Previous studies have shown that in subjects with DD ACE genotype plasma angiotensin II level is higher then in patients with I/D and I/I ACE genotype. On the other side studies have shown that DD ACE genotype predisposes patients with heart disease, no normal individuals, to left ventricular hyperthrophy (LVH). LVH is known single risk factor of cardiac death among patients with chronic renal failure (CRF) treated by haemodialysis (HD). Main factor of death haemodialyzed CRF subjects with diabetic nephropathy is cardiovascular complications. Aim of our study was to assess relationship between I/D ACE polymorphism and LVH in diabetic subjects with CRF treated by HD. We studied 44 diabetic subjects on regular bicarbonate HD (mean HD time >12 months) in age 51,5 (median; 25-75% 43-60 years). Left ventricular mess index (LVMI), relative wall thickness (RWT), ejection fraction (EF) and E to A wave flow (E/A) were estimated using echocardiography Doppler Scan (Siemens 450 SI). ACE I/D polymorphism in intron 16 was genotyped using the PCR method. Statistical analysis was performed using Kruskal-Wallis test and correlation tests. Selected results are presented in the table (median; 25%, 75%).

	LVMI g/m²	RWT I/I	EF %	E/A I/I
I/I ACE (N=6)	121 (120, 173)	0,67 (0,48, 0,75)	39 (35, 52)	0,70 (0,65, 0,71)
I/D ACE (N=12)	116 (84, 138)	0,57 (0,48, 0,61)	55 (43,56)	0,87 (0,76 0,87)
D/D ACE (N=26)	130 (108,148)	0,53 (0,48, 0,55)	51((47,59)	1.00 (0,78, 1.10)
Kruskal-Wallis test	NS	NS	NS	NS

Conclusion :
There are no significant relationship between I/D ACE polymorphism and LVH in diabetic patients treated by HD.

2064

URINARY ALBUMIN EXCRETION IN NEWLY DIAGNOSED NIDDM

V.ACHARI,DEPTT.OF MEDICINE,PATNA MEDICAL COLLEGE, PATNA,BIHAR, INDIA.

The study was aimed to determine the prevalence of albuminuria in newly diagnosed indian NIDDM patients. 168 (114 male,54 female) newly diagnosed diabetes with NIDDM in the age group 35-80 were selected for urinary albumin excretion studies along with 105 controls. The patients were initially screened for albuminuria by Micral Test and those who were borderline or positive had 24 hour urinary albumin studies. In all 15 (8.9%) had significant proteinuria,and 51 (30.4%) had micro-albuminuria, giving a total of 66 (39.3%) who had elevated urinary albumin excretion as compared to only 6 of the controls; this was strongly significant (p=0.0005).There was a slightly increased prevalence of proteinuria in 52 hypertensives; 25 had proteinuria of some degree. Patients with albuminuria were older (average age 57.03 against 43.05 in patients with normo-albuminuria). However,none of these differences were statistically significant. 12patients had retinopathy and 6 had evidence of peripheral neuropathy. This indicates that increased albumin excretion is common in Indian NIDDM patients at diagnosis and may occur without associated risk factors and other micro-vascular complications.

2065

MICROALBUMINURIA: EVALUATION OF SAMPLING AND DETECTION METHODS

C.González. S.Marcello, C.Borgarelli, P.Grassini, M.Bercellini, G.Ortensi, N.Romay Vázquez, H.Valli and P.Tesone. Ramos Mejía Hospital, Buenos Aires, Argentina.

Objective: to compare urinary albumin excretion rate (AER) results obtained with different sampling and detection methods. Design and method: 220 diabetic patients were studied after macroalbuminuria or urinary infection were excluded: in 110 AER was compared as measured by immunoturbidimetry (MAU) and by Micral II (Mic2) strips (gold-labeled antialbumin monoclonal antibodies) in samples collected simultaneously during 24hs and at random; in another 110 AER was measured by MAU and Mic2 in simultaneous 24hs and first matinal micturition (FMM) samples; albumin/creatinin (Alb/Cr) excretion ratio was compared in all 24hs, random and FMM samples. AER normal maximum value was considered 20 mg/l; Alb/Cr normal value must not exceed 3mg/mM. Since MAU results are quantitative and Mic2 results are semiquantitative, comparison was made by classifying them as concordant or discordant according to agreement or not in relation to normal or abnormal values. Concordance and discordance were then statistically analyzed by Pearson Chi² test. Results: AER: MAU 24hs vs. MAU random: 75.5% concordant ; MAU 24hs vs. MAU FMM: 91% concordant ($p<0.05$). Mic2 24hs vs.Mic2 random: 82% concordant; Mic2 24hs vs. Mic2 FMM: 94.5% concordant ($p<0.05$). MAU 24hs vs. Mic2 random: 78% concordant; MAU 24hs vs. Mic2 FMM: 93.6% concordant ($p<0.05$). MAU 24hs vs.Mic2 24hs: 96.8% concordant. Alb/Cr: 24hs vs. random: 71.8% concordant; Alb/Cr: 24hs vs. FMM: 91.8% concordant ($p<0.05$). Conclusion: urine collected at random was not a representative sample of AER during 24hs while FMM urine was representative both with MAU or with Mic2. Need of at least two AER abnormal results out of three consecutively spaced urine samples is stressed for the diagnosis of microalbuminuria. Alb/Cr ratio measured in FMM urine yields results comparable to 24hs samples..

THE PREVALENCE OF ALBUMINURIA AMONG PATIENTS WITH TYPE 2 DIABETES MELLITUS IN CENTRAL ANATOLIA, TURKEY

F.Keleştimur,S.Emeklioğlu,C.Utaş,K.Ünlühızarcı and F.Bayram. Erciyes University, Kayseri, Turkey

Microalbuminuria is an early marker of renal injury among the patients with diabetes mellitus. As demonstrated previously, poorly regulated blood glucose, high blood pressure and duration of diabetes increases urinary albumin excretion (UAE) and after manifest proteinuria ensues, renal functions deteriorates irreversibly. By the treatment of hypertension and tight glycaemic control the progression of nephropathy may be prevented during the microalbuminuric period. The present study was performed to determine the prevalence of diabetic nephropathy in Kayseri, Central Anatolia, where type 2 diabetes prevalence is high, 6.9%. Six hundred-eleven patients with diabetes, who were diagnosed and followed-up in Erciyes University Hospital between January 1993- September 1996, were included in the study. Blood pressure, HbA1c values, renal functions, UAE and duration of diabetes were recorded. Patiens were divided into three groups according to their UAEs. Among 611 patients, 292 (47.7%) were men, 319 (52.3%) were women. The frequency of normoalbuminuria, microalbuminuria and macroalbuminuria was 49.8%, 25.5% and 24.7% respectively. The prevalence of hypertension was 12.2% in normoalbuminuric group, 36.5% in microalbuminuric group and 72.8% in macroalbuminuric group. Creatinine clearance was significantly ($p<0.01$) lower in macroalbuminuric group (46.9± 2.4 ml/min.) than normoalbuminuric group (101± 0.1 ml/min) as determined by student-t test. The average duration of diabetes was 80.9± 3.9 months in normoalbuminuric group and 160± 17 months in macroalbuminuric group. Results are expressed as means± SD. In conclusion, we have found that the prevalence of albuminuria is rather high among the patients with type 2 diabetes mellitus in Kayseri, Central Anatolia.

SCREENING FOR MICROALBUMINURIA WITH MICRAL-TEST II

H.C.R. Simpson, E.M. Knowles, B.A. Cunningham, A.J. Wibberley and R.S. Fink, Diabetes Centre, Royal Berkshire Hospital, Royal Berkshire & Battle Hospitals NHS Trust, Reading and West Middlesex University Hospital Laboratory, LSH Trust

Microalbuminuria is a recognised marker for diabetic nephropathy. Current screening methods often involve a laboratory assay, which is expensive. This Study compared near patient testing, using Micral-Test II (Boehringer-Mannheim), with a laboratory (immunoprecipitation) method. 150 early morning diabetic clinic urines were tested, ranging from Albustix (Bayer Diagnostics) negative (70), trace (52), one plus (20) to two plusses (8). 66 urines measured < 20 mg/litre on laboratory assay, of which 65 were also read as < 20 mg/litre on Micral-Test II (specificity 98.5%). 84 samples measured 20 mg/litre or more on laboratory assay, of which 3 were < 20 mg/litre on Micral-Test II (sensitivity 96.4%). Comparing Micral-Test II to laboratory albumin/creatinine ratio reduced specificity to 71%, but sensitivity remained almost unchanged at 94.4%. 101 samples were tested with Micral-Test II in poor artificial light, among which there was one false positive and one false negative. 49 samples were tested in daylight, among which there were two false negative results. Micral-Test II is a reliable, cost-effective method of screening for microalbuminuria, detecting all values above 30 mg/litre in this study. The reading appears equally reliable in artificial light. Laboratory assay can be reserved for those screening positive on Micral-Test II

2068

MICROALBUMINURIA AND CLINICAL FEATURES AMONG BRAZILIAN NON-INSULIN-DEPENDENT DIABETIC PATIENTS

L.Bahia, ,M.F.Gonçalves, S.Balassiano, M.Skacel, R.Neves and M.Gomes
State University of Rio de Janeiro - Rio de Janeiro / Brasil

The purpose of our study was to investigate the frequency and clinical variables associated with microalbuminuria(Micro)among non-insulin-dependent diabetic patients.We studied 59 patients(38female,21male)aged59.6± 9.2 years(mean±SD)with diabetes duration of 11.6 ± 7.9 years. The patients collected three overnight urine for albumin excretion (OAER-10h) on three non-consecutive days and had blood sample collection for analysis of BFG and lipid profile (total cholesterol, HDL cholesterol, LDL cholesterol and triglycerides). Albumin concentration was determined by radio-immunoassay (DPC,LA) and lipid profile by colorimetric method (COBRA/MIRAS, ROCHE). Statistical analysis was performed by Fisher exact and Mann-Whitney tests and data were expressed as median (range). For univariate regression analysis OAER was log trasformed. Mean intraindividual coefficient of variation for OAER was 64.4%. Retinopathy was assessed by fundus examination after pupillary dilation. Neuropathy was assessed by neurological symptoms and clinical examination and coronary artery disease (CAD) by history of cardiac disease. Micro (2 out of 3 OAER ≥20μg/min and ≤200μg/min) was found in 23 (39%) and normoalbuminuria (Normo-OAER <20μg/min) in 36 (61%) . Micro was associated with clinical neuropathy (p-0.03), but not with retinopathy, CAD,systolic (sBP)and diastolic blood pressure (dBP),diabetes duration or smoking habits. The coefficient correlation between the mean of the three OAER and sBP was r=0.36, p<0.001. Retinopathy was noted in 34 (57.6%) and was associated with sBP(p-0.05)and diabetes duration 8 (0.3-20) vs 14 (1-30)years (p-0.003). Neuropathy was present in 46(80.7%) and associated with smoking habits (p-0.04) and diabetes duration 13 (1-30) vs 4 (0.3-15)years.
We concluded based in our data that there is no association between any single clinical or laboratorial abnormalities and diabetes chronic complications.

2069

EVALUATION OF RANDOM URINE SCREENING FOR MICROALBUMIN-URIA WITH MICRAL-TEST II

V.J.Heazlewood and P.A.Carroll. Redcliffe Hospital, Redcliffe, Australia.

Obtaining serial overnight or timed samples of urine from diabetic patients is often problematic and inconvenient. The aim of this study was to assess the clinical utility of Micral-Test II (Boehringer Mannhein) for detection of microalbuminuria using random urine samples. Urinalyses were performed on 108 diabetic patients, comprising 69 NIDDM (37M mean age 57 years, 32F mean age 58 years) and 39 IDDM (14M mean age 44 years, 25F mean age 50 years), who presented electively to a provincial hospital Diabetes Clinic. Within 1-2 days, 24 hour urine protein collections were achieved in the same subjects. Documentation of microalbuminuria was carried out using a standard reference method. The results showed that, using a Micral-Test II cut-off of 20 mg/L for microalbuminuria-positive urines, the test sensitivity was 89%, specificity 61%, positive predictive value 53% and negative predictive value 92%. Using a higher cut-off of 50 mg/L, the above parameters were 64%, 90%, 77% and 83%, respectively. With a lower cut-off of 10 mg/L (estimated on strip), no improvement in any parameter occurred (89%, 51%, 48%, 90%) compared to the 20 mg/L cut-off level. In conclusion, Micral-Test II yields a reliable semi-quantitative estimate of microalbuminuria via conveniently-obtained random urine samples from diabetic patients, regardless of potential confounding variables that may affect protein concentration in such samples.

