foetal life ; 2) it occurs independently of any hypertension ; 3) fibrosis is not the main factor involved in cardiac hypertrophy.

1719

ASSOCIATION BETWEEN LENS PROTEIN GLYCATION AND CATARACT DEVELOPMENT IN DIABETIC RATS

Z.Turk, I. Mišur, M.Sljepčević and B.Ročić Institute Vuk Vrhovac, Zagreb, Croatia

To assess the temporal association between glycation of lens proteins and the creation of polymeric products believed to contribute to the onset of cataract we followed the formation of early and late glycated adducts in the lenses of hyperglycaemic rats during a period of 5 months. We examined, whether phlorizin treatment of diabetic rats by inhibiting renal tubular glucose reabsorption influences advanced glycation process. The study groups included controls (C),untreated diabetic rats (D), and diabetic rats receiving insulin alone (DI) or in combination with phlorizin (DIP).Lenses were removed at 4 and 20 wk, and advanced glycated products in alkali-soluble lens proteins were determined by their spectrofluorescence (385/335nm).In 20-wk untreated diabetic as compared to control rats, a significant increase was observed in the fluorescence level (3.25±1.02 vs 1.61±0.17 FU/mg, p<0.001), while in 4-wk animals the increase was from 1.26±0.11 FU/mg in controls to 1.80±0.25 FU/mg in diabetics, p<0.001.Daily treatment of 20-wk diabetic rats with insulin alone (2.46±0.48 FU/mg) or in combination with phlorizin (2.30±0.26 FU/mg) did not significantly influence lens fluorescence level. The amount of glucose bound ketoamine linkage was estimated after acid hydrolysis as released 5-hydroxymethylfurfural (HMF).In 20-wk controls, it was slightly higher than in 4-wk controls (0.57±0.31vs0.41±0.20 nmolHMF/mg, respectively).The diabetic group showed a significant increase, however. In 4-wk diabetics, a level of 1.07±0.36 nmol HMF/mg was found, while in 20-wk animals the glycated protein amount rose to 2.46±0.79 nmol HMF/mg.In addition to the increases in glycated content with continuing diabetic hyperglycaemia, significant changes in protein composition of alkali-soluble lenses developed. The SDS-PAGE pattern showed an appearance of protein polymers of heterogeneous size (C-4wk: 3.0±1.1% vs C-20wk:17.9±2.9%; D-4wk:7.3±2.1% vs D-20wk:19.8±3.6%) and the proteins of high molecular weight (HMW).Only a small amount of these HMW proteins was present in controls (C-20wk: 2.5±1.2%) and short-term diabetes (D-4wk: 0.8±0.2%), whereas in long-term untreated diabetes there was a dramatic increase (D-20wk: 30.5±3.2%) with a corresponding decrease in other peaks. All diabetic animals from this group had macroscopically detectable cataractous lenses. The treatment with insulin or insulin/phlorizin followed the HMW protein level of the untreated animals (28.2±4.0% or 27.08±3.3% vs 30.52±3.32%) without beneficial effect.

1720

A SIMPLE METHOD FOR DETECTION OF ELASTIN PEPTIDES IN PATIENTS WITH DIABETIC MACROANGIOPATHY.

G.Nicoloff, University School of Medicine, Pleven, Bulgaria

Elastin is a main protein responsible for the elasticity of vascular wall. The elastin degradation is accelerated in atherosclerosis and soluble elastin-derived peptides (EDP) are then released and can reach the circulating blood. In this study was used a simple enzyme-linked immunosorbent assay (ELISA) for measurement of EDP in sera of 25 patients with diabetic macroangiopathy. The microtitre plates were coated directly with diluted (1:10) samples, standards or controls, blocked with 1% solution of bovine albumin to prevent non-specific protein binding to the plates, and EDP assigned with specific rabbit antibody. The specific antibody was detected with peroxidase linked goat anti-rabbit IgG and the color development of o-phenylenediamine was measured at 492 nm. Determinations were carried out in triplicate. Intra-assay variation was less than 7% and inter-assay variation -less than 10%. The new method was compared with sandwich version of ELISA. The mean level of EDP by sandwich version was 276±88 ng/ml vs. 251±76 ng/ml by new variant of ELISA (p>0.05). In conclusion, this modified variant of ELISA is a simple and faster method for detection of elastin degradation in diabetic macroangiopathy.

1721

CARDIOVASCULAR EFFECTS OF HYPERINSULINISM AND VAGOSYMPATHETIC CONTROL IN THE RAT WITH VENTROMEDIAN HYPOTHALAMIC LESIONS.

D. Mesangeau, L. Doaré, J. Pariès, J. Louis-Sylvestre and P. Valensi. LIPHA Research Center, Chilly-Mazarin. Laboratory of Nutrition and Metabolic Diseases, Paris-Nord University, Bondy. France.

Insulin has a well-demonstrated accelerating effect on heart rate, but its pressor effect is still debated. The cardiovascular effects of insulin mainly result from sympathetic activation. In order to test the cardiovascular effects of endogenous hyperinsulinism, the model of rats with ventromedian hypothalamic lesions (VMH) was used. Nine male VMH rats and 7 male SHAM rats were followed until 18 weeks after operation. In VMH rats, weight was significantly higher than in SHAM rats by the first week after operation, plasma insulin by 24 hours, reaching 224 ± 40 pmol/l at 1 week and being maximal at 8 weeks (476 ± 62 vs 38 ± 3 pmol/l in SHAM rats, $p < 0.001$), blood glucose was significantly lower since the first week. Heart rate (HR) and blood pressure (BP) were monitored by a telemetric method (Data Sciences System) after implantation of an aortic catheter and were weekly recorded during 24 hours. In VMH, HR was significantly lower by the first week ($p = 0.02$), reaching its lowest level at 4 weeks (306 ± 7 vs 399 ± 6 beats/min before operation). Systolic BP increased slowly in both groups and was significantly different only at 8 weeks (VMH : 129 ± 2 vs SHAM : 121 ± 3 mmHg, $p = 0.03$). In VMH rats a positive correlation was found between HR and weight and plasma insulin, and between systolic BP and weight. In conclusion, 1) VMH rats show an early, persistent and significant bradycardia, which is likely to result from an increase in parasympathetic activity and a decrease in sympathetic activity, and a moderate increase in BP associated with weight gain ; 2) both bradycardia and the delayed and moderate increase in systolic BP compared with the rapid and marked increase in plasma insulin suggests that the integrity of sympathetic control is necessary for insulin to induce its hemodynamic effects totally.

Macrovascular Disease – Epidemiology and Risk Factors

1722

ACE GENE POLYMORPHISM AND ARTERIOSCLEROSIS IN JAPANESE NIDDM PATIENTS

T.Tsujino, M.Kodama, T.Watarai, Y.Kajimoto, Y.Yamasaki, and M.Hori. Osaka University School of Medicine, Osaka, Japan

AIM: There is an insersion/deletion(I/D) polymorphism in the angiotensin converting enzyme(ACE) gene. ACE gene DD type was reported as a possible genetic risk factor for myocardial infarction(MI) in Caucasian and Japanese. We investigated the effect of ACE gene polymorphism on arteriosclerosis and MI in the Japanese diabetic patients. METHODS: Subjects investigated were 200 unrelated Japanese NIDDM patients. We measured the averaged thickness of the intimal plus medial thickness (IMT) of the carotid arteries of subjects using an ultrasound high resolution B-mode imaging. The genotypes of ACE gene were determined polymorphism using PCR amplification of the genomic DNA. Contribution of ACE gene polymorphism to IMT was evaluated with multiple regression analysis. Also we analyzed the association between past history of MI and ACE polymorphism using Kai square analysis.
RESULTS: The frequency of D allele was 0.34, which was lower than that of Caucasian as previous reported. Multiple regression analysis disclosed that existence of DD type increased IMT by 0.12 mm. In those with advanced arteriosclerosis (IMT≥1.3 mm), the prevalence of MI observed in NIDDM with DD type was more than that of nonDD type ($\chi 2=5.2$, $p=0.02$). But this was not the case with those lacking advanced arteriosclerosis(IMT<1.3 mm). CONCLUSION: Co-monitoring of IMT and ACE genotype may be useful for finding high risk individuals for MI in NIDDM patients.

1723

PREVALENCE, INCIDENCE AND FACTORS CONNECTED WITH ISCHEMIC HEART DISEASE IN IDDM AND NIDDM PATIENTS

A. Czech, P. Luźniak and J. Tatoń. Department of Internal Medicine and Diabetology, Warsaw Medical School, Warsaw, Poland.

Ischemic heart disease and myocardial infarction are the main causes of death of diabetic patients. To assess the impact of the selected external and internal connected with diabetes mellitus factors the prospective study was started aimed at the prevalence and incidence of ischemic heart disease and myocardial infarction in a large cohort of diabetics. 1643 patients were examined (309 diabetics type I, 1334 diabetics type II). The frequency of ischemic heart disease was 12.9% in diabetes type I and 35.6% in diabetes type II. The frequency of myocardial infarction was respectively 6.1% and 16.9%. In 39.6% of diabetics type II and in 12.5% of diabetics type I ischemia was found in ECG records in the absence of clinical symptoms (silent ischemia). During 3 - year observation 193 cases of ischemic heart disease were newly diagnosed (19 in diabetes type I and 174 in diabetes type II). 61 patients experienced myocardial infarction (7 in diabetes type I and 54 in diabetes type II). Then the relations between prevalence or incidence and the factors: age, sex, duration of diabetes mellitus, body mass index, arterial hypertension, total cholesterol triglycerides and creatinine levels, fasting and postprandial glycemia and 24-hour proteinuria were analysed. The most significant risk factors connected with development of ischemic heart disease were: age, duration of diabetes, postprandial glycemia, arterial hypertension and creatinine level. Conclusion. The study allowed to assess the connection between studied parameters and ischemic heart disease. This could serve for the practical use of the designing of the care program for the people from a group with the highest risk.

1724

GLN-ARG 192 POLYMORPHISM OF PARAOXONASE GENE IS NOT RELATED WITH CARDIOVASCULAR DISEASES IN PATIENTS WITH NIDDM. YS Kim, WS Kim, JT Woo, SW Kim, IM Yang, JW Kim, YK Choi. Kyung-Hee University, Seoul, Korea

Paraoxonase is located in a high-density-lipoprotein. It has been known to protect lipoproteins from oxidation. Paraoxonase has a genetic polymorphism with single amino acid substitution which arises from a glutamine(A isoform) to arginine(B isoform) interchange at position 192. In French Caucasian, paraoxogenase polymorphism was reported as an independent cardiovascular risk factor in patients with NIDDM. We investigated the relevance of this polymorphism to cardiovascular disease in Korean patients with NIDDM and normal subjects. Of the 66 patients, 30 had confirmed coronary artery disease or cerebral infarction. The other 36 had no history of such diseases and ECG abnormality. Sixty eight normal subjects had no medical history and family history of diabetes. The genotype frequency did not differ between patients with NIDDM and normal subjects(AA: 13.6 % *vs* 16.2 %, AB: 44 % *vs* 33.8 %, BB: 42.4 % *vs* 50 %). There was also no difference in genotype frequency between diabetic group with cardiovascular disease and diabetic group without cardiovascular disease(AA: 13.9 % *vs* 13.3 %, AB: 47,2 % *vs* 50 %, BB: 38,9 % *vs* 36.7 %). Compared with subjects homozygous for the A allele(AA genotype), the odds ratio of cardiovascular disease for subjects homozygous for the B allele was 0.8(95 % CI 1.3 ~ 1.7, $P = 0.784$) and that for those heterozygous for the B allele was 1.3(95 % CI -1.8 ~ 1.2, $P = 0.703$). These data suggest that the polymorphism of paraoxogenase is not an risk factor of cardiovascular disease in Korean patients with NIDDM.

1725

RISK FACTORS FOR THE ONSET OF CARDIOVASCULAR DISEASE DURING THE TREATMENT OF NIDDM

M.Higa, K.Iso, E.Kosugi, M.Arai, and T.Ujiie.
Department of Medicine, Saiseikai Kanagawa-ken Hospital, Yokohama, Japan.

The aim of our study was to evaluate the risk factors for the onset of cerebral infarction(CI) and myocardial infarction(MI) in NIDDM, retrospectively. 【METHOD】 In 92patients (33 with CI (DM-CI), 22 with MI (DM-MI) and 37 with no evidence of CI or MI (Control) during 3 years) ,the following risk factors were analyzed : age, sex, duration of DM, alcohol intake, smoking, BMI, blood pressure, serum lipid and HbA1c levels before the onset of CI or MI. 【RESULTS】 Male was significantly higher in DM-MI ($p<0.05$) than those in DM-CI . There were no significant differences in age, alcohol intake, smoking and duration of DM among 3 groups. In DM-CI, BMI (24.4 ± 4.0Kg/m^2), systolic and diastolic blood pressure (152.2 ± 18.9/86.7 ± 12.9mmHg), and serum triglyceride(TG) (167.8 ± 90.1mg/dl) were significantly higher ($p<0.01$) than those in the other 2 groups. Serum HDL-cholesterol (HDL-C) was significantly lower ($p<0.01$) in DM-CI (40.0 ± 8.7 mg/dl) and in DM-MI (42.1 ± 9.7mg/dl), and LDL-cholesterol (LDL-C) was significantly higher ($p<0.01$) in DM-CI (136.2 ± 32.4mg/dl) and in DM-MI (135.0 ± 32.0 mg/dl) than those in Control (63.6 ± 23.5mg/dl, 117.3 ± 24.0 mg/dl, respectively).However, total cholesterol showed no significant difference among 3groups. HbA1c level was significantly increased during 3 years in DM-CI. 【CONCLUSION】 Male, obesity, hypertension, high TG and LDL-C, low HDL-C, and HbA1c level are important predictors for the onset of cerebral infarction in NIDDM. Moreover, high LDL-C and low HDL-C are also predictors of myocardial infarction.

1726

MARKERS OF COAGULATION AND FIBRINOLYSIS ARE THE PREDICTIVE FACTORS OF CORONARY HEART DISEASE IN PATIENTS WITH NIDDM

K.NISHIDA and M.TSUJINO.
FUCHU METOROPOLITAN HOSPITAL, TOKYO,JAPAN

AIM: Coronary heart disease (CHD) is one of very important complications in patients with diabetes mellitus and is recently more and more notable because of its prevalence. However, its prediction still remained to be difficult. We investigated whether several markers of coagulation and fibrinolysis could be predictive factors of CHD in patients with DM. **METHOD:** 59 patients with NIDDM (mean age: 61.4 ± 11.0 years, 27 male and 32 female) were followed for 4 years. At the beginning of this study , blood samples were collected for measuring HbA1c, tissue factor (TF), thrombomodulin (TM) , fibrinogen (FBG), antithrombin III (ATIII), factor VII activity (FVIIa), tissue plasminogen activator (tPA), plasminogen activator inhibitor-1 (PAI-1), PA-PAI complex (PAIc), α_2-anti-plasmin-plasmin complex (PIC) . Urine samples were also collected for evaluation of urinary albumin index (UAI) calculated by dividing urinary albumin by urinary creatinine. In each patient, ECG was performed at the beginning and once a year during this study. The subjects were divided into 2 groups by onset of CHD(ischemic change of ECG, angina pectoris or acute myocardial infarction) during this study as follows: group H (onset (+)) and N(onset(-)). Differences of HbA1c, UAI and the markers between 2 groups were tested by Mann-Whitney test. Discriminant analysis was performed for investigating more contributable markers of the discrimination. **RESULT:** 11 patients(18.6%) had new onset of CHD. Significant differences between H and N were observed as follows; HbA_1c(8.53 vs.9.85%, $p<0.05$) · UAI(216.83 vs.1785.2mg/g·Cre, $P<0.001$) · TM(15.40 vs.24.39FU/ml, $p<0.025$) · FBG (242.5 vs.291.3mg/dl, $p<0.01$) · FVIIa (106.0 vs.128.1%, $p<0.01$) · PIC(58.14 vs. 62.50ng/ml, $p<0.025$) (mean, N vs. H, p value) . Discriminant analysis showed that PIC($p<0.025$), ATIII ($p<0.025$) and UAI ($p<0.01$) contributed to the discrimination. **CONCLUSION:** PIC and ATIII may be significant predictive factors of CHD in patients with NIDDM.

EFFECTS OF PHYSICAL EXERCISE ON CARDIOVASCULAR RISK FACTORS IN WELL CONTROLLED DIABETIC PATIENTS

M.Rigla, A.Caixàs, T.Prat#, J.Ubeda, J.López-Contreras*, J.Puig, J.M.Pou,A.Pérez. Endocrinology, Cardiology# and Internal Medicine* Dpts. H.Sant Pau. UAB. Barcelona. Spain.

The aim of the study was to evaluate the effect of physical training on cardiovascular risk factors in well-controlled diabetic patients. Fourteen normotensive type I (7 male, 7 female, age 25 ± 6 years, BMI 23.8±3 kg/m^2, HbA1c 6.6±0.8% (reference range 4.6-5.8%) and thirteen type II diabetic patients (male 9, female 4, age 55±5 years, BMI 26±6 kg/m^2, HbA1c 7.3±1%, 84 % normotensive) were included in a supervised physical training program (3-5 days/week, 1851±387 kcal/week) during 3 months. Parameters studied included fat distribution, glycemic control, lipid profile, blood pressure and plasma homocysteine levels. Satisfactory compliance was achieved in most of the patients. Differences were assessed by paired t-test and Wilcoxon test. VO_2 máx increased significatively ($p<0.005$). After three months, no significant changes were seen in HbA1c levels, and insulin dose decreased from 0.4 ±0.2 U/Kg/day to 0.31±0.1 U/Kg/day ($p<0.05$) only in type II diabetic patients. Waist and hip (WHR) perimeters decreased from 83.2± 12 cm and 99.7±7 cm to 81.4±11 cm and 96.9±6.5 cm respectively ($p<0.05$), while WHR and BMI remained unchanged. HDL cholesterol levels increased significantly in the whole group of patients (1.37±0.42 to 1.49±0.6; $p<0.05$) , while LDL cholesterol levels changed favourably only in the type II subset (3.41±1 to 3.14±0.8; $p<0.05$). Plasma homocysteine levels and systolic, diastolic and mean blood pressure were not modified after the exercise program. In conclusion, physical training reduces insulin requirements in type II diabetes and improves lipid profile, even in well-controlled normolipidemic diabetic patients (FIS 95/1252)

1728

CIRCULATING VASCULAR CELL ADHESION MOLECULE-1 AS A USEFUL MARKER FOR ATHEROSCLEROSIS IN NIDDM PATIENTS

M. Otsuki, S. Kasayama, K. Hashimoto,* Y. Morimoto* and T. Kishimoto. Dept. of Medicine III, Osaka University Medical School and Aizenbashi Hospital,* Osaka, Japan.

Vascular cell adhesion molecule-1 (VCAM-1) has been shown to be highly expressed in atherosclerotic lesions. Although soluble (s) VCAM-1 is detected in human sera, it remains unclear whether sVCAM-1 level is increased in atherosclerotic patients. In this study, sVCAM-1 concentrations were measured in sera from 65 patients with NIDDM. The mean (±SD) sVCAM-1 concentration was 908 ±132 ng/ml in 15 patients with symptomatic atherosclerotic vascular diseases, which was significantly higher than the age- and sex-matched patients without the atherosclerotic vascular disease (660±139 ng/ml, P<0.001). Among 50 patients without symptomatic atherosclerotic vascular disease, 22 patients (44 %) had early atherosclerosis of the carotid arteries, based on the evaluation by high-resolution B-mode ultrasonography. Their sVCAM-1 concentration was significantly higher than that in the patients without atherosclerosis of the carotid arteries (755±235 ng/ml vs. 617±122 ng/ml, P<0.02). In addition, there was a significant correlation between serum sVCAM-1 and the intimal plus medial thickness of the carotid arteries in the patients without symptomatic atherosclerotic vascular disease (r=0.544, p<0.001). These results indicate that circulating sVCAM-1 may be a useful marker to predict atherosclerotic lesions in NIDDM patients, even when the atherosclerosis is asymptomatic process.

1729

CIGARETTE-SMOKING AND THE PROGNOSIS OF DIABETIC PATIENTS. A 15-YEAR OBSERVATION OF NIDDM PATIENTS IN OSAKA, JAPAN.

A. Sasaki, M. Uehara, N. Horiuchi, K. Hasegawa and T. Shimizu.
Osaka Seijinbyo Center, Osaka, Japan.

The prognostic effects of cigarette smoking on diabetic patients were examined utilizing a long-term follow-up study. The subjects studied were 1,700 NIDDM patients with age at entry ≧ 35 years and with known history of smoking, who were first seen during 1960-1979 at our hospital, and followed up until the end of 1993, with the mean follow-up period of 14.8 ± 6.5 years. Smoking rates were 64.8% for males and 13.1% for females. The mortality rates per 1,000 person-years in male subjects were 32.1 for non-smokers and 37.6 for smokers, while the O/E ratios were 1.26 and 1.84 for non-smokers and smokers, respectively, both indicating statistically significant differences. The odds ratio of smokers to non-smokers in males was 1.45, and a significantly increased risk of dying in smokers compared with non-smokers was confirmed in Japanese male diabetic patients. But no significant increase in mortality was observed in female smokers. The analysis of odds ratios by causes of death indicated a significant increase in malignant neoplasms, especially in lung cancer, but cancer of other sites, such as stomach and liver, was appreciably increased. Increases in cardiovascular disease, heart and cerebrovascular disease, and in renal disease was also observed. In addition, a marked increase in pneumonia and bronchitis was noted. The odds ratio by causes of death were further analyzed in male subjects with and without proteinuria at the baseline. In the subjects with proteinuria, increases in heart disease, cerebrovascular disease and renal disease were remarkable, but no increase in malignant neoplasms was observed. By contrast, in the subjects without proteinuria, increases in malignant neoplasms and pneumonia and bronchitis were notable. Thus, it was indicated that causes of death in the smoker largely differed by presence or absence of the proteinuria at entry to the study.

1730

ANY ASSOCIATION BETWEEN LOW SERUM DHEAS LEVELS AND ISCHAEMIC HEART DISEASE IN NIDDM IS NEGATED BY AGE

L.Davies, K.Pryor, S.Twigg, G.Fulcher, P.Clifton-Bligh, E.Hibbert, A.McElduff, B.Robinson, and E.Wilmshurst. Royal North Shore Hospital, St Leonards, Australia

Patients with ischaemic heart disease (IHD) are reported to have lower serum levels of dehydroepiandrosterone sulfate (DHEAS) than control subjects, and furthermore, DHEAS supplementation in animal models appears to be protective for atherogenesis. Moreover non-diabetic subjects with the insulin resistance syndrome (Syndrome X) also have lower serum levels of DHEAS. In this study we aimed to determine the association between DHEAS levels and IHD in a population of patients with non-insulin-dependent diabetes mellitus (NIDDM).

Eighty-two males (59.7 ± 7.4yr) and 70 females (60.8 ± 12.2yr), known duration of diabetes 6.8 ± 7.4 and 6.9 ± 6.8 yr respectively, had DHEAS levels measured as part of an annual review for diabetes complications. The presence of IHD was determined by a history of myocardial infarction, angina or revascularisation procedure. By these criteria, 17 males (21%) and 6 females (9%) had clinical evidence of IHD. In males with IHD, DHEAS levels tended to be lower than those without IHD (3.05 ± 2.33 vs 4.5 ± 4.01uM; p =0.09). The findings were similar in females (1.35 ± 0.46 vs 3.22 ± 2.94uM; p= 0.126), but in both groups the difference was of borderline significance. In fact on multiple regression analysis, the major determinant of DHEAS levels in both males and females was age.

These data may be interpreted to indicate that low serum DHEAS levels may be associated with IHD diagnosed using clinical criteria. Alternatively, low DHEAS levels may be an epiphenomenon, loosely correlating with IHD due to the association of DHEAS levels with age. Larger cross sectional studies, and prospective studies involving DHEAS supplementation in NIDDM subjects may more clearly define any association.

1731

THE RISKS RELATED TO ISCHEMIC HEART DISEASES IN NON-SMOKER DIABETICS

A Banu, M. A. Sayeed, M. G. Kibriya and A. K. Azad Khan. Dhaka, Bangladesh

In general population obesity, hypertension, hyperglycemia, hyperlipidemia and smoking are known risk factors for ischemic heart diseases (IHD). But it is not known how much of which risk factors contribute to IHD in non-smoking group of non-insulin-dependent diabetes mellitus (NIDDM) subjects. To estimate the risk, from a total of 3,583 NIDDM subjects, we investigated 572 (M=262, F=310) randomly selected non-smokers of age 30-60yr with mean (SD) duration of diabetes 13.6 (3.6) mo. Diagnosis of IHD was based on cardiogram or exercise tolerance test or both when equivocal. Compared with non-IHD group the subjects with IHD had significantly higher age (p<0.001), higher waist to hip ratio (WHR, p=0.005), higher systolic and diastolic blood pressure (SBP and DBP, p<0.001) and higher fasting blood glucose (FBG, p<0.05). There was no difference of IHD prevalence between male and female diabetics (17.6 vs 18.1%). Compared with the male subjects the female had significantly higher body mass index (BMI, [wt in kg/ht in m^2], p<0.001), higher SBP (p=0.02) and total plasma cholesterol (CHOL p<0.001); whereas, the male had significantly higher WHR (p=0.009) and DBP (p=0.051). Both FBG and 2h after glucose (2-hBG) did not differ between men and women. Adjusting for age, sex and obesity, glycemia showed no association with WHR, SBP, DBP and CHOL; whereas, it showed signficant negative correlation with BMI (p<0.001). In contrast, BMI showed significant positive correlation with SBP (p<0.001) and DBP (p<0.01). Though IHD was not associated with increasing BMI it was significantly associated with increasing age (X^2 =18.2,p<0.0001) and high WHR (X^2 =8.1, p<0.04). Taking BMI, WHR, SBP, DBP, FBG, 2-hBG, CHOL and family history of diabetes or hypertesion as the independent risk variables and IHD as a dependent one, further analysis by stepwise logistic regression showed that high WHR (<0.95 vs > 1.1: OR, 3.0 95% confidence interval (CI) 2.2-3.8) and high DBP (<85 vs >95mmHg: OR, 12.6 95% CI 11.7-13.5) were the risks for IHD. When the age was included in the model it confounded the effect of WHR but not that of DBP. Therefore, it appears that the highest level of risk for IHD in non-smoker diabetics was observed with high DBP and increasing age, and moderate risk with high WHR.

1732

MALE HYPERTENSIVE NIDDM PATIENTS HAVE HIGHER SERUM INSULIN AND LOWER SEX HORMONES AND BINDING GLOBULIN.
C.Phenekos,A.Vrionidou,A.Garidou,E.Kanaki,V.Loi,A.Karfi and C.Tzioras. Deparment of Endocrinology,Red Cross Hospital,Athens,Greece.

Hyperinsulinemia and abnormalities of gonadal hormone concentrations have been implicated in the pathogenesis of cardiovascular disease in people with normal and abnormal glucose tolerance.We measured fasting serum insulin (IRI),sex hormone binding globulin (SHBG),free testosterone (FT) and total estradiol (E_2) concentrations in 95 non insulin dependent (NIDDM) male diabetic patients (mean age 62.06,range 39-75 years) on treatment either with diet or/and oral hypoglycaemic agents.57 patients were normotensive and 38 hypertensive.We applied multiple analysis of variance to detect differences between means and the LSD test for post-hoc comparisons.There was no difference in the glycaemic control between the groups as assessed by fasting plasma glucose and HbA1c levels. Body mass index was higher in the hypertensive group (28.7±0.6 versus 26.5±0.42),p=0.002,and was entered as covariate in the statistical model together with age and duration of disease although the latter ones did not differ significantly.We found that fasting insulin (Mean±SEM) was higher in the hypertensive compared to normotensive group (113.58±11.69 versus 79.85±6.02pmol/L),p=0.007,and SHBG was lower (34.15±2.18 versus 43.1±2.57 nmol/L),p=0.009.FT was also lower in the hypertensive group (49.26 ±2.35 versus 58.41±2.80 pmol/L),p=0.02 as was E_2 (104.9±8.03 versus 127.381±7.45 pmol/L),p=0.03.No difference was found in total,HDL cholesterol and triglycerides concentrations between the two groups.It is concluded that the male hypertensive NIDDM patients have higher insulin and lower SHBG levels,both indices of insulin resistance,and also lower free testosterone and total estradiol levels compared to normotensive patients.

1733

TOBACCO CONSUMPTION PATTERN IN DIABETIC POPULATION OF AN INDUSTRIAL UNIT

N Srivastava, M Joshi, P Shah, D Prabhakaran, SK Puri, KS Reddy, All India Inst Med Sci, New Delhi, India.

Purpose: To estimate prevalence and characterise the pattern of tobacco consumption amongst diabetics in an industrial population of north India.

Design: Cross sectional survey using a standardised structured interviewer administered questionnaire (Response rate: 89%) in diabetics (includes known and diagnosed on OGTT).

Results: None of 21 (0%) female and 110 of 252 (43.7%) male diabetics were current tobacco consumers; 0 and 7.5% reported to have used tobacco in the past. Of the male diabetics 34.0% smoked and 14.1% chewed tobacco. The mean age of smokers was similar to consumers of non-smoking forms of tobacco and non-consumers of tobacco. Of the male diabetic smokers 60 (70.0%) smoked cigarettes, 35 (40.2%) smoked *beedi*. Majority of cigarette smokers used it for 6 years or more (6-9yrs: 16.4%; ≥10yrs: 72.1%); data for *beedi* was similar (22.9% and 68.6% respectively). Cigarettes smoked per day were less than 6 in 55.0%, 6-10 in 31.7%, 11-20 in 10.0% and >20 in 3.3%. The respective numbers for *beedi* were 20.0%, 37.1%, 31.4% and 11.4%. Of the male diabetic workers consuming non-smoking form of tobacco 17 (47.2%) chewed tobacco, 22 (61%) consumed it with *paan*, and 3 (0.8%) consumed it with *paan masala*. Majority of individuals chewing tobacco were using it for over 6 years (58.8%). The respective numbers for tobacco with paan was 72.7%. A graded relationship between prevalence of tobacco consumption and socio economic status of diabetics was observed. Thirty four, 43%, 38%, 62%, and 56% of professional, clerical, skilled, semiskilled, and unskilled diabetic workers respectively consumed tobacco.

Conclusions: Consumption of tobacco was widely prevalent amongst diabetics in the industrial population. Beedi consumption and chewing tobacco contributed significantly to total tobacco exposure. Higher tobacco exposure in lower socio-economic class was apparent.

Paan: Betel leaf and betel nut often taken with tobacco leaves; *Paan masala*: perfumed powder of paan; *beedi:* tobacco packed in Tendu leaves.

1734

CORONARY ARTERY DISEASE RISK FACTORS AMONG POST MENOPAUSAL WOMEN.
Sarwono Waspadji, Maryantoro Oemardi, Pradana Soewondo, Imam Subekti, Sidartawan Soegondo, Slamet Suyono. Dept. of Med., School of Med., Univ. of Indonesia, Jakarta, Indonesia.

Post menopausal women is notorious to have higher prevalence of coronary artery disease (CAD), especially among diabetics. Whether higher risk factors occur in our post menopausal women is evaluated in this study as a part of a population study done in Kayuputih Subdistrict, Jakarta. Among 34,645 total population, 5.0% of the adults (age > 15 years) were randomly recruited (stratified clustered random sampling) to join this survey. Altogether there were 1,019 eligible respondents, comprising 478 male and 541 female subjects. The prevalence of CAD (ECG, Minnesota code), diabetes mellitus (WHO criteria, 1985), hypertension (JNC V criteria), obesity (BMI ≥ 27 kg/m^2 for male, and ≥ 25 kg/m^2 for female), high TC (≥ 240 mg/dl), high TG (≥ 200 mg/dl), high LDL-C (≥ 160 mg/dl), and low HDL-C (≤ 35 mg/dl) among female respondents of ≥ 50 years old were 22.7, 10.0, 57.3, 34.5, 9.1, 8.2, 6.4, and 49.1% respectively; while among the younger counterpart (< 50 years old) the corresponding figures were 28.3, 3.0, 14.4, 21.3, 2.6, 1.6, and 47.3%. For the menopausal diabetics the corresponding figures were even higher, namely 36.4, 63.6, 27.3, 36.4, 9.1, and 45.5% respectively for the prevalence of CAD, hypertension, obesity, high TC, high TG, high LDL-C and low HDL-C. All the differences between the menopausal women and their younger counterpart were highly significant (p <.01), except for HDL-C. The fasting plasma insulin level among the ≥ 50 years old respondents were similar (3.7 mU/L) as compared to the younger respondents (4.07 mU/L). As a conclusion, in our studies population we found higher CAD risk factors among menopausal respondents which might explain the higher occurrence of CAD in this population subset.

1735

CARDIOVASCULAR DISEASE IN IDDM: A TRANSATLANTIC COMPARISON OF RATES AND RISK FACTORS
T. Orchard, L. Stevens, K. Forrest and J. Fuller. University of Pittsburgh, Pittsburgh, USA and University College, London, UK

The reasons behind the dramatically increased rates of cardiovascular disease (CVD) in IDDM subjects are poorly understood. To better understand the development of CVD in IDDM, data from the Epidemiology of Diabetes Complications (EDC) study in the USA were compared to data from the 31 centers in the European study EURODIAB. Comparable age (mean = 28 years both studies) and duration subsamples (EDC: N = 567, EURODIAB: N = 1215) were drawn from each study. CVD prevalence (myocardial infarction, angina, coronary bypass surgery, stroke, or ischemic ECG changes (Minnesota codes 1.1, 1.2, 1.3, 4.1, 4.2, 4.3, 5.1, 5.2, 5.3, and 7.1) rates were similar in both studies for men (EURODIAB 18.1% v EDC 20.1%) and for women (18.9% v 19.9% respectively), except for angina (more frequent in EDC women, p = < 0.001). In men, hypertension and triglycerides independently predicted CVD in EDC subjects, while age and HDL cholesterol were predictors in EURODIAB. In women, age was a predictor in both populations along with hypertension (EURODIAB) or renal disease (EDC). HbA_{1c} was negatively related to CVD in EURODIAB women but showed a weak positive relationship in EDC women. Renal disease only related to CVD in EDC. We conclude that while overall rates are similar, the risk factor correlates of CVD in IDDM vary considerably by continent. The previously reported strong association between renal disease and cardiovascular disease is less marked in these analyses, while any relationship with glycemic control is inconsistent.

1736

GENDER INFLUENCE OF MACROVASCULAR DISEASE IN DIABETES

FWF Hanna, CJ Currie, CL Morgan, A Rees and JR Peters
Department of Medicine, University Hospital of Wales, Cardiff, UK.

We have demonstrated that diabetic (DM) women below 55 y are at lower risk of developing ischaemic heart disease (IHD) than DM men, while above 55, there is no significant difference. The male-to-female age-specific relative risk (RR) of IHD followed the same pattern in both DM and ND population but the event rate appeared to have occurred 10 years earlier in DM. To investigate the influence of gender on cerebrovascular disease (CVD) rates in DM vs. ND, we used primary event rates in a diabetic population (5602 DM out of total of 402,798). The number of cases of CVD was assessed in both DM and ND male and female populations over 4 y (1991-1995). In the DM population below 55y, the RR was 1.05 (confidence intervals CI 0.53-2.08, insignificant). In ND population, RR below 55 was 1.11 (CI 0.88-1.39, insignificant). The age-specific event rate curve in DM confirmed that between 55 and 75y, both sexes had the same event rate. Above 75y, however, women were more prone to CVD, presumably reflecting the greater number of women reaching that age. Shifting the event rate curve of ND population 10 years backwards resulted in virtual superimposition of the event rate curve of the DM and ND populations in both sexes. We conclude that 1) DM women below 55y, are not at increased risk of CVD, compared to DM men. 2) Unlike IHD, CVD risk is similar in both DM men and women below 75y. 3) As in IHD, DM population have the CVD event rate occurring approximately 10 years earlier.

1737

IDENTIFICATION AND EFFICACY OF MULTIPLE RISK FACTOR CONTROL IN DIABETIC MACROVASCULAR DISEASES

*Y.Hattori, M.Suzuki, **M.Takeuchi, ***T.Watarai, ***Y.Yamazaki, H.Inada, ****H.Nawata, *****H.Orimo and Y.Harano. National Cardiovascular Center, Osaka, Japan. *Konan University, Kobe, Japan. **Kobe City College of Technology, Kobe, Japan. ***Osaka University, Osaka, Japan. ****Fac., Med., Kyushu University, Fukuoka, Japan. *****Tokyo Hospital, Ministry of Finance, Tokyo, Japan. MSDM group, Japan.

Using 899 subjects with NIDDM who were registered to MSDM (Multiclinical Study for Diabetic Macroangiopathy), the correlation between diabetic macroangiopathy (MA) and risk factors have been evaluated in a cross-sectional study. In addition, a prospective study for developing MA is performed. Hypertension, diabetic neuropathy and low HDL cholesterol in subjects with MA were significantly more frequent compared with MA(-) when the duration of diabetes was adjusted. Brinkman index, TG, hypertension in subjects with MA were significantly associated with MA. The following cut-off levels were determined, based on the discriminating value to differentiate MA(+) from MA(-) group. BMI:24, chol: 200, TG:120, ApoB:110, FBS:140, S-BP:140, D-BP:90. Those fulfilled more than 5 had significantly less MA. In the prospective study, the existence of MI was related to the more frequent appearance of MA for subjects who had no previous MA. In subjects with MA, MA progressed more frequently in those who failed to attain control criteria more than 4 out of total 6 risk factors excluding ApoB. These results indicate that an effort to control the multiple risk factors seems to be essential for the prevention of diabetic macroangiopathy.

1738

SERUM FOLATE AND CORONARY HEART DISEASE IN TYPE II DIABETES

V.J.McCann*, K.G.Stanton, R.W.Parsons, F.M.van Bockxmeer, and S.Vasikaran
Royal Perth Hospital and University of Western Australia, Perth, Western Australia

Mild to moderate hyperhomocysteinaemia has recently been recognised as a risk factor for coronary heart disease and may be associated with deficiencies of vitamin cofactors particularly folate. We assessed the risk of coronary heart disease, mortality and serum folate levels in patients with Type II diabetes. Since 1973, patients attending the Royal Perth Hospital Diabetic Clinic have been invited to participate in a two yearly survey of diabetic complications and risk factors. Survival status of survey participants was ascertained at 31 December 1993 by computer linkage to the Registrar Generals Death Indices for 1973 to 1993 for Western Australia. The cause of death was defined according to the International Classification of Diseases ninth revision (ICD9) code for the underlying cause of death. If the code was related to diabetes the cause was redefined according to the primary cause of death. Coronary heart disease, as defined by a history of angina or previous myocardial infarction, was present in 21% of 1391 subjects with Type II diabetes at the initial visit. Significant risk factors for coronary heart disease after age and sex were triglycerides ($p<0.001$), folate ($p=0.005$) and cholesterol ($p=0.016$). The most common cause of death was coronary heart disease, accounting for 60% of all 542 deaths recorded. The risk factors showing the most significant associations with death from coronary heart disease, after adjusting for age and sex, were history of coronary heart disease at the initial visit, cholesterol ($p<0.001$, hazard ratio=2.2), plasma glucose ($p=0.007$), diastolic blood pressure ($p=0.008$), and folate ($p=0.022$). Low folate was a risk factor (hazard ratio=1.6) in those with normal cholesterol but did not add to the risk in those with high cholesterol. It is concluded that low serum folate is a significant risk factor for both the presence of and subsequent mortality from coronary heart disease in Type II diabetes. This risk may be mediated by homocysteine.

1739

ABDOMINAL FAT DISTRIBUTION AND CARDIOVASCULAR RISK STATUS IN TYPE 2 DIABETIC PATIENTS

D. Negreanu, N. Hâncu, G. Roman and A. Cerghizan. Diabetes Center & Clinic, Cluj-Napoca, Romania

One of the main objective in diabetes care is to reduce morbidity and mortality from coronary heart disease (CHD) by risk factor reduction. Many studies have suggested that abdominal distribution of adipose tissue (ADAT) may have higher predictive value for CHD. **Objective:** To assess the cardiovascular risk status (CVRS) in NIDDM patients, according to the values of a new parameter called abdominal index (AI), this represents waist/height ratio. **Method:** For the assessment of CVRS in medical practice European Task Forces on prevention of coronary heart disease have proposed a chart, that can predict the risk for coronary events in the next 10 years. In order to be more accurate in diabetes mellitus, we added other parameters and called this new chart: Eurochart '94. **Patients:** We have applied Eurochart '94 in 949 NIDDM patients (395 men): age 54.1±7.1 yrs.; diabetes duration 7.9±4.8 yrs. and 1082 control subjects.Waist/hip ratio and AI were also measured. **Results:** CVRS score (%) has been greater in NIDDM (21.07±1.1) than in control group (6.1±0.3). The prevalence of ADAT (AI>0.5) has been higher vs. non ADAT in both NIDDM (85.3%) and control subjects (58.1%), with CVRS increased accordingly. AI better described the ADAT that waist/hip ratio (96.6% vs. 58.0% in NIDDM patients and 87.5% vs. 40.1% in control subjects), while CVRS remained the same. **Conclusions**: ADAT is a common condition in NIDDM patients. CVRS is strongly influenced by NIDDM and ADAT. AI can better discriminate abdominal vs. non abdominal distribution of adipose tissue. AI is easier to be measured, as the errors which come from hip measurement are avoided.

1740

RISK FACTORS FOR ATHEROGENESIS IN TYPE 2 DIABETES AMONG VEGETARIANS AND NONVEGETARIANS

Mala Dharmalingam and Prasanna Kumar KM M.S.Ramaiah Medical College Bangalore India

The aim of the study was to study the differences in risk factors for atherogenesis among vegetarians and nonvegetarians.Total of 658 diabetic patients -395 men and 242 women were studied. They included 230 vegetarians and 428 nonvegetarians.They were studied for BMI ,waist hip ratio ,hypertension and dyslipidemia. Dietary patterns were assessed, with a food frequency questionnaire. There was no difference in cholesterol intake with reference to total calories prescribed to them. The patients were matched for other risk factors.23.5 % of vegetarians and 23.3% of non vegetarians had BMI of > 27 in men and 25 in women(p <0.01). W/H ratio of > 0.85 in women and 0.95 in men was present in 30.8% vegetarian and 41.6% non vegetarians ($p < 0.001$) hypertension was present in 22.% vegetarians and 26.6% in non vegetarians ($p < 0.05$) Cholesterol of > 200 mg/dl was present in 42.6% in vegetarians and 55% in non vegetarians ($p < 0.05$) Triglycerides of > 170 mg/dl was present in 47% vegetarians and 45.8% in non vegetarians ($p < 0.01$) HDL < 35 mg/dl was present in 23.5% in vegetarians and 26.6% in non vegetarians ($p < 0.05$). It can be concluded that non vegetarians had significantly more W/H ratio, hypertension high cholesterol and low HDL when compared to vegetarians. BMI and Triglycerides was not significantly different.

1741

OBESITY AND ITS RELATIONSHIP WITH RISK FACTOR IN SCHOOLERS OF QUITO (X SYNDROME)

Moreno M., Pasquel M., Caicedo R., Naranjo E., Narváez M. Central University Quito-Ecuador.

The index weist hip (ICC) is used in adults as an indicator of the distribution of fat tissue its relationship with the hyperinsulinism called X sindrome. Eventhough it is an index it has not been used or considered valid in children. We proposed to find out its validity in pediatric children taking the same cut points recomended for adults by the WHO.In a representative population of schoolars in Quito (n=678), anthropometric measurements were done, BMI was calculated and the ICC to relate then with eachother,also the arterial tension was determined and fasting blood was taken to value lipids (total cholesterol, LDL, HDL and TG). The results reveal that the 68% of the children have ICC at high risk and 21,4% al moderate risk. The relationship between the ICC with the BMI was significative (p=0,003), relating the risk determined by the ICC with risk factors we found that the 93% of the obese by BMI had an ICC at risk,the ICC at risk was present in a 100% of the children with high systolic and dyastolic pressure,in 94% with low HDL, in the 87% with high total cholesterol. Conclusion: the ICC in children has the same validity and significancy as the adult population and that the risk found in the studied population is high,having an important relationship with other risk factors.

1742

ALBUMINURIA AS A NEW MARKER OF DIABETIC PERIPHERAL VASCULAR DISEASE.

IK, Lee, KY Park, HW Lee*, KC Won*. Keimyung University, Yeungnam University*, Taegu, Korea.

Peripheral vascular disease is a common complication of diabetes. Recently, microalbuminuria is suggested as a new marker of diabetic macroangiopathy.

We studied the levels of abuminuria and other risk factors of atherosclerosis such as Lp(a), Plasminogen activator inhibitor-1, LDL-cholesterol, triglyceride, HDL-cholesterol, free fatty acid, Insulin, C-peptide, Hemoglobin A_1C in 196 diabetic patients with(102) or without diabetic peripheral vascular disease(94), which comfirmed by doppler flow velosity waveform analysis and angiography.

The prevalence of microalbuminuria and macroalbuminuria were 19.8% and 24.5% respectively. Risk factors for peripheral vascular disease in diabetic patients with macrovascular disease were evaluated by multivariate discriminant analysis and the following factors were identified by statistical significance of $P<0.05$: duration of diabetes, low density lipoprotein, high density lipoprotein, male, systolic blood pressure and amount of albuminura.

These datas suggest that the level of albuminuria in diabetic patients can be a new marker for the peripheral vascular disease.

1743

OBESITY AND BODY FAT DISTRIBUTION IN RELATION TO CHD RISK FACTORS

D Prabhakaran, P Shah, M Joshi, SK Puri, KS Reddy, All India Inst Med Sci, New Delhi, India.

Purpose: To investigate the relationship of CHD risk factors to over-weight (BMI ≥25kg/m²) and body fat distribution (Apple ≥0.85 in females ≥0.95 in males) in an industrial population.

Design: Analysis of data from a survey (N: 2420; ie. response: 84.7%) of an industrial population of North India. Categories of body fat distribution were: 1. Pear-Lean, 2. Pear-Overweight, 3. Apple-Lean, and 4. Apple Overweight.

Results	Female				Male			
	1	2	3	4	1	2	3	4
N [%]	71 [29]	44 [18]	42 [17]	87 [36]	691 [32]	40 [2]	731 [34]	714 [33]
Diastolic BP	74 (8)	73 (6)	75 (8)	78 (8)	80 (8)	84 (9)	83 (9)	87 (9)
Systolic BP	113(11)	110(9)	113(11)	118(15)	118(11)	122(12)	122(14)	126(14)
FP Glu*	94(21)	103(31)	102(29)	101(23)	98(30)	103(42)	101(34)	105(37)
HbA1 (%)	5.0(1.1)	5.4(1.7)	5.3(1.5)	5.7(1.8)	5.9(1.9)	5.6(2.0)	5.7(2.0)	6.1(2.2)
Cholesterol*	163(40)	160(38)	173(49)	172(37)	174(43)	164(45)	184(44)	186(45)
HDL chol*	46(13)	46(13)	42(12)	43(13)	39(12)	36(10)	36(11)	36(11)
C:H Ratio	3.7(1.1)	3.7(1.3)	4.4(1.9)	4.3(1.8)	4.8 (1.8)	4.8(1.5)	5.4(1.9)	5.7(2.0)
Triglyceride*	93(38)	99(53)	98(47)	124(70)	120(80)	153(67)	153(89)	173(109)
DM [%]	11.7	5.7	12.1	8.9	7.4	8.6	12.2	16.6
HT [%]	12.9	9.1	9.5	19.5	18.0	37.5	27.8	44.5

Data presented as Mean (SD) or percent [%]; FP Glu:Fasting Plasma glucose; chol: cholesterol; C:H: cholesterol :HDL cholesterol; HT: hypertension; DM: diabetes. *: mg/dL

Conclusions: Weight and body fat distribution is related to CHD risk factors in a graded manner; the maximum in apple shaped overweight and minimum in pear shaped lean individuals.

1744

RISK FACTORS FOR CORONARY HEART DISEASE IN NON INSULIN DEPENDENT DIABETICS WITH AND WITHOUTH DIABETIC NEPHROPATHY.

P.Lazzari and G.Madini,Diabetes Center,Hospital of Cremona, Italy

We studied 140 type 2 diabetics(71 M,69 F,age 66.7±7.1 yr) of whom 54(38.6%) with coronary heart disease(CHD) and 86 (61.4%) withouth coronary heart disease.The 2 groups were strictly comparable by sex,age and duration of disease.On the whole 88 subjects(62.9%) showed normoalbuminuria(No) (<30 mg/24 h),46(32.9%) microalbuminuria(Mi)(30-300 mg/24h) and 6(4.3%) macroalbuminuria(Ma)(>300 mg/24 h).CHD was less frequent in No(17%) than in Mi(76%) and Ma(66%)(chi-square for trend=25.3,p<0.00001).Hypertension was more frequent in patients with CHD in Mi(76%) than in No(18.8%,p=0.00001) and Ma(60%,p=NS).Systolic blood pressure was higher in patients with CHD than withouth CHD in No(176.4±26.1 vs 161+ 20.1,p=0.01),but was similar in Mi and Ma.Diastolic blood pressure,total and HDL-cholesterol,triglycerides,body mass index,fibrinogen,smoke,duration of diabetes,fasting glicemia,glycosilated hemoglobin,insulin therapy and insulin daily dosage were similar in patients with and withouth CHD in No,Mi,and Ma.The study confirms a significant association between CHD and increased albuminuria.Among the considered variables only hypertension and systolic blood pressure seem to be related to different albuminuria levels in the developement of CHD.The study suggests that their role could be less important when renal damage is established.

1745

ASSOCIATION OF CENTRAL OBESITY WITH CORONARY HEART DISEASE, BUT NOT WITH RETINOPATHY IN NIDDM

M. Boz, A. Giuliani, G. Michel, Department of Endocrinology, Centre Hospitalier, Luxembourg.

Obesity and especially abdominal (central) obesity is often associated with NIDDM and the complications of this disease. In a group of 55 consecutive non-selected NIDDM patients, 27 of 55 (49%) are severely obese (BMI > 30) and 40 of 55 (72%) have a waist-hip ratio (WHR) ≥ 0.9 (mean of the group 0,95 ; range 0,75-1,10). Some characteristics of the group are summarized : mean age 61,3 ± 1,37 years, known diabetes duration : 9,64 ± 0,9 years, BMI : 29,74 ± 0,62 kg/m^2, HbA_1c : 7,79 ± 0,25 %, C-Peptide : 3,27 ± 0,28 ng/ml and fasting insulinemia : 11,97 ± 0,9 mU/l. 31% of the patients have coronary heart disease (CHD), 24% have background or proliferative retinopathy and 33% have micro- or macroalbuminuria. CHD is statistically significantly correlated to WHR. Men present more CHD (32% vs 29%) in the same BMI, systolic and diastolic blood pressure levels in spite of having lower fasting insulinemias than women. There is no statistically significant correlation between WHR and retinopathy or nephropathy.

In conclusion : These data suggest an association of central obesity and CHD but no association with retinopathy or nephropathy in NIDDM patients especially male patients.

1746

MICROALBUMINURIA IS ASSOCIATED WITH PERIPHERAL ARTERIAL DISEASE IN DIABETIC SUBJECTS ONLY IF HYPERTENSION IS PRESENT

A. Jager[1], J.M. Dekker[1], G. Nijpels[1], L.M. Bouter[1], R.J. Heine[2], C.D.A. Stehouwer[2]
[1]Institute for Research in Extramural Medicine, Vrije Universiteit Amsterdam [2]Department of Internal Medicine, Vrije Universiteit, Amsterdam, NL

Microalbuminuria (MA) is a risk indicator for coronary heart disease in diabetic and in non-diabetic subjects. Whether this is also the case for peripheral arterial disease (PAD) is hardly investigated. Our aim was to study the associations between MA and PAD in the presence of hypertension and/or diabetes mellitus (DM). We investigated an age-, sex- and glucose tolerance stratified sample from a 50-74 year-old general Caucasian population (n=631) from the Hoorn Study. The urinary albumin concentration was measured in a first morning urine upon arising by radioimmunodiffusion, with a threshold of 6.2 mg/l. A valid albumin/creatinine ratio could be obtained from 580 subjects. The 53 non-valid ratios were excluded from further analyses. MA was defined as a ratio above 2.0 mg/mmol. Doppler-assisted systolic blood pressures were performed from brachial and posterior tibial arteries to calculate the ankle-brachial pressure index (ABPI). If the highest ABPI for either leg was less than 0.90, the subject was classified as having PAD (n=68). The prevalence of PAD was 7 and 19% for normo- and hypertensive subjects, and 8 and 15% for non-diabetic and diabetic subjects, respectively. Analyses were performed by multiple logistic regression. The table shows age- and sex adjusted OR (95% CI) of PAD in diabetic and/or hypertensive subjects compared to a control group in the absence or presence of MA.

		MA absent (n=482)	MA present (n=68)
control	(n=318)	1.0	0.7 (0.09 - 5.9)
DM only	(n=91)	1.4 (0.6 - 3.4)	2.1 (0.4 - 10.5)
HT only	(n=108)	0.8 (0.3 - 2.2)	3.6 (1.1 - 11.7)*
DM and HT	(n=64)	3.8 (1.6 - 9.3)*	6.3 (2.2 - 18.3)*

* $p < 0.05$ Wald-test

We conclude that in this Caucasian population peripheral arterial disease is not significantly associated with microalbuminuria in diabetic subjects. However in the co-presence of hypertension a pronounced association between microalbuminuria and peripheral arterial disease was observed.

1747

SYNDROME 'X' - MORE COMMON IN MEN OR WOMEN

S.R. Aravind, K.M. Prasanna Kumar & Mala D.,
Diacon Hospital, Bangalore, INDIA.

The Aim of the study was to see the association of Obesity, Hypertension, Lipid abnormalities & IHD among NIDDM Men & Women. The data of 13672 patients randomly selected from 2 different Hospitals were studied with the help of a computer aided statistical programme. Results showed Obesity among 44% of Women (BMI > 25) & 14% of Men (BMI > 27). Hypercholestrolaemia (> 200 mg/dl) was present in 14% of Women & 12% of Men. Hypertriglyceridaemia (> 170 mg/dl) was present in 12% of Women & 7% of Men. Hypertension was present in 32% of Women & 24% of Men. (Obesity was 52% among Women & 19% in Men in this sub group). IHD was present in 13% of Women & 12% of Men (Obesity was 45% among Women & 15% in Men in this sub group). Hypertension with IHD was 7% in Women & 5% in Men. (Obesity was 50% among Women & 18% in Men in this sub group). To Conclude, Obesity perse & its association with Hypertension & IHD is more among Women than Men. Hypertriglyceridaemia is significantly higher among Women than Men but, Prevelence of Hypercholestrolaemia shows no increased risk. Therefore, SYNDROME 'X' appears to be more common among South Indian Women than Men.

1748

MICROALBUMINURIA –AN INDEPENDENT NOVEL RISK FACTOR FOR IHD IN NON–DIABETICINDIVIDUALS.

Borch–JohnsenK, Jensen JS, Feldt–RasmussenB, Strandgaard S, Schroll M and Dan–MONICA,Centre of Preventive Medicine, Glostrup, Denmark.

Background: Previous, cross–sectional studies suggest that "micro–albuminuria" is associated with CVD, dyslipidaemia and increased blood pressure. **Aim:** To analyze whether microalbuminuria predicts subsequent development of IHD in a non–diabetic population based cohort. **Material:** In the first Danish MONICA–studyin 1983 we collected morning urine samples in 2,094 consecutive participants without renal disease, urinary tract infection, diabetes or IHD at entry. We measured urinary creatinine and albumin (ELISA–technique). All participants were followed until death, emigration or Dec.31.1993 and IHD was defined as a hospital discharge diagnosis or cause of death including the diagnoses: ICD–8; 410–414). **Results:** 80 individuals developed IHD during the follow–up period, and they were characterized by male preponderance, higher age, higher BMI, BP, cholesterol and proportion of current smokers. Microalbuminuria (MA) was defined as the 90th centile of the urinary alb./creatinine ratio. When adjusted for other risk factors, the RR of IHD in cases with microalbuminuria was 2.3 compared to the controls, and the 10 year disease free survival was 91.5% and 97%. respectively ($p<0.003$). Interaction between the effect of microalbuminuria and other well known risk factors was observed. RR's for the combined effects: MA+current smoking: 4.9, MA+Syst. hypertension: 6.3, MA+low LDL: 5.3 and MA+hypercholest: 7,1. **Conclusion:** Microalbuminuria is an independent predictor of IHD. Generalized vascular hyperpermeability (as demonstrated trough microalbuminuria) may explain the increased susceptibility to smoking, hypertension and dyslipidaemia in patients with microalbuminuria.

1749

THE COMPLICATIONS UNDER THE ICEBERG: HOW DANGEROUS IS IMPAIRED GLUCOSE TOLERANCE ?

N.Dinççağ, İ.Satman, K.Karşıdağ, Ş.Karadeniz, M.Sargın, A.Şengül, F.Salman and M.T.Yılmaz.
Institute for Experimental Medicine, Diabetes Research Unit, and Division of Diabetes, Istanbul Medical Faculty, Istanbul University, Istanbul, TURKEY

Persons with impaired glucose tolerance (IGT) have an increased risk for developing type 2 diabetes when compared to persons with normal glucose tolerance. Although it is known that long-term diabetic complications can be rarely seen during IGT, it has not yet been demonstrated whether IGT period has any influence on the incidence of complications. According to WHO's criteria (75 gr standard OGTT) 68 patients (40 female/28 male; mean age 53.3±10.2 years) were defined to have IGT and followed for an average period of 47 months before developing clinical diabetes. They were all obese (BMI: 29.3±4.7 kg/m2), %60 of them had family history for diabetes. During follow up period the sequence and prevalence of macro and microvascular complications were assessed by physical examinations and relevant laboratory tests. Hypertension developed in 29 (%42) cases, hyperlipidemia was found in 27 (%39) of them. Although all had normal visual acuity and normal fundus findings, they were studied by Farnworth-Munsell 10 hue test for colour vision and Arden's contrast gratings and found that they have significantly lower contrast sensitivity and colour vision functions than normal persons. There was no case with microalbuminuria by micral test. 7 patients (%10) were identified to have subclinical polyneuropathy by EMG. As a conclusion it is probable to say that factors other than hyperglycemia have influence on developing long-term diabetic complications.

1750

CORRELATION OF MICROALBUMINURIA WITH LEFT VENTRICULAR DIASTOLIC FUNCTION IN DIABETES MELLITUS

G.Ioannidis, O.Platis, M.Peppa, N.Hadjis, T.Zisis, L.Flessas and N.Thalassinos. Departments of Endocrinology and Cardiology 2nd, "Evangelismos" Hospital, 106 76 Athens, Greece

Microalbuminuria (MA), an index of nephropathy, is associated with increased Coronary Artery Disease (CAD) mortality and morbility in both types of diabetes. Echocardiographic alterations in Left Ventricular Diastolic Function (LVDF) are considered as an indicator of the presence of early CAD, in individuals without hypertension or cardiomyopathy. To investigate the relationship between these two indirect indices of CAD (MA and echocardiographic alterations in LVDF) in 64 normotensive and without cardiomyopathy diabetics were studied: 23 type 1 DM aged (m±SD) 29.3±8.9 years with disease duration (m±SD) 11.5±6.5 years and 41 type 2 DM aged (m±SD) 55.7±8.6 years with disease duration (m±SD) 11.7±8.2 years. No patient had clinical or ECG evidence of CAD. The diabetics of both types were divided according the presence of MA into groups: 16 MA normal/7 MA elevated in type 1 DM and 25 MA normal/17 MA elevated in type 2 DM. MA was measured in an overnight 8-hour urine collection by RIA while LVDF was determined as the ratio E/A waves (normal values >1) and the isovolumic relaxation time (IRT) (normal value 45-75 mm/sec) both indirect indices of CAD, on the two dimension echocardiography. No statistical difference was observed between the two groups in both types of DM for the ratio E/A 1.40±0.30 vs 1.21±0.20 type 1 DM, 0.94±0.29 vs 0.92±0.26 type 2 DM) or the IRT (71.0±16.6 vs 70.7±18.3 type 1 DM, 90.5±16.1 vs 82.2±11.9 type 2 DM). No correlation was found between MA and E/A or IRT in either type of DM. In conclusion these findings suggest that in both types of DM in the absence of hypertension or cardiomyopathy, MA is not related to echocardiographic alterations of LVDF which are considered indirect indices of CAD.

1751

CORRELATION OF CORONARY ARTERY DISEASE WITH MARKERS OF OBESITY IN DIABETES MELLITUS

N.Thalassinos, O.Platis, G.Ioannidis, T.Zisis, N.Hadjis, K.Alevizaki and I.Flessas. Departments of Endocrinology and Cardiology 2nd, "Evangelismos" Hospital, 106 76 Athens, Greece

The increased risk of type 2 diabetics to the development of Coronary Artery Disease (CAD) is well known but few data are available regarding the relationship between CAD and specific markers of obesity as the Body Mass Index (BMI) or central fat distribution expressed as the waist to hip ratio (W/H). To investigate this relationship 225 type 2 diabetics, 119 males and 106 females, aged (m±SD) 57.6±10.3 years and with disease duration (m±SD) 9.9±7.1 years were studied. The BMI was calculated in all the diabetics and in 112 of them the W/H was also measured. Normal values were considered for the BMI <27 and for the W/H <0.95 for males and <0.85 for females. In all the patients the presence of CAD was established by the past history of cardiac infarct/ischemia, ECG findings (WHO criteria) or after maximal treadmill stress test (Bruce classification). It was found that CAD was present in the BMI overweight group in 56.8% (29/51) of males and in 48.8% (22/45) of females whereas according to the W/H in 50.0% (13/26) and 57.1% (12/21) respectively, without statistical difference of the CAD incidence between normal and overweight diabetics using either marker of obesity. Comparing the incidence of CAD in the patients in whom both markers of obesity were available, this was again not statistically different between the two markers ($x^2=2.17$). In conclusion, obesity expressed by either the BMI or the W/H ratio does not seem to differentiate, at least at the moment of the study, type 2 diabetics with CAD.

1752

RELATIONSHIPS BETWEEN MACROVASCULAR DISEASES AND MICROALBUMINURIA IN TUNISIAN DIABETIC OUTPATIENTS
F.Kanoun,S.Idriss,and F.Ben Khalifa.Service d'endocrinologie Hopital La Rabta Tunis Tunisie.
The aim of this study was to estimate the prevalence rates of macrovascular diseases and of microalbuminuria in tunisian diabetic outpatients. This study is related to a sample including 249 diabetic patients,(83 IDDM and 166 NIDDM),sex ratio 1.02,mean age 45.1 +/- 6.6 years,duration of diabetes 8.9 +/- 7 years. Cardiovascular questionnaire responses (Rose method) and Minnesota code for ECG were used to identify coronary heart disease and leg vascular disease.Microalbuminuria was determined using turbidimetric method. Global prevalence of macrovascular diseases was 24.5% including coronary heart disease 14.5%, leg vascular disease 12.4% and stroke 1.6% Prevalence of hypertension was 20.5%. Positive microalbuminuria (from 30 to 300 mcg/mn)was found in 25.3% . Macrovascular diseases except hypertension were more frequent in men than in women. Macrovascular diseases were slightly but not significantly more frequent in microalbuminuric patients (27% vs 23%). Prevalence rates of macrovascular disease and microalbuminuria increase with age and duration of diabetes. Cardiovascular risk factors associated with microalbuminuria were obesity, hypertension and high cholesterol levels. We conclude that microalbuminuria and macrovascular diseases are frequent in tunisian diabetic patients. Microalbuminuria is associated with cardiovascular disease risk factors.

1753

INCREMENTAL FASTING PLASMA GLUCOSE LEVELS IN MALE SUBJECTS IS ASSOCIATED WITH INCREASING PREVALENCE OF CHD RISK FACTORS.

P Shah, D Prabhakaran, M Joshi, SK Puri, KS Reddy, All India Inst Med Sci, New Delhi, India.

Purpose: To estimate CHD risk factors in relation to fasting plasma glucose and OGTT status.

Design: Analysis of data from a survey (N: 2043 i.e. response: 79.2%) of an industrial population of North India. Based on fasting plasma glucose levels and plasma glucose response to OGTT subjects were divided in to 6 groups.

Results:

	fasting plasma glucose						
[mean (SD)]	≤80	80 to 99	100 to 119	120 to 139	IGT	fresh DM	known DM
N	334	629	430	88	81	363	101
Age (years)	41 (6)	41 (7)	41 (7)	41 (6)	42 (6)	43 (5)	45 (5)
BMI (kg/m²)	23.0(3.3)	23.3(3.5)	23.4(3.1)	24.2(3.6)	24.9(3.5)	24.2(3.0)	24.9(3.5)
Waist hip ratio	0.97 (0.06)	0.97 (0.06)	0.97 (0.06)	0.97 (0.06)	0.99 (0.06)	0.98 (0.05)	0.99 (0.06)
Diastolic BP (mm Hg)	83 (9.9)	82 (9.1)	85 (9.6)	84 (9.5)	86 (8.9)	87(10.2)	84 (9.3)
Systolic BP (mm Hg)	120 (14)	119 (12)	123 (12)	124 (12)	125 (13)	128 (17)	127 (16)
HbA1 (%)	5.6 (1.7)	5.6 (1.7)	6.0 (2.2)	5.9 (2.2)	6.1 (2.2)	6.2 (2.2)	7.3 (3.4)
Triglycerides*	137 (78)	140 (79)	142 (70)	153(155)	155 (82)	187(117)	235(197)
Cholesterol *	178 (48)	182 (44)	182 (42)	181 (36)	182 (45)	186 (48)	181 (44)
HDL cholesterol *	35.8(12)	36.9(11)	37.4(11)	37.5(10)	37.6(12)	32.8 (8)	36.1(11)
CH ratio	5.4 (2.0)	5.3 (2.0)	5.2 (1.8)	5.1 (1.5)	5.2 (1.9)	6.0 (2.1)	5.4 (2.1)

CH ratio: cholesterol :HDL cholesterol ratio; *:mg/dL

Conclusions: Increasing fasting plasma glucose levels considered as "non-diabetic" correlate with increasing coronary heart disease risk factors esp. triglycerides, and BP despite comparable waist to hip ratio.

1754

THE ROLE OF SYNDROME-27 ON DIABETIC ANGIOPATHY.

A.Tjokroprawiro, S.Adi, Hendromartono, A.Sutjahjo, H.Tandra. Diabetes And Nutrition Center Dr. Soetomo Hospital - Airlangga University School of Medicine. Surabaya-Indonesia.

Background: Askandar Tjokroprawiro (1996) has firstly coined the term "Syndrome-27" or **GIGULOCHIPS-SAF$_3$ARIL-PAC$_3$GE.** This syndrome described about 27 determinant factors responsible for the quality of blood vessels, and it stands for *Genetic, Insulin Resistance, Glucose control, Uric acid, Lipid triad, Obesity, Cigarette, Hypertension, Inactivity, Platelet hyperaggregation, Stress, Sex, Age, Fibrinogen, Factor VIIIc & VII, Free Radicals, Alcohol, Race, Inhibitors, Left Ventricular Hypertrophy, Platelet Activating Factors, Androgen, Cytokines, Corticosteroid, Catecholamines, Growth hormone, and Estrogen.* These 27 risk factors might constitute a coronary risk syndrome that could be called "Metabolic Cardiovascular Syndrome". ***Objective:*** To determine the independent risk factors, which have dominant contribution to the development of macro and microangiopathy (Diabetic Angiopathy=DA) in NIDDM. ***Patients and Methods:*** one hundred and twenty five NIDDM patients with DA and 125 NIDDM without DA were recruited for case control study. Multiple logistic regression analysis were used to determine the dominant and significant risk factors for DA. ***Results:*** The dominant factor that significantly contribute to the development of DA was Lipid Triad (OR:3.7 95% CI:1.9-7.3), followed respectively by Age (OR:3.4 95% CI:1.3-8.4),Genetic (OR:3.3 95% CI:1.3-7.8),Platelet Hyperaggregation (OR:2.6 95% CI:1.4-4.9),Hypertension (OR:2.4 95% CI:1.2-5.1),Hyperuricemia (OR:2.1 95% CI: 1.0-4.0), and Insulin Resistance (OR:2.0 95% CI:1.0-4.0). Factor analysis revealed joint effect of Lipid Triad, Age, and Inactivity increased the risk of DA (OR:10.0 95% CI: 1.2-81.0). ***Conclusion:*** Lipid Triad abnormalities was the most dominant independent risk factor for the development of DA.

1755

GLYCEMIC CONTROL AND CARDIOVASCULAR RISK FACTORS IN NIDDM ATTENDED IN PRIMARY CARE: A MULTICENTRIC STUDY

P.Roura, A.Muñoz, E. Hernandez, JF. Cano, C. Iglesias, M. Mata and the GedapS Group.Catalan Family and Community Medicine Society. Barcelona (Spain).

Aims: To assess glycemic control and cardiovascular risk factors (Total cholesterol, blood pressure, obesity and smoking) in NIDDM patients attended in Primary Health Centres (PHC) before an intervention programme. **Methods:** Cross-sectional study carried out in 1993-94 in 76 PHC (34.1% rural, 65.9 urban), by systematic sampling from 31.050 registered NIDDM and a total of 875.571 adult clinical records. The targets for control were the same used by the European NIDDM Policy Group. **Results:** The final sample included 2595 NIDDM patients (43.9% male). The mean age was 66,6 +/-10 years and the average evolution time was 8.1+/-5.9 years. Glycosilated Hemoglobin was registered in 73 % of patients, Total Cholesterol in 78 %, Blood Pressure in 95%, BMI in78%, and interrogated smoking in 92% of patients. There was a good/acceptable glycemic control in 50% of patients. Total cholesterol was lower than 250 mg/dl. in 72% and blood Pressure showed a bad control in 40% of patients. BMI was lower than 30 in 63% of cases. Smoking was present in a 13%, raising the prevalence to 29% in men and up to 42.4% in men younger than 60. There were 26.1% of patients younger than sixty with three or more cardiovascular risk factors with a poor control . This percentage was 15.6% in the patients older than sixty. There were no differences between genders. **Conclusions:** There was a acceptable glycemic control in more than a half of the diabetic patients, and the percentage of patients with acceptable cholesterol was satisfactory. The Blood Pressure control, presence of smoking and rate of patients with three or more risk factors with a bad control (specially those younger than sixty) can be widely improved.

1756

DIABETES COMPLICATIONS AND CARDIOVASCULAR RISK FACTORS IN A REPRESENTATIVE POPULATION SAMPLE OF DIABETES SUFFERERS

Phillips P, Wilson D, Beibly J, Taylor A.
The Queen Elizabeth Hopsital & South Australian Health Commission.

A sample of adults (n = 191), aged 40 years or older, with non-insulin dependent diabetes were recruited to the South Australian Diabetes Study from a representative popultion health interview survey. They were assessed for macro and micro-vasculr complications using well documented medical criteria and tests. 63 percent were found to have at least one micro-vascular problem and 62 percent at least one micro-vascular problem, despite the fact that the mean fasting HbA_{1c} level was 7.8 percent. The prevalence of macro-vascular disease was similar in both males and females however significantly more males suffered a micro-vascular problem ($p=0.04$). 52 Percent of the sample were hypertensive, 76 percent obese, 16 percent had elevated cholesterol and 15 percent were smokers. The prevalence of these risk factors was little changed according to the presence of diabetes complications.

Interestingly, this study also showed that the frequency of advice given by doctors about cardiovascular risk factors increased when complications were present. Patient rating of general practitioner advice was good, however, these results suggests that more education/intervention on cardiovascular risk factors can be done at an earlier stage of diabetes.

1757

HYPERTENSION, HYPERINSULINAEMIA AND OBESITY IN ADULT FINNS

Q.Qiao, S.-L.Kivelä and S.Keinänen-Kiukaanniemi. Department of Public Health Science and General Practice, University of Oulu, Unit of General Practice, Oulu University Hospital, Oulu, Finland

The aim of the study is to analyse the data obtained from a 2-year follow-up study of the middle-aged Finnish subjects (n=183) with a previous history of impaired glucose tolerance (IGT) in order to elucidate the longitudinal relationship between hypertension, fasting hyperinsulinaemia and obesity. Hypertension was defined as either systolic blood pressure ≥ 160 mmHg or diastolic blood pressure ≥ 95 mmHg or being on antihypertensive drug treatment regardless of the blood pressure value. Multiple logistic regression analyses shows that the odds ratios of elevated fasting insulin concentration at baseline were 1.14 (95% confidence interval 1.02-1.28) and 1.22 (95% confidence interval 1.01-1.47), respectively, for the prevalence and for the 2-year incidence of hypertension in subjects with IGT at baseline but reverting to normal glucose tolerance at follow-up. The association was independent of body mass index at baseline and weight gain during the two years. Body mass index and weight gain were not independently associated with the development of hypertension, but were the independent risk predictors for fasting hyperinsulinaemia (≥ 13 mU/l) at follow-up. The odds ratio of weight gain was 1.43 (95% confidence interval 1.03-1.98) for hyperinsulinaemia in lean (body mass index < 27 kg/m^2) and normoglycaemic subjects. It is concluded that elevated fasting insulin concentration preceded the onset of hypertension independent of body mass index and glucose intolerance, and may be a link between hypertension and obesity.

HYPERINSULINEMIA AND DYSLIPIDEMIA IN PATIENTS WITH PERIPHERAL VASCULAR DISEASE

H-D.KLIMM& and S.JACOB*. &Dpt.General Medicine, University of Heidelberg, *Dpt Endocrinology, Eberhard-Karls-University, Tübingen, Germany

In the pathogenesis of cardiovascular (cv) disease, the metabolic syndrome (MS) seems to play an important role. While epidemiological studies have identified hyperinsulinemia (HI) as a risk factor for coronary heart disease, there are virtually no studies looking at the association between peripheral vascular disease (pVD) and the MS. We investigated 59 elderly patients (mean age 69,4 years) with different degrees of peripheral arteriosclerosis as indicated by the tibio-brachial doppler-index (DI). According to DI, 3 subgroups were formed: while a DI>1,0 indicates no pathology (=Healthy), a 1,0>DI<0,8 suggests macroangiopathy (=at Risk) and DI <0,8 denotes marked pVD (=pVD). In all participants an oral glucose tolerance test (100g) with measurement of insulin levels was performed. Also, lipid profiles were determined in the fasted state. Glc and Ins sums were calculated by adding the values of the different time points (0+ 30+60 +120min). All groups were comparable in age, body-mass-index, waist-to hip-ratio and Total-Cholesterol.

	Sys.BP	Chol	LDL	HDL	TG	Glc-Sum	Ins-Sum
H	153±4.3	227±6.2	142±7.6	61±2.6	137±14	565±32	248±32
R	150±5.8	235±8.8	145±7.2	50±3.6*	172±22	581±29	317±47*
pVD	173±5.4*	247±9.4	163±8.8*	51±3.2*	192±31	586±20	324±44*

Although glc tolerance was similar in all groups, ins levels were 30% higher in R and pVD (*p<0,05, Wilcoxon), indicating that insulin resistance is compensated by HI. R and pVD also showed lower HDL and higher triglycerides (TG). LDL was elevated in pVD. Patients with pVD and those at risk display the cv risk pattern found in MS with dyslipidemia and HI. Therefore, in both groups intensive intervention, aimed at improving insulin sensitivity, will also improve atherogenic risk profile, as has already been shown in coronary heart disease.

CHARACTERISTICS OF METABOLIC X-SYNDROME IN NIDDM PATIENTS IN PRIMARY HEALTH CARE IN HUNGARY

K. Farkas, E. Noll and G. Jermendy. Bajcsy-Zsilinszky Hospital, Budapest, Hungary.

In order to evaluate the characteristics of x-syndrome a screening procedure was carried out in NIDDM patients registered within primary health care. Using clinical classification a total of 804 NIDDM patients was identified from 20 affiliated GPs within Budapest. A coexisting history of hypertension was found in 571 (71.0%) patients. Abnormal body mass index (>27 kg/m^2 in men, >26 kg/m^2 in women) values were recorded in 520 (64.7%) patients. Abnormal casual systolic (>160 mmHg) and diastolic (>95 mmHg) blood pressure was found in 292 (36.3%) and 140 (17.4%) patients, respectively. Elevated serum total cholesterol (>6.5 mmol/l) and triglycerides (>2.2 mmol/l) were observed in 212 (26.4%) and 325 (40.4%) patients, respectively. Abnormal values of HDL-cholesterol (<0.90 mmol/l) were documented in 102 (12.7%) patients. The waist-hip ratio was abnormal (>1.0) in 105 (13.1%) patients. Clustering of abnormal clinical and laboratory findings was found to be more prominent with women than with men. Within this study the frequency of microalbuminuria was 25.0 % while that of macroalbuminuria was 8.6% with a significant male predominance. More appropriate treatment should be provided at the primary health care level to decrease the risk of macrovascular complications in NIDDM patients with clustering of components of metabolic x-syndrome in Hungary.

1761

INCREASED INSULIN SECRETION AND SYMPATHETIC ACTIVITY IN NORMAL GLUCOSE TOLERANCE OFFSPRINGS OF TYPE II DIABETICS.

S. Frontoni, #S. Farrace, A. Caselli, *A. Barini, M. Pellegrinotti, #C. De Angelis, and S. Gambardella - Diabetology, University "Tor Vergata"; #D.A.S.R.S. Medicine, Pratica di Mare; *Biochemistry, UCSC, Rome, Italy.

Recent papers have shown that first degree relatives of patients with type II diabetes (NIDDM) display insulin resistance, although with normal tolerance. This observation raises the possibility that some of the typical metabolic and/or hemodynamic abnormalities of NIDDM may already be present in such subjects. The aim of our paper was, therefore, to investigate insulin secretion behaviour and its relationship to hemodynamic parameters in offspring of NIDDM with normal glucose tolerance. We studied 9 offspring of NIDDM (P), compared with 18 subjects without family history of diabetes (C), all with normal glucose tolerance. The two groups were comparable for age (C: 24.6±0.9 vs P: 25.1±2.3 years), sex, BMI (C: 23.6±0.5 vs P: 24.3±1.1 kg/m^2). All subjects underwent a 180 min oral glucose (75 g) tolerance test (OGTT). Continuous blood pressure monitoring was performed every 3 min by oscillometric method, throughout the study; a continuous ECG recording (Holter) was performed in order to calculate the heart rate variability, by a fast Fourier algorithm. The derived LF/HF (low/high frequency) ratio is an index of the sympatho-vagal balance. Before glucose ingestion, plasma insulin concentration (IRI) was similar in the two groups. From time 30 min and throughout the study, IRI was significantly increased in P (57±5.7) when compared to C (29.6±4.2 μU/ml), p<0.005. Blood glucose (BG), basally similar in the two groups, was also significantly increased in P (103.1±4.5) vs C (91.6±4.9 mg/dl), p<0.05, from time 120 min on. BG/IRI ratio was reduced in P vs C, thus suggesting the presence of hyperinsulinemia in the group of offspring. Diastolic blood pressure significantly decreased in P, but not in C during the first hour of the study (basal: 72.1±3.9 vs 63±2.8, p<0.002). Finally, LF/HF ratio was significantly increased in P (2.5±0.4 vs C: 1.7±0.2) from time 15 min. In conclusion, offspring of NIDDM with normal glucose tolerance display an increased insulin secretion; however they are not resistant to the hemodynamic effects of insulin, as suggested by the reduction of diastolic blood pressure, probably due to a direct effect of vasodilatation. This, in turn, may determine a chronic sympathetic activation, which could be involved in the pathogenesis of type II diabetes.

1762

CAN SYNDROME X LEAD TO ENLARGEMENT OF VARIOUS VISCERAL ORGANS ?

H.Doğan, M.Yenigün, F.Şar, Y.Altuntaş, Ç.Ordu, L.Ü.Temiz
Haseki State Hospital 4. Internal Medicine Departments, İstanbul, TURKEY.

Syndrom X are characterized by glucose intolerance, obesity, insulin resistance, dislipidemia and hypertension. Insulin is also a growth factor in various tissues to determine whether insulin resistance leads to enlargement of visceral organs, we measured fasting and postglucose 1- hour insulinemia, cholesterol , triglyceride, HDL-cho, LDL-cho, VLDL-cho and the length of liver, spleen and kidneys by ulrasonographic investigations in 30 patients with Syndrome X. (Age:57.3±8.7 yrs., Body mass index: 32±4.4 kg/m², Waist-Hip-Ratio:0.88±0.6) liver and renal function tests are normal in study and healthy groups. Levels of fasting and postglucose 1 - hour insulin were 13.6±6.9 and 64±48 in study group, 8.8±3.6 and 44±28 (IU/ml in healthy group (p<0.05). The length of liver was significantly increased according to healthy subjects in Syndrome X (p<0.001). The length of kidneys were increased insignificantly (p>0.05). The length of spleen was not found different each two groups (p>0.05). Fasting and postglucose insulin levels were not correlated with length of liver and body mass index. The levels of triglyceride was found increased in Syndrome X (p<0.01) but not correlated with the length of liver. As a conclusion the liver is the only organ enlarged in Syndrome X . This enlargement was not result of hepatosteatosis and is not correlated with body mass index and levels of insulin. It is suggested that hyperinsulinemia may stimulate also extra-vascular growth factors in organs. The cause of hepatomegaly may due to growth factors.

1763

HYPERINSULINEMIA AS A RISK FACTOR FOR CORONARY ARTERY DISEASE:
A CASE-CONTROL STUDY IN COLOMBIAN SUBJECTS

O. Alba, A. Calle and J. Navia. Instituto de Seguros Sociales, Clinica Shaio; Bogota DC, Colombia

Insulin Resistance syndrome (IRS) is a novel predictor for coronary Artery Disease (CAD). A case-control study was designed, looking for association in both traditional risk factors and hyperinsulinemia, related to CAD. Inclusion criteria for New incident cases, (n=77): Subjects of both sexes (M/F 60/17; mean age 52.7±9.5 SD, interval 32 to 68 years), with CAD documented by angiography (obstruction > 70% in at least one major epicardial coronary vessel). Exclusion criteria: Presence of NIDDM, secondary hyperlipidemias, disease and drugs with interference on carbohydrate and lipid metabolism (diuretics, β-Blockers, lipid-lowering drugs). Controls healthy subjects (n=74) was chosen at random from outpatient room, (M/F 52/22; mean age 50.7±9.9 SD, interval 32 to 74 years); without NIDDM nor CAD, with normal Thorax X-rays, normal EKG, normal exercise tolerance and someones (n=7) normal angiography. Information about demographic variables, self-reporting physical activity degree (working and recreational), clinical and familiar background, physical examination, anthropometric variables, fasting plasma lipids concentration, serum uric acid and fasting blood glucose and insulin as well as 30, 60 and 120 minutes postglucose load (75 gr); was available for analysis. All patients were living in Bogota DC City. There was no differences in physical activity degree in Cases vs Controls. Smoke was more prominent in Cases than in Controls. Hyperinsulinemia was defined as a value greater than percentile 75 in normal controls subjects for insulin levels 2 Hs. post-glucose load (30 uUI / mL); as well as a value greater than percentile 75 in normal controls subjects for Homeostasis Model measure (HOMA-IR) (1.50). Mean values ±SD and t-test P values for measured parameters in Cases vs Controls are shown. A Logistic Regression Analysis model (forward stepwise-conditional) for CAD were calculated as we can see in the next table:

Main Predictors for Coronary Artery Disease

Variable	ß (SE)	Odds Ratio (CI 95%)	Sig
Insulin 2hs (> 30 uUI/mL)	2.53 (0.5336)	12.58 (4.39 , 36.86)	0.0000
Smoke	1.86 (0.5229)	6.43 (2.30 , 17.90)	0.0004
Diastolic BP (> 80 mm Hg)	2.13 (0.8719)	8.46 (1.52 , 46.47)	0.0143
HDL-Cholest. (< 45 mg/dL)	1.18 (0.5088)	3.27 (1.20 , 8.82)	0.0197
Glucose 2 Hs (> 140 mg/dL)	1.56 (0.7275)	4.76 (1.14 , 19.80)	0.0319
Variables not in the equation: Sex, BMI (> 25 K/m²), Systolic BP (> 120 mm Hg), Total Cholesterol (>220 mg/dL), Triglycerides (>200 mg/dL), and HOMA-IR (> 1.50).			

We conclude that in subjects without NIDDM, hyperinsulinemia 2hs post glucose load, as well as Impaired Glucose Tolerance have a fundamental role as risks factors for CAD in addition to others known factors such as smoke, diastolic hypertension and HDL-Cholesterol.

1764

Coronary artery disease prevalence in diabetic persons: the effect of socio-economic status.

V. Connolly[a] and CM Kesson[b]. [a]Middlesbrough General Hospital,Ayresome Green Lane, Cleveland, TS5 5AZ. [b]The Victoria Infirmary NHS Trust, Langside Road, Glasgow, G42 9TY

Coronary artery disease (CAD) accounts for approximately 50 % of diabetes related mortality, which is not all accounted for by the major coronary risk factors. In Western countries coronary artery disease is more prevalent in persons of low socio-economic status. We studied the impact of socio-economic status on the prevalence of coronary risk factors and CAD in persons with diabetes. A profile of CAD risk factors was established for 1,553 individuals with diabetes. Socio-economic scores were calculated from four measures of material wealth. The presence of CAD was based on the Rose angina questionnaire, past medical history and resting 12 lead ECG. Smoking was less common in the most affluent group compared to the most deprived 19.9% v. 41.1% respectively ($p<0.001$). The mean body mass index was lower in the most affluent group compared with the most deprived 28.8 $kg.m^{-2}$ v. 30.4 $kg.m^{-2}$ ($p<0.002$). For individuals under 70 years of age the prevalence of CAD in the most affluent group was 17.2 % and in the most deprived group 31.4% (chi squared for linear trend, $p<0.0002$). A multiple logistic regression model was constructed including smoking, obesity, hypertension, hyperlipidaemia and hyperglycaemia. The calculated odds ratio for the prevalence of CAD in the most deprived category relative to the most affluent was 1.72 ($p<0.02$). Coronary artery bypass graft procedures were undertaken more commonly in the most affluent group 19.2% compared to the most deprived 7.4% ($p<0.03$). CAD is more common among persons with diabetes of low socio-economic status after accounting for major risk factors.

1765

The Level of Serum Insulin in Japanease Coronary Artery Disease.

S.Tomono, S.Kawazu.T.Ohno, T.Utsugi, N.Kato, Y.Itoh, Y.Ohyama, T.Uchiyama and R.Nagai Gunma, Japan

In 224 patients with coronary artery disease(CAD:183 males and 41 females, 34-72 years old) who underwent coronary angiography, plasma glucose(PG) and insulin(IRI) were concomitantly measured at 75g OGTT. Subjects were divided into three groups as follows: normal(Nor;36 cases), impaired glucose tolerance(IGT;136 cases) and NIDDM(52 cases) groups. Furthermore, NIDDM was divided into two groups: 34 patients who were newly diagnosed by OGTT (ND-DM) and 18 patients who were already established (known DM). The severity of coronary atherosclerosis was evaluated as a coronary index(CI), calculated according to Balcon's method. Although, there were no differences both of age and body mass index, serum fasting IRI(FIRI), ΣIRI(0,30,60,120 min), triglyceride and systolic blood pressure became higher acording to the severity of glucose intolerance. That is to say, fasting IRI were 5.4±3.8 μm/mℓ in Nor, 6.5±4.6 μm/mℓin IGT, 7.6±6.4 μm/mℓ in ND-DM and 6.2±6.4 μm/mℓ in known DM. ΣIRI were 124.1±80.7 μm/mℓ, 184.9±112.5 μm/mℓ, 155.3 ±74.7 μm/mℓ, 90.9±80.7 μm/mℓ, triglyceride were 141.2±65.5 mg /dℓ, 151.8±66.4 mg/dℓ, 161.8±63.0 mg/dℓ, and systolic blood pressure were 123±17 mmHg, 128±17 mmHg, 133±22 mmHg, respectively. However, HDL cholesterol showed no differences among them. In ND-DM, FIRI and ΣIRI were highest but they decreased in known DM. In the former three groups whose insulinogenic index(ΔIRI/ΔPG from 0 up to 30 min) was ≧0.4, the severity of CAD was significantly correlated to fasting IRI. We conclude that X syndrome could be seen in Japanese CAD.

1766

FREQUENCY, CARACTERISTICS AND EVOLUTION OF HYPERTENSION IN DIABETIC PATIENTS

S. BLOUZA, A. ABID , W HAMDI, I KHEDER and K. NAGATI
NATIONAL INSTITUTE OF NUTRITION
TUNIS TUNISIA

The aim of this prospective study concerned 318 diabetics observed during 1993-1994 is to evaluate the frequency, caracteristics and evolution of the highblood pressure (HBP) in diabetic patients. The results show that the frequency of the HBP is 23 % predominant in female patients (15,5 % VS 7,5 %). HBPis hyghly common with NIDDM 73,2 %, insulinotherapie require in 30 % Diabetes duration is 7,8 ± 5,8 ys. HBP is common at the same time with diabetics in 7,8 % of patients, before it in 3,6 % and after diabetes onset in 67,8 % in the majority it's a systolic high blood pressure. The mean systolic presssure is 151 ± 2,3 and the mean diastolic is 80 ± 3,2 mmHg.

1767

CORONARY HEART DISEASE (CHD) RISK FACTORS IN PERSONS WITH ENDOGENOUS HYPERINSULINAEMIA

Lj. Bajović, A. Đukić, M.Vučkoviić, S.Metiljević, M.Jovanović, M.Miloradović-Dpt. of endocrinology, Medical Faculty Kragujevac

The major goal of the research was finding out the risk factors frequency for obtaining CHD. The research enclosed 21 subject with endogenous hyperinsulinism (HI) according following criterion: Diabetes mellitus type II positive family history in the first and second degree relatives and exclude the presence of CHD (negative ergo-test). According to the insulinaemia movements during OGTT, subject with HI were registred (Group A), as well as subjects without HI (Group B). Next, each subject was exposed to the number of anthropological and biochemical examination, and the results were compared among itself, as well as against entire population. The results emphasize the importance of the following factors: android type of obesity (increased waist to hip ratio) (Group A vs B:0.90+/-0.04 vs 0.86 +/- 0.12; $p<0.01$); impaired glucose tolerance (Glicaemia 120 minute: Group A vs B: 8.24+/-1.33 vs 6.4+/-1.38mmol/l, $p<0.01$); diastolic arterial tension (Group A vs B: 92+/-10 vs 83+/-13 mmHg, $p<0.05$), atheroidic lipid profile- low HDL-cholesterole and high triglyceride ($p<0.05$) and acidum uricum (Group A vs B: 353+/-77 vs 309+/-76 nmol/l, $p<0.05$). It was concluded that persons with HI (Group A) had significaly more risk factors for CHD compared with Group B.

1768

Risk for death from cardiovascular diseases among Arab diabetic patients in the United Arab Emirates

O.Siitonen and E. Timgren, Ministry of Health, Tawam Hospital
Al Ain, United Arab Emirates

We studied the prevalence of cardiovascular diseases and mortality in diabetic and in non-diabetic subjects using medical records of expired patients from 1993 - 1996 in Tawam Hospital run by Ministry of Health.The diagnoses were based on previous history, medication, laboratory findings and ECG-changes.Altogether 734 charts were examined.Only nationals of Arab origin aged 15 yrs or more from the UAE,Oman,Yemen and Saudi-Arabia were included.The final study population comprised 260 men and 153 women.Of men 65 (26.0 %) and of women 54 (35.3%) were diabetic.Of diabetic patients 37 men (56.9%) and 36 women (66.6%),and of non-diabetic patients 37 (20.0%) men and 16 (16.8%) women died from a cardiovascular vascular disease.The risk for cardiovascular death was 2.8 fold for diabetic men and 3.9 fold for diabetic women.In diabetic subjects cerebrovascular disease was found in 18 (27.7%) men and in 18 (33.3%) women,and in non-diabetic subjetcs in 20 (10.8%) men and in 8 (8.4%) women.In diabetic subjects coronary heart disease was found in 34 (52.3%) men and in 31 (57%) women and in non-diabetic subjects in 40 (21.6%) men and 14 (14.7%) women.In diabetic subjects myocardial infarction was diagnosed in 19 (29.2%) men and in 16 (29.6%) women, and in non-diabetic subjects in 22 (11.9%) men and in 5 (5.3%) women.In diabetic subjects gangrene/amputation was diagnosed in 7 (10.8%) men and in 3 (5.5%) women,and in non-diabetic subjects in 9 (4.9%) men but in none of non-diabetic women.

1769

ESTIMATES OF INSULIN SENSITIVITY AND BETA-CELL MASS AS PREDICTORS OF CARDIOVASCULAR DISEASE IN ELDERLY MEN

E.J.M. Feskens and D. Kromhout, National Institute of Public Health and the Environment, Bilthoven, the Netherlands

The role of hyperinsulinaemia and insulin resistance as independent risk factors for cardiovascular disease remains debated. We previously reported that the prevalence of coronary heart disease is highest in subjects with the highest fasting insulin levels. These results were derived from data assembled in 1990 on a cohort of men born between 1900-1920. Recently the morbidity and mortality follow-up of the cohort was completed and associations with estimates of insulin sensitivity (IS) and beta-cell mass (BCM) as assessed by the HOMA-model (made available by prof. Turner, Oxford, calculations based on fasting glucose and C-peptide) were determined. Men with known diabetes were excluded from the analyses, leaving 446 subjects. Eleven percent of the men had impaired glucose tolerance and 9% had newly diagnosed diabetes. IS and BCM were inversely correlated (r=-0.58). In addition, BCM was significantly positively correlated with body mass index, fasting triglycerides, resting heart rate, serum creatinine, and inversely correlated with HDL-cholesterol. IS was positively correlated with HDL-cholesterol, and inversely associated with body mass index, triglycerides, systolic blood pressure, resting heart rate, and serum creatinine. During follow-up 106 men died, of which 55 had a cardiovascular cause of death. CVD mortality was elevated in men with IS below the median (16.2% versus 9.0%, p=0.02). Regarding BCM, CVD mortality was highest in men with levels above the median (17.4% versus 7.7%, p=0.002). After adjustment for age, other risk factors and the presence of CVD at baseline, the effects of IS (RR=0.54, 95% CI 0.30-0.98) and BCM (RR=2.26, 95% CI 1.25-4.07) remained significant. When IS and BCM were combined in one model, the effect of BCM was the strongest. The highest CVD mortality was seen in men with low IS and high BCM. These results indicate that hyperinsulinaemia is an independent risk factor for CVD and supports the hypothesis that the insulin resistance syndrome plays a role in the etiology of cardiovascular disease.

1770

COMPARATIVE EPIDEMIOLOGY OF ACUTE MYOCARDIAL INFARCTION IN DEFINED GENERAL AND DIABETIC POPULATIONS.

Z. Szczeklik-Kumala and J. Tatoń. Department of Internal Medicine and Diabetology, Warsaw Medical School, Warsaw, Poland.

The study was aimed at epidemiological, comparative assessment of the incidence and mortality due to acute myocardial infarction (AMI) in the strictly demographically defined, natural population of the District of Bródno (Warsaw) in the period between 1993 and 1995 (3 years). The incidence of AMI in general population under study was in average 0,4% that is 335 cases. Among them were 66 cases of AMI in diabetic persons. Since the total number of diabetics living in the District of Bródno (Warsaw) was 2320 the incidence of AMI characterizing diabetics was 2,8% that is 7 times more than in general population from the same enviromental conditions. The general hospital mortality due to AMI related to the general population was 21% (72 cases) and in the diabetic group 41% (27 cases), that is 1,9 times higher. The mortality in diabetic women (49%) was higher than in diabetic men (30%). These comparative observations are analysed in the relation to the structure of the AMI symptoms at clinical presentation, additional, cardiovascular morbidity in both groups and chronic vascular complications in the diabetic groups. The group of AMI patients without diabetes mellitus was characterised by lower incidence of heart and conductivity disturbances and by lower morbidity due to involvment of other arterial system beside the coronary. Conclusion: results point to the very high risk of total AMI in diabetics living in the same defined enviroment in spite of decreasing indexes of AMI incidence and mortality for general population. It shows the necessity of separate for diabetics, more active preventive and therapeutic programs. The results obtained in the study may be applied as the base for such development in different localities and defined population.

1771

IMPORTANCE OF CARDIOVASCULAR RISK ASSESSMENT IN DIABETES CARE

A. Cerghizan, N. Hâncu, D. Negreanu, M. Popitan and A. Săveanu - Diabetes Center & Clinic Cluj-Napoca, Romania

One of the main objective of the St. Vincent Declaration is to reduce morbidity and mortality from coronary heart disease (CHD) in the diabetic by risk factor reduction. **Objective :** To assess the global cardiovascular risk status (CVRS) in diabetes mellitus (DM) with a method that could be further recommended for practical purposes. **Method :** In 1994, European Task Forces on prevention of coronary heart disease have proposed a chart that can predict risk level % change of coronary events in the next 10 years. In order to be more useful in diabetes mellitus we added other parameters: body mass index, waist/hip ratio, HDL-cholesterol, triglycerides, retinopathy, microalbuminuria, personal and family history of CHD. This new chart has been called Eurochart '94.**Patients :** We have applied this Eurochart '94 in 949 NIDDM subjects, 341 IDDM subjects and 1082 control subjects. **Results :** CVRS score (%) has been greater in NIDDM insulin treated group (21.07±1.1) and NIDDM non insulin treated group (19.9±0.6) than in IDDM group (10.8±0.6) and control group (6.1±0.3). CVRS has been strong correlated with age (8.03±0.3 if age≤40 yrs and 17.22±0.4 if age > 40 yrs) and with diabetes duration (18.5±0.5 at onset and 23.8±0.59 after more than 10 yrs duration of diabetes). All the differences we found are statistically significant. **Conclusions** The assessment of CVRS is mandatory in prevention of CHD in DM. The Eurochart '94 is a useful and accessible tool, which can be recommended for all those involved in diabetes care.

1772

ASIAN INDIAN WOMEN WITH DIABETES ARE MORE PRONE FOR CEREBROVASCULAR DISEASE.

P.V. Rao, R. Sahay, A.K. Prasad and Shantaram V.
Nizam's Institute of Medical Sciences, Hyderabad, India.

Indian Council of Medical Research (ICMR) study of diabetes morbidity between 1984 and 1990 on 4637 subjects (M 2783, F 1854) with NIDDM from 9 teaching hospitals examined by standardized methodology, reported that while coronary artery disease (M 8.91, F 5.11 %), peripheral vascular disease (M 0.72, F 0.37%), nephropathy (M 15.42, F 13.27%) and retinopathy (M 16.25, 14.29%) were more frequent in men, cerebrovascular disease (M 1.63, F 1.75%) was ascertained in more women. To identify gender differences in diabetic vasculopathy at death, consecutive death records of 453 subjects (M 292, F 161) diagnosed as diabetic between 35 and 64 years age (type 2) and treated at a large University Hospital in South India were studied. Predominant morbidity factors (and prevalence %) at death in these diabetics were coronary heart disease (M 45.2, F 42.9%), nephropathy (M 37.0, F 30.4%), infections (M 30.8, F 34.2%), cerebral vessel disease (M 27.7, F 30.4%), ketosis (M 6.5, F 12.4%), neoplasms (M 4.8, F 6.8%) and cirrhosis (M 5.5, F 3.1%). The unpublished ICMR study on diabetes morbidity and the mortality data as presented here, suggest that Asian Indian women with diabetes (NIDDM, type 2) are more prone for cerebrovascular disease.

1773

RISK FACTORS AND CHRONIC COMPLICATIONS IN NON-INSULIN DEPENDENT DIABETES MELLITUS (NIDDM)

P. Ruggenenti, V. Gambara, I. Nosari, A. Perna, and G. Remuzzi
Mario Negri Institute for Pharmacological Research, Bergamo (Italy) and "Bergamo Diabetic Nephropathy Study Group"

Our study was aimed at investigating the relation between risk factors and long term complications in NIDDM. Analysis included 3364 patients with NIDDM (and 159 insulin dependent diabetics as controls). History, demographic and clinical data, mean arterial pressure (MAP), urinary albumin concentration in spot morning urines, HbA1c and body mass index (BMI) were recorded. Micro- and macro-albuminuria were defined as spot morning urine albumin concentration 20-200 μg/ml and >200 μg/ml, respectively. Retinopathy, neuropathy, ischemic heart disease (IHD), and peripheral artery disease (PAD) were diagnosed by standard procedures. Results of multivariate correlations between risk factors and complications in NIDDM patients are in the table.

	Micro	Macro	IHD	PAD	Retinopathy	Neuropathy
Prevalence (%)	24.6	14.4	19.8	20.5	20.5	12.1
Age	N.S.	N.S.	**0.0001**	**0.0009**	N.S.	N.S.
Sex	N.S.	**0.003**	N.S.	**0.0003**	N.S.	N.S.
Diabetes duration	**0.03**	**0.0001**	**0.002**	**0.0003**	**0.0001**	**0.0004**
Hypertension duration	N.S.	**0.01**	**0.0001**	**0.003**	N.S.	N.S.
HbA1c	**0.002**	**0.0001**	N.S.	N.S.	N.S.	N.S.
Mean arterial pressure	N.S.	**0.0008**	N.S.	N.S.	**0.01**	N.S.
Body mass index	**0.02**	**0.004**	**0.05**	N.S.	N.S.	**0.02**

N.S.: not significant, Micro: microalbuminuria; Macro: macroalbuminuria.

Retinopathy was the only complication associated with the type of diabetes (higher prevalence in IDDM). Albuminuria and retinopathy were associated with enhanced risk for all the other complications. Albuminuria and fundus evaluations may help identifying NIDDM patients at risk of renal and extra-renal complications in large population surveys.

1774

PREVALENCE OF ISCHAEMIC HEART DISEASE & PERIPHERAL VASCULAR DISEASE IN AN URBAN SOUTH INDIAN POPULATION

Mohan V, Premalatha G, Revathi S, Padma A, Shanthi CS, M.V.Diabetes Specialities Centre and Madras Diabetes Research Foundation, Madras, India.

In migrant Asian Indians high prevalence rates of ischaemic heart disease (IHD) have been recorded. There are few data from the Indian sub-continent and particularly from South India. The prevalence of ischaemic heart disease (IHD) and peripheral vascular disease (PVD) in Madras city was assessed by a house to house survey. A total of 613 individuals were tested which included 144 diabetics (DM), 98 with Impaired Glucose Tolerance (IGT) and 371 with Normal Glucose Tolerance (NGT). Rose angina questionaire was used for IHD and the WHO Multinational Study questionaire for PVD. Resting 12 lead ECGs were done and coded using Minnesota Coding system. Peripheral vascular doppler studies were done and an Ankle/Brachial index was <0.8 considered diagnostic of PVD. 42/144 with DM (29.1%), 13/98 with IGT (13.2%) and 28/371 (7.5%) with NGT had angina. Using ECG criteria, 125/613 (20.3%) had evidence of IHD The prevalence of PVD was low - overall 1.4% (9/613) and among diabetics 2.1% (3/144). The reasons for the discordance between prevalence rates of IHD and PVD in S.Indians merits further study.

1775

HYPERCHOLESTEROLEMIA AND CORONARY HEART DISEASE RISK STATUS IN DIABETIC PATIENTS FROM ROMANIA

D. Dabelea, G. Bacanu, D. Motiu, N. Voian and C. Vernic, University of Medicine and Pharmacy, Timisoara, Romania.

The prevalence of hypercholesterolemia, according to the National Cholesterol Education Program has been determined in 866 diabetic patients and 900 people without diabetes. Rates of elevated total and LDL cholesterol in persons with diabetes are greater than in those without diabetes, after adjusting for age and sex (39.83% vs. 27.55% and 33.14% vs. 29.33%, respectivelly). Moreover, the prevalence of all coronary heart disease (CHD) risk factors (except smoking) is significantly higher in diabetes. As far as 37.99% of diabetic patients and only 9.11% in the general population are at highest risk for future CHD events because of prior CHD or other atherosclerotic diseases. A high risk because of hypercholesterolemia together with at least 2 other CHD risk factors is present in 16.57% of diabetic subjects and 3.78% of non-diabetic people. No more than 2.28% of diabetic patients as compared to 17.11% of people without diabetes have a low risk because of high blood cholesterol but less than 2 other risk factors. Overall, CHD risk status is twice as much in diabetes (56.84%) as compared to the general population (30%).

1776

REMNANT LIPOPROTEIN AND MACROVASCULAR DISEASE IN DIABETIC PATIENTS

Toru Hiyoshi, Fumito Akasu , Michiyasu Yoshitsugu.
Japanese Red Cross Medical Center, Tokyo Japan

OBJECTIVE - Several reports suggested that remnant like lipoproteins (RLP) can promote atherogenesis. Recently, a new method has been developed to measure these lipoproteins. The aim of this study is to evaluate diagnostic advantage of RLP as a clinical marker of atherosclerosis in diabetic patients.
METHODS - 144 NIDDM patients (Male 77, Female 67) were measured carotid intima-media thickness (IMT) by B-mode ultrasonogram (SSA-270A, TOSHIBA Co.). Also we measured serum RLP-cholesterol (RLPc) by immunoseparation method using monoclonal anti-apoA1and anti-apoB (JIMRO Co.). Patients were divided in three groups according to their RLPc level and analyzed for glycemic control, average IMT and clinical events of macrovascular disease (i.e. cerebral vascular disease (CVD), coronary heart disease (CHD) and peripheral vascular disease (PVD)).
RESULTS - 48 patients as Group L (RLPc<2.5mg/dl) , 77 patients as Group N(2.5≦RLPc≦7.5) and Group H (RLPc>7.5) 19 were divided. Incidence of the macrovascular diseases (CVD/CHD/PVD) were as below. Group L 6.3%(1/1/1), Group N 16.9% (7/6/0), Group H 36.8% (1/5/1). Significantly higher incidence of macrovascular diseases was shown in the group of high RLPc (Average 16.7 ± 10.6mg/dl).
No significant differences of carotid IMT revealed in these 3 groups. Although IMT of the 23 cases which has macrovascular disease revealed greater than 121 non-macrovascular cases.
DISCUSSION - Assay for remnant lipoproteins could become an additional marker for high risk group screening of macrovascular disease in diabetic patients.

Macrovascular Disease and Atherosclerosis – Clinical Picture

1777

THE INFLUENCE OF INSULIN RESISTANCE ON CAROTID ARTERIAL WALL THICKNESS IN JAPANESE NIDDM PATIENTS.

H. Bessho[1], K. Ueda[2], R. Anaguchi[2], M. Arako[2], T. Kohnami[2], G. Matsumoto[2], T. Sanke[2] and K. Nanjo[2] *[1]Dept of Med, Kansai College of Oriental Medicine, Osaka, Japan; [2]Dept of Med, Wakayama Univ, Wakayama, Japan*

Insulin resistance and its associated compensatory hyperinsulinemia are considered to be etiologically related to the onset of NIDDM and diabetic pathophysiological states such as hypertension, obesity and atherosclerosis. The present study was designed to investigate the relationship between carotid arterial wall thickness measured ultrasonically and the degree of insulin resistance measured by the minimal model analysis in Japanese NIDDM patients.

We demonstrate that the advance of carotid arterial wall thickness (intimal plus medial thickness; IMT) of NIDDM patients was intense compared to that of non-diabetic group. Furthermore, negative correlation was significantly recognized between ΔIMT (progression of IMT per year) and SI (insulin sensitivity index) ($r=-0.489$, $p<0.05$). The systolic blood pressure in patients with highly advanced IMT was significantly ($p<0.05$) elevated than that in patients with low advanced IMT (141±3 vs 130±3 mmHg). These results suggest that the advance of IMT is influenced by the degree of insulin resistance. The improvement of not only hypertension but also insulin resistance are necessary for the protection of the advance in IMT.

1778

EARLY CARDIAC STRUCTURAL AND FUNCTIONAL ALTERATIONS IN IDDM

F. Paleari, S. Carugo, M. Failla, P. Gamba, A. Piperno, M. Pozzi, G. Mauri, R. Busnelli, L. Scandola, A. Grappiolo, C. Giannattasio and G. Mancia. Div.ne Medicina Generale 1ª, Cattedra di Medicina Interna, Università di Milano e Ospedale S. Gerardo di Monza. Istituto di Fisiologia Clinica e Ipertensione, Centro Auxologico Italiano, Milano, Italy.

IDDM is a major risk factor for congestive heart failure and ischemic heart disease. How early abnormalities of cardiac structure and function appear in the course of this condition in not yet clear, however. We have studied 60 normotensive IDDM patients (age 32 ± 1, duration of diabetes 11 ± 1 ys, means ± SE) with no clinical evidence of diabetic complications, and 61 age- and sex-matched healthy subjects (C). At the echocardiographic evaluation Left Ventricular Mass Index was similar in IDDM and C (107 ± 4 and 106 ± 3 g/m^2 in IDDM and C respectively) while the relative wall thickness (H/R = SWTd +LVPWTd / LVEDD) ratio (0.41 ± 0.08 and 0.37 ± 0.08) and the E/A (Doppler Mitral Flow peak E/A) ratio (1.3 ± 0.05 and 1.5 ± 0.05) were respectively greater and lower in the former than in the latter group ($p < 0.01$). All echocardiographic values were only slightly more abnormal in a third group of 40 IDDM patients with retinopathy or microalbuminuria (age 34 ± 2, duration of diabetes 15 ± 1 ys). Thus in uncomplicated IDDM patients there is already evidence of ventricular remodeling and abnormalities in diastolic function as in complicated IDDM patients. This suggests that alterations in cardiac structure and function are an early phenomenon in IDDM.

1779

RELATIONSHIP BETWEEN CAROTID ARTERIAL WALL THICKNESS AND INSULIN RESISTANCE IN NIDDM

T. Watarai, M. Ikeda, H. Matsushima, M. Kodama, M Kishimoto, M. Kubota, Y. Yamasaki, and M. Hori. Osaka University School of Medicine, Osaka, Japan

To investigate whether insulin resistance play a major role in the pathogenesis of diabetic macroangiopathy, we measured IMT (the intimal medial thickness of carotid arteries measured with ultrasound high-resolution B-mode imaging) as the index of atherosclerosis and evaluated its correlation with both insulin resistance of peripheral and splanchnic tissues in 53 NIDDM patients (36 males and 17 females, 53 ± 10 years old, duration of diabetes 11.4 ± 7.5 years, and average BMI 22.9 ± 3.2). Patients were divided to the three groups according to the grade of their leisure-time physical activity by the questionnaire. GIR (average glucose infusion rate) calculated from euglycemic hyperinsulinemic clamp was used as index of insulin resistance of peripheral tissue. Following to the glucose clamp as above, oral glucose was taken under the continuation of the clamp to measure HGU (hepatic glucose uptake) as index of insulin resistance in liver. GIR ($r=-0.32$, $p<0.05$) but not HGU ($r=0.139$) is significantly inversely related with IMT. Stepwise multi-variant analysis revealed that GIR remains as an independent risk factor for IMT (F value 3.6) following age, total cholesterol, and diastolic blood pressure (F value 19.0, 17.2, 7.4 respectively). On the other hand, FBS and HbA1c, the index of diabetes control, did not show statistically significant F value. According to the degree of habitual exercise, GIR was increased from 6.19 ± 1.02 to 6.38 ± 1.38 to 7.44 ± 1.80 mg/kg/min, in low, moderate and high active group, respectively, while IMT was decreased from 1.34 ± 0 33 to 1.20 ± 0.31 to 1.12 ± 0.29 mm respectively, in male NIDDM. These data suggest that insulin resistance in peripheral tissue per se is one of independent risk factors of carotid atherosclerosis and habitual exercise might reduce insulin resistance leading to attenuation of atherosclerosis.

1780

DIABETES AND MACROVASCULAR COMPLICATIONS. ODD RATIO FROM HOSPITAL DISCHARGE AS POPULATION INDICATORS.

Chávez-Domínguez. Rafael, Juárez-Herrera Ursulo and Ochoa Ceres. National Institute of Cardiology, México. MEXICO

It is well known that diabetes mellitus and macrovascular diseases have strong association; also that the selection bias introduced on admission to a highly specialized cardiovascular center might alter the association as expected from community. The aim of the study was to measure the magnitude of association at hospital discharge with recent data and see whether it could be used as change indicators for surveillance. It is assumed that optimal metabolic control of individuals decrease complications on the population and hospital information should follow the change. Method: information was obtained from 35,269 cases (2,970 deaths) from 1987 to 1995 on a discharge registry. Rates and proportions were calculated, stratification analysis was made among persons with diabetes (3,670) and non-diabetic (31,599). The coexistent diseases taken as macrovascular complications were: acute myocardial infarction (AMI) 4,223, ischemic heart disease (IHD) 12,458 or hypertension (HT) 6,878. Diseases taken as control for possible confounding variable interaction were drawn from 20-59 years old congenital heart disease (C) and rheumatic heart disease (R). As morbidity in male the odd ratio (O.R.) ± 95% Cornfield confidence interval (CI) revealed for AMI= 1.87 (1.66-2.09), IHD= 4.59 (4.1-5.13) and HT= 5.81 (4.04-8.35); in female AMI= 4.63 (3.88-5.51), IHD= 6.15 (5.46-6.95) HT= 4.99 (4.43-5.62). As mortality in male for AMI= 2.35 (1.67-3.27), IHD= 5.47 (3.83-8.12), HT= 5.26 (3.67-7.54); in female AMI= 4.07 (2.82-5.88), IHD= 7.39 (5.09-10.75), HT= 3.19 (2.88-3.54). Selection of 20 to 60 year of age revealed even higher figures, while the O.R. of C and R were below one. Therefore, the association remains and can be measured. The selection bias from hospital admission did not alter the known association. Hence, the indicators might work to asses long-term induced changes on diabetic macrovascular complications of community and to evaluate the impact of community interventions, such as the reinforcement of preventive measures and metabolic control.

1781

The participation of coagulo-fibrinolytic system in the progress of carotid atherosclerosis in subjects with BLDM and DM

M KODAMA, Y. YAMASAKI, K. SAKAMOTO, T. TSUJINO, K. ARAI, T. WATARAI, M. KUBOTA and M. HORI

First Department of Medicine, Osaka University School of Medicine, Osaka, JAPAN

AIM of Study: Whether coagulo-fibrinolytic abnormality observed in diabetics is primary or secondary to diabetic macroangiopathy remains to be clarified. We examined whether coagulo-fibrinolytic abnormality is responsible to diabetes itself or to advanced atherosclerosis in diabetics.

METHODS: The profiles of coagulo-fibrinolytic system and intimal plus medial arterial wall thickness of the carotid artery (IMT) were examined on 163 diabetic patients without any symptoms of diabetic macroangiopathy (DM; m/f: 114/26), 26 mild hyperglycemic subjects (BLDM; m/f: 20/6) and 6 normal subjects (N/C; m/f: 1/5) using ultrasound high resolution B-mode imaging.

RESULTS: PAI-1 antigen, tPA-PAI complex, and factor VII activity were significantly higher in BLDM with (IMT≥1.1mm) and without advanced caroitd atherosclerosis (IMT<1.1mm) than N/C. Fibrinogen concentration, vWF activity and PIC were significantly higher in DM with and without carotid atherosclerosis. Multivariant analysis disclosed that age, high total-cholesterol, duration of diabetes, smoking and high PAI-1 antigen were independent risk factors for carotid atherosclerosis in subjects with BLDM and DM.

CONCLUSION: These data showed that the coagulo-fibrinolytic abnormality in BLDM is quite different from that in DM irrespective of presence of the advanced carotid atherosclerosis. The high level of PAI-1 antigen might be an independent risk factor for progression of carotid atherosclerosis in subjects with mild hyperglycemia

1782

SILENT ISCHEMIC HEART DISEASE IN INSULIN-DEPENDENT DIABETES MELLITUS

Castells I, Rius F, Salinas I, Fraile M[1], Rubio L[1], Pereferrer D[2] and Sanmartí A. Endocrinology, Nuclear Medicine[1] and Cardiology Services[2]. Hospital "Germans Trias i Pujol". Badalona (Barcelona). Spain.

Aim: To study the prevalence of silent ischemic heart disease (SIHD) among patients with insulin-dependent diabetes mellitus (IDDM) and to identify factors influencing the developement of SIHD. **Methods**: We studied 32 patients (16 women, age 35.5 ± 10.1 years, duration of diabetes 20.5 ± 10.1 years); of these, 16 had diabetic nephropathy (seven with microalbuminuria and nine with overt diabetic nephropathy). Patients with history of any cardiac disease were excluded (clinical or electrocardiographic signs). Dipyridamole plus exercise thallium myocardial perfusion scintigraphy was performed on all patients. A general blood analysis was drawn and the presence of hypertension, smoking, treatment, years of IDDM, diabetic complications and family history (diabetes, hypertension, cardiovascular disease) were recorded. **Results**: We found seven (21.8%) patients with thallium studies suggesting SIHD. There were no differences among patients with and without nephropathy. Those with a family history of diabetes had a higher prevalence of SIHD (6.2% vs. 37.5%, $p < 0.05$). There were no differences in any other analyzed variable. **Conclusions**: There is a high prevalence of SIHD using thallium-dipiridamole scintigraphy in IDDM patients. The only factor associated to this finding is the family history of diabetes mellitus, probably as an inherited marker of cardiovascular risc. Long-term prognostic value of these findings are not know and follow-up of these patients will be needed. The absence of relationship with other diabetic complications is surprising, although the group of patients is still small; an alternative explanation would be a different pathogenesis between microvascular and macrovascular diabetic complications.

1783

PROGRESSION OF EARLY CAROTID ATHEROSCLEROSIS IN YOUNG IDDM PATIENTS

D. Frost, A. Friedl and W. Beischer
Bürgerhospital, Medizinische Klinik 3, Stuttgart (Germany)

By high-resolution ultrasound, the intima-media thickness (IMT) of the carotid artery can be exactly determined, an increased intima-media complex is a sign of early atherosclerosis. The IMT of the carotid artery also reflects the extent of general and coronary atherosclerosis. In former studies, we found intima-media thickening even in young IDDM patients. In this follow-up study we evaluated the development (progression/regression) of the IMT over a longer period. 106 IDDM patients (41 men, 65 women) who were not older than 40 years at the time of the first ultrasound reading of the carotid artery, were re-studied after two to three years (mean 28.8 ± 7.7 months; age 30.8 ± 6.3 y; diabetes duration [dd] 15.5 ± 8.8 y). We measured the IMT of the common carotid artery 1 to 1.5 cm proximal of the bulb with a high-resolution wide-frequency probe (5-10 MHz) and checked the patient's state of complications (albuminuria, retinopathy, limited joint mobility, hypercholesterolemia, hypertension). The IMT was significantly ($p<0.001$) greater at the time of the second investigation (mean of all patients: 0.64 ± 0.17 vs. 0.56 ± 0.14 mm). In 40 patients (37.7%, age 29.0 ± 6.6 y, dd 14.3 ± 8.7 y) the IMT did not increase or even decreased (mean 0.54 ± 0.09 mm, - 0.03 mm), in 66 patients (62.3%, age 32.0 ± 5.8 y, dd 16.3 ± 8.8 y) we observed an increase of the IMT (mean 0.70 ± 0.18 mm, + 0.14 mm). Patients with a progression of the IMT significantly more often had diabetic complications than patients with stable IMT (one or more of the above mentioned: 88% vs. 66% at the time of the second investigation, $p<0.05$) and more of them had developped new complications during the observation period (15% vs. 5%). Multiple regression analysis showed that, besides age, hypertension and albuminuria were independent variables contributing to the IMT ($p<0.01$), while there was no correlation for the other complications or diabetes duration, HbA1c and sex. The majority of young IDDM patients shows a progression of early carotid artery atherosclerosis over a two-to-three year period. Several diabetic complications accelerate intima-media thickening, especially patients with albuminuria and hypertension are at high risk.

1784

CARDIOVASCULAR PROGNOSIS FOR DIABETIC SUBJECTS WITH SILENT MYOCARDIAL ISCHEMIA

P. Valensi, B. Harfouche, R.N Sachs, B. Lormeau, F. Paycha, M. Leutenegger and J.R Attali. Endocrinology-Diabetology-Nutrition, Jean Verdier Hospital, Bondy ; Robert Debré Hospital, Nuclear Medicine, Reims, Louis Mourier Hospital, Colombes, France.

The predictive value of silent myocardial ischemia (SMI) for diabetic subjects has not yet been established. The aim was here to compare the cardiovascular course of diabetic patients with SMI (SMI+) with those without SMI (SMI-). 96 patients, 79 NIDD's and 17 IDD's, with ≥ 1 additional risk factors but without end-stage renal failure were followed for from 4 to 7 years. Thirty patients were SMI+ according to the results of an exercise test, a thallium dipyridamole myocardial scintigraphy and a 48-hour continuous ECG : 11 had significant stenoses found on coronarography (group 1), 14 had a normal coronary angiography (group 2) and 5 refused the coronarography (group 3). A cardiovascular event (myocardial infarction, heart rate abnormalities, heart failure, death of cardiac origin, amputation or stroke) occurred in 12 patients, 8 of whom had a cardiac event of which 3 died. Four of them were in group 1, 1 in group 2, 2 in group 3, and 5 were SMI-. Eight of them had retinopathy, 3 nephropathy, 3 peripheral neuropathy and 5 cardiac autonomic neuropathy (out of the 8 patients tested). The number of SMI+ patients who had a cardiovascular event (7/30 = 23.3%) was significantly higher than that for SMI- patients (5/66 = 7.6%) ($p < 0.01$). The 11 SMI+ patients with coronary stenoses were treated by vasodilative drugs or had an aorto-coronary bypass (1 case). Only one SMI+ patient complained of angor pectoris whereas 7 SMI- patients complained of this. This study suggests that SMI has a predictive value for a poor medium-term cardiovascular prognosis, and should be looked for in diabetic patients with cardiovascular risks and justifies adapting active therapeutic measures.

1785

IMPAIRED GLUCOSE TOLERANCE IS ASSOCIATED WITH INCREASED CARDIOVASCULAR RISK AND CAROTID INTIMA-MEDIA THICKNESS

T. Temelkova-Kurktschiev, C. Koehler, J. Gerber, K. Fuecker and M. Hanefeld. Institute of Clinical Metabolic Research, Technical University, Dresden, FRG

Impaired glucose tolerance (IGT) is known to be associated with increased incidence of cardiovascular disease (CVD), though the nature of this relationship remains not completely understood. Intima-media thickness (IMT) of the carotid artery was shown to be an indicator of CVD. Therefore, we decided to examine risk parameters and carotid IMT in age and weight matched first degree relatives of NIDDM patients with IGT or with normal glucose tolerance (NGT). Standard oral glucose tolerance test with 75 g glucose was conducted in 470 first degree relatives of index cases with NIDDM, aged 40-70 years and with BMI of 25-40 kg/m². Plasma glucose, real insulin (EIA) and proinsulin (EIA) were measured in a fasting state and 30′,60′,90′ and 120′ postprandially. Fasting plasma triglycerides, total and HDL cholesterol, PAI, tPA and v.Willebrand factor were measured by conventional methods. IMT of the common carotid artery was examined by B-mode duplex-ultrasound. Results: IGT was established in 30% of the examined subjects, whereas 59% had NGT. The IGT subjects did not differ significantly for BMI (28.8±4.6 vs. 27.2±4.6 kg/m²), WHR (0.94±0.09 vs. 0.92±0.09) and age (53.8±9.0 vs. 51.5±9.8). Nevertheless, these subjects showed increased carotid IMT (0.82±0.1 mm vs. 0.62±0.1 mm). Besides, IGT was characterized by a more expressed hyperinsulinemia (0′ 107±70; 30′ 572 ±445; 60′ 902±571; 90′ 943±589; 120′ 838±568 pmol/l) and hyperproinsulinemia (0′ 3.5±2.9; 30′ 6.5±4.4; 60′ 12.1±7.8; 90′ 16.3±10.1; 120′ 18.6±11.9 pmol/l) in comparison to the NGT group (insulin: 0′ 83±76; 30′ 553±476; 60′ 697±574; 90′ 550±454; 120′ 396±436 pmol/l and proinsulin: 0′ 2.4±2.9; 30′ 5.3±5.7; 60′ 8.5±7.2; 90′ 9.7±7.7; 120′ 9.1±6.4 pmol/l;; values in healthy controls: insulin: 0′ 65, 120′ 316 pmol/l; proinsulin 0′ 1.5, 120′ 6.9 pmol/l). 44% of the IGT group had hypertension (vs. 16% in the NGT group). PAI was slightly higher in the IGT subjects (43±26 vs. 35±31 ng/ml), whereas tPA (10.3±2.5 vs. 10.1±3.9 ng/ml) and v.Willebrand factor (101±32 vs. 100±45 %) did not differ. Triglycerides were moderately increased in IGT (2.81±2.71 vs. 1.59±0.94 mmol/l), total cholesterol (5.83±1.20 vs. 5.63±1.10 mmol/l) and HDL cholesterol (1.35±0.36 vs. 1.46±0.39 mmol/l) were similar. In conclusion: IGT subjects display an increased cardiovascular risk and carotid IMT than age and weight matched NIDDM relatives with normal glucose tolerance.

1786

DEVELOPMENT OF ECG-ABNORMALITIES IN PATIENTS WITH IMPAIRED GLUCOSE TOLERANCE

M.Hoshi, I.Hatanaka, T.Takimoto & M.Sekiya, Osaka Kosei-Nenkin Hospital, Osaka 553, JAPAN

Macrovascular lesions seem to develop in diabetics with rather mild metabolic derangement compaired with microvascular lesions. It has been reported thrombotic and/or obstructive carotid artery lesions were frequently detectable in echogram at almost the same rate in both impaired glucose tolerance (IGT) and non-insulin dependent diabetes mellitus (NIDDM). We calculated the rate of cumulative ECG-abnormalities for 20 years retrospectively and found the rate was almost the same in both IGT (23%,27% at 10,20 years) and NIDDM (21%,29% at 10,20 years). We divided 82 IGT into 16 IGT-Proper whose OGTT result stayed persistently in IGT pattern and 66 IGT/NIDDM whose OGTT result shifted transiently to NIDDM pattern though they were judged to be IGT retrospectively. High cumulative rate in IGT was explained with IGT/NIDDM (26%,30% at 10,20 years) vs IGT-Proper (13%,12% at 10,20 years). Analysis of baseline characteristics (IGT-Proper 16, IGT/NIDDM 66, and NIDDM 75) revealed serum total cholesterol ($P <.05$) and systolic blood pressure ($P <.005$) were significantly higher in both IGT/NIDDM and NIDDM than in IGT-Proper. To prevent the development of ECG-abnormalities in IGT, we emphasize to control serum total cholesterol and systolic blood pressure as well as blood glucose as antiathrogenic management in IGT.

Clinical Characteristics of Intima-media Thickness in Carotid, Femoral and Popliteal Arteries using B- mode Ultrasound Imaging in NIDDM.

M. Ikebuchi, M. Morita, M. Katsura and R. Todo. Osaka National Hospital, Osaka, Japan

Aim: In order to evaluate atherosclerotic changes in common carotid arteries (CA), femoral arteries (FA), and popliteal arteries (PA) in NIDDM, we measured intima-media thickness (IMT) in the far wall of respective arteries using B-mode ultrasound imaging in 32 NIDDM patients. Results: IMTs of FA were significantly higher than those of CA and PA in NIDDM. (FA; 1.13±0.08 mm、PA; 0.88±0.05 mm、CCA; 0.84±0.04 mm). Percent stenoses of FA and PA were significantly higher than those of CA. (FA; 27%, PA; 28%, CA 22%). Positive correlation was evidenced between two groups in these arteries. Simple regression analysis showed that IMTs of FA and PA were positively correlated with age, diabetic duration, or systolic and diastolic pressure. On the other hand, IMT of CA was positively correlated with age and systolic pressure. Thickening degrees of IMTs of FA and PA, which were correlated with DM duration and blood pressure, were higher than that of CA. IMTs of PA in NIDDM patients with diabetic retinopathy and neuropathy were higher than those in NIDDM without any complications, respectively. IMTs of FA and PA in NIDDM patients complicated with nephropathy were higher than those in NIDDM without complication. IMTs of FA and PA in diabetes with more than 5 years duration were positively correlated with urinary C peptide contents. Conclusion: These data indicated that progression of atherosclerotic changes in lower extremities (FA and PA) were more prominent than that of carotid artery in NIDDM while evaluation of IMTs of FA and PA using B-mode ultrasound imaging was proved useful for estimation of severities of atherosclerosis in NIDDM.

1788

INSULIN AND STRESS HORMONES IN CORONARY ARTERY DISEASE.

Aly. A. Abbassy, T. H. El-Badawy, A. G. El-Din, A. S. Omar, S. A. Mahmoud, A. A. Al-Aghouri, S. N. Assaad. Faculty of Medicine, Alexandria, Egypt.

The study was performed to find out the relation of insulin and hormones to coronary artery disease. Twenty non obese, non diabetic,normotensive men with CAD were studied [10 subjects with acute myocardial infarction (group la) and 10 with old ischemia (group 1b)]. Ten age matched men served as controls (groupII). Blood glucose was measured at 0,"0, 60,90 and 120 min after 75g oral glucose. Fasting serum insulin, GH, cortisol, T3 and T4, and plasma glucagon were estimated by RIA. Serum FFA, cholesterol, HDL and LDL cholesterol and triglycerides, and 24 hours urinary epinephrine (E) and norepinephrine (NE) were determined. Fasting serum insulin and blood glucose were increased in group la compared to those in groups Ib and III (30.7 ± 20.9 uU/ml and 5.5 ± 1.3 mmol /L versus 15.2 ± 5.9 uU/ml and 5 ± 0.8 mmol/L, and 12.9 ± 2.9 uU and 4.3 ± 0.4 mmol/L, p<0.001 and p<0.05 respectively. The 120 min blood glucose in group Ia was higher than that in groups Ib and II (p<0.01). Fasting serum insulin correlated directly with fasting and 120 min blood glucose as well as with serum LDL cholesterol in group I patients. Mean serum GH, T3 and T4, and plasma glucagon levels were comparable in the 3 groups; only mean serum cortisol and 24 hours urine E and NE were elevated in groups Ib and II, both correlated directly with serum FFA, p<0.001). No relation was detected between serum insulin and other hormones. We conclude that hyperinsulinemia with increased cortisol. E and NE secretion occurs in acute myocardial infarction but not in chronic coronary ischemia. The increase in the latter two hormones is responsible for the increase in serum FFA which creates an insulin resistant state.

1789

RELATIOMSHIP BETWEEN THE APPEARANCE OF MIDBAND BY PAGE AND CAROTID ATHEROSCLEROSIS

A. Ota, H. Takama, Y. Ogawa and N. Saito. St. Marianna University School of Medicine, Kawasaki, Japan.

<Aim> We study to elucidate the relationship between the appearance of midband and Lp(a) levels, which are risk factors for atherosclerosis, and atherosclerosis of common carotid artery (CCA) measured by ultrasonography in diabetic patients. < Subjects and Methods > Subjects were ninety-five patients (53 men and 42 women). Carotid intima-media thickness (IMT) on approximately 2cm proximal to the bifurcation of CCA was measured by ultrasonography, and classified one to four groups according to Salonen's categories. Category 1 is no atherosclerotic group. More category 2was regarded as an indicator of atherosclerosis.The midband in polyacrylamid gel electrophoresis (PAGE) is showed abnormal band between the bands of LDL and VLDL. <Result>(1) The appearance ratio of midband : Category 1 24.0%, Category 2 79.6%, Category 3 73.7%, Category 4 50.0%. (2) High Lp(a) levels were associated with midband positive group.

<Conclusion> The appearance ratio of midband increased with progression of carotid atherosclerosis. We concluded that a positive correlation between appearance of midband and IMT, which is used for screening of an indicator of atherosclerosis .

1790

SIGNIFICANT GREATER FREQUENCY OF MAJOR STENOSIS IN THE DISTAL CORONARY ARTERY SEGMENTS IN DIABETES

Okada,A., Kurosaka,K., Funakoshi,M., Iwashita,S., and Toyota,F. Chidoribashi General Hospital, Fukuoka, Japan

To compare angiographically-determined coronary disease in diabetics with controls, 2.761 people coming to cardic catheterization were reviewed respectively. In this study, we excluded people who had myocardial infarction, totally-occuluded vessels, intervention-history, and over 60 years age. We found 31 diabetics (NIDDM) (15 males, 16 females) and 36 controls (25 males, 11 females). There are no significant difference between diabetic and control groups in sex, age, and risk factors (hypercholesterolemia, hypertension, smoking). The localization of significant coronary artery stenosis was assessed using comparison between proximal and distal segments. The following results were obtained. The Gensini-score reflecting the severity of coronary heart disease for diabetics(DM) was 19±15 compared with 18±16 for controls(N.S.). 8 of 31 DM (26%) were diseased only in proximal segments compared with 19 of 36 (53%) for controls (P<0.03). 15 of 31 DM (48%) were diseased only in distal segments compared with 5 of 36 (14%) for controls (P<0.01). In males, 6 of 15 DM (40%) only in proximal segments, 13 of 25 (52%) controls (P<0.05). 6 of 15 DM (40%) only in distal segments, 3 of 25 (12%) controls (P<0.05). In females, 2 of 16 DM (13%) only in proximal segments, 5 of 11 (45%) controls (P<0.03). 9 of 16 DM (56%) only in distal segments, 2 of 11 (18%) controls (P<0.06). The cardiac index for DM was 4.1±1.1 l/min/m^2 compared with 3.8±0.7 for controls(N.S.). We conclude that stenosis of the distal coronary artery segments is more prevalent, and cardiac index isn't decreased in diabetes.

1791

ULTRASONOGRAPHICALLY ASSESSED CAROTID MORPHOLOGY IN DIABETICS

H. Takama, A. Ota and N. Saito. St. Marianna University School of Medicine, Kawasaki, Japan.

The aim of this study is to evaluate the relationship between ultrasonographically findings of common carotid artery(CCA) and obesity, the diabetic duration, the glycemic control and lipids in diabetics. We evaluated the intima-media thickness(IMT) of CCA used with ultrasonography in ninety diabetics. According to Salonen's classification, we divided ninety patients into 4 categories. The category 1 is nonstenotic CCA group, the category 2 is intimal-medial thickning group, the category 3 is the group with nonstenotic plaque and the category 4 is large stenotic plaque. We compared that IMT with obesity, diabetic duration, HbA1c, serum cholesterol, triglyceride, lipoproteins, apoproteins, Lp(a), RLP-cholesterol and aortic pulse wave velocity. Of the 90 patients examined, the ratio of category 1 was 40%, the category 2 was 18%, the category 3 was 30%, the category 4 was 12%. The stenotic group of IMT were associated with the history of obesity. There were no correlation between IMT and diabetic duration or HbA1c. The levels of serum cholesterol and triglyceride of category 4 in male were lower than category 1 and 2. These results suggested that category 4 had different process in arteriosclerosis compared with another categories.

1792

EVALUATION OF LEFT VENTRICLE DIASTOLIC FUNCTIONS WITH DOPPLER ECHOCARDIOGRAPHY IN YOUNG DIABETIC PATIENTS

S.Salman [(1)], F.Salman [(2)], M.Davutoğlu[(1)], G.Kantarcı[(1)], M.Sargın[(2)], A.M.Şengül[(2)], N.Erhan [(1)]
[(1)] Vakıf Gureba Hospital, Clinic of Internal Medicine [(2)] Istanbul University, Institude for Experimental Medicine, Istanbul-TURKEY

In this study, left ventricle diastolic functions of patients with no cardiac symptoms and its diagnostic value were investigated. It comprises 25 diabetic patients (mean age 31.5± 5.5 yrs., BMI 24.2±4.0 kg/m^2, heart rate 77.0±9.9 /min., mean dur. of diabetes mellitus (DM) 2.42± 2.25 yrs., Type 1 /Type 2 DM:15/10) and 14 healthy control (mean age 30.4±4.4 yr., BMI 24.4±2.2 kg/m^2, heart rate 72.9 ±9.2 /min). Two groups were matched regarding these parameters, with using two dimensional and M mode echocardiography, the systolic functions and heart valves were found to be normal. Doppler evaluation was performed to the patients from the level of mitral valve. Isovolumic relaxation time (IVRT) (ms), peak flow velocity of E and A waves (peak E, peak A) (cm/s), peak E/ peak A, integral of E and A waves (E_i, A_i) (cm), E_i/A_i, deceleration time of E wave (E_{DT}) (ms) were measured. The results were given below for diabetics vs controls. IVRT 84.0±15.7 ms; 73.5±7.6 ms ($p<0.02$), peak E 70.5±11.6 cm/s ; 72.8±12.0 cm/s (NS), peak A 55.2±8.7 cm/s; 48.2±5.5 cm/s ($p<0.001$), peak E/peak A 1.3±0.2 ; 1.5±0.2 ($p<0.001$), E_i 10.5±2.1 cm; 10.3±2.0 cm (NS), A_i 6.0±1.3 cm; 4.7±0.7cm ($p<0.001$), E_i/A_i 1.8±0.4; 2.2±0.3 ($p<0.01$), E_{DT} 182.2±18.2 ms; 163.2±13.8 ($p<0.001$). No significant difference in all parameters was detected regarding Type of DM. When diabetes regulation is considered the diastolic parameters between two groups was not significantly different (Group I: $HbA_{1C}\leq 8\%$ n:13; Group II: $HbA_{1C}>8\%$, n:12). As a conclusion, this study shows that in diabetic patients using Doppler echocardiography, a noninvasive method, it is possible to detect left ventricle dysfunctions in preclinical stage and this method can be widely used as a diagnostic test.

1793

ORGANIC AND FUNCTIONAL CHANGES OF ARTERIAL WALL IN NIDDM PATIENTS WITH CARDIOVASCULAR DISEASES

H.Taniwaki, T.Kawagishi, Y.Nishizawa, M. Emoto, Y.Okuno, S. Tanaka, K.Maekawa, and H.Morii. Second Department of Internal Medicine, Osaka City University Medical School, 1-5-7, Asahi-machi, Abeno-ku, Osaka, 545, JAPAN

The aim of this study is to assess the organic and functional changes of arterial wall in NIDDM patients with cardiovascular disease and to investigate the risk factors for these disease. The carotid intima-media thickness (IMT) was measured using B-mode ultrasonography and the stiffness of carotid artery wall was measured using echo-tracking system and aortic stiffness (PWV) was measured using pulse-wave velocimetry in 178 NIDDM patients. Carotid IMT was regarded as an index of organic change of arterial wall and carotid stiffness and aortic PWV were regarded as indices of functional change of arterial wall. The carotid IMT and stiffness, and aortic PWV were significantly higher in patients with CAD or PVD than in those without CAD or PVD ($p < 0.05$). The carotid stiffness and aortic PWV were significantly higher in patients with CVD than in those without CVD ($p < 0.05$), while there was no significantly difference in carotid IMT between patients with and without CVD. Multiple regression analysis showed that systolic blood pressure was an independent and common risk factor for CVD, increase in carotid stiffness and aortic PWV but not for CAD, PVD or increase in carotid IMT. The results suggests that CVD is related to the functional change of arterial wall rather than the organic change and that systolic blood pressure is an important factor for CVD and functional change of arterial wall.

1794

LEFT ATRIUM DILATION IN DIABETES MELLITUS : AN EARLY MARKER OF LEFT VENTRICULAR DYSFUNCTION ?

A. Douras, C. Loupa[1], D. Chrissos, A. Apostolides[2], M. Kalatzi[1] and D. Voyatzoglou[1]. ***2nd Dept. of Cardiology, [1]Diabetes Outpatient Clinic, [2]Dept. of Opthalmology, "A. Fleming" General Hospital, Athens, Greece***

One of left atrium dilation (LAD) causes is dysfunction of left ventricle (LV). Diabetes mellitus (DM) is associated with a specific cardiomyopathy. In this study, we investigate the prevalence of LAD in diabetic persons and its relation to LV dysfunction and/or other factors. We studied 27 patients (P) with DM (6 type I, 21 type II), 17 men & 10 women, age 31 - 70 yrs (x±SD : 54.3±10.6), with no other causes of LAD and without clinical, electrocardiographic or echocardiographic evidence of other cardiovascular diseases and without cardiac failure. Microangiopathy (MAG) was assessed by ophthalmoscopy. Long-term metabolic control (MC) was assessed by HbA1c (good MC : HbA1c≤7.2%). We screened LV function by color Doppler echocardiography study. A resting ejection fraction (EF) ≥50% characterized the normal systolic function of LV. We evaluated diastolic function by the transmitral flow indexes : isovolumic relaxation time (normal : 60-100 msec), deceleration time of E wave (normal : 160-240 msec), and ratio of peak E to atrial A wave velocity (normal : 1-2.4); 2 or more abnormal indexes characterized LV diastolic dysfunction (DD). LA dimension was estimated at the parasternal long axis (normal ≤ 4cm). *Results :* The duration (DU) of DM ranged from 0.7 to 32 yrs (9.6±3.9). 6 P had MAG. 10 P had good MC; HbA1c ranged from 5 to 13.7% (9.03±2.9). All P had normal systolic function; EF ranged from 53 to 70% (62.3±5.9). 15 P had DD. LA dimension ranged from 2.6 to 4.92 cm (3.9+0.57). 12 P had LAD (44.5%), 10 P out of whom had DD. 5 P out of the remaining 15 with normal LA had DD. LAD was not related to MC (p=0.2), DU (p=0.9), MAG (p=0.6) or age (p=0.09), but it was related to DD (x^2, p=0.03). *In conclusion :* Left atrium is often dilated in diabetic patients. LAD is related to subclinical diastolic dysfunction of LV, which it may indicate.

1795

The Cerebral Hemodynamic Changes Measured by Transcranial Doppler in Normotensive, Hypertensive and Diabetic Patients

Nam J.H, Lee J.H, Cha B.S., Lim S.K, Lee H.C, and Huh K.B, Korea

Objective: This study was designed to demonstrate cerebral hemodynamic changes as macrovascular complication related to diabetes mellitus and hypertension.

Method: We measured systolic velocities(Vs), diastolic velocities(Vd), mean velocities(Vm), and pulsatility indices (PI) of the middle cerebral artery (MCA) and the internal carotid artery (ICA) in stroke-free 37 normotensive diabetic(DM, M:F=15:22), 33 hypertensive diabetic(DMHT, M:F=16:17), 51 non-diabetic hypertensive(HT, M:F=25:26, duration ≥5 years) patients and 57 healthy controls(C, M:F=26:31), using a three-dimensional transcranial doppler sonography (Trans-scan, EME, Uberlingen, Germany).

Results: DM, DMHT and HT patients showed significantly higher PI of MCA, and DMHT patients also higher PI of ICA than C. PI of MCA in DMHT patients was more elevated than in DM.

(cm/sec)		C	DM	DMHT	HT
MCA	Vm	54.23±1.26	58.03±2.99	52.90±3.27	47.87±1.50*
	Vs	76.05±1.79	85.00±4.46*	79.71±4.94	70.19±2.33*
	Vd	37.87±0.98	38.63±2.16	32.85±2.30*	31.82±1.10*
	PI	0.71±015	0.81±0.21*	0.90±0.04*#	0.80±0.02*
ICA	Vm	25.07±0.63	25.37±1.15	24.00±0.97	23.70±0.71
	Vs	37.44±0.88	39.28±1.59	38.56±1.80	36.45±1.01
	Vd	17.43±0.53	17.44±0.87	15.61±0.64*	16.29±0.58
	PI	0.83±0.02	0.88±0.03	0.95±0.03*	0.88±0.03

*: $p<0.05$ compared with C, #: $p<0.05$ compared with DM

Conclusion: These results showed that the cerebral hemodynamic changes in diabetes mellitus and hypertension affect pulsatility of cerebral arteries, especially small arteries and arterioles. These atherosclerotic changes of cerebral arteries apppear to be more aggravated in diabetes mellitus combined with hypertension.

1796

DIASTOLIC DYSFUNCTION OF LEFT VENTRICLE IN DIABETIC PATIENTS WITH NORMAL SYSTOLIC FUNCTION

A. Douras, C. Loupa[1], D. Chrissos, A. Apostolides[2], M. Kalatzi[1] and D. Voyatzoglou[1]. *2nd Dept. of Cardiology, [1]Diabetes Outpatient Clinic, [2]Dept. of Opthalmology, "A. Fleming" General Hospital, Athens, Greece*

It is known that diabetes mellitus (DM) is associated with a specific cardiomyopathy with primary & preclinical diastolic dysfunction (DD) of left ventricle (LV). In this study, we investigate the prevalence of DD in diabetic persons and the factors to which it is related. We studied 27 patients (P) with DM (6 type I, 21 type II), 17 men & 10 women, age 31 - 70 yrs (x±SD : 54.3±10.6), with no clinical, electrocardiographic or echocardiographic evidence of other cardiovascular diseases and without cardiac or renal failure. Microangiopathy (MAG) was assessed by ophthalmoscopy. Long-term metabolic control (MC) was assessed by HbA1c (good MC : HbA1c≤7.2%). All P were screened for cardiac autonomic neuropathy (CAN) with 5 stndard clinical tests; the responses were graded as normal (0), borderline (0.5) or abnormal (1), and a score of 1 or more was considered as indicating CAN. Doppler echocardiography study was performed in all P; a resting ejection fraction (EF) ≥50% characterized the normal systolic function of LV. By the transmitral flow indexes : isovolumic relaxation time (normal : 60-100 msec), deceleration time of E wave (normal : 160-240 msec), and ratio of peak E to atrial A wave velocity (normal : 1-2.4) we evaluated diastolic function; 2 or more abnormal indexes characterized DD. *Results :* The duration (DU) of DM ranged from 0.7 to 32 yrs (9.6±3.9). 6 P had MAG. 14 P had CAN. 10 P had good MC; HbA1c ranged from 5 to 13.7% (9.03±2.9). EF ranged from 53 to 70% (62.3±5.9). 15 P (55.5%) presented DD - 14 P the pattern of delayed relaxation (DLR) and 1 P that of increased stifness. Between P with normal diastolic function and those with DD, no significant difference was found for age, MAG, DU or MC, but it was found for CAN (x^2, Fisher : p=0.038). *In conclusion :* In diabetic patients with normal systolic function of LV, more than half demonstrated DD, mostly DLR, which is related to cardiac autonomic neuropathy. Furthermore, echo study has a pivotal role in the follow-up of diabetic persons.

1797

CENTRAL ARTERIAL PRESSURE AND ITS IMPLICATIONS IN DIABETES

B. Brooks*, L. Molyneaux, M. Bonney, D. Celermajer and D.K. Yue. Diabetes Centre & Dept of Cardiology, Royal Prince Alfred Hospital, Sydney, Australia.

Atherosclerosis is more severe in diabetes. Whether diabetic subjects have increased arterial hardening, i.e. arteriosclerosis, is less clear. Arteriosclerosis increases pulse wave velocity, central arterial pressure and cardiac work load. We measured radial artery pressure waveform noninvasively by applanation tonometry (SphygmoCor™). Aortic waveform and pressure are derived using a transfer function developed from previous studies during cardiac catheterization. Radial pressure waveforms were obtained from 30 IDDM (Age 29.1 ± 7.8 yrs, HbA_{1c} 8.1 ± 2.1%, Duration 12.9 ± 9.4 yrs), 20 IDDM Controls (Age 32.5 ± 9.5 yrs), 48 NIDDM (Age 56.3 ± 9.6 yrs, HbA_{1c} 7.9 ± 2.0%, Duration 8.2 ± 6.3 yrs) and 15 NIDDM Controls (Age 59.6 ± 12.0 yrs). Aortic augmentation index (Aortic Aug %) is defined as {100 + (augmentation in systolic pressure expressed as a percentage of the pulse pressure)}. Subendocardial viability (SubE Viab) is defined as {(diastolic time x pressure)/(systolic time x pressure)}. Results shown as mean ± SD.

	Heart Rate (beats/min)	Aortic Systolic BP (mmHG)	Aortic Diastolic BP (mmHg)	Aortic Aug (%)	SubE Viab (%)
IDDM	74.2 ± 10.8	108.2 ± 18.5	75.5 ± 9.6	107 ± 17.9	136 ± 28.7
Control	65.4 ± 9.3[a]	99.6 ± 11.4[b]	71.5 ± 8.6	107 ± 19.2	162 ± 27.8[a]
NIDDM	72.1 ± 10.5	127.2 ± 17.1	84.2 ± 9.8	135 ± 18.0	137 ± 22.2
Control	70.2 ± 7.1	117.2 ± 14.9[c]	78.8 ± 8.6	132 ± 24.2	140 ± 18.4

[a] different to IDDM $p < 0.001$, [b] different to IDDM $p < 0.05$, [c] different to NIDDM $p < 0.05$ (unpaired t test)

Diabetic subjects have elevated central arterial pressure but no evidence of excessive augmentation. IDDM subjects do suffer from a relative rise in systolic work load in relation to diastolic filling time. Therefore, subtle changes in central cardiovascular parameters are present in diabetic subjects and could contribute to the cardiac disease in diabetes. (Supported by the Diabetes Australia Research Trust. SphygmoCor™ was a gift of Servier Laboratories).

1798

DIASTOLIC FUNCTION AND ARTERIAL COMPLIANCE ARE RELATED TO DURATION OF IDDM AND URINARY ALBUMIN EXCRETION.

O Snorgaard, J Faber, N Wiinberg, J Mehlsen, TJ Jakobsen and P Hildebrandt. Frederiksberg Hospital, Denmark.

Indexes of left ventricular diastolic and systolic function (M-mode and Doppler echocardiography) and arterial compliance (volumen-oscillometric method) were studied in 55 consecutive IDDM patients, age 40.8±12.7 yrs, disease duration 16.8±12.9 yrs and HbA1c 8.4±1.0 %. Peak velocity of late diastolic filling (Peak-A) was gradually elevated with the severity of the stratification after urinary albumin excretion (UAE): normoalbuminuric (N=40): 0.62±0.20 m/sec, microalbuminuric (N=11): 0.77±0.14 m/sec and macroalbuminuric (N=4): 1.1±0.13 m/sec, $p<0.0001$. Peak-A was strongly correlated to IDDM duration, independent of the level of UAE ($r=0.64$, $p<0.00001$ for all patients and $r=0.69$, $p<0.00001$ for normoalbuminuric patients). Peak velocity of early diastolic filling, deceleration time, isovolumetric relaxation time, and left ventricular ejection fraction were not correlated to disease duration and no differences were seen between risk-groups. Like Peak-A, Compliance (C) of the peripheral arteries at the ankle level (at transmural pressure 0 and 100 mmHg) were related to disease duration and level of UAE: C^0: $r= -0.42$, $p<0.005$ and 21.3±6.6, 18.5±5.8, 13.0±7.4 µl/mmHg/10 cm, $p=0.06$, respectively. C^{100}: $r= -0.53$, $p<0.0001$ and 7.6±2.3, 6.1±1.7, 4.0±0.1 µl/mmHg/10 cm, $p<0.01$. Stepwise multiple regression analyses for the variation in Peak-A and compliance showed that age, HbA1c and blood pressure were of no importance. We conclude, that the prominent feature of diastolic dysfunction in IDDM is an increasing peak velocity of late diastolic filling. This might be due to an increasing stiffness of the heart, as it is seen in the major arteries.

1799

RENO VASCULAR HYPERTENSION IN NIDDM WITH SEVERE SYSTEMIC HYPERTENSION

J.P Courrèges, J. Bacha, E. Aboud,and R. Lamarca. Service of Internal Medecine Diabetologia-Vascular diseases. Centre Hospitalier-11100 NARBONNE - FRANCE

Renal atherosclerosis can lead to severe hypertension(HT) witch is deliterius to vessels and kidney. Does a renovascular HT(RVHT) must be searched in NIDDM with severe HT ? witch are patients with high risk of RVHT ?

70 consecutive NIDDM with severe HT (≥ 3 hypotensive drugs), 49 F/21 M (SR 2,3), mean age :65,6 ± 7,7 yrs, diabetic duration:11,1 ± 5 yrs have had metabolic, ABPM and renal investigations : renal US - n = 70, color dupleix scan (CDS): n = 53, and/or arteriography : n = 19.

14 (20 %) renal artery stenosis ≥ 70 % (RAS): 8 unilateral/6 bilateral were prouved by arteriography. We compared classic HT vs R.V.H.T. There was no difference for age (yrs) : 65,6 ± 8 vs 71 ± 6,3, HT duration (yrs) : 13 ± 7,5 vs 12,7 ± 6, B.M.I : 31,5 ± 6 vs 27,6 ± 3,3, HBA1C(%): 8,9 ± 2,2 vs 8,8 ± 0,9, CT (mmol/l): 5,7 ± 1,3 vs 5,5 ± 0,6. Significant difference ($p < 0,05$) was noticed for S.R (F/M) : 3 vs 1, diabetic duration (yrs) : 11,2 ± 5,1 vs 16,5 ± 8,8, frequency of retinopathy (%) : 30 vs 64, smoking (%): 14 vs 43, triglycerides (mmol/l) : 1,9 ± 1,1 vs 2,6 ± 1,1, and ($p < 0,01$) for blood pressure level (mmHg) (SBP : 139 ± 21 vs 154 ± 7, DBP : 80 ± 14 vs 86 ± 16, MBP : 102 ± 16 vs 110 ± 6), frequency (%) of HT escape (≥ 140/SBP, ≥ 90/DBP) on ABPM : 30 vs 75 and 24 vs 39,insulin requirance (%): 35 vs 71, macroangiopathy (%): 55 vs 100, micro/macro albuminuria (%): 34 vs 93, creatinaemia (mmol/l): 80 ± 23 vs 129 ± 47 + clearance (ml/mn): 66 ± 41 vs 39 ± 13. We tried to determine a RVHT score for investigations : renal US : 43 % - n = 6/14 (4 uni/1 bilateral hypotrophies),and for clinic : in the group (n = 36) with a poor control HT(SBP≥ 160 ± DBP≥ 90 ± MBP ≥ 120) and/or renal function decrease (albuminuria ≥ 100 mg/24 h ± creatinaemia ≥ 120 mmol/l), we have found all the RAS (n = 14) with positive diagnostic score : 39 %. In the group(n = 34) with well controled HT + normal renal function, there was no R.A.S.

Conclusion : in NIDDM with severe HT, reno vascular HT is frequent (20%). It must be evocated in unstable HT and/or renal injury with macro angiopathy, old NIDDM (> 15 yrs), requiring insulin .Renal U.S and colour duplex scan may lead to arteriography to confirm renal artery stenosis.

1800

ANGIOGRAPHIC CHARACTERISTICS OF CORONARY ARTERY DISEASE IN PATIENTS WITH TYPE 2 DIABETES

P. Pajunen, MS. Nieminen, M-R. Taskinen and M. Syvänne. University of Helsinki, Helsinki, Finland.

The question of whether the severity or extent of coronary artery disease is different in diabetic patients compared with nondiabetic subjects is controversial. The aim of the present study was to compare the angiographic characteristics of coronary artery disease (CAD) utilizing quantitative coronary angiography (QCA) in a well-defined group of Type 2 diabetic patients (n=55) with those of individually matched nondiabetic control subjects. Both groups were undergoing clinically indicated elective coronary angiography. The QCA-derived parameters were incorporated into global perpatient indices describing severity and extent of CAD and overall atheroma burden. These indices were also calculated separately for different coronary segments, i.e. left main, proximal, mid, and distal segments and, also, for different vessel territories: left main, left anterior descending, left circumflex, and right coronary artery. No significant differences were found between the groups (global severity index, 51.5 ± 14.2 vs. 54.2 ± 13.2, p=NS; global extent index, 34.2 ± 13.2 vs. 32.2 ± 12.4, p=NS; global atheroma burden index, 26.8 ± 15.7 vs. 24.4 ± 11.9, p=NS). We also found no between-group differences in proximal, mid, or distal segments; in separate vessel territories; or in left ventricular function. In conclusion, we found no evidence to support the hypothesis that CAD would be more severe, extensive, or distal in Type 2 diabetic patients, compared with sex-, age, and BMI-matched control subjects, as evaluated by QCA.

24 HOURS AMBULATORY BLOOD PRESSURE MONITORING IN NON-INSULIN DEPENDENT DIABETICS

C.R. ANAND MOSES, S. ILANGO, M.R. SRIDEVI & A. SUNDARAM
KILPAUK MEDICAL COLLEGE HOSPITAL, MADRAS, INDIA

24 Hours ambulatory blood pressure monitoring (ABPM) was done in forty NIDDM subjects to study the diurnal blood pressure variation and to correlate them with cardiac autonomic neuropathy and left ventricular hypertrophy (LVH) Of them 21 were hypertensives and 19 normotensives. Male to female ratio was 25 : 15. Their mean age was 51.90 ± 7.12 years and the duration of diabetes ranged from 0 - 15 years. All patients underwent Cardiac autonomic function test and echo cardiography to assess left ventricular mass. Antihypertensive drugs were stopped 2 days prior to ABPM. Normally there is a 10 - 20% fall in mean systolic and diastolic blood pressure at night, these people are dippers. Those with less than 10% fall are non-dippers. In this study only 5 (16.5%) of the 40 subjects were dippers. Of them 2 were hypertensives and 3 were normotensives. All the 5 dippers had normal autonomic function. Of the 35 non-dippers 23 (65.72%) had evidence of cardiac autonomic neuropathy. All the 7 female non-dippers with hypertension and 3 out of 7 non-dipper female normotensives had LVH. Among males only 1 of the 12 non-dipper hypertensive and 1 of the 9 normotensive non-dipper had LVH. Of the 1 female and 4 male dippers 2 males had LVH. It is concluded that in this study (1) there is no significant difference in diurnal B.P. variation between hypertensive and normotensive diabetics. (2) 24 hrs. ABPM may help in early detection of Cardiac autonomic neuropathy (3) Female diabetics especially non-dippers are at increased risk of LVH.

1802

POOR GLYCAEMIC CONTROL PREDICTS CORONARY HEART DISEASE DEATH IN PATIENTS WITH INSULIN-DEPENDENT DIABETES

S. Lehto, T. Rönnemaa, K. Pyörälä and M. Laakso. Department of Medicine, University of Kuopio, Kuopio; Social Insurance Institution, Turku, Finland

The aim of our study was to examine the predictive value of cardiovascular risk factors with respect to coronary heart disease (CHD) death in patients with insulin-dependent diabetes mellitus (IDDM) without nephropathy. We examined a representative cohort of IDDM patients (113 men and 115 women), aged from 45 to 64 years, in eastern and western Finland in 1982-84. These patients were followed up to 7 years. Fifty-one patients (26 men, 25 women) with urinary excretion >300 mg/L and/or serum creatinine >110 umol/L in women and >120 umol/L in men were excluded. Altogether 20 IDDM patients (13 men (7.3 %) and 7 women (3.9 %) died of CHD during the follow-up. Univariate and multivariate Cox regression models were used to investigate the association of cardiovascular risk factors with the incidence of CHD death. In univariate analysis a previous history of myocardial infarction, glycated haemoglobin A_1 and the duration of diabetes were the only variables associated with the risk of CHD death ($p<0.001$). In multivariate analysis a previous history of myocardial infarction (Hazard ratio (HR) 8.0 (3.1-21.0, $p<0.001$), high glycated haemoglobin A_1 (>10.4 %, the highest tertile, HR 5.4 (1.4-20.4, $p=0.013$), and the duration of diabetes (>16 yrs, the highest tertile, HR 4.2 (1.3-12.9, $p<0.001$) were significantly associated with CHD death even after adjustment for other cardiovascular risk factors. In conclusion, our results indicate that poor glycaemic control is a strong predictor of CHD mortality in patients with IDDM without neuropathy.

1803

BLOOD PRESSURE AND TYPE I DIABETES COMPLICATIONS: DEFINITION OF HYPERTENSION CRITERIA USING 24 h-AMBULATORY BLOOD PRESSURE.

H. Mayaudon, B. Bauduceau, M. Ducorps, M. Pellan, G. Prévost, X. Chanudet and P. Larroque. Hôpital Bégin.94160 Saint-Mandé. France.

Hypertension criteria recommanded by WHO appear too high for diabetic patients. The aim of this study was to evaluate by casual measurement and 24 hours-ambulatory monitoring (24-ABPM) the blood pressure level able to reduce the frequency of type 1 diabetes vascular complications. **Patients and methods:** 77 patients with type 1 diabetes mellitus were studied. Physical examination, BP measurement, smoking habits and serum lipids were realized at the beginning of the study (Y0) and two years later (Y2). In the same time, a statement of diabetes and its complications (nephropathy, retinopathy, coronary heart disease and arteriopathy) was performed. A 24-ABPM was also performed at Y0. These 77 patients were divided in two groups according to urinary albumin excretion (UAE) rate at Y0 either lower than 30 (group 1; N = 56) or upper than 30 mg/ 24 hours (group 2; N = 21). At Y2, patients of group 1 were divided in two groups according to the same criteria (group 1a: UAE<30: N = 44 and group 1b: UAE>30: N = 12). All parameters were compared between group 1 and 2 then between groups 1a and 1b. **Results:** No statistically significant difference was found between group 1 and 2 for age, sex-ratio, body mass index, smoking habits and serum lipids, diabetes duration, glycemic control as well as casual BP. The mean systolic and diastolic 24-AMBP values were significantly higher in group 2 versus group 1 (24 h-SBP: 128±15 vs 115±14 mmHg, p<0.001 and 24 h-DBP: 77±8 vs 73±7, p<0.05). Frequency of others complications was significantly lower in group 1. Blood pressure evaluated by clinical measure and 24-AMBP did not differ significantly between groups 1a and 1b. Patients of group 1b were older than those of group 1a (61±14 vs 51.7±15.8 years, p<0.05) and diabetes duration was higher (21±7 vs 15.6±10.1 years, p< 0.02). **Conclusion:** This study confirms the influence of BP level on the frequency of type 1 diabetes complications. Using 24h-AMBP and considering our results, a level of 24h-SBP lower than 115±14 mmHg and 24h-DBP lower than 73±7 should to be able to reduce this frequency.