2070

RACE AND DIABETIC NEPHROPATHY IN SALVADOR, BRAZIL

J.Carreiro Pousada, I.Lessa M.Fujita and M.Brito.Federal University of Bahia,Brazil

Diabetic nephropathy (DN) is the main cause of end stage renal disease in the western developed countries. It is commonest in black people and other racial minorities.In Brazil, diabetes mellitus (DM) is the 3rd cause of dialysis, specially in white men. There is no racial difference on the population prevalence of DM, nevertheless it is unknown any relation among race and DN. The aim of the study was determining possible racial association to DN, and looking for racial differences related to gender, average ages at time of diagnosis, duration of disease and insulin therapy. Medical reports of post-mortem diabetic patients (natural death) were examined at the Bahia Federal University Hospital in Brazil, for the 1949-1994 period. Variables related to the objective, the causes of death and renal micorscopy were registred . The criteria for DN were pre-defined and the patients classified in a double-blind manner as; with DN, without DN and with possible DN. The race/color were described by the pathologists as: white, mulatto and black. Frequency ratios (R), χ^2 test for association and t test for average differences were performed for the statistical analysis. Of the 200 autopsied diabetic patients 16 were excluded by secondary diabetes or no registered race; 174 autopsied patients were assessed according to the charts where non-insulin-dependent diabetes mellitus (NIDDM) and insulin-dependent diabetes mellitus (IDDM) were taken into consideration. The other 10 probably had DN. Of the 174 diabetic patients, 71(40,8%) had DN. Diabetic nephropathy was more frequent in blacks than in whites in spite of a p>0,05, but with a R of 1,6 for black men as compared to whites and mulattos. The frequency of DN in black men and women was similar (R female/male=1,2). Black men with DN were diagnosed on an average 11 years after the whites. The black men patients with and without DN had the shortest duration of disease (about 2 years). In relation to the women, those non white without DN also had a short duration of disease. Black and mulatto NIDDM women with DN received insulin therapy more frequently than the white women. The authors pointed out several possible differences in gender and race in the natural history and/or clinical course of diabetes.

2071

ANALYSIS OF FIRST MORNING URINE SAMPLE AS SCREENING TEST FOR MICROALBUMINURIA BY RECEIVER-OPERATING CHARACTERISTICS CURVE

M.B.GOMES, M.L.LUCHETTI, L.R.BAHIA, L.G.K.AGUIAR and M.F.GONÇALVES
STATE UNIVERSITY OF RIO DE JANEIRO, RIO DE JANEIRO, BRAZIL

The aim of our study was to determine the efficacy of urinary albumin concentration ([ALB] - µg/ml) and albumin to creatinine ratio (ALB/Cr mg/mmol) in first morning urine sample (FMUS) for screening of microalbuminuria (MICRO). 50 IDDM and 30 NIDDM outpatients collected OAER and FMUS concomitantly on three non-consecutives days (T1,T2,T3). Timed overnight urinary albumin excretion (OAER-10h) was considered the gold standard. The data were analysed by receiver-operating characteristics (ROC) curve. MICRO (2 out of 3 OAER ≥ 20ug/min and < 200ug/min) was found in n=21 and normoalbuminuria (OAER < 20ug/min) in 59 patients. [ALB] was determined by radioimmunoassay (DPC, L.A.) and creatinine by Jaffé's method. The correlation coefficients between OAER and [ALB] were 0.75 (T1 - p<0.0001)), 0.77 (T2 - p<0.0001) and 0.69 (T3 - p<0.0001) and between OAER and ALB/Cr were 0.69 (T1 - p<0.0001)), 0.78 (T2 - p<0.0001)) and 0.75 (T3 - p<0.0001). The areas under ROC curves for [ALB] were T1=0,7180 (SE=0,016), T2=0,7238 (SE=0,0166) and T3=0,7256 (SE=0,0186) and for ALB/Cr were T1=0,7341 (SE=0,068), T2=0,7225 (SE=0,0164) and T3=0,7137 (SE=0,0189). No differences were found between the areas under ROC curves for [ALB] and ALB/Cr, respectively: T1 (p=0.24), T2 (p=0.48), T3 (p = 0,33), as well as when comparing the three FMUS for [ALB] and for ALB/Cr. The cut-off values for [ALB] with best sensitivity (Se) and specificity (Sp) were respectively; T1=13.75 (Se=91.7% and Sp=89.3%); T2=14 (Se=81.8% and Sp=86.2%); T3=14 (Se= 80% and Sp=84.6%); and for ALB/Cr were T1=2.25 (Se=70.8% and Sp=87.5%); T2=3.11 (Se=95.5% and Sp=87.9%); T3=2.84 (Se=86.7% and Sp=83.1%). In conclusion we noticed a good reproductibility for [ALB] and ALB/Cr and, although false positive and negative cases for MICRO could not be excluded, the cut-off points determined by ROC curves for [ALB] and ALB/Cr in FMUS had a good Se and Sp in predicting an OAER ≥ 20 µg/min.

2072

INCIDENCE AND DETERMINANTS OF MICROALBUMINURIA IN KOREAN SUBJECTS WITH NIDDM.

K.U.Lee, H.K.Kim, Y.E.Chung, J.Y.Park and S.K.Hong. University of Ulsan, Seoul, Korea

The incidence of diabetic nephropathy in NIDDM differs widely according to the race. Although clinical proteinuria is reportedly more common in NIDDM patients in the Far East Asians than in the Caucasians, data on the incidence of microalbuminuria are not available. This study was undertaken to know the incidence and the determinants of microalbuminuria in Korean NIDDM patients. A cohort of 188 Korean NIDDM patients with initial normoalbuminuria were followed prospectively for 5.5 ± 0.9 yrs. Of the 146 patients who finished the study (63 men, 83 women), 37 showed persistently elevated urinary albumin excretion (UAE; > 20 ug/min) during follow-up, giving an incidence of 52/1,000 person-years. When we compared the characteristics of the progressors and the non-progressors, age (65 ± 11 vs. 59 ± 10 yr, P < 0.05) and duration of diabetes (16.7 ± 7.9 vs. 11.1 ± 5.7 yr, P < 0.001) were higher in the progressors than in the non-progressors. The baseline UAE was significantly higher in the progressors (8.7 ± 4.3 vs. 6.7 ± 4.0 ug/min, P < 0.05). More patients in the progressors had retinopathy at baseline (51 % vs. 14 %, P < 0.001) and at the completion of follow-up (76 % vs. 28 %, P < 0.001). The mean FBS and HbA_1 values during follow-up period were significantly higher in the progressors than in the non-progressors (9.6 ± 2.1 vs. 8.7 + 0.9 mM, 11.1 ± 2.4 vs. 9.9 ± 2.0 %, P< 0.05 respectively). The mean systolic and diastolic blood pressures were also significantly higher in the progressors than in the non-progressors (146 ± 15 vs. 135 ± 16 mmHg, 88 ± 7 vs. 83 ± 8 mmHg, P < 0.001 respectively). Multiple logistic regression analysis revealed that duration of diabetes, mean FBS and mean systolic blood pressure are independent variables having a statistically significant influence on the development of microalbuminuria. Our data show that the incidence of microalbuminuria in Korean NIDDM patients is lower than that reported in Pima Indians (84/1,000 patients-year) but is as high as that in Caucasian IDDM patients (30 - 48/1,000 patients-year). It is suggested that poor glycemic control and high blood pressure are risk factors for development of microalbuminuria in NIDDM.

2073

MICROALBUMINURIA IN IDDM : IT´S AND SOME ASSOCIATED RISK FACTORS ARE DECRESED ?

*M.M. Campos *, P. Mezquita *, J.L. Herrera-Pombo **, M. Rigopoulos ***, F.Hawkins-Carranza ***, SH.Azriel ** and F. Escobar-Jimenez. Endocrine Unit´s from University Hospital´s Granada *, Jimenez Diaz Fundation ** and 12 de Octubre ***. Granada-Madrid (Spain).*

General prevalence of microalbuminuria (ma) in IDDM patients (IDDM-P) in Europe countries is known and in similar ranges. The influence of specialized care would be play some beneficial roles in diabetic nephropathy (DN) after some intervention programs. **AIMS :** reanalized ND prevalences in IDDM-P under long-term clinical observation period in order to stablish posibilities of clinical regression of ma and asociated metabolic risk factors. **PATIENTS AND METHODS :** 319 IDDM-P between 1970 and 1995 was observed. 51 % was male, 49 % female and age range between 1 and 42 y. Evolution time of disease was 12.8 ± 9.7 y. All treated with three-four daily insulin inyections and HbA1c, Cholesterol (CHO), TGL, HDL-CHO, Blood pressure (BP) as sistolic (SBP) and diastolic (DBP) studied and habitual biochemical parameters of neprophathy considered. Stadistical studies content variables for bivariant and multivariant analisys and as end-point target we search the acumulative incidence of DM and ma for one year interval-period after first examination.We use a SPSS Satd Pack for social sciences (Chicago, 1990) under a PC-computer system. **RESULTS :** we found ma in 29.5 % of IDDM-P. High BP was present in these patients : 29 % with SBP>140 and 40 % with DBP>90 mmHg. Tabac as cigarettes/day had a positive and stadistical correlation to ma excretion 10.2 ± 12.1 (p < 0.01) with stablish DN (p< 0.05). Mean of HbA1c was superior in ma patients : 8.2 ± 1.79 (p<0.02) and positive familiar antecedents of nephropathy was frecuently associated between IDDM with ma compared with non-ma IDDM-P (p<0.05). CHO was superior in ma group 31%, (p<0.01). A stadistical and significant reduction in prevalence cumulated ratios of ma was found between the diferent cohorts and the "time observation period" in years (p<0.01). **CONCLUSIONS :** Our rates of ma and asociated metabolic and cardiovascular risk factors are coincident with others european studies. We observed during last decade a reduction in we sugest that cumulated incidence of ma and the clinical intervention of specialist care at Diabetes Units must play some special role in our IDDM-P.

2074

PREVALENCE OF DIABETIC NEPHROPATHY IN PRIMARY CARE AND HOSPITALS OF AN URBAN AREA

W. Piehlmeier[1], R. Renner[2], T. Kimmerling[1], W. Schramm[1], K. Piwernetz[3], J. Fahn[4], S. Garbe[5] and R. Landgraf[1] [1]Department of Internal Medicine "Innenstadt", University of Munich [2]City Hospital Munich-Bogenhausen [3]DiabCare Office Munich/WHO [4]AOK Munich [5]Boehringer Mannheim GmbH

In a screening project for diabetic nephropathy inpatients and outpatients independent from age, sex, duration and type of diabetes or diabetes therapy were screened for micro- or macroalbuminuria unless one of 8 exclusion critera was present. After giving informed consent, the patients performed self-tests for microalbuminuria in the first morning urine on three days using dip-stick tests. The same urine samples were retested in the office or the hospital, in hospitals aliquots were additionally quantitatively analyzed. In case of >20 mg/l albumin on at least two days retest was assumed as positive and a urinalysis using the Combur-9 Test ® followed to rule out confounders and to differentiate between micro- and macroalbuminuria. In 58 randomly selected doctor`s offices in a large German city 647 diabetic patients were included (38 IDDM patients: age 36.0±15.1 yrs, duration of diabetes 15.1±10.1 yrs; 543 NIDDM patients: age 66.3±10.7 yrs, duration of diabetes 9.5±7.1 yrs; 33 patients had secondary diabetes and in 33 cases the type of diabetes was not documented. In 5 hospitals 361 diabetic patients were included: 141 IDDM patients: age 42.8±16.0 yrs, duration of diabetes 17.8±11.8 yrs; 194 NIDDM patients: age 65.5±11.0 yrs, duration of diabetes 9.7±8.1 yrs; 9 patients had secondary diabetes and in 17 cases the type of diabetes was not documented. In doctor`s offices (hospitals) following prevalences of an elevated urinary albumin concentration were observed: IDDM patients: microalbuminuria 19.9 % (13.5 %) macroalbuminuria 0 % (6.9 %), micro-/macroalbuminuria plus pathologic urinalysis 3.0 % (6.3 %). In NIDDM outpatients with clinical duration of diabetes <5y., 5-15y., >15y. prevalences were: microalbuminuria 17 %, 17 %, 28 %, macroalbuminuria 8 %, 13 %, 23 % and micro-/macroalbuminuria plus pathologic urinalysis 5 %; 4 %, 8 % respectively. Because of the high prevalences of previously unknown micro- and macroalbuminuria in diabetic patients, both in primary care and in hospitals, a regular screening for microalbuminuria should be performed.

2075

EFFECT OF PUBERTY ON URINARY ALBUMIN EXCRETION IN DIABETIC CHILDREN AND ADOLESCENTS;

L. Barkai and I. Vámosi. II. Dept. of Pediatrics, Imre Haynal University of Health Sciences and Borsod County Teaching Hospital, Miskolc, Hungary.

The aim of this prospective study was to examine the influence of puberty on the progression of urinary albumin excretion rate (AER) in peripubertal diabetic patients. Three groups of insulin-dependent diabetic patients (age>6 yrs, diabetes duration>2 yrs, AER<20 µg/min) matched for diabetes duration were selected on the basis of Tanner staging (T_{1-5}) and were followed up for 3 years: *prepubertal* (n=20, age: 7.5±1.2 yrs, T_1 throughout the study), *pubertal* (n=28, age: 11.0±0.5 yrs, T_2 at entry and T_4 at exit) and *postpubertal* (n=26, age: 15.2±0.7 yrs, T_5) groups. The average HbA_{1c} over the study period did not differ significantly in the study groups. At 6 monthly intervals, 24-h urine collection was used to determine AER by an immunonephelometric method. AER increased significantly over 3 years in the pubertal [median (IQ range): 4.9 (2.8-7.6) vs. 14.8 (12.0-18.6) µg/min; p=0.014] and postpubertal [4.6 (2.6-7.7) vs. 8.5 (6.2-12.3) µg/min; p=0.045] groups but not in prepubertal subjects [4.8 (2.5-8.1) vs. 5.1 (2.7-8.9) µg/min; p=0.901]. The annual progression of AER was significantly higher in the pubertal than in the prepubertal or postpubertal groups [3.3 (3.1-3.7) vs. 0.1 (0.1-0.3); p=0.012 and 1.3 (1.2-1.5) µg/min/yr; p=0.035, respectively]. None of the prepubertal subjects but 6 of pubertal and 2 of postpubertal patients developed microalbuminuria (AER>20 µg/min on two consecutive occasions) over 3 years. Multiple logistic regression analysis showed that the risk of development of microalbuminuria was increased in pubertal patients as compared with the prepubertal [adjusted OR (95% CI): 3.7 (1.8-9.1)] or postpubertal [adjusted OR: 1.8 (1.2-4.2)] subjects. In conclusion, higher progression rate of AER occures in pubertal years than before or after this period. This suggests that the pubertal milieu leads to an accelerated process of early kidney damage in diabetes.