1804

HYPERINSULINEMIA, CAROTID ATHEROSCLEROSIS AND LEFT VENTRICULAR HYPERTROPHY IN HYPERTENSIVES AND CONTROLS.

AO. Rantala, M. Päivänsalo, M. Lilja, H. Kauma, MJ. Savolainen, A. Reunanen, YA. Kesäniemi, Department of Internal Medicine, Department of Radiology, University of Oulu, Oulu, Finland

High serum insulin levels have been associated with atherosclerotic vascular disease and incident hypertension in the multiple metabolic syndrome (MMS). To examine the prevalence of MMS and hyperinsulinemia in relation to left ventricular hypertrophy (LVH) and intima-media thickness (IMT) oral glucose tolerance test, bilateral carotid ultrasonography and echocardiography were performed in a random sample of middle-aged (40-59 yrs) hypertensive subjects (261 men (HM), 258 women (HW)), and in age-matched controls (259 men (CM) and 267 women (CW)). The prevalence of MMS was 3.8-35.3% in HM, 0.8-13.5% in CM, 8.5-21.7% in HW and 0.8-5.6% in CW. Insulin correlated significantly with LVH in HW and CW but the relation was confounded by body mass index in multivariate analysis. The mean IMT among all the 1031 subjects was 0.83 mm (SD 0.14) being 12% higher in men than in women (p<0.001). In HM the amount of plaques was 28% higher (p<0.003) than in CM. In HW there were 18% more plaques than in CW (ns). IMT was correlated significantly to age, LDL cholesterol (LDL), LVH, systolic blood pressure (SBP) and pack-years of smoking. In univariate analysis age-adjusted insulin parameters showed a negative correlation with IMT in HW (p<0.03) and in HM (p<0.06). In stepwise regression analysis after adjustment for age, BMI, LDL, and SBP only 2-hour insulin tended to be negatively correlated with IMT (p=0.055). We conclude that in contrast to conventional risk factors such as age, LDL, SBP and smoking, insulin had no independent contribution to the extent of carotid atherosclerosis and LVH in this cross-sectional population-based study.

1805

DUPUYTREN'S DISEASE IN DIABETIC PATIENTS: ASSOCIATION WITH ATHEROSCLEROTIC VASCULAR DISEASES

IM Kantola, JSA Viikari, T Rönnemaa and PET Arkkila
Turku University Central Hospital, Turku, Finland

Previous studies have shown an association between diabetes related microvascular complications and Dupuytren's disease (DD). This study aimed to clarify if DD was also associated with macrovascular diseases in diabetic patients. We examined 297 type 1 (age±SD 33.2±10.0 years) and 139 type 2 (61.3±12.3 years) diabetic patients. History of myocardial infarction (MI), coronary heart disease (CHD), cerebrovascular disease (CeVD) and peripheral vascular disease (PVD) were evaluated. DD was present in 14% of both type 1 and 2 diabetic subjects. Type 1 diabetic patients with DD were older and had had diabetes longer than those without DD, whereas in type 2 no association between DD and age or duration of diabetes was found. There was no association between control of diabetes (HbA_{1c}) and the presence of DD. Proportion (%) of atherosclerotic vascular diseases in type 1 and 2 diabetic subjects with and without DD are shown in the table.

Prevalence of atherosclerotic vascular disease (%)

	No DD	With DD		No DD	With DD
Type 1			**Type 2**		
MI	2	7*	MI	17	30
CHD	6	12	CHD	39	60
CeVD	2	7*	CeVD	20	40
PVD	12	30**	PVD	25	39

**p<0.05 and **p<0.01, compared to diabetic subjects without DD.*

Conclusions: Type 1 diabetic subjects with DD had a history of MI, CeVD and PVD more frequently than subjects without DD, but these associations were fully explained by the age of diabetic subjects (logistic regression analysis). No significant association between DD and atherosclerotic vascular diseases was found in type 2 diabetic subjects.

1806

INFLUENCE OF DIABETES ON DEVELOPMENT OF CARDIOGENIC SHOCK DURING ACUTE MYOCARDIAL INFARCTION.

M. Ohta, T. Takano, H. Yokoyama, N. Fujita, K. Tanaka, N. Mori, Y. Tomita, J. Nejima, M. Takayama, H. Hashimoto, M. Ohtake, T. Aramaki, and H. Hayakawa. Nippon Medical School, Tokyo, Japan.

To clarify the relation between diabetes mellitus (DM) and cardiogenic shock (CS), clinical data of 458 consecutive pts hospitalized with acute myocardial infarction (AMI) were retrospectively analysed. Of 71 pts who developed CS, 52 had pre-hospital CS (PCS) and 19 in-hospital CS (ICS). Incidence of DM was not different between PCS, ICS, and non-CS (NCS) pts (32.2%, 31.6%, and 26.1%, respectively). However, a subgroup of ICS pts with aggravating pump failure (n=10) had significantly higher incidence of DM compared with another subgroup of ICS pts with re-infarction (n=9)(60.0% vs 0 %, P<0.05). Mean of maximum CPK excursion (max-CPK during re-infarction minus that on admission) in ICS pts with re-infarction was significantly greater than that in NCS pts with re-infarction (4986 ± 5826IU/l vs -737 ± 1626IU/l, P<0.001), indicating larger size of infarcts in the former group. Elapsed time after admission to CS in each individual of ICS with pump failure was less than 24 hours , whereas ICS pts with re-infarction developed CS in 3.2±1.9 hospital days. It is concluded that the influence of DM is more likely on cardiac performance than on cardiac vasculature in already infarcted heart, and that diabetic pts with AMI are at high risk of developing CS due to pump failure within 24 hours after admission.

1807

COMPUTERIZED EVALUATION OF PERIPHERAL VASCULAR DISEASE IN THE CLINICAL PRACTICE: THE AGREEMENT BETWEEN ANCKLE BRACHIAL INDEX (ABI) AND DOPPLER CONTINUOUS WAVE (DCW).

Piarulli F., Bax G. , Fagherazzi C., Fedele D.
Dept of Internal Medicine Chair Diseases of Metabolism Padua University Italy

The diagnosis of peripheral arterial disease is often made late in patients with diabetes. The consensus conference (Diabetes Care 16: 1199,1993) recommends to evaluate with DCW and/ or ABI all patients with more than 10 years of disease. These techniques can sometimes produce wrong diagnosis (NEJM 335:46,1996) above all in patients with diabetes where there are a lot of confounded factors (neuropathy, Monckeberg's sclerosis). We evaluated the agreement with K of Cohen between ABI, found with a new computerized system with three pletismographic probes, and DCW to verify if this new tool could useful to screen correctly peripheral arterial disease. 700 type2 diabetes patients were studied with ABI at rest and after exercise and DCW on leg arteries. K test was applied in 246 patients selected in four different groups: ABI very high (>1.20), normal (1-1.20) , borderline (0.80-0.99), small (<0.80) and with equal duration of disease. The agreement (κ) (5°–95° C.I.) was evaluated in these different clinical studies between ABI's and arterial DCW (normal or post occlusive signals). ABI's variability was 10-12%

N	age	Duration of Disease	ABI at the rest	κ (I.C 5°-95°)
40	69±7	9±3	0.66±.15	0.89 - 0.90
68	69±7	9±2	0.88±.06	0.74 - 0.85
96	65±6	9±2	1.06±.05	0.98 - 0.99
42	61±7	9±3	1.28±.08	1

In patients with diabetes ABI could produce wrong diagnosis (in 15-20%) of borderline situations respect DCW analysis. For screening peripheral arterial disease this new computerized tool produce a correct diagnosis without operator dependence problems of DCW. But borderline situation the specialized vascular assessment need.

1808

THROMBOLYTIC THERAPY IN DIABETICS WITH ACUTE MYOCARDIAL INFARCTIONS

K Shotliff, M Ferrar and SS Nussey. *Dept of Endocrinology and Diabetes, St George's Hospital, London, UK.*

Thrombolysis of diabetic patients with acute myocardial infarctions (MI) saves 37 lives per 1000 treated but may be withheld inappropriately. We wished to see whether this occured in our unit. We examined the medical records of all patients admitted to this hospital with an acute MI, from 4/95 to 3/96, to see who did not receive thrombolytic therapy. Of the 244 patients records examined, 47 (19.3%) were known to have diabetes (8 receiving insulin, 37 oral agents, 2 diet alone) with 28% (13/47) receiving thrombolysis compared to 39% (76/197) of the non-diabetics. Only 1/3 of patients were thrombolysed within 30 minutes of admission. In the diabetic group reasons for withholding thrombolysis were: 57.4% late presentation (32% in non-DM), 6.4% non-Q wave infarct and 4.3% contraindications. Two patients (4.3%) in the diabetic group, and 4 (2%) of the non-diabetic group, should have received thrombolysis but did not. In our unit the majority of patients are appropriately thrombolysed but the door to needle time needs to be reduced. Diabetic patients present later with a median duration of symptoms prior to admission of 15 hours compared to 6 hours in the non-DM. Improved education of both doctors and patients is needed to ensure earlier presentation and more rapid initiation of therapy.

1809

ULTRASOUND WAVEFORM COMPLEXES IN DORSALIS PEDIS AND POSTERIOR TIBIAL ARTERIES IN DIABETIC PATIENTS ASYMPTOMATIC FOR PERIPHERAL VASCULAR DISEASE

M J CICHERO AND C H LEE, TOA PAYOH HOSPITAL, SINGAPORE

Occlusive peripheral vascular disease is responsible for the development of ischemic foot lesions in diabetic patients. Examination of waveform complexes obtained with doppler ultrasound, particularly of their phasic characteristics, may be useful in the assessment of the peripheral vascular system in diabetic patients. The identification of diabetic patients with asymptomatic peripheral vascular disease may allow the institution of early preventive measures to retard progression. In patients who already have foot ulcers, ultrasound assessment of the perpheral vessels is helpful in prognosticating disease outcome and directing clinical management. We compared the doppler ultrasound waveform complexes of a cohort of 11 diabetic patients versus a age-matched control group of 6 nondiabetic patients. Inclusion criteria for the study group were: duration of diabetes of at least five years, age range between 35 to 65 years, no cigarette smoking, and no previous history of intermittent claudication, rest pain or foot ulceration. The control group was matched for all these criteria apart from diabetic status. The mean HbA_{1c} in the diabetic group was 9.4% compared to 5.3% in the control group ($p<0.01$). The dorsalis pedis and posterior tibial arteries in both lower limbs were studied using a ES1000SPM doppler ultrasound (Hadeco, Japan). A trace of 5 to 6 waveform complexes was obtained and recorded for each of the four arteries in each subject. Using a calibrated rule, the height of the first deflection in the waveform complex (the A wave), corresponding to flow velocity in the vessel, was measured. The phasic pattern of the waveform, particularly of the succeeding waves (B and C waves) in the complex, was also analyzed. We found that the mean height of the A wave in both left and right posterior tibial arteries in the diabetic group was significantly reduced compared to the control group (left posterior tibial 14.9 vs 24.4 cm/s, $P<0.05$, right posterior tibial 16.3 vs 29.7 cm/s, $p<0.01$). There was no significant difference in this study in the A wave height of the dorsalis pedis arteries between study and control subjects. Diabetic patients had flatter succeeding B and C waves, suggesting a loss of elasticity and compressibility in the arterial walls. We conclude that asymptomatic diabetic patients may have significant stenosis in their foot vessels, and that ultrasound vascular assessment may be useful in risk stratification.

1810

CEREBROVASCULAR DISEASE IN DIABETICS: AN EXPERIENCE AT BIRDEM HOSPITAL

H. Sirajul, A.R. Khan, T. Ahmed and A. Haque. *Bangladesh Institute of Research and Rehabilitation in Diabetes, Endocrine and Metabolic Disorders (BIRDEM), Dhaka, Bangladesh*

From March '95 to August '96, Medical Unit I received 105 cases of NIDDM patients of acute onset cerebrovascular disease. Of them 71 (M:F = 64:7) under went CT scan of brain to determine the type of lesion. Factors, such as age, sex, duration of diabetes, hypertension, smoking habit, aspirin intake, cardiac lesion, plasma lipids etc. were studied to find their relation with the pattern of CT lesion and outcome. The study documented infarction is the main form of lesion, haemorrhage is the major killer, hypertension is a common feature in all type. Cardiac lesion is more prominent infarction group. Duration of diabetes mellitus was more in infarction group than in the rest. Mean age of different type of lesions were almost identical. Cerebrovascular disease is a major problem in which a diabetic is crippled in moments is being encountered at BIRDEM Hospital round the year in a large number. Considering this the present study was designed to see the pattern of lesion in our NIDDM cerebrovascular disease patients and also to evaluate the factors related to course and outcome in them. The patients were selected from the admitted patients of acute onset cerebrovascular complications of NIDDM.

1811

CARDIAC AUTONOMIC NEUROPATHY HAS A HIGHER PREDICTIVE VALUE FOR CARDIAC EVENTS THAN SILENT MYOCARDIAL ISCHEMIA

P. Valensi, B. Harfouche, R.N Sachs, B. Lormeau, J. Pariès, F. Paycha, M. Leutenegger and J.R Attali. Endocrinology-Diabetology-Nutrition, Jean Verdier Hospital, Bondy ; Robert Debré Hospital, Reims ; Nuclear Medicine, Louis Mourier Hospital, Colombes, France.

The predictive value of silent myocardical ischemia (SMI) is not well known for diabetic subjects. The prognostic value of cardiac autonomic neuropathy (CAN) has been strongly suggested in the literature but has not yet been determined according to the presence or absence of ischemic heart disease. The aim of this study was to analyse the predictive value of these two complications of diabetes in a series of 63 patients, who had been followed for from 4 to 7 years, 52 NIDD's and 11 IDD's, with $\geqslant$ 2 additional cardiovascular risk factors without end-stage renal failure. Evidence of SMI was found in 18 of them during the initial assessment (exercise ECG, thallium dipyridamole myocardial scintigraphy and ECG recording for 48 hours) : 7 had significant stenoses on the coronary angiography, 9 had a normal coronary angiography and 2 refused this examination. Evidence of CAN was found in 26 of the 63 patients by means of 3 parasympathetic tests (Valsalva, deep-breathing, lying-to-standing). The frequency of CAN was not significantly different in the patients with SMI (5/18), in particular those with stenoses (2/7), and in the patients without SMI (21/45). A major cardiac event occurred in 4 patients (death, pulmonary edema, myocardial infarction), all of whom had CAN and two of whom had SMI. A noncardiac vascular event (stroke or amputation) occurred in 4 patients, one of whom had CAN and two SMI. This study does not provide positive proof of the involvement of cardiac neuropathy in the silent clinical aspect of the ischemic heart disease but suggests that CAN has a predictive value for a poor medium-term cardiac prognosis, independent of the presence of ischemic heart disease.

1812

CLINICAL EVALUATION OF CEREBROVASCULAR ACCIDENT WITH NIDDM.

H. M. Lee, S. H. Kwon and S. J. Lee.
Kangbuk Samsung Hospital, Seoul, Korea.

In patients with non-insulin-dependent diabetes mellitus(NIDDM), the risk of cerebrovascular accident(CVA) is known to be increased. Therefore, we evaluated the significances of variables with respect to the risk of CVA in NIDDM patients. We assessed retrospectively these variables in 160 subjects(82 men, 78 women), divided into 3 groups; 90 CVA with NIDDM patients(50 men, 40 women), 40 NIDDM patients(17 men, 23 women) and 30 CVA patients(15 men, 15 women). We found that the mean values of cholesterol(5.15±0.83 mmol/L), triglyceride(2.29 ±0.21 mmol/L) and blood pressure(systolic B.P 158.5±30.9 mmHg, diastolic B.P 97.5±17.3 mmHg) were higher in CVA with NIDDM patients than the others($p<0.05$). There were high incidences of lacunar infarcts in NIDDM patients(57.8%). But, there were no significances in the other variables($p>0.05$). Thus, we suggest that hypertension, hypercholesterolemia and hypertriglyceridemia in NIDDM patients could be associated with increase in the risk of CVA.

1813

QT INTERVAL LENGTH AND QT DISPERSION AS PREDICTORS OF MORTALITY IN NON-INSULIN-DEPENDENT DIABETES MELLITUS

M.-A. Gall[1], A. Sato[1], A. Major-Pedersen[1], L. Breum[1], P.K. Christensen[1], P. Rossing[1], A. Pietersen[2], J. Kastrup[2] and H.-H. Parving[1]. [1]Steno Diabetes Center, Gentofte, [2]Cardiological Laboratory, Rigshospitalet, Copenhagen, Denmark.

The aim of our prospective study was to evaluate the impact of the QT interval length and the QT dispersion on mortality in all (n=328) Caucasian NIDDM patients <65 years of age, attending our clinic in 1987. A resting ECG was recorded at baseline. Normoalbuminuria (urinary albumin excretion (UAE) <30 mg/24 h) was present in 191, microalbuminuria (UAE 30-299 mg/24 h) in 86, and macroalbuminuria (UAE ≥300 mg/24 h) in 51 patients at baseline. Mean age at entry was 54 ± 9 (SD) years. The minimum and the maximum QT intervals were measured in a 12-lead ECG and corrected for heart rate (QTc-min and QTc-max). QTc dispersion was defined as the difference between QTc-max and QTc-min. QTc-max was 450 (362-671) (median (range)) ms and QTc dispersion was 56 (0-268) ms. 61% (199/328) of the patients had prolonged QT interval defined as QTc-max ≥440 ms. During the 9-year follow-up period 100 (30%) patients had died; 44 patients from cardiac causes. 38% of patients with prolonged QT interval had died compared with 19% of patients with QTc-max within the normal range, $p<0.05$. Cox proportional hazard analyses revealed the following independent predictors of death:

	Mortality (relative risk (95% CI))	
	All-cause (N=65)	Cardiac (N=29)
Sex (males)	-	2.30 (1.15-4.49)
LogUAE (factor 10)	1.69 (1.33-2.14)	-
Age (1 yr)	1.08 (1.04-1.11)	1.09 (1.03-1.14)
HbA_{1c} (1%)	1.14 (1.03-1.26)	1.19 (1.02-1.38)
QTc-max (1 ms)	1.005 (1.000-1.010)	1.007 (0.999-1.014)*
s-cholesterol (1 mmol/l)	1.12 (1.00-1.24)	1.25 (1.08-1.45)
Systolic BP (1 mm Hg)	1.009 (1.000-1.018)	1.01 (1.00-1.03)
Duration of diabetes (1 yr)	-	1.05 (1.01-1.09)
		*P=0.07

We conclude that longer QT interval, but not increased QT dispersion indicate an increased mortality risk in NIDDM patients.

1814

ROLE OF FIBRINOGEN ON PATHOGENESIS OF THE STROKE IN NIDDM PATIENTS.

A.Becerra, A.Luengo[1], E.López, F.Almodóvar, N.Palacios, G.Piédrola and A.Hernández[2].Ramón y Cajal and [1]La Princesa Hospitals,Madrid, [2]Dr.Peset Hospital,Valencia; Spain.

In order to examine the role of the fibrinogen (FB) on the pathogenesis of the stroke in NIDDM patients we studied 32 consecutive patients with previous isquemic stroke confirmed with cranial CT, that have been examined at 48 hours of the stroke. We analized plasma glucose (PG), cholesterol (CH), triglycerides (TG), HDL-, LDL-, VLDL-cholesterol (VLDL), apolipoprotein (apo) AI and apo B, and FB [all by standard methods] levels, matched for age, sex, body mass index and arterial pressure in two groups, diabetics (n=16) and non-diabetics (n=16). The results obtained have been processed by the mean and standard deviation and the correlation between all them. The results were: PG 12.2±4.6 vs 5.5±0.6 mmol/l ($p<0.01$); CH 5.3±1.0 vs 5.1±1.2 mmol/l; TG 3.0±0.6 vs 2.9±0.8 mmol/l; HDL 0.9±0.2 vs 1.1±0.3 mmol/l; LDL 3.8±0.9 vs 3.4±1.1 mmol/l; VLDL 0.6±0.1 vs 0.6±0.2 mmol/l; apo AI 1.55 ±0.27 vs 1.51±0.27 g/l; apo B 1.31±0.23 vs 1.16±0.19 g/l, and FB 2.72±1.44 vs 5.34±1.49 g/l ($p<0.01$), in the diabetic and non-diabetic groups, respectively. We find a positive correlation ($r=0.7$; $p<0.01$; $n=16$) between FB and PG levels in the non-diabetic group, but not in the diabetic group ($r=0.1$). FB levels were lower in diabetic group than in non-diabetic group. The PG levels in acute phase of the stroke are correlated with FB levels only in non-diabetic group. Our results suggest a slight influence of the FB levels on the acute phase of the stroke in NIDDM patients.

1815

QTc INTERVAL AND QT DISPERSION PROLONGATION IN NIDDM PATIENTS WITH AUTONOMIC NEUROPATHY

Y. K. Cho, S. H. Kwon, and S. J. Lee
Kangbuk Samsung Hospital, Seoul, Korea

To clarify whether QTc interval and QT dispersion can be employed as objective and meaningful indicators for evaluating the severity of diabetic autonomic neuropathy, we investigated the relationship between NIDDM patients with diabetic autonomic neuropathy and QTc interval prolongation suggested to be induced by imbalance of sympathetic innervation on heart. Patients with NIDDM (n=60, age=61.18±10.4 yr), nondiabetic controls(n=50, age=59.3±7.36 yr)were included in this study. Performing standard cardiovascular autonomic function test (deep breathing test, lying to standing test, cough test, postural BP drop test), sixty NIDDM patients are divided into 3 groups (group I :normal n=3, II :borderline n=10, III :abnormal n=47)by the degree of diabetic autonomic neuropathy.We measured QT,QTc interval and QT dispersion in each diabetic group and nondiabetic control subjects. Statistically significant difference was observed in QTc interval and QT dispersion between diabetic and nondiabetic control group as followings ; Patients group QTc interval 435.7±37, controls 418.6±34 (msec) (p=0.015), QT dispersion 48.43±9.332, 39.41±6.277 (msec) (p=0.001) respectively. Furthermore, significant difference was observed in comparing three diabetic groups. These data provide further evidence of a relationship between the presence and severity of diabetic autonomic neuropathy and degree of QTc interval and QT dispersion prolongation.We suggest this QTc interval, QT dispersion prolongation may offer relatively prospective means of estimating diabetic autonomic neuropathy in patients with NIDDM.

1816

INSULIN RESISTANCE IN CORONARY ARTERY DISEASES AND CEREBRAL INFARCTION.

Y.Harano, M.Suzuki, A.Kanazawa, K.Ryomoto, D.Zhao and K.Shinozaki*. Dept. Atherosclerosis, Metab & Clin Nut, National Cardiovascular Center, Osaka, Japan. *3rd Dept. Med., Shiga University of Medical Science, Otsu, Japan.

In non-diabetic, non-obese, physically active patients with coronary artery diseases(CAD) or atherothrombotic cerebral infarction(A-CI), insulin sensitivity determined by SSPG method using Sandostatin was significantly reduced(40-50%). CAD includes both vasospastic(VS) and obstructive coronary diseases(OAP). The insulin resistance correlated with the carotid intima-media thickness determined ultrasonographically in VSAP and the degree of stenosis in OAP respectively. In A-CI, the resistance is correlated with low HDL-chol and low ratio of LDL-chol/LDL-ApoB, indicating the preponderance of small dense LDL. Compensatory hyperinsulinemia has been observed and subjects with these vascular lesions suffer from vicious cycle of potentialing multiple risk factor syndrome as well as tendency for developing diabetes. Efforts to maintain normal insulin sensitivity are particularly important to correct the vicious cycle and to prevent the initiation as well as progression of coronary and atherothrombotic cerebral diseases.

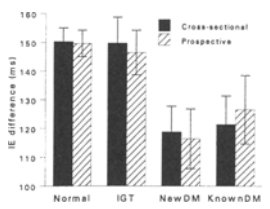
1817

HYPERGLYCEMIA, DIABETES AND AUTONOMIC CARDIAC DYSFUNCTION.

R.P. Stolk, M.C. de Bruyne, and D.E. Grobbee.
Department of Epidemiology, Utrecht University & Department of Medical Informatics, Erasmus University Rotterdam, The Netherlands.

We studied the association between glucose and autonomic cardiac function in a sample of 774 participants of the Rotterdam Study, a population based prospective cohort study. An oral glucose tolerance test was performed at baseline and at the follow-up examination after 2.1 years (range 1.2-4.5). Cardiac autonomic function was assessed at follow-up by the heart-rate responses on deep breathing and standing. At baseline the mean age was 64.4 years (SD 5.2), and random serum glucose 7.1 mmol/l (2.7). Mean fasting glucose at follow-up was 6.2 mmol/l (1.7).

Glucose at baseline was associated with a lower response to deep breathing: the age-adjusted regression coefficient was -3.5 mmol/l per millisecond difference (95%CI -6.2; -0.8, $p<0.01$). The association with glucose at follow-up was -5.8 mmol/l per ms (-10.0; -1.5, $p<0.01$). The same trends were observed for HbA1c, while insulin level showed no association, nor at baseline or follow-up. The age-adjusted difference during deep breathing according to glucose tolerance (normal, impaired, diabetes) is given in the figure. In subjects with diabetes cardiac autonomic function was significantly impaired compared to normal subjects ($p<0.01$). This was more evident in the cross-sectional analyses. All associations remained after adjustment for gender, body mass index or blood pressure. When using the heart rate responses after standing essentially the same results were obtained.



These results indicate that cardiac autonomic dysfunction, while associated with hyperglycemia, is the same in newly diagnosed as treated diabetes patients, suggesting that it is related to concurrent glucose levels.

1818

ESTIMATED PREVALENCE OF DIABETES MELLITUS IN ACUTE CEREBROVASCULAR DISEASE PATIENTS: THE CAPTURE-RECAPTURE METHOD

I Lessa, PA Mangieri, E A Reale, J Melo. Instituto de Saúde Coletiva, Federal University of Bahia, Brazil

Diabetes Mellitus (DM) has a high prevalence and is an important risk and prognostic factor for Cerebrovascular disease (CbVD) in Salvador. It is widely underestimated in acute CbVD patients. On the other hand, CbVD is the main cause of death in Brazil and Salvador has the highest standardized incidence rate reported in western countries. The study aim was to estimate the "prevalence" of DM among incident cases of CbVD using the capture-recature (C-R) method. Data sources: lab/ glycemia results for CbV patients and; medical records of CbV patients for identification of self-reported history of DM. Criteria for DM lab-test: glycemia value ≥160mg/dl for patients with either negative, positive out of treatment or unknown reported history of DM and any glycemic value for those with self-reported DM with comproved past or present treatment. Chapmann C-R method and 95% C I were used. The medical records data were corrected by excluding 6.6% of cases (probability of a DM positive history in nondiabetic CbVD patient). The C-R method was applied to the 3 medical assistance sectors. Results and conclusions: Among 1227 CbVD patients there were 331 DM cases in both sources and for the 3 assistance sectors. This figure corresponds to 70% of ascertainment of the estimated uncorrected value (n=470, CI: 406-538). The corrected identifyed value was 324 and the estimated = 454, CI= 399-509. The uncorrected and corrected "prevalences" were 27% and 26,4% and its estimated correspondents = 38.3%(CI: 33-44) and 37%(CI: 32.5-41.5). The lowest ascertainment probability was found in the public assistance sector Since the frequencies of questioning for DM and Lab-tests for glycemia were lower than those expected (≅ 100%), the C-R method was of great value to showing a) the expected "prevalence" of DM among CbVD patients; b) the quality of medical assistance for CbVD/DM inpatients; c) and to allert to possible unnecessary death in unrecognized and untreated diabetic patients with CbVD. As prevalence of DM and incidence of CbVD increase with age, this may explain the high "prevalence" of DM among CbV patients.These results may be used to the improvement of DM and cardiovascular disease programs and the quality of medical assistance.

1819

FACTORS THAT INFLUENCE THE DEVELOPMENT OF AUTONOMIC NEUROPATHY IN DIABETES MELLITUS: A HEART RATE VARIABILITY STUDY

H.Kudat[1], Ş.Demirel[1], K.Karşıdağ[2], V.Akkaya[1], A.B.Sözen[1], M.Özcan[1], D.Atılgan[1], İ.Satman[1], Ö.Güven[1], M.T.Yılmaz[2], F.Korkut[1]. [1]Istanbul University School of Medicine Cardiovascular Research Center, [2]Division of Diabetes, Department of Internal Medicine, Istanbul, Turkey.

One of the effect of diabetes on cardiovascular system with implications on prognosis is its potential to create autonomic neuropathy. For this reason 24 hour Holter recordings were examined for heart rate variability, a method gaining acceptance in the diagnosis of autonomic neuropathy. The study group comprising of 8 Type 1 and 19 Type 2 diabetic, 13 male and 14 female, with a mean age of 47.5± 10.9 (Range 30-70) (Group 1) was compared to 19 healty controls, 7 male, 12 female with a mean age of 47.8± 10.4 (Range 20-60)(Group 2). Age is not significantly different between groups. The heart rate variability parameters of the groups and their significance are as follows;

	Group 1	Group 2	p value
Mean heart rate	78.96 ± 8.80	77.16 ± 6.60	0.45
Mean NN	762.11 ± 86.1	786.16 ± 67.7	0.31
SDNN	102.81 ± 45.3	152.10 ± 42.9	0.001
SDANN	94.22 ± 41.96	138.36 ± 42.24	0.001
SD	35.44 ± 16.70	61.42 ± 15.93	0.0001
rMSSD	18.44 ± 8.68	35.42 ± 14.08	0.0001
pNN50	3.08 ± 4.42	11.19 ± 8.61	0.001

This results show that spectral analysis parameters of sympathic and parasympatic nervous system activity is decreased in diabetic patients compared to controls. There is no correlation between glycaemic control as assessed by HbA1c and heart rate variability parameters. When diabetic patients were grouped according to presence or absence of diabetic complications, patients with diabetic retinopathy and to a lesser extent patients with diabetic nephropathy and neuropathy formed a subgroup of diabetics with more severely affected heart rate variability parameters. We concluded that heart rate variability parameters for symphatic and parasymphatic nervous system activity were impaired in diabetics and this impairment was most excessive in the subgroup of diabetic patients with retinopathy.

1820

RELATIONSHIP BETWEEN CAROTID ARTERY PLAQUE AND CEREBRAL INFARCTION IN PATIENTS WITH NIDDM

T.S.PARK, K.H.LEE and H.S.BAEK

Chonbuk National University Medical School, ChonJu, Korea

The aim of this study was to investigate the relationships between extracranial carotid artery plaque and cerebral infarction using non-invasive B-mode ultrasonography brain computed tomography and MRI in patients with NIDDM. Ultrasound high resolution B-mode imaging of carotid arteries was conducted on cerebral infarction patients with NIDDM and without NIDDM, to define the plaque of carotid artery. Concurrently, total cholesterol, HDL cholesterol, serum triglyceride and HbA_{1c} were measured by standard laboratory technique. The incidence of cerebral infarction was increased in relation to extracranial carotid artery plaque existence. The frequency of carotid artery plaque was higher than in NIDDM patients with cerebral infarction(63% vs 35%, $p<0.05$). There was no significant difference in existence of carotid plaque in NIDDM patients and non diabetic patients with CVD. Multiple regression analysis showed that development of cerebral infarction in NIDDM patients was positively related to hypertension, hypercholesterolemia and carotid plaque. Existence of carotid plaque is closely related to cerebral infarction. So early detection of extracranial carotid plaque by B-mode ultrasonography is very useful to predict cerebral infarction in NIDDM patients.

1821

JUST TO FIND THE BEST NON-INVASIVE METHOD WHILE COMPARING CARDIAC STATUS IN NIDDM AND IDDM!

N.Keser,M.Özyazar,F.Ayan,S.Çelebi,N.Sırmacı and N.Barlaçık. University of Istanbul,Cerrahpaşa Medical Faculty,Istanbul-Turkey

The aim of the study is to find the best non-invasive method to compare cardiac status in diabetics.15 patients with IDDM and 14 patients with NIDDM (without hypertension or any other cardiac problem)are compared according to following parameters:Age,duration of DM, HbA1C, albuminuria, lipid profile; Echocardiographically obtained Left Ventricular Mass Index (LVMI reflects LV hypertrophy),Ejection Fraction (EF reflects systolic function),E/A ratio (reflects diastolic function obtained from doppler flow velocities of the mitral valve,where E=peak LV inflow in early diastole and A=flow in late diastole with atrial filling), Late potentials (including t-QRS, RMS, HFLA parameters obtained from Signal Averaged ECG which is a strong predictor of arrhythmia) and QT-dispersion (QTd) in ECG that is claimed to be related to autonom neuropathy and reflect high risk of sudden death.(QTd=QTmax- QTmin).

	age ** (year)	LVMI (N<90 g/m2)	E/A * (N>1)	QTd (N<40ms)	Albuminuria(RIA) (N<20mic/min)
NIDDM	57.1∓7.8	126∓34	0.87∓0.27	37.8∓23.3	176.4∓30.6
IDDM	27.6∓3.7	118.9∓47.9	1.25∓0.32	50∓27.08	288∓367

	Late potentials (LP) t-QRS (N<114 ms)	RMS voltage (N>20microvolt)	HFLA (N<38ms)
NIDDM	98.4∓8.9	76.5∓29.2	25.7∓8.6
IDDM	101.3∓6.7	91∓17.2	24∓5.9

****=p<0.001 *=p<0.05**

Although both groups had increased LVMI, there was no difference between the parameters except for advanced age and diastolic dysfunction (E/A <1) in NIDDM.Albuminuria was correlated to LVMI(p<0.05) and LP in both groups and to QTd in IDDM.So,NIDDM carries more risk for diastolic heart failure and both groups hold the same risk for arrhytmia and sudden death which are correlated to albuminuria.Serial follow up by echocardiography and albuminuria especially in NIDDM and by QTd mainly in IDDM will be convenient.

1822

CAROTID ARTERY STIFFNESS IN MICROALBUMINURIC IDDM.

J. Lambert, R.A. Smulders, M. Aarsen and C.D.A. Stehouwer. *Dept. of Internal Medicine, Academic Hospital Vrije Universiteit and Institute for Cardiovascular Research, Vrije Universiteit, Amsterdam, the Netherlands.*

In IDDM microalbuminuria is a risk factor for the development of atherosclerotic disease. We investigated arterial distensibility, as a marker of functional or structural vessel wall properties, of the common carotid artery in 24 microalbuminuric (MA) and 53 normoalbuminuric (NA) IDDM patients, and in 54 healthy control subjects (C) comparable for gender, age, number of smokers and lipids. The IDDM patients were all normotensive and had no signs of clinical vascular disease. Arterial distensibility was measured with an echo-doppler method (Wall Track System). The distensibility coefficient (DC) was different between the groups (MA: 21.6[SD7.5], NA: 24.8[5.9], C: 25.9[5.7] 10^{-3}/kPa; P=0.018), based on lower values in MA as compared to both other groups. In addition a difference in body mass-index (MA:24.4[2.6], NA:23.8[2.7], C:22.1[2.1]kg/m^2; P=0.0001), HbA1c (MA:8.8[1.3], NA:7.9[1.2], C:4.8[0.3]%; P<0.0001), mean arterial pressure (MAP) (MA:93.5[7.9], NA:87.0[7.9], C:83.9[7.3]mmHg; P<0.0001) and end-diastolic diameter (D) (MA:6.54[0.86], NA:6.31[0.69], C:6.03[0.43]mm; P=0.0037) was observed. Multiple regression analysis showed that only MAP, age and gender were significant determinants of the DC. After taking these variables into account, there was no difference left between the DC of the three groups.

Conclusions: The distensibility of the common carotid artery is decreased in microalbuminuric, normotensive IDDM patients, as compared to normoalbuminuric IDDM patients and healthy control subjects . Because the groups were comparable for the significant determinants of DC with exception of the MAP, it is suggested that the higher blood pressure in the microalbuminuric patients might be the main cause of the difference in DC, which seems not to be caused by a change in vascular wall properties itself.

1823

METFORMIN INCREASES TOTAL SERUM HOMOCYSTEINE LEVELS IN NON-DIABETIC MALE PATIENTS WITH CORONARY HEART DISEASE.

SM Carlsen,[a] I Følling,[a] V Grill,[a] KS Bjerve,[a] J Schneede[b] and H Refsum.[b] University Hospital of Trondheim,[a] Trondheim, Norway, and University of Bergen,[b] Bergen, Norway.

Background: The metabolism of the CVD risk factor homocysteine (Hcy) depends on the vitamins B_6, B_{12} and folate. The peroral antidiabetic drug metformin reduces serum vitamin B_{12} levels, and possibly also serum folate. **Aim of the study:** To investigate whether metformin treatment affects serum total Hcy (tHcy) levels. **Design:** 60 non-diabetic male patients with cardiovascular disease were included in an open, prospective, randomised study. During a four week run-in period, patients were given diet and lifestyle advice, and treated with lovastatin 40 mg/day. At week 0 metformin in doses up to 2000 mg/day was given to half the subjects. Lovastatin treatment was continued throughout the study in both the metformin group (M) and the control group (C). Total Hcy (tHcy), vitamin B_{12}, folate and methylmalonic acid (MMA) were measured. **Results:** Values given as mean ± SEM:

Variable	Treatment group	Week 0	Change week 0 to 12	Metformin effect (%)	p	Change week 0 to 40	Metformin effect (%)	p
tHcy (µmol/L)	C	12.8 ± 0.5	-0.4 ± 0.3			-1.6 ± 0.3		
	M	12.5 ± 0.5	0.5 ± 0.3	7.2	0.02	0.0 ± 0.5	13.8	0.02
Vit B_{12} (pmol/L)	C	362 ± 16	6 ± 7			32 ± 8		
	M	380 ± 16	-45 ± 10	-13.4	0.0001	-34 ± 16	-17.7	0.000
Folate (nmol/L)	C	8.30 ± 0.54	0.40 ± 0.43			1.14 ± 0.58		
	M	8.66 ± 0.57	0.24 ± 0.44	-2.0	ns.	0.50 ± 0.33	-8.0	0.06
MMA (nmol/L)	C	112 ± 12				1 ± 11		
	M	122 ± 13				1 ± 14	0.0	ns.

Conclusion: Metformin treatment increases total homocysteine levels. Since MMA levels are unaffected, it remains an open question whether the increase in tHcy levels is secondary to reduced vitamin B_{12} levels, folate levels, or a combination of both.

1824

CAROTID INTIMA-MEDIA THICKNESS IN SUBJECTS WITH IMPAIRED GLUCOSE TOLERANCE

K.Keven, S.Güllü, M A.Gürses, S.Aytaç, G. Erdoğan, N. Kamel and V.T. Cesur. University of Ankara, Ankara, Turkey.

Cardiovascular mortality was significantly higher in subjects with impaired glucose tolerance, although it has not been adequately explained by known risk factors. Since abnormal vascular wall structure could be a factor, we studied the carotid intima-media thickness (CIMT) which has shown to have an association with the grade of atherosclerosis, in 23 non-smoking glucose intolerant and 29 non-smoking normal subjects. Both glucose intolerant and normal subjects were similar in age (44±9 vs 39±9), body-mass index (29±4.5 vs 27±5), LDL (122±19 vs 115±22 mg/dL), HDL-cholesterol (41±5 vs 42±4 mg/dL), triglyceride (129±50 vs 127±45 mg/dL), and blood pressure (118±15 vs 121±16 mmHg systolic, 74±6 vs 77±8 mmHg diastolic). There were no significant statistical differences between groups. Left and right carotid arteries were scanned by a high resolution B-mode ultrasonography using a 7.5 MHz transducer. Three measurements of the intima media complex were taken from the far wall of the right and left common carotid artery, two cm proximal to the bulb. The average of the six measurements were evaluated. We found that impaired glucose tolerant subjects had significantly higher carotid intima-media thickness than the normal subjects (0.76±0.08 and 0.68±0.08 mm, respectively, $p<0.05$). According to our data, although both groups were similar for the risk factors of atherosclerosis, CIMT was significantly increased in glucose intolerant subjects. In conclusion, it can be suggested that increased CIMT may be an early evidence of the future macrovascular disease even in glucose intolerant subjects.

1825

ANTITHROMOGENIC DRUG RETARED PROGRESSION OF SILENT CEREBRAL INFARCTION (SCI) AND CAROTID ATHEROSCLEROSIS

S. Yoshida[1], T. Shinoda[1], N. Hakui[1], M. Kodama[2], T.Tsujino[2], Y. Yamasaki[2]
[1]Bell-Land Hospital, [2]Osaka University School of Medicine, Osaka, Japan

AIM: Diabetics and IGT subjects showed advanced atherosclerosis and higher incidence of cardiovascular diseases. However, there were no medication reported to be effective in attenuating atherosclerosis in diabetics.

METHODS: A controlled randamized open trial was done on 53 subjects with IGT and NIDDM. After baseline examination of carotid arterial wall thickness (IMT) and number of T2-enhanced high intensity area (HIA) (diameter $\geq$ 5mm) diagnosed by a radiologist on MRI brain imaging, an antithrombogenic drug, cilostazol (100mg /day), was given for following 2 years on 26 subjects (cilostazol group). The remaining 27 subjects were not given with any anti-thrombogenic drugs (non-treatment group). After 2 years, IMT and number of HIA were re-examined by the same physician.

RESULTS: At baseline examination, both groups showed no significant differences in fasting plasma glucose level (111 ± 25 vs 125 ± 37 mg/dl), HbA1c (6.4 ± 1.5 vs 7.0 ± 1.8 %), fasting plasma insulin concentration, systolic and diastolic blood pressure, serum lipid profiles, number of smokers, IMT, and number of HIA. During follow-up period, annual increase rate of IMT was significantly suppressed in cilostazol group, compared with non-treatment group (0.016 ± 0.020 vs 0.070 ± 0.040 mm/yr, $p<0.05$). In non-treatment group, averaged number of HIA increased from 0.34 ± 0.11 to 0.91 ± 0.22. In cilostazol group, increase in number of HIA significantly ($p<0.001$) was suppressed (from 0.76 ± 0.28 to 0.91 ± 0.32).

CONCLUSION: Two-year administration of cilostazol effectively retarded progression of carotid wall thickness and SCI in diabetics and IGT subjects. IMT and number of HIA are shown to be clinically useful parameters for evaluating the effectiveness of medication on diabetic macroangiopathy.

PS 47

Diabetic Foot – Pathogenesis, Risk Factors and Prevention

1826

PREDICTORS OF THE VIBRATION PERCEPTION THRESHOLD RISE TO LEVELS AT RISK FOR DIABETIC FOOT ULCERATION.

J. Anglada, L. García-Pascual, M. Balsells, C. del Pozo and M. Millán.
Endocrinology Dep. Hosp.Mútua Terrassa.University of Barcelona (Spain)

Our aim was to assess predictive factors associated to a rise in vibration perception threshold (VPT) to levels at risk for foot ulceration (VPT≥30V,Biothesiometer). A three years follow up, 325 diabetic patients (76% women, age 62±11 y, diabetes duration 13.7±6 y) was made. After 3 years, VPT increased to values ≥30 in fifty out of 188 patients who had VPT values <30 at the initial examination. Patients who shifted into VPT≥30, were older (63.6 ±8.5 vs 59±11.3 y; p<0.05), had longer diabetes duration (15.5±2.5 vs 13.9±6.5 y; p<0.01), and had previous lower ankle/braquial doppler index (ABI) (1.07±0.9 vs 1.13±0.16; p<0.05), higher VPT (19.5±2.4 vs 18.2± 4.4; p<0.05), more clinical ischemia (ischemic pain and pulses) (46 vs 25.7%; p<0.01) and more clinical neuropathy (symptoms and Rydel tuning fork test) (44 vs 28.5%; p<0.05) than those whose VPT remained <30 V. No differences were found in sex, height, HbA1c and creatinine levels. In a multiple logistic regression analysis, only clinical ischemia, ABI and clinical neuropathy remained as independent factors associated to a VPT rise. We conclude that about 30% of diabetic patients experience a short-medium term VPT clinically significative change, being peripheral vascular disease an important predictive factor for VPT deterioration.

1827

NITRIC OXIDE IN THE PATHOGENESIS OF DIABETIC FOOT ULCERS

Appleton I, Jude E*, Boulton A* and Ferguson M.W.J. School of Biological Sciences, The University of Manchester and Department of Medicine / Diabetes, Manchester Royal Infirmary*, Manchester, U.K.

Diabetic foot ulcers are a major clinical concern both in terms of cost and debility to the patient and have been estimated to affect approximately 2% of the diabetic population. The condition is more prevalent in males than females (2:1) and in the most severe cases amputation may be necessary. In view of the large numbers of the population affected by this condition an understanding of the basic mechanisms involved in the pathogenesis of the disease is vital. Nitric oxide (NO) is a free radical involved in host defence and vasodilatation of vascular smooth muscle. Recent evidence has implicated NO in the tissue destruction of a number of diseases. In this study we have therefore investigated the role of NO in diabetic foot ulcers. Age matched (40-60yrs) control (n=12), diabetic (n=22) and diabetic foot ulcer patients (n=11) were used in this study. Patients with evidence of predominant peripheral vascular disease, severe uncontrolled hypertension and nephropathy were excluded from the study. 6ml blood samples were taken and plasma nitrite levels determined by the Griess reaction. Results showed a significant (P<0.0001) decrease in plasma nitrite levels in diabetics (4.5±0.7μM) compared to controls (12.7±1.7μM). In contrast, diabetic foot ulcer patients had a significantly (P<0.05) elevated plasma nitrite in comnparison to diabetics. (P<0.05). Furthermore, there was a significant difference (P<0.01) between male diabetic patients (6.4±0.75μM nitrite) and females (1.8±1.7μM nitrite). The finding of raised plasma nitrite in ulcer patients may implicate NO in the pathogenesis of diabetic foot ulcers. Furthermore, males were found to have higher nitrite levels than females, which may help to explain the higher incidence of diabetic foot ulcers in men.

1828

DIABETICS WITH FOOT LESIONS AND AMPUTATIONS IN REGION OF „HORNÝ ŽITNÝ OSTROV" IN YEARS 1993-95.

J.Vozár, J.Adamka,*P.Holéczy, and R. Šeilingerová. Internal Dept. Spec.in Diabetes, Šamorín,and*Dept.of Surgery, ŽnSP, Bratislava, Slovak Republic.

We evaluated in a population based prospective study the incidence and prevalence of diabetics with foot lesions and amputations after establishment of Internal department specialized in diabetes and podiatric clinic in our region in a year 1992. The number of registered diabetics (RD) was 910, 1098,and 1205 (3,0, 3,6, and 3,9%) between 1993 and 1995 out of 30 592 total population (TP).In the last three years prevalence of diabetics with foot lesions (Wagner grade 2-5) increased from 62 to 98 /100 000 of TP (from 2,0 to 2,5% of all RD) and incidence of diabetics with new lesions decreased from 49 to 26/100 000 of TP (from 1,6 to 0.6 % of all RD). The incidence of repeated lesions also decreased. The prevalence of patients with minor amputations(below Chopart) increased from 20 to 29 /100 000 of TP (from 0,7% to 0,7% of all RD) while the number of patients with major amputations (Chopart and above) decreased from 20 to 10/ 100 000 of TP (from 0,7 to 0,2% of all RD). The incidence of patients with minor amputations increased from 3 to 10 /100 000 of TP (from 0,1 to 0,2% of all RD) while the number of patients with major amputations decreased from 7 to 0 /100 000 of TP (from 0,2to 0% of all RD). In conclusion the better educational and foot care in our region substantialy decreased the number of patients with new foot lesions and also a number of patients with major amputations.

1829

AUTOREGULATION OF THE SKIN MICROCIRCULATION IN HEALTHY SUBJECTS AND DIABETIC PATIENTS WITHOUT AND WITH VASCULAR COMPLICATIONS.

T. KHODABANDEHLOU[1] ; C LE DEVEHAT [1 2] ; M. VIMEUX [2]
[1] Unité de Recherches d'Hémorhéologie Clinique ; C.H. 58000 NEVERS France - [2] Service Diabétologie-Endocrinologie-Nutrition, Centre Hospitalier 58000 NEVERS France

The skin microvascular autoregulatory capacity was investigated in 14 healthy subjects, 21 diabetics without vascular complications and 29 with vascular complications. To assess this capacity, changes in skin blood flux (SBF) were recorded : ▪ on the pulp of the 2nd finger during a 30-second venous stasis induced by inflating a cuff at the base of the same finger to 50 mmHg ; ▪ from the dorsal surfaces of the foot and big toe during a 3-minute standing ; ▪ from the dorsal and plantar surfaces of the big toe during a passive lowering of either leg from the hip, so that the foot was 50 cm below the midaxillary line. SBF was measured at skin temperature, after acclimatization in 23±1°C, by laser doppler fluxmetry (PF4 Perimed). In healthy subjects, the same degree of microvascular vasoconstriction, i.e.same reduction in SBF, was observed irrespective of the site of measurement and the procedure used. In diabetic patients, the vasoconstriction elicited, on the pulp of the finger by venous stasis was normal By contrast, the vasoconstrictor responses to standing or lowering of the leg were impaired. In fact, there was in some patients, an increased SBF instead of a decreased one during standing or lowering of the leg. On average, a significant loss of the skin microvascular vasoconstriction during standing or lowering the leg was observed even in patients without complications. The loss was, however, more marked in patients with complications. These findings indicate that an early alteration of autoregulation is present in the skin microvasculature of diabetic feet, and is related to the diabetic disease rather than to late diabetic complications. The inability of diabetic skin microvasculature to respond normally to postural changes may be an important factor initiating the development of the foot complications.

1830

EVALUATION AND CLASIFICATION OF THE DIABETIC FOOT IN A RURAL COMUNITY OF COSTA RICA

Gamboa A.Y., Salazar S., Mora C., Arguedas C. Intern Medicine Hospital México, San José, Costa Rica.

Introduction: The diabetic foot is a public health problem, we know little about this problem in the rural areas. This study analyze this problem in the rural community of Costa Rica, Buenos Aires de Palmares.

Materials and Methods: From the data collected by EBAIS (Basic Equipment for Integrated Health Care), the diabetic feet were examined with the PATON-A scale. The metabolic control was assessed by the fasting glycemia media.

Results: 77 patients (154 feet) were examined, we found 74 feet (48%) to be green (low risk), 72 (46.8%) were yellow (moderate risk) and 8 (5.2%) were red (high risk). In 58 patients both feet were classified in the same category, in 30 both feet wew green, 13 had one green and the other yellow. The 8 red feet: 2 patient had both red, 5 had the other foot yellow and 1 had it green.

Table 1.

Feet Classifications and years of evolution of the Diabetes disease

Years of Decease	No. of feet	Feet classification		
		Green	Yellow	Red
0-4	62	42	20	0
5-9	42	16	21	1
10-14	28	12	12	4
15	20	2	15	3

All patients with feet had glycemia under 140 mg/dl and all with red feet were over 140 mg/dl.

Conclusions: The more severe the classification of the diabetic foot the worse glucemic control and the longer evolution of the disease.

1831

THE ACUTE AND LONG-TERM EFFECTS OF ANTIPLATELET AGENTS ON TRANSCUTANEOUS OXYGEN TENSION IN DIABETIC PATIENTS

C. H. Tseng and T. Y. Tai. National Taiwan University Hospital, Taipei, Taiwan.

To examine the acute and long-term effects of two antiplatelet agents, aspirin and ticlopidine, on transcutaneous oxygen tension ($PtcO_2$) in non-insulin-dependent diabetic patients, 20 subjects (11 wonen and 9 men, aged 65.8±9.5 years) with baseline $PtcO_2$ below 60 mmHg measured on the pulp of the right big toes, were recruited. The acute effects of both drugs were tested by measuring $PtcO_2$ before and continuously for 2 hours after taking either aspirin 100 mg or ticlopidine 250 mg; and then crossed over to the other drugs 2 weeks later. Long-term effects were evaluated after randomly dividing the subjects into 2 groups taking either aspirin 100 mg qd or ticlopidine 250 mg bid for 3 months. The results are shown in Table 1. This study showed beneficial effects of both aspirin and ticlopidine on $PtcO_2$ in diabetic patients after long-term usage, but no acute effects were observed.

Table 1. Acute and long-term effects of antiplatelet agents on transcutaneous oxygen tension

Effects evaluated		Antiplatelet agents	
		Aspirin	Ticlopidine
Acute	Before	27.9±6.9(n=17)	29.2±13.2(n=20)
	After	27.7±7.7	28.9±12.6
	p	NS	NS
Long-term	Before	28.9±8.0(n=8)	28.7±8.6(n=10)
	After	40.0±14.3	39.3±12.0
	p	< 0.05	< 0.05

Data expressed as mean ± SD and analyzed by paired t-test.
NS= non-significant

1832

CLINICAL OBSERVATION OF THE DISTRIBUTION OF FOOT ULCERATIONS IN ASIAN PATIENTS.

D.C. du PREEZ AND J.WALSH. TAN TOCK SENG HOSPITAL, SINGAPORE.

In June 1996 the Podiatry Clinic at Tan Tock Seng Hospital began to collate information on new NIDDM patients with foot ulcerations. Between June and November 1996, 62 patients were registered. Of the 62 patients 14 had more than one foot ulcer, 15 had an amputation and four had neuropathic osteoarthropathy. The aim of this study was to identify ulceration distribution of the foot and link ulcer formation with footwear and other cultural aspects. Of the 62 patients screened 38 (61.3%) were females and 24 (38.7%) male. Of the patients 47 (75.8%) Chinese, 11 (17.7%) Indian and 4 (6.4%) Malay's registered. The mean age was 57.7 years (range 42-85). In total 76 ulcers were noted, 18 (23.7%) over the plantar metatarsal area, 14 (18.4%) on the plantar surface of the hallux, 12 (15.8%) under the first metatarsal head, 10 (13.2%) on the apex of the digits and 8 (10.5%) on the dorsum of the digits. The other 14 (18.4%) were distributed over the remainder of the foot. A majority of the ulcers (71%) were located on the plantar aspect of the foot and forefoot region. Of the 62 patients 56 (90.3%) walked barefoot at home and at temple and 51 (82%) had been using incorrect footwear, such as slippers with interdigital thongs or shoes that are ill fitting, have insufficient cushioning or are worn out , adversely effecting patient foot biomechanics . From this observation it is felt that with better education and understanding of footcare and footwear many foot ulcerations are preventable in the Asian population.

1833

INCREASED LACTATE PRODUCTION IN CHRONIC DIABETIC WOUND FIBROBLASTS SHOWING DECREASED CELLULAR PROLIFERATION

K. Hehenberger*, J. Heilborn, K. Brismar*and A. Hansson***
***Department of Endocrinology, **Department of Dermatology and Venerology, Karolinska Hospital, Stockholm, Sweden**

In non-insulin dependent diabetes mellitus (NIDDM), insulin resistance is caused by primary genetic and secondary metabolic factors. Hyperglycaemia on its own induces insulin resistance by decreasing the numbers of glucose transporters, but also by affecting the insulin receptor. There is a high risk of amputation due to chronic diabetic foot ulcers possibly explained by the lack of granulation tissue formation caused by impaired fibroblast activity. Hyperglycaemia increases nonoxidative glycolysis, leading to increased lactate release. Patients with physiologic hyperinsulinemia show increased lactate efflux peripherally. Fibroblasts derived from chronic wounds in NIDDM-patients have decreased proliferation as have normal fibroblasts grown in high glucose. In this study we wanted to further explore the possible mechanisms explaining these observations. Fibroblasts were derived from normal uninjured skin and chronic NIDDM wounds. Cellular proliferation was measured by a fluorometric method using Hoechst dye. After the addition of NIDDM fibroblast conditioned media to normal fibroblasts, it was found that their proliferation was significantly decreased. Conditioned nedia from NIDDM fibroblasts showed significantly higher lactate levels compared to conditioned media from normal fibroblasts. D- but not L-lactate caused a dose-dependent decrease in the proliferation of normal fibroblasts. There is an increase in lactate level in the medium when normal fibroblasts are cultured in high glucose. In conclusion, the decreased proliferation in fibroblasts derived from chronic NIDDM wounds and normal fibroblasts cultured in high glucose is associated with altered glucose utilisation, and more specifically increased non-oxidative metabolism. We suggest that excessive lactate production may be of importance for the impaired healing process seen in the chronic diabetic wound.

1834

EPIDEMIOLOGICAL SURVEY FOR THE DETECTION ON NON-TRAUMATIC LOWER EXTREMITY AMPUTATIONS IN DIABETIC PATIENTS IN THE UMBRIA REGION (ITALY)

L. Scionti, R. Norgiolini, G. Luca, F. Porcellati, A. Nicolucci and M. Massi Benedetti on behalf of Cooperative Study Group of "Progetto Umbria Diabete", Department of Internal Medicine, Endocrine and Metabolic Sciences, University of Perugia, Italy

One of the five year targets of the Saint Vincent Declaration (SVD) is to reduce by 50% non-traumatic lower extremity amputations (LEAs) in diabetic patients. An epidemiological observatory has been created in our region and an epidemiological survey for the detection of all non-traumatic LEAs performed in Umbria was carried out by the Cooperative Study Group CSG) of the Progetto Umbria Diabete (PUD). The diabetic Centres of the region were involved in the study and an ad hoc protocol was developed to collect data; the registries of all surgical (n°23) and Orthopedics (n° 11) divisions were used to identify the subjects. Data were stored and analyzed by our Department. In 1991 196 LEAs (n° 106 in diabetics and n° 90 in normal subjects) were performed in Umbria region. The incidence of LEAs in diabetic subjects was 42.16/10000/year while in non diabetic was 1.77/10000/year. These results, quite similar to those reported in the literature, are based upon a previous epidemiological survey which indicated a prevalence of known diabetes mellitus of 3.1% in our region. According to the surgical records peripheral vascular disease was the major cause of LEA for both diabetic and non diabetic patient. However the infection of bones and/or soft tissue was present in at least 25% of LEAs carried out in diabetic patient, whereas this happened only in 11% of LEAs in non diabetic subjects. With the same methodology we collected information related to diabetic and non diabetic patients who underwent LEA in 1992 (n°=204), 1993 (n°=200) and 1994 (n°=147). These results indicate a decrease of LEAs by 25% with a similar decrease of incidence both in diabetics and non diabetics. These figures also indicate: a) the usefulness of ad hoc sensitization plans which were developed during the collection of the data, b) the possibility to reduce LEAs also in those areas which provides a baseline satisfactory quality of care, c) the effectiveness of tertiary intervention plans which non affected the glico-metabolic balance. The Cooperative Study Group of the PUD aims to a further reduction of the incidence of LEAs through primary and secondary intervention.

1835

BETA-1,3-D POLYGLUCOSE AND GROWTH FACTORS IMPROVE WOUND HEALING IN DIABETES MELLITUS.

M.Berdal, R.Seljelid and T.G.Jenssen, University of Tromsø, Tromsø, Norway.

Healing of diabetic wounds is delayed not only by neuropathic changes and local ischemia, but also by way of altered cellular mechanisms in the healing wound. During the early phase of the healing process the macrophages infiltrate the wound and take part in the inflammatory response by producing cytokines [e.g. Tumor Necrosis Factor-α(TNF-α)] and growth factors [e.g. Platelet-Derived Growth Factor (PDGF) and Insulin-like Growth Factor-1(IGF-1)]. Monocyte-macrophage dysfunctions such as reduced chemotaxis and inappropriate cytokine activity have been described in diabetes mellitus. Beta-1,3-D polyglucose is known to improve macrophage chemotaxis and secretory activity.The present study was undertaken to see if [a] β-1,3-D polyglucose and [b] PDGF +IGF-1 would improve wound healing. Cutaneous wounds were established on the back of either diabetic(C57Bl-db/db)- or non-diabetic (C57Bl-db/+)-mice. Five groups were studied: 1 db/db-mice with placebo wound treatment (n=7, average blood glucose(BG) 24,2±3,2 mmol/l), 2 db/db-mice treated with insulin (n=8, average BG 14,4± 4,5 mmol/l), 3 db/db-mice treated locally with PDGF +IGF-1 (n=7, average BG 22,6±3,1mmol/l) 4 db/db-mice treated locally with β-1,3-D polyglucose (n=7, average BG 29,5±1,9mmol/l) and 5 non-diabetic control mice without treatment (n=10, average BG 8,6±0,7 mmol/l). Biopsies from untreated diabetic wounds showed decreased infiltration of macrophages. The LPS-stimulated release of TNF-α from isolated peritoneal macrophages was only 1/8 of that from non-diabetic mice. The percentage reduction in wound area was after 10 days for group 1-5: 17±4, 18±7, 35±3, 37±7 and 58±5 % (mean±SEM, p<0,05). The corresponding results after 16 days were:64±6, 62±5, 73±3, 71±7 and 96±1 % (p<0,05). Conclusion: Macrophage function as judged by TNF-α release, is impaired in diabetes. Topic applications of β-1,3-D polyglucose or PDGF+IGF-1 in diabetic mice improve wound healing significantly despite serious hyperglycemia.

1836

DIABETIC FOOT IN PRIMARY HEALTH CARE. A COMMUNITY BASED STUDY.

Gimbert RM, Méndez A.,Llussà J Tomás P,Cano JF, Roura P and the GedapS Group Catalan Family and Community Medicine Society. Barcelona (Spain)

Objectives: To asses prevalence of diabetic foot in Non-Insulin-Dependent Diabetes Mellitus (NIDDM) in Primary Health Care and to analyze its relationship with clinico-biological variables.**Patients and Methods**.- Cross-sectional study carried out during 1993-94 in 76 PHC Centres, attending 1.256.193 adults . 2.595 NIDDM were selected by systematic sampling from 31.050 registered NIDDM . Each patient contributed once (either with an ulcer/lesion or amputatión) to this study.Results.-Diabetic foot was reported in 260 of the 2595 patients (10% , CI 95%: 8.85-11.15).Fifty-five patients (2.1% , CI: 1.55-2.65) had undergone amputation in any moment of his life. During the study 205 patients reported ulcers/lesions (7.9%, CI : 6.86-8.94). We found significant differences in the mean age (4.53 years higher in the Diabetic Foot Group (DFG), CI , 3.32-5.74), average diabetes evolution(2.75 years longer in DFG , CI: 1.64-3.87), microvascular complications prevalence(32.1% higher in DFG, CI:24.6-39.6), macrovascular disease (15.9 % higher in DFG CI, 9.6-22.2) and current level of HbA1c (0.55 % higher in DFG, CI 0.22-0.87).The number of current smokers was higher in DFG (5.1% , CI: 0.7-9.5), specially in men older than fifty (9.7%, CI:0.3-19.1).**Conclusions**.- Diabetic foot is close related with long standing diabetes (>10 years), poor glycaemic control and presence of any kind of micro/macro vas cular complications. Our data suggest the need to carry out specific interventions on foot care in all patients with more than 10 years of diabetes evolution.It is urgent to stress anti tobacco counseling in diabetics, specially in those with previous foot lesions

1837

MULTICHANNEL LASER DOPPLER PERFUSIN MEASUREMENTS IN DIABETIC PATIENTS.

M.Jasik, A.Liebert*, J.Juskowa, W.Karnafel and R.Maniewski*,
University School of Medicine, and Polish Academy of Sciences*, Warsaw, Poland

The purpose of this study was to investigate the skin microcirculation in patients with IDDM. The study group comprised 67 patients divided into four subgroups: 13 women and 11 men were heathy and had no family history of diabetes; 19 women and 24 men had IDDM. The studied measurements included 7 parameters determined during rest and postocclusive reactive hyperaemia. They were performed with multichannel laser Doppler fluxmetry using 10 surface probes localized in distal part of the lower limb. The most significant data localized the probe on toe and probe under the knee. The maximum of hyperaemic response (MAX) was significantly lower in the diabetic patients as compared to the healthy subjects ($p<0.01$). The time of peak flow (TM) was higher ($p<0.01$) in diabetic patients as compared to the control subjects. The half time of hyperaemia (TH) was significant longer ($p<0.05$) for diabetic groups.
Conclusion: the laser Doppler method is helpful to identify patients with risk development diabetic foot complications. The most valuable data is MAX, TM and TH; the best localization of the probe seem to be the most distal point of foot.

1838

ANALYSIS OF PATIENTS WITH DIABETIC FOOT ULCERS

Dr. Arif YÖNEM, Dr. Ömer AZAL, Dr. Saip TOPRAK, Dr. Ahmet ÇORAKÇI, Dr. Metin ÖZATA, and Dr. M. Ali GÜNDOĞAN. Gülhane Military Medical Academy, Department of Endocrinology, Ankara, Turkey.

Foot problems still remain one of the most common reasons for hospital admission among diabetic patients. The rate of lower limb amputations is 15 times higher in diabetic patients compared with non-diabetic patients. In the present study 62 patients (44 males and 18 females; mean age 61.8 years) with diabetic foot ulcers were analysed. The mean duration of diabetes was 14.1 years (1-35 years). Forthy-seven out of 62 patients were on oral antidiabetic therapy and 15 patients were on insulin therapy before admission to hospital. Physical and neurological examination of patients revealed that 90.3 % of patients have peripheric neuropathy, 51.6 % have nephropathy (>500 mg/gün proteinuria), 19.3 have chronic renal failure, 48.4 % have diabetic retinopathy, and 58.1 %have arterial hypertension. On admission to hospital, the mean fasting blood glucose level was 237.23 mg/dL (77-478 mg/dL), mean plasma cholesterol level was 191.13 mg/dL (115-274 mg/dL) and mean plasma triglyceride level was 136.55 mg/dL).Wagner classification of diabetic foot ulcers was as follows; 16 patients (30.6 %) were grade 2, 23 patients (37 %) were grade 3, 19 patients (29 %) were grade 4 and 2 patients were grade 5.The pathologic states that contribute to diabetic foot ulcers were neuropathy (34 %), vascular disease (15 %), and both of them (51 %). Gangrenous lesions occured 61 % on digits, 20 % on the heel, 12 % on the dorsa of feet, and 7 % at the metatarsal region.Infections of diabetic foot ulcers contained various types of bacteria.These were staphylococcus epidermidis, staphylococcus aureus. E coli, proteus species and group B streptococci Infection was present in 78 % of patients. In spite of infection, white blood cell count mildly elevated but the erythrocyte sedimantion rate was characteristically elevatad (mean 86.21 mm/h). Two- agent therapy with imipenem and metranidasole was initiated intravenously. The healing rates of ulcers was 78 % with antibiotic therapy and local wound care. Twenty-five out of (40 %) patients underwent amputation. Nine percent of these patients underwent second amputation in the following three years. This high rate of amputations may be due to later admission of patients to hospital. At the hospital staying time for the patients was mean 24.6 days (6-82 days). Diabetic foot ulcers are associated with a high degree of morbidity and mortality. It is possible to determine which patients are at risk for ulceration and to place them in education programs. When ulcers do occur, it is important to take a systematic approach to management.

1839

LASER DOPPLER EVALUATION OF MICROCIRCULATION IN THE EARLY DIABETIC FOOT SYNDROME

J.Walewski, J.Tatoń, A.Czech and R Kuczerowski. Department of Internal Medicine and Diabetology, Warsaw Medical School, Warsaw, Poland

Recognition of early microcirculatory disturbances in feet of diabetics may facilitate the pathogenic interpretation of the diabetic foot syndrome, selection the patients at risk of developing clinical problems and serve as the base for designing the preventive measures. This could be particularly true in diabetics with peripheral neuropathy.Therefore the study aimed at the assesment of functional parameters of the foot microcirculation in IDDM patients presenting signs of peripheral neuropathy but without any symptoms of the diabetic foot syndrome was undertaken. For comparision 20 IDDM subjects with the signs of peripherial neuropathy and 10 IDDM subjects without this complication were studied both clinically and metabolically. All of them were underwent the examination of microcirculation of the feet with the use of Laser Doppler Flowmeter. The parameters measured were: resting blood flow, post-occlusive , hyperemic response, flow change after heating to 44°C and the flow on dependency. In IDDM subjects with peripheral neuropathy the folowing functional microcirculatory abnormalities were found :delay and decrease in post-occlusive, hyperemic response (4.5 ± 1,8 s in neuropathic vs 8.5 ± 2,4 s in non-neuropathic IDDM), decrease of the peak flow (36 ± 7,6 PU in non neuropatic vs 18 ± 5,6 PU in neuropatic IDDM) and also impairment of the response of the skin floow to local heating peak flow at 44°C (48 ± 7,4 PU vs 12 ± 3,4 PU in non neuropatic IDDM). Also the veno-arteriolar reflex measured as the ratio of resting to standing flow in the feet skin was significantly decreased (80% in non-neuropathic versus 35% in neuropathic IDDM). Conclusion: Laser Doppler Flowmetry discovers the very early functional abnormalities in the microcirculation of the skin in the feet of IDDM with peripheral neuropathy, when none of the typical symptoms of the diabetic foot syndrom is present. It points to the significance of the relation between neuropathic and microcirculatory disturbances in the early pathogenesis of diabetic foot syndrom.

1840

PROFILE OF DIABETIC FOOT INFECTIONS IN A SEMI URBAN AREA IN A DEVELOPING COUNTRY.

H. YALAMANCHI, S. YALAMANCHI, DIABETIC CARE CENTRE, VIJAYAWADA, INDIA.

Aim of the study is to look at the incidence, risk factors, association of other complications and the outcome of foot infections in a Diabetic Clinic population. In India where bare foot walking is the norm, rat bites and ants are some causes for foot infection and people report quite late, a dedicated team approach has resulted in a excellent salvage of the limbs. In a restrospective analysis of 8000 people with Diabetes 5.17% presented with foot problems varying from trophic ulcers to Gangrene and all were between 30-60 years age group. Of them 64.2% were males and 35.8% were females. NIDDM contributed for 99% and IDDM 1%. Incidence of Neuropathy was 64%, Ischaemic Heart disease 33%, Nephropathy 19% and Retinopathy 14% Peripheral Vascular disease in 32%. Smoking, Hypertension and Lipid abnormalities as risk factors were seen in 26% 29% and 18% respectively. The healing rate was 89%, disarticulation of toes in 8% and Below Knee Ampulation was done in 3%. In conclusion the foot problems in Diabetics need a multidisciplinary approach alongwith aggressive glycaemic control, proper footcare and education to achieve higher success rates.

1841

HYDROSTATIC MEASUREMENT OF ARTERIAL BLOOD PRESSURE IN THE ISCHAEMIC DIABETIC LIMB

S.Morbach, and B.Hiller. Diabetic Foot Clinic, Marienkrankenhaus Soest/Germany,

Background: hydrostatic measurement of systolic arterial pressure in the big toe (hydrostatic toe pressure HTP) has recently proven useful for detection of critical limb ischaemia (CLI) in cross-sectional studies of diabetic patients. **Aim:** to further evaluate this new method in a clinical setting. **Patients and methods:** HTP was measured twice in 49 legs of 45 patients with CLI, before and after surgical(n=41) or angioplastic (n=8) arterial reconstruction (AR). A 8 MHz Dopplerprobe (Hadeco/Japan) was used for monitoring pulsations in a digital artery of the 1st toe for assessment of HTP (upper detection limit 60-70 mmHg, depending on the length of the leg). Simultaneously, the conventional ankle/brachial index (ABI) was assessed with sphygmomanometry and 8 MHz Dopplerprobe. **Results:** Before AR, HTP was 28 (SD 21) mmHg in 47, and > 70 mmHg in 2 legs. After AR, HTP rose to 50 (SD 8) mmHg in 17, and > 70 mmHg in 32 legs. ABI was 0.54 (SD 0.29) before and 0.94 (SD 0.20) after AR. **Conclusion:** Synchroneous increase of both, HTP and ABI, after successful AR confirms the accuracy of the HTP measurement.

1842

A TIME TREND ANALYSIS OF DIABETES (DM) RELATED LOWER EXTREMITY AMPUTATIONS (LEA) IN ONTARIO, CANADA

A. Angel, J. Hux, G. Anderson and D. DeBoer. Institute for Clinical Evaluative Sciences, North York, Canada.

As a proxy for the effectiveness of long term diabetes care we examined LEA rates in the province of Ontario (pop. 11.08 mil) from 1990 - 1995 using an inclusive database of all hospital discharge abstracts. The annual number of all cause amputations ranged from 2423 - 2551; however the proportion related to diabetes increased progressively from 49% in 1990 to 59% in 1995 ($p< .01$). The age adjusted LEA rate in DM males increased progressively from 39.4 in 1990 to 46.4 in 1995 (per 10^4 DM men) $p< .01$, while the rates in DM women remained constant at 18.8 in 1990 to 18.6 in 1995 (per 10^4 DM women). Over the study interval 19% of DM amputees had 2 amputations and 7.2% had 3 or more procedures. Diabetes-specific rates for toe, foot, below knee and above knee amputations increased progressively till age 79, then consistently decreased in both men and women. Analysis of variations in LEA rates amongst 7 health planning regions indicates a significant North-South gradient of 1.7; lower in southern urban communities vs. more remote and rural areas. Coincident with this apparent increase in DM-related LEA, our analysis of trends in antidiabetic drug treatment among all persons aged 65+ showed exponential($p<.01$) increases in the use of oral hypoglycemic agents (particularly glyburide and metformin) and insulin and combinations thereof. Conclusion: Despite increasing efforts to improve glycemic control there is no evident impact on limb preservation. LEA in DM is an increasing health care burden (men > women) and will require new, targetted and aggressive preventive strategies.

1843

REDUCED CUTANEOUS BLOOD FLOW IN RESPONSE TO A HYPERAEMIC INSULT IN DIABETIC SUBJECTS WITH EVIDENCE OF NEUROPATHY

BA Merrigan, M Rossi[a], N Standfield and A Dornhorst[a]. Department of Surgery and [a]Department of Endocrinology, Royal Postgraduate Medical School, The Hammersmith Hospital, London, UK

Abnormal vascular control mechanisms have been implicated in the pathogenesis of the diabetic neuropathic limb. To investigate this further, we used Laser Doppler flowmetry (LDF) to study changes in cutaneous blood flow (CBF) in response to an ischaemic event. CBF was measured in the pulp skin at the toe, before and after an ischaemic insult in 2 groups of diabetic subjects, 16 with peripheral and/or autonomic neuropathy and 18 without. All had palpable pedal pulses and ankle-brachial pressure indices of > 1.0. Subjects with and without neuropathy were matched for age and body mass index {(mean ± SD) 60.9 ± 10.4 Vs. 54.6 ± 15.2 years and 29.6 ± 4.3 Vs. 29.6 ± 7.6 kg m^{-2}, respectively}. The percentage change (ratio of the peak flux to the resting flux) in CBF after hyperaemic insult was reduced in subjects with neuropathy {407 ± 238 Vs. 552 ± 239%, $p<0.05$}, while the time to maximum flux after removal of the ischaemic insult was similar {27.1 ± 19.1 Vs. 29.9 ± 15 7 seconds}. These results demonstrate that following a hyperaemic insult, diabetic subjects with neuropathy have an impaired increase in blood flow to the limb. This abnormality may be implicated in the development of neuropathic complications.

1844

EVALUATING DIABETIC PATIENTS WITH FOOT ULCERATIONS IN TURKEY

N. BAŞKAL, Ş. DAĞCI ILGIN, S.GÜLLÜ, N. KAMEL and G ERDOĞAN Department of Endocrinology and Metabolic Diseases. Ankara University Medical School İbn-i Sina Hospital Ankara TURKEY

We recently reviewed diabetic patients with diabetic foot ulcers. Fortysix patients (48 % male, 52 % female - with median age of 50 ± 9 years) who were admitted to our department and hospitalized for diabetic foot problems between July 1995 and November 1996 were evaluated. Duration of diabetes was below 12 months in 10 % , 1- 5 years 10 % , 5 - 10 years 16 % and over 10 years 64 % of the patients. Thirty two percents had a previous diabetic foot history and 10 % experienced amputations before. On admission, 45 % were on insulin treatment while 55 % were receiving oral agents. Cigarette smoking prevalence was 42 %. Sixtyfour percent were hypercholesterolemic and 90 % had poor glycemic control (Hb A_{1c} > 7 %). On foot examination, 45 % had dry foot, 10 % callus formation, 32 % tinea pedis, 10 % hallux valgus deformity. Hospitalization for diabetic foot costs a lot for a developing country like Turkey. In another study of us we demonstrated the efficacy of education on improving glysemic control in diabetic patients. On questionnaire, most of our patients were found to have little knowledge about diabetes and diabetic foot care because they had never participated to an education program. Most of them also had low sociocultural - economic statues and poor hygienic conditions. They also didnot know the untoward effects of poor glycemic control on their disease progression. In conclusion, we think that in order to prevent diabetic foot ulcerations, uneventful amputations and unnecessary hospitalizations educational interventions, especially specific to diabetic foot care is imperative. To improve the quality of life and sociocultural conditions, routine and regular systemic foot examinations should be taken into consideration.

1845

PLANTAR CALLUS DENSITY IN DIABETIC NEUROPATHIC AND NEUROISCHAEMIC FEET MAY BE DEPENDANT ON BLOOD FLOW.

AVM Foster,A Gough,DL Pitei,S Spencer,S Wilson and ME Edmonds, Diabetic Foot Clinic, King's College Hospital, London, UK.

Plantar ulceration is a common complication of the neuropathic foot but rarely seen in the neuro-ischaemic foot. An association has previously been suggested between dense plantar callus and subsequent neuropathic ulceration. This report demonstrates that plantar callus density is markedly increased in neuropathic feet compared with neuro-ischaemic feet even though similar degrees of neuropathy are present. We studied 50 diabetic patients with history of plantar ulcer and severe neuropathy. 25 patients(Group A) had palpable pedal pulses and 25(Group B)had absent pulses and low pressure index (mean ± SD): 0.6 ± 0.14. The two groups were matched for age (A=64.5yrs, B=7lyrs [*p=0.103*], duration of diabetes (A=I6.00yrs, B=22.5yrs [*p=0.625*], sex (A=Ml4 Fll, B=M13 Fl2], type (A=IDDM 8 NIDDM I7, B=IDDM 3 NIDDM 22). Plantar callus was removed from site of previous ulcer by sharp debridement by the podiatrist and dry weight determined. The removal area was traced on an acetate sheet and density of callus was calculated in g/cm^2. Time since previous callus removal was noted. There was no significant difference between the two groups regarding area of callus removed (A=2.25cm^2, B=2.92cm^2)[*p=0.907*], treatment interval (A=30.00days, B=26.00days) [*p=0.263*] or vibration perception threshold (A=43.6±I5.6 volts, B=45.7±7.31) but callus density was significantly increased in the neuropathic group with good blood flow and palpable pedal pulses (A=0.169g/cm^2, B=0.018) [*p<0.0001*].

THE EPIDEMIOLOGY OF LOWER EXTREMITIES AMPUTATIONS IN THE CITY OF ROME IN THE PERIOD FROM 1984 TO 1993

Uccioli L., Durola L., Monticone G., Testa G., Sidoti A., Suraci C., Amoretti R., Saponara C., Schachter I., Gargiulo P., Allegra C., Ghirlanda G. and Menzinger G. Amputations study group of Rome - "Diabetic foot " project - Ministry of Health.

Since italian epidemiologic data on amputations in diabetic people are not available, the aim of our study was to investigate the number and the causes of amputations annually carried out in Rome, to detect the possible risk factors and to evaluate the mortality rate after three years from amputation. In Italy Hospitals have to bury amputated limbs in the cemeteries, where, in a dedicated register, the surname, the name, the hospital of origin and the date of amputation have to be indicated. Starting from these data the research has been completed by recovering case sheets in every hospital and with informations obtained directly from patients or their relatives.Three great hospital centers have been utilized to create the checking sample.From 1984 to 1995 3.953 amputations had been carried out in Rome, with an annual mean of 330±11; during this period the incidence did not vary significantly. The causes of amputations were as follows: 48.7% of cases diabetes, alone or associated to peripheral vascular disease (PVD); 35.7% peripheral vascular disease alone; the other 15.6% were trauma, neoplasia and burns.Since Rome resident population is about 2.800.000 and non-traumatic amputations observed in resident patients are 260/yr the incidence rate is about 9.3/100.000 inhabitants. Since the prevalence of diabetes in Rome is about 2.6% and the number of amputations in diabetic resident people is about 130/yr, the extimated incidence is 1.8/1.000 diabetics. The hospital admission period was 57±38 days for diabetic patients and 62+/-60 days for patients withPVD. The age at the time of amputation was significantly lower in diabetics (68.8±9.9) than in patients with PVD (75.5±10.3) ($p<0.01$). A good rehabilitation was possible in 46% of patients, while 43% were obliged to the use of wheel-chair and 11% to stay in bed. The mortality rate after one years from tha amputation was 28%, 40% at three years and 60% at five years.

1847

DIABETIC FOOT RISK FACTORS FOR CHILDREN AND ADOLESCENTS WITH DIABETES

S.E.Doll, I.V.Gourieva, E.P.Kasatkina, V.V.Bardin, V.N.Sokolovskaya, B.G.Spivak

Diabetes Foot Centre International Diabetes Program, Russian Academy of Advanced Medical Studies, Moscow, Russia

Objective: Little investigation has focused on the early screening of the risk factors and prevention of the diabetic foot formation in children and adolescents with diabetes. We examined 50 diabetic children. The age of the group was 14,5 ±3,0 years, the desease duration - 6,4 ±3,8 years (M±SD).

Methods: Neuropathy was assessed using Neuropathy Disability Score (NDS) and modified Autonomic Disability Score (ADS) according to Ewing. We used pedography (EMED system) for measuring the peak pressure (PP) in the 7 points of the right and left plantar surfaces: hallux - H, the first metatarsal head - MTH1, the third metatarsal head - MTH3, the fifth metatarsals head - MTH5, the middle of the plantar arch - M, the right and the left part of the heel RH and LH.

Results: The prevalence of the sensomotor (NDS>5) and the autonomic (the pathology of>1 cardiovascular test) neuropathy was 58% and 12,8% in correspondence. Unsatisfactory metabolic control (HbA level - 11,1±2,6) was determined in the group).

The NDS correlated positively with the age, the desease duration and the HbA level ($r_1=0,58$, $r_2=0,62$, $r_3=0,72$, $p<0,05$). The abnormal distribution of PP under the metatarsal heads was revealed: $MTH_1<MTH_3>MTH_5$ and "pes cavus" was diagnosed in 48% of patients. There was no ulcers or hyperkeratoses in the group. The linear regression analysis revealed the high correlation between NDS and PP MTH_1, MTH_3, MTH_5, RH, LH ($r_1=0,74$; $r_2=0,8$; $r_3=0,76$; $r_4=0,82$; $r_5=0,84$; $p<0,05$), HbA level and PP MTH1,3,5, RH and LH ($r_1=0,86$; $r_2=0,93$; $r_3=0,87$; $r_4=0,95$; $r_5=0,9$; $p<0,001$).

Conclusion: The data suggest that abnormal foot pressure in diabetic children and adolescents is related to the neuropathy and the HbA level and considered to be the predisposed factors to the developing of neuropathic ulcers.

1848

COMPARISON OF PREVALENCE OF LOWER EXTREMITIY MALFORMATIONS AND PRE-LESIONS IN DIABETIC SUBJECTS AND A CONTROL GROUP.

G. Segalini, A. Aldeghi, A. Morabito, M. Radice. and Lombardy Diabetic Foot Study, Milan, Italy

A multicenter study was carried out on a randomized sample of 33.554 out-patients attending 21 diabetes centres in Lombardia Region. A high prevalence of malformations (36.2%) and pre-lesions (48.9%) was found out. To establish if there was an increased prevalence of such changes in diabetic subjects, we studied a sample of non diabetic subjects, matched by gender and age. Cases: 5813 diabetic patients (D), 2982 men and 2831 women, average age 63.3± 11.6. Controls: 587 non diabetic subjects (C), 287 men and 300 women, average age: 65.8±14.2. A complete examination of the lower extremities was performed in all patients, with exploration of Achilles tendon reflexes and vibration perception (by tuning fork). The comparison between D and C does not show statistically significant differences concerning malformations, but for the flat foot (8.9% vs 4.8% respectively, $p<0.05$). Significant differences were found either for cutaneous and ungueal changes and for pre-lesions. A significant reduction of peripheral pulses, reflexes and vibration perception was found.

	maceration %	fissure %	hyperkeratoses %	Total pre-lesions %
D	13.2	7.1	33.3	48.9
	p<0.001	p<0.001	p<0.001	p<0.001
C	3.4	1.9	22.8	26.9

	cutaneous lesions%	ungueal lesions%	pathological pulses%	pathological O-T Reflexes%	vibration perception %
D	33.3	21.7	39.6	57.5	57.1
	p<0.05	p<0.001	p<0.001	p<0.001	p<0.001
C	27.8	12.4	28.9	35.5	37.6

Our results stand the damage either of macro and microcircle or peripheral and vegetative nervous system in diabetic subjects. It would be possible to implement the primary prevention of lower extremity amputations in diabetic patients using simple and low cost procedures. foot clinical examination.

1849

RISK FACTORS FOR DIABETIC FOOT DEVELOPMENT IN TYPE II DIABETIC PATIENTS

V.I.Pankiv, N.D.Tronko*, A.S.Efimov* and V.I.Kravchenko*. Central Regional Hospital, Kolomyja, *Institute of Endocrinology and Metabolism, Kiev, Ukraine

The aim of the study was to determine the prevalence of foot pathology and to examine possible risk factors associated with foot ulcers in NIDDM patients compared to age-matched controls. We examined 2 groups of NIDDM patients above 50 years of age: patients with diabetes and previous or present foot ulcers; patients with diabetes without foot ulcers, and control group without diabetes. In the foot diseased group, diabetes duration was longer (17±10 vs 9±7 years), insulin treatment was more common (84% vs 8%), fasting blood glucose and HbA_{1c} were significantly higher (11,7±4,1 mmol/l; 9,6%±1,8%) than in the diabetic group without foot ulcers (8,2±1,7 mmol/l; 7,5%±1,6%). Body mass index did not differ between the groups. Current or previous alcoholic problems were more common in the foot diseased group (27%) compared to the diabetic group without foot ulcers (11%) and the control non- diabetic group (6%). The foot diseased patients had ulcers (previous or present) of probably neuropathic origin in 54% and probably ischemic origin in 34%. In the 12% the ulcers were of mixed type. Callosities, dry skin, redness as well as hammer toes, hallus valgus, ingrowing nails, mycosis of nails and fissures were more common in the foot diseased patients. They emphasise the need of screening diabetic patients with regard to changes predisposing for diabetic foot disease. Our study shows that psychosocial problems, long standing diabetes duration and poor metabolic control seem to be importance for the development of diabetic foot ulcers.

1850

THE INCIDENCE OF LOWER LIMB AMPUTATION IN LEEDS, UK: SETTING A BASELINE FOR ST. VINCENT.

H.J.Bodansky[1], C.M.Airey[2], S.M.Chell[2], N.Unwin[3] and D.D.R.Williams[2]. Leeds General Infirmary, Leeds UK[1], Nuffield Institute for Health, University of Leeds, Leeds UK[2] and Department of Medicine University of Newcastle, Newcastle upon Tyne, UK[3].

Lower limb amputation (LLA) is an important diabetes outcome which is avoidable in many cases through provision of appropriate care. The St. Vincent Declaration aimed to halve diabetic LLAs within five years. At the end of 1993 a new diabetes service was introduced in Leeds (UK). To evaluate its effectiveness in addressing LLA outcome we collected data on incidence for 18 months preceding its introduction (July 1992-December 1993). From operating theatres, hospital discharge data and from the regional prosthetic centre we identified 353 LLAs, 112 carried out in 100 people with diabetes. This is an incidence of 32 $x10^{-5}$ in the general population and 510 $x10^{-5}$ in the diabetic population per annum (assumed 2% prevalence of diabetes). Patient and operation details were abstracted from case notes. Mean age (SD) at index amputation for patients with diabetes was 67.5(11.1) years with 75% carried out on males. Where smoking history was available (65%) 82% of operations were in smokers or ex-smokers. 41% of LLAs were classified as minor, 22% were below knee and 35% above knee. Mortality was 40% at 36 months. These baseline data will be used to assess progress towards St. Vincent targets in Leeds.

1851

RISK FACTORS FOR THE DEVELOPMENT OF DIABETIC FOOT: THE IMPORTANCE OF ITS EVALUATION

G. Benitez, F. Cañete, C.M. Palacios, S. Benitez,G. Pereira, S. Logwin, L. Barriocanal, M. López, H. Espinoza and J.T. Jimenez. Diabetes and Endocrinology Unit, 3rd Internal Medicine Div., Hospital de Clinicas, National University of Asuncion. Asuncion, Paraguay.

Peripheral vascular disease (PVD) and diabetic neuropathy (DN) are frequent cause of morbidity in non-insulindependent diabetic patients (NIDD). Intermittent claudication and foot ulcer carries a major risk of lower extremity amputation and usually they are the consequence of many concurrent facilitating pathologic conditions which individually carries a risk for the limb. The aim of the study was to evaluate the potential accumulated risk for the development of diabetic foot in a population of NIDD patients. 28 NIDD patients; 13 male (mean age 51.4±10 years) and 15 female(mean age 50.7±10 years), range of age 38 to 60 years old, were studied. Diabetes duration was 4.7±5.4 for men and 10.5±7 for women. Peripheral vascular condition was determined using Doppler technic to establish the ankle/braquial ratio for the systolic blood pressure; a ratio <1.0 was taken as indicating of PVD and a ratio >1.5 established the presence of calcified arteries. Neurologic function tests to explore somatic and autonomic conditions were performed. The mean of two blood pressure was taken to establish the presence of hypertension as another risk factor. Serum lipids by enzimatic methods, and lipoproteins were also determined. A clinical questionnaire specifically about habits; smoking and sedentarism was also established. We found that 23% of men showed ankle/braquial criteria <1.0, diagnostic for PVD and another 23% had Doppler criteria for arterial calcification, 54% of them were current smokers and 52% showed neuropathic compromise. Hypertension was found in 38% and dyslipedemia in 31% of men population. Regard to female population; 13% showed criteria for arterial calcification, 20% a ankle/braquial ratio <1.0 and only 13% were smokers. Neuropathy was found in 33% of women, 46% were hypertensive and 60% showed dyslipedemia. Trying to establish parameters for accumulated risk for diabetic foot we gave an score of 1 to each major individual risk (arteriopathy, neuropathy and tabaquism) and 0.5 to each minor risk (hypertension, dyslipedemia ans sedentarism). Two categories was then stated: A) Those who scored ≥3. 5 were diagnosed as carrying major risk for the development of diabetic foot. B) Those who scored ≤3. 0 as with minor risk for dibetic foot. Then we found that 31% of men had an score 3. 5 or higher meanwhile only 13.3% of women reach that score. Therefore, men population although with less duration of diabetes presented higher accumulated risk for diabetic foot than diabetic women. Perhaps we can speculate that the smoking habits, more prevalent among men in our population, makes for such a difference. However, women were more frequently hypertensive and dyslipidemic than men, probably because they have been diabetic for a much longer period of time. Finally, we think that it is important to try to establish the potential risk for diabetic foot because it would allow us to educate and try to take some preventive measures.

1852

SAINT VINCENT DECLARATION AND DIABETIC FOOT- EXPERIENCE OF A MULTIDISCIPLINARY TEAM APPROCH.

Rodrigues D[1], Geraldes E[1], Paiva I[1], Ruas L[1], Barros L[1], Paiva S[1], Oliva S[2], Gonçalves O[3], Carvalheiro M[1], Ruas M M A[1].

[1]Department of Endocrinology, Diabetes and Metabolism, [2]Department of Orthopaedy and [3]Department of Vascular Surgery. University Hospital of Coimbra-Portugal.

Aim: To evaluate the results of diabetic foot care in patients with foot problems. Patients and methods: Since 1991 a multidisciplinary team (endocrinologist, nurse educator, vascular surgeon and orthopaedist) was created to follow diabetic patients with foot problems. Between January 1991 and December 1995 we studied 192 patients: 120 men and 72 women with a mean age of 62±8 and 66±10 years, respectively. The type of diabetes, clinical presentation, metabolic control (HbA1c, blood pressure, total cholesterol, HDL cholesterol and triglycerides), prevalence of other diabetic complications (retinopathy and nefropathy) and amputation rates were analysed. Results: A total of 192 diabetics were studied and 172 (89.6 %) had NIDDM and 20 (10,4%) IDDM. The foot was predominantly neuropathic in 133 (69.2%) cases and predominantly vascular in 59 (30.7%). The mean HbA1c was 8.4±1.5%. Hypertension was present in 107 (55.7%) patients and dyslipidemia in 36 (18.7%). 123 patients had other diabetic complications: retinopathy in 123 (64%) and nefropathy in 56 (29%). The prevalence of amputed patients was 18.2% (n=35) and the prevalence of amputations was 24.4% (n=47): major 31.9% (n=15) and minor 68% (n=32).The evolution of annual results was also analysed and there was not any significant difference between years, except for the lower major amputation rate found in the last year (9%). Conclusions: According to St. Vincent declaration a multidisciplinary team approach was created for diabetic patients with foot problems. In this cohort the high amputation rate, was probably justified by the fact that all this diabetic patients had important foot problems. The lower major amputation rate of the last year suggests an improvement of diabetes care in this area.

1853

EVALUATION SOME OF POTENTIONAL RISK FACTORS IN THE SCRINING PROGRAM FOR DIABETIC FOOT .

E.U.Komeljagina, A.S.Ametov, I.V.Gourieva, V.V.Bardin.
Diabetic Foot Centre, International Diabetes Program, Institute of Working Ability and Rehabilitation, Moskow,Russia

In addition to well known risk factors for diabetic foot ulcers (i.g. peripheral sensomotor and autonomic neuropathy, large vessel disease) such factors as limited joint mobility (cheiroarthropathy and limited hallux dorsiflexion) may lead to foot leasions. The poor selfcare plays the essential role due to the lack of patient education . The aim of this study was to investigate the trigger mechanism leading to breakdown of the foot and the influence of limited hallux dorsiflexion and cheiroarthropathy at the foot damage.145 IDDM and NIDDM patients aged 18-69 years , 2-35 years of diabetes duration took part in this study.There was the high correlation between the limited hallux dorsiflexion and peak plantar pressures in the two points (measured by EMED pedography system): hallux and 1 metatarsal head (r_1=0,9 p<0,001, r_2 = 0,8 p< 0,001); between the LJM and peak plantar pressures points (r_1= 0,8 p<0,01, r_2= 0,9 p< 0,001).

The patients were divided into 3 groups: 85 without ulceration (U-), 29 with plantar (intrinsic) ulcers (UI) and 31 with dorsal (extrinsic) ulcers (UE). In UI group there was nobody with the signes of large vessel desease, but in UE group 31,4 % of patients had ankle/brachial ratio< 0,6.The patients of UI and UE groups were intrviewed about the provoking factors for the foot damage. In UI group 33% of ulcers were the results of poorly fitting shoes, 23% related to failed self care, 19% to minor trauma, 14% could not mentioned any reason. In UE group 32% of ulcers was due to mycosis , 17% related to poor shoes, 23% to mechanical trauma.

CONCLUSION. The data suggest that cheiroarthropathy and limited hallux dorsiflexion are simple methods and could be included in scrining program for the diabetic foot. All the patients should be screened for adequate selfcare by interviewing or special questionnarie.Whatever once identified patients with the signes of interdigital mycosis and large vessel disease should be considered as the risk for a foot ulceration.

1854

PREVENTIVE CARE OF THE DIABETIC FOOT, PROPOSAL OF A COSTA RICA ATENTION MODEL

Salazar S., Mora C., Arguedas C. Intern Medicine Hospital México, San José-Costa Rica.

Introduction: Most physicians and nurses in Costa Rica don't educate and don't examine the feet of the diabetic patient. It is important to teach the Health Care Personal to pay more attention to the diabetic foot and to educate the patients in its preventive care.

Objective: Propose an attention model from the EBAIS (Basic Equipment of Integrated Health Care) to the tertiary hospital in order to reduce in 50% foot amputations in the next 5 years.

Material and Methods: **1)** To create a National Committee for the Diabetic Foot Care. That will be in charge of continuous educational programs for health care teams. **2)** The PATON-A classification scale will be used by the EBAIS: the green feet (low risk) will be taken care by the EBAIS, the yellow feet (medium risk) will be sent to the secon level of attention hospitals and the red feet will be sent to the tertiary level attention hospitals. **3)** There will be an active communication system among the different attention levels. There will be yearly Seminars about the diabetic foot, to analyze policies and accomplishments.

Conclusions: With this Model we pretend to increase the knowledge of the health professional, the patient and the general population about the preventive care of the diabetic foot in order to decrease at least in 20% the severe complications of the diabetic foot in the next five years.

1855

ANALYSIS OF RISK FACTORS FOR THE DIABETIC FOOT AND EDUCATION STRESS THE IMPORTANCE OF NON-INVASIVE EXAMINATION OF NEUROPATHY AND ANGIOPATHY.

A.Jirkovská, V.Wosková, V.Bartoš and J.Skibová. Institute for Clinical and Experimental Medicine, Prague, Czech Republic.

The aim of the study was to compare various risk factors for the diabetic foot and education level of patients with active or previous foot ulcers (Group 1) and without it (Group 2) examined consecutively by specially trained nurses in 6 diabetes clinics and 1 surgical department in a model area during 1 year. There was no significant difference between Group 1 (44 persons) and Group 2 (278 persons) in mean age (67±10 and 65±10 years, respectively), type of diabetes (Type 2 in 95% and 93%) and its duration (15±14 and 13±7 years). Significant differences between Groups 1 and 2 were found in non-invasive examination of neuropathy by monofilaments (2.7±2.6 vs 5.4±2.8 sensitive points, $p<0.001$) and by bio-thesiometer (vibration pressure threshold - VPT 36±16, CI 30-41 vs 25±12 , CI 23-27 V , $p<0.001$). The number of patients with VPT over 30 V was significantly different (74 and 47%, $p<0.001$), that of patients with VPT of 25-29 V was similar (7 and 8.6%). No significant differences were found in subjective symptoms of neuropathy. The Doppler ankle/arm index was significantly different between Groups 1 and 2 (0.82±0.43, CI 0.68-0.97 and 0.92±0.26, CI 0.89-0.95, $p<0.05$). Only the number of patients with an ankle/arm index under 0.8, not under 1, differed significantly between both groups. In Group 1, a low Doppler index was more common (57%) than AF murmurs (32%), non-palpable peripheral pulsations (29%), and claudications (41%). Diabetes compensation in this group was significantly worse (HbAlc 8.6±2 vs 8.0±1.5%, $p<0.05$) and creatinine levels higher (113±57 vs 94±25 µmol/l, $p < 0.01$). The number of some orthopedic deformities and skin abnormalities was the same in both groups. The level of foot-related knowledge was low in either group, 52% of correct answers. We conclude that simple non-invasive examination of neuropathy and angiopathy with age-related risk values and HbAlc determination are good risk factor characteristics also of elderly patients with the diabetic foot.

1856

STUDIES OF DIABETIC AMPUTATIONS IN LITHUANIA: SCOPE FOR PREVENTION.

V.Dargis, O.Pantelejeva, A.Jonushaite, L.Vileikyte ✶ and A.J.M.Boulton ✶. *Amputee Rehabilitation Hospital, Kaunas, Lithuania and ✶Manchester Royal Infirmary, Manchester, UK.*

A comprehensive diabetic foot care service at the Lithuanian Amputee Rehabilitation Hospital has been established with the specific aim of identifying risk factors for ulceration providing preventative education, diabetic footwear and chiropody. Among all 922 amputees referred during 1991 - 1995 for artificial limb provision 188 (20%) of amputations were related to traumatic, 397 (43%) to vascular, 264 (29%) to diabetic and 73 (8%) to other causes. Of 264 patients, 89% had NIDDM, and 49% had diabetes duration < 10 years. From 1994 - 1996, all amputees were examined using quantitative sensory testing and Doppler techniques: 40% were purely neuropathic, 54% neuroischaemic and 6% purely ischaemic. This centre should be able to achieve significant reductions in amputations as many are potentially preventable being of neuropathic aetiology. The screening to identify "high-risk" patients who might benefit from foot care education, chiropody and diabetic footwear is extremely important in Lithuania to reduce diabetic amputations.

1857

PERIPHERAL ARTERIAL OCCLUSIVE DISEASE AND ITS RISK FACTORS IN NON-INSULIN DEPENDENT DIABETIC PATIENTS

M.Kallio, C.Forsblom, P-H Groop, K.Tötterman, M.Lepäntalo, IV Department of Surgery and Department of Medicine, Helsinki University Hospital, Finland.

We aimed to assess the prevalence of objectively verified peripheral arterial occlusive disease (PAOD) in NIDDM patients. Another purpose was to detect risk factors for PAOD during a prospective 11-year (range 7-14 yrs) follow-up. 130 (64F, 66M) NIDDM patients were randomly selected from the register of the local Diabetic Association. At baseline, 21 patients (16%) were diagnosed with PAOD, based upon an ankle-brachial index (ABI) <0.90. In an age and sex-matched non-diabetic control group, only 1 out of 47 subjects (2%) had PAOD. Medial sclerosis was excluded by measurement of great toe blood pressure. During the study 29 patients (22%) died and two were lost. Of the 88 non-PAOD patients at baseline 20 patients (23%) developed PAOD during follow-up. At baseline PAOD was associated with microalbuminuria ($p=0.0007$), hypertension ($p=0.03$), duration of smoking ($p=0.01$), and diabetes duration ($p=0.04$), as well as age ($p=0.003$). In a logistic regression analysis independent risk factors for PAOD were microalbuminuria ($p=0.02$), and age ($p=0.009$). At follow-up risk factors for PAOD were current or previous smoking ($p=0.05$), duration of smoking ($p=0.02$), triglycerides ($p=0.0002$), total cholesterol ($p=0.0003$), and LDL-cholesterol ($p=0.009$), at baseline as well as age ($p=0.02$) at follow-up. In the logistic regression analysis HDL-cholesterol ($p=0.009$), cholesterol ($p=0.004$) at baseline and age at follow-up ($p=0.004$) were significant predictors of PAOD Current or previous smoking was borderline significant ($p=0.05$). As to glucose, HbA1c, C-peptide values before and 6 min after a glucagone dose, body mass index, sex or mode of treatment did not predict PAOD. In conclusion, PAOD is much more common in NIDDM patients than in the non-diabetic population. Microalbuminuria, dyslipidemia, hypertension and smoking are the strongest predictors of peripheral arterial occlusive disease in diabetic patients

1858

FOOT RE-ULCERATIONS IN DIABETES: WHICH IMPORTANT MARKERS FOR EFFECTIVE PREVENTION ?

B. Peter-Riesch[1], J-Ph. Assal[1], G.Reiber[2].Div. of Therapeutic Education for Chronic Diseases, University Hospital, Geneva, Switzerland[1], Seattle VA Medical Center, Seattle, USA[2].

Objective: Repetitive foot ulcerations aggravate manyfold (2-6x) the risk of amputation. Factors determining foot reulceration have been analysed at the time of a 2nd foot ulcer episode. **Methods:** 268 patients were followed in a prospective, observational multicentric study from Oct 1994 to May 1996 among 3 VA hospitals and 1 private clinic [US] + 1 Swiss hospital [Geneva]. Trigger events having led to foot ulceration were analysed in patients presenting for multiple episodes. Causal factors of the 2nd ulcer were compared to those of the 1st ulcer. **Results:** Out of the 268 enrolled patients 152 presented a history of a prior ulcer (56.8%), in contrast only 26/268 patients presented during the twenty months study period for a 2nd foot ulcer (10%). During the healing time of the first ulcer NO other ulcer developed. In 2/3 of the 26 patients the same trigger mechanism caused the 2nd ulceration as to compared to the first one. The three major causal factors were 1) shoes 2) blisters 3) errors in self-care. Repetition of the first causal factor at the time of the 2nd ulcer underlines the importance of educational strategies focused on each patients personal pivotal event. **Conclusion:** The low incidence of reulcerations while the patient is under medical supervision for an existing foot ulcer highlights the impact of regular foot clinic visits in prevention of relapses. The repetition of the same causal factor in the same patient having led to foot reulceration gives excellent information for tailoring specific educational and follow-up strategies.

1859

RISK FACTORS FOR MAJOR LOWER EXTREMITY AMPUTATIONS IN DIABETIC PATIENTS

P.Kozlovski[1], V.Ivanov[2]. 1. Clinical Centre of Endocrinology
2. National Centre for Prosthetics, Sofia, Bulgaria

The objective of the study was to determine the risk factors for major lower limb amputations. We studied 43 diabetic amputees (29 men and 14 women, with 26 thigh and 17 leg amputations), admitted to a centre for prosthetics 5 to 12 months after the amputation. They were compared to 43 age and sex-matched controls without foot lesions or amputation, admitted to an inpatient diabetic clinic. We found that rural population and those with lower educational level were at higher risk for amputation. The presence of neuropathy, ischemic heart disease and a history of intermittent claudication, but not retinopathy, nephropathy and history of stroke, were predictive for a major amputation. Systolic (158.8±25.6) vs 150.2±21.1) and diastolic (95.3±10.9 vs 90.4±11.9) blood pressure tended to be higher in amputees without reaching statistical significance. Vibration perception threshold measured at the great toe with the tuning fork of Rydel-Seiffer, was significantly lower in amputees (3.47±1.9 vs 4.73±2.0, $p<0.01$). Fasting and postprandial blood glucose measured at the time of admission to the clinics did not show any difference between the groups, neither did BMI, type and duration of diabetes. There were more amputees who reported high alcohol consumption ($p<0.05$), but smokers were similar in both groups. Amputees had less diabetes related knowledge than the control group. Risk factors for major lower limb amputation should be taken into account in the development of a preventive diabetic foot programme.

1860

PREVENTION OF DIABETIC FOOT ULCERS IN PATIENTS WITH AND WITHOUT PREVIOUS FOOT ULCERS.

C.Metzger, and M.Presch. Diabetic foot clinic, Elisabeth-Krankenhaus Gelsenkirchen/Germany

Background: Foot ulceration(FU) in relation to diabetic neuropathy and/or peripheral ischaemic vessel disease (PIVD) is triggered by external trauma,e.g.from improper footcare and footwear. **Aim:** to prospectively assess ulcer development in 2 cohorts of patients (81% NIDDM, 20% PIVD, 100% neuropathy, duration of diabetes 18 yrs) over a period of 2 years. **Patients and methods:** 21 patients with neither previous FU nor gross foot deformity comprised group A. Another 31 patients with acute FU, a history of FU(n=31) and minor amputations (n=8), and significant foot deformity were recruited after healing of the FU (group B). Both groups received regular footcare and medical footwear (ready made shoes in 16, bespoke shoes in 36 cases). **Results:** in group A,1 patient developed 1 FU, versus 14 patients developing 22 FUs in group B($p<0.05$). FU was caused by footwear (77%),and self-made chiropody(25%). Footwear-related FU was due to temporarily wearing ordinary shoes (27%), to mismatch between foot and bespoke shoe(27%),and to toe-caps (23%).Compliance with medical footwear was reported to be high(85%)in both groups. **Conclusion:** Failure to prevent FU was related to a history of FU and foot deformity, as well as to bespoke footwear (which may be too difficult to design for deformed neuropathic feet).

1861

RISK FACTORS FOR HIGH LEVEL AMPUTATION IN DIABETIC FOOT

S-H. Hsieh, H-Y. Chang, J-F. Chen, Brend R-S. Hsu, J-H Juang, J-D. Lin and H-S. Huang. Chang Gung Memorial Hospital, Taipei, Taiwan, R.O.C.

To realize the risk factors for high level amputation (ie:below-knee & above knee amputation), 107 admission patients who were diagnosed as diabetic foot during the period of January 1995 to June 1995 in Chang Gung Memorial Hospital were studied retrospectively. There were 54 male and 53 female, 70 patients (65%) of them admitted to Metabolic ward with a multidisciplinary foot-care team, the others (35%) admitted to orthopedic, plastic surgery, general medicine or trauma team ward. Two groups were subclassified. The cases who received high level amputation were Group A (35 patients). The cases who received no or minor operation (such as toe amputation, debridement, skin graft,...) were Group B (72 patients). Statistical comparison were performed between these two groups by Student's t test, Chi Square and stepwise logistic regression test. Group A was significantly older, lower ischemic index, higher levels of WBC, BUN, Cr, CRP and lower levels of Hb, albumin, HbA1C. However, the levels of cholesterol, triglyceride, the duration of DM, the existence of proteinuria, hypertension, old CVA, heart disease or smoking history did not reveal significantly different. Stepwise logistic regression show older age and higher white count level were risk factors and for those whose Diabetes duration longer than 5 years, older age and no DM team care had significant increase risk. We concluded that patients with diabetic foot in this Medical Center, older age and higher level WBC were increase risk for high level amputation and DM team care do decrease high level amputation to those DM duration > 5 years.

1862

APPROACHING ST VINCENT; REDUCING THE INCIDENCE OF DIABETIC LOWER LIMB AMPUTATION IN LEEDS, UK.

C.M.Airey[1], S.M.Chell[1], H.J.Bodansky[2], N.Unwin[3] and D.D.R.Williams[1]. Nuffield Institute for Health, University of Leeds, Leeds UK[1], Leeds General Infirmary, Leeds UK[2] and Department of Medicine University of Newcastle, Newcastle upon Tyne, UK[3].

Lower limb amputation (LLA) is one of the most important endpoints in diabetes, it is a major cause of morbidity and mortality and is known to be avoidable in the majority of cases through the provision of appropriate education and health care. As such, it is a target of the St. Vincent Declaration which aimed to halve diabetic LLAs within five years. At the end of 1993 a new diabetes service was introduced into a metropolitan health district in the UK. In order to evaluate its effectiveness in addressing LLA outcome we compared data currently being gathered (July 1995-June 1996) as part of an international study, with data collected for a 12 month period preceding the establishment of the service (July 1992-June 1993). Identical case ascertainment strategies were utilized for both periods. Using information recorded in operating theatre registers, hospital discharge data and by the regional prosthetic centre we uniquely identified a total of 273 in '92/'93 and 222 LLAs in '95/'96. Of these procedures, 81 and 60 were carried out in people with diabetes respectively. This represents a decrease in LLA incidence of 15.6% in the non-diabetic population and 25.9% in the diabetic population over the intervening 3 year period. Accompanying this decrease there was a concomitant reduction in the level of procedure with only 22% of the amputations being carried out above knee in the more recent time period compared to 35% in '92/'93. In conclusion, set against a background of falling incidence of LLA in the general population, amputations in people with diabetes in Leeds are approaching the target set by St. Vincent.

1863

RISK FACTORS PREDICTING SEVERE FOOT ULCER AND AMPUTATIONS IN PATIENTS WITH NIDDM

T.H.Lee, J.H.Park, J.H.Lee, D.J.Chung, and M.Y.Chung. Chonnam University, Kwangju, Korea.

Diabetic foot lesion is a one of the major cause of morbidity in patients with diabetes. Therefore, a case contol study was utilized to quantify the contribution of various risk factors to the risk of severe diabetic foot lesion required surgical intervention including lower extremity amputation. At baseline, risk factors for diabetic foot lesion were determined in 262 NIDDM patients aged 40 to 70 years in 1990. These patients were followed up annually for 5 years with respect to foot lesions. Case patients had had an incident surgical intervention between 1990 and 1995; control subjects had no diabetic foot lesion by 1995. Foot conditions and health status prior to the pivotal event led to the surgical treatment were obtained by medical record review. We identified 25 subjects including 11 amputees and randomly selected 237 contols for comparison. After adjustment for sex and age, risk for severe diabetic foot lesion required surgical intervention was associated with peripheral neuropathy (OR 12.5, 95% CI 5.6-52), peripheral vascular disease (OR 11.3, 95% CI 5.0-34), autonomic neuropathy (OR 10.0, 95% CI 3.6-43), retinopathy (OR 7.7, 95% CI 3.6-27), glycated hemoglobin (OR 2.9, 95% CI, 1.7-6.2), smoking (OR 2.6, 95% CI, 1.0-3.0) and microalbuminuria (OR 1.8, 95% CI, 1.1-2.1). After controlling for these differences, the ORs for severe diabetic foot lesion with peripheral vascular disease was 4.1 (95% CI 2.1-10.4), with peripheral neuropathy, 4.0 (95% CI 1.8-12.4), with glycated hemoglobin, 2.5 (95% CI 1.5-5.3), with retinopathy, 2.5 (95% CI 1.0-4.6), with autonomic neuropathy, 2.3 (95% CI 1.0-7.5), with smoking, 1.6 (1.0-3.0) and with microalbuminuria, 1.0 (95% CI 0.7-1.6).

1864

THE FATES OF PATIENTS WITH DIABETES MELLITUS AFTER AMPUTATION OF A LOWER LIMB

Karnafel W., Eneser M. Department of Gastroenterology and Metabolic Diseases, University Medical School, Warsaw, Poland.

The aim of the study was to analyze factors that affected the survival time of 125 patients with diabetes mellitus (DM) and 121 patients with normal glucose tolerance (NGT), to whom amputations of the lower limb in consequence of gangrene were performed. In a 5-year follow-up study 80 patients with DM (64 percent) and 39 patients with NGT (32 percent) died.

Among the examined patients with DM were 72 men and 53 women [mean age 69.2 ± 10.1 (± SD) yrs], and among these with NGT 92 men and 29 women (mean age 66.2 ± 12.2 yrs).

In statistical analysis (Cox proportional model) in patients with DM the following predictors of death were identified:
age (p=0.0001), duration of DM (p=0.03), systolic arterial hypertension (p=0.006), peripheral arterial disease (p=0.0007), diabetic nephropathy (p=0.0065). In the patients with NGT only age was significant predictor of death (p=0.0001).

Conclusion: The necessity of performance of amputation of a lower limb in a patients with DM provides information on unsuccessful course of the disease.

1865

PREDICTION OF DIABETIC FOOT ULCER OCCURRENCE BY A TREE STRUCTURED ANALYSIS OF PROSPECTIVE SURVIVAL DATA.

E. Boyko, J. Ahroni, A. Ciampi, A. Couturier, V. Stensel, R. Forsberg and D. Smith. University of Washington, Seattle, USA, and McGill University, Montreal, Canada

There has been little prospective research on risk factors for diabetic foot ulcer that simultaneously considers the structural, neurologic, and vascular factors obtained from a clinical evaluation. We prospectively followed 729 diabetic general medicine clinic enrollees without foot ulcer for the development of this lesion. Baseline assessment included a medical history and physical examination that focused on diabetes and the lower limbs; testing for sensory neuropathy using the 5.07 monofilament (SN); autonomic function (orthostatic blood pressure drop (BPD); foot deformity; and glycosylated hemoglobin (GHB) and serum creatinine (CR). Foot ulcer was defined as a full thickness defect that required > 2 weeks to heal. Mailed, telephone, and in-person contacts at regular intervals were used to assure capture of all incident foot ulcers. A recursive partitioning and amalgamation algorithm (RECPAM) that considers time to event (foot ulcer) was used to separate this population into groups based on magnitude of risk. Subjects were elderly (mean age 63.2 yrs) males (98%) with NIDDM (93.4%) and a mean diabetes duration of 11.4 yrs. Subjects were followed for 2.5 years on average for foot ulcer occurrence, during which time 118 ulcers occurred. Seven of twenty variables considered were found to significantly alter risk (SN, history of peripheral vascular disease (PVD), history of amputation (AMP), BPD, GHB, hallux limitus (HL), and CR. Four different risk groups were identified: 1) SN-, PVD- (n=273); 2) [SN+, AMP+, GHB < 13.7%] or [SN+, AMP-, and BPD > 31 mm Hg or HL+ or CR > 186 μM] (n=123); 3) SN+, AMP+, GHB > 13.7% (n=15); and 4) remaining patients (n=318). Proportion developing foot ulcer and relative risk (RR) with 95% confidence limits in groups 2-4 compared to group 1 are: 1) 2.6%, RR=1 (referent); 2) 39.8%, RR=21.5 (9.8 - 47.2); 3) 80%, RR=79.0 (30.9 - 202.5); 4) 15.7%, RR=5.9, (2.7 - 12.9). We conclude that multiple factors contribute to the risk of diabetic foot ulcer. Information on these easily obtained risk factors may be used to classify diabetic patients as to their risk of developing foot ulcer.

1866

POTENTIAL ECONOMIC BENEFITS OF STRATEGIES TO PREVENT LOWER-EXTREMITY AMPUTATION IN PERSONS WITH DIABETES

J.Kotsanos, D.Ollendorf, W.Wishner, M.Friedman, T.Cooper, M.Bittoni and G.Oster. Eli Lilly and Company, Indianapolis and Policy Analysis, Inc., Brookline, USA.

Objectives. To estimate the potential economic benefits of selected strategies from published literature—educational interventions, multi-disciplinary clinics, and insurance coverage for therapeutic shoes—to reduce the incidence of lower-extremity amputation among persons with diabetes. *Methods.* We developed a model to estimate the expected incidence and associated costs of lower extremity amputation in a hypothetical cohort of 10,000 persons with diabetes. Prevention strategies were assumed to be targeted at persons with a history of foot ulcer, and benefits were estimated over a period of three years. *Results.* The total potential economic benefits (discounted) of strategies to reduce amputation risk ranged from $1.9 to $2.9 million ($2,798 to $4,286 per person with a history of foot ulcer) over three years. Benefits were highest for educational interventions. Most benefits were found to accrue among persons aged 70 years and older. *Conclusions.* Strategies to reduce the risk of lower-extremity amputation may generate substantial economic benefits, and should be a standard component of routine diabetes care. These strategies may best be achieved through government payers, the health care team, patients and their advocates, in partnership with the health care industry.

1867

RISK FACTORS FOR FOOT ULCERATION IN A DIABETIC OUTPATIENT CLINIC: A FIVE YEARS FOLLOW-UP

R. MINGARDI, L. UCCIOLI, P. PASQUALITTO, M. STRAZZABOSCO, G. ERLE and G. MENZINGER VICENZA AND ROMA (ITALY)

1007 diabetic patients (age 64±11 yrs, M/F 49.6/50.4% duration 13.5±9 yrs, 71 IDDM and 929 NIDDM) were observed for the first time in the outpatient clinic in the period 7/11/91-30/9/95.They were fully characterized for metabolic control and long term diabetic complications, expecially of the lower limbs, with an extensive protocol. No patients showed foot ulceration at the inclusion in the study. In the follow-up period (42.3±11.2 (12.3-59.2) months) the ulcer incidence was 4.8% with a mean annual rate of 1.2%. Between them 4 subjects (~8%) had lower limb amputation after 1 yr ulceration. Age, weight, BMI, type and duration of diabetes, metabolic control at the time of inclusion, severity of retinopathy and nephropathy, previous cerebral or cardiac vascular diseases, the presence of claudicatio, as well as the absolute value of the ankle brachial index were unable to differentiate patients who would or would not develop foot ulceration. In the univariate analysis the factors able to differentiate those patients were represented by: absence of pedal pulses ($p<0.01$), absence of ankle jerks ($p<0.005$), VPT >25 mV ($p>0.001$), presence of foot deformities ($p<0.01$) and presence of a previous foot ulceration ($p<0.001$). In the multivariate analysis adjusted for all parameters the factors still able to discriminate patients at risk of ulceration were: previous ulceration (OR 6.4 (CI 95% 2.95-14.3)), absence of ankle jerks (OR 4.1(CI 95% 1.59-10.61)) and VPT >25 mV(OR 3.81(CI 95% 1.69-8.61)). In addition for each unitary increment of VPT in the absolute value there was a 3% increment in the risk of ulceration. In conclusion this prospective study demonstrates that an accurate clinical examination with the combination of few simple parameters discriminates patients with an increased risk of foot ulceration.

1868

MANAGEMENT OF THE DIABETIC FOOT IN HOSPITAL : COSTS AND BENEFITS

A.Benotmane - F. Ayad. University of Oran,Algeria

The aim of this work is to assess the costs of the diabetic foot lesions seen at a university hospital from january 1989 through december 1993. A total of 163 cases of diabetic foot were reviewed in 132 patients (88 women and 44 men). Lesions were allocated into three groups according to the Wagner classification. We evaluated direct costs (hospital stay, medical treatment, surgical treatment, investigation) and indirect costs (amputation and in-hospital mortality). X^2 test and analysis of variance were used to compare the different groups. More than nine percent (9.16%) of all hospitalized diabetic patients were reported to have foot problems. Almost all the patients (95.50%) were older than 40 years. The first foot lesion appeared at 59.64±11.74 years. The M/F ratio was significant (M/F = 1.64; $p<0.01$). The mean costs and mean durations varied according to the Wagner classification. The mean costs of hospitalization were calculated to be 79.31, 136.18 and 176.41 KDA (1KDA = 1000 algerian dinars), for the groups 1, 2 and 3 respectively ($p<0.001$). The mean cost of a foot lesion was evaluated to be 5611$ US (1$ US was about 23.84 dinars in 1993). The mean durations of hospitalization were calculated to be 26.87, 48.25 and 57.12 days for the groups 1, 2 and 3 respectively ($p<0.001$). More than seventeen percent (17.43%) of patients underwent major amputation. Foot function was preserved in 74% of cases. In-hospital mortality (9%) was present only in patients staged Wagner 4+5 (group 3). More than seventy nine percent (79.11%) of the total financial costs were attributed to hospital stay. Forty two out of 57 patients (73.68%) that had an occupation obtained a rest. The total duration of rest was 3780 days. Direct and indirect costs due to diabetic foot are high. It is necessary to invest more money in Prevention in order to minimize this complication and lessen those costs.

1869

WHO'S AT RISK FOR FOOT ULCERATION?

LA Lavery, DG Armstrong, SA Vela, TL Quebedeaux, and JG Fleischli
Dept. of Orthopaedics, Univ. of Texas Health Science Center, San Antonio, USA

Previous studies of risk factors for ulcerations have identified peripheral neuropathy, vascular disease, limited joint mobility, body mass, foot deformities, abnormal foot pressures, a history of ulceration or amputation, nephropathy, and impaired visual acuity as important factors. However, we have been unable to identify any existing work that considers all of these factors in the same analysis. Therefore, the purpose of this study was to evaluate risk factors for foot ulcerations among persons with diabetes.This project was conducted as a case-control study, 225 age-matched patients, 46.7% male, were enrolled with a ratio of approximately 1:2 case:controls (76 cases:149 controls). All patients met the following criteria: 1)The presence of diabetes mellitus based on World Health Organization criteria (6.2% type I), 2) evaluation by medicine and ophthalmology services within the past 6 months, 3) glycosylated hemoglobin, complete blood count, urinalysis, creatinine and blood urea nitrogen laboratory studies performed in the past 3 months. Cases were defined as subjects that met the above criteria with an existing foot ulceration or a history of a foot ulceration. Controls were defined as subjects with no history of foot ulceration. Using a stepwise logistic regression model (alpha < 0.05), elevated plantar pressure (> 65 N/cm^2), previous history of amputation, duration of diabetes (>10 years), foot deformities (hallux rigidus or hammertoes), male gender, poor diabetes control (HbA1c >9%), one or more subjective symptoms of neuropathy, and elevated vibration perception threshold (> 25 V) were significantly associated with neuropathic ulceration. 77.6% of ulcerated patients had a rigid deformity directly associated with the site of ulceration. No significant associations were noted between vascular disease (ankle brachial systolic pressure index <80, nephropathy, transcutaneous oxygen tension <30mmHg, or palpable pedal pulses), level of formal education, nephropathy, retinopathy, impaired vision, or obesity and foot ulceration. The results suggest that neuropathy, deformity, commensurate high plantar pressures and history of amputation are significantly associated with presence of foot ulceration.

1870

INCREASED FOLLOWED BY DECREASED NUMBER OF MAJOR AMPUTATIONS IN DIABETICS DURING ECONOMICAL SANCTIONS

D.Tešić[1], D.Ilić[1], P.Pantelinac[1] and S. Avramov[2]. Clinic of Endocrinology, Diabetes and Metabolic Diseases[1], Clinic of Vascular Surgery[2], Faculty of Medicine, Novi Sad, Serbia.

The National programme in order to reduce amputations for diabetic gangrene have included the following diagnostic procedures: bidirectional CW Doppler flowmetry of the arteries with 8 and 4 MHz sound, the segmental blood pressure measurements, digital photopletismography of the big toe, evaluation and calculation of the neuropathy disability score. 1993. year was characterized by serious deficiency of all drugs especially antibiotics. The number of the lower limb amputations was observed and estimated for the period 1991.-1995. year. There are about 300,000 inhabitants on the territory covered by the Regional Health Centre, and out of this number 8,000 patients were diabetics treated with antidiabetics. 6,400 patients were treated with drugs and 1,600 patients with insulin.

	No of amputations (A)		*A.Crural*		*A.Femoral*	
	Total	**DM** (%)	Total	**DM**(%)	Total	**DM**(%)
1991.	158	79 (50)	43	24 (55.8)	72	25(34.7)
1992.	165	***84*** (50.9)	41	***25***(61)	69	***28***(40.6)
1993.	184	**102 (55.4)**	51	***34*****(66.7)**	89	***39*****(43.8)**
1994.	142	***56*** (39.4)	28	***9*** (32)	80	***30***(37.5)
1995.	130	63 (48.5)	25	18(72)	78	30(38.5)

Statistical evaluation showed increase in the major limb amputations in 1993. year (X^2 p 0.089), followed with a significant decrease (X^2 p <0.01) in 1994. year. The number of transmetatarsal and toes amputations in this period was unchanged. The possibilities to perform diagnostic procedures and surgical interventions were not diminished in this period, but it was concluded that the above results show the importance of the drug therapy, especially of the antibiotics which were deficient to pre the performed amputations. The significant decrease of the amputations from 1994. could be the matter for further speculations.

1871

MORE THAN HALF OF THE DIABETES POPULATION HAS INCREASED RISK TO DEVELOP CHRONIC FOOT ULCERS.

K. Sparre, B. Arvered, M. Matero, G. Jörneskog and K. Brismar. Department of Endocrinology & Diabetology, Karolinska Hospital, Stockholm, Sweden.

Preventive care has been effective in diabetes to lower the rate of foot ulcers (FU) and amputation. The aims of the study were to characterise diabetes patients with FU and to find an easy screening method to identify patients at risk. 50 consecutive diabetics referred to the foot clinic at Karolinska Hospital with chronic FU were examined and answered a questionnaire. A model protocol for foot examination was designed. 323 diabetics, randomly selected, in Primary Health Care (PHC) were examined in accordance to the protocol. The patients were diagnosed to have no signs of complications (group 1), signs of neuropathy (np) (group 2), or both neuropathy, angiopathy (ap) and/or earlier chronic FU (group 3). The examination was performed by trained chiropodists, practical or registered nurses. The results showed that patients with chronic FU (mean age 66.4 years) had a mean diabetes duration of 20.5 years. All had signs of np and 67 % had ap. Mean HbA1c was 11.8%. The healing time for a recurrent chronic FU was longer than for the previous one. The patients without FU (mean age 60 years), had diabetes duration of 9.4 years. Six % had been treated for chronic ulcers. Neuropathy was found in 54%. Autonomous np was most common (70%). 19% had deformities and 38% calluses. Signs of microangiopathy were found in 17.5% and severe macroangiopathy in 5.2%. 26% had impaired vision, which made their self care difficult. The mean value for HbA1C was 7.8% (reference<5.2%). 36% had regular chiropody. In conclusion patients with chronic FU had a longer diabetes duration and worse metabolic control. The healing time for a recurrent FU was significantly prolonged. More than half of patients with diabetes in PHC had risk factors for chronic FU, especially np, local changes and unacceptable metabolic control. Only 40% had no or low risk, 10% a high risk to develop chronic FU. Only a minority had access to medical chiropody. The model protocol to identify patients at risk was easy to use in regular foot examinations and patient education.

1872

THE ROLE OF NEUROPATHY IN THE DEVELOPMENT OF DIABETIC FOOT ULCERATION.

Toton Suryotono, Sarwono Waspadji, ImamSubekti, Maryantoro Oemardi, and Slamet Suyono. Department of Medicine, Faculty of Medicine, University of Indonesia, Salemba 6, Jakarta 10430, Indonesia.

There are many factors playing a role in the development of diabetic foot ulceration, mostly are combination of neuropathy, compromise vascular condition and superimposed infection. The aim of this study was to determine the contribution of neuropathy in the development of foot ulceration. A case control study was conducted, recruiting patients admitted to Ciptomangunkusumo hospital for diabetic foot ulcer from.April to September 1996. As a control group, diabetic patients without foot ulceration attending our diabetic clinic were asked to join this study, matched for sex, age, and nutritional status. Neuropathic parameters performed in this study were Semmesweinstein monofilament (5.07), vibratory sensation as measured by vibrameter, heart beat variation (RR interval) during deep breathing measured by SRR5 heart rate recorder, orthostatic hypotension and knee tendon reflex test. Patients with an ankle brachial index of < 0.9 (using simple doppler apparatus) were excluded. Univariate analysis was used to calculate odds ratio for each independent factor. There were 67 subjects with diabetic foot ulceration and 84 diabetics without foot ulceration eligible for statistical evaluation. No differences in age, gender, BMI, years of known diabetes and means HBA1c were found between both groups. Monofilament was the best predictor for the development of foot ulceration (OR = 10.48, 95 % c.i. 4.02-28.22). Abnormal heart beat variation had the OR of 7.71 (95 % c.i. 2.77-22.27), while absent of knee reflex gave rise to OR of 4.32, 95 % c.i. 1.86-10.19). Abnormal vibratory sensation (>43 vhz) contributed OR of 2.63 (95 % c.i.1.23-5.65), while orthostatic hypotension showed the lowest OR (0.89, 95 % c.i. 0.33-2.35). In conclusion, diabetic neuropathy plays an important role in the development of foot ulceration. Semmesweinstein monofilament 5.07 was the best predictor for the development of foot ulceration. Other neurologic parameter abnormalities had less important contributions as a predictor of the development of diabetic foot ulceration

PS 48

Diabetic Foot – Clinical Picture and Treatment

1873

CONSERVATIVE SURGERY VERSUS CONVENTIONAL THERAPY FOR DIABETIC FOOT: A RANDOMIZED TRIAL

A. Piaggesi, E. Schipani, F. Campi, F. Baccetti and R. Navalesi. Cattedra di Malattie del Metabolismo, Università di Pisa, Pisa, Italy.

We compared conservative surgical treatment of non infected neuropathic foot ulcers to conventional therapy in a group of diabetic outpatients. 41 patients who came to our foot clinic for the first time from January to December 1995 with a non complicated neuropathic ulcer were randomized into two groups: Group A [N. 20 patients (17 NIDDM/3 IDDM), age 63.24±13.46 yrs, duration of diabetes (DD) 18.2±8.41 yrs, HbA1c 9.5±3.8%] received a conventional treatment, consisting in medications and relieving of weight; Group B [N. 21 patients (19 NIDDM/2 IDDM), age 65.53±9.87 yrs, DD 16.84±10.61 yrs; HbA1c 8.9±2.2%] underwent surgical ulcerectomy, eventual remodelling or removal of bone segments underlying the lesion and surgical suture. Healing rate was lower (79.2%) in group A than in group B (95.5%; p<0.05), and healing time was longer in group A (128.91±86.60 days), than in group B (46.73±38.94 days; p<0.001). Infective complications occurred significantly more often in group A patients (12.5%) than in group B (4.5%, p<0.05), as well as relapses of ulcerations (8 in group A versus 3 in group B patients; p<0.05). Patients' satisfaction was higher in group B patients (p<0.05) than in group A ones. Surgical treatment of neuropathic foot ulcers is an effective approach compared to conventional treatment in terms of healing time, complications and relapses.

1874

THE METHODS OF DIAGNOSTICS AND TREATMENT OF THE DIABETIC FOOT.

Y.O.Markevych, N I Boyko, A.A.Serhiyenko, Y.M.Vendzylovych and M.P.Pavlovsky, Y.S.Erin. Lviv State Medical University, Ukraine.

The results of investigation and treatment of 320 severe cases of diabetes mellitus with diabetic foot have been summarized and analized The age of the patients ranged from 21 to 69. The average dose of 63,5±12,1 units of insulin was injected daily.

The following investigations were performed: polarography, capillaroscopy, ultrasonic dopplerography of the vessels of the lower extremity, roentgenoscopy of pedal bones. The immune condition of the body, the level of hormones (hydrocortisone, aldosterone, corticotrophin, somatotrophin, calcitonin) in the blood serum and the process of lipid peroxidation were studied.

All patients were observed to develop the thinning of the osseous cortical layer; 87% had 2 to 3-fold increase of calcitonin level and the decreased level of calcium in the blood. 92% of patients had disturbances of pallesthesia, thermosthesia and algesthesia. 78% were noted to have the increased concentration of fibrin and fibrinogen in the blood plasma and the increase of thrombocytes' aggregation qualities. Those changes caused the disturbances of flow-rate characteristics, i.e., slowed-down blood flow venous stasis, thrombogenesis. Magistral flow and pulse index in crural and pedal arteries were diminished in 96% of patients.

Conservative complex treatment proved beneficial for every stage of metabolism and for microcirculation.

196 patients with phlegmone were operated. In cases of marginal dry gangrene on the foot, necrectomy was performed In cases of destructed bones and purulent foci on the foot, excision within healthy tissues was made. The wound was sutured and drained. When gangrenous hallux was aggreavated by progressing infection the tendon of the musculus flexor longus hallucis was excised within healthy tissue.

Complex treatment was aimed at the adequate correction of carbohydrate, lipid, protein, water-electrolyte metabolism and flow-rate characteristics and at the possibility to perform "smaller" surgery. As a result, the number of amputations of lower extremities decreased considerably.

1875

VASCULAR DISEASE OF THE LOWER EXTREMITIES IN RENAL DYSFUNCTION PATIENTS

K. Hosokawa, Y. Atsumi, A. Mokubo, T. Asahina, A.Shimada, H.Tomonari, T.Kuriyama and K. Matsuoka. Saiseikai Central Hospital, Tokyo, Japan.

Background: Renal Failure is one of risk factors of diabetic foot. Amputation rate in patients under hemodialysis is high. Hemodialysis patients have arteriosclerosis obliterans so often. Objective: To determine the incidence of vascular disease in renal dysfunciton diabetic and nondiabetic patients with creatinine level above 1.4mg/dl. Research design and method: Subjects: 110 diabetic and nondiabetic patients who took the color doppler ultrasonography. Age: average 64yr(range 34-88yr). Of the 82 diabetics 35 were receiving hemodialysis and 47 were not. Of the 25 nondiabetics 12 subjects were receiving hemodialysis and 13 were without hemodialysis. Results: Results of the doppler were divided into two groups: normal and significant findings (plaque, calcification, stenosis or obstruction). 1. Diabetic prehemodialysis patients group: the percentage of patients who had the significant findings was 62%. Especially the percentage of patients who had the findings of stenosis or obstruction was as high as 47%. 2. Diabetic hemodialysis patients group: the percentage of the significant findings was 74%. The percentage of stenosis or obstruction was 54%. 3. Nondiabetic prehemodialysis patients group: the percentage of significant findings was 30%. Only two(15%) patients had the findings of stenosis. 4. Nondiabetic hemodialysis patients group: the percentage of significant findings was 33%. The number of patients who had stenosis was four(8%). Conclusion: The probability of development of vascular diseases of diabetic renal dysfunction patients even in prehemodialysis stage is high.

1876

FROM THE EXPERIENCE OF «DIABETIC FOOT» CENTRE IN MINSK

Kholodova H., Mokhort T., Shutova V., Beloded I., Romeiko D.
Rep. Belarus, Minsk, Inst. Of Advanced Medical Studies.

In April 1996 Specialized Center «Diabetic Foot» was stared in Minsk as outcome and consequence of St'Vincent Declaration and introduction of National Program «Diabetes Mellitus in Republic of Belarus». The Center has two parts: an out-patient consulting room and an in-patient department. A qualified doctor and a nurse with a special training work at the out-patient department. 615 patients had their examinations in this out-patient consulting room. Specialized examination included: taking the patients case history, follow-up of the disease, determining risk factors, foot examination, Doppler ultrasound measurements of vessels, vibration perception threshold and temperature discrimination of threshold measurements. It was found out that 13,1% of the patients examined had a diabetic foot syndrome. 86,3% them had neuropathic, and 13,6% had severe neuro-ischemic lesions. 54,5% of patients with ulcers received complex out-patient therapy. 18,1% of patients had severe infections lesions or gangrene. They were hospitalized to the city hospital № 10 where a 30-bed department for diabetic foot patients is located. The in-patient department staff includes experienced surgeons and a diabetologist who have a special training in this field. The joint efforts of the medical personnel allowed to decrease by 18,8% the number of high (above the knee) amputations and to determine risk groups and introduce prophylactic treatment. In the future the Center is planning to carry out their screening program for early diagnosis of the syndrome of the diabetic foot to prevent amputations.

1877

GRANULOCYTE COLONY STIMULATING FACTOR (G-CSF) IMPROVES NEUTROPHIL FUNCTION AND CLINICAL OUTCOME IN LIMB THREATENING INFECTION.

A Gough, A V M Foster. P J Watkins and M E Edmonds. *Kings Diabetes Centre, Kings College Hospital, London, UK.*

Lower extremity infection continues to be a cause of significant morbidity and mortality. Neutrophil superoxide generation, a crucial part of neutrophil bactericidal activity, is impaired in diabetes. In a randomised, double-blind placebo controlled trial we assessed the effects of systemic treatment with the haematopoietic growth factor G-CSF on neutrophil superoxide generation and clinical outcome in patients with severe foot sepsis, necessitating hospital admission. Individuals were matched for age, sex, duration of diabetes, vascular disease and were randomised to either **G-CSF** therapy (**G**; n=20), 5 $\mu g\ kg^{-1}\ day^{-1}$, subcutaneously for 7 days or **Placebo** (**P**; n=20). Both groups received similar antibiotic and insulin treatment. Baseline metabolic control was similar, HbA1c [median; (range)], **G**9.2%; (5.5-12.3) vs. **P**8.7%; (5.5-12.9), *p=0.49.* Initial opsonised zymosan stimulated superoxide levels (nmol/10^6 neutrophils/30 min.) were also similar [mean ± SE]. **G**6.8 ± 1.9, **P**7.2 ± 1.4, *p>0.05.* After 7 days treatment the G-CSF group showed neutrophilia, absolute neutrophil counts, [mean ± SE, $x10^9$ /L], **G**20.9 ± 1.7, **P**4.1 ± 0.4, *p<0.0001* with significantly improved superoxide levels, **G**15.2 ± 1.5 vs. **P**6.6 ± 0.8, *p<0.001.* No G-CSF patients required surgery/amputation vs. 4 placebo, χ^2=4.44, *p<0.05.* Deep tissue swabs became sterile quicker in G-CSF patients, [median; (range)], **G** 4 (2-10) days vs. **P** 8 (2-79), *p=0.007.* Improved neutrophil function in the G-CSF group was also associated with more rapid cellulitis resolution, **G** 7 (5-20) days vs. **P** 12 (5-93), *p=0.01,* shorter hospital stay **G** 10 (7-31) days vs. **P** 16.5 (9-100), *p=0.007,* and reduced intra-venous antibiotic requirements. **G** 8.5 (5-30) days vs. **P** 14.5 (8-63), *p=0.02.* G-CSF increases neutrophil superoxide generation in patients with foot infections and this may have clinical benefits.

1878

DIABETIC FOOT ULCER MANAGEMENT - EXPERIENCE OF IBRAHIM MEMORIAL DIABETES HOSPITAL.

H. Kabir Chowdhury, M. H. Khan, E. Hoque and T.K. Maitra. Ibrahim Memorial Diabetes Hospital, Dhaka, Bangladesh.

Foot ulcer is a dreadful complication of diabetes mellitus. About 27% of our surgical admissions are due to foot ulcer. In the surgical out-patient dept. 40% of the patients are treated for foot ulcer. One recent study on 167 patients showed that 65% of these patients are known diabetic, 57% on admission had blood sugar >10 mmol. Elderly patients with a mean age of 52 years are more commonly affected. Male female ratio was 4 : 1. Only 21% patients gave any historyof trauma and 22% of these patients and macroangiopathy. Various reasons, like microangiopathy, poor nutrition, uncontrolled diabetes, delay in treatment, wrong or inadequate treatment by different types of healers, all account in many ways for the devastating results of these cases and at the same time makes management difficult. Patience, time, enthusiasm and above all a challenge to fight the problem is all that is required to treat this condition. Patients has taught us many important lessons like (a) Diabetic foot ulcers are deceptive - what is seen from outside more is hidden inside. (b) Once bone and joints are involved it is better to sacrifice that part early. (c) Serial amputations can reduce number of major amputations. (d) Diabetic patients can tolerate very large incision far better then any deep infection. (e) Initial antibiotic therapy should be aggressive, etc. At present our policy is aggressive debridement, 2-3 times daily dressing, not to use any corrosive in the wound, frequent follow up, and amputations when necessary. We are not yet happy with the results. We are using hydrocolloid dressing which seems to be helping granulation tissue to grow in clean cases. Local musle rotation was found helpful to save heelpad. When patients are gravely ill due to septicaemia with renal or cardiac failure an early guillotine amputation even under local anesthesia can save many life.

1879

TOPICAL APPLICATION OF GROWTH HORMONE CAN ACCELERATE WOUND HEALING IN DIABETIC FOOT ULCERS

R. Carvalho, J.Dores, A.P.Marques, L. Serra and B.Serra. Serviço de Endocrinologia. Hospital Geral de Santo António. Porto. Portugal

Diabetic foot ulcers are a serious complication of Diabetes Mellitus, carrying enormous economic and social costs for the Institutions and patients. Previous studies have demonstrated that there are GH receptors in the different structures of the skin and the promotion of local growth could be done directly by GH and throughout mRNA IGF-1 production. In order to evaluate if the topical application of r-hGH could accelerate the rate of closure of diabetic foot ulcers, the authors designed a randomised, single blind and crossed study. Fourteen patients (7 male, 7 female) with neurophatic foot ulcers matched with a control group (6 male, 4 female) for age, duration of diabetes, HbA1c, IGF-1, IGFBP3 and baseline wound's area were assigned to be treated with a solution containing r-hGH (0,2 IU/cm^2 of wound area), thrice a week. For ethical reasons foot ulcers should be crossed to the opposite group every 2 weeks if a reduction greater than 25% of the baseline area was not seen. The wounds were photographed weekly and images were submitted to computerised planimetry. The data obtained were plotted statistically. Mean rate of closure at the second week of treatment was significantly greater in the r-hGH treated group compared with the control group (34,6 ±21,1% Vs 7,8 ±24,9 %, p<0.01). Since the patients in the control group significantly crossed to the r-hGH treated group, the placebo group was reduced to 4 patients at the second week, which became subsequent statistical analysis quite difficult at the 30th day and totally impossible at the 45th day of the survey. At the 30th day the results still showed an higher mean rate of wound closure in the hGH treated group compared with the control group, although statistically not significant (37,2 ±27,5% Vs 15,4±13,6%, p=0,08). However the rate of cure of the 20 r-hGH treated ulcers was halved in relation to the ulcers treated classically in our Department (43,2 ±15,6 days Vs 90,2 ± 25,3 days). The authors concluded that topical application of r-hGH might be a valuable complement to the classical treatment of neurophatic foot ulcers, promoting the acceleration of wound closure. Larger studies will be needed to confirm these data and to evaluate if this kind of treatment could be extensible to the neuroischaemic foot.

1880

THE DIABETIC FOOT: SOME ASPECTS OF EARLY DIAGNOSIS

A.A.Serhiyenko,Z.Y.Kozytsky,L.M.Serhiyenko,Y.S.Erin and Y.V.Ablitsov. Department of Endocrinology, Lviv Medical University, Lviv, Ukraine

Macrovascular disorders appear more frequently and proceed more difficult in patients with diabetes mellitus but the specific mechanisms of their development are studied insufficiently.We have carried out the analysis of pecualiarities of enzymes activity, levels of phospholipids and fatty acids, level of the ^{125}I-6-ketoprostaglandin F_{1a} (6-ketoPGF$_{1a}$), ^{125}I-thromboxane B_2 (TXB$_2$) in the membranes of erythrocytes, blood plasma and the lower extremities arteries' wall in patients with diabetic macrovessel complications (n=17).Simultaneously, 11 patients with atherosclerotic macrovessel complications and invariable indices of oral glucose tolerance test were examined. More considerable 'anaerobization' of metabolism has been found in vessel's tissue diabetic patients which is accompanied by increase of total lactatedehydrogenase (LDH) of activity and deplacement of isoenzymes spectrum to catode fraction.The considerable depression the activity of protein-kinase C (PK-C), Na^+,K^+-ATPase, Ca^{2+},Mg^{2+}-ATPase in RBC's membrane and arteries' wall at progressing diabetic vascular disorders indicates their role in diabetic angiopathy pathogenesis.Between decreasing of PK-C and Na^+,K^+-ATPase and Ca^{2+},Mg^{2+}-ATPase activity there exists certain correlation which in probably conditioned by Ca^{2+}-phospholipid-dependent phosphorylation of those ATPases. That may lead to disorders of the metabolism of phosphatidilnositole,the synthesis of eicosanoids and to promotion the accumulation of free calcium in the cell's cytoplasm.The progressing of the diabetic macroangiopathies cause leads to considerable increase of TXB$_2$and decrease of 6-ketoPGF$_{1a}$ levels, which may promote to vasoconstriction effect,proaggregability, blood rheologic disorders and to intensification the adhesion of blood cells to endothelium. The increase of TXB$_2$/6-ketoPGF$_{1a}$ ratio is a sensitive criterium of introduction and progress of diabetic angiopathies. The appearance and progressing of diabetic angiopathies is accompanied by the decrease of phospolipides, polyunsaturated fatty acids and the increase of free cholesterol and saturated fatty acids in the membrane erythrocyte's and in the tissues of arteries' wall. Our results support the hypothesis that disorders of the metabolism of phosphatidilinositole, the synthesis of eicosanoids may be beneficial in development of diabetes macrovascular complications.

1881

FOOT AMPUTATION IN DIABETICS: PREVENTABLE AND NONPREVENTABLE FACTORS. I. Vereanu, C. Ionescu-Tirgoviste, S. Pruna, R. Strachinariu, D. Avram and L.C.Nwabudike. Clinic of Diabetes, "Institute N.C.Paulescu" Bucharest, Romania.

This is an analysis of 473 diabetic patients admitted into the surgical department of the Cantacuzino Hospital for diabetic gangrene in two different years: 1991 (238 cases) and 1994 (235 cases) of which: 371M (78.4%) /102F(21.5%); NIDDM patients: 298 (63.0%); 49 cases (10.4%) were primary insulin-dependent and 126 (26.6%) were secondary insulin treated patients. Duration of diabetes was 9.3± 6.9 yrs. The surgical treatment was conservative in 50 cases (11.8%). Minor amputations: toes-124 cases (26.2%); transmetatarsian-82 cases (17.3%); major amputations: below knee-61 cases (12.9%); above knee-51 cases (31.9%). **Medical risk factors** encountered in order of frequency were: high perception thresholds for pain, temperature and vibration in 100% of cases; bilateral absence of Achilles tendon reflexes in 100% of cases; low nutritional blood flow (due to arteropathy or microangiopathy or sympathetic denervation of arterioles) in 100% of cases; type of diabetes (NIDDM in 63% of cases); long duration of diabetes (61%>10yrs.). **Medical risk indicators**: high blood glucose and glycated hemoglobin (87%); high (>30mg./24h) albumin excretion rate in 78% of cases. **Non-medical (socio-economic and behavioural) indicators:** low socio-economic status (84% low income earners); male gender (78%); poor educational level (73%); old age (71.7%>60yrs.); poor clinic attendance (92% without regular check-ups in the past year and 54% in the past 5yrs.); poor self-conservative behaviour leading to late presentation at the physician (lesions>10 days old at presentation in 72% of cases). **Trigger factors for leg ulceration** were divided into 3 categories: *preventable*: ill-fitting shoes, various traumas and burns in 76.7% of cases; *partially preventable*: increased pressure points, hyperkeratoses with fissuring, and fungal infections in 10.9% of cases; *non-preventable*: arteriopathic and microangiopathic ischaemia; diabetic bullae in 12.3%. Our cases were considered predominantly neuropathic in 83% of cases and predominantly vascular in 17% of cases. **Conclusion:** two-thirds of amputations are preventable if the patients are well informed and motivated and if the foot care team (diabetologist, chiropodist, nurse and surgeon) is committed.

1882

Impact of specialised care on time course and outcome of recurrent diabetic foot lesions

S.Morbach, Ch.Viergutz, H.R. Ochs. Diabetic Foot Clinic, Marienkrankenhaus Soest / Germany

Background: Avoidance of amputation in diabetics with foot ulceration by specialised care has been demonstrated recently. In the healed high risk for reulceration persists. Little is known on the influence of a diabetic foot clinic on the course of a second lesion. **Aim:** To analyse the impact of a dedicated diabetic foot clinic on time course and outcome of recurrent ulceration in diabetic patients. **Patients and methods:** 30 consecutive patients (10m/20f; average age 71,2 years; average diabetes duration 17,9 years) who relapsed after a diabetic foot lesion were analysed. Data on healing time, severity of the lesion at presentation (wagner-classification), hospitalization rate and need of amputation were sampled for both events.
Results: Average healing time was shortened to 24 days (SD 24,5) after initial presentation refering the second lesion compared to 69 days (SD 49,5) on the first (p=0,00001, Wilcoxon). Treatment duration was reduced by 65% for the whole population, 70% for pure neuropathics and 60% in critical limb ischemia respectively. Need for initial hospitalization declined from 73% to 7% (p=0,0001). Amputation had been performed in 23% of the patients before first contacting our clinic. On the first lesion 10% had to be treated by minor-amputation, on the relapses no amputation was required.
Conclusion: Specialised care by a diabetic foot clinic suceeds in improving outcome of high risk patients with recurrent foot ulceration. Treatment duration, need of hospital admission and amputation are proven to be reduced significantly.

1883

FREQUENCY OF LOWER LIMB AMPUTATIONS IN 147 TURKISH PATIENTS WITH DIABETIC FOOT SYNDROME

A. Gürlek, O. Gedik and M. Bayraktar, Hacettepe University Department of Endocrinology, Ankara, Turkey

There is large discrepancy regarding the incidence of diabetes-related lower limb amputations among various populations and ethnic groups. To our knowledge, there are no data regarding the frequency of lower limb amputations in Turkish diabetic population. In the present study, in a reference hospital setting, we evaluated the medical records (1986-96) of 147 patients (11 IDDM and 136 NIDDM) in respect of 195 hospitalizations due to diabetic foot ulcers. As to the predisposing factors, peripheral macrovascular disease and distal symmetric polyneuropathy were noted in 55.1% and 73.5% of the patients, respectively. History of cigarette smoking (more than 1 pack-year) was positive in 30.6%. of the patients. Medical therapy alone (i.e.,debridement and antibiotics) and lower limb amputations (below toe; minor and above toe; major) were performed in 59.2% and 40.8% of the patients, respectively. Implantation of a skin graft or island flap was performed in 6.8% of the patients in order to accelerate the healing of large defects. The most frequent isolate from deep wound cultures were found to be Staphylococcus Aureus (21.8%) and, as to the whole study period, overall mortality rate was 8.8%. Our data suggest that nearly half of the Turkish patients who admit due to diabetic foot ulcers undergo some kind of a lower limb amputation in our group. High frequency of associated risk factors such as peripheral vascular insufficiency may, at least in part, explain the high frequency of these amputations.

1884

HOW DOES DELAY IN SEEKING CARE FOR A DIABETIC FOOT LESION INFLUENCE OUTCOME?

del Aguila MA, Pugh J and Reiber GE, VA Puget Sound Health Care System, Seattle, USA

Objective: To identify patient characteristics that were associated with delay in seeking care for diabetic foot lesions, and to examine the independent association between time to presentation and foot lesion outcome. Design/Methods: Patients in this study were enrolled in the Diabetes Ulcer Outcome Study (DUOS), an observational study of foot ulcer treatment and outcome conducted at three VA medical centers and 3 non-VA facilities. Patients were enrolled from 1 Oct 1994 - 30 June 1996, and followed prospectively throughout the course of their treatment. A trained research assistant (RA) collected standardized information from each patient regarding demographic factors, diabetes and ulcer history, and general health. Lesion characteristics and treatment were recorded by the RA at each outpatient and inpatient visit. Patients were followed until outcome: healing, amputation, or death. Results: Three hundred two patients were enrolled in DUOS, of whom 272 (90%) provided a lesion onset date. Half of these patients reported seeking care within the first week, while 20% waited over four weeks. A forward stepwise linear regression model yielded two predictors of shorter time to presentation: education regarding proper footwear (26% shorter delay in seeking care, 95% CI 10%-41% shorter), and persons to help with foot care (compared to no helpers, each additional person resulted in 16% shorter delay, 95% CI 4%-27% shorter). Delay in seeking care was positively correlated with ulcer severity at presentation (Pearson's product moment r^2=.16, p=.004). However, after adjusting for confounding factors, a delay in seeking care was not associated with healing, or lesion duration. Conclusions: Half of all patients obtain care within 7 days of finding a foot lesion. Outpatient education regarding footwear, and help with foot care were independently associated with shorter delay in presentation for care. A longer time to obtaining care was associated with increasing ulcer severity, but there is no independent association with ulcer healing or duration.

1885

DEATH AND INSTITUTIONALIZATION FOLLOWING DIABETES-RELATED LOWER EXTREMITY AMPUTATION

LA Lavery, WH van Houtum and DG Armstrong
Dept. of Orthopaedics, Univ. of Texas Health Science Center, San Antonio, USA

We are unaware of any report in the medical literature that has discussed risk factors for both mortality and discharge disposition following lower extremity amputation (LEA). Our aim was to report risk factors associated with in-hospital mortality and the need for institutional care in diabetics with LEAs. We abstracted data for every hospitalization for a LEA from January 1 to December 31, 1993 in 6 metropolitan statistical areas in South Texas. Amputation level was categorized as foot, leg or thigh. Discharge status categories were: home, nursing home, rehabilitation facility and death. We used the Kaplan scale of cogent comorbidities to determine the relationship of 12 disease categories and their association with discharge status. There were 1,043 LEAs in South Texas in 1993. While only 2.3% of the population was admitted from an institutional care facility, over 25% were discharged to one. Of the total population, 18.5% were discharged to a nursing home, 7.0% to a rehabilitation facility and 5.1% died within the period of hospitalization. We performed a univariate analysis. Factors with a $p<0.25$ were included in a stepwise logistic regression analysis with an α of 0.05. High level (leg or thigh) amputation, peripheral vascular disease, male gender, and absense of advanced locomotor impairment were associated with discharge to a rehabilitation facility. For discharge to a nursing home significant associations were found with: female gender, advanced age (>65), single marital status, high level amputation, and advanced cerebrovascular disease and locomotor impairment. Death following a LEA was strongly associated with female gender, high level amputation, advanced renal disease, anemia, and congestive heart failure. We conclude that a significant number of patients either die or require long-term care following a diabetes-related LEA, thus further adding to the burden of this sequela. Several clinical parameters are significantly associated with discharge status after this procedure. More prospective clinical research is needed to verify the associations and to clarify their application in practice.

1886

GAIT ANALYSIS IN DIABETIC UNILATERAL LOWER LIMB AMPUTEES.

C.H.M. van Schie[a], C.A. Abbott[a], L. Vileikyte[b], JE Shaw[b], AL Carrington[a], J Kulkarni[a], E. van Ross[a] and A.J.M. Boulton[b]. [a]Disablement Services Centre, Withington Hospital and [b]Diabetes Centre, Manchester.

Unilateral amputation changes the walking pattern and could affect the foot of the remaining limb. Gait was analysed in 23 diabetic amputees (Stanmore mobility grades 4 or 5), at 8 ± 2 months (mean ± sd) and in 7 non-diabetic amputees at 10 ± 3 months after amputation. Diabetic amputees were matched with diabetic non-amputees, with and without neuropathy. Subjects walked at their own selected pace over a Kistler force plate. Maximum horizontal (posterior (P), anterior (A), medial (M) and lateral (L)) and vertical (V) ground reaction force, ground contact time (GCT) and force-time integral (FTI) were measured. For the diabetic amputees, all gait parameters, (except M) were greater in the remaining compared to artificial limb ($p<0.01$), whereas there were no differences between legs in the non-amputees. Maximum A, P, M, L and V forces (% body weight) for the artificial and remaining limb were respectively 8.6 vs 10, 7.3 vs 11.5, 7.1 vs 7.1, 1.2 vs 2.5 and 101.4 vs 105.4, GCT (msec) and FTI (Nsec) were respectively 1042.6 vs 1109.6 and 586.7 vs 701.6. FTI and GCT were greater and maximum V force were smaller in the remaining limb of amputees compared to the non-amputees ($p<0.001$). The non-diabetic amputees had significant lower FTI's than the diabetic amputees (409 and 510 vs 586 and 701 for artificial and remaining limb), although walking speed, GCT and maximum forces were not different between the two groups. Only the FTI and maximum V force were different between legs in the non-diabetic amputees, with a significant difference for FTI. The results of the non-diabetic amputees suggest greater differences between legs for the diabetic amputees. Thus, the asymmetric walking pattern and the greater force-time integral in the remaining limb of the diabetic unilateral amputees may further increase the already high risk for foot ulceration, thus exacerbating the risk for amputation of the remaining limb.

1887

DIABETES MELLITUS SURVIVAL AFTER LOWER EXTREMITY AMPUTATIONS.

Spichler, D., Spichler, ERS., Franco, LJ and Lessa, I. Health Ministry, Health State Secretariat of Rio de Janeiro,Federal Fluminense University,Federal University of Sao Paulo, Federal University of Bahia, Brazil.

Lower Extremity Amputations (LEAs) in diabetics are an important medical social problem in Brazil. Lack of proper medical care and metabolic control, result in disability, earlier retirement of work, and preventable deaths. The aim of this paper is to determine the survival of amputee diabetic patients. This is a prognostic coorte study, involving all diabetics LEAs that occurred between January 1990 trough December 1994, living in Rio de Janeiro municipality, metropolitan region, followed up by three years after the surgical procedure. Amputation data came from all sources available to identify Diabetic cases, also including amputtee register (AR).Amputtee death certificates were reviewed in the same period for all deaths registered in the State of Rio de Janeiro (336,182). The end point for analysis was death of diabetic amputtee or the closing date of the study. Data were analyzed trough a survival table. Sex differences were compared by x^2 Mantel test. There were 419 diabetic LEAs, being 221 in men (52,7%) and 198 in women (47,9%). In this period occurred 111 deaths in diabetic patients (26,5%), the rate was 24,0% for men and 29,3% for women. Survival probability after 36 months from diabetic amputtees, was 57,9% for men,and 49,5% for women (x^2 1.39 $p>0.005$). During the first 15 days the survival probability was 90% for men, and 87% for women;after 60 days, 84% for men and 79,8% for women. However no statistically significant difference was observed in the survival probability between genders at 36 months; it was always lower for women, since the first days. These results suggest poor medical care or late demand, a finding not expected.The speed survival rate decreased in the first month of follow-up,suggesting death by infection (sepsis),even when amputtee are more prone to this kinds of risk. All deaths were reviewed except if any patient migrated to other state and died there. These results pointed out to the necessity of appropriate health care and monitoring metabolic changes proper to Diabetes Mellitus.

1888

DOES DIABETIC NEUROPATHY AFFECT THE FORCES USED DURING WALKING ?

C.H.M. van Schie, J.E. Shaw and A.J.M. Boulton. Diabetes Centre, Manchester Royal Infirmary, UK.

Neuropathy might affect the forces controlling walking, and abnormal forces may be an important cause of elevated foot pressures. The aim of the study was to investigate the effect of neuropathy on ground reaction forces. We measured vertical, medial and lateral impulses (force-time integrals) and ground contact times using a Kistler force plate mounted in an 8 meter walkway, in 15 non-diabetic controls (C), 35 diabetic controls (D), 35 diabetic patients with neuropathy (DN) 17 with previous neuropathic ulceration (DNU), and 14 patients with Charcot neuro-arthropathy (CH). The mean (sd) vertical impulses (expressed as % body weight) were C-55.4 (5.5), D-59.0 (6.1), DN-58.3 (4.9), DNU-61.5 (6.0) and CH-62.5 (7.2). D, DNU and CH were significantly greater than C ($p<0.001$). The lateral impulses were C-0.12 (0.07), D-0.09 (0.08), DN-0.10 (0.09), DNU-0.12 (0.10), CH-0.06 (0.05). CH was different from all others, but only significant for DNU and C ($p<0.05$). No differences were observed in medial impulses. The ground contact times (msec) were C-664 (71), D-712 (73), DN-702 (64), DNU-746 (69), CH-767 (88). CH and DNU were significantly longer than C ($p<0.01$). Increased impulses were mainly due to increased ground contact times and not directly attributable to neuropathy. Thus, neuropathy does not seem to alter the impulses except when combined with structural changes as in Charcot neuro-arthropathy.