2076

CHANGE OF GFR AND URINARY ALBUMIN EXCRETION RATE IN NIDDM PATIENTS WITH MICROALBUMINURIA

K.U.Lee, H.J.Kim, Y.E.Chung, J.Y.Park and S.K.Hong. University of Ulsan, Seoul, Korea

Microalbuminuria is a well-established marker for incipient nephropathy in inulin-dependent diabetes mellitus (IDDM). In contrast, the meaning of microalbuminuria in non-insulin-dependent diabetes mellitus (NIDDM) is complex. The presence of microalbuminuria in NIDDM patients is closely linked to cardiovascular disease and mortality. Microalbuminuria progresses to overt proteinuria in NIDDM patients, but not as consistently as it does in IDDM patients. We previously suggested that microalbuminuria in the presence of retinopathy may represent a state of real incipient diabetic nephropathy in NIDDM with declining glomerular filtration rate (GFR), while the significance of microalbuminuria in the absence of retinopathy may be more heterogenous. To further test this hypothesis, we followed the changes in GFR and urinary albumin excretion rate (UAE) in microalbuminuric NIDDM patients with and without retinopathy for 3.3 ± 0.6 years. Among 52 NIDDM patients with initial microalbuminuria (UAE; 20 - 200 ug/min), 31 had retinopathy from the baseline (group A), while 18 patients did not have retinopathy throughout the study (group B). UAE significantly increased in group A (66.2 ± 43.0 to 416.1 ± 729.3 ug/min, $P < 0.05$) but not in group B (53.0 ± 40.3 to 78.3 ± 69.0 ug/min, NS). GFR significantly decreased both in group A (116.2 ± 26.5 to 84.8 ± 24.2 ml/min/1.73 m^2, $P < 0.001$) and group B (134.8 ± 27.7 to 119.3 ± 27.7 ml/min/1.73 m^2, $P < 0.001$), but the magnitude of changes in GFR was significantly higher in group A than in group B (9.7 ± 6.6 vs. 4.6 ± 4.8 ml/min/1.73 m^2/ year, $P < 0.01$). Twenty six percent of group A patients (8/31) progressed to overt proteinuria in group A, while 11 % (2/18) of group B patients developed overt proteinuria. These results again suggest that the meaning of microalbuminuria in NIDDM may be complex. Microalbuminuira in the presence of retinopathy predicts aggravation of albuminuria and decline in GFR. In contrast, the renal function in microalbuminuric NIDDM patients in the absence of retinopathy may remain stable for years.

2077

PROGRESSION FROM MICROALBUMINURIA TO DIABETIC NEPHROPATHY

P Rossing, P Hougaard, K Borch-Johnsen and H-H Parving, Steno Diabetes Center, Copenhagen, Denmark

An uncontrolled study has suggested that microalbuminuria is a poor predictor of progression to diabetic nephropathy in IDDM of long duration (>15 years). Our aim was to evaluate putative predictors, including duration of diabetes, for the progression from persistent microalbuminuria (30-300mg/24h) to diabetic nephropathy. 181 IDDM patients with persistent microalbuminuria (>300 mg/24h) were identified in 1984. They were followed with yearly examinations for up to 10 years (mean (SD) 7.9 (2.6) years. 45 % of patients with a duration of <15 years and 26 % of patients with a duration of ≥15 years of diabetes progressed to overt nephropathy (p=0.01). The yearly incidence of nephropathy (% per year) according to duration of diabetes are given in the table:

Duration of diabetes (years)	5-10	10-15	15-20	20-25	25-30	30-35	35-40	40-45
Incidence of nephropahty	7.6	10.2	9.5	4.3	2.7	2.9	2.6	4.5

At baseline there were significant differences ($p<0.05$) between non-progressors vs progressors in albuminuria (geometric mean (antilog SE)) 77 (1.06) vs 116 (1.09) and duration of diabetes (mean (SE)) 24 (1) vs 20 (1.5) years, whereas there were no differences in arterial blood pressure 139/83 (1.7/0.9) vs 137/84 (2.2/1.2) mm Hg, haemoglobin A_{1c} 9.2 (0.18) vs 9.4 (0.3) %, s-creatinine, height, BMI, age, insulindose, retinopathy, antihypertensive medication, smoking or socio-economic status. A stepwise Cox regression analysis with the above mentioned baseline variables as independent variables revealed that elevated albuminuria and short duration of diabetes were the only factors associated with progression to nephropathy. Omission of albuminuria from the analysis made no difference. At baseline 15% with short duration and 17% with long duration of diabetes were on antihypertensive medication, and at end of follow-up it was 77 and 75% respectively (mainly ACE inhibition). This renoprotective treatment probably explains the lower rate of progression compared to previous studies dealing with the natural history. In conclusion albuminuria and short duration of diabetes are risk factors for progression to diabetic nephropathy in microalbuminuric IDDM patients. However long duration does not exclude progression.

2078

CHARACTERISTICS OF DIABETIC NEPHROPATHY IN NIDDM PATIENTS

M. Molnar, I. Wittmann, Á.Vörös, J. Nagy
Second Department of Medicine, University Medical School of Pécs, Hungary.

Contrary to the well-known features of diabetic nephropathy (DN) in IDDM patients (pts) the prevalence, course and risk factors of DN in NIDDM pts are not clear. The aim of our study was to assess the prevalence of microalbuminuria (MA) and macroalbuminuria (MAA), their relationship with some known risk factors and with other diabetic complications in 200 NIDDM pts (100 females and 100 males). 68 pts (33 %) were normalbuminuric (NA), 55 (26 %) MA and 77 (41 %) MAA. There was no significant difference among the three groups in the age, BMI, known duration of diabetes and hypertension.The BMI (kg/m2) was high in each group (28.8±5.29, 28.0±5.2, and 29.8±4.6, mean±SD). 65% of pts had hypertension in NA, 77% in MA and 81% in MAA group. The GFR (ml/min/1.73m2) was 71.9±26.8 in NA pts, 82.3±36.8 in MA pts and 56.3±32 in MAA pts. There was no significant relationship between the urinary albumin excretion (UAE) and glycemic control, cholesterol, HDL cholesterol, but the UAE was significantly positively correlated with triglicerides, (P<0.01), uric acid (P<0.01), serum creatinine (P<0.01) and negatively with GFR (P<0.01). There was no significant relationship between the UAE and kidney size. Diabetic retinopathy occurs already in NA pts (27 %) and 51 % of MAA patients were without retinopathy. 56 % of NA pts, 57 % of MA pts and 93 % of MAA pts had macroangiopathy. We conclude that (1) there is already impaired renal function in NIDDM pts with NA and MA (2) well-known cardiovascular risk factors seem to be the risk factors of DN (3) renal lesion of NIDDM pts may have caused by other diseases, than diabetes (atherosclerosis, hypertension e.g.) (4) unlike in IDDM, where the strict glycemic control is the main preventive factor of DN, in NIDDM the control of hypertension, hyperlipidemia, obesity, hyperuricemia may have priority.

2079

VASCULAR RISK FACTORS IN PARENTS OF PATIENTS WITH INSULIN DEPENDENT DIABETES AND NEPHROPATHY

R.S. Lindsay[1], J.A. Little[1], A.J. Jaap[1], P.L. Padfield[2], J. D. Walker[1] and K.J. Hardy[1], Department of Diabetes, Royal Infirmary of Edinburgh[1] and Department of Medicine Western General Hospital[2], Edinburgh, Scotland, U.K.

Parents of patients with diabetic nephropathy (DN) have an increased risk of vascular death suggesting a common familial risk factor, proposed to be hypertension. We have examined cardiovascular risk factors in parents of diabetic patients with (PN) and without nephropathy (PC).

65 patients with IDDM and DN and matched controls were interviewed and 87% of parents identified either as alive or the cause of death ascertained (PN114, PC 113). For all parents, a previous diagnosis of hypertension was obtained in 22% of PN and 14% of PC (Fisher's exact test, P= 0.17) and 23% of PN and 12% of PC of those parents who were still alive (PN 65, PC 74: P=0.11).

If both parents were living (PN, n=26 pairs, PC, n=35 pairs) they were invited to attend for 24 hour ambulatory blood pressure monitoring (ABPM) and measurement of cardiovascular risk factors. Parents with known angina were excluded as medication could not be withdrawn (PN 5 pairs, PC 11 pairs), while others were unwilling to take part (PN 9 pairs PC 12 pairs). Antihypertensive medication was withdrawn in 25% of PN and 17% of PC. In 2 parents(PN) antihypertensive medication had to be restarted due to rises in blood pressure and these pairs were excluded.

Age was similar in both parent groups (PN 66± 2 years, 10 pairs *vs* PC 65± 1years, 12 pairs) as was mean 24-hour systolic ABP (PN 133± 5 mmHg *vs* PC 131± 4mmHg. P=0.79), diastolic ABP (77± 2 mmHg in both groups). total cholesterol, body mass index and waist hip ratio.

While suggesting an increase in the prevalence of hypertension in parents of patients with DN, in those with two living parents the familial predisposition to DN in offspring is not explained by blood pressure alone.

2080

URINARY ALBUMIN EXCRETION RATE AND CARDIOVASCULAR DISEASE IN SPANIARD TYPE 2 DIABETIC PATIENTS.

F. Relimpio, A. Pumar, F. Losada, D. Acosta, F. Morales and R. Astorga. Servicio de Endocrinología. Hospital Universitario Virgen del Rocío (Seville, Spain).

To assess the frequency of urinary albumin excretion abnormalities and their associations with cardiovascular disease or its classical risk factors in type 2 diabetes mellitus, 1348 clinic-proceeding patients have been studied retrospectively. The overnight urinary albumin excretion rate, blood pressure, smoking, ophthalmic and cardiovascular status, current therapies, estimates of glycemic control, plasma lipids, serum creatinine and uric acid have been ascertained. 767 (56.8%) patients were found normoalbuminuric, 461 (34.1%) microalbuminuric and 120 (8.9%) macroalbuminuric. In bivariate analyses, the urinary albumin excretion rate had statistically significant ($p<0.05$) relationships with age, duration of diabetes, male sex, waist-to-hip ratio, systolic and diastolic pressure, coronary heart disease, cerebrovascular disease, peripheral vascular disease, hypertension, antihypertensive therapy, laser-treated retinopathy, need of insulin therapy, smoking habit, fasting glycaemia, HbA_{1c}, creatinine, uric acid, triglycerides, HDL-cholesterol and apolipoprotein B. Almost statistically significant ($p<0.1$) relationships were found with hypolipidaemic therapy, insulin dose, non-HDL-cholesterol, apolipoprotein A_1 and lipoprotein (a). In a multivariate stepwise logistic regression model, HbA_{1c}, creatinine, hypertension, male sex, age, diastolic blood pressure, coronary heart disease and hypolipidaemic therapy were sequentially selected as variables independently associated with the UAER category. Micro and macroalbuminuria are frequent abnormalities associated with poorly controlled and complicated disease, with surrogate markers of insulin resistance, with overt cardiovascular disease and with the male sex.

2081

PREDISPOSITION TO VASCULAR DEATH IN PARENTS OF PATIENTS WITH INSULIN DEPENDENT DIABETES AND NEPHROPATHY

R.S. Lindsay[1], J.A. Little[1], A.J. Jaap[1], P.L. Padfield[2], J. D. Walker[1] and K.J. Hardy[1], Department of Diabetes, Royal Infirmary of Edinburgh[1] and Department of Medicine Western General Hospital[2], Edinburgh, Scotland, U.K.

To further examine the previously reported increased prevalence of vascular disease in parents of IDDM patients with diabetic nephropathy (DN) we have ascertained ages and causes of death in the parents of cases with DN and controls, in a background population with a high rate of vascular disease.

65 IDDM patients with DN (serum creatinine >120μmols/l and ACR >20 $mg.mmol^{-1}$) were identified from our database and matched for age, sex, and duration of diabetes to control patients without diabetic nephropathy. 87% of all parents were identified as either living or the cause of death ascertained by retrieval of death certificates.

Kaplan-Meier survival analysis revealed that parents of patients with diabetic nephropathy (PN) had an increased rate of death from vascular causes (PN 49% of all deaths *vs* PC 33%, P<0.05) and particularly stroke (PN 18% of all deaths *vs* PC 3% P<0.01). While the total number of deaths was not significantly different between groups (PN 43% dead vs PC 34% , P=0.07), living parents of IDDM patients with DN were younger than those of controls (PN 67± 1 years *vs* PC 70± 1, P<0.05).

We conclude that parents of patients with nephropathy are more likely to die from vascular disease, especially stroke, supporting the hypothesis that a common familial factor may predispose both to vascular disease and to the development of diabetic kidney disease.

2082

GLOMERULAR HYPERFILTRATION IN JAPANESE NIDDM PATIENTS WITH NORMO- AND MICROALBUMINURIA.

Y.Jin,S.Umezawa,A.Kanamori,K.Matoba,Y.Yajima.
Kitasato Univ. Schl.of Med.,Sagamihara, Japan

The aim of this study was to investigate the significance of glomerular hyperfiltration(HF) in the pathogenesis and progression of renal impairment in Japanese NIDDM patients with incipient nephropathy. GFR(4hr iohexol clearance) and urinary albumin excretion were measured in 112 nortensive, normo- and microalbuminuric NIDDM patients(DM) of age 44.7+9.6 years and 44age-matched normal control subjects(NC). In NC, GFR showed a linear decline with age in the regression equation of Y=-0.84+127.9(r=-0.503). Based on this, the cut-off values of GFR($ml/min/1.48m^2$) for HF in each decade of age were determined as 140 in 20s, 130 in 30s, 120 in 40s, 110 in 50s. GFR in DM was higher than NC throughout all ages. HF was found in 18.8% of DM. There were no significant differences in duration of diabetes, HbA1c,blood pressure and UAE between normo- and hyperfiltrating DM. In microalbuminuric DM, the decline rate of GFR, as assessed from the regression equation , was significantly higher than in normoalbuminuric DM. In conclusion, 1) GFR in healthy adult Japanese declines at the rate of 0.84 $ml/min/1.48 m^2$/year, and 2) based on the age-adjusted cut-off values of GFR, HF was present in 19% of cases and HF may be a risk factor of progression of diabetic nephropathy in normo- and microalbuminuric Japanese NIDDM patients.

2083

FACTORS ASSOCIATED WITH ABNORMAL BLOOD PRESSURE PATTERN IN NORMOTENSIVE NORMOALBUMINURIC IDDM PATIENTS

M. Pecis, M.J. Azevedo, R. Moraes, E. Ferlin, and J.L. Gross. Endocrine Unit, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil.

The aim of this study was to analyse the autonomic function in normoalbuminuric IDDM patients with a blunted fall in nocturnal blood pressure (BP). Thyrty-five normotensive, normoalbuminuric [albumin excretion rate (AER)<20 μg/min] with normal cardiovascular autonomic tests were studied. Glomerular filtration rate (GFR) was measured by ^{51}CrEDTA, extracellular volume (ECV) by the ^{51}CrEDTA distribution volume and AER by RIE. 24h ambulatory BP was measured by a portable monitor (Del Mar Avionics, auscultatory technique) at 10min intervals during the day and 15min intervals during the night. 24h ECG (Holter Analyser-Del Mar Avionics, model 750A) was recorded and heart rate variability (HRV) was calculated in time domain [mean of normal RR interval, standard deviation (SD) of normal RR intervals in 5 min, mean of SD of normal RR intervals in 5 min, SD of normal RR intervals, root square mean of successive differences of adjacent RR intervals and percent of successive differences between adjacent RR intervals > 50 ms] and in frequency domain [power spectral analysis: low frequency (LF) and high frequency (HF) component, in a 256 sec in a sitting position and during sleep]. Patients with diastolic BP night/day (DBP N/D) ratio >0.9 were considered non-dippers (0.96 ± 0.67; n=12) and the others dippers (0.84 ± 0.37). GFR was higher in non-dippers than in dippers (148.8 ± 24.9; 129.3 ± 23.1 ml/min/1.73m^2; p=0.03). ECV tended to be higher in non-dippers (22.7 ± 3.8 l/1.73m^2) than in dippers (20.4 ± 3.0 l/1.73m^2 ; p=0.058). HRV indexes in time domain did not differ between the groups. Non-dippers presented a higher LF component than dippers in the sitting position [0.38 ± 0.12 normalized units (NU); 0. 27 ± 0.11 NU; p=0.02] and during the sleep (0.28 ± 0.13 NU; 0.18 ± 0.10 NU; p=0.02). The HF component during sleep was lower in non-dippers (0.34 ± 0.11 NU) than in dippers (0.48 ± 0.19 NU; p=0.03). In conclusion, a blunted fall in nocturnal DBP is associated with a higher GFR and sympathetic activity in normoalbuminuric normotensive IDDM patients.

2084

INCREASED URINARY ALBUMIN EXCRETION IN PATIENTS WITH IMPAIRED GLUCOSE TOLERANCE. JM. Lu, CY. Pan, H. Tian, et al. Department of Endocrinology, Chinese PLA General Hospital, Beijing, 100853, China

In order to observe the urinary albumin excretion (UAE) of impaired glucose tolerance (IGT) and its related factors. The UAE was measured in 772 cases of IGT and 787 normal controls. The results showed that the UAE (6. 84+6. 30ug/min) and the incidence of microalbuminuria (10. 5%) were significantly higher than that of normal subjects (5. 20+4. 28ug/min and 4. 32%, respectively). In addition, BMI, blood pressure, serum levels of Ch, Tg, Cr were remarkedly higher, while serum HDL-ch level was lower than that of normals. The UAE (8. 32+8. 84ug/min) in IGT patients with hypertension was higher than that of IGT patients with normal blood pressure (6. 29+5. 16ug/min)

Among the IGT patients, the UAE (7. 07+6. 45ug/min) in obesity patients was higher than non-obesity (5. 77+4. 53 ug/min). Multiple analysis showed that UAE in IGT and normal subjects had significantly positive correlation with BMI, MBP, 2h blood glucose, and significantly negative correlation with serum HDL-ch. It was suggested that the UAE was elevated in IGT, and they had more risk factors of cardiovascular diseases.

Key words Impaired glucose tolerance Urinary albumin excretion

2085

RENAL MORPHOLOGICAL CHANGES PREDICT URINARY ALBUMIN EXCRETION RATE 6 YEARS LATER IN PATIENTS WITH IDDM AND MICROALBUMINURIA.

H.-J. Bangstad [1], R. Østerby [3], K, A. Hartmann [2], T. J. Berg [1], K. Dahl-Jørgensen [1] and K.F. Hanssen [1]. Aker University Hospital [1], Rikshospitalet [2], Oslo, Norway and Århus Kommunehospital [3], Denmark.

We investigated in a prospective 6 years study the relationship between morphological changes at start, GFR at start, hyperglycemia and blood pressure during the study and urinary albumin excretion rate (AER) at the end of the study in 18 patients with IDDM and microalbuminuria. Age *(median and range)*: 19 (18-29) yrs, duration of diabetes 12 (7-18) yrs, HbA1$_c$ 10.3 (7.9-12.6) % mean AER 31 (15-194) ug/min. Renal biopsies were taken at 0 and 2,5 years, HbA1$_c$ and AER were measured 3-4 times a year. Glomerular structures were assessed by stereological methods. AER *(median + 95 CI)* decreased (NS) during the study, from 31 (18-40) to 18 (7-90) μg/min. Only 4 patients increased their AER and 7 patients were no longer microalbuminuric at the end of the study. HbA1$_c$ (mean + 95 CI) was reduced from 10.1 (9.2-11.1) to 8.4 (7.8-9.1)% (p=0.01). Mean arterial blood pressure (MAP) remained unchanged, 96 (92-100) to 95 (91-98) mm Hg. AER at 6 years (AER$_6$) showed a significant positiv linear correlation with the morphological changes at the start of the study [basement membrane thickness (BMT), r=0.71, mesangial volume fraction (r=0.46) and matrix volume fraction (r=0.42)], but not with mean 6-yrs HbA1c (r=0.26). In a stepwise regression analysis with AER$_6$ as the dependent variable, BMT (p=10^{-5}), mean 6-years HbA1c (p=10^{-3}) systolic BP (p=0.005) at 6 years and GFR (p=0.04) at the start of the study contributed significantly to the explained variation (R^2 = 0.86). With change in AER during the study as the dependent variabel, BMT (p=0.006) at start of the study and systolic BP (p=0.01) at 6 years contributed significantly (R^2=0.53). We conclude that the degree of morphological glomerulopathy after 10 years duration of diabetes is highly predictive of kidney funcion measured by AER six years later and that the development in AER is influenced by the level of hyperglycemia and possibly by systolic blood pressure.

2086

GLUCOSE-INSULIN AXIS AND MICROALBUMINURIA AMONG FIRST DEGREE RELATIVES OF NEPHROPATHS

D.Simmons, C.Thompson, J.Collins and A. Cecil., Middlemore and Auckland Hospitals University of Auckland, Auckland, New Zealand

Diabetic nephropathy (DN) is common among Polynesians. We investigated whether the risk for DN was independent of the risk for NIDDM. A 2x2 factorial design was used: Polynesians ± a first degree relative with NIDDM (FHDM±) ± a first degree relative with nephropathy (FHN±). FHN were recruited through patients with end stage renal failure. Other subjects were recruited through randomly selected households. Subjects attended for a 75g oral glucose tolerance test and provided timed 2 hour urine samples for urinary albumin:creatinine ratio (UACR) on three separate days. Subjects ± FHN (n=173 and 174 respectively) were well matched for age, body mass index and blood pressure. FHN+ (vs FHN-) had a higher fasting glucose (FBG:5.1±0.7 vs 4.6±0.8 mmol/l, p<0.001), a similar 2 hour glucose (2HBG: 5.1±1.4 vs 5.0±1 mmol/l), a lower fasting and 2 hour geometric mean insulin (FINS:17.8 vs 22.9, 2HINS: 43.7 vs 70.8 mU/l, p<0.01) and a similar geometric mean UACR (1.26 mg/mmol creatinine). Subjects ± FHDM were well matched for age (n=181 and 166 respectively). FHDM+ (vs FHDM-) were more obese (33.3±7.4 vs 31.3±6.7 kg/m^2, p<0.05), had a higher systolic blood pressure (113±14 vs 110±16 mm Hg, p<0.05), a higher FBG (5.0±0.8 vs 4.7±0.8, p<0.001) but comparable FINS and 2HINS (20.4 vs 20.4; 55.0 vs 57.5 mU/l) and UACR (1.14 vs 1.24). Overall 12% of subjects had microalbuminuria with no differences between family history groups. FHN+ are relatively hyperglycaemic and hypoinsulinaemic, while FHDM+ are hyperglycaemic with a "normal" insulin (ie insulin resistant). Presence of microalbuminuria was independent of family history.

2087

GLOMERULAR FILTRATION RATE AND MICROALBUMINURIA IN NEWLY DIAGNOSED IDDM PATIENTS M. Georgescu, T. Popa, C. Serafinceanu, I. Ferariu, T. Mogos, R. Strachinaru, C. Ionescu-Tirgoviste, Clinic of Diabetes, Institute "N.C. Paulescu", Romania

Both glomerular hyperfiltration and microalbuminuria were found to be markers for early stages of diabetic nephropathy. Hyperfiltration was often associated with renal hypertrophy and increased intraglomerular pressure leading to enhanced transglomerular passage of plasma proteins which might predispose to the accumulation within glomeruli of extracellular matrix and to the expansion of the mesangium. This is the baseline analysis of a prospective study regarding renal function in IDDM patients. The glomerular filtration rate (GFR) was determined by 24h clearance of endogenous creatinine and microalbuminuria determined by imunoturbidimetry. Hyperfiltration was defined by a GFR value > 115 ml/min/1.75m^2 in females and 130ml/min/1.75 m^2 in males. Microalbuminuria was defined as albumin excretion between 30-300mg/24h (20-200μg/min) and macroalbuminuria > 300mg/24h (>200μg/min). This study included 50 newly diagnosed IDDM patients, 31M/19F, aged 34.28 yrs +/- 16.95 (38.9 yrs +/- 17.78 for males and 28.95 yrs +/- 17.71 for females) of which < 20yrs, 15 patients (19.4% M and 48% F); 21-40 yrs, 15 patients (29% M and 32% F) and > 40 yrs, 20 patients (51.6% M and 22% F). Of the 31 males, 15 (51%) had hyperfiltration more often in the young (<20yrs.) or older (>40yrs.) age groups. Of 19 females, hyperfiltration was encountered in 12 cases (63%) more often in age groups over 20 yrs. Microalbuminuria was found in 7 cases in males (22.58% M) and in 4 cases in females (20.5% F). In addition we found AER with borderline values 20-30 mg/24h in 9 cases, 7 males (23% M) and 2 females (11% F), which represent a possible risk group for further renal disease. It is important to follow this group up prospectively in its evolution to microalbuminuria. The correlation coefficient between GFR and AER is very low (0.11) and shows a lack of correlation between these variables at the onset of disease. This correlation could become tight as the disease advances.

CELL REPLICATION AND Na/H ACTIVITY IN INSULIN-DEPENDENT DIABETIC PATIENTS WITH PROTEINURIA.

G. Meregalli, G. Zerbini, F. Podestà, R. Mangili, R. Ghelardi, D. Gabellini, F. Ferrara and G. Pozza, Istituto Scientifico San Raffaele, Milano, Italy.

Higher Na/H exchange (NHE) activity and thymidine incorporation may characterise human skin fibroblasts (HSF) from patients with IDDM and overt nephropathy (DN). Whether this may be paralleled by enhanced cell replication is unclear. Primary HSF cultures were obtained from 16 patients with IDDM and overt nephropathy, and from 17 age-matched patients with long-term IDDM but normoalbuminuria. Glycated haemoglobin levels was comparably distributed in both groups (HbAIc, 8.7±0.3 vs 9.3±0.3 %, p=NS). HSF were studied at the 6th passage. Cell proliferation rates were higher in the patients with DN, as measured by counting cells on day 2, 5 and 7 after seeding 10,000 cells/well (0.179±0.016 vs 0.127±0.013 10^5cells·day^{-1}, p=0.015). Enhanced proliferation was paralleled by increased activity rates of NHE among the patients with DN, both at pH_i=6.2 (Vmax, 12.6±1.3 vs 6.6±0.9 mmol/l/min, p=0.0006) and at pH_i=6.5 (2.2±0.3 vs 1.3±0.3 mmol/l/min, p=0.023). These findings were not associated with differences in resting pH_i (6.87±0.02 vs 6.84±0.02, p=NS), nor with older patient age or longer duration of diabetes. Cytofluorimetric analyses in subsets of syncronised cell cultures suggested that cells in phase S were present in similar proportions among these groups of patients (17.8±4.2 vs 25.6±3.1 %, p=NS), G0-G1 (62.9±3.7 vs 56.9±2.4 %, p=NS) and G2-M (19.3±1.9 vs 17.5±2.6%, p=NS). These findings support the idea that faster *in vitro* replication rates may characterise HSF in diabetic nephropathy and further corroborate the association of proteinuria with higher activity of NHE. The genetic mechanisms that may underlie these abnormalities remain to be clarified.