1889

AMPUTATION AND REAMPUTATION OF THE DIABETIC FOOT

Armstrong DG, Lavery LA, vanHoutum WH, Harkless LB
Dept. of Orthopaedics, Univ. of Texas Health Science Center, San Antonio, USA

We have observed that while numerous studies have focused on lower extremity amputations in general, amputations at the level of the foot are often treated as a single level or not stratified by specific site within the foot. In the majority of cases, this is due to the fact that data is gathered from secondary databases which do not provide specific documentation about amputation location. It is perhaps for this reason that we have not encountered any works in the medical literature that have reported on a large number of foot amputations, categorizing them by specific level and etiology. The purpose of this manuscript is to compare level of foot amputation by age, prevalence of arterial disease as a precipitating factor, gender, and ethnicity in persons with diabetes mellitus. We abstracted the medical records for each hospitalization for a lower extremity amputation from January 1 to December 31, 1993 in six metropolitan statistical areas (MSA's) in South Texas. Amputation level was defined by ICD-9-CM codes and were categorized as foot, leg, and thigh amputations. Foot level amputations were further subcategorized as hallux/first ray, middle, fifth, multiple digit/ray, and midfoot amputations. Only the highest amputation level for each individual was used in the analysis. Of 1043 subjects receiving a lower extremity amputation in South Texas in the year 1993, 477 received their amputation at the level of the foot. African Americans requiring a foot level amputation were at significantly higher risk to receive a midfoot-level amputation than were the rest of the population. Nearly 40% of all subjects receiving a foot-level amputation had a previous history of amputation. However, nearly 40% of subjects receiving foot amputations were without any pre or peri-admission diagnosis of peripheral arterial occlusive disease, suggesting a causal pathway dependent primarily on neuropathy. This implies that better screening of diabetic patients with appropriate risk-directed treatment at the primary care level may significantly impact the large number of preventable diabetes-related lower extremity amputations.

1890

DIABETIC NEURO-ISCHAEMIC FOOT: ELEVATED PLANTAR PRESSURES AND CONTACT TIME, BUT NO PLANTAR ULCERATION

D.L. Pitei [a], D. Van Der Meer [b], A. Foster [a], P.J. Watkins [a] and M.E. Edmonds [a], [a] King's College Hospital, London, [b] Musgrave Systems Ltd., Llangollen, UK

Diabetic neuropathic feet tend to develop ulceration on the plantar surface, whereas neuro-ischaemic feet tend to ulcerate on the margins of the foot. The reason for this difference in pattern of ulceration is not fully elucidated. High foot pressures have been implicated in the aetiology of foot ulceration, but time of pressure loading (contact time) on the soft tissues of the foot may also be important. The latter has not been studied previously in the neuro-ischaemic foot. The aim of our study was to measure dynamic barefoot pressures and contact time using the Musgrave Footprint System (Musgrave Systems Ltd.) in 15 neuropathic patients (vibration perception threshold (VPT)=40±11.5V (Mean±SD), pressure index (PI)>1), 20 neuro-ischaemic patients (VPT=39.3±10.5V, PI<0.7) and 8 non-diabetic controls (VPT=6.8±2.4V, PI>1). Peak pressures (at the first metatarsal head) were significantly higher in both the neuropathic (4.0±0.48 kg/cm^2, $p<0.05$) and neuro-ischaemic patients (3.36±0.34 kg/cm^2, $p<0.05$) as compared with non-diabetic controls (2.43±0.15 kg/cm^2). Contact time was 602.9±30.3 msec in the control group, whereas both the neuropathic (854.0±54.1 msec, $p<0.005$) and the neuro-ischaemic group (962.4±53.4 msec, $p<0.001$) showed significantly elevated contact time. There was no statistically significant difference in plantar pressures and contact times between the neuropathic and the neuro-ischaemic groups despite the trend to different sites for ulcer formation in the two groups. Further factors, in addition to high plantar pressures and prolonged contact time need to be considered in the aetiology of diabetic foot ulceration.

1891

DIABETIC FOOT ULCER - RISK FACTORS OF AMPUTATIONS

W.Zarzycki, M.Pędich*, J.Myśliwiec and M.Górska
Department of Endocrinology, Medical Academy Białystok, Poland and *Department of Endocrinology and Internal Disease of Regional Hospital Bialystok, Poland

The incidence of diabetes related amputations is an declared index of diabetological-care system in the country. Related to this a substantial reduction of amputations was declared a primary objective by WHO and IDF (St. Vincent Declaration). The purpose of this study was to estimate risk factors of amputations with advanced symptoms of diabetic foot - a neurop[athic ulcer. Analysis was made on 58 patients with symptoms of neuropathic ulcer - 42 men and 16 women aged 61 ± 14 and 67 ± 12 respectively. A mean period of diabetes lasting 12 years. All patients were hospitalised after an attempt of treatment as out-patients including paramedic procedures. In most of them (85%) the predominant symptoms was general infection, in some cases accompanied by a high fever. Diabetic retinopathy was present in 54 (94%), diabetic nephropathy in 50 cases (86%). Arterial blood flow was diminished to a different degree in all patients. In 20 cases (34%) pharmacological treatment and minor surgical procedures were not sufficient and required total amputation.. Patients who had undergone amputations were mostly males and subjects who did not attend courses on diabetic education. The group of patients with amputations in comparison with paliatively treated had more advanced signs of nephropathy (proteinuria and diminished creatinin clearance - 49.3 ml/min vs 71.2 ml/min, $p<0.001$)), neuropathy (Valsalva manoeuver) and retinopathy. It is concluded that the diabetic foot ulcer problem refers mainly to patients with microangiopathic complications. Our results also indicate that proper education of diabetics results in reduction of incidents of complication of diabetic foot and in consequence a dramatic reduction in amputations.

1892

A NOVEL METHODOLOGY TO EVALUATE THE DURABILITY OF INSOLE MATERIALS FOR HIGH RISK DIABETICS

K.A. Athanasiou, L.A. Lavery, D.R. Lanctot, and S.A. Vela
Univ. of Texas Health Science Center, San Antonio Texas, USA

Viscoelastic inserts are commonly used as artificial shock absorbers to prevent neuropathic foot ulcerations by decreasing pressure on the sole of the foot. The aim of this study was to develop a rational platform for biomechanical characterizations of insole material durability. This novel methodology consists of *in vivo* gait analysis and *in vitro* bioengineering measurements, applied on 2 insole materials (PPT and Pelite) worn by 8 diabetic volunteers for 12 weeks. Gait analysis, using the Emed pedar system, was performed every 3 weeks, to obtain temporal changes in the plantar foot pressure profile. Mechanical testing (compressive modulus) was also performede at 3 week intervals. The hypothesis was that a correlation exists between *in vivo* gait analysis and *in vitro* mechanical testing. Results demonstrate significant differences in the compressive stiffness of the 2 insoles as well as the rate of change over time. PPT insoles had a compressive stiffness 125% greater than Pelite insoles at time 0. After 12 weeks, insoles were essentially the same. Peak pressures decreased by 20% for both materials over 12 weeks. Neither material showed an elevation in pressure. Comparisons of peak pressures and compressive moduli show a relationship between the two measurements, such that a drop in pressure corresponds to a drop in modulus. Good correlations were found between pressure-time integral and modulus (r^2=0.93), and energy and modulus (r^2=0.87). In conclusion, we have established a new bioengineering protocol, based on gait analysis, viscoelastic characterizations, and biomaterial analyses, to study temporal variations in the structure-function relationships of insole materials. Based on these results, it is conceivable that a quick, inexpensive biomechanical test, which is based on creep or stress relaxation responses, can be established to indirectly evaluate pressure distributions on patients' feet as well as material "wear".

1893

TOE AMPUTATION AND TISSUE DEBRIDEMENT USING LARVAE OF THE GREEN BOTTLE FLY (LUCILIA SERICATA).

G Rayman, A Mackie, G Stansfield, A Rayman and T Ballagh.

The Diabetes Foot Clinic, Ipswich Hospital, Suffolk, UK.

The management of gangrenous lesions in the ischaemic foot where vascular intervention is not possible or has been unsuccessful is limited. Local surgical and enzymatic debridement (varidase) may be hazardous and auto-amputation of necrotic toes may be protracted with the risk of intercurrent infection. We describe our experience with the use of the larvae (maggots) of the green bottle fly (Lucilia sericata) to excise necrotic tissue. Three diabetic patients with black gangrenous tissue including toes which had not separated for 12, 8, 6 months respectively were treated. Between 100-150 immature (1-2 mm length) larvae were applied at each treatment under a fine nylon mesh. Larvae were removed after 48-72 hours. Approximately 50% of the larvae survived, growing to between 6 and 10 mm in length. The number of treatments varied with the extent of the lesions and the survival of the larvae, but between 2 and 5 treatments, applied at weekly intervals were used. In all patients necrotic tissue and mummified toes were completely separated to reveal healthy granulation tissue. One patient found the treatment moderately uncomfortable and psychologically disturbing but despite this was willing to continue because of the obvious benefit. Thus, our initial experience suggests that larval treatment is a successful, safe and relatively quick way of amputating gangrenous toes and debriding necrotic tissue in the ischaemic foot.

1894

QUANTITATIVE ASSESSMENT OF THE PLANTAR PRESSURE DISTRIBUTION IN DIABETIC PATIENTS WITH NEUROPATHIC FOOT DISORDERS

St. Zimny, E. Schifferdecker and H. Schatz, Medizinische Universitätsklinik Bergmannsheil, Ruhr-Universität Bochum, Germany

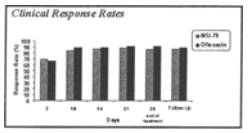
Pressure distribution on the sole during walking has been considered a useful indicator in the assessment and treatment of neuropathic foot disorders. **Methods:** Using the fastscan dynamic insole pedobarograph (Megascan Hannover) pedobarograms of 30 normal adult subjects with no foot disorders and 30 diabetic patients (9 IDDM and 21 NIDDM) with neuropathic foot without ulcers were recorded and the pressure distribution patterns of the metatarsal head I-III region, the metatarsal head IV-V region and the heel for each feet in both groups were analysed, also the area of peak plantar pressure on the whole sole. **Results:** Plantar pressure [g/cm^2] of the metatarsal head IV-V region in the diabetic group was significantly higher compared with the control group in both feet (Mean +/- SD: 1971+/-614 vs.1422+/-605 for the left feet, 2441+/-1832 vs.1469+/-667 for the right feet respectively). P<0,03 and 0,005. For statistical analysis we used the U-test. A non-significant higher plantar pressure was found in the metatarsal head I-III of the right foot and in the heel of both feet in both groups. The area of the maximum peak pressure [cm^2] of the whole sole of both feet was significantly smaller (90+/-21 vs. 106+/-10, p<0,004 for the left feet respective 84+/-20 vs. 106+/-20, p<0,005, for the right feet) in the diabetic group compared to the control group. **Conclusion:** In contrast to the current literature we recorded high plantar pressures especially under the metatarsal head IV-V region of diabetic patients with neuropathic foot disorders. 28 % of recorded cases of the metatarsal head IV-V region showed a plantar pressure above 2500 g/cm^2.

1895

TREATMENT OF INFECTED DIABETIC FOOT ULCERS:
TOPICAL MSI -78 VS. ORAL OFLOXACIN.

B.A. Lipsky, D. MacDonald, P.A. Litka and the MSI-78-303 Study Group. University of Washington and VA Medical Center, Seattle, WA, USA and Magainin Pharmaceuticals Inc., Plymouth Meeting, PA, USA.

MSI-78, a novel synthetic antibiotic peptide, was evaluated for treating patients with infected diabetic foot ulcers. In a prospective, double-blind trial, 490 diabetic adults with an infected foot ulcer suitable for outpatient management were randomized to either MSI-78 1% topical cream and placebo ofloxacin, or active ofloxacin and topical placebo cream (vehicle). Infection was diagnosed by clinical criteria, i.e., purulence or ≥2 signs of inflammation. Patients with severe infections, osteomyelitis or gangrene were excluded. All ulcers were cultured at baseline and day 3 of treatment, and subsequently if clinical signs of infection persisted. Treatment lasted from 14 to 28 days, and patients were followed-up 14 days after the end of treatment. Treatment efficacy was assessed primarily by clinical response, i.e., improvement or resolution of infection, and secondarily by overall microbiological response, i.e., resolution, improvement, colonization, superinfection, failure. The intent-to-treat analysis of clinical response rates showed statistical equivalence of the two treatment regimens at all time points (95% incidence interval of the difference method), with rates ranging from 84-93% (see figure). Overall microbiological responses were similar for the two groups. The frequency of amputation or osteomyelitis of the affected site were similar for the two groups. Treatment was well tolerated in both groups, but insomnia was significantly more frequent with ofloxacin. Thus, topical MSI-78 was highly effective and offered a similar therapeutic benefit as systemic ofloxacin, with a somewhat better adverse experience profile.



1896

BIOMECHANICAL COMPARISON OF TREATMENT STRATEGIES TO REDUCE PRESSURES AT THE SITE OF NEUROPATHIC ULCERS

J.G. Fleischli, L.A. Lavery, S.A. Vela,
Dept. of Orthopaedics, Univ. of Texas Health Science Center, San Antonio, USA

High pressure on the sole of the foot has been identified as an important causative factor in the development of neuropathic ulcers in persons with diabetes mellitus. There is little scientific data to compare the effectiveness of commonly used modalities to reduce these areas of high pressure. Our aim was to compare the effectiveness of total contact casts (TCC), "half-shoes" (HS), rigid soled post-operative shoes (RSS), accommodative felt & polyethylene foam padding (AD), and removable walking casts (RWC) to reduce peak plantar foot pressures at the site of neuropathic ulcerations in diabetics. We compared the reduction in peak pressures at ulcer sites under the great toe (n=7) and ball of the foot (n=19) using the 5 treatments described above. A rubber soled canvas oxford shoe was used to establish baseline pressure values. With the Novel Pedar in-shoe pressure measurement system, data from 32 mid-gait steps was collected for each treatment. Data was analyzed by evaluation of mean pressure and percent change from the baseline. We used Tukey's Studentized Range Test for simultaneous multiple comparisons between treatments with an α =0.05. RWC's reduced plantar pressures significantly better than other treatments for ulcers under the ball of the foot. For great toe ulcers, TCC's and RWC's reduced pressure better than the other treatments. There was a consistent pattern in the ability of the devices evaluated to effectively reduce foot pressures at ulcer sites. Removable cast walkers were as effective or more effective than TCC's. Half-shoes were consistently the third most effective modality followed by accommodative dressings and post-operative shoes. Clinical studies are needed to fully evaluate healing times, complications and patient satisfaction.

AVERAGE PEAK PRESSURE &PERCENT CHANGE FROM BASELINE*

* N/cm^2 (%Δ)	RWC	TCC	HS	AD	RSS
Forefoot	7.5(85) >	12.4(76) >	17.8(66) >	27.1(48) >	33.7(36)
Hallux	4.9(79) =	3.5(85) >	8.7(64) >	15.8(34) >	22.2 (7)

1897

ANTIBIOTIC TREATMENT OF DIABETIC FOOT ULCERS, DOES IT MATTER? AN ANALYSIS OF 95 CASES

I.Bruckner,N.Malaxa Hosp., Bucharest, Romania and
E.Chatelau, University of Dusseldorf, Dusseldorf, Germany

Background: The role of antibiotics (AB) in the treatment of diabetic foot infections is unclear. **Aim**: to relate the treatment response of diabetic foot infection to microbiological findings and to AB treatment. **Materials and methods**: 95 consecutive cases of foot lesions, Wagner stage < 4, were analysed, of which routine microbiological assessment was available (swabs, isolation of up to 4 germs per case, sensitivity testing against to 30 different AB). Swabs were taken because of suspected nosocomial infection (n=51), because of high risk feet (n=31) and at random (n=13). Standard treatment, i.e. absolute pressure relief, daily wound care (necrosectomy) and sterile dressing, was applied in every case. **Setting**: outpatient diabetic foot clinic. **Results**: Of the 95 cases, 5 were sterile; 191 isolates were cultured (22 different germs, 43% staph.). 22 cases, stage <4, were treated without AB (all improved). 73/95 cases started oral AB [at random cephalexin (CE) or clindamycin (CL)] prior to knowing culture results; 64 of these 73 improved, although 20% of isolated were resistant to CE, and 16% to CL. 9/73 cases improved only after changing AB according to culture. **Conclusion**: In diabetic outpatients, low-grade foot-lesions may improve despite unsuitable (or even without any) AB in approx. 50% of cases and in 40% with CE or CL as first-line AB. Cases requiring differentiated AB treatment need to be defined.

1898

TRANSCUTANEOUS OXYGEN TENSION AND TOE PRESSURE AS PREDICTORS FOR OUTCOME OF DIABETIC FOOT ULCERS

M. Kalani, K. Brismar, B. Fagrell, J. Östergren, and G. Jörneskog.
Department of Endocrinology and Diabetology, and Department of Internal Medicin, Karolinska Hospital, Stockholm, Sweden.

The possibility to predict outcome of chronic foot ulcers in diabetic patients is limited. A common method is measurement of toe blood pressure (TBP). Transcutaneous oxygen tension ($tcPO_2$) is another noninvasive method, which reflects local blood flow and oxygenation. The present study was undertaken to compare the predictive value of $tcPO_2$ and TBP for ulcer healing in patients with diabetes and chronic foot ulcers. Fortysix (34 male) patients were investigated. The age was 61±12, and diabetes duration 26±14 years. $TcPO_2$ (mmHg) was measured at the dorsum of the foot, and TBP (mmHg) with a mini cuff using laser Doppler fluxmetry as detector. The ulcer healing was evaluated by measuring the ulcer area. After a follow up time of 1 year the patients were divided into 4 groups according to outcome, i. e. increase or decrease of ulcer area, healed with intact skin, or amputated. The results are presented as x±SD.

	Amputation n=4	Increase n=8	Decrease n=15	Healed n=19
$TcPO_2$ (mmHg)	0.5±0.6*	18±14*	49±11	48±19
TBP (mmHg)	58±33	50±24	76±28	47±31

* $p<0.01$ as compared to patients with healed or decreased ulcer area.

Ten out of 12 patients, who deteriorated had $tcPO_2 < 25$ mmHg, while 31 out of 34 patients who improved had $tcPO_2 > 25$ mmHg. The sensitivity and specificity for $tcPO_2$ at 25 mmHg were 83 and 91%, respectively, while the corresponding values for TBP at 50 mmHg were 58 and 79%. $TcPO_2$ measurement provided a higher positive predictive value (77%), as compared with TBP (50%). In conclusion, the results show that $tcPO_2$ is a better predicator for ulcer healing than measurement of TBP in diabetic patients with chronic foot ulcers, and that the probability of ulcer healing is low when $tcPO_2 < 25$ mmHg.

1899

BACTERIAL FLORA OF DIABETIC FOOT INFECTIONS

V.BOŽIKOV, J.ŠKRLIN
University Hospital Dubrava, Zagreb, Croatia

Foot infections are common and most serious complications of diabetes mellitus. The management of the infection requires deep.tissue cultures. The aim of this study was to determine to what degree each particularmicroorganism is present in the different tissues and the different grade of lesion. In 399 isolates taken from deep tissue in 217 patients we confirmed the polymicrobial nature at the diabetic foot infection. The most frequently isolated species were gram-positive (55.9%) and gram-negative (39.1%) aerobes, but only 1% anaerobes (because of technical difficulties - great distance bewteen hospital and laboratory). The most commonly isolated microorganisms were Staphylococci and Streptococci, followed by Proteus, Pseudomonas, Enterobacter, Escherichia colli and Candida species. The average number of isolates per patient was 1.8. Additionally, in 39 patients the biopsy of deep tissues and bones was performed, and similar flora was obtained.

1900

TIP-THERM: A SIMPLE SCREENING METHOD FOR TEMPERATURE SENSATION

R. Windecker, S. Kindermann and M. Spraul. Heinrich-Heine-University, Düsseldorf, Germany

Loss of temperature and pain sensation is responsible for most neuropathic diabetic foot lesions. The determination of vibration sensation is often used as screening method for diabetic neuropathy. However, the relationship between the loss of vibration and the increased risk for foot lesions is for patients not directly obvious, whereas, temperature sensation is related with the contents of diabetes education programmes. Therefore, we tested the validity of Tip-Therm® as a screening method for the loss of temperature sensation in 50 patients with diabetes (age 48 ± 15, diabetes duration 16 ± 11; mean±SD). Tip-Therm® looks like a thick pencil and is made out of 2 materials with different conductivity for heat (steel and plastic) and has a defined geometry. When touching the skin a subjective temperature difference is felt. For comparision, temperature sensation was measured with a Thermocross® and vibration sensation with a graduated tuning fork. All temperature sensation were determined on the dorsum of the foot. In an earlier study, normal temperature sensation measured with a Thermocross® was <10°C temperature difference. All 26 patients with normal temperature sensation (<10°C) recognised the different subjective temperature sensation with Tip-Therm®, and 20 of the 24 patients with disturbed temperature sensation (≥10°C) were unable to recognise the difference. In conclusion, Tip-Therm® (Axon, Düsseldorf, FRG) is a simple, reliable and inexpensive screening method for the determination of a disturbed temperature sensation in diabetic neuropathy.

1901

DIABETIC FOOT: CLINICAL AND BACTERIOLOGIC ANALYSIS.

Calañas-Continente, A.J.; Jimena, L.; Arce, C.; Gálvez, M.A. and Benito, P.
Hospital Universitario "Reina Sofía", Córdoba, Spain.

The **aim** of the study was to analyze the clinical and microbiological characteristics of foot ulcers treated at the Out-Patient Diabetic Clinic in the last five years. **Methods:** We have reviewed 160 NIDDM patients (86 female, 74 male) with foot ulcers; mean age: 68'13 ± 11 years and diabetes duration of 26'17 ± 11 years. 67% of these patients were treated with insulin (mostly with two doses NPH). Swabs from the base of the ulcer were taken in 131 patients and cultivated in aerobic and anaerobic conditions. **Results:** Foot ulcers begin in diabetic women about 60-70 years old and later in diabetic men. There was no significant difference between men and women regarding the kind of lesion. An average of 2'26 ± 1'4 species per patient were isolated. Sixty-four percent of diabetics had two or less organisms per lesion. The most frequent isolates were: Gram-positive cocci, 50%; Gram-negative bacilli, 42%: (Enterobacteriaceae, Pseudomonas) and Gram-positive bacilli, 3'19%: (Corynebacterium). When we compared this with the species isolated in the reinfection we can state that the infection caused by gram-positive cocci (50 vs. 43'40%, p< 0'05) and gram-negative bacilli (42 vs. 41%, p< 0'05) decreases whereas the infection caused by gram-positive bacilli increases (3'19% vs. 15'09%, p<0'05). 60% of our patients were permanently discharged. **Conclusions**: The diabetic foot infection has a polimicrobian nature being the combination of gram-positive cocci and gram-negative bacilli the most common association assessed. The bacteriological features change in the reinfection. We conclude that early diagnose and treatment allow us to avoid more aggressive therapies and at the same time we are able to increase the discharge rate so that an improvement in the life quality of the patients is achieved.

1902

THE LIPSTICK TEST, AN EASY WAY TO STUDY LOCAL PRESSURE ON THE DIABETIC FOOT.

K. Brismar and K. Sparre. Department of Endocrinology & Diabetology, Karolinska Hospital, Stockholm, Sweden.

Treatment of chronic foot ulcers (FU) in diabetes patients includes the relief of pressure at wounds and yet make it possible for the patient to walk. Due to neuropathy the patient does not feel the pressure of ill-fitting shoes or insoles. The aim of the study was to find and use an easy method to test local pressure on wounds from shoes, insoles or orthosis and the effect of non-weight-bearing corrections. About 100 patients with diabetes and FU are regularly treated at the foot clinic, Karolinska Hospital (Stockholm) by a diabetes team of physician, chiropodist, nurse and orthopaedic technician. All patients are treated with orthotic shoes with supportive insoles. At each visit the pressure from shoes and insoles at the FU is examined using the lipstick test; a piece of surgical tape is put on the bandage covering the wound. The site of the wound is marked with lipstick and a similar piece of tape is put on the sole where the wound is to be relieved, thereafter the patient puts on his shoes and walks about 10 m. If the site for pressure relief is coloured with lipstick the orthopaedic technician adjusts the sole and/or the orthotic shoe. We have found that the supportive insoles need, when they are new, several adjustments followed by repeated adjustments at least every third month. The fitness of the soles are crucial for wound healing. In conclusion the lipstick test has proved to correctly demonstrate local pressure at the wound site from ill-fitting shoes or insoles. The lipstick test is easy to perform and the cost is practically none.

1903

MICROBIOLOGY OF DIABETIC FOOT INFECTIONS

C. Loupa, M. Zouberi Koliomichali and D. Voyatzoglou. *Diabetes Outpatient Clinic, 2nd Dept. of Internal Medicine & Microbiology Laboratory, "A. Fleming" General Hospital, Athens, Greece*

In this study we recorded the microbiological flora of diabetic foot infections and the susceptibility of isolates to antibiotics. We studied 22 diabetic patients with lower extremity ulcers (12 neuropathic, 8 neuroischemic and 2 unclassified). Infections were followed by amputation in 5 cases (22.7%) . Swab cultures from the bottom of ulcer were obtained from all patients. *Results :* 2 cultures were sterile; most of the remaining 20 were polymicrobial (mean : 2.25 organisms). The commonest microorganism was *Staphylococcus* sp (21.7% of isolates), followed by *Pseudomonas* sp (19.5%), *E. coli* (17.3%) and anaerobes (13% of isolates). Gram (+) aerobes were isolated in 65% of positive cultures, whereas Gram (-) aerobes in 80% and anaerobes in 20%. 50% of Staphylococci were methicillin-resistant. *Staphylococcus* isolates were 100% susceptible to netilmicin and 90% to amikacin, followed by quinolones (80%), ticarcillin (70%), amoxycillin/clavulanate, co-trimoxazole (60%) and 3rd gen. cephalosporins (40%). *Pseudomonas* isolates was 88% susceptible to quinolones, followed by imipenem, aztreonam, netilmicin, amikacin (77%), ticarcillin (66%), 3rd gen. cephalosporins (44%); isolates were 100% resistant to amoxycillin/clavulanate, co-trimoxazole, 2nd gen. cephalosporins. *E. coli* isolates were 100% susceptible to ticarcillin, 3rd gen. cephalosporins, imipenem, aztreonam, quinolones, 85% to netilmicin, amikacin, 2nd gen. cephalosporins, and 57% to amoxycillin/clavulanate & co-trimoxazole. *In conclusion :* Initial empirical therapy of diabetic foot infections must be active against *staphylococcus, pseudomonas, E. coli,* and also against anaerobic bacteria.-

1904

FACTORS ASSOCIATED WITH AN ABNORMAL RESULT OF THE SEMMES-WEINSTEIN TEST FOR PERIPHERAL NEUROPATHY

HW de Valk, T Römkens, AJ van Dijk AJ, DW Erkelens. University Hospital, Utrecht, The Netherlands.

Peripheral neuropathy is a major factor in the pathogenesis of the diabetic foot which is a major source of morbidity. A predictive test is of great benefit by identifying patients at higher risk for the development of a diabetic foot. The Semmes-Weinstein monofilament test (SWM) assesses the pressure threshold and has been shown to predict development of diabetic foot. We assessed clincal and demographic factors associated with abnormal SWM. One hundred consecutive patients with insulin-dependent diabetes mellitus were investigated. Mean age: 38.2 years (range: 18-65), median duration of disease: 14 years (range: 0.1-61); 38 were male. Medical history: smoking, use of alcohol, hypaesthesia and/or hyperaesthesia. Physical examination: weight, length, blood pressure, Achilles tendon reflex (ATR), pedal vibration threshold. Laboratory variables: mean HbA1c during the previous year, last HbA1c, plasma lipids, creatinine and urinary albumine/creatinine ratio (UAR). Presence of nephropathy, proliferative retinopathy, and hypertension were defined using preset criteria. Variables were either dichotomous or dichotomised using median or established cut-off points. The results from two legs were pooled (200 feet examined). The filament 5.07 was used and applied to 7 plantar sites. SWM was abnormal if the filament was not felt on ≥1 site. The associations were tested with the Chi square test; variables with a $p<0.05$ were entered in a logistic regression model. Abnormal SWM was associated with younger age (≤36 years; $p<0.001$), longer duration of disease (>14 years; $p<0.001$), hypertension ($p=0.02$), nephropathy ($p<0.001$), retinopathy ($p<0.001$), presence of both hyperaesthesia and hypaesthesia ($p<0.001$), absence of ATR ($p<0.001$), higher plasma creatinine (≥75 μmol/l; $p=0.014$) and elevated UAR (UAR >3.0; $p=0.046$). Older age ($p=0.047$), longer duration of disease ($p=0.048$), presence of hyperaesthesia and hypaesthesia ($p=0.047$) and absence of ATR ($p=0.025$) were independently associated with abnormal SWM. Thus, duration of disease, simultaneous presence of negative and positive neuropathic symptoms and the absence of the Achilles tendon reflex are associated with abnormal SWM, indicating decreased protective sensitivity and increased chance of ulceration.

1905

BACTERIAL INFECTIONS IN DIABETIC FOOT : INDIAN EXPERIENCE.

S. R. Sathe, N. A. Pathare, G. V. Talvalkar and O. P. Bharadwaj. All India Institute of Diabetes, Mumbai, INDIA.

Bacterial infections in foot lesions in diabetes greatly increase morbidity. We studied infections in diabetic foot in 270 (M = 212; F = 58), age (61.78 ± 10.85 yr). Samples for culture were collected during surgery from incised tissue or drainage material. Results showed presence of a mixed bacterial flora. A total of 551 aerobic and 224 anaerobic microorganisms were isolated with an average of > 3 per sample. Aerobic organisms included Staphylococcus (aureus, intermedius, epidermidis, haemolyticans, homonis) 42.06%, Streptococcus (pneumoniae, pyogenes, viridans) 34.13%, Proteus (mirabilis, vulgaris) 36.51%, Klebsiella (pneumoniae, pneumoniae-ozaene, oxytoca) 30.56%, Enterobactor (aerogenes, agglomerans, cloacae) 22.22%, E-coli 19.44%, Pseudomonas (aeruginosa, maltophilia, putrefaciens) 11.90%. Anaerobic organisms included Anaerobic Streptococci 34.13%, Peptostreptococcus (anaerobius, magnus, micros) 29.76%, Bacteroides (fragilis, melaninogenicus) 18.25% and MRSA 4.71%. Gram-positive aerobes were sensitive to Ampicillin-Sulbactum 91.33%, Quinolones (Ciprofloxacin, Ofloxacin) 93.16 - 94.53% and Cephalosporins (Cefotaxime, Ceftazidime, Ceftriazone and Cefaperazone) 90.42 - 91.79%. Gram-positive anaerobes were sensitive to Vancomycin 92%, Piepracillin 86.3%, Ampicillin-Sulbactum 75.4% and Cephalosporins 84 - 91.4%. Gram-negative aerobes were comparatively more resistant, they were sensitive to Amikacin 95.15%, Quinolones 74.78 - 82.68% and Cephalosporins 59.58 - 79.56%. Gram-negative anaerobes were sensitive to Metronidazole 91.9%, Cephalosporins 79.6 - 89.8% and Ampicillin-Sulbactum 63.3%. Proper isolation and identification of microorganisms and use of appropriate therapeutic agent can be of great value in the management of diabetic foot lesions.

1906

DECREASE OF PAIN SENSATION AS MEASURED BY NOCICEPTIVE FLEXION REFLEXE IN DIABETIC POLYNEUROPATHY.

G. Charpentier[1], I. Budi[1], M. Varroud-Vial[1], B. Chassande[2] and J.C. Willer[2].
1.Service de Diabétologie, Hôpital de Corbeil, Corbeil, France
2. Service d'Explorations Fonctionnelles Neurologiques, CHU Pitié-Salpétrière, Paris, France.

Foot ulcers are the main complication of diabetic polyneuropathy (PNP) and could lead to amputations. They are associated with loss of pain perception, wihch is now objectivable with the use of R III reflex threshold (R III). This was measured in 24 normal subjects 32 ± 9 years old, and in 50 diabetics, 52 ± 12 years old, suffering of NDDM (39) or IDDM (11) of 15 ± 9 years duration. They were distributed in 5 groups following clinical PNP status (G1 = no PNP, G5 : history of plantar ulcer and/or toe amputation). R III Threshold is lower in normal subject (10,0 ± 1,21 mA), than in all diabetic groups ($p < 0,04$). Among diabetics, only group 5 is higher (39,3 ± 8,2 mA) than the others ($p < 0,001$). There is no significant difference between the others. R III is correlated to Thompson's sensitivo-reflex score ($p < 0,001$), the amplitude of sural nerve action potential ($p < 0,01$), tuning fork graduated index ($p < 0,05$) but not to sympathetic cutaneous response ($p = 0,10$). Increased R III threshold is in good relation with severe PNP with attendant foot lesions, but cannot be used alone, as a fully reliable predictor of « at risk foot », before occurrence of foot lesions. The PNP pronostic seems better related to clinical sensitivo-motor score ($F = 19,9$, $p < 0,001$) and to tuning fork vibratory perception ($F = 10,3$, $P < 0,001$) than to R III ($F = 4,4$, $p < 0,005$), amplitude of sural nerve action pentotial ($F = 3,85$, $p = 0,01$) or sympathetic cutaneous response ($F = 3,25$, $p = 0,02$). R III threshold measure is interesting to study the Aδ fibers in diabetic PNP, but its clinical usefulness is to be assessed

1907

MICROBIOLOGICAL FINDINGS OF DIABETIC FOOT INFECTIONS IN HUNGARY

E. Hernandez, M. Kajetán, M. Konkoly Thege and G. Jermendy. Bajcsy-Zsilinszky Hospital and Béla Johan Institute, Budapest, Hungary.

Diabetic foot infections have well known microbiological characteristics. As infections can vary depending upon geographical location and as such data have not been collected from the Hungarian diabetic population microbiological investigations were carried out in 60 Hungarian diabetic patients (21 women, 39 men; age 43 - 89 years). Specimens from infected foot lesions were taken for aerobic and anaerobic culturing immediately after the patient's hospitalisation. Two lesions proved to be sterile. *Candida* alone was identified in one patient. In the remaining 57 patients a total of 134 bacterial strains was isolated and, in addition, *Candida* species were identified in 3 cultures. The average number of species per lesion was established at 2.38. Of the 57 patients 45 were positive for only aerobic isolates whereas the cultures of 12 patients were positive for both aerobic and anaerobic isolates. The most common gram-positive aerobic organisms were *Staphylococcus aureus* (24), *Streptococcus* species (16) and *Enterococcus* (13) while *E. coli*, *Enterobacter cloacae* and *Proteus mirabilis* predominated within the aerobic Gram-negative enterics. In anti-microbial susceptibility testing amoxicillin-clavulanate proved to be the most effective. The first Hungarian microbiological survey corroborated that diabetic foot infections have a polymicrobial nature regardless of geographic occurrence.

1908

.INSENSIBILITY TO THE 5.07 MONOFILAMENT IN NON-INSULIN-DEPENDENT DIABETICS Llussà J., Tomàs P., Méndez A., Gimbert RM., Bundó M., CanoJF. and GedapS Group. Catalan Family and Community Medicine Society. Barcelona (Spain)

Background: Diabetic foot is a prioritary problem in Non-Insulin-Dependent Diabetic Patients (NIDDM) and its precocious detection and prevention should be pioritary in Primary Health Care (PHC).**Aims:** Estimation of the prevalence of 5.07 monofilament insensibility in a non selected NIDDM population. Measurement of the interexplorator concordance , in order to prove its reproducibility.**Methods:** Sixty-two NIDDM from five urban PHC Centres were included, in a transversal multicentric design study. Twenty-four men (38.7%), and 38 female (61.3%), aged between 50 and 70 years (Mean age 67 years), with more than five years from the diagnosis , and without previous feet ulcers/amputations, were tested with the 5.07 monofilament in three points of each foot. The test was repeated at the insensible points, and the patient was considered "insensible to the monofilament" when one or more points were insensible twice. A trained explorator instructed four doctors and a nurse in order to repeat the test, and the concordance between both explorations was measured by the Kappa index.**Results:** Sixteen patients were insensible to the monofilament in the second exploration (25.8% CI95%:14.4-36.7). The Kappa index between the first exploration (performed by different professionals in PHC Centres) and the second (single trained explorator) was 64.5% (CI: 43.12-85.43).**Conclusions:** The estimated insensibility prevalence to the 5.07 monofilament is slightly higher than the found in the medical literature. The test is useful and easily applicable to PHC. The obtained concordance has been acceptable. but it needs a minimal training referred to the exploration itself as well as to the way of interrogating the patient.Further studies are needed to validate the 5.07 monofilament as a screening test in the detection of NIDDP at risk for diabetic foot.

1909

MICROBIOLOGY OF INFECTED DIABETIC FOOT. L. Mancini, G. Marra, C. Saponara, F. Toscanella, P. Magnani, D. Pitocco, Ghirlanda G. Department of Internal Medicine and Geriatry. Rome, Italy.

Infections of the lower extremity resulting from skin ulceration in the patients with diabetes mellitus cause significant disability and morbidity, and are expensive in term of medical care.The microbiology of an infected foot ulcer is complex because of the presence of both aerobic and anaerobic Gram-negative bacilli and Gram-positive cocci. Aim of our study is to describe the bacterial population in infected foot lesions of 51 consecutive diabetic outpatients referred to our Foot Clinic between January '95 and June '96. Eighty-five cultures were performed on the specimens obtained from foot ulcers, abscesses, bullae, osteomyelitis.We isolated 115 bacteriological species; Gram-positive cocci were the patogens most common isolated (76.5%;n=88). *Staphylococci* were the microbiological agents most frequent(46%;n=53), particularly *Staph Aureus* was isolated in 19.1%(n=22), *Staph Epidermidis* in 12.1%(n=14), *Staph Simulans* in 10.4% (n=14).*Streptococci* were isolated in 20% (n=23), particularly *Enterococci* in 12,1%. Gram-negative bacilli were isolated in 23.5% (n=27), particularly *Pseudomonas Aeruginosa* (6%; n=7). The 45.8% (n=39) of the cultures perfomed were polimicrobial. *Staphylococci* were observed in 69.5% (n=32) of the monomicrobial infections, particularly *S. Aureus* in 38.4% (n=15). *Streptococci* were observed in 48% (n=19) , Gram neg in 38.4% (n=15) of the polimicrobial infections. The association between *Streptococcus* and *Staphylococcus* was the microbiological association most frequently observed (38.4%;n=15).There was only two cases of anaerobical species observed(1.7%). Our study shows that *Staphylococci* are the bacteriological species more present in infected diabetic foot and are the only pathogen in two-third of monomicrobial infections. Streptococcical species were the pathogen more present in polimicrobial infections, particularly with *Staphylococci*, supposing a sinergistic action of these species. We observed few anaerobic species, probably because outpatients clinic shows a specific infection pattern, different from that seen in hospitalized patients.

1910

MANAGEMENT OF DIABETIC FOOT:COMPARATIVE ANALYSIS IN DIFFERENT STAGES.

S.Pandey, B.C.Mishra, S.C.Mohanty, D.K.Roy and P. K.Mallick, S.C.B.Medical College, Cuttack, India.

To study bacteriological spectrum & sensitivity in advanced foot lesion, Comparison of new therapy "Collagenase(Salutyl) & Tetrachlorodecaoxide (Oxo-ferrin) Solution" with traditional methods. 38 cases with diabetic foot ulcers(6-14cm) in various stages slough, suppuration, pregangrene were vigorously treated by division into controls n-12 & study group n-26 & result is encouraging in cure & lowering morbidity. Good glycaemic control was kept. Both groups were investigated alike & pus/exudate culture was done. Controls underwent mechanical debridement Saline wash & antiseptic dressing with appropriate antibiotic. n-26 had Saline wash, Salutyl ointment for slough removal followed by combined Oxoferrin soaked twice daily dressing from day 4-7 till end. Treatment documented with serial photographs, measurements & ful thickness biopsy showing increased granulation infiltrated cells, capillary nos, & tissue strength. 19 pts. had complete healing with epithelialisation by 28 days,3 pts. by 37 days & 2 needed graft 2 pts. failed due to concomitant disease 5 of n-12 had partial healing in 45 days followed by graft 2 had gangrene & underwent amputation. Study was cost effective, statistically ($p<0.05$), clinically & epidemiologically successful & significant for a third world country.

1911

THE PREVALENCE OF FUNGAL INFECTION IN DIABETICS

P.Ilanne-Parikka, J.Huhtanen , S.A. Salo .The Diabetes Center of the Finnish Diabetes Association and K.Kuokkanen ,Tampere University Hospital, Department of Dermatology and Venerology. Tampere, Finland

The Diabetic Foot Disease is one major complication associated with diabetes. Regular examination of the feet, identifying diabetics at risk for foot ulceration and the treatment of the predisposing factors such as peripheral atherosclerosis, neuropathy and abnormal pressure loading and increased susceptibility to infection make up the preventative and educational strategy in the management of the diabetic foot

We examined the feet of 105 consecutive diabetics aged 21 to 58 years, who took part in an education course at the Finnish Diabetes Center in Tampere in autumn 1996. If any clinical lesions were noticed in the nails,in the toe webs or in the skin of the soles specimens for mycological examination. were taken.

In all 96 samples from 68 patients were cultured. The prevalence in 105 diabetics of any lesions in the nails was 40%, in toe webs 40 % and in the skin of the soles 12 %. The real prevalence of dermatophyte infection was 12.4 % for nails, 8.6 % for toe webs and 11% for skin. The prevalence of yeast infection was 7.6 % for nails, 1% for toe webs and 1 % for skin. 3 patients had both dermatophyte and yeast infection in nail specimen and 1 in skin specimen. The fungal infection rate was therefore 17.1 % for the nails and 19 % for the skin and overall 26.6 % for both .

1912

RECURRENT VS.NON-RECURRENT DIABETIC FOOT ULCER DISEASE: IMPACT OF PHYSICAL ACTIVITY

F. Ahrweiler, E.Chantelau. Diabetic Foot Clinic Heinrich-Heine-University of Düsseldorf/FRG.

Background: Increased plantar pressure, inappropriate footwear, and poor foot care are established risk factors for neuropathic diabetic foot ulcer disease(NDFUD). Is physical activity (e.g. walking) also a risk factor? Aim: To assess the average physical activity in patients with recurrent vs. non-recurrent NDFUD (ulcer vs. no ulcer within 12 months prior to the study). Patients and methods: 60 diabetic patients were studied(48% females,28% IDDM,72% NIDDM,mean(SD) age 61(10) yrs,duration of diabetes 23(11) yrs), with non-recurrent NDFUD (n=20),and with recurrent NDFUD(n=20). 20 diabetic control patients without any NDFUD, and 20 non-diabetic control subjects were also studied, all matched for sex and age. Physical activity was recorded in arbitrary units(AU) by an accelerometer(Suzuken Ltd. Japan) worn at the hip for 7 consecutive days. Results: patients with recurrent NDFUD displayed similar activity (24(8)AU) as control subjects, either diabetic (23(12)AU),or healthy(27(9)AU)). However, patients with non-recurrent NDFUD exhibited significantly less physical activity (18 (11)AU,$p<0.05$ vs.healthy controls). Conclusions: patients with non-recurrent NDFUD were the least active of all study groups. Thus, low (habitual) physical activity may protect against recurrent NDFUD.

1913

DIAGNOSIS OF OSTEOMYELITIS IN THE DIABETIC FOOT WITH A COMBINED BONE AND HMPAO LEUCOCYTES SCINTIGRAPHIES.

D Maugendre, J-Y Poirier, , F Hennion, A Devillers, A Moisan, H Allannic
Dep. of Endocrinology and Dep. of Nuclear Medicine. Rennes. France.

The specificity of routine radiography and bone scintigraphy are too low to reliably detect foot osteomyelitis in diabetic patients because of osteoarthropathy, previous skin ulcers or postoperative healing. On the contrary, the accumulation of leucocytes is more specific of an infectious process. 27 diabetic patients with possible foot osteomyelitis (37 foot ulcers) were included in a prospective study with standart radiography, 99mTC MDP three-phase bone scintigraphy and 99mTc-HMPAO leucocytes scintigraphy performed within four days. The congruence of abnormal focal uptake of HMPAO and MDP was considered as positive. The final diagnostic was based on the following criteria : a) osteomyelitis if standard radiography and/or surgical biopsy (bacteriology and/or histology) were positive ; b) absence of osteomyelitis if two successive radiographies within 3 weeks were negative and a good evolution was observed without antiobiotherapy. Results a) 20 ulcerations were associated with osteomyelitis : the combined scintigraphy was positive in 18 cases (2 false-negative) including 7 lesions one to two weeks before the radiological abnormalities. At the end of a eight-week antibiotherapy a second combined scintigraphy was performed in 9 patients (10 ulcerations) : all sites were negative for HMPAO leucocytes. b) Of the 17 cases without osteomyelitis, the combined scintigraphy was negative in 16 (one false positive) including 13 cases with focal uptake of HMPAO leucocytes without focal uptake of MDP (soft tissue infection). Conclusion : The combined bone scintigraphy and HMPAO leucocytes scintigraphy with a very good spatial resolution is a very sensitive (90%) and very specific (94%) method to detect osteomyelitis in the diabetic foot ulcerations.

1914

EFFECT OF INDUSTRIALLY PRODUCED TOVEY-LIKE FOOTWEAR ON DIABETIC FOOT ULCER RECURRENCE.

F.Striesow, E.Chantelau. Diabetic Foot Clinic, Heinrich-Heine University of Düsseldorf/FRG.

Background: Ordinary fashion footwear is an important trigger of diabetic foot ulcer disease. Bespoke medical footwear, hand-made with shock-absorbing insole (at least 30% reduction of peak plantar pressures),and soft upper (no toe cap!), as suggested 1984 by F.Tovey,has proven to prevent foot ulcer recurrence (FUR).Aim: To assess whether ready-made medical footwear can have similar effects. Patients and methods: 46 patients (28% females,83%NIDDM,17%IDDM; median (95%CI) age 63(60-66) years, without relevant foot deformities were supplied with <3 pairs of ready-made medical shoes (Diabeticus/Thanner, FRG) after healing of a foot ulcer. They were followed-up for 12(10-14) months. Results: There were 20 patients with FUR after 8(6-10) months, in 16 of whom FURs were related to footwear. Patients without footwear related FUR (n=30) had worn the medical shoes for 50 (20-75)% of the day; patients with footwear-related FUR (n=16) had worn the medical shoes for 10(0-30)%, and ordinary footwear for the rest of the day ($p<0.05$). Conclusion: Ready-made Tovey-like shoes, when worn most of the day, satisfactorily protect undeformed diabetic feet against footwear related FUR.

1915

DIABETIC FOOT OSTEOMYELITIS : PROSPECTIVE EVALUATION WITH ^{99m}Tc - LEUKOCYTE / BONE SCINTIGRAPHY AND MR IMAGING.

L. Vesco, J.L. Montazel, S. Kretz, A. Rahmouni, L. Perlemuter, M. Meignan and H. Bouladour - Henri Mondor Hospital, Créteil, France.

Diagnostic of foot osteomyelitis among diabetic patients may be extremely difficult because of coexistent disease processes such as chronic oedema, soft-tissue infection and neuroosteoarthropathy. In this prospective study, we compare the bone scan with ^{99m}Tc leukocyte scintigraphy and MR imaging to diagnostic osteomyelitis in twenty diabetic foot neuropathic ulcerations with forteen osteoarthropathy. The diagnostic of osteomyelitis is made clinically or with plain film if it was evident (bone involved) or with the follow up without antibiotherapy if the imaging process tested are discordant. Osteomyelitis is present in thirteen diabetic foot ulcerations, only seven are suspected clinically. High signal intensity in the bone marrow is demonstrated on T1 and T2 fat-saturation MR imagings with Gadolinium enhancement, in twelve cases who developed osteomyelitis (sensitivity 92,6%). Bone scan with ^{99m}Tc leucocyte scintigraphy is effective in 9 cases (sensitivity 69.2%). Among the seven diabetic foot ulcerations without osteomyelitis, six have no element for this diagnostic in MR imaging and in bone scan with ^{99m}Tc leucocyte scintigraphy. One false positive result reduce the specificity to 85,7% for both methods. Osteoarthropathy did not influence these results. In conclusion, our study suggests that MR imaging appears to be the most sensitive method for diagnosing osteomyelitis in diabetic foot neuropathic ulcerations with or without osteoarthropathy. The specificity is identical with bone scan with ^{99m}Tc leukocyte scintigraphy and MR imaging. Furthers studies are necessary to confirm these preliminary results especially in diabetic foot ulcerations with osteoarthropathy.

1916

THE FOOT-EYE-KIDNEY DIABETIC SYNDROME

Arguedas C., Mora C., García R., Salazar S., Sancho C. Intern Med. Hosp. México, San José, Costa Rica.

During the last 4 years we have been using the nemotecnic clinical classification of the diabetic foot PATON (Big Foot in English). This approach allow our health care system to have a clear idea of the foot's rish of the diabetic and handle is by a stratify system that cover all the country. This classification is very simple and can be done by any health care profesional.

Frecuently we found that the high risk (red) foot has also a severe diabetic retinopathy and nephropathy. We call this the PIORI Syndrome by its spanish initial for foot, eye and kidney.

In this study we wanted to show the prevalence of diabetic retinopathy and nephropathy in the patients with high (red), moderate (yellow) and low (green) risk feet.

We take at randon from our Out-Patient Diabetic Clinic, 10 patients with low rish diabetic foot accordind with the PATON classification, 10 moderate risk and 10 high risk feet. All with more tan 15 year of been knowing as diabetics. The patients were seen by an oftalmologist and fluorescein angiogram were practiced. A 24 hrs urine was collected and the nephropathy was defined as the excretion of more than 300 mg of albumin.

Table I. Prevalence of nephropathy and retinopathy

	Green	Yellow	Red
Nephropathy	3	4	10
Proliferative Retinopathy	0	0	9

No difference was found in term of year of evolution, metabolic control, age, sex, BMI and type of diabetes.

We conclude that clearly a Syndrome that involved the foot the eye and the kidney is identified. The PATON classification allow a selection of the severity of all the microangiopathic lessions in the diabetic.

1917

DIABETIC NEUROPATHY AND OSTEOPOROSIS IN THE DIABETIC FOOT

KS Kim, SN Choi, HC Bae, HK Chung, YS Oh and SH Shinn, Chung-Ang University, Seoul, Korea

Diabetic foot is more vulnerable to the calcaneus avulsion fracture than non-diabetic foot The complications of diabetes mellitus, neuropathy, vascular insuficiency and Charcot arthropathy may accelerate the osteoporosis of the calcaneus of diabetic patients. The aim of this study was to evaluate whether the severity of the diabetic complications correlate with the bone mineral density of calcaneus bone. We studied the correlation of bone mineral density of diabetic patient and the severity of their diabetic complications. We recruited 24 diabetic and 20 non-diabetic control women with age matching. We measured bone mineral density of femur and bone mineral density of calcaneus, nerve conduction velocity and other biochemical parameters. We evaluated the severity of their retinopathy and nephropathy. also. We classified study population into mild, moderate and severe group according to their neuropathic severity. Bone mineral density of calcaneus were 0 612 ± 0.19, 0 565 ± 0.13 and 0.432 ± 0.14 (g/cm^2) in mild, moderate and severe group($p < 0\ 05$). Severely complicated group had more retinopathy and nephropathy. No statistically significant differences were found in the age, osteocalcin, deoxypyridinoline, alkaline phosphatase, BMI and HbA_1C between groups. In conclusion, the severity of the diabetic complications is correlated with degree of the osteoporosis of the diabetic foot bone and may be the risk factor of foot fracture in the diabetic foot.

1918

TRANSCUTANEOUS OXYGEN TENSION - REPRODUCIBILITY IN DIABETIC PATIENTS WITH PERIPHERAL ARTERIAL OCCLUSIVE DISEASE

K. Djavani, B. Fagrell, K. Brismar, G. Jörneskog
Department of Endocrinology and Diabetology, and Department of Internal Medicine, Karolinska Hospital, Stockholm,Sweden.

Transcutaneous oxygen tension ($tcPO_2$) is a non invasive method, which reflects local blood flow and oxygenation. The aim of the present study was to evaluate the reproducibility of $tcPO_2$ measurements in diabetic patients with peripheral arterial occlusive disease (PAOD). Ten male diabetic patients with PAOD were investigated (toe/arm blood pressure index ≤ 0.7). Age was 65±13 (mean±SD) years, and diabetes duration 33±6 years. Toe blood pressure (mmHg) and $tcPO_2$ (mmHg) were measured daily for 3 days. Toe blood pressure was measured with a mini cuff and laser Doppler fluxmetry as detector. $TcPO_2$ was measured at a reference point (I_2 dx), the dorsum of the foot, and at the base of dig I-II. The results showed that $tcPO_2$ at I_2 dx (59±8 mmHg) was higher ($p<0.001$), as compared to the dorsum of the foot (21±20 mm Hg) and base of dig I-II (24±20 mmHg). Significant correlations were seen between $tcPO_2$ day I-II-III at each measuring site: (I_2 dx, $r=0.83$; $p<0.01$); dorsum of the foot, $r=0.95$; $p=0.0001$; base of dig I-II, $r=0.95$; $p=0.0001$). No systemic differences were observed between the three $tcPO_2$ measurements with paired t-test ($p=0.35$-0.96). Neither were there any differences between the three toe blood pressure determinations (toe blood pressure 49±39 mmHg). In conclusion, the present study showed that the reproducibility of $tcPO_2$ and toe blood pressure are good in diabetic patients with PAOD.

1919

TREATMENT OF CHARCOT'S ARTHROPATHY : MEASUREMENT OF RESPONSE BY QUANTITATIVE BONE SCANNING

M McGill, T Bolton, R Uren, R Donnelly, D.K. Yue. Royal Prince Alfred Hospital, Sydney, Australia

Charcot's arthropathy is characterised by gross disorganisation of the foot resulting in intractable neuropathic ulceration. Immobilisation of the affected joint by casting gives the impression of reduced disease activity, but scientific evaluation of treatment options is rarely made due to a lack of suitable objective assessment methods. In this study we investigated quantitative bone scanning (QBS) as a method for monitoring response to casting. Nine patients (mean age 55.5±12.3yr, duration 9.9± 5.5yr and duration of arthropathy before presentation 5.0±5.6mth) had their affected foot cast. Foot skin temperature measured by a Thermistor (Takara Instruments, Japan) showed that the affected foot was significantly hotter than the control foot at baseline (3.4±2.0°C,z=2.3;p=0.02) and 3 months after application (2.5±2.0° C,z=2.2;p=0.03) but not after 6 months (1.3±1.0°C). Patients underwent QBS, at baseline, 3 and 6 months after casting, with 99mTc-labelled diphosphonates to quantitate isotope uptake in an accurately measured area. Repeated measures (ANOVA) of the absolute Tc uptake, and the ratio of the affected vs the unaffected foot, for dynamic (blood flow) and delayed (bone uptake) phases of QBS are shown in the Table. Strong correlation exists between changes in dynamic and delayed phases isotope uptake at both 3 and 6 months ($r=0.8$;$p<0.02$).

	Tc Uptake (%) of affected foot	Dynamic phase (affected/unaffected)	Delayed phase (affected/unaffected)
Baseline	2.0±0.8	2.4 ± 1.5	2.2 ± 1.0
3 months	1.5±0.8 *	1.7 ± 0.8*	1.6 ± 0.4*
6 months	1.4±0.8 *	1.4 ± 0.3*	1.5 ± 0.5

**different to baseline* $p< 0.05$

These results indicate casting produces a decrease in skin temperature and bone isotope uptake of the affected foot in Charcot's Arthropathy. Whether the changes represent an intrinsic improvement in bone disease or reflect a decrease in blood flow to the limb through immobilisation by casting requires further investigation. QBS provides an objective measurement of activity in Charcot's Arthropathy.

1920

DEMONSTRATION OF INSULIN RESISTANCE IN ARTERIOSCLEROSIS OBLITERANS AND PARTIAL IMPROVEMENT BY PROSTAGLANDIN.

A. Kanazawa, M. Suzuki, D. Zaho, M. Ikebuchi and Y. Harano.
National Cardiovascular Center, Osaka, Japan.

To determine whether insulin resistance is present in arteriosclerosis obliterans (ASO) subjects, we performed both 75g-oral glucose tolerance test (OGTT) and insulin sensitivity test in non obese ,non diabetic and non hypertensive ASO subjects. Furthermore in order to investigate whether administration of prostaglandin E1 derivative(limaprost,Ono, Japan) affects insulin sensitivity in ASO subjects, insulin sensitivity test was performed before and after limaprost (30 μ g/day) administration. Insulin sensitivity was determined by the Steady-State Plasma Glucose (SSPG) method using sandostatin. SSPG significantly elevated in ASO subjects over control(8.1±0.7 vs 5.7±0.4mmol/L,mean±SE,$P<0.01$,t-test) and insulin resistance in ASO was noted. Area under the curve of immunoreactive insulin during 75g-OGTT tended to be higher,but,not significant and the degree of compensatory hyperinsulinemia was not so strong as coronary artery disease. SSPG significantly reduced after limaprost administration (from 10.6±0.7 to 8.5±0.6mmol/L, $P<0.05$), indicating the improvement of insulin sensitivity. These results indicate that insulin resistance is demonstrated in ASO, however, compensated hyperinsulinemia has not been observed. Limaprost administration has improved insulin sensitivity for glucose metabolism.

1921

IS CHARCOT OSTEOARTHROPATHY OF THE DIABETIC FOOT RELATED TO OSTEOPENIA?

S.Clasen,E.Chantelau,I.Heimlich,R.Windecker.
Heinrich-Heine-University,Düsseldorf/Germany

Background: Charcot osteoarthropathy (COA) of the diabetic foot is believed to result from (neurotrophic ?) osteopenia; however, prompt restitution of destroyed bone structures following non-weight-bearing contradicts this view. **Aim:** to assess bone density in the vincinity (distal tibia) of chronic "healed" diabetic COA. **Patients and methods:** 10 women and 12 men were studied, 6 with bilateral,and 16 with unilateral diabetic COA of the feet (n=28 feet with COA).For control purposes, 26 legs of 13 healthy persons matched for age, sex, and body weight were studied. Bone mineral density(BMD,g/cm²) was assessed by photon absorptiometry. **Results:** BMD was 0.98 (SD 0.15) in 16 legs with COA, versus 1.03 (SD 0.18)in 16 unaffected legs($p<0.05$.).In all 28 legs with COA,BMD was 1.09(SD 0.25). In the controls,BMD was 1.05(SD 0.31)in the right,and 1.14(SD 0.14) in the left leg, respectively (n.s.).**Conclusion:** No difference was found by overall comparison of BMD in COA and control legs. In legs with COA, BMD was diminished by $\leq$ 5% compared to legs without COA within the same diabetic patients; this is supposed to be the consequence of therapeutic pressure relief rather than the cause of COA.

1922

ENDOVASCULAR REVASCULARIZATION BY MECHANICAL ATHERECTOMY IN DIABETIC FOOT.

Ghirlanda G, Citterio F, Mancini L, Pitocco D, Toscanella F, Saponara C, Greco A.V. Department of Internal Medicine and Geriatry, Surgery and Radiology. Rome. ITALY

Diabetes is the leading cause of amputations in developed country. Owing to the infrapopliteal site of arterial occlusion classical percutaneous balloon angioplasty cannot be performed. Revascularization is achieved mainly by distal by-passes with autologous saphenous vein, that cannot always be performed for general or local contraindications. Mechanical atherectomy with rotational Auth's device appears to be a particularly suitable technique in the treatment of distal arterial occlusions. We studied 66 patients with type 2 diabetes that were referred to our department for revascularization or amputation because of ischaemic trophic lesions of the foot. Digital subtraction angiography showed an occlusion of the femoral superficial artery in 18 patients, while popliteal and tibial arteries were occluded in 29 patients and significantly stenotic in 19 patients. Four patients were not treated due to the length of the obstruction and/or the lack of a suitable pedal circulation. Mechanical atherectomy was performed in 62 patients without any significant side effect and resulted in immediate patency of the treated arteries. In 57 patients vessels have been patent for a mean follow-up period of 29 months (range 4-49 months) with a limb salvage rate of 95%. One patient had occlusion of the treated segment after 3 months without recurrence of necrosis. Two patients were amputated, one did not improve because of a poor run-off of the pedal circulation and one had a severe infection. We conclude that mechanical atherectomy is a safe and effective endoluminal recanalization procedure in diabetic patients with limb threatening ischaemia due to infrainguinal arterial disease, mainly in those with general or local contraindications to by-pass surgery.

1923

EFFICACY OF DIFFERENT SHOES AND INSOLES IN REDUCING PLANTAR PRESSURES IN DIABETIC NEUROPHATIC PATIENTS

L. UCCIOLI, M. TOFFOLO, A. VOLPE, P. PASQUALITTO,A. FERRI, G. MONTICONE AND G. MENZINGER ROMA and MONTEBELLUNA (TV) ITALY

Diabetic patients with peripheral neuropathy develope foot ulcerations in areas of high plantar pressure.The recent development of small thin sensors has allowed the reliable measurement of in-shoe foot pressures. We have utilized this device (Dinatto by BT Italy) to evaluate the effect of various manufactured shoes and different insoles (Podiabetes by Buratto, Italy) in reducing plantar pressures in diabetic neuropathic patients. 9 diabetic patients (7M/2F) age 61±5 yrs, duration of disease 13±8yrs, VPT 35±7mV were included in this study. Mean plantar pressures (N/cm²) under metatarsal heads in static (SMP) and dinamic (DMP) condition and peak plantar pressures in dinamic condition (DPP) were evaluated in the following experimental conditions: Barefoot (B), with the own old shoes (OS), with two types of manufactured shoes designed with super depth in soft thermoformable leather and flexible soles (Type 1) or rigid with a rocker bottom (Type 2) completed with three different insoles : a single layer of Alcapy (3mm) (Type A); a layer of alcapy (3mm) + a layer of alcaform 167 (5mm) (Type B); a customized insole made by alcapi+ alcaform 167 and 200 (Type C).

	B	OS	1A	1B	1C	2A	2B	2C
SMP	4.6±3	4.6±2.6	4.6±2.3	4.1±2.2	4.3±2.9	3.4±2*°	3±1.5*°	2.8±1*°
DMP	17±7	20±11*	17±8°	16±7°	14±7°	14±7°	12±4*°	12±5*°
DPP	269±63	328±84*	291±92°	269±55°	265±59°	264±77°	249±49°	250±42°

* $p<0.01$ vs B; ° $p<0.01$ vs OS

Our data show the ability of manufactured shoes and insoles in reducing plantar pressures. The different results obtained with the different solutions suggest that the perscription of shoes and insoles may be tailored to the specific needs of diabetic patients with peripheral neuropathy and high plantar pressures.

1924

EVALUATION OF ANGIOGRAHPIC FINDINGS OF THE LOWER LIMB IN DIABETICS TREATED AT A FOOT CLINIC - A 3-YEAR RETROSPECTIVE STUDY

Wosková V., Jirkovská A., Peregrin J., Skibová J. Institute for Clinical and Experimental Medicine, Department of Diabetes, Prague, Czech Republic

The aim of the study was to evaluate retrospectively angiographic findings of the lower limbs of diabetics, treated at a diabetic foot clinic, in terms of the indications, outcome, future therapeutic strategy, and the incidence of complications over a 3-year period. A retrospective study was conducted to evaluate 71 diabetics (17 and 54 with Type-1 and 2 diabetes, respectively, 47 males, 24 females, with a mean age of 60 ± 12 years and diabetes duration of 16 ± 9 years) undergoing angiography (AG) of the lower limb End-stage diabetic nephropathy was present in 16 pts (234%), with 10 treated by hemodialysis. The criteria assessed included indications for AG, angiographic findings, future therapeutic strategy, and the incidence of immediate complications post-AG in a total of 89 limbs. Angiographic findings were evaluated as positive in the presence of arterial occlusion or a stenosis > 50%. The examination was performed using intra-arterial digital subtraction angiography with a non-ionic contrast medium during a short hospitalization in a diabetes center. In 49 pts (69%) the indications for examination included defects involving the leg (gangrene 39%, non-healing ulcers 30%), resting pain in 9 pts (13%), claudications in 8 pts (11%), and elective amputation in 5 pts (7%). An analysis of 89 AG demonstrated most often crural bed involvement (96%), with involvement of the femoral region in 53%, the popliteal artery in 22% and the pelvic artery in 15%. Based on AG, vascular intervention was indicated in 68 limbs (76%), it was technically impossible in 15 limbs (17%) because of an advanced finding; AG was negative in 6 limbs (7%). Out of the 89 limbs, percutaneous transluminal angioplasty was indicated in 46 (51%), bypass in 17 limbs (19%), combined revascularization in 5 (6%). AG-related complications occurred in 3 pts (4.2%); all involved bleeding from the groin which required surgical revision in 1 case and was associated with acute renal insufficiency with full renal function normalization in 1 case. In diabetics with the diabetic foot of suspected vascular etiology, it is appropriate to indicate early AG since, if adequate care is provided to the patient, it is relatively safely and often results in a vascular intervention, primarily PTA.

CYTOKINES AND SOLUBLE CELL ADHESION MOLECULES IN VITREOUS HUMOR

N.Yoshioka, M.Takeda, H.Imaizumi, U.Okushiba S,Kuwajima and N.Wada.
Sapporo City General Hospital, Sapporo, Japan

To explore mechanisms in the pathogenesis of diabetic retinopathy, we examined the vitreous of sixty six patients with proliferative diabetic retinopathy(PDR) and fifty patients without diabetes mellitus for the presence of tumor necrosis factor-α(TNF-α), interleukin-6(IL-6),soluble intracellular adhesion molecule-1 (ICAM-1), vasculer cell adhesion molecule-1(VCAM-1), P-selectin and E-selectin. Vitreous samples were obtained, undiluted from the patients with PDR and patients with miscellaneous retinal diseases prior to vitrectomy. Cytokines and cell adhesion molecules were measured by enzyme-linked immunoadsorbent assays. The levels of TNF-α, VCAM-1, P-selectin and E-selectine were not different for patients with PDR and those without diabetes mellitus. However, levels of IL-6 and ICAM-1 were significantly(P<0.001) elevated in patients with PDR compared to levels in patients without diabetes mellitus(IL-6: 175±46pg/ml vs 10±2pg/ml; ICAM-1:12.8±9.4ng/ml vs 2.1 ±2.8ng/ml). Elevated levels of IL-6 and ICAM-1 in the vitreous of patients with PDR, implicating a role for these cytokine and cell adhesion molecule in the pathogenesis of PDR by enhancing immune action and inflammation.

1926

BIMOCLOMOL (BRLP-42) PREVENTS AND CORRECTS EARLY RETINAL NEUROSENSORY DYSFUNCTION IN DIABETIC RATS

K. Bíró, *S.Tóth. BIOREX Res. & Dev. Co., Veszprém, *Dept. of Anaesth., Semmelweis Medical University, Budapest, Hungary.

Oscillatory potentials (OPs), the neuronal components of flash-evoked electroretinogram (ERG) are of clinical importance in prognosis and diagnosis of diabetic retinopathy (DR). Diabetes reduces the amplitude and increases the latency of OPs. The effect of Bimoclomol (former code BRLP-42; Biorex, Hungary) on streptozotocin (STZ 45 mg/kg)-induced ERG abnormalities was assessed using scotopic ERGs under anaesthesia. Daily oral treatment with 20 mg/kg BRLP-42 was either preventive or curative, given 1 day or 1 month following the onset of diabetes. 50 mg/kg aminoguanidine served as reference. Groups of 10 male Crl Wistar rats were investigated: nondiabetic, diabetic, and BRLP-42- or aminoguanidine-treated diabetic groups. All the ERG waves were impaired with 2-month diabetes. The reduction ($p<0.001$) in amplitudes of glycin sensitive OP3 (70.2%) and of GABA mediated OP2 (90.0%) was protected by both BRLP-42 (by 48.0±4.2%, and 37.4±7.4%, resp.; $p<0.01$) and the reference compound to a similar extent. Curative treatment improved the deficits by 86.3±30.5%, and 36.7±10.0%, resp.; $p < 0.05$). The significant prolongation of peak latencies due to diabetes was normalised for OP3 and inhibited by 68% for OP2 after pretreatment with BRLP-42. Diabetic alterations in the main waves of ERG were also improved. Our results demonstrate the reduction in severity of DR possibly by protecting basement membrane thickness of retinal vessels which is known to correlate with OP latencies. This effect can be beneficial in the treatment of retinopathy. The mechanism of action of BRLP-42 on retinal dysfunctions is unknown The relationship between changes in OP latencies and the thickness of basement membrane suggests a direction for further studies.

1927

VITREOUS LEVELS OF VASCULAR ENDOTHELIAL GROWTH FACTOR ARE NOT INFLUENCED BY ITS SERUM CONCENTRATIONS

R. Burgos, R. Simó, M. García*, C. Mateo#, J. Mesa, L. Audí* and A. Carrascosa*. Diabetes Unit, #Ophthalmology Deptartment and *Pediatric Research Unit. Hospital Vall d'Hebron. Barcelona. Spain.

Vascular endothelial growth factor (VEGF) plays a major role in the development of intraocular neovascularization in proliferative diabetic retinopathy (PDR). The source of intravitreous VEGF is presumably ischemic retina, but increased levels derived from serum could not be excluded. The aim of the study is to determine the intravitreous concentrations of VEGF in diabetic patients with PDR and to investigate whether serum VEGF could contribute to intravitreous concentration. For this purpose, we included 20 diabetic patients (5 type 1 and 15 type 2) with PDR in whom a vitrectomy was performed (group A). Nondiabetic patients ($n=13$) with other conditions requiring vitrectomy served as a control group (group B). In all cases, a recent vitreous hemorrhage was excluded. In both groups, VEGF was determined in serum and undiluted vitreous samples obtained simultaneously. Furthermore, serum VEGF was determined in 69 healthy controls (group C) and 39 diabetic patients without late complications (group D) . Vitreous and serum VEGF was determined by ELISA (R&D Systems, Abingdon); intra-assay CV 3.8 %, interassay CV 5.1 %. Statistics: Student's t-test and ANOVA. Results: Intravitreous concentrations of VEGF were strikingly higher in group A (2101.6 ± SD 1628.9 pg/ml, median 1756 pg/ml, range 334.5-6662) in comparison with group B (12 ± SD 8.1 pg/ml, median 9 pg/ml, range 9-38.2); $p<0.0001$. We did not observed differences in serum VEGF among the groups included in the study (group A 183.2 ± 123 pg/ml, group B 221.5 ± 147.1 pg/ml, group C 231.5 ± 188.1 pg/ml, and group D 214.7 ± 171.8 pg/ml); p=ns. We conclude that the high vitreous levels of VEGF obtained in diabetic patients with PDR could not be attributed to serum diffusion across blood-retinal barrier. Furthermore, our results suggest that intraocular synthesis is the main contributing factor for the high VEGF concentrations observed in these patients.

1928

NUMBER OF (A-C)n REPEAT IN THE UPSTREAM OF ALDOSE REDUCTASE GENE CORRELATES WITH DIABETIC RETINOPATHY

Y. Ikegishi, M. Tawata, K. Aida and T. Onaya.Third Department of Internal Medicine, Yamanashi Medical University, Tamaho, Yamanashi, Japan

The polyol pathway has been implicated in the pathogenesis of diabetic microangiopathies. We studied the correlation between the number of (A-C)n repeat region in 2.1 kb upstream of the transcription start site of aldose reductase (AR) gene and retinopathy in Japanese patients with non-insulin-dependent diabetes mellitus. We also measured erythrocyte AR activity. We classified the 45 patients into two groups. The first group consisted of 20 patients with proliferative retinopathy within 8 years' duration and defined as "with retinopathy". Second group consisted of 25 patients with no evidence for retinopathy, nephropathy or neuropathy even after 10 years' duration and defined as "without retinopathy". Japanese subjects showed 10 allelic types in this region. The most prevelent allele was 24 times in (A-C) repeat and designated as Z allele. Those with Z+2 allele (25 times in (A-C) repeat) have significantly less chances to develop retinopathy, whereas those with Z-4 allele (22 times in (A-C) repeat) have significantly more chances to develop proliferative retinopathy. Most of the patients with proliferative retinopathy had nephropathy and neuropathy as well. Erythrocyte AR activity was significantly elevated in those with Z-2 allele compared to those with Z+4 allele. In addition, erythrocyte AR activity was significantly lower in those with Z+2 allele compared to those with Z allele. Our study also revealed two nucleotide changes from "TC" to "CT" in this region compared to Chinese. The present study suggests that the number of (A-C)n repeat in 2.1 kb upstream of AR gene may determine AR activity and may be one of the factors influencing predisposition to diabetic microangiopathies.

1929

SERUM LEVELS OF VASCULAR ENDOTHELIAL GROWTH FACTOR ARE NOT INCREASED IN DIABETIC RETINOPATHY

R. Simó, R. Burgos, M. García*, C. Mateo#, C. Hernández, J. Mesa, A. Carrascosa* and L. Audí*. Diabetes Unit, #Ophthalmology Dept. and *Pediatric Research Unit. Hospital Vall d'Hebron, Barcelona, Spain.

Vascular endothelial growth factor (VEGF) has been involved in the etiopathogenic events of diabetic retinopathy (DR) and increased levels have been observed in the vitreous of diabetic patients with proliferative retinopathy. However, there are no studies about the possible relationship between serum VEGF concentrations and DR. For this purpose, we included 28 consecutive diabetic patients (6 type 1 and 22 type 2) with DR attended by the Diabetic Retinopathy Unit (8 non-proliferative DR and 20 proliferative DR). Diabetic patients (n=39, 18 type 1 and 21 type 2) without DR and 69 healthy controls matched by age were used as control groups. In all cases we excluded systemic diseases other than diabetes mellitus. VEGF was determined in duplicated serum samples by ELISA (R&D Systems, Abingdon, UK); intra-assay CV 3.8 %, interassay CV 5.1 %. Statistics: Student's t-test and ANOVA. Results: we did not observed differences in serum VEGF concentrations in diabetic patients compared with healthy control group (210.9 ± SD 157.5 pg/ml vs 231.5 ± SD 188.1 pg/ml; p=ns). In diabetic patients with DR we obtained similar levels of VEGF than in diabetic patients without DR (205.6 ± SD 138 pg/ml vs 214.7 ± SD 171.8 pg/ml; p=n.s). Furthermore, we did not observed any relationship between serum VEGF concentrations and the severity of diabetic retinopathy (nonproliferative DR patients: 261.7 ± SD 163.6 pg/ml vs proliferative DR patients: 183.1 ± SD 123 pg/ml; p=n.s). We conclude that serum levels of VEGF are not related with the presence and the degree of diabetic retinopathy.

1930

DIABETIC-LIKE RETINOPATHY: EARLY AND LATE INTERVENTION THERAPIES IN THE GALACTOSE-FED RAT MODEL.

W.G. Robison, Jr.[1], J.L. Jacot[1], J.P. Glover[1], M.D. Basso[2] and T.C. Hohman[2] National Eye Institute, NIH, Bethesda, MD[1], USA; Wyeth-Ayerst Laboratories, Princeton, NJ[2], USA.

The aim was to determine whether diabetic-like retinal capillary basement membrane thickening (RCBMT) in the galactose-fed rat could be halted or ameliorated with early or late interventions by withdrawal of the galactose diet or treatment with the aldose reductase inhibitor ARI-509. Weanling S-D rats were divided randomly into 8 groups and fed Purina laboratory chow (#5001) plus: 50% starch—*CONTROL (**CON**)*; 50% D-galactose—*GALACTOSE (**GAL**)*; 50% D-galactose with ARI-509 at 10 or 25 mg/kg/day—*LOW and HIGH DOSE PREVENTION (**LDP; HDP**)*; 50% D-galactose for 4 or 8 months, then intervention by adding ARI-509 (25 mg/kg/day)—*4-MONTH and 8-MONTH INTERVENTION (**4IN; 8IN**)*; or galactose withdrawal from the diet at either 4 or 8 months—*4-MONTH and 8-MONTH GALACTOSE WITHDRAWAL (**4GW; 8GW**)*. At 4, 8, 16, and 24-month time points, tissue carbohydrate levels and RCBMT in the outer plexiform layer were determined for all groups (n = 5 to 8). Retinal polyol was reduced by 95% and 100% in all ARI-treated and galactose withdrawal groups, respectively. Mean RCBMT in ***GAL*** rats, became almost 2-fold greater (189 ± 9.4 nm) than in ***CON*** rats (103 ± 3.4 nm) by 24 months. Prevention of RCBMT was statistically significant ($p < 0.05$) in both the ***LDP*** and ***HDP*** groups at all time points. In contrast, a significant decrease in mean RCBMT compared to ***GAL*** rats was not found in either the intervention or withdrawal groups until 24 months (***4IN***, 166 ± 10.3 nm; ***8IN***, 161 ± 8.2 nm; ***4GW***, 136 ± 5.1 nm; ***8GW***, 163 ± 9.6 nm). The lack of a reversal and the long delay before the effects of either early or late intervention treatment were observed are consistent with findings from the Diabetes Control and Complications Trial.

1931

SUPPRESSION OF ENDOGENOUS OSMOREGULATORY GENES IN HUMAN RETINAL PIGMENT EPITHELIAL CELLS TRANSFECTED TO OVEREXPRESS ALDOSE REDUCTASE.

MJ Stevens, DR Larkin, Y Hosaka, F Porcellati, TP Thomas, JM Masterson, PD Killen and DA Greene. University of Michigan, Ann Arbor, USA.

Human retinal pigment epithelial (RPE) cells, a pathophysiologically relevant model for diabetic complications, demonstrate heterogeneous basal aldose reductase (AR) gene expression and activity. In 20 mM glucose, high AR-expressing RPE 91 cells exhibit exaggerated sorbitol accumulation and depletion of taurine and myo-inositol rendering them rate-limiting for their normal metabolic functions. The mechanism linking high AR gene expression to intracellular osmolyte depletion is unknown. The relationship of basal AR gene expression to steady state mRNA levels of the Na-taurine co-transporter (TT) was explored in low AR expressing RPE 47 cells and RPE 47 cells stably transfected to overexpress AR (to reproduce the phenotype of the RPE 91). Total cellular RNA was extracted from hypertonically-stressed RPE cells, size selected (>1 kb) and used to prepare a cDNA library in pcDNAI. Screening with a partial human AR cDNA yielded recombinant plasmids which were screened for function by transiently transfecting COS cells and measuring AR enzymatic activity. The clone with highest AR activity was selected for stable transformation in RPE 47 cells. RPE 47 cells were co-transfected with pRSV-neo-pcDNA1-AR27 and a clone identified (RPE 75) which expressed 4 x elevated AR enzymatic activity relative to untransfected RPE 47 cells and reproduced basal RPE 91 AR activity. To assess the effect of AR overexpression on other osmoregulated genes, RPE 47 cells, stably transfected RPE 75 cells and RPE 91 cells were exposed to 5 mM glucose for 24 h, and Northern blots prepared and sequentially hybridized with a 900 bp TT cDNA and a partial human AR cDNA and normalized to 28S. In RPE 75 cells, basal expression of the transfected AR gene was increased 3.5-fold vs. RPE 47 cells, reproducing the RPE 91 level. In RPE 75 cells, basal levels of the endogenous AR and TT were decreased by 38% and 44%, respectively compared to the untransfected RPE 47, the decreased level of TT mRNA being identical to that in RPE 91 cells. These data are consistent with reciprocal suppression of endogenous osmoregulatory genes in response to overexpression of AR, suggesting complex interactions among osmoregulatory genes.

1932

EFFECT OF ANTIOXIDANTS ON DEVELOPMENT OF RETINOPATHY IN DIABETES AND EXPERIMENTAL GALACTOSEMIA.

T.S. Kern, R.A. Kowluru, and R.L. Engerman. University of Wisconsin-Madison, U. S. A.