2089

THE CHANGE IN RENAL BLOOD FLOW IN THE EARLY DIABETIC NEPHROPATHY.

X. Zhen, S.Wang#, Y. Zhou#, and Z. Zhu*. Department of endocrinology and #Division of untralsound, Daping Hospital, Third Military Medical University, Chongqing, P.R. China and *Department of Physiology, University of North Carolina at Chapel Hill, Chapel Hill, U.S.A

Diabetic nephropathy (DN) is a progressive renal disease. Although persistent proteinuria is a characteristic of DN, this sign represents a serious dysfunction of kidney in late DN. Thus, it is important to evaluate the change of renal function in early DN. The present study examined the relationship between the change of renal blood flow (RBF) and the impairment of renal function in NIDDM. 68 NIDDM (mean age 46 years old, male 37, female 31) and 40 normal control (mean age 42 years old, male 16 and female 24) were included in this study. According to the period of NIDDM, patients were subdivided into two groups (Group I < 5 years, n=30 and Group II > 5 years, n=38). The RBF was measured using duplex ultrasound. The resistive index (RI), calculated from the duplex doppler waveform, was compared with clinical and laboratory finding. In present study, RI > 0.70 and urea> 25 ug/ml were defined as renal dysfunction. It was found that abnormal rate of RI was 17% in group I and 74% in group, and increase of serum urea level was 40% in group I and 89% in group II. RI and serum urea level were significantly higher in group II than that in group I and normal control (RI: 0.71±0.05 vs 0.65±0.08 and 0.62±0.04, p< 0.01; serum urea level (ug/ml): 86±10 vs 42±5 and 19±5, p< 0.01). Both abnormal rates of RI and urea were 13 % in group I and 63% in group II. It concluded that the decrease of RBF is closely related to the period of illness and the impairment degree of renal function in DN.

PREVALENCE OF GAD_{65} AND IA-2 AUTOANTIBODIES IN IDDM PATIENTS WITH NEPHROPATHY.

G. Zerbini, E. Bazzigaluppi, R. Mangili, E. Bosi, E. Bonifacio. Istituto Scientifico San Raffaele, Milano, Italy.

Diabetic nephropathy develops in about one third of patients affected by insulin-dependent diabetes mellitus (IDDM). The reason only this subset of IDDM patients develops nephropathy is unknown. Circulating autoantibodies to islet antigens are found in the majority of patients at IDDM onset, and in a minority of patients antibodies persist throughout life. Whether islet antibody persistence underlies a susceptibility to develop diabetic nephropathy is presently controversial. We studied the prevalence of GAD_{65} and IA-2 antibodies in a total 100 IDDM patients either characterised by normoalbuminuria, as defined by an albumin excretion rate lower than 20 µg/min (n=52) or by presence of established diabetic nephropathy, as defined by an albumin excretion rate higher than 200 µg/min in two out of three consecutive overnight urine collections (n=48). The two groups of patients had similar age (42.3±1.6 vs 42.9±1.6) and duration of diabetes (25.5±1.1 vs 24.5±1.2). No patients were on hemodialysis. GAD_{65} and IA-2 antibodies were measured by radiobinding assays with [^{35}S]-methionine labelled in vitro translated recombinant antigens. There were no differences in the prevalence (30.8% vs 39.6%) of GAD_{65}-antibodies between patients with normo- and macroalbuminuria. IA-2 antibody prevalence was low, suggesting that their prevalence declines after disease onset, and did not differ between groups (9.6% vs 12.5%). These data suggest that persistence of islet autoantibodies does not appear to be directly related to the presence, and perhaps development, of diabetic nephropathy in IDDM patients.

2091

HYPERFILTRATION IN NON-COMPLICATED IDDM IS UNRELATED TO METABOLIC CONTROL, BLOOD PRESSURE OR PLASMA VOLUME.

G.Vervoort, J.Wetzels, J.Lutterman, J.Berden and P.Smits. University Hospital St. Radboud, Nijmegen, The Netherlands.

Intra-glomerular hypertension and hyperfiltration are dominant features in the pathogenesis of diabetic nephropathy in IDDM. The exact pathogenesis of early hyperfiltration remains elusive. In a prospective study we will assess the role of hyperfiltration in the genesis of diabetic renal disease. Therefore we have studied at entry 54 non-complicated IDDM patients (DP) and 50 healthy control subjects (C) in whom renal function, blood pressure (BP), sodium-lithium countertransport (Na-Li-CT), plasma volume and transcapillary escape of albumin (TER_{alb}), basal albumin excretion ratio (AER) and metabolic control were measured. Renal clearances of inulin and PAH were used as markers of GFR and ERPF respectively. Glucose concentrations were controlled in IDDM patients with levels between 5.0 and 8.0 mmol/l during the study. Blood pressure was measured intra-arterially during cannulation of the brachial artery. Plasma volume and TER_{alb} were measured by ^{125}I-albumin injection. The disappearance rate of ^{125}I-albumin was measured and extrapolation to time zero was used for calculation of the plasma volume. HbA1c was used as a measure of metabolic control. Results are expressed as means±SE. Data were analyzed by *t*-test for Gaussian distribution and Mann-Whitney-U test for non-normally distributed data. Glomerular filtration rate (GFR) was significantly increased in DP (GFR 120±2 in DP and 106±2 ml/min/1.73m^2 in C, $P<0.01$). GFR of 130 ml/min/1.73m^2 was the upper limit in C. DP were divided into quartiles. Hyperfiltration (GFR > 130ml/min/1.73m2) was found in the highest quartile (n=13). Those were compared to the lowest quartile of DP (n=13, GFR 100±2 ml/min/1.73m^2). There were no significant differences between non-hyperfiltrating and hyperfiltrating DP with respect to blood pressure (MAP 80.5±1.8 versus 82.5±2.0 mmHg), Na-Li-CT (V_{max} and K_m 733±70 and 55±4 and 826±81 and 70±4 respectively), plasma volume (2900±143 versus 3114±156 ml), TER_{alb} (5.1±0.6 versus 4.9±0.4 %/hr), basal AER (6.4±1.3 and 9.1±1.3 µg/min) and HbA1c (8.4±0.4 versus 8.4±0.4%). There were no differences in age (26.5±1.8 and 27.8±1.9 yr) or diabetes duration (8.4±0.6 and 8.2±0.8 yr). It is therefore concluded that hyperfiltration in non-complicated diabetic patients is not related to BP, plasma volume, capillary and glomerular leakage of albumin, plasma volume or metabolic control.

2092

PROTEINURIA IS STILL USEFUL FOR THE DIAGNOSIS OF OVERT DIABETIC NEPHROPATHY.

T. Zelmanovitz, J.L. Gross, J.R. Oliveira and M.J. Azevedo. Endocrine Unit, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil.

The aim of this study was to assess the performance of urinary total protein measurements in timed 24h urine collection (24hUP) and in a diurnal random urine specimen (RUS) for the diagnosis of overt diabetic nephropathy. One-hundred-sixty seven diabetic patients (20 IDDM, 147 NIDDM; 78 females; aged 20 - 84 years) collected 217 timed 24h urine specimens. Albumin was measured by immunoturbidimetry, total protein by the sulfosalicylic acid technique and creatinine by Jaffé's method. According to 24h urinary albumin excretion rate (UAER), samples were divided into Normoalbuminuric (Normo;UAER<20 µg/min; n=84), Microalbuminuric (Micro; UAER 20-200 µg/min; n=78) and Macroalbuminuric (Macro; UAER ≥ 200 µg/min; n=55). Eighty-six patients also collected 106 RUS (Normo,n=47; Micro, n=37; Macro, n=22) after completing timed 24h urine collection and urinary protein concentration (UPC) and protein:creatinine ratio (UPCR) were measured. The relationship between 24h UAER vs 24hUP and RUS (UPC and UPCR) were calculated by Spearman's correlation coefficients (rS). The receiver operating characteristics (ROC) curve approach was used to analyze the performance of the diagnostic tests. The rS of 24h UAER vs 24hUP was 0.95 ($p < 0.001$) and of 24h UAER vs UPC and UPCR were 0.76 and 0.73, respectively ($p < 0.001$). The calculated areas (± SE) under the ROC curve for the diagnosis of overt diabetic nephropathy for 24hUP was 0.9987 ± 0.001, for UPC 0.9805 ± 0.014 and for UPCR 0.9708 ± 0.015. On the ROC curves the first points with 100% sensitivity were: for 24hUP 541mg (specificity 95 7%), for UPC 185 mg/L (specificity 72.6%) and for UPCR 0.2 (specificity 77.4%). In conclusion, 24hUP presented a better performance than UPC and UPCR for the diagnosis of overt diabetic nephropathy. The 24h proteinuria presented an almost perfect accuracy for the diagnosis of clinical diabetic nephropathy, is simpler and less expensive than UAER and yet can be used in the evaluation of clinical nephropathy.

2093

IMPAIRED AUTOREGULATION OF GLOMERULAR FILTRATION RATE IN NON INSULIN DEPENDENT DIABETIC PATIENTS WITH DIABETIC NEPHROPATHY

PK Christensen, HP Hansen and H-H Parving, Steno Diabetes Center, Gentofte, Denmark.

Afferent arteriolar hyalinosis frequently present in diabetic glomerulosclerosis, might impair the normal myogenic responses to pressure changes leading to impaired autoregulation of glomerular filtration rate (GFR). To evaluate this hypothesis we investigated the effect of acute lowering of arterial blood pressure (BP) upon kidney function in 14 non insulin dependent diabetic (NIDDM) patients with diabetic nephropathy and 12 NIDDM patients with normoalbuminuria. The study was performed twice within 2 weeks with the subjects receiving an intravenous injection of either clonidine (150-225 µg) or saline (0.154 mmol/l) in random order. We assessed GFR (single bolus ^{51}Cr-EDTA plasma clearance technique), albuminuria (ELISA), and BP (TAKEDA TM-2420). The two groups were well matched with respect to demographic data and baseline GFR (ml/min/1.73 m^2) 90 (SEM 6) vs 93 (4) and baseline BP (mm Hg) 164/85 (5/2) vs 167/92 (5/3) in patients with and without nephropathy, respectively. The clonidine injection induced similar reductions in mean arterial blood pressure 19 and 21 mm Hg, respectively. While GFR and urinary albumin excretion rate remained nearly unchanged in the control group after clonidine, GFR diminished from 90 (6) to 81 (7) ml/min/1.73 m^2 ($p = 0.006$) and albuminuria declined from 708 (antilog SE 1.3) to 532(1.2) µg/min ($p=0.06$) in nephropathic patients. A significant correlation between relative reductions (%) in MABP and in GFR ($r = 0.78$, $p<0.001$) was demonstrated in albuminuric NIDDM patients. A complete pressure passive vasculature was found in 4 out of 14 patients with nephropathy (Δ GFR% = Δ MABP%). Our study suggests that NIDDM patients with diabetic nephropathy frequently are suffering from impaired/abolished autoregulation of GFR.

2094

PHYSICIAN'S OFFICE EVALUATION OF A NEW 7- MINUTE QUANTITATIVE ASSAY FOR URINARY ALBUMIN AND CREATININE.

R. Guthrie, C. Hiar, C. Kilo, B. Childs, R. Fisher, M. Pinson and D. Parker. W. Co. Internal Medicine, St. Louis, MO, Mid-America Diabetes Assoc., Wichita, KS, Bayer Corporation, Elkhart, IN USA.

Increased levels of albumin excretion are an early indicator of diabetic nephropathy. Early recognition may lead to more timely medical intervention and decreased need for kidney dialysis and/or transplants. Most quantitative albumin estimations do not provide rapid results to the physician. A new method has been developed by Bayer, using a dry cartridge format in the DCA 2000® Analyzer. The cartridge contains reagents for both albumin and creatinine assays. The concentration of albumin is measured by an immunoturbidimetric method, and the creatinine by a modified Benedict-Behre reaction. Results of the two analytes, as well as an albumin/creatinine ratio, are available in 7 minutes. The objective of the clinical evaluations was to assess the performance of the DCA 2000 methods in the hands of typical end-users. Overnight timed and random specimens were tested (58 - Site 1, 49 - Site 2). Results for the two specimen types were equivalent. DCA albumin results were compared to immunoturbidimetric methods and creatinine results to kinetic Jaffe methods. DCA results correlated well with comparative methods (Albumin: y = 0.1 + 0.857x, r = 0.99, (Site 1); y = 0.6+1.06x, r = 0.99 (Site 2). Creatinine correlations: y = (-)2.3 + 1.02x, r = 1.00 (Site 1); y = (-)3.0+1.12x, r = 0.99 (Site 2). Albumin precision on two levels of controls was 3.4 - 6.6% CV. Creatinine precision was 2.6 - 3.6%CV. It is concluded that the DCA 2000 method is sensitive, reliable and provides albumin, creatinine and albumin/creatinine ratio results to the clinician during the patient's office visit. The method correlates well with immunoturbidimetric methods. The simplicity of the test allows physician's office personnel to do the test routinely. This will permit detection of earlier stages of diabetic nephropathy and effective counseling while the patient is still in the office.

2095

EXERCISE-INDUCED VARIABILITY OF GLOMERULAR FILTRATION RATE (GFR) IN DIABETIC SUBJECTS.

M. Sambataro, K. Thomaseth, G. Pacini, and F. Piarulli. LADSEB-CNR), Padua, and Antidiabetes Center, Hospital of Portoviro, Italy.

Introduction. Plasma clearance rate of intravenously given ^{51}Cr-EDTA (CrB) bolus (radioactive edetic acid), calculated by computer analysis (TS–method, Sambataro-Thomaseth, JANS, 1996), provides accurate description of GFR without need of steady-state condition and resting body position during the test. Moreover, GFR changes due to physiological cardiovascular stimulation have never been investigated. Aim. (i) to verify the accuracy of GFR measurement using the TS-method after CrB, in different physiological operative conditions; (ii) to evaluate changes of GFR in NIDDM after acute maximal muscular exercise. Subjects and Methods. An intravenous bolus of 1 μCi/kg of ^{51}Cr-EDTA was performed in 13 NIDDM patients (age 53-68 yr; BMI 30±1 kg/m^2; AER<150 mg/24h). The plasma clearance was calculated by multiexponential model using a weighted least squares estimation routine. Basal GFR was assessed in all subjects. After 6 months, 5 randomly selected patients (D1) underwent a maximal muscular stress by Tapis Roulant (5 km/h for 5 min with 12% slope) immediately before a CrB test (mGFR); the other 8 patients (D2) were instead reinvestigated at rest (rGFR). Results. Basal GFR (bGFR) was 102±6(SE) ml/min/1.73m^2 in all subjects, but was different in the two subgroups: 122±7 in D1 and 91±6 in D2 (p<0.007). D1 after muscular exercise had similar renal function of D2 at rest (mGFR=90±7, rGFR=86±8, p=0.711), with lower GFR in the two operative conditions (D1: bGFR–mGFR = 31±7; D2: bGFR–rGFR = 5.0±4.6) (p<0.007). Linear regressions between repeated GFR yielded r^2=0.726, slope=1.2, p=0.007 for D2 (bGFR vs. rGFR), and r^2=0.27, slope=0.5, p=0.37 for D1 (bGFR vs. mGFR). Conclusions. (i) Redistribution of vascular blood flow by maximal muscular exercise is a physiological variability factor of renal filtration rate; (ii) the hyperfiltering glomerular high risk condition in diabetes could be a functional and not an anatomical factor; (iii) modelling analysis of tracer plasma disappearance rate well quantifies the effects of rapid physiological stimuli on renal function; (iv) the TS-method gives accurate descriptions of physiological variations of GFR.

A NEW RELIABLE AND RAPID METHOD FOR ESTIMATION OF URINARY ALBUMIN CONCENTRATION

S. Garg, C. Hiar, L. Pennington, I. Osberg, and R. Hamilton. Barbara Davis Center for Childhood Diabetes, (UCHSC), Denver, CO and Bayer Corporation, Diagnostics Division, Elkhart, IN, USA

A new method has been developed by Bayer using a dry cartridge format in the DCA2000® analyzer. The method, which gives a urinary albumin and creatinine results in seven minutes, uses an immunoturbidimetric reaction for albumin and a modified Benedict-Behre reaction for creatinine. Results of the two analytes are combined for an albumin/creatinine ratio. Overnight, 24-hour, and spot urine samples were analyzed from 105 subjects with Type 1 diabetes mellitus. Comparisons were made using the DCA2000® methods against a RIA method for albumin and a kinetic Jaffe method for creatinine. DCA methods correlated well with RIA results, y = (-) 1.0 + 0.899x, r = 0.99 and Jaffe results y = (-) 1.4 + 1.07x, r = 0.99. The correlation was equivalent with the three types of collections (overnight, spot or 24 hrs.). Diagnostic performance expressed as Sensitivity, Specificity, Positive and Negative Predictive Values was greater than 97%. Total precision (CV) using two levels of controls was 5.8% and 2.7% (32 and 201 mg/L albumin); 2.8% and 2.2% (100 and 396 mg/dL creatinine). Finally, 75 urine samples were tested in duplicate using DCA2000® and a Beckman Array® immunoturbidimetric method. The correlation was excellent (y=0.6+0.992x, r=1.00). The albumin precision was 3-4% CV. It is concluded that the DCA2000® cartridge assay is sensitive, reliable, and rapidly provides the albumin/creatinine ratio as well as individual test results to the clinician. The new method correlates well with both RIA and immunoturbidimetric methods. The rapid availability of results will allow physicians' office personnel to do the test routinely and will allow patients to receive effective counseling while still in the doctor's office.

2097

DETERMINANTS OF GLOMERULAR HYPERFILTRATION IN IDDM PATIENTS

L.Todaro, A.Manto, P.Cotroneo, A.Manto jr, C. Vellante*, G.D'Errico* D.Pitocco and G.Ghirlanda.
Institute of Internal Medicine e Geriatrics.*Institute of Nuclear Medicine Catholic University of Sacred Heart, Rome, Italy.

The increase of glomerular filtration rate (GFR) is considered characteristic of early diabetic nephropathy in patients with IDDM. Actually it is not know the real predicting value of hyperfiltration for development of incipient and overt nephropathy. In a cross-sectional study of 171 normotensive, normoalbuminuric IDDM patients (mean age 32,4±9,2 yrs, duration of disease 14±7 yrs) and 20 controls subjects (mean age 33±10 yrs) we have evaluated GFR and renal plasma flow (ERPF) by single injection of Cr^{51}EDTA and I^{125}Hippuran and we studied the relationship between GFR and ERPF, age, sex, IDDM duration, HbA1c, BMI. Mean value of GFR was 113±20 ml/min/1.73m^2 in controls and 141±25 ml/min/1.73m^2 in IDDM (p<0.0001); ERPF was 474±99 ml/min/1.73m^2 and 633±140 ml/min/1.73m^2 respectively (p<0.002), while FF (GFR/ERPF) was similar in controls and patients (0.23±0.03 vs 0.23±0.02 p=ns). Patients with GFR more than 95° percentile of controls (135 ml/min/1.73m^2) are defined hyperfiltering: they represent the 53% of our population study. An inverse correlation between age and GFR is well known. In a simple regression analysis we found the same correlation between GFR and age (p<0,01 but in a multiple regression analysis including ERPF, age, sex, IDDM duration, HbA1c, BMI, ERPF was the only independent determinat of GFR (p<0.0001). In our cross-sectional study ERPF seems the only determinat of glomerular hyperfiltration in IDDM.This is probably due to vasodilation of afferent arterioles caused by hyperglycaemia per se.

DIABETIC NEPHROPATHY SCREENING WITH MICRAL TEST
M.Santoso,L.Gunawan,U.Sukaton.Diabetic Endorine clinic Pelni Hospital Ukrida Med.Fac.Jakarta-Indonesia
Back grouhd: Micral test is semikuantitatif protein urine test,especially to detect microalbumin uria on incipient Diabetic Nephropathy.This screening test is very usefull and practicable primary faster diagnostic for out patient and study epidemiology ;Normal result micral test negatif (0-15mg/ml),threshold (15-30mg/ml),+(20-80mg/ml),++(80-100mg/ml). Aim and method: We pre formed study incidence of incipient diabetic Nephropathy from 200 NIDDM was suffered from diabetic more than one year and we collect urine sample after excercise from diabetic club and 50 normal control group. Result: Up to the final study 195 NIDDM was ixamined by micral test consist of 62 male and 133 female, all group got sulfonylurea and dieet normal renal function and liver function,Micral test result 37% male was normal, 21 % threshold 23% + and 19% ++, in the male group + and ++ result mostly come from 56-65 age group and female group from 46 - 55 age group .
Comparing with control group significant different positif-result ($P < 0{,}001$).
Conclussion : Micral test is a simple test to detect incipicient Diabetic Nepropathy.

RENAL RESERVE CAPACITY IN TYPE 1 DIABETIC SUBJECTS AFTER ORAL PROTEIN LOAD

A. Siebenhofer[1], G. Brunner[1], A. Wutte[1], S. Zitta[1], G. Sendlhofer[1], T. Lang[2], W. Estelberger[3], G. Reibnegger[3], and T.R. Pieber[1]. [1]Department of Internal Medicine, Diabetes and Metabolism, [2]Department of Surgery, Division of Laboratory Medicine, [3]Institute of Medical Chemistry, University Graz, Austria

AIM: Glomerular hyperfiltration is a known feature in insulin dependent diabetes mellitus (IDDM). In this study we defined glomerular filtration rate (GFR) and renal reserve capacity in IDDM patients without any clinical sign of diabetic nephropathy.
METHODS: A single shot sinistrin and p-aminohippurate (PAH) clearance was used to measure GFR and renal plasma flow (RPF) before and after ingestion of a protein load (1g/kg body weight). The kinetic marker data were evaluated by a two compartment modelling. During the whole experiment blood glucose in the diabetic subjects was kept between 120 and 199 mg/dl by variable i.v. insulin infusion.
RESULTS: GFR and RPF were measured in 10 well controlled IDDM patients ([mean±SD] age: 33±7 years, diabetes duration 12±8 years, BMI: 24±3, HbA1c: 7.6±0.6) and 10 controls (age: 29±5, BMI: 22±2). All subjects were normotensive (RR<130/85) and had normal albumin excretion (4±3 and 3±1 mg/24h). Basal GFR in the diabetic subjects was elevated (139±17 ml/min/1.73 [normal range 80-130] compared to the control group (116±16, $p<0.02$). After protein load GFR decreased in the diabetic group to 127±12 ($p<0.01$), whereas the healthy subjects showed an increase to 128±8 ($p<0.05$) reflecting the renal reserve capacity. Furthermore, in the diabetic patients we found a significant correlation between the baseline GFR and the respective decreases after protein load($r=0.73$, $p<0.05$). RPF and total renal resistance did not change in both groups.
CONCLUSION: GFR in IDDM subjects without nephropathy is elevated and decreases after oral protein load. This lack of renal reserve capacity may be explained by intrarenal haemodynamic changes.

EFFECTIVE SCREENING FOR DIABETIC NEPHROPATHY BY SELF-TEST FOR MICROALBUMINURIA

R. Landgraf[1], W. Piehlmeier[1], R. Renner[2], T. Kimmerling[1], K. Piwernetz[3], J. Fahn[4], S. Garbe[5] and R. Landgraf[1] [1]Department of Internal Medicine "Innenstadt", University of Munich [2]City Hospital Munich-Bogenhausen [3]DiabCare Office Munich/WHO [4]AOK Munich [5]Boehringer Mannheim GmbH

The accuracy of two consecutive versions of a qualitative self-test for microalbuminuria (Micral-Test ® and Micral-Test ® S) was assessed in comparison to quantitative analysis by immunoturbidimetry in diabetic patients. For evaluation of the Micral-Test ® 339 diabetics from hospitals independent of age, sex, duration and type or therapy of diabetes were included in a screening program for microalbuminuria unless one of eight defined exclusion criteria was present. The patients performed a self-test for microalbuminuria on three days within one week in the first morning urine. All urine samples were retested by a quantitative analysis of urinary albumin concentration using immunoturbidimetry. 24 patients could not be analyzed due to incorrect number of urine samples. In the second part of the study the new version of the self-test, Micral-Test S, was evaluated in 112 consecutive diabetic inpatients following the same methods. Four patients had to be excluded due to insufficient number of urin samples. Statistical analysis included frequency distribution of test results and evaluation of sensitivity, specifity, positive and negative predictive values. If at least two positive out of three self-tests during one week are necessary for assessment of an elevated urinary albumin concentration, the Micral-Test shows a sensitivity of 0.70, specificity of 0.81, positive predictive value of 0.63 and a negative predictive value of 0.85. The new version Micral-Test S showed a better accuracy with a sensitivity of 0.81, specificity of 0.92, positive predictive value of 0.71 and negative predictive value of 0.95. When the assessment of microalbuminuria, however, was based on at least one positive out of three self-tests using the Micral-Test S, sensitivity increased to 0.90 at the cost of a decrease of specificity to 0.77. The improved sensitivity and specificity of the the new version, Micral-Test S, reflects a better practicability. Due to these data and the fact that only in few cases a regular microalbuminuria screening in primary care is performed, the self-test Micral-Test S should be integrated into widespread screening programs for incipient diabetic nephropathy using the capabilities of most diabetics for self-monitoring like blood and urinary glucose, ketonuria and blood pressure.

Large kidneys as marker for subsequent nephropathy in IDDM.

H.-J. Baumgartl, P. Banholzer, M. Haslbeck and E. Standl. Diabetes Research Institute and City Hospital Munich Schwabing, Germany.