Dietary supplementation with 0.1% α-tocopherol acetate and 1% ascorbic acid has been reported by us to inhibit the diabetes- or galactosemia-induced increase in lipid peroxides (measured as TBARS) in retina and the decrease in activities of retinal ATPases and enzymes involved in protection from oxidative stress. Long-term studies of the effects of antioxidants on the development of retinopathy were conducted using this same diet. Alloxan-diabetic rats and nondiabetic rats fed 30% galactose diet randomly were assigned to receive diet supplemented with the antioxidants or standard diet. 18 months of diabetes or galactosemia resulted in pericyte loss, acellular capillaries and basement membrane thickening (i.e., lesions consistent with the early stages of retinopathy), and consumption of antioxidant diet significantly ($P<0.05$) inhibited the development of acellular capillaries in retinas of diabetic rats. The number of pericyte ghosts in antioxidant-treated rats tended to be less than in diabetic controls, but the decrease did not achieve statistical significance. Thickness of capillary basement membrane was not influenced by the antioxidant diet. GHb intentionally was kept comparable between diabetic groups, so the beneficial effect of antioxidants on the frequency of acellular capillaries seems not due to a difference in glycemia between groups. The antioxidants normalized a diabetes-induced increase in osmotic fragility of erythrocytes (an estimate of oxidative stress, demonstrating efficacy of the therapy. Galactose-fed rats showed no defect in osmotic fragility, and antioxidants caused no significant inhibition of galactose-induced metabolic abnormalities or histopathology in the retina. Galactosemic rats were not hyperphagic like diabetic rats (consuming only 48% the amount of antioxidants consumed by diabetics), perhaps accounting for the lesser effect of antioxidant diet on galactose-induced retinopathy. Supplemental antioxidants inhibited the development of retinal acellular capillaries in diabetic rats, but whether oxidative stress is a major factor in the development of diabetic retinopathy requires further investigation.

1933

ANTI-ANGIOGENIC ACTIVITY OF AQUEOUS HUMOR DECREASED IN DIABETIC MAN.

K.Hayasaka, S.Oikawa, H.Kotake, E.Hashizume, H.Midorikawa, A.Sekikawa, K.Hoshi, S.Hara, Y.Ishigaki, R.Sano, N.Suzuki, and T.Toyota. Sendai Kousei Hospital and Tohoku University, Sendai, Japan.

Neovascularization is an important event in diabetic ocular disease such as proliferative retinopathy. VEGF, bFGF and other cytokines play a role to progress angiogenesis. On the other hand, we have previously shown that anti-angiogenic activity has been present in aqueous humor(AH). Recently we found that TGFß2 was the major factor of anti-angiogenicity in AH. In the present study, we checked this activity and TGFß2 concentration of AH from diabetic patients. AH was obtained from patients undergoing ocular surgery. Angiogenic activity was estimated by the proliferation of HUVECs cultured with 20% AH. TGFß2 concentration was measured by ELISA (Amersham's kit) with or without acidifing AH. The number of HUVECs increased from 0.5(x10^4/well) to 14.7±0.8(m±SE, n=6) in the control culture, 6.1±0.7(n=5) ($p<0.01$ vs control) in nondiabetic AH supplemented, and 9.3±0.8(n=8) ($p<0.01$ vs control, $p<0.05$ vs nondiabetic)in diabetic AH supplemented. Total TGFß2 concentration of diabetic AH (diabetic 6.4±0.7 ng/ml, n=27) wasn't different from of non-diabetics (7.0±0.7, n=27). But the ratio of activated form was lower in diabetics(7.7±0.7 %, n=10) compared to nondiabetic (12.4±2.0, n=10, $p<0.05$). These results suggests that less activation of TGFß2 in diabetic AH caused lowering anti-angiogenic activity. The less anti-angiogenic activity of diabetic AH might be involved in promotion of neovascularization in diabetic ocular disease.

1934

EARLY TREATMENT WITH PHENSUCCINAL ATTENUATES DIABETIC RETINOPATHY DEVELOPMENT IN RATS

V. Poltorack, N. Gorbenko, N. Dumbrova, A. Gladkih, E. Maltsew and S. Ilina. Ukrainian Scientific Research Institute of Endocrine Diseases Pharmacotherapy, Kharkov, Ukraine

Taking into consideration the susceptibility of diabetic retinas to oxidative stress we evaluated the impact of a new low-toxic succinic derivative phensuccinal (P) with antioxidant properties on diabetic retinopathy (DR) development in rats. The newborn (2-3 days of age) rats were injected with streptozotocin (100 mg/kg i.p.) and randomized into a control diabetic group (CD, n=6) and P-treated one (PD) (P-25 mg/kg/day in the diet for 3 months, n=7). Antioxidant effect of P was assessed in liver homogenate by spectrophotometric determination of malonic dialdehyde (MDA), vitamin A and β-carotenoids. The severity of the alterations in retina was evaluated by scores in light and electron microscopic studies (blind). CD animals showed retinal capillary basement membrane (RCBM) irregularities, a significant (1.7 fold, $p<0.01$) increase in RCBM thickness (RCBMT) compared to normal controls (n=7), substantial edema and vacuolation in neural elements, abnormalities in endothelial cells and pericytes. P-treatment inhibited DR development reflected in absence of retinal neural elements edema, almost normal arrangement of endothelial cells and pericytes, more compact and even RCBM as well as a significant decrease RCBMT in comparison with CD rats (by 27.4%, $p<0.02$). Treatment with P improved glucose tolerance ($p<0.05$), reduced by 2.5 fold ($p<0.01$) MDA content, increased by 2 fold ($p<0.001$) vitamin A and β-carotenoids contents. Thus P possesses angioprotective effect due to improvement of oxidative parameters in diabetic rats and could be a beneficial agent for DR treatment.

1935

AGEs PROMOTE DIABETIC RETINOPATHY BY THE PRODUCTION OF VASCULAR ENDOTHELIAL GROWTH FACTOR

H. Obayashi, K. Nakano, H. Shigeta, H. Hasegawa, C. Hirata, M. Fujii, Y. Kitagawa, N. Nakamura and M. Kondo. First Department of Internal Medicine, Kyoto Prefectural University of Medicine, Kyoto, Japan

Recent studies have suggested that advanced glycation endproducts (AGEs) play an important role in the pathogenesis of diabetic complications. The aims of the present study were to prove the increment of AGEs and vascular endothelial growth factor (VEGF) in vitreous fluid of patients with proliferative diabetic retinopathy (PDR) and to clarify the effect of AGEs on VEGF mRNA expression *in vitro*. We evaluated AGEs production by measuring crossline, a novel AGE-product which has both crosslink and fluorescence similar to AGE-proteins *in vivo*. Vitreous samples were obtained during vitrectomy from 14 patients with PDR and 14 patients without diabetes received vitrectomy due to retinal detachment (n=7) or epiretinal membrane (n=7). Crossline and VEGF levels were determined by competitive ELISA. *In vitro* study, the expression of VEGF mRNA was analyzed by quantitative RT-PCR after the treatment of Müller cells, the strong candidate for VEGF production, with 50 μg/ml of AGE-BSA or BSA. The crossline levels in the vitreous of patients with PDR were significantly higher than those without diabetes ($P<0.05$). The VEGF levels in the vitreous were also significantly higher increased in patients with PDR ($P<0.01$). Furthermore, there was the positve correlation between crossline and VEGF levels in the vitreous samples of patients with PDR ($P<0.05$). The expression of VEGF mRNA was enhanced by the presence of AGEs when compared with the absence of AGEs. AGEs in vitreous fluid could promote intraocular neovascularization in diabetes through the production of VEGF from retinal cells. These results demonstrated that AGEs plays an important role in the initiation and progression of intraocular neovascularization in diabetic retinopathy.

1936

EFFECTS OF TAURINE AND VITAMIN E SUPPLEMENTATION ON OXIDATIVE STRESS AND NA/K ATPASE ACTIVITY IN THE RETINA OF STREPTOZOTOCIN-INDUCED DIABETIC RAT.

M.A.S. Di Leo[1], S.A. Santini[2], D. Lepore[3], G. Marra[1], S. Caputo[1], S. Cercone[1], F. Rao Genovese[3], A.V. Greco[1] and G. Ghirlanda[1]. Institutes of [1]Internal Medicine, [2]Biochemistry and [3]Ophthalmology, Catholic University, Rome, Italy.

To examine the effect of dietary supplementation with two endogenous antioxidant agents, taurine and vitamin E, on diabetic retinas, we evaluated the formation of conjugated dienes (CD) and the changes of membrane-bound enzymes such as (Na,K)-ATPase activity in retinas from male Wistar adult non-diabetic and streptozotocin-induced diabetic (STZ-D) rats. Diabetic animals were assigned to three groups: untreated; taurine supplementation by 5% w/w; vitamin E supplementation by 200 IU/kg of diet. After induction of diabetes, (STZ-D) rats were sacrificed at 2, 4 and 8 weeks and their retinas removed. (Na,K)-ATPase activity and conjugated dienes (CD) were measured spectrophotometrically and expressed as μmol Pi/h/mg protein and μmol/mg protein, respectively. Results are given as means ± SD. The levels of CD were 3.7 ± 0.3 in control retinas. We found a significantly increase ($p<0.0001$) of CD at 4 weeks (8 ± 0.3) in diabetic retinas of untreated rats, but not in retinas of vitamin E-treated and taurine-treated rats. Retinal (Na,K)-ATPase activity was reduced at 4 weeks (55.4 ± 7.7; $p=0.03$) and at 8 weeks (56.3 ± 6.9; $p=0.04$) in untreated animals with respect to that of control rats (104.3 ± 18.1), whereas ATPase activity in taurine-treated diabetic rats was found to increase by 2.1-fold after 2 weeks, and also after 1 and 2 (1.5-fold) months. Supplementation with vitamin E did not significantly reduce ATPase activity in (STZ-D) rats, although a progressive reduction was found at 4 weeks (84.7 ± 26) and at 8 weeks (73.8 ± 25.5). Our results suggest that hyperglycaemia produces an oxidative damage in diabetic retinas causing a dysfunction of membrane-dependent (Na,K)-ATPase. Treatment with taurine and vitamin E can modify diabetes-induced abnormalities in rat retinal membrane activities.

1937

IGF SYSTEM GENE EXPRESSION IN HYPOXIC RETINA.

E.Averbukh[1], O.Weiss[2], R.Yanko[2], R.Moshe[2], I.Nephesh[2], L.Yanko[1] and I.Raz[2].
Departments of Ophthalmology[1] and Internal Medicine[2], Hadassah University Hospital, Jerusalem, Israel.

Neovascular response in the diabetic eye is related to the development of retinal ischemia. To study the effect of relative ischemia on the IGF system in retina we used a model of neonatal rat retina that produce neovascularization when exposed to alternating levels of oxygen. We examined the influence of 24 hours hypoxia (10±1% oxygen), 48 hours hyperoxia (75±5% oxygen) and relative hypoxia (shifting from 48 hours 75% oxygen to 24 hours in room air) on the expression of the IGF system e.g. IGF-I, IGF-I receptor (IGF-IR)and IGF binding proteins 1,2 and 3 (IGFBP1,2,3) in retina using solution hybridization RNase protection assay. Gene expression was analyzed by densitometry and the numbers are given as percent of control (room air). Hypoxia induced a significant increase in IGF-IR, IGFBP2 and IGFBP3 mRNA and significant decrease in IGF-I mRNA (see table). Relative hypoxia also caused an increase in IGF-IR, IGFBP2 and IGFBP3 mRNA but did not change the expression of retinal IGF-I. We showed that relative hypoxia, similar to hypoxia, caused increase in IGF-IR, IGFBP2 and IGFBP3 gene expression, but unlike in hypoxic state IGF-I mRNA was not decreased. Thus we conclude that during relative retinal hypoxia that induces retinal neovascularization in newborn rat, there is overall up-regulation of the IGF system gene expression that might cause increased local activity of IGF-I in retina.

	Hypoxia 10% O_2	Hyperoxia 75% O_2	Relative Hypoxia
IGF-I	68%	117%	111%
IGF-IR	196%	97%	150%
IGFBP-2	208%	135%	161%
IGFBP-3	411%	109%	216%
IGFBP-1	Not Detected		

1938

PREVENTION OF THE DEPLETION OF NITRIC OXIDE SYNTHASE CONTAINING NEURONS IN THE DIABETIC RAT BY AMINOGUANIDINE.

T. Soulis*, E Roufail, ME Cooper* and SM Rees. *Department of Medicine, Austin and Repatriation Medical Centre (Repatriation Campus), The University of Melbourne, Department of Anatomy and Cell Biology, Melbourne, Australia.

A close association of nitric oxide synthase immunoreactive neurons (NOS-ir) to the retinal vasculature has been demonstrated suggesting a mechanism by which retinal blood flow and metabolism are linked. Aminoguanidine (AG), an inhibitor of advanced glycation and NO synthase activity, has been shown to attenuate the progression of retinal disease in experimental diabetes. The present study has examined the effects of diabetes on the population of NADPH diaphorase-positive (NADPHd) and NOS-ir neurons in the diabetic rat retina. In addition, the role of advanced glycation and the NO system in these diabetic retinal changes has been explored by the use of pharmacological inhibitors of these systems. Male Sprague Dawley rats (200-250g) were randomised into Control or rendered Diabetic via streptozotocin injection (50mg/kg). Control rats were randomised to receive no treatment or AG (2g/l). Diabetic rats were further randomised to receive no treatment, AG (1g/l) or a non-pressoric dosage of the NOS inhibitor L-NAME (5mg/L). Rats were followed for 3 or 32 weeks. At the various time points, the right eye from each rat was dissected and fixed in buffered 4% paraformaldehyde for 2h. Retinas were stained for NADPHd. Counting of cells was performed double blind (mean ± SEM).

		NADPHd histochemistry	
Group	n	3 weeks	32 weeks
Control	9	2715±39*	2944±144
Diabetic	9	1946±48	2283±148†
Control+AG	6	2278±129	2587±186
Diabetic+AG	7	2137±131	2939±31‡
Diabetic+L-NAME	7	1689±230	2392±93†

*p<0.05 versus all groups, †p<0.05 versus control, ‡p<0.05 versus Diabetic

A correlation between NOS-ir and NADPHd staining in the treated diabetic rat retina was demonstrated. The number of NADPHd-positive neurons per retina was reduced after 3 weeks of diabetes and persisted at 32 weeks. AG therapy restored the number of NADPHd-positive neurons at week 32 whereas L-NAME did not affect this parameter. This study indicates that the retinoprotective effect of aminoguanidine cannot be reproduced by L-NAME and is likely to be mediated by a decrease of advanced glycation rather than via inhibition of NOS.

1939

TREATMENT BY SOMATOSTATIN ANALOG, OCTREOTIDE, OF ISCHEMIA INDUCED NEOVASCULARIZATION IN NEWBORN RAT.

R.Yanko[1], M. Halpert[2], I. Shmaya[1], E. Averbukh[2], and I. Raz[1].
Departments of Internal Medicine[1] and Ophthalmology[2], Hadassah University Hospital, Jerusalem, Israel.

Octreotide was shown to prevent angiogenesis in diverse in vitro models of neovascularization. It's effect on proliferative (ischemia related) diabetic retinopathy is controversial. We used 48 hour cycles of alternating 10% and 50% oxygen during the first 14 days of newborn rats, followed by 4 days in room air to induce neovascularization. Half of the rats were injected with octreotide 10 µg x 2 daily during the whole period. At 18 days the rats were sacrificed, blood samples were taken and the eyes were enucleated and placed in formaldehyde. Ten representative slices of each eye were examined. Assessment of pathology was done using four parameters (table 1), each was assigned a value between 0 (non existent) and 3 (severe). Octreotide group included 52 eyes and the control group 59 eyes. In spite of the high octreotide levels in the treated group, growth hormone (GH) levels were not significantly decreased (from 64±33 to 45±13 µg/l) and IGF-I levels were not changed at all (75±12 to 86±19 µg/l). We failed to demonstrate any inhibition of neovascularization by octreotide. Octreotide did not prevent ischemia related neovascularization. However in this model octreotide did not significantly decrease levels of GH and IGF-I. Other drugs that better suppress GH are still worth trying.

Table 1. Pathologic findings in the eyes

Parameters	*Octreo.*	*Control*	*P-value*
Dilated vessels	1.6 ±0.9	1.8±1.0	0.09
Retinal hemorrhage	0.9±1.2	0.8±1.0	0.17
Vitreal hemorrhage	0.9±1.2	0.8±1.1	0.48
Neovascularization	0.7±1.1	0.5±0.9	0.11
Numbers represent average score ± SD.			

1940

OXIDATIVE DAMAGES TO OCULAR STRUCTURES IN DIABETIC PATIENTS ARE RELATED TO RETINAL FREE RADICAL PRODUCTION

I. Grattagliano, G. Vendemiale, *T. Micelli-Ferrari, A. Signorile, *F. Boscia, G. Serviddio, *L. Cardia, E. Altomare. Department of Internal Medicine and *Institute of Clinica Oculistica, University of Bari, Bari, Italy.

Retinal participation to the genesis of ocular complications during diabetes is supported by the observation of a concorrent higher rate of lipid and protein oxidation and decreased concentration of antioxidants both in the vitreous and in cataractous lenses obtained from diabetic subjects affected by background retinopathy compared to diabetic patients non affected by retinopathy and to non diabetic subjects. These alterations were even more pronounced in the presence of a proliferative retinopathy, thus suggesting that the retina may be a place for free radical production. Therefore, to confirm this hypothesis, the concentration and redox state of the proteins in the subretinal fluid (SF) of patients undergoing retinal detachment surgery have been evaluated.

Diabetic (n=8) and non diabetic (n=9) subjects with comparable age, degree of myopia and evolution time of the retinal detachment were considered for this study. The SF was obtained by puncture after sclerotomy; the concentrations of total proteins, sulfhydryl (P-SH) and carbonyl (DNPH) proteins were determined in the ocular samples with spectrophotometric methods. The levels of malondialdehyde (MDA) was measured by HPLC.

The protein concentration in the SF did not differ between diabetic and non diabetic patients. A higher concentrations of MDA (2.58 ± 0.31 vs 1.12 ± 0.22 nmol/mg protein, $p<0.01$) and DNPH (3.18 ± 0.36 vs 2.02 ± 0.28 nmol/mg protein, $p<0.02$) were observed in the SF of diabetic subjects, compared to non diabetic patients; the highest values were documented in patients affected by proliferative retinopathy. In the same subjects the lowest content of P-SH was noted (5.16 ± 1.32 nmol/mg protein, $p<0.01$ compared to diabetic patients without proliferative retinopathy).

In conclusion, it can be suggested that the retina partecipates to the genesis of diabetic eye complication by free radical production and that lipid and protein oxidation are events associated with retinal detachment and are involved in the onset of diabetes related ocular injury.

1941

IMMUNOHISTOCHEMICAL CHARACTERISATION OF RETINAL GLIAL CELL CHANGES IN DIABETIC RETINOPATHY

Toke Bek
Department of Ophthalmology, Århus University Hospital, DENMARK

Purpose: Occlusion of the retinal vascular bed is supposed to be a key factor in the development of proliferative diabetic retinopathy. A previous study has shown that the material occluding retinal vessels displays immunoreactivity to retinal glial cells. In the present study the glial cell changes secondary to diabetic retinopathy were further characterised. **Methods:** Immunohistochemistry to glial fibrillary acid protein (GFAP) and vimentin (all glial cell types), S-100 protein (perivascular glial cells), carbonic anhydrase (CAH-II) and CD-57 antigen (Müller cells), and CD-68 antigen (microglia) was performed on five eyes of five normal persons and on ten areas of vascular occlusion from ten eyes of six diabetic patients. **Results:** In the retina from diabetic patients immunoreactivity to S-100 protein in perivascular glial cells was significantly higher than in normals, except for areas of vascular occlusion where S-100 protein immunoreactivity was absent. The material accumulated to occlude the retinal vessels displayed immunoreactivity to vimentin, GFAP, CAH-II and CD-57 antigen, but not to S-100 protein, or CD-68 antigens. **Conclusions:** Diabetic retinopathy is characterised by activation of the retinal perivascular glial cells, but this cell type disappears in areas of vascular occlusion. The material accumulated to occlude retinal vessels represents invaded Müller cells.

1942

OXIDATIVE STATUS AND ANTIOXIDATIVE DEFENSE MECHANISMS OF DIABETIC CATARACTOUS AND CLEAR LENSES

Erel O.,Alçelik T., Koçyiğit A., Avcı Ş., Aktepe N, Fac. of Med.,Univ.of Harran, Sanlıurfa, Turkey

Oxidative status and antioxidative defense mechanisms were investigated in diabetic cataractous and clear lenses. Lens malondialdehide concentration(MDA) was measured to evaluate oxidative stress and lens total vitamin C (Vit C), non-protein sulphydryl compounds concentration (NPSC), glucose-6-phosphate dehydrogenase (G6PDH), catalase, superoxide dismutase(SOD), glutathione peroxidase (GSHPx)enzymes activities were measured in 15 diabetic cataractous lenses and 6 clear lenses. Lens MDA concentration of diabetic cataractous lenses were higher three times than that of clear lenses($p=0.02$). However, lens total vitamin C concentrations were decreased than clear lenses($p = 0.000$). Difference between diabetic and clear lens NPSC concentrations was not significant. Lens specific G6PDH, catalase and GSHPx enzyme activities were higher than that of clear lenses($p= 0.001$, $p=0.01$, $p=0.001$, respectively). SOD activities were lower than clear lens($p= 0.002$). As a preliminary report an important positive correlation between lens G6PDH and catalase activities($p=0.000$ $r= 0.81$) and negative significant correlation with SOD activities were determined($p=0.000$ $r=0.70$, $p= 0.000$ $r=0.82$). H_2O_2 is occurred in lens by photochemical oxidation and lens metabolism. Antioxidatives, Vit C and NPSC are used, and catalase, GSHPx activities increase to remove H_2O_2. In diabetic lens, insufficiency of these antioxidative mechanisms and inhibition of SOD by increased concentration of H_2O_2 led to oxidative damage of lens and development of cataract. Beside of this, increased activity of diabetic cataractous lens G6PDH that is key enzyme of pentose phosphate pathway (HMP) shows that HMP possesses an important antioxidant role in lens.

1943

DIABETES PREVENTS DARK-INDUCED RETINAL HYPEREMIA.

J.R. Williamson, Y. Ido, and K. Chang, Washington Univ., St. Louis, USA.

These studies were undertake to assess the effects of diabetes of 3 weeks duration on dark-induced retinal hyperemia. Dark adaptation increases retinal glucose metabolism and blood flow and causes borderline to mild hypoxia in the outer retina. Increased glucose metabolism via the sorbitol pathway in diabetic rats also is associated with increased retinal blood flow and with 'hypoxia-like' cytosolic reductive stress (an increased ratio of free cytosolic NADH/NAD^+). Dark-induced hyperemia was assessed in 2 independent studies in control (C) and streptozotocin-diabetic (D) male Sprague-Dawley rats and in diabetics treated with aldose reductase inhibitors, sorbinil (D+S) and zopolrestat (D+Z), at a dose of 0.2 mmol/kg bwt/day. After anesthesia with thiopental (80 mg/kg bwt) the head was wrapped with black cloth except for 1 eye. Vascular conductance (blood flow in µl/g retina/min normalized to 100 mmHg mean arterial pressure, mean±SD, N=8 to 12) was assessed 30 min later in the dark-adapted (DA) and the contralateral room light-exposed (LE) eye with a plasma soluble tracer (^{3}H-desmethylimipramine, mol wt=276). Conductance in C increased 9.6±2.1 % in DA eyes to 434±39 vs 387±41 in LE ($p<0.0001$). Conductance in DA and LE eyes did not differ in D in either study, although conductance in LE of D was increased 12 % vs LE in C to 432±42 in one study ($p=0.026$) and 32 % to 507±46 in the other ($p=0.0027$). Conductance was not increased in DA vs LE in D +S, but was increased 6.5±4.5 % ($p=0.0023$ for DA vs LE in D+Z, and $p=0.15$ vs the 9.6 % increase in C). In conclusion, these observations demonstrate that dark adaptation causes retinal hyperemia in normal rats and that this response is prevented by diabetes. The role of increased sorbitol pathway metabolism in mediating impaired dark-induced hyperemia in diabetic rats is unclear in view of the normalization by zopolrestat, but not by sorbinil, of dark-induced hyperemia.

1944

TRACE ELEMENT CONTEND IN THE DIABETIC CATARACT AND TRANSPARENT LENS

Koçyiğit A., Erel Ö., Alçelik T., Avcı Ş., Aktepe N., Gür S, Fac.of Med., Univ. of Harran, Şanlıurfa, Turkey

The contend of trace elements Cu, Zn, Mn, Cr, Fe, Pb, Sb, and Ni in 15 diabetic cataract lenses and 12 transparent lenses were determined by graphit furnace atomic absorption spectrophotometry. It was faund that the contend of the elements in diabetic cortical cataract lenses were markedly increased from those in transparent lenses. Comparing transparent lenses with diabetic cortical cataract lenses, accumulation of Cu, Ni, Cr and Fe about six times, Mn and Pb about tree times, Zn and Sb about two time were higher in diabetic cataractous lenses than transparent lenses. There were significant relationship between Mn and Zn ($r=0.0739$, $p<0.05$), Sb and Zn ($r=0.763$, $p<0.05$), Pb and Zn ($r=0.824$, $p<0.01$), Sb and Mn ($r=0.994$, $p=0.000$), Sb and Ni ($r=0.986$, $p=0.000$), Pb and Cr ($r=0.741$, $p<0.05$), Ni and Mn ($r=0.992$, $p=0.000$). It was therefore inferred that the occurance of diabetic cataract was directly or indirectly related to the deficiency of trace elements.

1945

RELATIONSHIP BETWEEN ERYTHROCYTE ALDOSE REDUCTASE LEVELS AND DIABETIC RETINOPATHY IN NIDDM PATIENTS.

T.Tanimoto[1], K.Maekawa[1], S.Okada[1], E.Kubo[2], Y.Takahashi[2] and Y.Akagi[2]. [1]National Institute of Health Sciences, Osaka, Japan, [2]Fukui Medical School, Fukui, Japan.

The most important diabetic complication on the eye is diabetic retinopathy, because its progression leads directly to blindness. Since the acceleration of polyol pathway may initiate diabetic retinopathy, we consider that the enzyme aldose reductase (AR) probably modify the progression of diabetic retinopathy. In this study, we have measured AR levels in erythrocyte of diabetic patients in order to elucidate the relationship between the incidence of diabetic retinopathy and AR levels. The AR levels in erythrocyte of peripheral blood were determined in 531 NIDDM patients and 219 healthy human subjects by the ELISA method. Clinical parameters of diabetic patients (n=531) : gender (male/female), 284/247; age, 60.7±11.3 years; duration of diabetes, 12.1± 8.8 years; fasting blood glucose, 9.5±3.1 mmol/L; HbA1c, 8.2±1.8%, AR, 10.5±3.0 ng/mgHb. The levels of AR did not correlate with age, duration of diabetes, fasting blood glucose and HbA1c. In the all diabetic patients, the incidence of retinopathy (including non-proliferative and proliferative) was 47.1%. The AR levels in the patients with retinopathy was significantly higher than in those without ($p<0.02$), and the levels of the patients without retinopathy was almost same with that of healthy human subjects (10.1±2.0 ng/mgHb). In 531 patients, the levels of AR showed no significant correlation with the incidence of diabetic retinopathy. However, in 194 patients with duration of diabetes from 10 to 20 years, the incidence of diabetic retinopathy was significantly increased in proportion to the amount of AR ($p<0.05$, χ^2 test). The incidences were 72.2% and 33.3% in the patients having not less than 13 ng /mgHb and not more than 7 ng/mgHb of AR, respectively. We concluded that high AR levels are related to the development of diabetic retinopathy.

1946

IRON METABOLISM OF DIABETIC CATARACTOUS AND CLEAR LENSES; PRELIMINARY STUDY

Erel O., Koçyiğit A., Alçelik T., Avcı Ş., Aktepe N, Fac. of Med., Univ.of Harran, Sanlıurfa, Turkey

Lens iron, transferrin and ferritin concentrations were determined in 15 diabetic cataractous lenses and 6 clear lenses. Lens iron concentration was determined by electrothermal atomic absorbtion spectrometer, lens transferrin concentration was investigated by two different techniques, immunological method and dynamic colorimetric iron binding measurement method, lens ferritin concentration was firstly determined by immunochemiluminecance methods. Lens iron concentrations are 13.82 ± 12.4 ng/mg dry weight and 2.57 ± 0.94 ng/mg dry weight, in diabetic cataractous lenses and clear lenses respectively($p=0.001$), no lens transferrin concentration was determined by immunological and colorimetric iron binding method in two groups. Lens ferritin concentrations are 64.96 ± 47.05 U/mg protein, 294.50 ± 56.50 U/mg protein, , in diabetic cataractous lenses and clear lenses respectively($p=0.001$). In diabetic cataractous lenses, accumulation of iron may be result of loss of selective permeability of lens, and the decrease of ferritin concentration may be result of the destruction of natural protein structure of ferritin by oxidants. Both of the increased iron and the decreased ferritin concentrations will be attend to the acceleration of the oxidative mechanisms of the lens and the development of the cataractogenesis.

1947

HIGH LEVELS OF ERYTHROCYTE ALDOSE REDUCTASE IN NIDDM PATIENTS WITH DIABETIC RETINOPATHY

Y. Kitagawa, C. Hirata, N. Ichio, K. Wada, K. Nakano, H. Shigeta, M. Yamaguchi, H. Obayashi, N. Nakamura and M. Kondo. Dept. of Endocrinol., Osaka General Hospital of West Japan Railway Company. Dept. of Med., Kyoto Pref. Univ. of Med. Osaka and Kyoto, Japan

The key role of aldose reductase (AR) in the development of various diabetic complication has been postulated. There has been, however, little study on the association between susceptibility to diabetic complications and the level of tissue AR in human subjects. To elucidate relationships between AR levels and diabetic complications, AR levels in erythrocytes of peripheral blood were determined in 470 NIDDM patients by the specific two-site ELISA based on purified recombinant human AR. AR levels showed no significant correlation with sex, age, duration of diabetes, fasting blood glucose and the average HbA1c of the patients. No significant difference was demonstrated between the enzyme levels of the 470 patients and 50 healthy controls. In 182 patients with duration of diabetes equal to and more than 10 years, the AR levels of patients with retinopathy (n=96) were higher than those in patients without retinopathy (n=86), but the average HbA1c levels during the recent 2-year period were also higher in the patients with retinopathy. To reduce the influence of the differance of the average HbA1c levels, we compared the AR levels in the patients with HbA1c level less than 7%. In these patients, the AR levels of patients with retinopathy (n=14, non-proliferative) were significantly higher than those in patients without retinopathy (n=45) (12.1 ng/mg Hb vs 9.8 ng/mg Hb, $P<0.01$). Between the two groups, there were no statistical differences in age, duration of diabetes, average HbA1c levels and average maximum and minimum blood pressure recorded during the recent 2-year period. AR levels were not significantly different between the patients with and without nephropathy. These results suggest that high AR levels in erythrocytes are related to the development of diabetic retinopathy.

Retinopathy – Epidemiology, Clinical and Treatment

1948

Can digitised colour 35mm transparencies be used to diagnose diabetic retinopathy?

L.D.George[a], C.Leverton[b], S.Young[b], F.Dunstan[b], D.R.Owens[a].
[a]Diabetes Research Unit, Llandough Hospital and [b]Departments of Media Resources and Medical Statistics, UHW, Cardiff, UK.

Retinal photography is an adjunct to ophthalmoscopy in screening for diabetic retinopathy (DR). Digital retinal cameras allow a retinal image to be immediately displayed on a high resolution video display monitor. We conducted a pilot study to investigate the agreement in retinopathy grading from digitised images in comparison to the original colour transparencies as 35mm slides. 150 macula centred, 45°, non stereoscopic retinal images were digitised onto CD ROM by Kodak at base resolution of 768x512 pixels. The anonymised images were displayed on a 17" monitor running Windows at 800x600 resolution in 64,000 colours and graded in random order. Alternatively the transparencies were graded on a Slidex viewer. A quality control set were also graded with exact agreement in 93% of cases overall (91% (73/80) of PC images and 94% (75/80) of slide images). Compared to colour transparencies, 95% (84/88) of sight threatening diabetic retinopathy (STDR) and 100% (62/62) of non STDR cases were diagnosed using the PC. One case of pre-proliferative DR showing multiple cotton wool spots masked by the light reflections in the image viewed by the PC in a young patient was graded as non STDR. Three cases of non proliferative DR, one of poor photographic quality and two of which had hard exudates discernible despite reflections on the retina when viewing the colour transparencies but masked by the reflections when grading from the PC were graded as non STDR from the PC. There was good agreement between PC displayed digitised retinal images and 35mm colour transparencies.

1949

HBA_{1c} FROM DIABETES ONSET AND PREVALENCE OF RETINOPATHY

CE Kullberg[1], HJ Arnqvist[2], Kerstin Finnström[3] and Johnny Ludvigsson[4]; for the VISS-study group. [1] Dept. of Internal Medicine, Faculty of Health Sciences, and [2] Dept. of Endocrinology, [3] Dept. of Ophthalmology, [4] Dept. Of Child Health, University Hospital, Linköping, Sweden.

The VISS study (Vascular complications In Southeast Sweden) aims to investigate prevalence and incidence of vascular complications in relation to HbA_{1c} from diabetes onset, in a population with of Type 1 diabetes, from well defined geographic area. The study population comprise all patients with Type 1 diabetes onset before the age of 36, onset during 1983-1987, and at the time of onset living within the counties of Östergötland, Kalmar or Jönköping. Retinopathy was examined with fundus photography during 1994-95. All photos were evaluated by two ophthalmologists, and retinopathy was classified according to a modified Airlie House protocol. 353 sets of fundus photographs have been evaluated. For 252 patients (71%) no sign of retinopathy was seen. Patients with mean HbA_{1c} from diabetes onset in the highest quartile (>8.6% HbA_{1c}) had a relative risk of 4.2 (95% CI 2.3<RR <7.8) to have retinopathy compared to patients in the lowest quartile (<6.6% HbA_{1c}). Logistic regression with presence of retinopathy as dependent variable indicated significant impact from mean HbA_{1c} from diabetes onset, duration, and diastolic blood pressure, but no influence from age, sex or systolic blood pressure. Sixty-one of 166 (39%) patients with diabetes onset after 14 years of age had retinopathy, compared to 41 of 188 (22%) patients with younger onset (relative risk 1.7; 95% CI 1.2<RR<2.4). Prevalence of retinopathy was strongly associated with long-term mean HbA_{1c}. Patients with onset after 14 years of age had significantly more retinopathy than patients with younger onset.

1950

SUPERIORITY OF ELECTRONIC IMAGING IN DIABETIC RETINOPATHY SCREENING

REJ Ryder, N Kong, AS Bates, F Game, J Sim, A Ward, J Welch, and EE Kritzinger. City Hospital, Birmingham, England.

We aimed to compare two systems of instant retinal photographic imaging for diabetic retinopathy screening - the traditional Polaroid system (Canon CR4 45NM) and a new electronic imaging system (Canon CR5 45NM) which can produce an enlarged retinal image on a computer monitor screen. 213 eyes from 107 diabetic patients, including 14 already attending an ophthalmologist, were photographed through dilated pupils by both systems in random order and the images were analysed blind. Diabetic retinopathy was present in 58 eyes of which 55/58 (95%) were detected on the electronic imaging system and only 49/58 (84%) on the Polaroid. Of 34 eyes requiring referral to an ophthalmologist according to standard European criteria, 34/34 (100%) were detected on the electronic imaging system and only 24/34 (71%) on the Polaroid. Side by side comparisons showed the electronic imaging system to be considerably superior to Polaroid at lesion detection. Computer printouts of the images, both colour or black & white, of sufficient quality to show the lesions missed by Polaroid, could also be obtained. Most of the important lesions missed on the Polaroid but detected on the electronic image were hard exudates or haemorrhages within one disc diameter of the macula. Using linear analogue scales to compare the brightness of the flash, the patients assessed the electronic imaging system as significantly less bright than the Polaroid system ($p<0.0001$). Their comments suggested that the discomfort of the flash of the electronic imaging camera was considerably less than the Polaroid equivalent. Other potential advantages of electronic imaging in diabetic retinopathy screening include ready storage/retrieval of digitised images; image enhancement and analysis using image analysis software; and electronic transfer of images to ophthalmologists and primary care doctors. Electronic imaging systems represent a major potential advance for the improvement of diabetic retinopathy screening, with increased detection of sight threatening retinopathy compared to Polaroid.

1951

INCIDENCE AND TIME-TREND OF OCULAR COMPLICATIONS OF IDDM IN JAPAN

Michihiko Maruyama, Masato Matsushima, Kanae Shimizu, Rimei Nishimura, Keiko Asao, Hironari Sano, Naoko Tajima, DERI mortality study group. Department of Internal Medicine (III), Jikei University School of Medicine.

No previous study has reported the prognosis regarding diabetic ocular complications among Japanese with IDDM in a population-based setting. The aim of this study is, therefore, to evaluate the incidence and time-trend of ocular complications by following-up the DERI (Diabetes Epidemiology Research International) cohort consisting of 1428 individuals with IDDM. The subjects were diagnosed as having diabetes during 1965-79 with onset of diabetes <18 years of age. We have traced 75% of the cohort (1064/1428) regarding ocular complications until January 1, 1995. The study revealed that the incidence rates of blindness and photocoagulation therapy were 3.7%, 19.4% for 15-year observation, and 9.7%, 41.0% for 25-year observation, respectively. Of interest is that the incidence rate, for 15-year observation, of blindness for subjects diagnosed during 1965-69 (old cohort) was higher compared to those diagnosed during 1975-79 (new cohort) (353 vs. 106/100,000 person years); in contrast, there was no difference in incidence of photocoagulation therapy between old and new cohort (978 vs. 1023/100,000 person years). The results suggested that the prognosis of ocular complication has been recently improved, the reason of which may be increased prevalence of photocoagulation therapy in Japanese IDDM patients.

1952

SCREENING FOR EARLY DIABETIC RETINOPATHY BY A HIGH RESOLUTION COMPUTER VISION SYSTEM.

S.C. Lee. University of Oklahoma, Norman, Oklahoma, USA

Diabetic retinopathy has been identified as one of the most common causes of blindness. One of the disturbing problems that diabetic patients face is that they may be suffering from a gradual or acute potential loss of vision and not recognize it. Although diabetic retinopathy is a treatable disease, early detection is essential to ensure that the patient receives appropriate preventive treatment. The main aim of this study is to introduce a method for screening for early diabetic retinopathy. The method is based on the use of a high resolution computer vision system. It can provide a resolution of 10,000 pixels per inch and can differentiate over 16 million different shades of colors that no human eyes can match. Computer quantitative algorithms for screening for early diabetic retinopathy have been developed and implemented. A substantial number of early diabetic retinopathy cases have been studied. The results show that the computer system can detect diabetic retinopathy much earlier than an ophthalmologist can. Another major advantage of having such a system is that it provides a mass-screening means for detecting early diabetic retinopathy at low cost.

1953

OPHTHALMOLOGIC COMPLICATIONS IN INSULIN DEPENDENT DIABETES MELLITUS

C. Orellana, M. Pérez, J. Robalino. Diabetes Ecuadorian Foundation (FED). Quito - Ecuador.

We wanted to know the frequency of ophthalmologic complications in 94 insulin dependent diabetes mellitus patients. It was a descriptive observational study. We used an univariate analysis; Interest II and Quattro softwares. We revised results of complete ophthalmologic examination: corrected visual acuity, tonometry, slit lamp inspection and fundoscopic test using midriatic drug. Diabetic retinophaty diagnostic was made by biomicroscopy. We found 19.14% of simple retinopathy, 6.38% of simple retinopathy + maculopathy and 4.23% of proliferative retinopathy. Additionally, we observed 8.51% of cataracts (1.06% on left eye, 2.12% on right eye and 5.31% bilateral). Moreover, we found 23.33% of impairment visual acuity on left eye, 25.84% on right eye and 3.35% of blindness. Finally, 6.66% of patients had photocoagulation. For simple retinopathy, it was present after a mean time of 18.1 years (SD 2.74), for maculopathy, 14.5 years (SD 3.34) and for proliferative retinopathy, 20.8 years (1.75). We concluded that diabetic retinopathy prevalence, loss vision and cataracts were significative.

1954

NEW BLINDNESS IN DIABETES REDUCED BY 11% PER YEAR IN STOCKHOLM COUNTY

L. B. Bäcklund, P. V. Algvere and U. Rosenqvist, Departments of Ophthalmology, Karolinska Institutet, St. Erik's Eye Hospital, Stockholm, and Social Medicine, University of Uppsala, Sweden

Main aim: To develop a method for assessing all-cause blindness incidence in diabetes, and to evaluate interventions. **Background:** Mobile fundus photography teams for early diagnosis of diabetic retinopathy reached 10 000 persons with diabetes in primary care. **Methods:** Referrals stating diabetes ($n = 2\,272$) to vision rehabilitation centres 1981-1995 were registered (1995 pop. 1 725 756). Blindness was defined (WHO, ICD 10) as best-corrected visual acuity (VA) of the better eye less than 3/60 (0.05); 172 persons were blind from all causes. Trend tests used Poisson regression analysis. **Results:** Referrals with VA 6/15–6/24 increased, perhaps causing differential misclassification bias. The number of referrals with diabetes and blindness per five-year period fell from 93 (1981–85) to 51 (1986–90) to 28 (1991–95); average annual incidence rate for referrals with blindness per five-year period was reduced from 1.2 (95% CI 0.97–1.5) to 0.63 (0.47–0.83) to 0.33 (0.22–0.48) per 100 000 population; mean yearly reduction 11% (7–15%), test for trend $p < 0.001$. **Conclusion:** This is the first geographical region where a proxy measure for new blindness in diabetes was reduced by one third or more in five years, reaching one of the St Vincent Declaration main targets.

1955

MAIN INDEPENDENT RISK FACTORS FOR DIABETIC RETINOPATHY IN MEXICANS.

G.E. Sotomayor, I. Fuentes, A. Mayorga, E. Garza, J. Escobedo and J.C. Bravo. Instituto Mexicano del Seguro Social, Mexico City, Mexico.

Mexicans are a high risk group for non-insulin-dependent diabetes mellitus, and diabetic retinopathy (DR) is one of the main complications and a frequent cause of severe vision loss. Nevertheless few studies have estimated the occurrence of DR in Mexico, and none has studied its risk factors. The authors conducted a cross-sectional study to estimate the strength of the association between DR and its related risk factors. Thirteen percent of the diabetic population in a primary care medical unit were included in the study. A total of 129 men and 261 women received a detailed eye examination by direct ophtalmoscopy trough dilated pupils. Both nonproliferative and proliferative DR were considered for analysis, defined by the more severely affected eye. A logistic regression analysis was used to assess the independent effect of each risk factor while controlling for potential confounders. Odds ratio (OR) and 95% confidence intervals ($CI_{95\%}$) were employed as a measure of effect. The risk of DR increased by 29% for each year of duration of diabetes (OR 1.3; $CI_{95\%}$ 1.2-1.4), and by 46% for each milligram increase in serum creatinine (OR 1.46; $CI_{95\%}$ 0.9-2,4). Those patients with good metabolic control had a 60% diminished risk of DR (OR 0.41; $CI_{95\%}$ 0.23-0.72), even after controlling for age, sex and age of diagnosis of diabetes. Hypertension was related only to proliferative DR (OR 2.3; $CI_{95\%}$ 0.9 - 5.9). DR is closely related to the duration of diabetes and the presence of diabetic nephropathy. Metabolic control is an important predictor of DR in Mexicans, and a potentially modifiable risk factor. An integral diabetes program should be implemented in the Medical System in Mexico.

1956

DIAGNOSING AND TREATMENT OF DIABETIC RETINOPATHY FOR CHILDREN.

Mylenkaja T.M., Dedov I.I., Bessmertnaya E.G..
National Endocrinology Center , Moscow, Russia.

We have examined 38 children aged from three to fourteen with the 1st type of diabetes. In the cases up to five years long diabetes it was revealed initial pathological changes such as: mild venous dilatation, microaneurysmas, single haemorrhages and irregular contours of optic nerve disk. Another group contained the children with duration of diabetes from 6 to 12 years and the 67 % of the patients had changes on eye-bottom, the 38 % of them had irregular contours of optic nerve disk. The 66 % of the children had mild twisted vessels capillary dilatation, microaneurismas, the 28 % of them had more severe current of retinopathy. Development of neovascular abnormalities within optic nerve disk area was found in the 11 % of the cases, the others 17 % of eyes had hard exudates and drusen had been recognized in a part of patients. The reasons for fotocoagulation treatment for children are:

1. presence a lot of microaneurismas, retinal haemorrhages, capillary dilatation;

2. growing pathological changes on the eye-bottom in 3..6 months after revealing diabetic retinopathy in spite of diabetic compensation.

It had been made the fotocoagulation of retinae for 10 children. The 84 % of the patients had the stabilization of process after 6 months.

All children with the 1st type of diabetes mellitus need early diagnoses of retinal changes but it is important to make photocoagulation in the case of disease progress.

1957

RURAL URBAN DIFFERENCES IN THE PREVALENCE OF DIABETIC RETINOPATHY IN MEXICO.

J. Escobedo-de la Peña, G.E. Sotomayor-Flores, A. Mayorga and I.H. Fernández. Instituto Mexicano del Seguro Social, Mexico City, Mexico.

The prevalence of non-insulin-dependent diabetes mellitus (NIDDM) is increasing in rural areas of Mexico. However, no study has estimated their prevalence of diabetic retinopathy (DR). The authors conducted a cross-sectional study to estimate the prevalence of DR in a small rural town of the southwestern state of Oaxaca. Sixty-two diabetics, which conformed 91% from all diabetics in the town, received a detailed eye examination by direct ophtalmoscopy trough dilated pupils. Both nonproliferative and proliferative DR were considered for analysis, defined by the more severely affected eye. Thirteen percent of the diabetic population in a primary care medical unit from Mexico City, were also included. Theprevalence of DR was lower in the rural population (35.5%), than in the urban (43.1%). However the main difference was in the prevalence of proliferative DR, which was present in 14.8% of the urban diabetics and in only 4.8% of the rural ones. When there was a poor metabolic control the prevalence of DR was equally high in both urban (57.1%) and rural (62%) diabetics, although the prevalence of proliferative DR was higher in those with poor metabolic control living in the city (20.6%) than in those living in the town (10.3%). The estimated prevalence was adjusted by age, sex, duration of the disease and metabolic control. The adjusted prevalence of DR was 42.2% in the urban diabetics and 27.6% in those living in the rural town. Since the occurrence of NIDDM is increasing in rural communities, it is expected that the prevalence of diabetic complications will also increase. DR is an increasing challenge to the Health System in Mexico, even in rural communities.

1958

SPECIFIC FEATERES EYE – LESIONS IN DIABETIC CHILDREN.

L. Sherbacheva, T.Milenkaya, T.Kouraeva, V.Maksimova, I.Mishina, N.Gubanov and V.Peterkova. Endocrinology Research Center, Moscow, Russia.

During 1995/96 years 176 children with IDDM aged 3-15 years were examined in children's department of the Endocrinology Center. The average duration of disease was 6,3 ± 0,9. The onset of IDDM in the age up to 5 years was in 65 (36,9%), up to 10 years - 81 (46%) and from 10 to 15 years - 30 (17,1%) patients. Ophtalmoscopy, retinal photography and video recording with laser scan camera (CLSO, Zeiss) were performed. Optical nerve disk hyperaemia and papillit was discovered in 30,7% of patients, blood vessels were dilated in 18,2%, microaneurysms were found in 24,4%, retinal haemorrhages - in 15,9%, early stage of cataract - in 23,3%. Diabetic retinopathy was diagnosed in 21 children (12%). The second observation was performed after 6-12 months. After treatment steady state in fundus was achieved in 89,2% of patients, improvement - in 4%, progression of process in 6,8%. Laser coagulation of retina has been done for 8 children (4,5%). Further progression of diabetic retinopathy was stopped in 6 children. **Conclusion:** Early diagnostics of diabetic retinopathy and laser coagulation are the basis of the favourable prognosis.

1959

DECREASED PREVALENCE OF DIABETIC RETINOPATHY BUT INCREASED PREVALENCE OF PIGMENTARY RETINOPATHY IN DIABETES DUE TO A MITOCHONDRIAL DNA MUTATION

D.J. Holmes-Walker*[1], P Mitchell[3], CM Sue[2], JGL Morris[2] and SC Boyages[1] Departments of Diabetes and Endocrinology[1], and Neurology[2] Westmead Hospital, and Department of Ophthalmology[3], University of Sydney, Sydney, Australia.

Pigmentary retinopathy (PRet) is a recognised feature of mitochondrial genome (mtDNA) mutations. While the association of PRet with maternal inheritance diabetes and deafness (MIDD) is well recognised, the relationship between diabetes mellitus (DM), PRet and diabetic retinopathy (DR) has not previously been explored. The aim of this study, therefore, was to determine the prevalence of PRet in subjects with the 3243 mutation of mtDNA, to ascertain whether diabetes alters the phenotypic expression of PRet and to determine if there was any association between the presence of PRet and DR. Twenty maternal line family members (10 DM, 3 IGT, 7 NGT) had ophthalmic examination. Slit lamp was used in 18 of 20, with retinal photography of seven standard fields. Fluorescein angiography was performed in 13 of 20 subjects. Visual acuity was relatively preserved in all subjects (6/6-6/18). Nine of 10 DM subjects had clear cut PRet while 2 of 3 IGT subjects and 2 of 7 NGT subjects had PRet. A strong association between the presence of DM and PRet was found, χ^2_{2df} 6.83, p=0.03, and an even stronger association was found between the presence of abnormal GT and PRet, χ^2_{1df} 6.28, p=0.01. Age was not found to be a significant determinant of PRet. The odds ratio for PRet in subjects with abnormal GT was 13.7 (95% CI 1.5-127, p=0.02, R^2=0.25). The mean age of onset of DM was 44.3 ±15.4 yrs and the mean duration of DM at the time of retinal examination was 15.4 ± 7.4 yrs. Of the 9 DM subjects with PRet, two had mild background DR with microaneurysms only (duration of DM 17 and 21 yrs). No DM subject had proliferative DR. The mean HbA1c in the DM group was 8.9±1.3% (NR<6%) with 8/10 having an HbA1c >8%. Of the 20 subjects examined only one DM subject had evidence of early cortical cataract (80yrs). In conclusion, we propose that changes to normal glucose disposal within the retinal pigment epithelium (RPE) which occur as a consequence of reduced oxidative phosphorylation capacity may explain both the increase in PRet and the absence of DR and cataract. The former may be due to an increase in lactate and decrease in ATP production by the RPE while the latter may be due to a reduction in glucose disposal by the polyol pathway. A greater understanding of the effect of mtDNA mutations has the potential to give insight into the mechanisms of DR and other complications of DM.

1960

DIABETIC RETINOPATHY AND PREGNANCY

B. Zarzycka, *M. Kinalski, W. Zarzycki, A. Krętowski, J. Topolska and I. Kinalska
Department of Endocrinology and Institute of Gynecology and Obstetrics* Medical School Białystok, Poland

Pregnancy was reported as an important risk factor in the development of diabetic retinopathy in women with Type 1. diabetes. The aim of the study was to estimate the ophtalmological status in Type 1. diabetic women before and during pregnancy as well as postpartum. 116 diabetics divided according to the White scale on 1 A, 63 B, 33 C, 18 D and 1 R were investigated. The control of diabetes was within the criteria of fast normoglycemia. Women included to White's D and R planned their pregnancies. The ophtalmology investigations were performed at each trimester. In 16% women with early diabetic eye complications pharmacological treatment (Calcium dobesilate, Quinax, Pentoxifillin, flavonoides) and/or adequate laser treatment were performed. Diabetic retinopathy was found in D and R classes of White. In A, B and C classes changes in the fundus of the eye before, during and after pregnancy were not confirmed. The exception were two C class patients with I ° retinopathy during pregnancy which persisted in the postpartum period. No progression of retinopathy was observed in 18 patients in White's D with diabetic retinopathy; in only one case regression after delivery was observed. In one patient included in class R the laser therapy during pregnancy caused the involution of diabetic retinopathy. These observations indicate that very good metabolic control of diabetes and ophtalmological investigation connected with adequate therapy of the initial changes in the eye did not progress in diabetic retinopathy in the presented group of diabetic pregnant women.

1961

FREQUENCY OF ADVANCED DIABETIC RETINOPATHY IN HOSPITALIZED PATIENTS.

A. Sánchez, R. Parma, A. González, M. Echecury, N. Vázquez, A. Libman.
Servicio de Endocrinología, Hospital Español, Rosario, SF, Argentina.

In order to ascertain the frequency of diabetic retinopathy (DR) among hospitalized diabetic patients, 354 medical records of such patients seen in consultation by the Endocrinology Service during a 12-year period were reviewed. The presence of chronic complications of diabetes was established according to clinical data and complementary studies obtained from the records. Fundus examination through dilated pupils, performed by trained ophthalmologists, had been informed grading the findings as follows: I and II (background DR), III (preproliferative), and IV (proliferative). Patients' age (mean±SD) was 63.9±11.8 years (range, 16-90). There were 176 women and 178 men; 23 patients had type I and 331 type II diabetes DR was found in 56.3% of women and 50.6% of men. It was present in 52.2% of type I and 53.5% of type II patients. Mean age was similar in subjects with and without DR, but the duration of diabetes was significantly longer in the former (10.4±10.9 vs. 8.4±10.0 years; P<0.05). Subjects with DR had significantly higher frequency of other chronic complications (P<0.001), with the exception of coronary insufficiency, and required insulin treatment more frequently than those without. High blood pressure was present equally in both groups. Of 190 patients presenting DR, 45 had received previous laser photocoagulation. Of the remaining 145 patients, 45 had grade I, 49 grade II, 34 grade III, and 19 grade IV DR. Thus, the relative frequencies of these grades among the 309 diabetic inpatients without previous laser treatment were, respectively, 13.9, 15.8, 11.0, and 6.1%. DR was detected by funduscopy in over 50% of hospitalized diabetic patients. The frequency of advanced grades (III, IV) was 17.1%, exceeding the reported prevalence among ambulatory patients. Funduscopy should be done regularly in diabetic patients admitted to a hospital, especially among those presenting chronic complications of diabetes. This would yield a considerable number of previously undiagnosed cases of DR, including many with preproliferative and proliferative changes, where photocoagulation is urgently needed.

1962

LONG-TERM EFFECTS OF PREGNANCY ON DIABETIC COMPLICATIONS

R. Kaaja, L. Sjöberg, T. Hellstedt, I. Immonen, T. Sane, K. Teramo, Dept of Obstetrics and Gynecology, Ophtalmology and Dept of Medicine, Helsinki University Hospital, Helsinki, Finland.

The aim of our study was to establish whether pregnancy affects long-term development and progression of retinopathy and nephropathy in diabetics compared to nulliparous diabetic women. Twenty-eight diabetic women who had delivered in 1983-85 at Helsinki University Central Hospital and 17 nulliparous controls matched according to age, duration of diabetes and degree of vascular complications were personally interviewed and the current retinal status and renal function were assessed seven years later, in 1990-92. Serum creatinine, creatinine clearance, nocturnal albuminuria and HbA1c were measured and color fundus photography carried out. The results were compared to the status in 1983-85.
Of those who had been pregnant, five of 26 (19.2%) had experienced worsening of retinopathy. In three of these, proliferative retinopathy had developed out of only minimal background changes. In the control group, progression had occurred more often (8/16, P<0.05). The groups did not differ from each other regarding progression of nephropathy. The frequent controls during pregnancy could have provided the women with more knowledge about their disease and motivated to better self-care.

1963

PREVALENCE OF RETINOPATHY IN DIABETIC PATIENTS ATTENDING THE TIKUR ANBESSA HOSPITAL (TAH) DIABETIC CLINIC. SEYOUM B, MENGISTU Z, BERHANU P, ABDULKADIR J, FELEKE Y, WORKU Y, AYANA G, ADDIS ABABA UNIVERSITY, ADDIS ABABA, ETHIOPIA.

A total of 302 patients was selected by taking alternate patients from regular attendants of the TAH diabetic clinic to determine the prevalence of retinopathy. The mean age was 41.4 years (range 14-85). There were 160 males (53%) and 142 females (47%). One hundred forty (46.45) were type 1 and 162 (53.6%) were type 11. The mean duration of diabetes was 9.4 years; mean haemoglobin A1c (HgA1c) was 10.4%. On the day of the examination the mean fasting blood glucose (FBG) and random blood glucose (RBG) were 195.5mg% and 273.1mg% respectively. The mean serum total cholesterol, triglycerides, LDL, VLDL and HDL were 166.5mg%, 129.9mg%, 94.5mg%, 24.4mg%, and 44.3mg% respectively. The overall prevalence of retinopathy was 37.8% out of which 113 patients (36.1%) had background retinopathy and 5 patients (1.7%) had proliferative retinopathy. The retina could not be visualized in three patients because of dense cataract. Retinopathy correlated positively with age, duration of diabetes and blood pressure r=0.19 (95%CI 0.14 to 0.30), r=0.43 (95%CI 0.33 to 0.52) and r=0.25 (95%CI 0.14 to 0.35) respectively. However retinopathy has no significant correlation with HgAlc and serum lipids. Prevalence of retinopathy was comparable in type I & type II (P>0.05). The prevalence of retinopathy in our patients relative to the duration of diabetes mellitus is high. Therefore, improvement of facilities for the diagnosis and treatment of retinopathy is recommended.

1964

THE EFFECT OF PREGNANCY ON MINIMAL DIABETIC RETINOPATHY

T. Hellstedt, R. Kaaja, K. Teramo and I. Immonen, Dept. of Ophthalmology and Dept. of Obstetrics and Gynecology, Helsinki University Hospital, Helsinki, Finland

The aim of our study was to analyze the formation and disappearance rates of individual microaneurysms(MAs) during pregnancy in diabetic patients with mild background retinopathy. Fundus photographs were taken at the 12th, 24th and 32-36th weeks of pregnancy and 3, 6 and 12 months after delivery from 21 type 1 diabetics. MAs were localized twice from fundus photographs using a computerized system. We found that MA count was highest 3 months after delivery and not during pregnancy. Since the hormonal and hemodynamic effects of pregnancy are mostly normalized by six weeks postpartum, there seems to be a delay in the response of the retina to the stimuli aggravating retinopathy. There was a flare up of MAs during pregnancy in patients having HbA1c mean levels below the median value of 6.38. Also patients with a higher than the median (0.76) decrease in HbA1c level compared to prepregnancy HbA1c, developed more MAs during the course of pregnancy. It is known that rapid normalization of glucose levels can aggravate retinopathy. Our results indicate that a similar phenomen occurs also in patients with minimal retinopathy.

1965

Aggravation/progression factors of diabetic retinopathy

Hiroko Yoshimura, Hitomi Fujii, ,Takaichi Miyakawa.Depart of Endocrine Metabolilsm ,Tachikawa Sohgo Hp.Tadasumi Nakano Departof Endocrinology,Tokyo Metropolitan Tama Geriatric Hp

Purpose;To retrospectively assess progression factors for diabetic retinopathy.Methods;555 patients examined in the ophthalmology dept.of our hospital among 710 pts randomly selected.Subjects:361 males,349 females,34 IDDM pts,673NIDDM pts,and 3 other pts.age 61.0 yr;history of illness,11.4±8.2 yr; neglect/interruption,2.5±5.1 yr.period of examination in the ophthalmology dept.:4.6±3.4 yr. Results: Retinopathy at the time of the initial examination was found to be associated with length of both history of illness and neglect in the following order;proliferative , pre-proliferative ,simple,and no retinopathy.271 pts had not yet developed retinopathy ,109 had developed retinopathy,21 with retinopathy that had improved,87 with no change,64 worse,and 3 others ,and also 24 pts with worsening of 2 grades or more.The interval between not having retinopathy and the time when 50% developped it was 11.5yr,and significantly longer than the 7.3-yr progressin interval from simple and the 7.6-yr after proliferative.Conclusion:Mean HbA1c,BP,and history of neglect/interruption of treatment affect the onset and progression of retinopathy after ophthalmologic management,but history of illness has no effect.

1966

THE EFFECT OF LISINOPRIL ON RETINOPATHY IN PEOPLE WITH INSULIN DEPENDENT DIABETES MELLITUS (IDDM).

The EUCLID Study Group. EUCLID Study Group Co-ordinating Centre, EURODIAB, Department of Epidemiology and Public Health, University College London, WC1E 6BT, UK.

Several studies have examined the effects of ACE inhibitors on diabetic nephropathy, but their effects on retinopathy are less well understood. We examined the effect of the ACE inhibitor lisinopril on the progression of retinopathy in the EUCLID study. EUCLID is a 2 year randomised controlled clinical trial of lisinopril versus placebo in 530 IDDM men and women with normo or microalbuminuria, aged 20-59 years recruited from 18 European centres. Resting blood pressure at entry was between ≥ 75 and ≤ 90 mmHg diastolic, and ≤ 155 mmHg systolic. Retinopathy was assessed without knowledge of treatment status from retinal photographs taken at baseline and 24 months. Gradable photographs from both visits were available for 336 patients. Baseline prevalence of any retinopathy was 66% (111/169) in the placebo group, and 60% (100/167) in the lisinopril group (p=0.3). The majority of these had minimal non-proliferative retinopathy (60% in the placebo, and 64% in the treatment groups). Retinopathy was classified into 5 groups (none to proliferative). Progression was defined as a level of retinopathy that was at least one grade higher than that at baseline in the worst eye. The proportion of progressors was 26% and 12% in the placebo and lisinopril groups respectively (p=0.002). Thus the risk of progression was 0.41 (95% CI 0.23-0.74, p=0.003), in the lisinopril versus placebo group. This did not alter when adjustment was made for centre, sex, age, duration of diabetes, glycaemic control, baseline AER and blood pressure (0.45, 95% CI 0.24-0.83, p=0.01). We conclude that lisinopril has beneficial effects on diabetic retinopathy, even in those with little or no renal disease and minimal retinopathy, and that this is not fully accounted for by effects on blood pressure.

1967

THE ROLE OF THE RENIN-ANGIOTENSIN SYSTEM (RAS) IN THE PATHOGENESIS OF RETINOPATHY IN CHINESE NIDDM PATIENTS

G.N. Thomas, J.C.N. Chan, V.T.F. Yeung, D. Lam, R.Y. Young, C.S. Cockram and J.A.J.H. Critchley. The Chinese University of Hong Kong, The Prince of Wales Hospital (PWH), Shatin, Hong Kong.

Genetic polymorphisms in the RAS may be involved in the pathogenesis of microangiopathic complications such as nephropathy. Local and systemic haemodynamic factors have been implicated in diabetic retinopathy. A total of 89 Chinese NIDDM patients newly referred to the PWH diabetes clinic were examined by an ophthalmologist for the presence and severity of retinopathy. The relationships between three RAS gene polymorphisms, angiotensinogen M235T, angiotensin-converting enzyme insertion/ deletion (ACE I/D) and angiotensin II type 1 receptor (AT1R) A1166C, were investigated in patients with (n=30) or without (n=59) retinopathy (RET).

Table 1 RAS gene frequencies in patients with or without retinopathy

Chinese NIDDM patients								
ACE	no RET n=59	RET n=30	AGT	no RET n=59	RET n=30	AT1R	no RET n=59	RET n=30
DD	10.2%	6.7%	TT	79.7%	80%	CC	0%	0%
ID	37.3%	40%	MT	16.9%	20%	AC	13.6%	13.5%
II	52.5%	53.3%	MM	3.4%	0%	AA	86.3%	86.5%
D freq	0.29	0.27	T freq	0.88	0.9	C freq	0.07	0.07
I freq	0.71	0.73	M freq	0.12	0.1	A freq	0.93	0.93

Patients with retinopathy had longer duration of diabetes (7.4±6.3y vs 3.8±6.2y, p<0.01), higher systolic BP (153±25 mm Hg vs 131±23 mm Hg, p<0.001) and prevalence of nephropathy (68% vs 28%, p<0.001). There was no significant difference in the RAS genotype frequencies between patients with or without retinopathy, even when analysed according to the use of insulin or prevalence of proliferative retinopathy. Thus in Chinese there is no evidence that the RAS genetic polymorphisms play a role in the development of retinopathy.

1968

INSULIN LISPRO (HUMALOG®) AND THE RENAL AND RETINAL COMPLICATIONS OF TYPE 1 DIABETES

S. Garg, K. Susarla, W. Jackson, G. Icaza, J. Anderson, and P. Chase. Barbara Davis Center for Childhood Diabetes, (UCHSC), Denver, CO and Eli Lilly & Company, Indianapolis IN.

The renal and retinal changes associated with Type 1 diabetes were compared in subjects randomized to receive either a rapid-acting human insulin analog, insulin-lispro (Humalog®), or Humulin® regular insulin in this pilot study. Twenty-six young subjects (16 females and 10 males) with Type 1 diabetes for a mean duration of diabetes of 12.1 years (range = 2.3 to 24.0 years) participated in this prospective three year clinical trial. The duration of diabetes (p=0.8; Student t-test) and the gender distribution (p=0.4, Fisher's exact test) were similar in the two groups. The glycosylated hemoglobin values were not significantly different at baseline or after one or two years between the two groups. Retinal and renal evaluations included seven standard field color retinal photography and timed overnight urinary measurements of albumin excretion rates (AERs) prior to beginning the study, after one year, and after two years. There were no differences in retinal p=0.2; repeated categorical analysis) or renal (p=0.3; repeated categorical analysis) complications of diabetes between the two treated groups over time. Longitudinal data evaluation did not reveal any differences in worsening or improvement of the grade of diabetic retinopathy or in AER values between the two groups (p>0.05, Fisher's exact test). This pilot data suggests that the new insulin analog (Humalog®) is safe and is not associated with deterioration of diabetic retinopathy or nephropathy.

1969

DIABETIC RETINOPATHY AND HbA1c-ASSESSMENT BY A LOG-LOGISTIC REGRESSION MODEL

H.Fujii, H.Yoshimura, T.Miyagawa. Department of Endocrinology and Metabolism, Tachikawa Sogo Hospital, and T.Nakano. Dept. of Endocrin. Tokyo Metropolitan Tama Geriatric Hospital, Tokyo, Japan.

Purpose: The relationship between the onset and progression of diabetic retinopathy and HbA1c was assessed by using a log-logistic model. **Method**: 585 patients examined in the ophthalmology dept. of our hospital among 710 pts randomly selected. Retinopathy progression factors were assessed by using a log-logistic regression model. **Subject**: 299 males, 286 females, 30 IDDM, 554 NIDDM, 1 other. 60.9 ±5.2yr. history of illness 11.8±8.3yr; neglect/interruption of treatment 2.7±5.2yr, period of examination in the ophthalmology dept. 4.6±3.4yr. Insulin 177 pts, SU agents 230, diet 178.

Results: 264pts without retinopathy, 109 with, 21 retinopathy improved, 85 no change, 64 worse, 24 worsening of 2 grades. It would be necessary to control HbA1c to 6.9%(onset alone, 7.0% and progression alone, 6.7%) or less in order to decrease the frequency of onset and progression below 5%. There was no association between HbA1c and the presence or absence of hospitalization for instruction at the initial examination, lipids, dBP, HCV infection, degree of obesity, or past maximum obesity.

Conclusions: To prevent diabetic retinopathy, after start of ophthalmologic examinations, HbA1c must be reduced to below 7.0%, and to prevent progression, to below 6.7%. Even stricter control is required in diabetics with a history of neglect/interruption of treatment.

1970

ACCELERATION OF DIABETIC RETINOPATHY FOLLOWING IMPROVED GLYCEMIC CONTROL: A REPORT ON 13 CASES

E.Chantelau, and H.Eggert. Heinrich-Heine-University of Düsseldorf/Germany.

Background: Improving glycaemic control(GC) not always improves the status of diabetic retinopathy(DR); the opposite may occur,i.e. the worsening of background retinopathy (BDR). We collected clinical data of IDDM patients in whom this phenomenon could be ascertained. **Patients and methods:** patients from a diabetes outpatient clinic with a documented decrease in HbA1c by > 0.5% per month and associated impairment of BDR (> 1 step according to EURODIAB complication study) were studied in retrospect (n=10)and prospectively (n=3).**Results:** 5 men and 8 women were identified, mean (SD)age 26(7)yrs, duration of IDDM 13 (3)yrs.Proteinuria was normal in 4/13, <500 mg/l in 5/13,and >500 mg/l in 4/13 patients, blood pressure was elevated in 4/13 patients. The initial HbA1c (HPLC; normal <5.6%)was 11.9(2.4)%,and declined by 1.2 (0.7)% per month upon improving GC.BDR progressed from stage 1-2 by ≥ 1 step, requiring laser coagulation (which came too late for 7 patients to prevent proliferative DR from bleeding).In 3/13 cases(1 with Mauriac's syndrome),serum IGF-1 was monitored prospectively demonstrating an increase by up to 100% prior to deterioration of BDR.**Conclusion:** In certain young IDDM patients improving GC may coincide with deterioration of BDR,which might be mediated by a reduced tolerance of the retina against IGF-1.

1971

VON WILLEBRAND FACTOR AND ITS RELATION TO THE GRADE OF RETINOPATHY IN NON INSULIN DEPENDENT DIABETIC PATIENTS

M El-Bahrawi, A Al-Amin, I Shaala, E Gaber and E El-Sayed. University of Alexandria, Alexandria, Egypt.

Von Willebrand factor (vWF) is secreted by endothelial cells and megakaryocytes, and it promotes the adhesion of platelets to the thrombogenic subendothelial substance. In the present study, the level of vWF has been assayed by the platelets aggregation method; Behring Werke, in 45 NIDDM patients and 10 normal healthy controls to find the relation (if any) between vWF levels and the grade of retinopathy. Diabetic patients were classified into three groups, the first group consisted of 15 patients with no retinopathy, the second group consisted of 15 patients with non proliferative retinopathy, the third group consisted of 15 patients with proliferative retinopathy. All selected diabetic patients were free from medical diseases except diabetes and were not receiving drugs except oral hypoglycemics. The groups were matched for age, body mass index, mean blood pressure and renal function. The diabetic groups were matched for the duration of the disease and the glycemic control. Patients and controls with microalbuminuira were excluded. The results of the present study showed that the mean level of vWF showed no significant difference between diabetics and controls. Using the "F" and Scheffe tests, there was no significant difference between the three studied groups as regards vWF level. Moreover, no significant correlation was found between the level of vWF and any of the following parameters; body mass index, glycosylated hemoglobin, cholesterol or triglycerides in diabetics as well as in controls. From the present study it can be concluded that endothelial damage as evidenced by elevated vWF may not be a major factor in the pathogenesis of diabetic retinopathy to the same degree as it is suggested in diabetic nephropathy.

1972

The effect of glycaemic control and the introduction of insulin therapy on retinopathy in non-insulin dependent diabetes mellitus

M Henricsson[a], A Nilsson[b], L Janzon[c], and L Groop[d]
Helsingborg Hospital[a,b], and Lund University[c,d], Malmö, Sweden

To study the progression of diabetic retinopathy in relation to diabetes treatment and glycaemic control in patients with NIDDM (non-insulin dependent diabetes mellitus), we performed a prospective study in a cohort of 1,378 diabetic patients, aged ≥ 40 years at diagnosis, 333 of whom were treated with insulin, and 1,045 of whom were treated with oral antihyperglycaemic agents or diet alone. In the latter group 174 patients changed to insulin therapy during follow-up. We used the Wisconsin scale to grade retinopathy, recorded blindness (visual acuity ≤ 0.1) and visual impairment (visual acuity 0.2-0.4), and measured the average HbA_{1c} for each patient during a mean 3.1-year study period. Poor glycaemic control and moderate non-proliferative retinopathy at baseline were significantly associated with retinopathy progression. A non-linear relationship was found between mean HbA_{1c} and the 5-year risk of progression of retinopathy ≥ 3 levels with a threshold value of about 8.0 %. In contrast, insulin treatment at baseline was not associated with an increased risk of retinopathy progression. Patients who changed treatment from oral agents or diet alone to insulin therapy had an increased risk of retinopathy progression compared with all other patients in the study. The increase in risk remained even after controlling for mean HbA_{1c}. Progression ≥ 3 levels was significantly associated with a higher incidence of macular oedema and deterioration of visual acuity. The relative risk for blindness/visual impairment due to retinopathy was 2.7 (95 % confidence interval 1.8-4.0) in the group with changed treatment compared with all the other patients in the study. Poor glycaemic control (HbA_{1c} %) before the start of insulin therapy and any retinopathy at baseline were significant risk factors for progression in the group with changed treatment (both $p < 0.01$).

1973

VARIABLES ASSOCIATED WITH RETINOPATHY IN PATIENTS WITH NIDDM FROM A MULTI-ETHNIC URBAN AUSTRALIAN COMMUNITY

WA Davis, TME Davis and DG Bruce, University Department of Medicine, Fremantle Hospital, Australia.

Cross-sectional data from 925 evaluable patients with NIDDM of the first 1,000 recruited to the Fremantle Diabetes Study (a prospective study of ethnic differences in care, control and complications in diabetic patients drawn from a population base of 118,000) were analysed to identify variables associated with the presence of retinopathy. Ethnicity was defined in two ways; using only region of birth and from self-perception of ethnic background in combination with other objective demographic data. Those born in Australia formed 52%, in Southern Europe 19%, in the UK/Ireland 16% and in Asia 4%. Ethnic background was Anglo-Celt in 63%, Southern European in 20%, Asian in 3% and Aboriginal in 1%. Retinopathy, found in 17% overall, was assessed from direct and/or indirect ophthalmoscopy, and/or more detailed ophthalmological data in a proportion of patients assessed for photocoagulation. Multiple logistic regression analysis revealed that the known risk factors duration of diabetes, fasting plasma glucose, HDL-cholesterol, systolic blood pressure and treatment type were significantly and independently associated with the risk of any retinopathy ($P<0.05$). Of simple categorical socioeconomic variables incorporated in the model, educational attainment was inversely associated with retinopathy risk ($P=0.01$). After adjusting for these significant variables, region of birth was not a risk factor for retinopathy although birth in Asia was of borderline significance ($P=0.051$). When ethnic background was included, Asian ethnicity was associated with a signficantly increased risk of retinopathy ($P=0.01$). These data confirm that conventional risk factors for diabetic retinopathy operate in an urban Australian population. Lower educational attainment and Asian ethnicity are also significant risk factors, findings which could be used to ensure better targetting of retinopathy screening.

1974

Complication free duration is not a protective factor for the development of retinopathy in elderly diabetic patients.

Ohad Cohen, Clara Norenberg and Eylon Neumann.INSTITUTE OF ENDOCRINOLOGY, SHEBA MEDICAL CENTER, TEL HASHOMER,*REGIONAL DIABETIC RESEARCH AND TREATMENT UNIT, KUPAT HOLIM CLLALIT, NETHANIA.

Aim: To assess whether long complication free duration can define elderly patients in lower risk for future development of diabetic retinopathy. **Methods:** 10 year clinic based study of a regional diabetic outpatient clinic serving a 150,000 urban population. Data on 647 type 2 diabetic patients, free of diabetic retinopathy, older than 50 years and followed for more than 4 years is analyzed. **Measurements:** Data included demographic and clinical information on arrival, updated every 3-6 months and yearly direct ophtalmoscopy. All the data was prospectively compiled on relational databases. **Statistical analysis** Statistical analysis was performed with student's T test x^2 when appropriate, discriminant analysis for defining significant and independent variables for predicting retinopathy was performed using process discriminant. **Results:** 8.5% of patients without retinopathy at the age of 50 developed retinopathy during 4 years of follow-up. These patients are characterized by longer duration and younger onset of diabetes in comparison to the group without retinopathy at 4 year follow-up. Clustering of micro- and macro- vascular complications were noted. Discriminant analysis showed the following factors to be significantly and independently predictors of the development of retinopathy in the elderly :Duration of diabetes, BMI and glucose control. **Conclusions:** Long complication free period does not define elderly patients with type 2 DM patients at lower risk for future development of retinopathy. On the contrary, the increase in disease duration is significantly associated with the development of retinopathy in this age group as described in younger patients.

1975

Association of NIDDM with cataract and retinopathy

Sarita Bajaj , K.J.Singh, D.Sharma

M.L.N.Medical College, Allahabad, India.

443 consecutive patients of NIDDM were examined by an endocrinologist and an ophthalmologist independently. Apart from routine investigations fundus examination was carried out by direct ophthalmoscope after dilating the pupils. Cataract status was evaluated by slit lamp examination. The mean age of the patients was 47.9 years and mean duration of diabetes was 7.1 years. Of 351 patients having no evidence of retinopathy the mean age was 46.4 years and mean duration of diabetes was 6.0 years, whereas these were 53.1 and 11.6 years respectively in patients showing diabetic retinopathy. Correlations between age of patients with diabetic retinopathy and cataract were statistically significant ($p<0.05$). Similarly correlations of duration of diabetes with retinopathy and cataract were also significant ($p<0.05$). Correlation of retinopathy and cataract was not statistically significant. Drusen bodies (observed in 3.2%) was the only feature where the two observers were not in conformity.

1976

CHANGES OF NONPROLIFERATIVE RETINOPATHY IN NONINSULIN-DEPENDENT DIABETIC PATIENTS.

W-T. Lu, S-S. Yarng, F-H. Liu, H-S. Huang, J-D. Lin and J-H. Juang. Chang Gung Memorial Hospital, Taipei, Taiwan, R.O.C.

To known the nature course of mild to moderate nonproliferative retinopathy in noninsulin-dependent diabetes mellitus, we followed 191 diabetic patients at our metabolic clinic. Twice examinations in one year were performed by using Canon CR-45 UAF non-mydratic fundus photography. Modified Airlie House Classification of diabetic retinopathy was used. There were 97 males and 94 females with the mean age of 57 years and mean duration of 7 years. Among these patients, 13 were treated with insulin, 162 with oral hypoglycemic agents (OHA), 8 with OHA and insulin, and 8 with diet alone. The patients were divided into 4 groups.

	Retinopathy		
Group	Initial	Final	No (%)
A	Negative	Negative	117 (61)
B	Negative	Positive	21 (11)
C	Positive	Negative	9 (5)
D	Positive	Positive	44 (23)

In group B and C, the changes of blood pressure and blood glucose were not related to the changes of retinopathy. The change of glycohemoglobulin (HbA1c) level was lower in group C (0.6 ± 0.1 %) when compared to the patients of group D (1.5 ± 0.3 %) (p=0.009). The differences were analysed by Student's t test. Our data indicate mild or moderate nonproliferative retinopathy may reverse in some cases and the glycemic control may contribute to it.

1977

ABSENCE OF AN ASSOCIATION BETWEEN SERUM SIALIC ACID AND RETINOPATHY IN SOUTH INDIAN NIDDM PATIENTS.

Deepa R, Rema M, Karkuzhali K, Mohan V, M.V. Diabetes Specialities Centre and Madras Diabetes Research Foundation, Madras, India.

An association between serum total sialic acid and various diabetic complications including retinopathy has been reported in European NIDDM patients. We studied serum sialic acid levels in healthy non diabetic controls and in three groups of non insulin dependent diabetes mellitus (NIDDM) patients, namely background diabetic retinopathy (BDR), proliferative diabetic retinopathy (PDR) and those without any retinopathy. Serum sialic acid concentrations were not significantly different between the four study groups: controls (2.27 ± 0.48 mmol/L), NIDDM without retinopathy (2.50 ± 0.46 mmol/L, NIDDM with BDR (2.27 ± 0.50 mmol/L) and NIDDM with PDR (2.43 ± 0.55 mmol/L). These results suggest that there is no association between diabetic retinopathy and sialic acid in South Indian NIDDM patients.

1978

THE FOLLOW-UP RESULTS OF DIABETIC RETINOPATHY WITH A PROPOSAL OF CLASSIFICATION BASED ON A MULTINATIONAL STUDY

E. Miki, Shikata Memorial Miki Clinic, Chiba, Japan

The results concerning diabetic retinopathy of the World Health Organization Multinational Study of Vascular Disease of Diabetes (WHO MSVDD), carried out since 1975, initially in 14 centers in 13 counties, is presented. Based on this data, a simplified yet objective system of recording diabetic retiinopathy suitable for usual medical description and practice seems possible. After a follow-up of 8.4± 2.8 years of WHO MSVDD, 2877 (71.6%) out of 4018 surviving patients in 10 centers of 9 countries participated in funduscopic examination using the same method as in the prevalence study. Simple and objective methods were tried and adoptedin WHO MSVDD, including fundus examination. Retinopathy developed on the average in 47.7% (range: 29.7-76.4%), while the progression to proliferative diabetic retinopathy occurred in 9.7% (range: 3.5- 22.6%). The risk factors for the incidence of retinopathy were: therapeutic regimen, serum cholesterol, systolic blood pressure, and renal disease, while those for the progression to proliferative retinopathy were: therapeutic regimen, renal disease, duration of diabetes, diastolic blood pressure, and age at baseline. Concerning the incidence of retinopathy, the increase or decrease in sensitivity due to different observers (i.e., ophthalmologists vs. internists) seems important besides true changes. In contrast to macroangiopathy, which was found to be very variable among the centers, the progression of diabetic retinopathy seems tobe more uniform. In view of the absence of a simple and objective method of classifying diabetic retinopathy suitable for daily medical practice and description, the experience obtained in this study seems very meaningful for future utilization.