Approximately 30-40% of IDDM patients develop diabetic nephropathy. Previous examinations on the significance of the kidney size prior to the manifestation of nephropathy produced varying results. A longitudinal study, therefore, was designed to assess the correlation between sonographically determined kidney size and kidney function over eight years, and to evaluate a potential risk pattern. Data could be collected from 71 (59%, m38/f33) of initially 120 IDDM patients whose sonographically determined kidney volume (cm^3=Lcm x W cm x D cm x pi/6) and kidney function (creatinine, albuminuria) had been examined eight years ago, and who had a diabetes duration of 1 month to 25 years at that time. KV of more than 170 cm^3 was defined as large kidney on the basis of 44 age matched healthy controls. During the observation period, eight (6,7%) diabetic patients had died (7 in terminal renal insufficiency), 4 (3,3%) presently require dialysis and 1 (0,8%) has received a kidney transplant. All deceased patients due to renal insufficiency had normal or slightly increased creatinine values eight years ago, yet enlarged kidneys at the time (> 170 cm^3). Of the IDDM patients who had large kidneys, 42% developed pathological creatinine values (>106µmol/l) versus 20% in the group of patients with a kidney volume of under 170 cm^3 ($p<0,05$). In additon, all eight diabetic patients had a kidney volume of over 170 cm^3 whose creatinine values rose more than 50% during the observation period. The examined endpoints (serum creatinine > 106µmol/l, creatinine increase of more than 50% in the past eight years, death in terminal renal insufficiency, receiving dialysis and/or renal transplantation) were reached from 77% of patients with initially normal creatinine, but a large kidney volume, in contrast to only 20% of patients with normal kidney volume ($p<0,0001$). These results indicate that large kidneys might be a morphological marker for subsequent diabetic nephropathy and as a consequence renal insufficiency.

PERFORMANCE CHARACTERISTICS OF MICRAL TEST AND SPOT URINE ALBUMIN CONCENTRATION FOR DETECTION OF MICROALBUMINURIA IN DIABETIC PATIENTS

C H LEE AND S FOOK-CHONG, TOA PAYOH HOSPITAL, SINGAPORE

Microalbuminuria is both an independent predictor of progressive renal disease and a clinical marker of atherosclerotic heart disease and premature cardiovascular death in diabetic individuals. The definition of microalbuminuria in IDDM and NIDDM is generally accepted as a urinary albumin excretion rate of 20-200 ug/min (30-300 mg/day). Because of the difficulties involved in estimating urinary albumin excretion rates, many physicians use simple dipstick methods to detect microalbuminuria. One of these methods, the Micral test (Boehringer-Mannheim, Germany) has been shown to be a clinically useful test, and readings between 20 to 200 mg/l are regarded as indicative of microalbuminuria. However, being semi-quantitative, and affected by fluctuations in urine output, the Micral test has many limitations. Our study sought to define the performance of the Micral test and the spot urine albumin concentration (UAC-RIA) as measured with a double antibody radioimmunoassay method (sensitivity 0.3 mg/l) against the spot urine albumin-creatinine ratio (ACR). We studied 211 patients (175 NIDDM, 36 IDDM) attending the Toa Payoh Hospital Diabetes Center. Early morning spot urine specimens were first tested using the Micral test and the Albustix test (Ames, USA). The same urine specimens were then immediately sent for radioimmunossay for urine albumin concentration, as well as estimation of urine creatinine concentration. We found a linear relationship between ACR and UAC-RIA (ACR=1.316 X UAC-RIA, r=0.888, p<0.0005). Using a reference ACR level of <30 mg/g as a cutoff to delineate normoalbuminuria from microalbuminuria, and subjecting the UAC-RIA data to receiver operating characteristics analysis (ROCLAB program) we found that the UAC-RIA value that yielded optimum sensitivity and specificity as a cutoff for microalbuminuria was 53 mg/l (sensitivity 91%, specificity 95%). Micral test (semi-quantitatively rated as 10, 20, 50 or 100 mg/l) demonstrated a clear correlation with both UAC-RIA and ACR values. As the Micral cutoff that most closely approximated a UAC-RIA of 53 mg/l was 50 mg/l, we feel the latter would be a more useful cutoff for microalbuminuria than the traditionally suggested value of 20 mg/l. We conclude that both the ACR and UAC-RIA are useful screening tests for microalbuminuria, and that a Micral test of >50 mg/l is a useful office screening method for microalbuminuria in diabetic patients.

2103

INCREASED FREQUENCY OF MICRO- AND MACROALBUMINURIA IN SINGLE-KIDNEY NIDDM PATIENTS.

S.P. Silveiro, L.A. Costa and J.L. Gross. Endocrine Unit, Hospital de Clínicas de Porto Alegre, RS, Brazil

The role of glomerular hyperfiltration as a risk factor for future development of diabetic nephropathy is still unsettled. The presence of a single kidney represents a state of pronounced hyperfiltration. We have previously demonstrated that single-kidney NIDDM patients have a higher frequency of renal disease when compared to NIDDM patients with both kidneys. We are now comparing the prevalence of renal disease between single-kidney individuals with and without NIDDM. The aim of this study was to analyse the prevalence of micro- and macroalbuminuria in 20 single-kidney NIDDM patients, 13W/7M, aged 63.7 ± 9.9 (50-84) yrs with diabetes duration of 10.9 ± 9.8 (1-40) yrs. Seventeen non-diabetic individuals with one kidney, 15W/2M, aged 56.8 ± 13.2 (35-75) yrs formed the control group which was age-, sex- and body mass index-matched with the NIDDM group. The period of time with one kidney was similar in the diabetic patients [23.4 ± 17.2 (5-63) yrs] and in the control group [20.7 ± 17.6 (5-73) yrs]. Albumin excretion rate (AER) was measured in 24-h urine samples, by immunoturbidimetry. Glomerular filtration rate (GFR) was measured by ^{51}Cr-EDTA single injection method. The prevalences of micro- (AER 20-200 µg/min) and macroalbuminuria (AER >200µg/min) were significantly higher in the diabetic group (45% and 25%, respectively) in comparison with the non-diabetic group (18% and 6%; p<0.05). There were no differences between the groups regarding GFR (67.2 ± 22 vs. 73.5 ± 20 ml/min/1.73m^2), mean blood pressure levels (106 ± 17 vs. 106 ± 21 mmHg), serum cholesterol (5.66 ± 0.98 vs. 5.39 ± 1.2 mmol/L) and HDL (1.3 ± 0.4 vs. 1.2 ± 0.3 mmol/L), respectively, in non-diabetic individuals and NIDDM patients. Serum triglycerides were significantly higher in diabetic patients (1.4 vs. 2.3 mmol/L) In conclusion, hyperfiltration related to the single-kidney status is associated with an increased frequency of renal disease only in the presence of diabetes.

2104

Utility of the urine glycated albumin/serum glycated albumin ratio as a marker for diabetic nephropathy

Inoue,M.,Maehata,E.*,Yano,M.*,Shiba,T.*,Yamakado,M.*,Inoue,T. and Suzuki,S. Showa University Fujigaoka Hospital,Yokohama and Mitsui Memorial Hospital,Tokyo*,Japan

Measuring albumin in urine is essential to diagnosing initial nephropathic lesions at an early stage. An albumin excretion value of less than 30 mg/g. Creat.,a value from 30 mg/g Creat. to 300 mg/g Creat.,or a value of 300mg/g. Creat. of above are defined as normoalbuminuria, microalbuminuria, or macroalbuminuria,respectively. We studied the ratio of glycated albumin in urine to that in serum (GA ratio) as a possible marker for the onset of diabetic nephropathy. Compared to an GA ratio of 2.099 ±0.300 (means±SD) for controls consisting of 11 healthy adult subjects (61.5 ± 5.4 years), the GA ratio was 2.097 ± 0.577 for a normoalbuminuria group of 14 subjects (60.4 ± 3.6 years) , 1.271 ± 0.394 for a microalbuminuria group of 15 subjects (59.1 ± 9.7 years) , and 0.950 ± 0.075 for a macroalbuminuria group of 13 subjects (60.5 ± 11.8 years). In the progression from normoalbuminuria to the onset of nephropathy, GA ratios gradually declined from 2.000, clustering at a value of 1.000. This indicates that a GA ratio of about 1.000 represents the region of irreversible injury. Further, the point of intersection between the line of about this ratio of 1.000 and the regression curve determind polynomially for the GA ratio in the microalbuminuria group corresponded to a value of about 150 mg/g.Creat.. The above findings thus suggest that a GA ratio of about 1.000 marks the onset of diabetic nephropathy, and the threshold value for the onset of nephropathy in the progression from microalbuminuria is that of about 150 mg/g Creat..

2105

LOW BIRTH WEIGHT - A PROGRESSION PROMOTER IN DIABETIC NEPHROPATHY?

P Jacobsen, P Rossing, L Tarnow, K Rossing, FS. Nielsen, BV Hansen, BM Brenner and H-H Parving. Steno Diabetes Center, Copenhagen Denmark, #Harvard Medical School, Brigham and Women's Hospital, Boston, Massachusetts

Intrauterine growth retardation, defined as birth weight below the 10 th centile, gives rise to a reduction in nephron number. Oligonephropathy has been suggested to increase the risk for systemic and glomerular hypertension in adult life as well as enhance risk for expression of renal disease following exposure to injurious renal stimuli e.g diabetes mellitus. The aim of this study was to determine if low birth weight is a risk factor for progression of established diabetic nephropathy. We investigated 114 (66 men) IDDM patients with diabetic nephropathy (persistent albuminuria > 300 mg / 24 hours) (mean age (SD) 41 (9) years, mean duration of diabetes 32 (8) years). All patients had been followed for at least 3 years, median (range) 9 (3-17) with at least 3 measurements (9 (3-28)) of GFR (51Cr-EDTA). 79 % of the patients were treated with one or several antihypertensive agents. Information about weight at birth was obtained from the midwifes original registrations. The mean (SD) rate of decline in GFR was 3.4 (3.7) ml/min/year. There was no correlation in univariate analysis between birth weight and rate of decline in GFR, neither in men nor in women. A backwards stepwise multiple regression analysis with rate of decline in GFR as dependent variable and mean values of albuminuria, haemoglobin A1c, arterial blood pressure, and s-cholesterol during the whole observation period in addition to sex and birth weight as independent variables revealed a significant association only with albuminuria and haemoglobin A1c. Furthermore, the 10 patients with intrauterine growth retardation had a rate of decline in GFR similar to the 104 patients with birth weight above the 10 th centile, mean (SE): 2.0 (0.6) vs 3.2 (0.4) ml/min/year, respectively (ns). In conclusion, our study does not suggest that low birth weight is associated with accelerated progression of diabetic nephropathy in IDDM patients.

2106

URINARY ALBUMIN TO CREATININE RATIOS 10 AND 16 YEARS AFTER DIAGNOSIS OF NIDDM.

T.D.R.Hockaday, H.Doll, B.Pim and F.Tunbridge. Radcliffe Infirmary, Oxford, England.

Renal deterioration in the early years after diagnosis of diabetes has been associated with hyperglycaemic degree: does this relationship hold later? The urinary albumin:creatinine (A/C) ratio was measured radio-immunologically in 77 patients less than 82 years old 16 years after their diagnosis as NIDDM. The mean value was 11.2±SD 29.7mg/mmol: 42 had values below 2.0 and 18 values above 6.0mg/mmol. The values were unrelated to age, gender, mode of hypoglycaemic therapy or fasting glycaemia either then ($p<0.15$), at diagnosis or as a mean of the levels 1,3,5 and 10 years later, but were correlated non-parametrically directly with systolic blood pressure ($p<0.002$) and sub-scapular skin-fold thickness ($p<0.006$) and inversely with 10-50 min. post-glucose growth hormone radio-immunoassay levels ($p<0.005$). The A/C values of 52 of these patients had also been measured 10 years after diagnosis (along then with 46 other such patients). The results correlated with those at 16 years ($p<0.001$) but had a smaller mean at 2.8±3.9 mg/mmol ($p<O.O2$). All 98 10-year values were correlated with past glycaemia, either at diagnosis or averaged over several years (both $p<0.004$) as well as systolic blood pressure ($p<0.04$). These results typically were also related to mortality in the next 6 years ($p<0.02$). The changes from 10-16 years were correlated with 10-year plasma triglyceride ($p<0.001$) and BMI ($p<0.01$) values but not with glycaemia or blood pressure. The results, while confirming glycaemia and blood pressure as associates of albuminuria in diabetic patients, also suggest its evolution to be at least a 2-stage process.

2107

IMPAIRED NOCTURNAL DECLINE IN ARTERIAL BLOOD PRESSURE IN NORMO- AND MICROALBUMINURIC NIDDM PATIENTS.

P. Gæde, F.S. Nielsen, P. Vedel, T. Hansen, O.B. Pedersen and H.-H. Parving, Steno Diabetes•Center, Gentofte Denmark.

Lack of the normal nocturnal decline in arterial blood pressure is associated with increased cardiovascular complications in diabetic and non-diabetic subjects. The insertion(I) / deletion(D) polymorphism in the angiotensin converting enzyme gene (ACE/ID) is associated with ischaemic heart disease which is prevalent in NIDDM patients with elevated urinary albumin excretion rate (UAE). The aim of our study was to describe the diurnal rhythm of arterial blood pressure (A&D TM2420) and to evaluate the impact of the ACE/ID polymorphism in 135 microalbuminuric NIDDM patients (UAE 30-300 mg/24h, 55 (SD, 7) years, 103 men, group 1). As control groups we used 41 normoalbuminuric NIDDM patients (UAE < 30 mg/24h, 58 (6) years, 32 men, group 2) and 22 non-diabetic subjects (58 (8) years, 15 men, group 3) matched for age and sex. Patients in group 1 were studied on their usual antihypertensive treatment (AHT) (50%) whereas patients in group 2 had their previous AHT (30%) withdrawn. None of the patients in group 3 had received any AHT. The nocturnal blood pressure reduction (daytime-nighttime)/daytime (mean (SE)) was impaired in group 1, 11.6 (0.8) % and in group 2, 10.0 (1.5) % as compared with group 3, 17.6 (1.7) % ($p < 0.01$, ANOVA). In group 1 the nocturnal reduction in blood pressure was similar in patients with or without AHT 12.2 (1.1) % vs 10.8 (1.2) % (NS). In group 1 patients without AHT no significant difference in the nocturnal blood pressure reduction was observed comparing patients with II genotype (n = 15) 14.9 (1.7) %, ID genotype (n = 29) 11.1 (1.8) % and DD genotype (n = 24) 11.8 (2.0) % ($p = 0.47$, ANOVA). In conclusion: the nocturnal blood pressure reduction is equally impaired in normo- and microalbuminuric NIDDM patients as compared with non-diabetic control subjects. The ACE/ID polymorphism does not have a major impact on the diurnal blood pressure rhythm in microalbuminuric NIDDM patients.