1979

RETINOPATHY AT DIAGNOSIS IN SOUTH INDIAN NIDDM PATIENTS: ASSESSMENT BY RETINAL PHOTOGRAPHY

Rema M, Ponniah M and Mohan V, M.V.Diabetes Specialities Centre and Madras Diabetes Research Foundation, Madras, India.

To assess the prevalence of retinopathy at the time of diagnosis of diabetes, 157 consecutive newly diagnosed (<1 month duration) NIDDM patients attending our centre were studied. Retinopathy was assessed clinically (direct and indirect ophthalmoscopy) and by retinal photography after full mydriasis. Four retinal fields were studied by 35 mm colour transparencies using a 50-VT Topcon retinal camera. Photographs were graded by two independent observers using a modification of the Early Treatment Diabetic Retinopathy Study (ETDRS) classification system. In 5 patients photographs could not be graded due to cataract (2 patients) and poor quality of photographs (3 patients). Eleven of the remaining 152 patients (7.2%) had diabetic retinopathy. All patients had non-proliferative (background) retinopathy but 2 had evidence of maculopathy.The prevalence of retinopathy at diagnosis in South Indian NIDDM patients appears to be lower than that reported in Europeans.

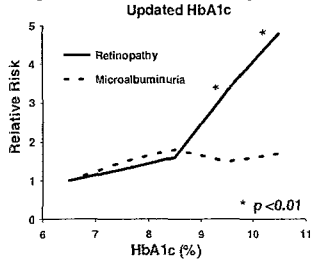
1980

DIABETIC COMPLICATIONS IN NIDDM: RELATIONSHIP TO UPDATED HbA1c.

M. Constantino, L. Molyneaux, M. McGill, K. Willey, B. Brooks, D.K. Yue,. Royal Prince Alfred Hospital, Sydney, Australia.

The DCCT reported a smooth relationship between HbA1c (ie mean HbA1c during follow up) and diabetic complications in IDDM. Krolewski et al reported their findings on microalbuminuria (MA) and retinopathy (RET) in IDDM, noting that the risk increased abruptly at an HbA1c threshold of about 8%. The precise relationship between glycaemic exposure and complications in NIDDM is less well defined . Data of 832 NIDDM patients (age: 56.8 ± 10.8 yrs [mean±SD]; duration: 5.7 ± 5.9 yrs; HbA1c: 8.1 ± 1.7% [nr:3.5-6%]) attending our Diabetes Centre for Complications Assessment more than once (2.8 ± 1.8 visits;range: 2-6) over a mean interval of 34 months were analysed. Of those with no RET (n=707) or no MA (30-300mg/L) (n=399) at initial visit, annual incidence of RET was 4.9% (95% CI 4.0-5.8) and MA was 7.0% (95% CI 5.6-8.3). Incidence of developing RET and MA and their relative risk (RR) adjusted for duration of diabetes and the interval between visits were then stratified according to updated HbA1c (Fig 1). We conclude that for NIDDM patients, high glycaemic exposure significantly increases the risk of RET particularly at updated HbA1c of >9% . The corresponding increase in risk of microalbuminuria is more gradual with no clear HbA1c threshold .

Figure 1: Relative Risk According to Updated HbA1c



1981

PREVALENCE, INCIDENCE AND FACTORS CONNECTED WITH DIABETIC RETINOPATHY IN IDDM AND NIDDM PATIENTS

P. Luźniak, A. Czech and J. Tatoń. Department of Internal Medicine and Diabetology, Warsaw Medical School, Warsaw, Poland.

Diabetic retinopathy is the most frequent microvascular sequele of chronic long term IDDM and also very frequent complication of NIDDM. Many studies are pointing now to the possibility of prevention and early treatment of this syndrome from both ophthalmological and diabetological point of view. Therefore early identification of diabetic persons of higher risk of retinopathy development seems to be of crucial importance in practice. The study was undertaken to determine risk factors in 2 groups, that is in IDDM and NIDDM patients. One group comprises 309 IDDM and the other 1334 NIDDM subjects. Morbidity due to all forms of retinopathy was 55.4% in IDDM and 31.4% in NIDDM, the frequency of proliferative retinopathy was respectively 11.0% and 1.3%. The incidence of all forms of retinopathy in 3 - year prospective study was 6.1% per year in IDDM and 3.9% per year in NIDDM. The incidence of proliferative retinopathy was respectively 1.3% per year and 0.6% per year. In the second part of the study the identification of selected factors connected with high risk of development of diabetic retinopathy was undertaken. The following factors were examined: age, sex, diabetes mellitus duration, body mass index, arterial hypertension, total cholesterol triglycerides and creatinine levels, fasting and postprandial glycemia and 24-hour proteinuria. Conclusion. The most significant risk factors connected with development of retinopathy were: diabetes duration, fasting glycemia and proteinuria. On the base of this study, practical algorythms were proposed, with proposals of preventive action.

1982

QUANTUM HEMOTHERAPY IN THE PATIENTS WITH DIABETIC RETINOPATHY.

O. Repko and P. Bezdetko. Kharkov Advanced Training Institute for Doctors, Kharkov, Ukraine.

We have studied the influence of trancutaneus laser radiation of blood (TLRB) upon ophtalmologic lymphocirculation indices of 68 patients with nonproliterative diabetic retinopathy (DR). Radiation power was 20 mw and wavelength was 630 nm. Fluorescent lymphangiography demonstrated essential changes of bulbar conjunctiva lymph flow. Medium diameter of lymphaticus (DL) has increased to 0,27 ± 0,02 mm and linear lymph flow rate (LLR) has fallen to 4,2 ± 0,12 mm/min compared with age norm (0,19 ± 0,03 mm and 6,9 ± 0,16 mm/min). Volumetric lymph flow rate (VLR) has increased to 1,9 ± 0,09 mm^3/min (norm.: 0,7 ± 0,11 mm^3/min). After the course of TLRB this indices were: DL = 0,24 ± 0,01 mm; LLR = 5,6 ± 0,12 mm/min; VLR = = 1,2 ± 0,11 mm^3/min. This indices were more statistical expressible than in control group (23 patients). Given results confirm pathogenetic directness of TLRB in tritment and prophylaxis of tissue ishemia in DR.

1983

PREDICTIVE FACTORS FOR THE PRESENCE OF DIABETIC RETINOPATHY IN CHINESE NIDDM PATIENTS

N.Wat, J. Michon, K.S.L. Lam.University of Hong Kong, Hong Kong

Despite recent improvements in diabetes care and the general acceptance that good glycaemic control reduces the risk of microvascular complications, diabetic retinopathy remains a leading cause of blindness. Even though effective treatment with laser photocoagulation is available, timely intervention is often difficult as sight-threatening stages are often asymptomatic. We randomly selected 607 (Male266;Female341) NIDDM patients with no visual complaints from the University Diabetes Clinic and screened for the presence of any diabetic retinopathy using direct fundoscopy with pupillary dilatation. These patients had a follow up of 10.3 ± 6.6 years since diagnosis, with mean fasting blood glucose of 8.9±3.0 mmol/l, glycosylated haemoglobin (HbA1c) of 7.8± 1.9%, systolic blood pressure 139±18 mmHg and diastolic blood pressure 79±8.9 mmHg (mean ± SD). Their glycaemic control was achieved by diet only (1.3%), oral hypoglycaemic agents (66.2%) or insulin (32.4%). Elevated serum creatinine levels (>120umol/l) was found in 11.6%. Serum albumin level was 42.6 ± 4.2 g/dL. Fasting total cholesterol and triglyceride levels were 5.5 ± 0.05 and 2.1 ± 0.08mmol/l (mean±SE) respectively. Proteinuria was found in 13% of patients (albustix≥ 1+). Peripheral neuropathy (vibration perception threshold >25 on either right or left extremity) was found in 23%. Diabetic retinopathy was found to be present in 19% (116/609) of the patients. (Early Treatment Diabetic Retinopathy Study Classification: mild nonproliferative 68%; moderate nonproliferative 16%; early proliferative 2% and macular oedema 14%). Multiple regression analysis showed that proteinuria ($P < 0.0001$), glycosylated haemoglobin A1c ($P < 0.005$), duration of known disease ($P < 0.005$) and vibration perception threshold values ($P < 0.05$) were predictive of underlying diabetic retinopathy. All other variables tested were not significant. Use of a dipstick test for proteinuria can serve as a simple and economic way of screening for at risk NIDDM patients for further opthalmological examination. This strategy should be an useful alternative in countries where population-based screening for diabetic retinopathy is not feasible.

1984

VISCODELAMINATION DURING VITREOUS SURGERY FOR SEVERE DIABETIC RETINOPATHY

Tadashi OKANO, Masahiro OSAKO
Dept. of Ophthalmology, Tokyo Medical College Kasumigaura Hospital, Ibaraki, JAPAN

Viscodelamination technique was employed during vitreous surgery in 217 eyes with taut preretinal fibrovascular membrane and tractional retinal detachment in advanced diabetic retinopathy. As a routine procedure, 1% sodium hyaluronate was injected to separate the epiretinal membrane and the adherent vitreous corfex from the retina. The preretinal membrane was then severed with scissors. Out of all the 217 eyes, anatomical improvement was attained in 155 (72%), unchange in 38 (17%) deterioration in 24 (11%) when evaluated at 25 months on average after surgery. Improved visual acuity was attained in 123 (57%), unchanged in 66 (30%), deterioreted in 28 (13%) out of 217 eyes. Iatrogenic retinal breaks developed in 73 eyes (34%) during surgery which could be treated with intraocular photocoagulation. The viscodelamination technique thus proved to be safe and effective means as adjunct to vitreous surgery to separate epiretinal membrane and the vitreous cortex from the retina.

1985

RISK FACTORS FOR THE PROGRESSION TO PROLIFERATIVE *RETINOPATHY IN JAPANESE NIDDMPATIENTS.*

Nakagami T., Kawahara R., Hori S., Omori Y., Tokyo Women's Medical College, Tokyo, Japan

-Aim- To examine risk factors for the progression to proliferative retinopathy from simple retinopathy in Japanese NIDDM patients. - Subjects- and Methods- 159 NIDDM patients with simple retinopaty first visited our Diabetes Center from 1983-1985. Their age at diagnosis ranged from 30-65 years. The optic fundi were examined at least annually. HbAlc *values of each patients were measured every month. The prevalence of* proliferative retinopathy in the 10th year after registration was compared in 5 groups stratified by mean HbAlc values for ten years, in 2 groups stratified by mean diastolic blood pressure for ten years and in 2 groups strafified by the duration of diabetes at registration. Multiple logistic regression analysis was used to assess the ralationship between proliferative retinopathy and covariate. - Results - The prevalence of proliferative retinopathy was 0%(0/1) in the group with mean HbAlc below 6%, 7.7% (2/25) in the group with mean HbAlc of 6-6.9%, 5.3%(3/57) in the group with mean HbAlc of 7-7.9%, 12.5%(5/40) in the group with mean HbAlc of 8-8.9% and 30.6%(11/36) when the mean HbAlc exceeded 9%. The prevalence of proliferative retinopathy increased with the increase in the mean HbAlc values over 10 years(trend $p<0.005$). The prevalence of proliferative retinopathy of the patients with a duration over 10 years was 2.5 times higher than that of the patients with a duration less than 10 years($p<0.05$). The prevalence of proliferative retinopathy of the patients *with diastolic blood pressure above 90mmHg was 6 times higher than that* of the patients with diastolic blood pressure less than 90mmHg($p<0.005$). Multiple logistic regression analysis revealed that mean HbAlc, diastolic blood pressure and duration of diabetes were the risk factors for the progression to proliferative retinopathy from simple retinopathy. - Conclusion - This data suggests that better control of blood glucose and diastolic blood pressure might decrease the progression to proliferative retinopathy from simple retinopathy in Japanese NIDDM patients.

1986

VISUAL EVOKED POTENTIALS IN PEOPLE WITH IMPAIRED GLUCOSE TOLERANCE

Ş. Karadeniz(1), S. Karamürsel(2), N. Dinççağ(1,3), K.Karşıdağ (1,3), İ. Satman(1,3) and M.T.Yılmaz(1,3). (1)Istanbul University, Institute for Experimental Medicine,(2)Istanbul University, Istanbul Medical Faculty, Department of Physiology (3)Istanbul Medical Faculty, Div. of Diabetes, Istanbul, TURKEY.

This study is conducted in order to evaluate the visual pathways from the retina to the occipital cortex in people with impaired glucose tolerance (IGT). We studied visual evoked potentials in 17 patients with IGT, as proposed by WHO's criteria, (34 eye, mean chr. age 50.7±10.5yrs), and in 19 controls with normal oral glucose tolerance (38 eye, mean chr.age 48.9±11.2yrs). Eyes with low vision or any anterior or posterior segment findings are excluded. The test was performed monocularly with two different checkerboard pattern sizes (subtending 30 and 60 minutes of arc). Patients with IGT showed a significant delay in peak latencies of P100 wave (LP100) (in ms) compared to the controls (with pattern size of 30 minutes of arc 114.9±8.5 vs 100.4±5.0, $p<0.001$; with pattern size of 60 minutes of arc 118.5±10.9 vs 101.2±4.4, $p<0.001$). Amplitudes (μV) were also significantly decreased in patients with IGT (pattern size of 30 minutes of arc 2.5±2.2 vs 3.9±1.5, $p<0.05$; with pattern size of 60 minutes of arc 3.0±1.5 vs 4.2±2.0, $p<0.05$). No interocular differences were detected regarding LP100 and amplitudes. As a conclusion, these findings indicate to a subclinical disease and shows that the visual pathway is not spared from involvement in people with IGT.

PERIPAPILLARY RETINAL CAPILLARY FLOW IN DIABETICS USING CONFOCAL SCANNING LASER DOPPLER FLOWMETRY

Y.Yamana and M.Matsuo. Yamana Eye Clinic, Fukuoka, JAPAN

<Purpose>: There have been reports that blood flows in the retinal artery and vein varied according to the stage of diabetic retinopathy, but there has been no report to date concerning the flow in the capillary vessels. Here we report the results of our investigation into changes in the peripapillary retinal capillary flow at various stages of diabetic retinopathy. <Subjects & Methods>:We examined 211 eyes of 121 diabetics (56 males and 65 females) aged from 34 to 78 years. By diabetic retinopathy stage there were 83 with non-diabetic retinopathy (NDR), 90 with simple retinopathy (SDR), 26with preproliferative retinopathy (PPDR), and 12 with proliferative retinopathy (PDR). The capillary flow rate was measured by scanning laser doppler flowmetry using a Heidelberg Retina Flowmeter (HRF), which combines the confocal laser scanning technique with laser doppler flowmetry and enables non-invasive two-dimensional mapping of the retinal perfusion. Four areas were measured :- the nasal tempolar region, the upper tempolar region, the lower perpapillary retina region, and the ONH disc. The field examined was 10x2.5 degrees with each field frame consisting of 10x10 pixels. The peripapillary retina and the ONH were scanned by the laser at 795 nm. Data were obtained on 30 points per quadrant of the retina. <Results>:The average capillary flow rate was 465.6 ±2.2 AU for those with NDR, 476.7 ± 1.9 AU for those with SDR, 489.0 ± 3.5 AU for those with PPDR, and 577.8 ± 4.0 AU for those with PDR. <Conclusion>:The capillary flow rate of diabetics were markedly elevated, compared to normal values[1], even at the early stage NDR, and the capillary flow rate then increased with the progression of diabetes stage.

ASSESSMENT OF RETINOPATHY AND COLOUR VISION IN MATURITY-ONSET DIABETES OF THE YOUNG

BC Lee, M Appleton, D Taylor, J Jacob, AT Hattersley, AC Shore and JE Tooke. University of Exeter, Exeter, UK.

Maturity-onset diabetes of the young (MODY) is a discrete form of NIDDM and it has been suggested that these patients are protected from microvascular complications. Impaired tritan (blue/green) colour vision has been reported in IDDM, NIDDM and in subjects with fasting hyperglycaemia, and is associated with the development of retinopathy. No systematic analysis of the retinal status or function has been made in MODY. We assessed colour discrimination sensitivity by using the Sussex Colour Screener to determine whether there is functional disturbance of colour vision in 18 (9M:9F) subjects with MODY, mean duration of diabetes 13.1 ± 10.4 years (mean ± SD), and age and sex matched normoglycaemic controls (37.5 ± 10.7 v 38.2 ± 11.1 years). The mean glycated haemoglobin of the MODY group (normal range 4.0-6.0%) was 6.8 ± 1.8%. Retinal status was also examined in the patients by using conventional ophthalmoscopy and retinal photography. Retinal photographs were evaluated by an independent ophthalmologist in a single blind study. Tritan discrimination sensitivity was significant reduced in MODY patients (41.07 ± 7.76 v 46.57 ± 7.03 arbitrary units $p<0.05$ Mann-Whitney). Impaired colour vision correlated with degree of retinopathy (R_S=–0.5885, p=0.018). 50% of the MODY patients had background retinopathy, 4 in one eye and 5 in both eyes. Background retinopathy was absent in 4 individuals with diabetes less than 5 years duration. Maculopathy and proliferative retinopathy were not detected. These results suggest that MODY patients are not protected from developing retinopathy or functional abnormality even when reasonable glycaemic control is achieved.

Nephropathy – Experimental and Renal Damage

1989

EFFECT OF NITRIC OXIDE SYNTHASE INHIBITOR AND TEMOCAPRIL ON PROGRESSION OF EXPERIMENTAL DIABETIC NEPHROPATHY

T.Yoshida, M.Morino, T.Suzuki, A.Ohtake and N.Sasaki. Department of Pediatrics, Saitama Medical School. Saitama, Japan.

The aim of the study is to clarify the effect of nitric oxide synthase inhibitor : N-nitro-L-arginine (NNA) and temocapril (TP) on the development of diabetic nephropathy in rats previously treated with streptozotocin. Rats were divided into six groups four weeks after the development of diabetes : Group 1drank tap water; Group 2 drank tap water with L-arginine; Group 3 water with NNA; Group 4 water with TP; Group 5 with NNA and TP; Group 6 water with TP and Arg. Control rats drank tap water and water with Arg. Blood pressure, body weight, blood glucose, urine volume and urinary albumin were measured before and at eight, 16 and 21 weeks. Urine albumin increased significantly in diabetic rats. Among them, Group 3 and Group 5 had significantly increased albuminuria more than other diabetic groups at 16 and 21 weeks. Albuminuria at 21 weeks in Group 5 is lower than in Group 3. However it is not statistically significant. Blood pressure also elevated in diabetic rats. In Group 3 and Group 5, that of 8 weeks correlated significantly with albuminuria at 16 and 21 weeks. It decreased after 16 weeks in Group 4 and Group 6. The present study showed the significant effect of nitric oxide synthase inhibitor on the development of albuminuria. Temocapril had significant effect of ameliorating the blood pressure. The result also showed that the elevation of blood pressure may contribute to the development of diabetic nephropathy.

1990

CRONOBIOLOGY OF BLOOD PRESSURE (BP) IN BB-RATS

U. Fischer, S. Berg, P. Heinke and A. Dunger. Gerhardt Katsch Institute of Diabetes, Karlsburg, and Inselklinik, Heringsdorf, Germany.

Alterations in rhythmic BP pattern were reported in human and animal hypertension. This study evaluates these patterns in diabetic (d) and nondiabetic (nd) BB-rats. - Systolic (SYS) and diastolic (DIA) BP, heart rate (HR) and muscular activity (MA) were monitored over 48h at 5min intervals in insulin pellet-treated dBB (diabetes duration 150d), in ndBB, and in age-matched hypertonic (SHR) and normotonic (WOK) controls by means of implanted telemetric BP monitoring system (Data Science Int). - Results: Cross correlation showed excellent synchronisation among all variables. BB-rats had marginally elevated average BP but reduced HR. The amplitudes of all daily rhythms and their % of total variance were elevated, and the acrophases were delayed in BB-rats. Spectral analysis of ultradian periods revealed a shift towards longer periods but no difference in the normalized spectral estimates in BB-rats. - Conclusion: BB-rats exhibit a tendency towards hypertension. The concomitant alterations in the rhythmic patterns of MA, BP and HR appear to be related to diabetes rather than to hypertension.

MESANGIAL CELL AND MATRIX PROTEOGLYCANS: RESPONSE TO GLUCOSE AND ASCORBIC ACID

A.V.McAuliffe, E.J.Fisher, S.V.McLennan, D.K.Yue and J.R.Turtle. University of Sydney, New South Wales, Australia.

Proteoglycans (PG) are highly charged glycosylated proteins attached to mesangial cell (MC) membranes and embedded in mesangial matrix (MM). Expansion of the glomerular mesangium is the most consistent lesion of diabetic nephropathy and abnormalities of PG affecting cell-cell and cell-matrix interactions are thought to play a significant role in this process. AA, an important regulator of extra cellular matrix synthesis, is metabolised abnormally in diabetes. In this study we examined the effects of 0.28mM ascorbic acid (AA) on PG synthesis and its deposition in matrix in rat MC grown in 9mM (LG) or 25mM (HG) glucose for 8 days. PG were measured by labelling with 50μCi of [^{35}S] sulphate present in the culture media and in terms of DPM and precipitablity with 2.5% cetylpyridinium chloride. Activity was corrected for μgDNA (raw data) and [^{35}S] sulphate specific activity (corrected data) and expressed as a % of 9mM glucose values (mean±sem). AA increased ^{35}S-labelled PG in cells and matrix. After correction for [^{35}S] sulphate specific activity this remained elevated in the matrix. HG suppressed the effect of AA in both cells and matrix.

	LG-AA	LG+AA (raw data)	LG + AA (corrected data)	HG + AA (corrected data)
		^{35}S-labelled PG		
Cells	100±5	[a]129±7	108±7	[b]70±6
Matrix	100±11	[a]162±11	[c]142±16	[b]87±9

ANOVA: [a]significantly different to LG-AA, $P < 0.001$.
[b]significantly different to LG-/+AA, $p < 0.0001$.
[c]significantly different to LG-AA and HG+AA, $p < 0.0001$.

These results indicate that HG inhibits the action of AA on sulphation of PG, perhaps by impairing glucosaminyl N-deacetylase activity. This may be of particular importance in diabetes where AA level is already compromised. These findings may be of importance in the pathogenesis of diabetic nephropathy.

1992

INCREASED BLOOD PRESSURE (BP) AND ALBUMINURIA AT DIABETES ONSET IN BB RATS

S. Berg, A. Dunger, I. Klöting and U. Fischer Gerhardt Katsch Institute of Diabetes, Karlsburg, and Inselklinik, Heringsdorf, Germany

Increased arterial BP is the most important risk factor for the progression of diabetic nephropathy. It is not proved whether elevated BP results from or precedes the impairment of kidney function. Therefore diabetes-susceptible BB rats were monitored during the interval when their diabetes usually becomes manifest (DM), using an implanted telemetric BP monitoring system. Systolic (SYS) and diastolic (DIA) BP, heart rate (HR), motor activity (MA) and renal excretion of albumin (AE), N-acetyl-ß-D-glucosaminidase (NAG), creatinine and urea were followed at weekly intervals and evaluated in diabetic (dBB, n=3) rats and in animals not having developed diabetes (ndBB, n=3). Results: Average daily SYS was elevated in d vs. nd rats, and it increased in a time-dependent manner in d animals only. DIA was not elevated at but shortly after DM. The increase in BP at diabetes onset was associated with an increased excretion of albumin and of NAG (0.96±0.7 U/d and 0.22±0.1, at DM vs. before DM). The HR of dBB decreased as diabetes developed and was significantly lower after DM (308±1.4 beats/min) compared to ndBB (342±0.9 beats/min). MA was significantly higher in dBB vs. ndBB at all times of examination but was not related to DM. Conclusion: dBB rats are prone to hypertension which may predict an approaching DM and alteration of kidney function.

1993

RELATIONSHIP BETWEEN CIRCULATING NITRIC OXIDE AND ENDOTHELIN LEVEL IN DIABETIC NEPHROPATHY

Zhang Shenglan, Yan Hui and Wang Suxia, General Hospital of Jinan Command, Jinan, China.

Circulating NO (NO) and ET LEVEL was determined in 30 normal subjects and 63 diabetic patients. Patients were divided into 3 groups based on the urinary albuminexcretion rate (UAER): SDM group (UAER<20ug/min, 20 patients), IDN group (20ug/min≤UAER≤200ug/min, 19 patients), ODN group (UAER>200ug/min, 24 patients). Serum NO level was significantly higher in SDM group (68.66±12.37umol/l) and IDN group (63.43±11.09umol/l) than in normal subjects (44.92±9.04umol/l, p<0.01). Compared with normal subjects NO concentration was descent but no significant difference in ODN group (36.28±10.18umol/l, p>0.05). Plasma ET level was markedly elevatde inSDM group (68.92±11.96ng/l, p< 0.05), IDN group (79.22±19.21ng/l, p<0.01), ODN group (137.16±39.92ng/l, p<0.01) compareed with normal subjects (59.12±11.62ng/l). SerumNO level was negatively correlated with plasma ET leves in 63 diabetic patients. The results suggested that NO may play a poor role in the development of DN, but ET aggravated this bad effect.

1994

EFFECT OF HIGH GLUCOSE ON EXTRACELLULAR MATRIX PRODUCTION BY MOUSE GLOMERULAR EPITHELIAL CELLS

*R. Cipriani, *S. Scarpa, A. Gabriele, M. Sensi, *F. Vasaturo, L. Guidobaldi, **U. Di Mario and S. Morano. Endocrinology, *Experimental Medicine, University "La Sapienza", Rome; **Experimental Medicine, University of Catanzaro, Italy.*

Extracellular matrix (ECM) plays an important role in structural organization and in biophysical properties of the glomerular filtration barrier. Changes in this structure are involved in the pathogenesis of diabetic nephropathy. Glomerular epithelial cells (GECs) contribute to the ECM component production. In this study we investigated the effects of high and normal glucose concentrations on GEC capacity of synthetizing laminin (LM), fibronectin (FN) and type IV collagen. Mouse GECs were incubated in media containing physiological (5mM) and elevated (30mM) glucose and iso-osmolar (30mM) mannitol concentrations. Intracytoplasmic LM, FN and type IV collagen were evaluated by immunofluorescence. Metabolic labelling with 35S-methionine was performed to demonstrate LM, FN and type IV collagen synthesis by GECs. LM was the extracellular matrix component produced in higher amount in all the three experimental conditions in comparison to FN and type IV collagen. Laminin was completely cell associated in GEC cultured in normal glucose concentrations. The synthesis of this glycoprotein was raised by high glucose and mannitol that induced also a release of about 20% in the cell medium, in comparison to normal glucose. Fibronectin was produced in reduced amount than LM in normal glucose incubated GECs and it was localized in prevalence in the extracellular compartement. Cell associated FN and the release of this protein into the medium were not affected by high glucose and mannitol. Type IV collagen was synthesized in small amount and was almost exclusively cell associated. High glucose did not modify the production and the secretion of this glycoprotein into the medium. These results indicate that GECs are involved in the ECM production and that high glucose can modify the ECM protein concentrations at the glomerular basement membrane level. Osmotic effects may play a role in the increased synthesis and accumulation of these proteins in diabetic nephropathy.

1995

EVIDENCE FOR IMPAIRMENT OF DETOXIFICATION OF 3-DEOXY GLUCOSONE TO 3-DEOXYFRUCTOSE IN DIABETES

S.Lal, B. S. Szwergold, M. Walker, W. Randall, F. Kappler, *P. J. Beisswenger and T. Brown. Fox Chase Cancer Center, Philadelphia, PA, USA and *Dartmouth-Hitchcock Medical Center, Lebanon, NH, USA.

An important factor in the development of diabetic complications is 3-deoxyglucosone (3DG), a key intermediate in the non-enzymatic glycation of proteins. Given the toxic potential of 3DG, cellular processes exist for its detoxification, specifically by reduction at the C-1 to 3-deoxyfructose (3DF). In this study, we have measured the levels of 3DG and 3DF in urine from three groups of volunteers: a) normoglycemics (n=19), b) type I diabetics with little or no complications (n=28) and c) type II diabetics with no renal impairment (n=30). Second-voided fasted urine samples were collected from these individuals and the levels of 3DG and 3DF measured by GC/MS and HPLC, respectively. Both 3DG and 3DF were significantly elevated in type I and type II diabetics relative to normals (see table). While these increases were significant, a far more dramatic difference was observed when the levels of 3DG were correlated with 3DF. The differential increases of 3DF with respect to 3DG (slope), coefficient of regression (R^2) and significance (P value) were calculated from these correlations (see table). These data suggest

	3DG μm/g Cr	3DF μm/g Cr	Δ3DF/Δ3DG (Slope)	R^2	P Value
Normals	2.7 ± 0.9	92 ± 15	39.9	0.72	$< 10^{-6}$
Type Is	4.6 ± 3.6	125 ± 71	9.2	0.27	< 0.004
Type IIs	8.45 ± 10	171 ± 152	9.5	0.39	$< 10^{-4}$

a possible impairment of the reductive detoxification of 3DG in diabetics. This metabolic deficit may be a contributing factor to the development of diabetic complications.

1996

EFFECT OF GLUCOSE ON GENE EXPRESSION OF TISSUE INHIBITOR METALLOPROTEINASE-1 IN HUMAN MESANGIAL CELLS

A.K. Death, S. McLennan, D.K. Yue and J.R. Turtle. Department of Medicine, University of Sydney, Australia.

Matrix metalloproteinases and their inhibitors (TIMPs) have been implicated in mediating extracellular matrix accumulation and maybe involved in the mesangium expansion of diabetic nephropathy. In this study we investigated TIMP-1 expression in human mesangial cells exposed to high and low glucose concentrations. TIMP-1 expression is regulated by many factors including a protein kinase C (PKC)-dependent mechanism. To test whether any effect of glucose is mediated by PKC, TIMP-1 mRNA levels were also measured in human mesangial cells grown in high and low glucose and then exposed to a PKC-agonist, phorbol myristate acetate (PMA). Competitive RT-PCR was used to quantitate mRNA levels for TIMP-1 because of the increased sensitivity of this method compared with Northern blot analysis. An internal RNA competitive reference standard which differs from the wild-type mRNA by an 80 base pair deletion was used to control for the efficiency of the RT and PCR steps. Exposure of mesangial cells to high glucose concentrations led to a 57 ± 17% ($p<0.01$) decrease in TIMP-1 mRNA levels relative to the low glucose controls. This differs from previous in vivo and in vitro studies using Northern blot analysis to measure TIMP-1 mRNA levels in rat glomeruli or mesangial cells. A 6 hour exposure of mesangial cells to 10 μM PMA led to a 2.5-fold ($p<0.05$) increase in TIMP-1 mRNA levels in mesangial cells grown in low glucose conditions but this effect was abolished by high glucose concentration. In conclusion, TIMP-1 expression is reduced in a diabetic mileau. High glucose appears to inhibit the effect of PKC on TIMP-1 expression (supported by NH&MRC).

1997

THE MEASUREMENT OF ADVANCED GLYCATION ENDPRODUCT (AGE) SPECIFIC FLUORESCENCE IN CIRCULATION AND URINE

K. Yanagisawa, Z. Makita, Y. Miyoshi, S. Obara, K. Tsuchida, T. Atsumi, K. Shiroshita and T. Koike. Internal Medicine II, Hokkaido University School of Medicine, Sapporo, JAPAN

The late rearrangement products that accumulate by glycation of proteins, advanced glycation endproduct (AGE), have been implicated in the pathogenesis of diabetic complications. It was shown that circulating AGE increase in blood of diabetic patients with end-stage renal disease, and also shown reactive AGE in low molecular weight fraction of their serum, cut-off 10kDa, as AGE peptide (AGE-p). The aim of this study was evaluate the relation of AGE-p levels and diabetic nephropathy. To assess AGE-p in diabetic patients, AGE specific fluorescence (F: excitation 370 nm, emission 440nm) of AGE-p in serum and urine were examined in 101 diabetic subjects with several levels of renal complications; 24 with normoalbuminuria (N), 19 with microalbuminuria (m), 16 with macroalbuminuria (M), 22 with chronic renal failure (C) and 20 with hemodialysis (H). We also assessed age, duration of diabetes, serum creatinine level and HbA1c in these patients. The fluorescent characteristics of AGE-p in serum and urine were similar to those of AGE-BSA. Emission maximum were expressed a single major peak in 440-450nm. F of serum AGE-p in C and H (3.70±0.57 and 16.6±1.55, AU, mean±SE) were significantly higher than N, m and M(1.37±0.08, 1.61±0.35 and 1.41±0.10, $p<0.005$). Also in urine, F of AGE-p in C and H (1.63±0.24 and 1.63±0.13 AU/gCr) were higher than N, m and M(0.56±0.10, 0.65±0.23 and 0.57±0.09, $p<0.05$). F of serum AGE-p and serum creatinine levels were strongly correlated ($r=0.9$, $p<0.001$). These findings suggested that renal function may play a major role for the mechanism of AGE accumulation and excretion on diabetic subjects, and the measurement of AGE specific fluorescence of AGE-p may serve as a useful test to detect circulating reactive AGE levels.

1998

MODULATION OF GALECTIN-3 / AGE-RECEPTOR-3 EXPRESSION BY THE DIABETIC MILIEU IN CULTURED RAT MESANGIAL CELLS

G. Pugliese[1], F. Pricci[1], G. Romeo[1], G. Leto[2], R. Gradini[1], C. Santangelo[1], L. Lenti[1], V. Cirulli[3], A. Hayek[3], F.-T. Liu[3], L. Frigeri[3], and U. Di Mario[2]
Universities of [1]Rome "La Sapienza" and [2]RC-Catanzaro, Italy, and [3]The Whittier Institute, UCSD, La Jolla, CA, USA

Advanced glycation end-products (AGEs) have been postulated to mediate hyperglycemia-induced glomerular injury, via binding to cell surface receptors. The 32 kD protein Galectin-3 (Gal-3) has been recently identified as the AGE-receptor 3 (AGE-R3). This study was aimed at evaluating Gal-3 expression in cultured rat mesangial cells (RMC) and its modulation by the diabetic *milieu*. To accomplish this objective, RMC were (a) cultured for 1-4 weeks in media containing normal glucose (5.5mM, NG), high glucose (30mM, HG), or iso-osmolar mannitol (M); or (b) grown for 4 days on dishes previously coated with nonglycated or native bovine serum albumin (BSA), glycated BSA with AGE formation (BSA-AGE), or glycated BSA in which AGE formation was reduced by aminoguanidine (BSA-AM). Gal-3 expression was evaluated by FACS and immunofluorescence using a rabbit anti-rat Gal-3 polyclonal antibody and a swine anti-rabbit IgG-FITC to reveal the reaction. No Gal-3 was demonstrable in RMC cultured in NG (although it became evident after passage 15), whereas cells grown on BSA showed a positive staining with a diffuse (cytoplasmic) fluorescence pattern. Prolonged exposure (3-4 weeks) of RMC to HG, but not to M, as well as growing cells on BSA-AGE and, to a lesser extent, BSA-AM, induced or significantly incresed Gal-3 expression, as assessed by both FACS analysis and immunofluorescence. Moreover, cell cultured under these conditions showed a unique patchy distribution of Gal-3 fluorescence, in addition to the diffuse pattern. Confocal microscopy indicated both a cytoplasmic and cell surface localization of granules compatible with the reported Gal-3 receptor function. These results indicate that (1) Gal-3/AGE-R3 is not expressed under basal conditions in RMC; (2) AGEs induce (or upregulate) the expression of their own receptors; and (3) the effect of AGEs is mimicked by prolonged exposure to HG, possibly due to a time-dependent AGE formation.

1999

Urinary excretion of Glucagon-Like Peptide 1 (GLP1) 7-36 amide: a possible indicator of early tubular dysfunction in type 2 (non insulin-dependent) diabetes.

R. Lugari, *L. Sarti, *S. Coppi, C. Dell'Anna, P. Sbordone, M. Bianco, A. Gnudi, *R. Zandomeneghi.
Department of Endocrinology, University of Parma, *Department of Internal Medicine, University of Modena, Italy.

The metabolism of GLP1, the most important physiologic insulinotropic factor so far described in man, is unknown. Plasma GLP1 is reported to be markedly increased in uremic subjects, suggesting that the kidney plays a role in the removal of the circulating peptide. Beside this only observation in man, studies in the rat demostrate that the renal clearance of GLP1 involves its glomerular filtration and subsequent tubular degradation. In condition of maintained glomerular function, thus, the negligible urinary excretion of the peptide would confirm the integrity of tubular function. Aim of this study was to investigate the urinary excretion of GLP1 in non insulin-dependent diabetes, evaluating different conditions of renal function. 29 type 2 diabetics and 7 healthy volunteers were studied. On the basis of urinary albumin excretion rate (UAE) 4 groups of subjects were individuated: group 1= control subjects (n=7; UAE=3.4±2.6 ug/ml/min; M±SD), group 2= normo-albuminuric diabetic patients (n=8;UAE=5.2±3.1), group 3=microalbuminuric patients (n=11;UAE=81.7±14.6), group 4=macro-proteinuric patients (n=10; UAE=448.9±94.8). Mean values of urinary GLP1 (RIA; pg/min) resulted significantly different between the groups ($p<0.03$). With respect to group 1 (275.5±132.1) the urinary peptide excretion increased in group 2 (490.4±211.5, $p<0.05$) and further in group 3 (648.6±305,$p<0.01$), whereas no significant difference resulted between macroproteinuric patients (317.9±183.3) and controls. Mean values of glomerular filtration rate (GFR), evaluated as creatinine clearance, was significantly lower in group 4 (57.4±2 ml/min) with respect to both controls and normoalbuminuric diabetic patients (105.6±6.1, 91.2±17.3; $p<0.01$). Considering all subjects examined, a significant relationship resulted between urinary GLP1 and GFR ($p=0.004$). In conclusion: 1) the increase of the peptide excretion observed in normoalbuminuric diabetic patients could indicate an early tubular dysfunction in condition of still maintained glomerular integrity, 2) the tubular defect seems to become more evident with the onset of glomerular involvement, 3) in condition of overt diabetic nephropathy the tubular damage, in terms of urinary peptide excretion, would be masked by the advanced decline of glomerular function.

2000

Role of p21 Ras Signaling Pathway in Cultured Rat Mesangial Cells in High Glucose Media.

Tamotsu Yokota, Kazunori Utsunomiya, Hideaki Kurata, Hideki Ohta, Kanae Simizu and Naoko Tajima. Jikei University School of Medicine, Tokyo, Japan

HMG-CoA reductase inhibitor pravastatin, which inhibits farnesylation of p21Ras has the preventive effect on the development of diabetic nephropathy in STZ rats. In order to clarify the role of Ras signaling pathway in the pathogenesis of diabetic nephropathy, we examined the influence of high glucose and pravastatin on the expression p21Ras and TGF-β in culturted rat mesangial cells. Cells were incubated with 5mM(N), 25mM(H), and 25mM glucose in the presence of 500μM pravastatin(P), and after harvesting at 48hrs of the exposure to each culture condition, we examined the expression of H-ras and TGF-β mRNA with Northern blot, p21Ras in the membrane fractions and the ratio of Ras-GTP/GDP with immunoblotting method. There were no changes in the expression of H-ras mRNA among N, H, and P. On the other hand, the expression of p21Ras in the membrane fractions and active form of Ras-GTP was significantly increased in H compared to N, however, these changes were suppresed in P. The expression of TGF-β mRNA was also suppressed by addition of pravastatin into high glucoe media. These data suggest that in mesangial cells in high glucose media, p21Ras is overexpressed in the plasma membrane via translocation from cytoplasm. Pravastatin suppresse the translocation of p21Ras by inhibiting farnesylation and also suppresses the expression of TGF-β, which may result in prevention of diabetic nephropathy.

2001

URINARY KAPPA LIGHT CHAIN AS A PREDICTOR OF EARLY DIABETIC NEPHROPATHY: FIVE-YEARS FOLLOW UP STUDY

Y. Ieki, E. Takazakura. Kurobe City Hospital, Kurobe, Japan.

To evaluate whether urinary excretion of kappa light chain(KLC) can be used as a predictor for developement of early diabetic nephropathy, we measured the concentrations of KLC and albumin in first-voided morning urine samples from 107 diabetic patients(NIDDM 103, IDDM 4) without overt proteinuria(urinary albumin creatinine ratio(ACR)< 150mg/gCr). In the patients with increased excretion of urinary KLC creatinine ratio(KCR)(≧5.8mg/gCr), ACR significantly increased both in normoalbuminuric(ACR<20mg/gCr) and microalbuminuric(20≦ ACR< 150mg/gCr) patients after 5 years, whereas in normal KCR (<5.8mg/gCr), ACR showed no significant change both in normo- and microalbuminuric patients. The number of patients with increase in ACR for 5 years was significantly large among the patients with increased KCR. Multiple regression analysis demonstrated that KCR was a significant risk factor for increasing ACR after 5 years. KCR showed no significant change both in normo- and microalbuminuric patients for 5 years. These results suggest that urinary excretion of KLC might provide a useful predictive marker for developement of early diabetic nephropathy.

2002

ROLE OF THROMBOXANE A2 ON RENAL HEMODYNAMICS IN NON-INSULIN-DEPENDENT DIABETIC RATS.

K.URIU, K.KAIZU, A.MATSUOKA, K.KAI, AND S.ETO.
Univ. Occup. Environ. Health, Kitakyusyu, Japan.

Thromboxane (TX) A2 plays an important role on renal hyperfiltration in streptozotocine (STZ)-induced diabetic rats, whereas it's role on renal hemodynamics in non-insulin-dependent diabetic (NIDDM) rats remains unknown. To clarify the issue, the effects of intravenous infusion of TXA2 synthetase inhibitor (OKY-046, 6 mg/kg/h) on clearance of inulin and para-aminohippurate (Cin, CPAH) under anesthesia were evaluated in spontaneously NIDDM rats, OLETF (n=8), and control rats, LETO (n=7) at the age of 10 months. OLETF showed obesity, moderate hyperglycemia (12.7± 0.9 mmol/l), and hyperinsulinemia (336±26 pmol/l). Urinary TXB2 excretion (U-TXB2) was slightly higher and the ratio of U-TXB2 to urinary 6-keto prostaglandin F1α (6-kPG) was higher in OLETF (TXB2/6-kPG: 0.22±0.04 vs 0.12 ±0.02, $p<0.05$). OLETF had significantly higher Cin and CPAH than LETO (Cin: 1.1±0.1 vs 0.7±0.1 ml/min/100gBW, CPAH: 3.1±0.2 vs 2.3±0.3 ml/min /100gBW, $p<0.01$). OKY-046 did not restore Cin and CPAH in OLETF although it significantly decreased U-TXB2 and ameliorated TXB2/6-kPG in OLETF. In conclusion, in contrast to STZ-induced diabetic rats, TXA2 was not involved in renal hyperfiltration in OLETF. TXA2 may contribute to renal injuries in OLETF through mechanisms other than hemodynamic injury.

2003

Uric Acid and Blood Sugar Control as Factors Influencing Urinary Transferrin in NIDDM Patients

M. Shinada, Department of Medicine, Atsuta National Health Insurance Hospital, Atsuta, Japan

This study investigated factors facilitating urinary transferrin excretion comparing with those influencing urinary albumin excretion in NIDDM patients without proteinuria. We examined the correlation between urinary transferrin/ urinary albumin ratio (T/A ratio) and clinical factors including serum uric acid, which was reported to provide an antioxidant defense. Twenty-one male NIDDM patients (Age: 58±13 years old) without proteinuria or pyuria were studied for 1 year. Transferrin was measured by the latex agglutination method and albumin by immunoturbidity in overnight urine. Age, known duration of diabetes, blood pressure, body weight, HbA1c, and serum uric acid were recorded as clinical factors. The T/A ratio in healthy control subjects was 0.052± 0.017 (mean±SD) (n=90). The T/A ratio in patients was significantly higher than that of controls ($p<0.01$). Patients were divided into two groups after the T/A ratio was followed for 1 year. Group A: patients with a decreased T/A ratio (n=10) (T/A: 0.131±0.059→0.082±0.020), Group B: patients with a stable T/A ratio (n=11) (T/A: 0.080±0.044→0.099± 0.034). We found a significant improvement in HbA1c in group A ($p<0.01$), but not in group B. There was a significant correlation between the T/A ratio and serum uric acid in group B ($r=-0.706$, $p<0.02$), but not in group A. We suggest that the excretion of transferrin comparing with that of albumin demonstrated the amelioration of glycemic control and may be linked to an antioxidant defense by uric acid.

2004

THROMBOSPONDIN PROMOTES THE PRODUCTION OF MESANGIAL MATRIX PROTEINS THROUGH ACTIVATING TGF-β IN HUMAN MESANGIAL CELLS

H. Tada, H. Ishii M. Tsukamoto and S. Isogai, Toho University School of Medicine, Tokyo, Japan.

Thrombospondin (TSP), a multifunctional glycoprotein, is synthesized by mesangial cells (MCs). The role of TSP, however, has not been established in the pathogenesis of diabetic nephropathy. To clarify this, TSP production from human MCs exposed to various concentrations of glucose was measured by ELISA. We also studied the effects of TSP on the production of fibronectin and type IV collagen by ELISA, and on the ability of activating latent TGF-β assessed by the binding capacity to type II receptors, respectively in MCs. Incubating MCs with high glucose media resulted in the increase of TSP in both media and cell layers in a glucose-dose dependent manner. The production of fibronectin and type IV collagen was enhanced by the addition of TSP in a TSP-dose dependent manner. These effects of TSP were blocked by the simultaneous addition of neutralizing antibodies to TGF-β. The activation of latent TGF-β was increased by the addition of TSP to MCs, while the amount of latent TGF-β secreted from MCs was unchanged. These results indicate that TSP production from MCs is enhanced by high concentrations of glucose, and that TSP promotes the production of mesangial matrix proteins through activating latent TGF-β. Therefore, TSP may participate in the pathogenesis of diabetic nephropathy.

2005

THE VALUE OF MICROTRANSFERRINURIA IN EARLY DIAGNOSIS OF DIABETIC NEPHROPATHY

H.Li, W.Y.Shen, D.H.Xu and Z.H.Tong. Department of Endocrinology, 1st affiliated Hospital, Zhejiang Medical University, Hangzhou, China.

To evaluate the significance of microtransferrinuria in early diagnosis of diabetic nephropathy, the urinary excretions of albumin (ALB), transferrin (TF) and a1-microglobulin (a1-MG) were measured in samples of 24 hour urine from 25 healthy subjects and 63 diabetic patients (55 with NIDDM and 8 with IDDM). Diabetic patients were grouped according to their ALB excretion (AER) into normal albuminuria (group I, AER <30mg/24h), microalbuminuria (group II, AER 30-300mg/24h) and macroalbuminuria (group III, AER > 300mg/24h). The urinary excretions of TF and a1-MG in all groups exceed those for healthy controls. The urinary excretions of TF and a1-MG were highest in group III subjects, followed by group II and group I subjects. Prevalence of increased values (calculated by using an upper limit of normal range, ie, exceed the 95 th percentile value found in healthy controls) were in 41.03%, 85.76% and 100% of group I, group II and group III patients for TF, in 38.46%, 92.31% and 100% of group I, group II and group III for a1-MG, respectively. The urine excretion of TF and a1-MG was positively related with that of ALB, but there was no relationship between the excretion of TF or a1-MG and FBG or GHbA1. Conclutions: 1.Urinary TF is increased earlier in diabetics than ALB and may be a more sensitive marker for detecting diabetics. The proximal tubular impairment might occur independently on the glomerular alterations in the course of diabetic nephropathy.

2006

TGFβ1 IN DIABETIC NEPHROPATHY - A TRANSGENIC MODEL

C.Birch-Nielsen, P. Hjorth, L. Rasmussen, K.Gross, N.Sarvetnick, and L. Wogensen. Research Laboratory of Biochemical Pathology and Medical Research Laboratory, Aarhus Kommunehospital, Aarhus. Denmark.

Several findings support a key role of TGFβ in diabetic nephropathy, particularly on the accumulation of glomerular extracellular matrix components (ECM).The aim of the present study was to study the effects of TGFβ1 in the glomerulus *i n vivo*. We have created a transgenic mouse with localized production of TGFβ1 in the kidney. TGFβ1 production is targeted to the juxta-glomerular cells in the kidney by the Ren1c promoter. Microinjection of the DNA construct into fertilized eggs resulted in five transgenic founders out of 25 pups born. We have continued breeding with one transgenic line. Reverse transcription of total RNA followed by PCR with transgene specific primers demonstrated the presence of a transgene specific transcription product. The localization was tested by in situ hybridization. The presence of biological active TGFβ1 in transgenic mice is indicated by increased synthesis of glycosaminglycans as evaluated in cultured kidney slices from transgenic (2044 arbitrary units/mg, n=7) and non-transgenic mice (1061 arbitrary units/mg, n=7) ($p<0.01$). In line 1725 all transgenic mice tested so far (n=15) have accumulations of ECM in their glomeruli. Only in older transgenic mice (6-8 month) or in more advanced cases do we observe interstitial fibrosis. The volume fraction of the glomerular tuft stained with antibodies against the basement components collagen IV and laminin increases in transgenic mice compared to sex- and age matched non-transgenic littermates ($p<0.01$ and $p<0.05$, respectively). The transgenic mice exhibit a variable degree of proteinuria. The youngest mice tested so far are newborn mice. It seems that glomerular changes develop between 1 and 2 month of age. Electronmicroscopy indicates that a very early change in the transgenic mice is a widening of the basmement membrane. In conclusion, we have established a transgenic mouse with localized expression of TGFβ1 in the glomerulus. The model is used to explore the biological effects of TGFβ1 on glomerulus function *in vivo* in relation to diabetic nephropathy. Our transgenic model has several advantages: First, we do not genetically manipulate the cells we actually want to study (the glomerular cells). Second, in contrast to other studies, we do not have any secondary effects induced by failure of other organs due to circulating levels of TGFβ1.

2007

MEASUREMENT OF URINARY IgG IN NIDDM

Y.Nakamura and M.Shitara. Maebashi Red Cross Hospital,Maebashi,Japan.

In an attempt to evaluate the mechanisms of diabetic nephropathy, we measured the urinary IgG(IgG) in 143 NIDDM patients, as well as urinary transferrin(TF) and urinary albumin(Alb) which were well known as to be predictive for later clinical diabetic nephropathy. Reference data of urinary IgG were obtained from 38 normal glucose-toleranced (NR) and 28 impaired glucose-toleranced persons (IGT). Urinary IgG of NR was 2.81±0.2 mg/gCr and that of IGT was 4.71±0.60mg/gCr, significantly higher than NR. The TF(0.66±0.08 mg/gCr) in IGT was also significantly higher than that in NR(0.43±0.05mg/gCr), but Alb was not (6.06±0.62mg/gCr for IGT, 5.47±0.53mg/gCr for NR). According to reference data for IgG, NIDDM were allocated to 5 groups. The IgG was ≦3.0mg/gCr and TF was ≦1.0mg/gCr in G1 (N=13); IgG was >3.0mg/gCr but ≦5.0mg/gCr, and TF was ≦1.0mg/gCr in G2(N=19); IgG was >5.0mg/gCr, and TF was ≦1.0 mg/gCr in G3(N=22); TF was >1.0mg/gCr, and Alb was ≦20mg/gCr in G4(N=36); Alb was >20mg/gCr in G5(N=53). The IgG showed the significant increase as the group increase (2.31±0.22, 3.94±0.14, 6.85±0.49, 8.94±0.77 25.99±4.93 mg/gCr, respectively), however TF and Alb didn't show the significant increase in G1, G2, and G3; but significantly increased in G3 and G4. The average age, BMI, BP, Cr and NAG in each group showed no difference. The HbA1C and contraction period tended to increase as the group increase. No patients in G1 showed the diabetic retinopathy, 6 patients in G2, 8 in G3, 6 in G4, and 15 in G5.**[Conclusion]** IgG seems to be filtrate from the kidney early stage in diabetes, possibly earlier than TF or Alb.

2008

GROWTH FACTORS AND DIABETIC NEPHROPATHY: AN EXPERIMENTAL AND CLINICAL STUDY.

MR Rifaie, N Sayed-Ahmed, M Abul-Magd, H El Soutohi, F El Houseini, M Sobh, and AM El Nahas*. Mansoura University, Mansoura, EGYPT; and * Sheffield Kidney Institue, Sheffield, UK.

The aim of this work was to investigate if some growth promoting polypeptides have a relation to the diabetic renal disease, relying on studying their distribution in the renal tissue, both in experimental and clinical situations. The experimental part included 50 Wistar rats with streptozotocin (STZ)-induced diabetes mellitus (day 0) and 20 sham animals. A group of 5 STZ- and 2 sham animals were sacrificed on days 0, 2, 4, 7, 9, 14, 30, 60, 120, and 150. The kidneys were examined for evidence of renal growth and prepared for immunohistochemical and pathological studies. In the clinical part, renal biopsies from 5 diabetic patients were studied. All renal tissues were stained for routine microscopical evaluation as well as for immunohistochemistry for the following growth factors: Epidermal growth factor (EGF), EGF-receptor, transforming growth factor beta (TGFb), fibroblast growth factor (FGF), platelet-derived growth factor (PDGF), and interleukin-6 (IL-6). Tubular lesions in the form of vacuolations were noticed early in the time course of diabetes with stuffing of some tubular cells with glycogen and fat. Immunostaining for growth factors was demonstrated in consistent patterns in different stages of diabetic renal disease both in animals and in humans. Some of the growth factor immunostaining patterns were co-localized with the tubular lesions early in the disease, others with the interstitial expansion late in the disease. Glomerular staining for PDGF was shown to be related to the advanced cases of glomerulosclerosis. The localization and distribution of growth factors in the diabetic kidneys might suggest a role in pathogenesis of diabetic renal disease.

2009

INCREASED PLASMA AND URINARY CONCENTRARTIONS OF EXTRACELLULAR GLUTATHION PEROXIDASE (eGPx) IN NON-INSULIN-DEPENDENT-DIABETIC (NIDDM) PATIENTS

H.Nakata, M.Saito, M.Tobishima and Y.Itami, Nikko Memorial Hospital, Muroran, Japan. T.Honjoh, Yokohama. K.Takahashi, Sapporo, Japan.

It is well known that diabetic patients have high risk of microangiopathy and atheroscrelosis. Recently, Oxygen radicals is considered to play an important role in the production and development of atherosclerosis. GPx that is one of the major antioxidant enzymes, catalyses the reduction of H_2O_2 to alcohols. Therefore in NIDDM, we determined plasma and urinary concentrations of eGPx, and examined its relationship with diabetic control and complications, especially nephropathy. Eighty NIDDM subjects(46 male and 34 female) and 30 healthy subjects were investigated. Plasma and urinary concenrations of eGPx were measured with the ELISA method (Clin.Chim.Acta. 236: 93; 1995). Diabetic patients were allocated to three groups according to their levels of urinary albumin excretion: group 1 (30 mg/g.Cr), group 2(30-300), Group 3(>300). Urinary NAG levels were also measured. Plasma eGPx level in diabetics was significantly higher than that of controls (17.8 to 23.0 μ g/ml, $p<0.05$). Plasma eGPx levels were not correlated with fasting plasma glucose and HbA1c levels. There was no difference in plasma eGPx levels among three groups. Urinary levels of eGPx in group 3 increased significantly as compared with those in group 1 and group 2 (group 1: 44.6 ng/ml, group 2: 42.6, group 3: 280.6). Moreover, urinary eGPx levels were correlated with urinary NAG levels ($rS=0.357$, $p<0.01$). In diabetic patients, plasma eGPx levels increased as compared with normal subjects. Moreover, urinary eGPx levels with clinical macroalbuminuria were higher than those without nephropathy. The increased rate of eGPx synthesis in proximal tubular epitherial cells may contribute to the elevated levels of plasma eGPx found in diabetic patients. Urinary eGPx levels might be a marker of nephropathy in NIDDM.

2010

TRASFORMING GROWTH FACTOR-β_1 MODULATES INSULIN-LIKE GROWTH FACTOR BINDING PROTEIN-3 IN KIDNEY ENDOTHELIAL CELLS

L.Pala, S. Giannini, B. Cresci, A.Ciucci , G. Galli and C. M. Rotella. Section of Metabolic Disease and Diabetes. University of Florence. Florence. Italy.

We previously reported that TGF-β_1 and IGF-I differentially modulate in a dose response manner the level of IGFBP-3 decreasing and increasing, respectively, its presence in human kidney endothelial cells (GEN). The aim of our study is to investigate the role that this BP-3 regulation could have on GEN growth control. Conditioned medium (CM) from GEN was harvested after 48 h serum-free culture and electrophoresed on SDS-PAGE and then incubated with [^{125} IGF-II]. The TGF-β_1 effect on BP-3 GEN probably involves a non-enzimatic activity since the addition of 10 nM protease inhibitors (aprotinin, EDTA and PMSF) did not block the effect of TGF-β_1 Our preliminary results seem to confirm that both TGF-β_1 and IGF-I could regulate the BP-3 level in controlling the expression of specific GEN BP-3 mRNA. Since the two growth factors modulate the level of IGFBP-3 which may have both inhibitory or stimulatory actions, we examined the effect of TGF-β_1 on GEN mitogenesis. At this purpose we mesasured GEN cell growth in regular medium with TGF-β_1 alone or in combination with IGF-I at different times by a haemocytometer count. TGF-β_1 significantly reduced cell growth starting from 12 hours even if a significant increase of the IGF-I level was detected by a specific commercial radioimmunoassay. Moreover the addition of IGF-I in presence of TGF-β_1 did not modify this inhibitory effect. Finally, the policlonal antibody against BP-3 added to the regular GEN cell growth medium dramatically decreased the mitogenesis of these cells. We conclude that: i) the classic inhibitory effect of TGF-β_1 on endothelial cell growth could be, in part, explained by the decreased BP-3 level; ii) the mitogenic effect of IGF-I observed in endothelial cells could explain instead with the BP-3 level increased; iii) the addition of an Ab-BP-3 reduces mitogeniesis; iv) the increased IGF availability induced by TGF-β_1 is not able to stimulate cell growth due to the lack of a simultaneous BP-3 increase. These results suggest the primary role played by BP-3 in the regulation of endothelial cell growth.

2011

URINE MICRO-FDP(FIBRIN/FIBRINOGEN DEGRADATION PRODUCTS) -A CANDIDATE FOR EARLIER MARKER FOR DIABETIC NEPHROPATHY-

T.Mori, G.Yoshino, N.Kasatori, S.Namba, F.Ishibashi and T. Urayama. Toho University, Tokyo, Japan

We have developed a highly sensitive assay method for the detection of FDP in urine specimens and explored the possibility that urine micro-FDP can be an earlier marker for diabetic nephropathy. We examined 196 NIDDMs, 15 hyperlipidemics, 25 hypertensives and 142 non-diabetic healthy volunteers (N). Urine (early morning) FDP was measured essencially by chemiluminescent enzyme-linked immunoassay with dioxetane derivative substrate for the labelled alkaline phosphatase. The detection limit is 1 ng/ml, which is approximately 1/100 of conventional turbidimetric method based on latex aggregation. The CV was 5.5%. Abnormally high level of urine FDP (above mean+2SD of group N) was found in 68% (45/66) of NIDDMs with normo-albuminuria. More than 90% (30/33) of NIDDMs with micro- or macroalbuminuria and 69% (39/57) of those with elevated urine transferrin levels had abnormally high urine FDP levels. There were no significant differences in either plasma FDP or D-dimer levels between NIDDMs with normo-albuminuria and group N. Only 20% (6/30) of non-diabetic hypertensives had elevated urine FDP, while all hyper-tensive NIDDMs showed abnormally high urine FDP. Even within NIDDMs with normoalbuminuria, elevation of HbA1c had significant effect on increase in urine FDP. Neither hyperlipidemia nor smoking had any significant effect on urine FDP levels. Thus, urine micro-FDP can be a new candidate for an earlier marker for diabetic nephropathy.

2012

THE IGF SYSTEM IN EARLY DIABETIC NEPHROPATHY IN THE SAND RAT.

I. Raz[1], A. Holberg[1], B. Hirshberg[1], M. Filip[2], Y. Barshavit[2], R. Moshe[1], I. Nephesh[1], A. Flyvbjerg[3] and O. Weiss[1]. Hadassah University Hospital[1], Jerusalem, Israel; Soroka University Hospital[2], Beer Sheba, Israel and Aarhus Kommune Hospital[3], Aarhus, Denmark.

Early increase in kidney IGF-I secondary to increased IGFBP1 was shown to correlate with the increase in renal perfusion and size in streptozotocin (STZ) induced hypoinsulinemic diabetes in the rat (animal model for IDDM). The increase in renal IGFBP1 and IGF-I in this model was related to the hypoinsulinemic state induced by STZ. We studied the influence of hyperglycemia in the setting of normoinsulinemia on renal perfusion and size and on the IGF system in hyprglycemic normoinsulinemic sand rats (animal model for NIDDM). Induction of diabetes by special diet 40 days after weaning resulted in average blood glucose of 270±14 mg% within 2 days as compared to 82±6 mg% in the control group. A 50% increase in GFR was seen two weeks after induction of diabetes ($P<0.05$), however 24 hour urine albumin excretion was similar in both groups. Kidney size was similar after 5 days of diabetes, but was increased by 15% after 15 and 30 days of diabetes while heart size was unchanged. Serum IGF-I, IGFBP1,2,3 and 4, and GH were unchanged after 5, 15 and 30 days of diabetes. Renal IGF-I mRNA, IGF-I receptor mRNA and IGFBP1 mRNA were unchanged by the diabetic state. Renal IGF-I and IGFBP1,2,3 and 4 levels were unchanged after 5, 15 and 30 days of diabetes. In conclusion, kidney hyperperfusion and enlargement is characteristic of the normoinsulinemic hyperglycemic state, but tends to be less pronounced and to develop at a later stage. In this model, renal hypertrophy and hyperperfusion developed devoid of any change in the IGF system.

2013

PLASMA AND URINARY ENDOTHELIN-1 (ET-1) AS MARKER OF DIABETIC NEPHROPATHY.

M.Cassone-Faldetta, O. Laurenti, C. Bravi, C. Bellini, A. Armiento, C. Ferri and G. De Mattia. Institute of I Clinica Medica, University "La Sapienza", Rome, Italy.

The vasoconstrictive peptide ET-1 can be found in both human blood and urine. Aim of this study was to verify the role played by ET-1 as marker of early renal damage. We evaluated plasma and urinary ET-1 levels in 27 lean, normotensive non-insulin dependent diabetic (NIDDM) patients (16 males and 11 females, mean age 59±8 years, HbA1c <6%, 18 normo and 9 microalbuminurics), and in 12 age and sex-matched healthy subjects. Statistical analysis was conducted by Student's t-test for paired and unpaired data. Compared to controls, a significant increase of plasma ET-1 in NIDDM patients (respectively 0.6±0.1 vs 1.72±0.38 pg/mL, $p<0.001$) was found. Among these latter, plasma ET-1 levels were significantly higher in microalbuminuric than in normoalbuminuric patients (1.97±0.58 vs 1.59±0.14, $p<0.02$). Urinary ET-1 values were higher in controls than in diabetic patients (70.1±15.2 vs 44.0±20.8 pg/min, $p<0.05$) and no difference was noted between micro and normoalbuminuric patients (48.5±20.1 vs 40.8±21.6 pg/min). Since filtered ET-1 is destroyed by the neutral endopeptidases of proximal tubulus, urinary ET-1 is believed to be distally produced. According to our results, plasma ET-1, as microalbuminuria, is expression of a generalized endothelial dysfunction, and can be used also as marker of glomerular damage. On the contrary, urinary ET-1 levels reflect mainly tubular function and can be used in early diagnosis of subclinical tubular damage.

2014

THE IGF SYSTEM IN EARLY DIABETIC NEPHROPATHY IN NORMOINSULINEMIC HYPERGLYCEMIC RATS.

I. Raz[1], Z. Haramati[1], B. Hirshberg[1], R. Moshe[1], I. Nephesh[1], O. Weiss[1] and A. Flyvbjerg[2]. Internal Medicine Department[1], Hadassah University Hospital, Jerusalem, Israel and Institute of Experimental Clinical Research[2], Aarhus Kommune Hospital, Aarhus, Denmark.

A marked increase in renal perfusion and size is characteristic of STZ induced hypoinsulinemic hyperglycemic state in the rat (animal model of IDDM). Early increase in kidney IGF-I secondary to increased IGFBP1 was shown to correlate with the increase in renal perfusion and size in this model of IDDM. However, since the increase in renal IGFBP1 in this model was related to hypoinsulinemia, we studied the influence of hyperglycemia in the setting of normoinsulinemia on renal perfusion and size and on the IGF system in hyperglycemic normoinsulinemic rats (animal model of NIDDM). Injection of 50 mg/Kg of STZ to normal rats resulted in normal glucose on fast with non fast hyperglycemia. Fast and postprandial insulin levels were similar to those in non diabetic control rats. Induction of STZ diabetes resulted in 30% increase in GFR ($p<0.05$) within the first week of diabetes. Kidney size was similar after 10 days of diabetes but was increased by 33% and 36% after 30 and 48 days of diabetes respectively. Serum IGF-I and IGFBP3 decreased significantly after 10 days of diabetes. GH and 30 KDA Bps (BP1 + BP2) were unchanged. Renal IGFBP1 mRNA was unchanged after 10, 30 and 48 days of diabetes. 30 KDA Bps protein were significantly increased in the medulla after 30 and 48 days of diabetes. IGFBP3 also significantly increased in the medulla and cortex of the diabetic rat after 30 and 48 days. We conclude that kidney hypertrophy is similar in normoinsulinemic hyperglycemic state when compared to hypoinsulinemic hyperglycemic state, but tends to develop at a later stage. Increase in renal IGFBP1 and IGFBP3 and decrease in serum IGFBP-3 might play an important role in the development of renal hypertrophy in rats with hyperglycemic normoinsulinemic state.

2015

URINARY GLYCOSAMINOGLYCAN EXCRETION (GAGe) IN NIDDM AND IDDM PATIENTS

N. Cédola, O. Rebolledo, S. Actis Dato and C. Refi - CENEXA and C. Posgrado Clínica Nutr. y Endocrinología, F. Cs. Médicas, UNLP, La Plata, Argentina

In diabetes mellitus, the quantity and quality of proteoglycan and its GAG chains are modified in different vascular and tissular components. The aim of this work was to evaluate the clinical characteristics, the degree of metabolic control (HbA_1), 24-hr urinary GAGe by the carbazol method, and microalbuminuria (MA) by RIA in 35 IDDM, 27 NIDDM, and 32 non-diabetic subjects (C).

	n	GAGe mmol/creat. mol	GAGe mg/ 24 h
Controls	32	4.39 ± 0.47	10.2 ± 0.9
Total diabetic population	62	6.17 ± 0.60*	15.7 ± 1.4***
IDDM without AH	26	7.06 ± 1.15**	16.6 ± 2.3∧
NIDDM with AH	17	5.47 ± 0.68	17.0 ± 2.6**
IDDM without MA	30	6.93 ± 1.02*	16.2 ± 2.1**
NIDDM with MA	10	6.36 ± 0.99	19.3 ± 3.4**
IDDM HbA_1 > 10%	21	7.39 ± 1.10**	18.8 ± 2.6∧
NIDDM HbA_1 > 10%	21	5.73 ± 0.77	16.0 ± 2.6*

vs. C = ∧: $p < 0.005$; ***: $p<0.01$; **: $p < 0.02$; *: $p< 0.05$

We found that diabetic subjects had a significantly higher GAGe, particularly uncompensated diabetics (HbA_1 > 10%), compared to C. The increase in GAGe preceded the development of MA in IDDM. That was not the case in NIDDM, in which such increase was more frequent in hypertensive patients (AH). The increase in GAGe could be an early indicator of dysmetabolism of these compounds and therefore of the development of diabetes chronic complications.

2016

Role of growth hormone-induced IGF-1 in the modulation of renal haemodynamics in normoalbuminuric insulin-dependent diabetic patients

S. Bacci, M. Garrubba, S. De Cosmo, G. Placentino, A. Liuzzi and GC Viberti ^Division of Endocrinolgy IRCC "Casa Sollievo della Sofferenza" San Giovanni Rotondo, Italy and ^Unit for Metabolic Medicine UMDS Guy's Hospital, London, U.K.

An increase in glomerural filtration rate (GFR) has been proposed as a risk factor the development of diabetic nephropathy but it is still unclear whether physiological levels of GH and IGF-1 play a role in these haemodynamic changes. We investigated in a dose-response study the role of GH induced IGF1 in the modulation of renal haemodynamics in normoalbuminuric, normofiltering insulin-dependent diabetic patients We measured GFR and renal plasma flow (RPF) by inulin and para-aminohippurate renal clearances at basaline and 23 hrs after the injection of different doses of GH (0.1, 0.2, 0.4 U/Kg of body weight) in 7 normoalbuminuric, normofiltering insulin-dependent diabetic patients during sustained euglycaemia. Age of patients was 27 yrs (22-34), duration of diabetes: 8 yrs (5-12), creatinine clearance 118±12 ml/min (112-128) and albumin excretion rate: 10 micr/min (2-14). Plama levels of GH increased significantly after 1 hr (from 0.6±0.2 at baseline to 16±4, 30±8, 130±12 ng/ml for 0.1, 0.2 and 0.4 U/kg respectively). Plasma levels of IGF-1 reached a peak 22-24 hrs after GH injection (from 160±15 at baseline to 232±10 ($p<0.05$), 260±64 ($p<0.05$), 410±70 ($p<0.01$) ng/ml for 0.1, 0.2 and 0.4 U/kg of GH respectively). Basal values of GFR and RPF were 122±12 and 550±106 ml/min respectively and did not changed after the injection of 0.1 and 0.2 U//Kg of GH. They significantly increased to 170±22 ml/min and 620 ml/min ($p<0.05$ for both) after the somministration of 0.4 U/kg of GH. The increase coincided with the IGF-1 peak. These results demonstrate that physiological and supraphysiological increase of IGF-1 have no effect on renal haemodynamics. Only pharmacological levels of growth hormone-induced IGF-1 appear to modify renal haemodynamics. These casts doubts on the role of IGF-1 in the pathophysiology of renal disfunction in diabetics.

2017

URINARY HEPARAN SULFATE IN NORMOALBUMINURIC DIABETIC PATIENTS. Bonavita CD, Elbert A, Paglione AM, Bragagnolo J, Mainetti H, Ruiz M, Clinical Biochemistry Depart.Faculty of Pharmacy and Biochemistry. Diabetology Division . Hospital de Clinicas. Buenos Aires. Argentina.

The decrease of the heparan sulfate (HS)in the glomerular basal membrane was described as a lesion in diabetic nephropathy. This decrease should be produce by less synthesis because of the deficient action of the N-Glusaminil Deacetilase enzyme or the lost of the HS by the increase in the catabolism or in excretion. We compare the urinary HS excretion in normoalbuminuric diabetics and in a control group. We studied 42 diabetics :17males (6IDDM, 11NIDDM, age range 20-83 years), and 25 females (6 IDDM,19NIDDM, age range 17-83 years). We compared with a control group: 12 males(age range 25-76years)and 12 females (age range 18-73years). The urinary HS dosage was done by a precipitation with Br-Cetiltrimetilamonio, hydrolisis and quantification of glycosamine by the Smith-Gilkerson reaction. The results obtained (expressed in mg. of glycosamine/24 hours) were:

	Diabetics (mean ±SD)	Controls (mean ±SD)
Males	0.93 ± 0.50*	0.43 ± 0.16
Females	0.55±0.31#	0.28±0.17^

***vs Male controls P<0.001,#vs. Females controls P<0.001,^vsMales controls**

Conclusions: 1. Males excrete more urinary HS than females,

2. Diabetics excrete more urinary HS than controls

2018

INCREASED ACTIVITY OF GLOMERULAR CYTOSOLIC PHOSPHOLIPASE A2 IN NIDDM RATS. Y. Furuya, S. Tagami, H. Yoshimura, T. Horida, S. Sakaue, K. Aoki, J. Ishii, A. Hasegawa, J. Hirokawa and Y. Kawakami. First Department of Medicine, Hokkaido University, Sapporo, Japan.

Cytosolic phospholipaseA2 (cPLA2) is a rate-limiting step in eicosanoid biosynthesis and is potentially involved in glomerular hyperfiltration which leads to diabetic nephropathy. In an attempt to clarify the temporal relationships of plasma levels of glucose, the activity of glomerular cPLA2, creatinine clearance and histological changes in glomeruli, we used Otsuka Long Evans Tokushima Fatty (OLETF) rats that spontaneously develop NIDDM. Groups of 5-6 OLETF rats were compared to control rats at the ages of 8, 30 and 46 weeks. The plasma level of glucose was significantly higher in OLETF rats than in control rats at 30 and 46 weeks of age (OLETF vs. control; 160±28 vs.111 ± 11, 201 ± 91 vs.109 ± 21 mg/dl, respectively). Although pathological changes in glomeruli of OLETF rats appeared only at 46 weeks of age, the activity of cPLA2 was significantly higher in OLETF rats than in control rats at 30 weeks (2138±502 vs.1297±199 dpm, $p<0.001$), but not at 46 weeks. The creatinine clearance had a tendency to increase again only at 30 weeks in OLETF rats. Furthermore, the activity of cPLA2 at 30 weeks had significant correlations with plasma levels of glucose ($r=0.67$; $p<0.01$) and with creatinine clearance ($r=0.52$; $p<0.05$) in OLETF rats. We then conducted an additional in vitro experiment using mesangial cells and found that cells cultured with a high concentration (27.5 mM) of glucose for 5 days exhibited a marked increase in the activity of cPLA2 compared to those cultured with a physiologic concentration of glucose (1473±391 vs. 742±251 dpm, $p<0.01$). These data suggest that increased activity of glomerular cPLA2 and glomerular hyperfiltration occur prior to the development of morphological changes in OLETF rats, presumably due to an elevation in the plasma level of glucose.

2019

RELATION AMONG GLOMERULAR BARRIERS, TUBULAR PROTEINS AND PROGNOSIS OF DIABETIC NEPHROPATHY. M.Satoh, N.Kunii, K.Manome and K.Izumi.Fukushima workmen's compensatory hospital. Fukushima, Japan.

This study was performed to clarify the relation between glomerular basement membrane (GBM) and tubular derangements and prognosis of diabetic nephropathy . In 49 patients with NIDDM, clearances of creatinine (Ccr), IgG (CIgG) and transferrin (Ctrf), urinary excretion of albumin (UAE), N-acetyl-β-D-glucosaminidase (NAG) and β_2-microglobulin (β_2MG) were examined. These patients were followed 24 months. Twenty subjects were examined as control. In diabetics, mean Ccr 92.4, CIgG 15.7 x 10^{-4} , Ctrf 102.3 x 10^{-4} ml/min, UAE 103.3 mg/g cr., NAG 4.1 U/l, β_2 MG 524.3 mg/l and CIgG/Ctrf ratio was 1.12. Renal function was deteriorated in 7 diabetics. In these cases, UAE, NAG * and β_2 MG were elevated. Ctrf*, CIgG/Ctrf ratio* were decreased and CIgG was elevated (*:P<0.05). In poor prognostic diabetic nephropathy, derangement of size barrier and selectivity of GBM is prominent. Charge barrier is also destructed, however, mechanisms of urinary excretion of trf and IgG may be not identical. Tubulointerstitial damage will disturb renal function.

2020

HIGH GLUCOSE-INDUCED TRANSFORMING GROWTH FACTOR ß1 PRODUCTION IS MEDIATED BY THE HEXOSAMINE PATHWAY

Verena Kolm[1], Ulrich Sauer[1] and E. D. Schleicher[2]
[1]Institute for Diabetes Research, München, Germany
[2]Department for Internal Medicine, Endocrinology and Pathobiochemistry, Tübingen, Germany

Previous studies revealed that exposure of mesangial cells to high glucose concentrations induces the production of matrix proteins mediated by transforming growth factor ß1 (TGF-ß1). It was the aim of our study to elucidate the molecular mechanism by which elevated glucose levels induce TGF-ß1. Production of matrix proteins and TGF-ß protein was tested by ELISA. Bioactive TGF-ß was determined by the antiproliferative activity in the mink lung epithelial cell assay. Expression of TGF-ß1 was estimated by non-radioactive *in situ* hybridization. First, we tested if structural analogues of D-glucose may mimic the high glucose effect in cultured mesangial cells. We found that D-glucosamine was strikingly more potent than D-glucose itself in enhancing the production of TGF-ß protein and subsequent production of the matrix components heparan sulfate proteoglycan and fibronectin in a time- and dose-dependent manner. Since neutralizing antibodies to TGF-ß abolished the glucosamine-induced effects on mesangial matrix production glucosamine act through induction of TGF-ß. D-glucosamine also promoted conversion of latent TGF-ß to the active form. Therefore, we suggested that the hexosamine biosynthetic pathway the key enzyme of which is glutamine: fructose-6-phosphate amidotransferase (GFAT) contributes to the high glucose-induced increase in TGF-ß1 production. Inhibition of GFAT by the substrate analogue azaserine or by inhibition of GFAT protein synthesis with antisense oligonucleotide prevented the high glucose-induced increase in TGF-ß1 expression and bioactivity and subsequent effects on mesangial cell proliferation and matrix production. Overall, our study indicates that the flux of glucose metabolism through the GFAT catalyzed hexosamine biosynthetic pathway is involved in the glucose-induced mesangial production of TGF-ß leading to increased matrix production.

GLOMERULAR FILTRATION OF IMMUNOGLOBULINS ALTERS THE PATTERN OF TUBULAR FUNCTION IN DIABETIC PATIENTS WITH NEPHROPATHY. S.B.Solerte,M.Fioravanti,S.Severgnini,N.Cerutti,M.A.Netti, M.Locatelli and E.Ferrari , Department of Internal Medicine University of Pavia,Piazza Borromeo 2,27100 Pavia(Italy)

A role of tubular component in the mechanism of proteinuria is not excluded in diabetic patients with nephropathy. In this context,the tubular marker $\alpha_1$microglobulin(UM) was evaluated(by nephelometry)in relation to the urinary excretion rates of albumin(UAER),IgG(UIgGER)and IgA(UIgAER) and to glomerular filtration rate(GFR,51-Cr EDTA)in diabetic patients without nephropathy(NNDP,n=97) and with incipient (INDP,n=45)and overt nephropathy(ONDP,n=26).Urinary UM was below the upper normal limit(10 mg/L)in NNDP and hyperfiltering normoalbuminuric patients(7±1.2 SD mg/L and 6.7±1.1 mg/L).Fifteen INDP(34%)showed UM in normal limits,whereas 30 INDP(66%)presented UM above 10 mg/L;the highest UM values were associated to UAER>50 ug/min and to UIgGER>11 ug/min. Lower UIgGER(<9 ug/min)was found in INDP with normal UM, than in INDP with UM>10 mg/L. All ONDP showed UM above 10 mg/L(mean=30±9 mg/L);the highest UM values were associated to UIgAER>40 ug/min and to UIgGER>150 ug/min. No significant correlations among UM,GFR and glycated haemoglobin levels were found in the three groups of patients.A tubular component of proteinuria might be suggested in overt nephropathy and in the late stage of incipient nephropathy. In particular,the tubular overload of filtered immunoglobulins might be associated with the progression of proteinuria and of renal microangiopathic derangement.

2022

COMPARISON OF THE EFFECTS OF AMINOGUANIDINE, ENALAPRIL, VITAMIN C AND VITAMINS C+E COMBINATION ON DIABETIC NEUROPATHY AND NEPHROPATHY IN STREPTOZOTOCİN-DIABETIC RATS

M. Özata[1], O. Yıldız[2], S. Şenöz[2], Y. Kütükçü[3], A. Aydın[3], A. Çorakçı[1], A. Işımer[2] and M.A. Gündoğan[2]. Dept. of Endocrinology and Metabolism[1], Medical Pharmacology[2] and Neurology[3] Gülhane School of Medicine, Ankara, Turkey

The effects of aminoguanidine (AG), enalapril (ENA), vitamin C (VITC) and vitamins C+E combination (VITC+E) on diabetic neuropathy and diabetic nephropathy was compared in streptozotocin- diabetic rats. For this purpose, 40 diabetic adult male Wistar albino rats that were randomly divided into five groups and 8 non-diabetic rats as a normal control group were selected for this study. After induction of diabetes, group 1 (n=8) was treated by the AG in the drinking water (500mg/L), group 2(n:8) was treated by ENA (50mg/L) in the drinking water, group 3(n:8) was treated by VITC (150mg/L) in the drinking water, group 4(n:8) was treated by vitamin C (150mg/kg) in the drinking water, plus vitamin E (500mg/kg) in normal rat chow for 4 months and group 5 (n:8) was a non-treated diabetic control group. Somatosensorial evoked potential (SEP) latency was measured by stimulating via caudal nerve and recording via cortex and nerve conduction velocity (NCV) was measured from caudal nerve every month. Urinary protein excretion and urine volume were also measured during the study. Moreover, fractional kidney weight (FKW) and, neural levels of TBARS were measured at the end of the study. Diabetes caused deficits in SEP and NCV ($p<0.05$ vs. non-diabetic control rats, respectively). All treatment modalities restored SEP latencies ($p<0.05$ vs. non-diabetic control group),but most significant improvement was observed in VITC+E treated group. VIT C and especially VITC+E and AG restored NCV during the study, but ENA has no effect on NCV. FKW was found to be significantly greater in diabetic-control-, VITC-, and VITC+E- treated groups when compared to in normal control group ($p<0.05$). However, slight , but not significant, decrease in FKW was detected in ENA- and AG-treated groups. Neuronal TBARS levels were decreased in all groups but not in ENA-treated group. The most significant decrease in urinary protein excretion and urine volume was found in ENA- and AG- treated groups ($p< 0.05$ vs. diabetic control group). Weight and the glucose level were not influenced by the treatments. Our results suggest that VITC and especially VITC+E combination , and AG have beneficial effects on both central and peripheral neuropathies, but ENA has beneficial effects only on central neuropathy. Moreover, ENA and AG are more effective treatment than VITC and VITC+E for diabetic nephropathy. These beneficial effects are not associated with the regulation of glicemia, but may be related in part with prevention of lipid peroxidation.

URINARY ENZYMES AS A MARKER OF TUBULOINTERSTITIAL CHANGES IN NIDDM AND IGT SUBJECTS

RMA Roesli*, AL Arifin*, SHK Kariadi*, MM Elseviers** and ME De Broe**, I De Leeuw**. University Padjadjaran,Bandung Indonesia*. University of Antwerp, Belgium**.

It is proposed that tubulointerstitial changes due to peritubular microangiopathy may even predate glomerular changes in diabetic patients. Several urinary-enzymes have been used as marker of tubulo epithelial damage. N-acetyl-β-D-glucosaminidase (NAG) is the most commonly used marker. More specific tubular markers have been developed by the University of Antwerp, Belgium, which are human-intestinal-alkaline-phosphatase (h-IAP), restricted to the brush border of the S3 segment, and tissue-non-specific-isoenzyme (TNAP) ,excreted mainly in the S1 and S2 tubular segments. The purposes of this study was to identify the role of NAG, h-IAP and TNAP in detecting early tubulointerstitial changes in NIDDM , IGT and normal-glucose-tolerance subjects. 176 NIDDM and 108 IGT subjects whose diagnosis was confirmed with Oral-Glucose-Tolerance-Test (OGTT), participated in this study. To obtain a general picture of the basic values in the population, 53 participants living in the same area who have a normal glucose tolerance after OGTT were used as the *control group*. The urinary enzyme assays were performed on second morning urine samples. The values of the urinary enzymes (h-IAP,TNAP and NAG) were corrected to creatinine urine (U/gram creatinine). The mean values and 95% of confident interval in Control, IGT and NIDDM for h-IAP(U/g) were 1.07(CI=0.64-1.51), 1.68(CI=1.31-2.04), 2.61(CI=2.09-3.14) respectively, for NAG(U/g) were 3.65(CI=3.06-4.2), 5.94(CI=5.35-6.54), 10.7(CI=8.69-12.7), respectevely whereas for TNAP(U/g) were 1.49(CI=1.26-1.69), 0.19(CI=0.06-0.31), 1.15(CI=0.65-1.48) respectively. It is clearly shown that the mean values of h-IAP and NAG increased in a stepwise pattern from the lowest value in the control group to the highest value in the NIDDM group, wheras TNAP did not follow this pattern. The percentage of subjects with high h-IAP increased from 11.3% in the control group to 21.3% in the IGT group and to 40.3% in the NIDDM group. The NAG showed a more prominent stepwise pattern which were 15.1%, 50.9% and 72.3% respectively. On the other hand, the TNAP did not follow this pattern. There are not sufficient references to explain the correlation between the levels of glucose tolerance and h-IAP and NAG. However, glucose tolerance states reflects insulin resistancy and blood glucose levels. It can be speculated that the tubulointerstitial changes,specifically the S3 segment, which was shown by the increases of h-IAP and NAG assay, are associated with the glucose tolerance status of the patient.

2024

PROGRESSION OF NEPHROPATHY IN SPONTANEOUS DIABETIC RATS IS PREVENTED BY OPB-9195, A NOVEL INHIBITOR OF ADVANCED GLYCATION.

S.Nakamura, Z.Makita, S.Ishikawa*, K.Yasumura*, W.Fujii, K.Yanagisawa, T.Kawata and T.Koike. Dept. of Med. II, Hokkaido Univ. Sch. of Med., Sapporo and *Otsuka Pharmaceu. Co., L.T.D., Otsu, JAPAN

Irreversible advanced glycation endproducts (AGEs) formation is considered to be a factor contributing to the complications of diabetes. OPB-9195, a novel inhibitor of advanced glycation, effectively inhibited AGEs-derived cross-linking and the formation of AGEs in dose-dependent manner in vitro. To evaluate the therapeutic effect of OPB-9195, we investigated the pathological findings of kidneys as well as serum levels of AGEs in spontaneous diabetic rats, Otsuka-Long-Evans-Tokushima-Fatty (OLETF) rats. OLETF rats were randomized into a non-treated group (n-Tx: n=12) and OPB-9195-treated group (Tx: n=12). OPB-9195 had been administrated to Tx rats from 24 weeks of age, and the rats in the two groups were killed at 24, 44 and 56 weeks of age. Serum levels of AGEs in Tx were significantly lower than those in n-Tx at 44 and 56 weeks of age (5.3±0.6 v.s.10.0±2.5, 6.9±0.9 v.s.15.1±2.0U/ml, P<0.01). PAS-positive nodular lesions and exudative changes that were present in n-Tx sections at 56 weeks of age were practically nil in Tx sections, and the percentage of sclerotic glomeruli was significantly ameliorated in Tx at 44 weeks of age in microscopic examination (3.1±1.0 v.s. 9.7±4.1%, P<0.05). Sclerosis index and urine albumin excretion were also significantly lower in Tx than those in n-Tx even at 56 weeks of age (0.54±0.01 v.s. 0.71±0.01, 7.5±6.2 v.s.18.6±4.8mg/mgCr, P<0.05). Immunohistochemical staining of AGEs deposition in glomeruli of Tx was markedly diminished compared to n-Tx at 56 weeks of age. In conclusion, OPB-9195 prevents the progression of diabetic nephropathy by lowering serum levels of AGEs and attenuating AGEs deposition in glomeruli in OLETF rats.

2025

ELEVATED URINARY ENZYMES LEVELS ASSOCIATED WITH HIGH BLOOD GLUCOSE LEVELS

AL Arifin*, RMA Roesli*, SHK Kariadi*, A Meheus** and ME De Broe**, I De Leeuw**. University Padjadjaran,Bandung Indonesia*. University of Antwerp, Belgium**.

Diabetes mellitus and the associated glycosuria may lead to tubular dysfunction. The excretion of urinary enzymes such as N-acetyl-β-D-glucosaminidase (NAG) and other proteins may be increased early in the diabetic process and be independent of the excretion of albumin. Recently, studies on alkaline phosphatase, which are ectoenzyme localized on the brush border of proximal tubular cells, have given promising results as markers of early tubular involvement. Human-Intestinal-alkaline phosphatase (hIAP) is exclusively localized in the S3-segment while tissue-non specific isoenzyme (hTNAP) is present all along the proximal tubule. The purposes of this study was to identify the increase of NAG, h-IAP and TNAP levels in association with high glucose levels. 176 NIDDM , 108 IGT and 59 subjects whose diagnosis was confirmed with OGTT, participated in this study. Regardless of their diagnosis or treatment they were classified according to their fasting blood glucose of 80-120, 120-140,140-200 and > 200 mg/dl, and 2 hours after glucose load blood sugar levels of 80-160, 160-180, 180-240, and >240 mg/dl. The cut-off points for the elevated urinary enzymes levels were: IAP ≥ 2 U/gr creatinine, NAG ≥ 5 U/gr creatinine and TNAP ≥ 2.5 U/gr creatinine. This study revealed that the higher the blood glucose level is associated with higher percentage of subjects with high urinary enzymes, as can be seen in this following table.

Elevated Urinary Enzymes	FASTING BLOOD SUGAR <120 n=205	120-140 n= 30	140 - 200 n =47	> 200 n=61	2-HOURS AFTER LOAD <160 n=93	160-180 n=38	180-240 n=87	>240 n=123
IAP %	19.5	26.7	42.6	57.4	11.8	28.9	32.2	50 5
NAG %	41	66.7	80.9	86.9	31.2	36 8	60 9	78.9
TNAP %	3.9	13.3	19.1	36.1	4.3	5.3	5.7	25 2

It can ,therefore, be speculated that the renal tubular cells, specifically the S3 segment is impaired ,which associated to high blood glucose levels.

2026

RENAL PROTECTIVE EFFECT OF PERINDOPRIL IN EXPERIMENTAL DIABETIC RATS

YF Liu, CY Pan AND JM Lu. Dept. of Endocrinology, General Hospital of PLA, Beijing China

The purpose was to observe the renal protective effect of perindopril in STZ-induced diabetic rats. Methods: the blood glucose levels were maintained > 16.7mmol/L in 64 diabetic rats. The DP group (n=32) was treated with perindopril (1mg/Kg/d) and the DC group (n=32) was was diabetic control. 20 rats were normal controls (NC group) . 24h urinary protein excretion (PRO) were measured at 1, 3, 6 months, The left kidneys were processed for morphological examination. Mean glomerular plana area (MGPA), mean glomerular volume (MGV) were calculated using sterological method. Results: during the study, PRO in both diabetic groups were higher than that of DC group. At 6 month, proteinuria in DP group was decreased remarkedly (DC and DP vs NC: P<0.01, respectively, DC vs DP: P<0.05). After treatment, the MGPA and MGV in DP group were smaller significantly than that of DC group (MGPA: DC 7351.1 ±167.5, DP: 6828 ±159.5um², P<0.01, MGV: DC 814.7 ±26.9, DP: 706.45 ±25.1 um³, P<0.01). DC and DP group showed significant mesangial expansion, glomerular basement membrance (GBM) thickness and fusion of epithelial cell foot process, But thickness of GBM were alleviated to a certain extent in DP group. Conclusion: perindopril could decrease proteinuria and alleviate the pathological changes of kidney in diabetic rats.

2027

URINARY EXCRETION OF PANCREATIC STONE PROTEIN IN DIABETIC NEPHROPATHY

H. Sobajima, T. Niwa, S. Naruse, M. Kitagawa, and T. Hayakawa
Ogaki Municipal Hospital, Ogaki and Nagoya University, Nagoya, Japan.

Urinary pancreatic stone protein (PSP) levels were measured in 68 diabetic patients and 170 healthy controls to investigate the relationship between the progression of diabetic nephropathy and PSP excretion. Urinary albumin, N-acetyl-β-glucosaminidase (NAG), α1-microglobulin, creatinine clearance, and the blood PSP level were also determined in the diabetic patients. The urinary glucose level and glycemic control did not influence the urinary PSP level. In patients with normoalbuminuria (urinary albumin < 20 mg/gCr, n=31), microalbuminuria (20-200 mg/gCr, n=19), and macroalbuminuria (>200 mg/gCr, n=18), the mean urinary PSP level was 347, 507, and 860 μg/gCr, respectively. These levels were significantly higher than the level in normal volunteers (168 μg/gCr, $p<0.01$). A significant positive correlation was observed between the urinary PSP level and the NAG or α1-microglobulin levels ($p<0.01$). There was a stronger correlation with α1-microglobulin. Blood PSP levels were also elevated in patients who had renal impairment with a decreased creatinine clearance. In conclusion, urinary PSP excretion was increased from the initial stage of diabetic nephropathy and this increase became more marked as nephropathy progressed. Increased PSP excretion may reflect renal tubular dysfunction.

2028

RENAL IMPAIRMENT AND PATHOLOGY ARE PREVENTED BY PERINDOPRIL TREATMENT IN DIABETIC TRANSGENIC REN-2 RATS.

DJ. Kelly, JL. Berka, TJ. Allen*, ME. Cooper* and SL. Skinner. Departments of Physiology and Medicine*, University of Melbourne, Parkville, Australia.

Diabetic microvascular disease responds readily to angiotensin converting enzyme inhibition suggesting that an amplified tissue renin-angiotensin system (RAS) may be causative in diabetic pathology. The transgenic (TG) Ren-2 rat which by phenotype exhibits enhanced tissue renin and high plasma prorenin provides an opportunity to test this hypothesis. Six week old female, Sprague-Dawley (SD) and heterozygous TG rats were given either streptozotocin (STZ, 55 mg/kg) or citrate buffer (control) by tail vein injection and sacrificed at 4(SD,TG), 12(TG) and 24(SD) weeks. A further group of diabetic TG received perindopril (P, 2mg/L) in their drinking water for 12 weeks. Plasma glucose (diabetic >18mmol/L) was measured weekly. Systolic BP in 12 week TG rats was unchanged with diabetes (229±7mmHg) but decreased to normotensive levels with P (149±11mmHg). Body weights of diabetic rats and diabetic + P were significantly lower than controls ($p<0.01$). Plasma electrolytes were normal except in 12 week diabetic TG rats which were hyperkalaemic (6.7±0.3 mmol/l). Renal impairment was apparent in these diabetic TG rats and was corrected by P; GFR fell from 3.5±0.1 to 1.6±0.3 ml/min ($p<0.05$), while with P the decline was largely prevented (2.4±0.2 ml/min, $p<0.05$). Albumin excretion rate (AER) was elevated with diabetes (0.3x/÷1.4 to 1x/÷1.4mg/24 hours, $p<0.05$) but ameliorated with P (0.7x/÷1.3mg/24 hours). In 12 week diabetic TG kidneys, but not controls, glomeruli displayed twice as much sclerosis (glomerulosclerotic index, $p<0.01$), tubules were vacuolated and contained glycogen and efferent arterioles were hyalinized. In kidney medulla, interstitial fibrosis and inflammatory cells were present and tubules were dilated and degenerated. These changes were markedly reduced with P. At 12 weeks, diabetic TG kidneys displayed increased renin immunolabelling in juxtaglomerular cells (JG) compared with controls or diabetic SD, and renin was also present in the cytoplasm of proximal tubules. With P, renin immunolabelling in JG cells was more intense while it disappeared from proximal tubules. Plasma total renin collected from the tail vein of conscious diabetic SD and TG rats was unchanged despite an increase in kidney renin content in diabetic TG from 4 to 12 weeks (0.52±0.1 to 2.1±0.68GU/kidney, $p<0.01$). The TG Ren-2 rat displays rapid onset diabetic renal impairment with florid glomerular and tubulointerstitial pathology. The preservation of renal function and structure with perindopril provides further evidence that the renal RAS is related causally to the development of severe diabetic renal disease.

2029

INCREASED URINARY EXCRETION OF BIOLOGICALY ACTIVE TUMOR NECROSIS FACTOR α IN DIABETIC NEPHROPATHY.

G.Winkler (1), F. Salamon (2), I. Szilvási (3), D. Salamon (3), G. Speer (3), I. Karádi (3), L. Romics (3) and K. Cseh (3). 1st Department of Medicine (1), 2nd Department of Medicine (2), St. John Hospital, 3rd Department of Medicine, Semmelweis University (3), Budapest Hungary.

In a follow up study of 9 months we investigated the diagnostic value of TNFα in diabetic microangiopathy (samples obtained in intervals of 6 weeks). Plasma and urinary TNF bioactivity were detected by using the L929 cell cytotoxicity assay in the following groups. 59 patients with NIDDM (group 1), 16 patients with IDDM (group 2) and 30 matched healthy controls (group 3). Recombinant human TNFα (Sigma) served as a standard. Monoclonal neutralizing TNFα antibody (Boehringer) was applied to detect the TNFα cytotoxicity in the samples. A significant elevation of the plasma TNFα levels was observed both in NIDDM and IDDM patients with diabetic microangiopathy (retino-, nephro-, neuropathy, alone or in combination, TNFα concentration x±SE pg/mL group1: 139±21, group 2: 95±19) as compared to group 3 (22±8) or to the patients of group 1 (62±9) and group 2 (27±7) without microangiopathy. The urinary TNFα bioactivity was detectable only in diabetic nephropathy (microalbumin excretion >30mg/day, TNFα x±SE in group 1 and 2: 24±3 pg/mL) as compared to patients without nephropathy and controls (below the detection limit). According to our observation, TNFα may play a role in the pathophysiology of diabetic microangiopathy. Urinary TNFα bioactivity can serve as a diagnostic marker for diabetic nephropathy.

ALOND® REDUCES HIGH URINARY ALBUMIN EXCRETION BUT NOT BLOOD PRESSURE IN CONSCIOUS DIABETIC RATS.

P. Oates and C. Ellery. Pfizer Inc, Central Research Div., Groton, USA.

Aldose reductase inhibitor (ARI) zopolrestat (Alond®) (AL) reduces elevated urinary albumin excretion (UAE) in non-insulinized diabetic rats (e.g., *Pharmacology,* 52:292, 1996) by a mechanism that is unknown. The present aim was to determine if an AL dose effective vs. UAE alters 24-hr mean arterial blood pressure (MAP), a potentially important determinant of UAE, in conscious chronically diabetic rats. Radiotelemetry pressure units (Data Sciences International) were surgically implanted in ~160 g SD rats. After 12 days, streptozocin (STZ)-diabetes was induced, and MAP was monitored continuously in unrestrained rats for 15 weeks. AL (~100 mg/kg bw) was added to the diet at ~12 weeks and was removed from the diet at ~14 weeks, with monitoring continued for 1 more week. Results: During 12±2 weeks of untreated diabetes, 24-hr MAP gradually declined from ~100 mm Hg to a stable baseline of 84.7±7.7 mm Hg (N=13 rats), the average (avg) of the 7 days preceding AL treatment. Addition of AL to the diet had no detectable effect on MAP, either initially or during 14±4 days. That is, avg MAP on AL was 84.9±7.4 mm Hg; ΔMAP vs. preceding 7-day baseline = +0.2±2.5 mmHg (NS, paired t-test, N=13). When AL was discontinued, MAP the following week was unchanged, 84.4±8.0 mm Hg; ΔMAP vs. preceding time on AL = -0.5±3.7 mmHg (NS, N=13). We conclude: 1) Arterial hypotension develops in chronic non-insulinized STZ diabetic rats; 2) under conditions previously described where ARI AL reduces UAE, AL has no detectable effect on systemic MAP; therefore 3) it is likely that AL reduces UAE independently of any effect on systemic MAP, most likely by normalizing renal microvascular pressure, flow, and/or capillary permeability.

Diagnostic Significance of Urinary Immunoglobulin G in Diabetic Nephropathy

Yashima,I., Hirayama,T.,Yamada,H.,Kanauchi,M.,and Dohi,K.,Japan

We evaluated the diagnostic utility of urinary immunoglobulin G (IgG) in patients with diabetic nephropathy by comparing findings with those of renal biopsy speciments. A total of 55 diabetic patients were divided into 4 groups, D_0, D_I, D_{II} and D_{III-IV} according to the severity of diffuse glomerular lesions using Gellman's criteria. Twenty-five non-diabetic volunteers were used as controls. Using 24-hour urine specimens, IgG was measured by an enzyme-linked immunosorbent-assay (ELISA). In addition, urine samples were assayed for albumin, α_1-microglobulin, β_2-microglobulin and N-acetyl-β-D-glucosaminidase. The urinary excretion of IgG was significantly increased in diabetic patients as compared with the healthy controls. Among diabetic patients, IgG excretion was significantly higher in the D_I, D_{II} and D_{III-IV} groups than in the D_0 group, and in D_{III-IV} when compared to either D_I or D_{II}. Urinary IgG levels above the 95 percentile for healthy controls indicate the presence of significant urinary IgG levels. Diabetic patients showing the significant urinary IgG were significantly increased in D_I and D_{II} groups compared to those showing microalbuminuria. There was no correlation between the IgG excretion and other laboratory indices evaluated. These findings indicate that urinary IgG may be useful in detecting the early stage of diabetic nephropathy.

2032

AN ALDOSE REDUCTASE INHIBITOR (EPALRESTST) PREVENTS GLUCOSE-INDUCED UP-REGULATION OF TGF-β IN CULTURED HUMAN MESANGIAL CELLS

H. Ishii, H. Tada, H. Kawai and S. Isogai, Toho University School of Medicine, Tokyo, Japan.

TGF-β has been thought to be a key factor in the pathogenesis of diabetic nephropathy. This study was performed to clarify the effect of epalrestat (EP), an aldose reductase inhibitor, on glucose-induced up-regulation of TGF-β in cultured human mesangial cells (MCs). Human MCs were cultured with RPMI-1640 medium supplemented with 5 and 33 mmol/l glucose in the presence or absence of 10^{-5} mol/l EP. TGF-β secreted into the medium was measured by ELISA. The amounts of fibronectin in the medium and cell layer were also determined by ELISA. Protein kinase C (PKC) activities in the cytosolic and membrane fractions were measured by a electrophoresis method using a fluorescent protein substrates. The amount of TGF-β was greater in 33 mmol/l glucose than that in 5 mmol/l glucose. The production of fibronectin was simultaneously enhanced by a high concentration of glucose. The increases in both TGF-β and fibronectin were completely prevented by the addition of EP to high glucose media. PKC activities were increased in membrane fractions of MCs exposed to high glucose media. Increased PKC activities in membrane fractions were also abolished by EP. These results indicate that EP prevents glucose-induced up-regulation of TGF-β, presumably by suppressing PKC activation in human MCs.

2033

DIRECT ASSAY OF URINARY TYPE IV COLLAGEN IN DIABETICS WITH A SENSITIVE ENZYME IMMUNOASSAY

S. Ohgaku, M. Fujikawa, T. Asahi, Y. Hirai, M. Kobayashi and Obata*, Toyama Medical and Pharmaceutical University, Fuji Chemical Industries, Ltd*. Toyama, Japan

Aim. In order to evaluate clinical significance of urinary type IV collagen (uCL-IV) in diabetic nephropathy, we have developed a sensitive enzyme immunoassay (EIA). Methods. Concentrations of uCL-IV were directly determined with a one-step sandwich EIA, utilizing two monoclonal antibodies to different sites of human type IV collagen. 142 diabetics were divided into 4 groups according to renal functions. Group I normoalbuminuria n=76, Group II microalbuminuria n=31, Group III overt albuminuria n=18, Group IV chronic renal failure n=17. Urinary transferrin , α1-microglobulin , β2-microglobulin were also determined. Results. Concentrations of uCL-IV (mg/gCreatinine, Mean $\pm$ SD, reference value below 3.74) in group I, II, III and IV were 3.43 $\pm$ 3.81, 12.3 $\pm$ 30.1, 16.5 $\pm$ 17.9, 36.3 $\pm$ 21.5, respectively ($p<0.01$ between every two group by unpaired t-test).
Conclusion. The evaluation of uCL-IV by direct assay gives information on the activity of structurally altering glomerular processes, and will contribute to better management from the early stage of diabetic nephropathy.

2034

COMPLICATIONS IN A NON-HUMAN PRIMATE MODEL OF IDDM AND THE EFFECTS OF AMINOGUANIDINE.

A Birrell[1], S Heffernan[2], S Scott[2], A Ansselin[3], D Church[4], A Gillin[1] and D Yue[2], The Departments of Endocrinology[2] and Renal Medicine[1], RPAH, Camperdown, 2050 and The Departments of Veterinary Science[4] and Physiology[3], The University of Sydney, 2052.

Aminoguanidine (AG) affects the formation of advanced glycated endproducts and nitric oxide which are thought to alter cellular function in diabetes. The aim of this study was to assess diabetic complications and the effects of AG in a non-human primate model of diabetes. Twenty-five male baboons (*Papio hamadryas,* 8 diabetic, 5 AG treated diabetic, 5 AG treated control and 7 control) were used in this study. The motor and sensory nerve conduction velocity (MNCV, SNCV) were measured using standard recording techniques and presented as % change from the mean value of the age-matched controls. Renal function was measured by glomerular filtration rate (GFR, ^{3}H-inulin). Glomerular basement membrane (GBM) thickness and mesangial volume (MV) were determined by morphometry at yearly biopsies.

	HbA1c	GFR	GBM	MV	MNCV	SNCV
	%	ml/min/kg	nm	%	%	%
Control	4.9±0.7	2.0±0.2	387±10	18±2	-	-
IDDM	8.9±0.3*	2.8±0.6*	444±73*	20±3	-16.3*	-8.4
IDDM/AG	11.2±0.5*	-	-	-	-20*	-6.7
Control/AG	4.4±0.5	-	-	-	-6.1	+4.2

* Significant at $P < 0.05$ level using analysis of variance with Bonferroni test. Renal structural and functional changes occur early in baboons with IDDM. Treatment with AG did not abolish slowing of the nerve conduction velocity. The results of other parameters in the AG treated animals are pending. THE EPITHELIAL SODIUM-POTASSIUM CHANNEL GENE (ENaC) IN RELATION TO HYPERTENSION AND DIABETIC NEPHROPATHY

O. Melander[1], M. Orho[1], K. Bengtsson[2], J. Fagerudd[3], P.H. Groop[3], U.L. Hulthén[1] and Leif Groop[1]. Dept. of Endocrinology, Lund University, Malmö, Sweden[1], Primary Health Care Centre in Skara, Skaraborg Institute, Sweden[2] and Helsinki University Hospital, Finland[3]

ENaC consists of three subunits (α, β and γ), and is expressed in the distal convoluted tubules in the kidney. We and others have found mutations in the gene coding for the C-terminal parts of the β and γ subunits of ENaC in patients with Liddle's syndrome which is characterized by hypokalemic hypertension with low renin and aldosterone values because of endogenous hyperactivity of ENaC. In this study we tested whether the gene is involved in the developement of primary hypertension (HT) or diabetic nephropathy (DN) as salt retention has been suggested to play a major role in the pathogenesis of these disorders. The C-terminal parts of the β- and γ-subunit genes were screened for polymorphisms using SSCP and DNA sequencing in 105 Swedish HT patients (64 males/41 females, age 55.7±14.1y, BMI 27.6±4.5kg/m^2, SBP 149.8±18.4mmHg, DBP 88.3±10.8 mmHg) and in 20 Finnish IDDM patients with overt DN(10m, 10f)/50 NIDDM patients with incipient or overt DN (20m/30f, age 68.3±11.7y, BMI 28.5±5.2kg/m^2, AER 199.4±525.6μg/min). All the HT patients were on antihypertensive medication. Incipient DN was defined as AER>20μg/min and overt DN as AER >200μg/min. 109 Swedish normotensive subjects (60m/49f, age 58.9±10.2y, BMI 25.5±3.3kg/m^2, SBP 126.7±14.7mmHg, DBP 74.3±8.7mmHg) and 80 Finnish nondiabetic subjects (42m/38f, age 59.7±8.5y, BMI 26.1±3.1 kg/m^2, AER 3.6±2.2μg/min) served as controls. In the γ-subunit, a common nonsense mutation was found in codon 650 (CTC->CTG). To test if this polymorphism is associated with HT or DN the genotype frequencies in the HT- and DN-groups were compared with the frequencies in the corresponding control groups. The genotype frequency distribution of the codon 650 polymorphism did not differ between HT patients (CC 65.7%, CG 33.3%, GG 1%) and control subjects (CC 66.0%, CG 31.1%, GG 2.8%) nor between the DN patients (CC 62.9%, CG 32.9%, GG 4.3%) and control subjects (CC 63.8%, CG 35.0%, GG 1.2%). Conclusions: We found a novel polymorphism in the ENaC gene which can be used for further studies evaluating the role of this gene in HT and DN. Preliminary studies did not find support for a role of the ENaC gene in HT or DN.

2036

DIABETIC NEPHROPATHY IN IDDM PATIENTS IN SPAIN. ESTUDIO DIAMANTE. Esmatjes E, de Alvaro F for the Spanish Diabetic Nephropathy Study Group.

The **aim** of this cross-sectional study was to establish the prevalence of renal involvement and to identify associations with its most impor-tant possible determinants in a large group of patients with IDDM.

Patients and methods 1822 patientes (50.5% males, mean age 30.5±9.7 years, diabetes duration 14.1±9.2 years) controled in Endocrinology Units of 18 spanish hospitals were studied. Urinary albumin excretion, plasma creatinine, lipid profile, HbA_{1c}, as well as, familiar history of hypertension and nephropathy tobacco consumption, arterial blood pressure and BMI was evaluated.

Results The prevalence of microalbuminuria, clinical nephropathy (macroalbuminuria + renal failure) and hypertension were, respectively 14.1%, 8.5% and 11.3%. Risk factors associated with greater renal affection were male sex (p=0.003), age (p=0.000), diabetes duration (p=0.0001), arterial hypertension (p=0.00000) BMI (p=0.012) and familiar history of nephropathy (p=0.0017). The prevalence of smokers (former+current) was higher in male patients with microalbuminuria (65%) and clinical nephropathy (68%) than in patients with normal renal function (54%, p<0.05). Moreover, HbA_{1c} (p=0.001), total colesterol (p=0.000) and triglycerides (p=0.000) levels were higher in renal affected patients.

Conclusions The prevalence of diabetic nephropathy Type 1 diabetics patients in Spain is similar to that observed in other european countries. The association between diabetic nephropathy and hypertension, lipid abnormalities, metabolic control and male sex is confirmed and tobacco consumption appears as an aditional risk factor to be consider in diabetes care.

2037

SODIUM-LITHIUM COUNTERTRANSPORT PREDICTS INCIDENT NEPHROPATHY IN WOMEN BUT NOT IN MEN WITH IDDM

Kimberly Y-Z Forrest, Clareann H. Bunker, Trevor J. Orchard, University of Pittsburgh, Pittsburgh, USA

Some but not all cross-sectional studies have suggested that sodium-lithium countertransport (NaLiCT) could be a useful marker for diabetic nephropathy. In this study we examined the ability of NaLiCT to predict the incidence of nephropathy in IDDM. Study subjects were from the Epidemiology of Diabetes Complications Study, an ongoing 10-yr prospective study of childhood onset IDDM. Participants were clinically examined at baseline and biennially thereafter. Microalbuminuria (MA) was diagnosed as an albumin excretion rate (AER) between 20-200 μg/min, and overt nephropathy (ON), AER >200 μg/min in 2 of 3 timed urine samples. NaLiCT was measured in 122 subjects who were free of MA, and in 237 subjects, free of ON at baseline, and who also provided 6 years followup data. During the 6 years, 32 (15 males) developed MA, and 16 developed ON (7 females). Mean (SD) (mmol Li/l RBC/hr) baseline NaLiCT by 6-yr incidence of nephropathy are shown in the table:

	MA-	MA+	ON-	ON+
Males	.39(.16)	.40(.08)	.40(.15)	.36(.06)
Females	.33(.10)	.46(.17)*	.39(.14)	.53(.19)†

* P = .02; † P=.05

NaLiCT was not significantly correlated with HbA_1 or IDDM duration, but positively correlated with triglycerides. Using .40 mmol NaLiCT as a cutoff, the rates of MA or ON were similar between low and high NaLiCT groups in males; however, in females, those with high NaLiCT showed an increased risk of developing MA or ON (43% vs. 19% for MA, p=.04; 15% vs. 3% for ON, p=.02). Multivariate analyses show that the independent predictors of MA are HbA_1, waist to hip ratio, and triglycerides for females, and HbA_1 for males; the independent predictors of ON are NaLiCT and hypertension for females, and hypertension for males. The results suggest that NaLiCT is a strong predictor of incident diabetic nephropathy in women but not men IDDM, and the association is independent of hypertension.

2038

ASSOCIATION OF NEUROCLINICAL AND ELETROPHYSIOLOGICAL FINDINGS AND MICROALBUMINURIA IN BRAZILIAN IDDM PATIENTS.

M.SKACEL,S.L.BALASSIANO,M.JARDIM,C.COHEN,G.R.SILVA JR AND M.B.GOMES - STATE UNIVERSITY OF RIO DE JANEIRO,RIO DE JANEIRO,BRAZIL

The aim of our study was to investigate the association between the neurological examination,eletrophysiological study (ES) and microalbuminuria (MICRO).The neurological symptoms were scored as present or absent.The tactil sensory testing was performed with the Semmes-Weinstein monofilaments.The vibratory and the pinpricking pain of the fingers and toes was scored as normal,decreased or absent.The reflexes were scored using the NIMDS Myothatic Reflex Scale.The eletrophysiological assessment were done on the Nihon Kohden-Neuropack2.The routine nerve sensory conduction(SC) studies were done on the median(M),radial(R),ulnar(U) and sural (S)nerves.The motor nerve conduction velocity(MC) were performed on the median and peroneal..From 52 IDDM patients (22male) aged 24.6±7.1 years with diabetes duration of 9.1 ± 6.1 years, 36 were submitted to the above examination and collected three timed overnight albumin excretion (OAER) on three non-consecutive days.Albumin concentration was determined by radio-immunoassay (DPC,LA).Micro (2 out of 3 OAER ≥ 20 ug/min and < 200 ug/min) was found in 6 (16,6%) and Normo in 30 (83,4%) . Statistical analysis was done by Mann-Whitney and Fisher exact test. Neurological symptoms were present in 12 (33%) patients, with no association with sex, HbA1c and systemic blood pressure, but was asssociated with smoking habit (p= 0.04).There is a association between the Micro and the presence of neurological signs and symptoms (p<0.05). The ankle reflex was absent in 26 (72,2%) ,8 (25%) had pinpriking anesthesia, and 3 (8,3%) tactil anesthesia. A decrease in SC on the right M and right U was observed in Micro vs Normo 46(0-51)vs 51(0-60) p=0.05, and 44(0-22)vs 50(41-64) p=0.05,respectively.The MC on the right M was decreased in Micro vs Normo 50(47-52)vs57(38-96) p=0.008 respectively.In conclusion neuropathy was associated with Micro and the SC and MC were more affected on the right side in this group of patients.

2039

ABNORMAL FUNCTION OF MULTIPLE MEMBRANE TRANSPORT SYSTEMS IN FAMILIES OF TYPE 1 DIABETICS.

E. Matteucci, C. Bertoni, E. Boldrini, F. Piazza, F. Ruberti, and O. Giampietro. Clinica Medica II, Pisa, Italy.

To search for recurrent features which distinguish type 1 insulin-dependent diabetes mellitus (IDDM) and its familiar background, we studied 52 type 1 diabetics (33±12 y; disease duration 14±9 y; 13 with microalbuminuria, 14 with retinopathy) and 54 parents of IDDM patients (55±9 y), 43 siblings (34±9 y), and 47 healthy control subjects (44±14 y, range 23-77) by measuring hemato-urinary analytes and erythrocyte Na/H antiport.

IDDM patients had higher Na/H antiport activity than healthy controls (8.10±3.25 vs 6.27±2.45 mmol/L h, $p<0.01$), apart from the presence of diabetic nephropathy; unexpectedly, retinopathic diabetic patients showed the highest exchange rates. Parents had overactive Na/H antiport (9.02±3.85 vs 6.94±2.20, $p<0.05$); except 6 of them, who had impaired glucose tolerance, remaining parents had 24 h-glycosuria lower than controls (0.4±1.5 vs 0.7±0.5 mmol/24h, $p<0.001$). Parents of retinopathics showed the highest exchange activity (10.39±3.88) associated with higher mean arterial blood pressure (101±6 vs 92±6 mmHg, $p=0.01$) than controls. Siblings had overactive Na/H exchange (8.41±3.60 vs 6.26±2.50, $p<0.01$) and lower urinary glucose output (0.2±0.5 vs 0.6±0.6, $p<0.001$); also urinary uric acid output, measured in 26 of them, resulted lower than in controls (2.5±0.8 vs 3.3±1.2 mmol/24 h, $p<0.05$).

We suggest the presence of a primary abnormality in Na/H antiport activity in families of IDDM patients, associated with secondary involvement of those transport systems which are influenced by transmembrane electrical/chemical H^+ gradient (such as glucose and urate uptake in the proximal tubule).

2040

Microalbuminuria and retinopathy among prepubertal children and post-pubertal Brazilian insulin dependent diabetic patients.

M.R.LUCCHETTI, E.CUNHA, F.GONÇALVES, R.NEVES and M.GOMES STATE UNIVERSITY OF RIO DE JANEIRO, RIO DE JANEIRO, BRAZIL.

The aim of our cross-sectional study was to determine the frequency and clinical variables associated with retinopathy and microalbuminuria(Micro) among prepubertal children(PPC) and post-pubertal(PPB) IDDM patients.For this purpose we have studied 78 IDDM patients (37 male) aged (mean±SD) 17.9 ±8.3 years with diabetes duration of 5.1±5.2 years. There were 64 PPB and 14 PPC which collected three timed overnight albumin excretion (OAER-10h) on three non-consecutive days. Albumin concentration was determined by radio-immunoassay (DPC,LA).Statistical analysis was performed by Fisher exact and Mann-Whitney tests and data were expressed as median(range).For stepwise multiple regression analysis OAER was log transformed. Mean intraindividual coefficient of variation for OAER was 60%. Micro (2 out of 3 OAER ≥20μg/min and <200μg/min) was found in 8 (10.3%) and normoalbuminuria (Normo-OAER<20μg/min) in 70 (89.7%) patients. Retinopathy was noted in 4(5.3%) and was more frequent in Micro than Normo patients, $p=0.03$. An increase in OAER was observed in PPB in comparison with PPC, respectively: 8.6(0.4-105.2) vs 2.4(0.3-18.2)μg/min,$p=0.002$.A stratified analysis has shown that this difference was only significant in patients with <5 years of diabetes duration with an OAER of 5.5(0.4-52.4)μg/min and 0.9(0.3-18.2)μg/min, $p=0.009$ for PPB and PPC respectively.The stepwise multiple regression analysis performed in the pooled diabetic group with mean of the three OAER samples and the following independent variables:age,diabetes duration, body mass index, HbA1, and systolic(sBP) and diastolic blood pressure has shown that age and sBP were significant ($r=0.47$, $p=0.0004$; $r=0.50$, $p=0.0001$) respectively. In conclusion our study has observed that Micro and retinopathy were more frequent in PPB than in PPC IDDM patients. sBP and age were the most important clinical variables associated with microalbuminuria.

2041

HIGH GLUCOSE INCREASES FOS & JUN PRODUCTION BY MESANGIAL CELLS:A LINK TO HIGH TGF-β_1 EXPRESSION?

P. Williams, J. Filipovic and D. Yue. Dept. of Endocrinology, Royal Prince Alfred Hospital, Sydney, Australia.

Glomerulosclerosis and diabetic nephropathy are triggered by exposure to high glucose (HG). TGF-β_1 is a factor thought to mediate this process. Therefore the cellular events that link exposure to HG with increased TGF-β production is of great importance. Activator protein-1 (AP-1; a heterodimer of c-fos and c-jun) is elevated in response to HG and we hypothesise that AP-1 increases TGF-β expression through the AP-1 transcription initiation sites in the TGF-β gene promoter. Therefore this study investigates the changes of fos and jun in response to HG. Cultured human fetal mesangial cells were harvested directly into SDS sample electrophoresis buffer after exposure to HG in serum free conditions for 24 and 48h. Further comparisons were made between cell exposed to HG for 24 & 48h and then incubated in LG for a further 48h (24/48;48/48). Densitometry was carried out on western blots probed with specific antibodies and detected with ECL (Amersham). Results are expressed as a ratio of HG/LG.

	24	48	24/48	48/48
c-jun	1.52±0.19*	1.80±0.09*	1.46±0.28*	1.81±0.38*
c-fos	1.99±0.16*	1.53±0.02*	1.20±0.10*	1.31±0.01*

* indicates significant difference from a ratio of 1.0 $p<0.05$

These results confirm that HG causes significant elevation of the c-fos and c-jun levels in mesangial cells which persist even after the HG has been removed. These results support the hypothesis that HG may elevate TGF-β levels through the AP-1 sites of the gene.

MICROALBUMINURIA IN PREGNANCY COMPLICATED BY DIABETES.

J.Topolska, B.Zarzycka, M.Kinalski, I.Kinalska.
Department of Endocrinology of Medical School, Białystok.

The aim of the study was to investigate the effect of pregnancy in patients with IDDM (insulin dependent diabetes) and GDM (gestational diabetes) on renal function and to evaluate microalbuminuria during pregnancy and after delivery. The study included 22 pregnant women with IDDM and 28 with GDM. All the patients were treated with human insulin by the intensive insulin therapy method. Five GDM patients required insulin treatment whereas the other 23 were on a diabetic diet only. In all the patients microalbuminuria, glomerular filtration, serum creatinine concentration, urin examination, becteriuria, glycohaemoglobin concentration (HbA1c) and eye fundus examination were performed at each trimester of pregnancy and after delivery. All the patients had normal creatinine concentrations (mean - 0.65mg/dl) and blood pressure. No significant bacteriuria was noted. A marked microalbuminuria (>15ug/min) developed in 6 IDDM patients. During pregnancy microalbuminuria values ranged from 17.7 to 364.6ug/min (mean 86.9ug/min). After delivery, normalization of albuminuria (mean 10.46ug/min) was noted in all the IDDM patients. In the patients with microalbuminuria the HbA1c level (mean 6.8%), glomerular filtration (mean 154.26ml/min) and weight of the newborn (mean 3831g) were significantly higher than in the patients without microalbuminuria. In 5 GDM patients a marked microalbuminuria - mean 75.3ug/min (19.4 - 280.0ug/min) was also observed. In this group too a higher level of HbA1c (mean 6.5%), glomerular filtration (mean 155.6ml/min) and a greater newborn weight (mean 4028g) than in the group without microalbuminuria was observed. The values of microalbuminuria in this group also became normal after pregnancy (mean 12.3ug/min).

Conclusions: 1) Glycaemic control had a marked effect on microalbuminuria during pregnancy. 2) The microalbuminuria occuring in IDDM and GDM patients without renal failure was of a transient nature. 3) Pregnancy did not essentially impair kidney function in diabetic patients.

2043

LACK OF RELATION BETWEEN RENAL KALLIKREIN GENE POLYMORPHISM AND DIABETIC NEPHROPATHY. F. Torremocha*, R. Maréchaud*, M. Marre, P. Passa, M. Rodier, F. Alhenc-Gelas and X. Jeunemaitre for the GENEDIAB group. *Poitiers, France and Belgium. The kallikrein-kinin system is involved in the renal blood flow regulation, which is altered in diabetes. We have previously identified two mutations (R53H,Q121E) on the renal kallikrein gene (hKLK1) showing that R53H is associated with a low urinary kallikrein excretion rate. We tested the relationship between these two polymorphisms and renal disease in 489 insulin dependent diabetes mellitus (IDDM) subjects exposed to microangiopathy (IDDM before age of 35 years, affected by a proliferative retinopathy), who were recruited in 17 diabetic clinics in France and Belgium (GENEDIAB study). These subjects (276 men and 213 women, 44±12 year-old, diabetes duration of 29±10 years) were staged from case records as follows: 1 : no nephropathy, 2 : incipient (microalbuminuria), 3 : established (proteinuria), 4 : advanced nephropathy (plasma creatinine > 150 µmol/l or renal remplacement therapy). The R53H and Q121E polymorphisms were determined by the Allele Specific Oligonucleotide (ASO) hybridation technique.

Polymorphisms	Stages				*p*
	1 (n=156)	2 (n=105)	3 (n=124)	4 (n=104)	
allele frequency					
R53H	.044	.024	.056	.038	*0,69*
Q121E	.301	.342	.326	.394	*0,05*

The R53H polymorphism is not associated with the diabetic nephropathy. The is a slight, but not significant, association between Q121E and the nephropathy stage. These data suggest that both R53H and Q121E polymorphisms are not major factors contributing to the pathogenesis of diabetic nephropathy.

2044

DOES NEPHROMEGALY PREDICT EARLY NEPHROPATHY IN NORMOALBUMINURIC DIABETICS ?

Ç. Ordu, M.Yenigün, F. Şar, G.Tanırgan, L.Ü.Temiz, Y.Altuntaş
Haseki State Hospital 4. Internal Medicine and Biochemistry Departments, İstanbul , TURKEY.

It has been suggested that glomerular filtration rate and kidney size increase before microalbuminuria develops. In this study, we investigated whether nephromegaly in normoalbuminuric period would be an early sign of nephropathy. Thus glomerular filtration rate, kidney size and albuminuria were measured in 30 normoalbuminuric (Group I), 25 microalbuminuric (Group II) and 30 macroalbuminuric (Group III) diabetic patients (Age:48±10; 53 ±12; 55±12 years). Glomerular filtration rate was estimated from creatinine clearence; kidney size was measured by ultrasonography and albuminuria was detected by immunoturbidometric method. Glomerular filtration rate values were found 130±67 ml/min; 98±50 ml/min and 48±29 ml/min, respectively ($p<0.05$ in all groups) right and left kidney sizes were found 110±9/113±10 mm, 103±9/108±8 mm and 87±13/94±14 mm, respectively ($p<0.01$ in all groups) albuminuria levels were found 0.85±0.27 mg/dl; 6.83±4.46 mg/dl and 40±12 mg/dl respectively. Significant inverse correlation was found between kidney size and albuminuria. ($r=-0.71$, $p<0.05$ in Group I; $r=-0.68$, $p<0.05$ in Group II and $r=-0.69$, $p<0.05$ in Group III) Significant correlation was found between glomerular filtration rate and kidney size in all groups ($r=0.46$; $r=0.52$; $r=0.56$ respectively, $p<0.05$). In conclusion, demonstration of increase in kidney size by ultrasonography during normoalbuminuric period may practically show decrease in renal functions.

EFFECT OF ACE GENE ON DIABETIC NEPHROPATHY IN NIDDM PATIENTS WITH INSULIN RESISTANCE

N.Kuramoto, T.Izuka[1], H.Itou1, M.Omura1, A.Kanatsuka, H.Tsuchida[2], T.Nishikawa[1], H.Makino[3] and Y.Saitou
Chiba univ., Chiba, [1]Yokohama Rosai Hospital, Yokohama, [2]Sakura National Hospital, Sakura, [3]Ehime univ., Ehime, Japan

We aim to evaluate the effect of angiotensin converting enzyme (ACE) gene on the onset and/or progression of diabetic nephropathy in NIDDM with significant insulin resistance. Insertion/deletion (I/D) polymorphism of ACE gene was determined by PCR method in 49 NIDDM subjects who had normal renal function and were not medicated with ACE inhibitor. Mean glucose-infusion-rate (M-value) was calculated under euglycemic hyperinsulinemic clamp. Mean M-value in 115 NIDDM patients was 6.18mg/min/kg. The patients whose M-value was more than the mean value were classified into control group (n=15). The patients whose M-value was less than the mean value were classified into 3 groups . Group A: albumin excretion rate (AER) was less than 15µg/min (n=14), Group B: AER was from 15 to 70 µg/min (n=11), Group C: AER was more than 70 µg/min (n=9). Duration of the disease, BMI, blood pressure and glycemic control were not different among the groups. The frequency of D-allele in Group B and C was significantly higher than that in the control and Group A (0.591, 0.722, 0.233 and 0.214, respectively) ($p<0.01$). This suggests that ACE genotype (D-allele) have effect on the onset and/or progression of diabetic nephropathy in NIDDM subjects with significant insulin resistance.

2046

PREVALENCE AND CLINICAL FEATURES OF HYPERTENSION IN AN OUTPATIENT DIABETES CLINIC

A.Di Benedetto,G.Romano,M.P.Riccio,S.Alvaro,G.Squadrito and D.Cucinotta.University of Messina,Messina,Italy.

Aim of this study was to observe the prevalence of hypertension in a large,unselected diabetic population attending an outpatient clinic and to assess its relationship with some demographic,metabolic and clinical parameters. 668 consecutive diabetic patients were studied:53 had IDDM (21 males,mean age 31.5±13.4,mean diabetes duration 13.1±10.2 years) and 615 had NIDDM (285 males,mean age 61.7±9.9,known diabetes duration 11.3±8.8 years).Hypertension was defined by WHO criteria (blood pressure) 160/95 mmHg as a mean of 3 readings after a 5-min resting or the patient being on treatment).Hypertension was observed in 7/53 (13.2%) IDDM patients and was associated with increased age (52±12 vs 28±10,$p<0.0001$) and diabetes duration (19±12 vs 12±8,$p<0.001$) and with higher urinary albumin (72±88 vs 8±15 µg/ml,$p<0.0001$) and serum creatinine (1.2±.6 vs .8±.2 mg/dl,$p<0.005$) levels. 54% (332/615) of NIDDM patients were hypertensive; with respect to the normotensive ones they were older (65±8 vs 58±10,$p<0.0001$) and had a longer diabetes duration (13±9 vs 10±7,$p<0.005$), a greater body mass index (BMI,30±5 vs 27±7,$p<0.005$),higher serum cholesterol (213±43 vs 201±42 mg/dl,$p<0.001$) and uric acid (4.6±1.4 vs 3.8±1.1mg/dl,$p<0.0001$) levels and an increased prevalence of retinopathy (139/332 vs 78/283 patients,$p<0.01$) and coronary heart disease (CHD,85/332 vs 47/283,$p<0.05$).Also in this group microalbuminuria (32±64 vs 12±21,$p<0.0001$) and serum creatinine (1.1±.7 vs .9±.2,$p<0.0001$) were higher in hypertensive than in normotensive patients.These results indicate that,in an outpatient diabetes setting,there is a high prevalence (more than 50%) of hypertension,which is closely related to NIDDM. Age,diabetes duration and impaired kidney function seem to be risk factors for hypertension both in IDDM and in NIDDM;moreover in NIDDM hypertension is associated with other features of the insulin-resistance syndrome (BMI,cholesterol,uric acid) and with an increased morbidity for vascular complications (CHD and retinopathy).

2047

RENAL RESPONSE TO HYPERGLYCÆMIA AND ANGIOTENSIN I CONVERTING ENZYME DELETION (D) ALLELE IN IDDM.

M. Marre(1,2), Y. Gallois(1), F. Bled(1), F. Pean(1), B. Bouhanick(1), J.J. Lejeune(1) and F. Alhenc-Gelas(2), 1-Angers, 2-INSERM U367 - France

The Angiotensin I Converting Enzyme (ACE) Insertion/Deletion (I/D) polymorphism is a candidate gene for risk of nephropathy in IDDM patients. Facing to generalized capillary vasodilation provoked by hyperglycæmia, constitutively low (ACE II genotype) or high (ID or DD genotypes) ACE levels would produce low/high renal Angiotensin II and subsequently affect glomerular hydrostatic pressures. We studied Glomerular Filtration Rate (GFR) and Effective Renal Plasma Flow (ERPF) (^{125}I-Iodothalamate and ^{131}I-Hippurate infusion of 27 normotensive, normoalbuminuric IDDM patients during two consecutive 90-min periods of near-normoglycæmia (5.7±1.8 mmol/l), then hyperglycæmia (14.9±2.2 mmol/l), according to ACE D allele absence or presence. Nine patients with II genotypes were matched with 18 (1 case/2controls) others with ID (n=8) or DD (n=10) genotypes for age (34±10 years), sex (6 M/3 F), and IDDM duration (14±9 years). Plasma ACE were different in patients with II genotype vs others: 374±90 vs 541±138 µg/l (p=0.0032). During normoglycæmia, patients with II genotypes did not differ from others for GFR (146±22 vs 138±16 ml/min/1.73m^2) or ERPF (607±93 vs 632±68 ml/min/1.73m^2). During hyperglycæmia, GFR of patients with II genotype did not vary (-6.6±11.5% of initial values), while it increased in others (+4.3±6.7%, p=0.0045); ERPF varied similarly: II genotype -8.2±12.8% vs others +6.7±11.2% (p=0.006). Thus, ACE D allele can lead to changes in renal hæmodynamics able to produce nephropathy in response to hyperglycæmia.

2048

MICROALBUMINURIA IS ASSOCIATED WITH DIABETES COMPLICATIONS IN AFRICAN TYPE 2 PATIENTS.

E. Sobngwi, J-C Mbanya, K.B. Ngu, J. Ngogang and E. Moukouri. Centre Hospitalier et Universitaire (CHU) de Yaoundé, Cameroon.

The relationship between microalbuminuria, chronic complications and cardiovascular risk factors was studied in 55 black African type 2 diabetic patients (27 microalbuminuric and 28 normoalbuminuric) matched for age, BMI, and known duration of diabetes. Microalbuminuria was diagnosed as urinary albumin excretion > 20µg/min on an overnight urine sample. Blood pressure measurements, serum lipids dosage, fundoscopy and effort testing were performed in all the patients. Echocardiography was used to evaluate left ventricular mass and ejection fraction. The two subgroups were compared with regards to the variables studied using t-test and χ^2 test with Yates correction where necessary. Results were as follows:

	Normoalbuminuria (n = 28)	Microalbuminuria (n = 27)	p-value
Systolic blood pressure[1]	133 ± 21 mm Hg	145 ± 23 mm Hg	0.04
Diastolic blood pressure[1]	81 ± 9 mm Hg	90 ± 15 mm Hg	0.009
Retinopathy	11.1 %	67.9 %	0.00006
Neuropathy	37.0 %	64.3 %	0.04
ST segment depression	7.4 %	10.7 %	
Left ventricular mass[1]	125 ± 50 g/m^2	158 ± 40 g/m^2	0.04
Ejection fraction[1]	52 ± 9 %	47 ± 10 %	
Total cholesterol[1]	4.4 ± 1.7 mmol/l	4.1 ± 1.4 mmol/l	
LDL cholesterol[1]	3.2 ± 1.7 mmol/l	2.6 ± 1.5 mmol/l	
HDL cholesterol[1]	1.0 ± 0.5 mmol/l	1.2 ± 0.5 mmol/l	
Triglycerides[1]	1.1 ± 0.7 mmol/l	1.5 ± 0.8 mmol/l	

[1] Mean ± standard deviation

We conclude that microalbuminuria is associated with increased blood pressure, left ventricular hypertrophy, diabetic neuropathy and retinopathy in the population studied. Ischaemia, serum lipids and left ventricular systolic dysfunction were not associated with microalbuminuria.

2049

POLYMORPHISM OF THE ANGIOTENSIN CONVERTING ENZYME (ACE) GENE IN PATIENTS WITH DIABETIC NEPHROPATHY.

E. Semetkowska-Jurkiewicz, M. Nowakowski, J. Bigda, R. Pawłowski, K. Narkiewicz, L. Bieniaszewski, M. Chrostowska, B. Krupa-Wojciechowska, Department of Hypertension and Diabetology, Medical University of Gdańsk, Poland

Diabetic nephropathy appears in about 10 to 30% of insulin-dependent (IDDM) patients. It is supposed that genetic predisposition to hypertension may be responsible for the development of diabetic nephropathy. Several studies on the ACE gene polymorphism have demonstrated that DD genotype is associated with an increased risk of cardiovascular diseases. The aim of this study was the determine wheater there is a potential association between ACE polymorphism and diabetic nephropathy in IDDM patients. The study was carried out in two groups. Group I consisted of 145 normotensive non-diabetic men (twenty-four hour ambulatory blood pressure) whose age was 23±2 years, mean blood pressure 127/77 mmHg. Group II consisted of 64 IDDM patients with incipient or overt diabetic nephropathy. Their age was 38±8 years, the duration of diabetes was 19±7 years, the mean blood pressure was 139/83 mmHg. The examination of the insertion/deletion I/D polymorphism in intron 16 of ACE gene was performed using the polymerase chain reaction. The following results were obtained:

Genotype	Group I n=145	Group II n=64
DD	38 (26%)	26 (41%)
ID	74 (51%)	31 (48%)
II	33(23%)	7 (11%)
D allele frequency	0.52	0.67

Conclusion: It seems that the presence of the D allele of the ACE gene can be a marker of diabetic nephropathy.

2050

RELATIONSHIP BETWEEN URINARY EXCRETION OF ALBUMIN, TRANSFERRIN, AND DIABETIC RETINOPATHY IN NIDDM.

A. Sasaki, S. Oikawa, E. Sakuma, H. Kotake, S. Abe, and T. Toyota. Miyagi Cancer Center and Tohoku University School of Medicine, Miyagi, Japan

In order to study the relationship between the early change of retina and microproteinuria, we measured urinary transferrin (uTf), urinary albumin (uAlb), and a simple latex agglutination test (SLAT) of uAlb in 245 non-insulin-dependent diabetes. We divided the subjects by the levels of albuminuria by radioimmunoassay; the lower group (less than 30mg/l) and the higher group (more than 30mg/l in uAlb), and compared the frequency of positive cases in SLAT. In all subjects uAlb was 22.7 ± 1.5 (mg/l, mean± SE) and uTf was 2.91 ± 0.27 (mg/gCr). UTf significantly correlated (r=0.74, p<0.001) with uAlb. UAlb and uTf of the subjects with no diabetic retinopathy (NDR, n=157) were 20.3± 1.8 and 2.62 ± 0.34, those with background retinopathy (SDR, n=57) were 27.9± 3.3 and 3.40± 0.52, and those with proliferative retinopathy (PDR, n=31) were 25.6 ± 4.0, and 3.47 ± 0.83. UAlb of the subjects with SDR were significantly higher than those with NDR (p<0.03). UTf of the subjects with SDR and PDR were significantly higher than those with NDR (p<0.04, p<0.05, respectively). In the subjects with SDR, the frequency of positive cases in SLAT was higher (n=11, 78.6%) in patients with more than 30mg/l in uAlb and more than 1.0mg/gCr in uTf (n=14, 24.6%). In the study of the subjects with PDR, the frequency of positive cases in SLAT was higher (n=7, 100%) in patients with more than 30mg/l in uAlb and more than 1.0mg/gCr in uTf (n=7, 22.6%). We concluded that the SLAT was a useful study to check the uAlb excretion for a lot of out-patients of diabetics as the first screening test and the measurement of uTf would be an indicator of an early sign of diabetic vascular complications.

2051

MICROALBUMINURIA, HYPERTENSION AND ANGIOTENSIN CONVERTING ENZYME GENE POLYMORPHISM IN IDDM

A.Ciechanowicz, E.Mamos, D.Ryszkiewicz, M.Naruszewicz and S.Czekalski. University School of Medicine, Szczecin, Poland

Recent studies yielded conflicting results concerning the predictive role of insertion/deletion (I/D) polymorphism of angiotensin-converting-enzyme (ACE) gene for the development of diabetic nephropathy (DN) in IDDM. However, the DN in DD homozygotes seems to progress more rapidly compared with II and ID subjects. The aim of our study was to evaluate the frequency of ACE genotypes and alleles in three groups of patients with the long-lasting IDDM: 1 - with incipient nephropathy (IN, n=19), 2 - normoalbuminuric normotensive (NN, n=11), 3 - normoalbuminuric hypertensive (NH, n=6). The I/D polymorphism was assessed by PCR method.

Genotypes distribution in the whole study group was in Hardy-Weinberg equilibrium. Genotypes frequency: IN (4 DD, 9 ID, 6 II), NN (4 DD, 7 ID, 0 II), NH (0 DD, 3 ID, 3 II) - χ^2=7.27, p < 0.122. No significant difference in the frequency of ACE genotypes has been found among three groups. However, we observed the lack of DD homozygotes in NH and the lack of II homozygotes in NN. Alleles frequency: IN (17 D, 21 I), NN (15 D, 7 I), NH (3 D, 9 I) - χ^2=6.28, p < 0.043. There was a significant difference in the alleles frequency in the study groups with reduced representation of D allele in NH patients. These preliminary results failed to confirm the II genotype as a marker for reduced risk of microalbuminuria and hypertension in IDDM.

2052

RISK FACTORS FOR MICROALBUMINURIA AND MACROPROTEINURIA IN IDDM AND INSULIN-TREATED NIDDM PATIENTS

J.Fövényi, G.Kocsis, E.Thaisz, L.Lehotkai, A.Grosz and T.Sallai. Péterfy Teaching Hospital, Budapest, Hungary.

Aim of the study was: analysing the rate of 24 hr albumin excretion, its change during the last two years, the prevalence rates of retinopathy and hypertension and their correlation with albuminuria in 445 IDDM (189 males) and 456 insulin-treated NIDDM (131 males) patients who were cared at our Outpatient Department. The diabetes duration of the two groups of patients (13,8±10,4 vs. 13,7±7,7 yr.) and their actual HbA_{1c} level (7,8±1,5 vs. 7,7±1,4%) were identical The prevalence rate of microalbuminuria among IDDM patients was lower (18 vs. 27%, p<0.01), but that of macroproteinuria was similar (5 vs. 6%). Prevalence rate of all forms of retinopathy was also similar (38 vs. 41%). Hypertension joined with 17% of IDDM and with 54% of NIDDM patients (p<0.001). Positive correlations were found between hypertension and microalbuminuria and between hypertension and macroproteinuria only in IDDM patients (p<0.001) but between hypertension and retinopathy (p<0,01) and between albuminuria and retinopathy (p<0.01) in both groups of patients respectively. Analysing the change in rate of albuminuria during the last two year period we found, that 30% of both IDDM and NIDDM patients with microalbuminuria in 1996 had normal albumin excretion in 1994 and 30% of IDDM and 66% of NIDDM patients with macroproteinuria in 1996 had microalbuminuria two years before. No correlation was found between progression of albuminuria and the prevalence of hypertension in either group of patients. On the basis of these data we have to pay particular attention both to the increased risk of nephropathy in insulin-treated NIDDM patients, and to the importance of effective treatment of hypertension in diabetes mellitus.

2053

AGE, SEX AND DRIFT OF ANGIOTENSIN I-CONVERTING ENZYME GENE ALLELES: IS THIS RELEVANT TO DIABETIC ANGIOPATHY?

Y.Kondratiev[1,2], L.Demurov[2], L.Chugunova[1], M.Shamkhalova[1], M.Shestakova[1], G.Mamaeva[1], M.Balabolkin[1], V.Nosikov[2], and I.Dedov[1], [1]Endocrinology Research Centre and [2]National Research Centre "GosNII Genetika", Moscow, Russia

Previously, we reported high frequency of D (deletion) allele of angiotensin I-converting enzyme (ACE) gene and DD homozygosity in general population, and protective effect of I (insertion) allele in IDDM patients with diabetic nephropathy (DN) and NIDDM patients with myocardial infarction (MI). DN and MI may dramatically reduce life expectancy in diabetes mellitus. Now we tested interference of ID/ACE alleles and genotypes with age and sex in mixed cohort of healthy donors (n=168) and IDDM/NIDDM patients (n=194) as a model of interaction of genetic and non-genetic risk factors influencing survival. All subjects (n=362) were divided in 3 groups: 1 – "young" (mean age 28.8±6.6 yr.; range 17-40 yr.; n=140); 2 – "middle" (mean age 50.2±6.2 yr.; range 40-60 yr.; n=155); 3 – "elderly" (mean age 65.7±3.8 yr., range 61-77 yr.; n=73). Clear though non-significant ID/ACE allele and genotype drifting was observed: I and D allele frequencies in 1, 2 and 3 groups were 0.371, 0.403, 0.425; and 0.629, 0.597, 0.575, respectively. Prevalence of D allele-containing ID/ACE genotypes also changed: II – 19.2, 18.7, 19.3%; whereas ID – 35.7, 43.2, 46.6%; and DD – 45, 38.1, 34.2%, respectively. When total mixed group was considered as males (mean age 41.8±14.9 yr.; n=163) vs. females (mean age 40±15.2 yr.; n=199), evident but non-significant displacement of these markers was also observed: I allele – 0.377 vs. 0.407; D allele – 0.623 vs. 0.593; II genotype – 17.2 vs. 20.1%; ID genotype – 41.1 vs. 41.2%; DD genotype – 41.7 vs. 38.7%, respectively. Since current data on mortality rate and distribution of other risk factors in different age strata of both diabetic and general Moscow populations were unavailable, our preliminary results should be interpreted carefully. We, however, conclude that ID/ACE alleles and genotypes may interfere with age and sex thereby providing a balance of various survival factors. Therefore, it should be taken into account in clinical interpretation of ACE genotyping results.

2054

SERUM SIALIC ACID LEVELS IN NIDDM PATIENTS WITH AND WITHOUT DIABETIC NEPHROPATHY. IS IT A RISK FACTOR?

S. Iraklianou, S. Kamaratos, I. Laskaris, S. Irakliotou, D. Damianaki, A. Melidonis.
Diabetic Unit, Tzanio Hospital, Piraeus-GREECE

PURPOSE: Sialic Acid is one of the acute phase reactants, with a very important role in maintaining the negative charge of renal glomerular basement membrane. Increased serum levels of sialic acid are recently mentioned as a high risk factor for cardiovascular disease. Additionaly, there are studies that support that patients with NIDDM and albuminuria have 20-40 times higher death rates from cardiovascular disease than those with NIDDM without albuminuria. We are examining the possible relation between serum levels of sialic acid and diabetic nephropathy.

MATERIAL-METHODS: We measured serum levels of sialic acid, cholesterol, tg, creatinine and HBA_{1C} in three groups of patients with NIDDM.

GROUP A: 26 patients with NIDDM without albuminuria.
GROUP B: 18 patients with NIDDM with microalbuminuria.
GROUP C: 28 patients with NIDDM with macroalbuminuria.
GROUP D: 18 adult subjects as control group without D.M.

We also examined the correlation between serum levels of sialic acid and albuminuria in patients with NIDDM.

We used the photometric method for measurement of total serum levels of sialic acid and we refined as microalbuminuria the daily excretion of albumin from 30 mg/24h to 30 mg/24h. All groups were comparable to age (61.6 - 61.3 - 64.5 - 50.8 yrs) sex, B.M.I. (28.5 - 29.12 - 30.06 - 29.01), smoking frequency (81% - 33% - 35% - 30%), duration; of diabetes mellitus (11.3 - 12.1 - 12.8).

RESULTS: Group A had higher serum levels of sialic acid than group D 70.61 to 64.15 (p<0.05). In comparison, group A had higher sialic acid levels (82.9±13, p<0.001 and 79.41, p<0.001) groups B and C.

The multifactorial analyses between serum levels of sialic acid and the other parameters was statisticaly significant for serum levels of triglycerides in group A, for serum levels of total cholesterol and triglycerides in group B and finally for serum levels of triglycerides and G.F.R. in group C.

CONCLUSION: Serum levels of static acid are significantly higher early and later stages of diabetic nephropathy.

We could consider sialic acid as a risk factor for the development and progression of diabetic nephropathin NIDDM.

2055

RELATIONSHIP BETWEEN ACE GENE POLYMORPHISM AND NEPHROPATY IN TURKISH DIABETIC POPULATION.

M.Alikasifoglu, T.Erbas, E.Tuncbilek, B.Anar and O.Gedik.
Hacettepe Medical School, Departments of Clinical Genetic and Endocrinology, Ankara, Turkey.

Angiotensin-converting enzyme (ACE) is involved in the metabolism of two major vasoactive peptides, convertion anjiotensin I into anjiotensin II and inactivation bradykinin. The insertion/deletion (I/D) polymorphism in intron 16 of the ACE gene is related to susceptibility to nephropathy in IDDM and macrovascular complications in NIDDM, although some investigation do not support this association. Ethnic/race-related variance in ACE gene polymorphism is known. Therefore we have examined the relationship between this ACE gene polymorphism and presence of nephropathy in Turkish subjects with IDDM and NIDDM. ACE genotyping was performed using the polymerase chain reaction(PCR). We studied 108 subjects with NIDDM and 28 subjects with IDDM. Twenty-five percent of IDDM patients and 50% of NIDDM patients had microalbuminuria or overt proteinuria. The DD, ID and II genotypes were present in 25%, 57.1% and 17.9% in IDDM subjects, respectively. The DD, ID and II genotypes were present in 15.7%, 65.7% and 18.5% in NIDDM subjects, respectively. The frequency of ACE I/D genotype was similar to subjects with IDDM and NIDDM. There was no difference in genotype distribution between NIDDM patients with microalbuminuria or overt nephropathy and those with normoalbuminuria: 16.6%/70.4%/13.0% vs. 14.8%/61.1%/24.1% had DD/ID/II genotypes, respectively. According to our results, ACE genotype frequency does not seen to be a useful marker in determining genetic susceptibility to diabetic nephropathy.

2056

MICROALBUMINURIA, PROTEINURIA AND LIPID RISK FACTORS IN NIDDM

H. Vaverková, R. Chlup, D. Novotný, L. Ficker and J. Bártek, University of Olomouc, Olomouc, Czech Republic

Main aim of the study was to evaluate concentrations of various lipids, lipoproteins /including Lp(a)/ and apoproteins in NIDDM subjects and their relationship to the presence of microalbuminuria and proteinuria. We compared 145 NIDDM patiens (35 of them without microalbuminuria, 83 with microalbuminuria and 27 with proteinuria or renal insufficiency) with a control group of 58 healthy subjects. All NIDDM subgroups had significantly higher total serum triglycerides, total cholesterol/HDL-C ratio and apo B and lower HDL-C than the control group. Microalbuminuria correlated significantly and positively with creatinine ($r=0.3731$, $p<0.001$) and serum triglycerides ($r=0.2498$, $p<0.05$) and negatively with HDL-C ($r=-0.2622$, $p<0.05$) (Spearman rank correlations). The risk concentrations of Lp(a) >30 mg/dl were significantly more prevalent in microalbuminuric group than in the control group (36.2% vs. 17.2%, $p<0.05$). Newetheless median Lp(a) concentrations in these subgroups were not significantly different, as well as other lipid parameters. The group with albuminuria or renal insufficiency had significantly higher total cholesterol (TC) (6.79±2.73 vs. 5.53, $p<0.0001$), TC/HDL-C (8.03±6.61 vs. 5.52±1.75, $p<0.001$) and LDL-C/HDL-C (3.64±1.29 vs. 2.91±1.06, $p<0.001$) ratios and C-peptide (3.19±1.35 vs. 2.44±0.99, $p<0.05$) than the patients without microalbuminuria. In conclusion, proteinuria in NIDDM is associated with a very atherogenic lipid profile. Minor lipoprotein changes start to be apparent even in microalbuminuria.

2057

Relationship Between Angiotensin I converting Enzyme Gene polymorphism and diabetic nephropathy

Tong Zhong Hang Luan Mng Zhi
Department of Endocrinology, First Affiliated hospital
Zhejiang medical University, Hangzhou, 310003

Diabetic nephropathy (DN) of non- insulin dependent diabetes mellitus (NIDDM) is probably diagnoged by renal hemodynamic abnormalities and by a genetic predispositon. Angiotensin I converting enzyme (ACE) regulates renal circulation through angiotensin II formation and kinins metabolism. An Insertion/ deletion polymorphism of the ACE gene is strongly associated with the level of ACE. We used PCR to detect the polymorphism of the ACE gene and studied the relationship between this polymorphism and DN : We compared 85 unrelated NIDDM individuals and 40 healthy compared 85 unrelated NIDDM individuals and 40 healthy controls, ACE genotype distribution was hot different; compared 46 NIDDM with DN petents to 39 NIDDM without DN subject, an imbiance of genotype distribution was observed, the frequencies of DD genotype and D allele are significantly higher in patients with DN ($P<0.05$), the D allele is associated with DN, a relative risk for the D allele was observed (odds ratio 2.8, $P< 0.05$). Identification of NIDDM patients with DD gentype would help early detection and treatment of DN.

ASSESSMENT OF MICROALBUMINURIA IN TAIWANESE DIABETIC PATIENTS — COMPARISON BETWEEN 24-HOUR, EARLY MORNING SPOT URINE AND SEMIQUANTITATIVE DIPSTICK TEST.

Jung-Fu Chen, J-H Sun, H-Y Chang, S-H Hsieh, C Ho, J-D Lin.
Division of Endocrinology & Metabolism, Chang Gung Memorial Hospital,Taiwan.

Purpose: To determine which methods as early morning spot urine Albumin/Cr ratios and semiquantitative dipstick Micral-test could be alternatives to 24-hr urinary collections for assessment of microalbuminuria.

Materials & Methods: We measured 159 NIDDM Taiwanese outpatients (85 female, 74 male, age 57.4±11.6), collected urinary samples at the same day included (1)24-hr collections (2)early morning spot ruine, assessed albumin (immunonephelometry), creatinine, and by semiquantitative Micral-Test (Boehringer Mannheim).

Results & Disscussions:

1. Overall prevalence of microalbuminuria (>30mg/24-hr) in 159 Taiwanese NIDDM outpatients is 34.6%(24-hr), 33.9% (spot urine Albumin/Cr), 36.5%(Micral-Test), comparable to other's investigations.
2. There are strong correlations between 24 hr urine and spot urine Albumin/Cr ($R=0.49\sim0.89$, $p=0.0001$) when less or more than 30 mg/24-hr separatively, also good correlations between 24-hr urine and spot urine Micral-Test ($R=0.31\sim0.69$, $P=0.0001$) although less stronger.
3. Take 24-hr urine collections of microalbuminuria (>30mg) as standard, early morning spot urine Albumin/Cr ratios showed good sensitivity 89%, specificity 93%, and positive predictive value of 87%, false positive rate 6.6%, so early morning spot urine can be choosed as screening test of microalbuminuria instead of timed urine collections.
4. Semiquantitative Dipstick Micral-Test had an overall sensitivity 94%, specificity 58%, positive predictive valure 54%, negative predictive value 95%, false positive results 42% which suggested positive Micral-test should be confirmed by timed collections or spot urine method, and negative test could be accepted and retested annually.

No association of the polymorphisms of angiotensin-I converting enzyme (ACE) and angiotensinogen (AGT) genes with diabetic nephropathy in Japanese long-standing IDDM patients.

Miura J, Uchigata Y, Satoh A, Yokoyama H, Omori Y
Diabetes Center, Tokyo Women's Medical College, Tokyo, Japan

Aim: The aim of this study is to investigate whether the polymorphisms of the ACE and AGT genes are associated with diabetic nephropathy in IDDM patients. **Subjects and Methods:** 137 Japanese IDDM patients (M/F=58/79) with a duration of over 15 years were selected in terms of matching in current age, onset age and glycemic control of normo(N), micro(M), and macro(A) albuminuria groups. Plasma ACE activity and angiotensin II were measured, and DNA from PBMC was amplified by PCR using specific primers of ACE and AGT genes. Each PCR product was electrophoresed through 10% PAGE following ethidium bromide stain-ing. Chi-square test was used for statistical analysis. **Results:** The number of (N), (M) and (A) groups were 75/36/25. Plasma ACE activity and angiotensin II levels in these groups were 16.0±5.2, 16.1±6.6 and 13.1±6.1 IU/L/37℃ (NS), and 98.3±93.0, 90.5±107.8 and 137 ±161.7 pg/ml (NS). The ACE DD/DI/II genotype in these groups were 8/40/27, 7/16/13 and 3/10/12 (NS). Plasma ACE activity level was significantly higher in DD genotype group among other ACE genotypes (P=0.0008), but DD genotype was not related with nephropathy. The AGT TT/TM/MM genotype in these groups were 47/17/2, 16/13/0 and 17/4/3 (NS). ACE activity and angiotensin II levels were not related to AGT gene polymorphism. **Conclusion:** The development of diabetic nephropathy in Japanese long-standing IDDM patients was not related to ACE or AGT gene polymorphism and these activity or levels.

ETHNIC INFLUENCES ON NEPHROPATHY IN PATIENTS WITH NIDDM FROM A MULTI-ETHNIC URBAN AUSTRALIAN COMMUNITY

TME Davis, WA Davis, D Ridley and DG Bruce, University Department of Medicine, Fremantle Hospital, Australia.

Cross-sectional data from the first 1,000 patients with NIDDM recruited to the Fremantle Diabetes Study (a prospective study of ethnic differences in care, control and complications in diabetics drawn from a population base of 118,000) were used to identify variables associated with diabetic nephropathy. The logarithm of the urinary albumin/creatinine ratio (lnACR) was determined for each patient and an estimate of the glomerular filtration rate (eGRF) was calculated from serum creatinine using the Cockroft-Gault formula corrected for body surface area. Ethnicity was assessed from self-perception of ethnic background and other demographic data, with Anglo-Celts forming 63%, Southern Europeans 20%, Asians 3% and Aborigines 1%. There was an overall significant inverse correlation between lnACR and eGFR (r=-0.19; P<0.0001). Multiple logistic regression analysis revealed that age, sex, diabetes duration, treatment type, waist-hip ratio, supine systolic and diastolic blood pressure, fasting plasma glucose, serum creatinine and fasting serum triglycerides were significantly and independently associated with lnACR (P<0.03). After adjusting for these variables and adding ethnic background to the model, only Aboriginal ethnicity was associated with lnACR (P=0.003). The variables significantly associated with eGFR, once those used in its calculation (age, sex, weight and height) had been excluded, were fasting plasma glucose, and fasting serum HDL-cholesterol and triglycerides (P<0.01), with only Aboriginal ethnicity predictive of eGFR when ethnic background was included (P=0.02).These data suggest that lnACR and eGFR are related indices of renal function which identify Aboriginal ethnicity as a risk factor for nephropathy. Whilst eGFR is associated primarily with indices of metabolic control, urinary albumin excretion is a more hybrid variable which reflects other factors not necessarily related to renal disease or diabetes.

ANALYSIS OF ACE POLYMORPHISM IN NIDDM SIB-PAIRS CONCORDANT FOR NORMAL OR INCREASED BLOOD PRESSURE VALUES AND ALBUMIN EXCRETION RATE.

A. Solini, M. Velussi, B. Muollo, F. Frigato, M. Maioli*, G.C. Tonolo*, A. Sfriso, M. Trevisan, M. Sambataro, G. Giacchetti°, F. Mantero°, G. Crepaldi and R. Nosadini*. Universities of Padova, Sassari* and Ancona°, Italy.

Nephropathy risk in diabetes appears increased by essential hypertension. Some case-control studies have indicated an association between allele D of angiotensin-converting enzyme (ACE) polymorphism and renal complication in diabetes, while others have not. We have evaluated the possible relation of ACE genotype (identified by PCR amplification of genomic DNA extracted from peripheral leukocytes) with nephropathy and hypertension in a population of NIDDM sib-pairs from North-East of Italy and Sardinia with and without hypertension and abnormal albumin excretion rate. We used the non parametric test of Bishop et al. with X^2 test to compare the observed allele frequencies with the expected values under no linkage. We studied 46 sibships concordant for NIDDM and microalbuminuria (MA+); 116 sibships concordant for NIDDM and normoalbuminuria (MA-); 76 sibships concordant for NIDDM and hypertension (H+) and 38 sibships concordant for NIDDM and normal blood pressure values (H-). There were not significant differences in the four groups of sib-pairs concerning either allelic frequencies (MA+ expected: DD 18, ID 46, II 28 vs observed: DD 21, ID 40, II 31; MA- expected: DD 82, ID 112, II 38 vs observed: DD 77, ID 122, II 33; H+ expected: DD 55, ID 73, II 24 vs observed: DD 56, ID 70, II 26; H- expected: DD 28, ID 36, II 12 vs observed: DD 33, ID 27, II 16) or number of affected sib pairs sharing 0, 1 or 2 alleles IBS respect to expected values under no linkage (MA+ expected: X_0 1, X_1 16 and X_2 29 vs observed: X_0 0, X_1 18 and X_2 28; MA- expected: X_0 3, X_1 40 and X_2 73 vs observed: X_0 6, X_1 32 and X_2 78; H+ expected: X_0 2, X_1 26 and X_2 48 vs observed: X_0 2, X_1 24 and X_2 50; H- expected X_0 1, X_1 13 and X_2 24 vs observed X_0 1, X_1 15 and X_2 22, all p=n.s.). Our results suggest that the presence of allele D is not associated with hypertension or micro-macroalbuminuria in NIDDM sib-pairs, and that ACE genotype does not contribute to the genetic susceptibility to nephropathy and hypertension in NIDDM.

THE PREVELENCE OF MICRO AND MACRO ALBUMINURIA IN NIDDM PATIENTS IN NELLORE, ANDHRA PRADESH, INDIA

Dr. CHICHILI RAJITHA
DIABETES CLINIC, BRINDAVANAM, NELLORE - 1, INDIA

The purpose of the present study is to determine the prevelence of micro and macro albuminuria in NIDDM patients and their relationship with some risk factors.

2086 NIDDM patients who attended to our clinic between 1993 to 1995 were investigated for Albumin Excretion Rate (AER).

The prevelence of micro albuminuria (AER 20 to 200 micro grams/litre) is 32.5%, macro albuminurea (AER greater than 200 micro grams/litre) is 17.6%. In comparision with normo albuminuric subjects both micro and macro albuminuric diabetic subjects had significantly longer duration of diabetes, high levels of blood pressure both systolic and diastolic, Fasting blood glucose, HbAlc and Serum triglycerides.

This study showed high prevelence of micro and macro albuminuria in NIDDM subjects who were ar risk for other long term complications of diabetes like Nephropathy and Cardio Vascular complications.

NO.OF NIDDM PATIENTS	NIDDM WITH MICRO ALBUMINURIA	NIDDM WITH MACRO ALBUMINURIA
2086	679 (32.5%)	367 (17.6%)