2108

URINARY PROTEINS AND DIABETIC COMPLICATIONS IN NIDDM

H.Nakano, K.Okazaki, T.Suzuki, K.Sasai, K.Oba, and S.Metori, Nippon Medical School, Tokyo, Japan.

The aim of this study is to clarify the clinical significance of urinary proteins in NIDDM. Urinary albumin index (Alb), N-acetyl-beta-D-glucosaminidase index (NAG), alpha 1-microglobulin (AMG), beta 2-microglobulin (BMG), immunoglobulin-G (Ig-G), and transferrin (Tf) in random spot urine samples were determined 60 NIDDM patients aged 39 to 86. Pateints were divided four groups; normoalbuminuria, microalbuminuria (≧20mg/g·Cr), proteinuria (Albustix positive) and overt nephropathy (Cr>2mg/dl). Multiple regression analysis was used to investigate the relationship between Alb index, NAG index, AMG, BMG, Tf, or Ig-G value (dependent variable) and independent variables (age, fasting plasma glucose(FPG), lipoprotein(a), systolic blood pressure, HDL-cholesterol(HDL-C), LDL cholesterol, srum thrombomodulin(Tm), pulse wave velocity of aorta, common carotid artery blood velocity and ankle pressure index(API)). Mean Alb index, AMG, BMG, Tf, and Ig-G values significantly tended to increase with the degree of diabetic nephropathy. Mean NAG index was different among 4 groups, but not different between normoalbuminuric group and microalbuminuric group. On multiple regression analysis, the independent predictive factors for NAG index was FPG, for Alb index or Tf was Tm, for AMG or Ig-G were HDL-C and Tm, and for BMG were age, HDL-C and API.

We concluded that these parameters without NAG index in random spot urine samples may serve as early functional indicators of diabetic nephropathy ,and also as indicators of macroangiopathy.

2109

24-H BLOOD PRESSURE AND AUTONOMIC FUNCTION IS RELATED TO ALBUMIN EXCRETION IN NORMOALBUMINURIC IDDM PATIENTS.

P.L. Poulsen, E. Ebbehøj, K.W. Hansen and C.E. Mogensen, Med. Dept. M, Aarhus University Hospital, Aarhus Kommunehospital, Aarhus, Denmark.

Background: Significant changes in both blood pressure, autonomic function and kidney ultrastructure are observed in IDDM patients with microalbuminuria. Intervention strategies are evaluated at even earlier stages of disease. Identification of patients at risk of developing microalbuminuria must be based on thorough knowledge of the relations between key pathophysiological parameters in normoalbuminuric patients. *Aim*: To characterize interactions of urinary albumin excretion (UAE), 24-h ambulatory blood pressure (AMBP), and sympathovagal balance in a large group of normoalbuminuric IDDM patients. *Methods*: In 117 normoalbuminuric (UAE <20 µg/min) patients we performed 24-h AMBP (Spacelabs 90207), with assessment of diurnal blood pressure and heart rate (HR) variation, and short-term (three times 5 min.) power spectral analysis of RR interval oscillations, as well as conventional cardiovascular reflex tests. *Results:* Patients with UAE above the median (4.2 µg/min) had significantly higher 24-h systolic and diastolic AMBP (125±10.1 / 76±7.2 mmHg) compared to the low normoal-buminuric group (120±8.4 / 74±5.1 mmHg), $p<0.01$ and 0.02, respectively. Patients with UAE above the median had significantly reduced short-term RR interval variability including both the high frequency component (5.47 ±1.36 versus 6.10±1.43 ln ms^2), and low frequency component (5.48±1.18 compared to 5.80±1.41ln ms^2), $p<0.02$ and $p=0.04$. In addition, patients with high-normal UAE had reduced mean RR level (faster heart rates) 916ms ±108 compared to 963ms ±140, $p<0.04$. These differences were not explained by age, duration of diabetes, gender, level of physical activity, or cigarette smoking. HbA_{1c} was significantly higher (8.6±1.2 versus 8.2%±1.0, $p=0.03$) in the group with high normal UAE. *Conclusions:* Comparing normoalbuminuric IDDM patients with UAE above and below the median value, we found significantly higher AMBP in combination with significant differences in sympathovagal balance (attenuation in vagal tone and concomitantly increased sympathic activity) and significantly poorer glycemic control in the group with high-normal albumin excretion. Our data demonstrate interactions between albumin excretion, blood pressure, autonomic function, and glycemic status, already present in the normoalbuminuric range and may describe a syndrome indicative of later complications.

INCIDENCE OF UREMIC NEPHROPATHY IN IDDM IN FINLAND

C. Grönhagen-Riska, A. Reunanen, K. Sahipakka and S. Stenman, Div. of Nephrology, Helsinki University Hospital, The Public Health Institute and the Finnish Registry of Kidney Diseases, Helsinki, Finland

Finland has the highest incidence of IDDM in the world. We have investigated the incidence of uremic DNP related to period of and age at debut, gender and area of living in order to detect possible variations in epidemiology. We have extracted data from two large national registries; one registering all Finnish IDDM patients with disease debut before 30 years of age from 1964 onwards, or living in 1967, and the other, The Finnish Registry of Kidney Diseases (FRKD), which has registered all patients that have entered chronic renal replacement therapy (RRT), 572 patients between 1972 and 1995. They comprise renal death out of 14 775 patients with diabetes debut between 1960-1989. When calculating renal death in IDDM, pre-dialysis death associated with uremia or far advanced DNP should be added. We therefor investigated causes of death of patients who had died over 10 years after debut, but who had not entered RRT. Fifteen % of these deaths were associated with far advanced DNP. Adding these numbers, we calculate that 25% of Finnish IDDM patients, who have survived 10 years, will have end stage diabetic renal disease at death. So far, there has not been any detectable decrease in renal death, although median renal survival time from diabetes debut to RRT has increased from 21.8 y. in the '70:s to 26.8 y. in the '90:s (P<0.001). Patients with IDDM debut during puberty, 12-15.9 years, have a higher relative risk (1.25, CI 1.01-1.55, P=0.042) than other IDDM patients to develop DNP. Renal survival is similar in males and females. The relative risk for DNP is higher in the Northern and Eastern (where prevalence of hypertension and cardiovascular morbidity are higher) compared with the Southern and Western regions of the country (1.31, CI 1.11-1.45, P=0.005). Our results indicate the need to identify risk patients and to intensify early therapeutic measures, and for increasing RRT resources.

2111

RENAL SODIUM AND DOPAMINE HANDLING IN DIABETIC CHILDREN WITH FAMILY HISTORY OF ESSENTIAL HYPERTENSION

A. Körner, L. Szűcs, L. Madácsy and T. Tulassay, First Department Paediatrics, Semmelweis Medical University, Budapest, Hungary

Diabetic nephropathy (DN) develops only in a subset of patients with type 1 diabetes mellitus (DM). It has been suggested, that diabetic patients with a genetic trait for essential hypertension (EH) are susceptible for DN. Since sodium handling is altered both in DM and EH , and dopamine (DA) is the main natriuretic hormone, the **aim** of our study was to assess the difference in sodium and DA excretion after sodium challenge in diabetic patients with and without a genetic trait for essential hypertension. **Patients and Methods:** Eight diabetic children with (FH+) and eight patients without (FH-) a family history of hypertension have been studied. Age, duration of diabetes, metabolic control (HbA1c) and body mass index were comparable in the two groups. All patients underwent a 3 day sodium challenge by ingesting 8g NaCl per day beside a sodium and carbohydrate fixed diet. Blood pressure was recorded by ambulatory blood pressure monitoring, and urinary DA excretion was measured by HPLC before and after the sodium load. **Results:** Systolic and diastolic blood pressure were unaltered and comparable in the two groups before and after sodium challenge. After sodium load urinary sodium excretion was significantly higher ($p< 0.03$) in FH- group (212± 47 mmol/day) compared to FH+ group (146±51 mmol/day). Natriuresis was accompanied by significantly ($p< 0.005$) higher urinary DA excretion in the FH- group (2.48±0.7 µmol/day) compared to the FH- children (1.48±0.3 µmol/day). **Conclusion:** Diabetic children with a family history of EH fail to increase urinary sodium and DA excretion following high salt diet. The importance of these phenomena in the development of DN is unknown.

2112

OUTCOME OF UREMIC NEPHROPATHY IN IDDM IN FINLAND

C. Grönhagen-Riska and S. Stenman, Div. of Nephrology, Helsinki University Hospital and The Finnish Registry of Kidney Diseases

We have investigated the outcome of renal replacement therapy (RRT) of 909 patients with end stage diabetic nephropathy (DNP) of IDDM with debut < 30 years of age, who have entered RRT between 1972 and 1995. Patient characteristics and results of therapy are presented according to period of initial RRT, and as median or per cent.

	'71-80	'81-85	'86-90	'91-95
No. of pats, M/F	104/56	135/73	164/93	165/119
Age at debut, M/F, y	13.6/9.5	12.9/11.3	13.7/10.9	12.1/11.2
Interval debut-RRT, M/F,y	21.8/21.5	22.9/23.0	24.3/23.6	26.8/26.2
% transplanted (Tx)	58	63	62	....
Survival in RRT, M/F, y, Tx+	3.0/2.4	8.9/12.9	>10/>10	....
Tx-	0.4/0.9	1.3/1.5	2.0/1.5	1.9/1.5
CV deaths, %, Tx+/Tx-	80/68	78/75	70/70	80/74

After 1993 the yearly number of new IDDM patients entering RRT has not increased. Females with DNP have constantly had their IDDM debut 1-3 years younger of age than males. Time from debut until start of RRT (length of renal survival in patients entering RRT) has successively increased by about 5 years within the follow-up period (P<0.001). Life table analyses indicate that the 5-year survival of transplanted diabetics has improved from 45% to >90%, whereas patients, who have not been considered suitable for Tx, have a poor prognosis. The proportion of cardiovascular (CV) deaths remains unchanged, in spite of the drastic survival improvement in time. Thus improvement of therapy has occurred, but outcome with regard to renal death and causes of patient death are basically unchanged.

2113

THE EFFECT OF THE DIETARY SODIUM INTAKE ON URINARY ALBUMIN EXCRETION IN THE PATIENTS WITH IDDM AND INCIPIENT DIABETIC NEPHROPATHY.

E. Mamos, A. Stefański, L. Majkowska and S.Czekalski. University School of Medicine, Szczecin, Poland

It has generally been accepted that hypertension in patients with insulin-dependent diabetes mellitus (IDDM) is salt-sensitive, i.e. it depends on a dietary sodium intake. The aim of the study was to evaluate an influence of the dietary sodium intake on the urinary albumin excretion (UAE) in patients with IDDM. We investigated 30 patients with IDDM and incipient diabetic nephropathy (UAE 20-200µg/min) with mean duration of diabetes 16.7±7.2 years and average age 40.7±8.3 years. The control group consisted of 20 patients with IDDM and normoalbuminuria (UAE < 20µg/min). Microalbuminuria was estimated twice: on normal sodium diet (mean urinary sodium excretion 83,1 mmol/24h) and on high sodium diet (mean urinary sodium 302,6 mmol/24h), using RIA method. We found significantly lower ($p<0,001$) UAE in the patients with incipient nephropathy on the normal sodium diet in comparison with the patients on the high sodium diet (47.48±18.7 µg/min vs 76.6±29.1 µg/min). Also in the control group we found significantly lower UAE in the patients on the normal sodium diet compared with those on the high sodium diet. In the group of patients with incipient nephropathy an increase in microalbuminuria on the high sodium diet was accompanied by a significant ($p<0.01$) increase of the mean arterial pressure (MAP) (93.8±11.2 vs 98.9±9.1 mm Hg), which was not observed in the control group of patients with normoalbuminuria (89.6±7.8 vs 90.4±8.6 mm Hg). We conclude that dietary sodium intake influences markedly UAE and MAP in incipient diabetic nephropathy; therefore an excessive sodium chloride intake should be avoided in these patients.

2114

HUGE INCREASE OF END STAGE RENAL DISEASE (ESRD) IN DIABETIC PATIENTS: THE FRENCH SURVEY .

S.Halimi.[1],D. Zmirou [2], P.Y.Benhamou [1], M.Maghlaoua [3], and D.Cordonnier [3].Department of Diabetology 1, Epidemiology 2 and Nephrology 3. University Hospital Grenoble.France.

In all developped countries diabetes represents the first cause of ESRD in the USA prevalence rate 35% of dialysed patients. For France we conducted the first national survey on this topic: in1989 (mainland) and in1992 (overseas territories = OT).Results were: a very low prevalence for mainland (6.9% : 884 on 12903)) the lowest of developped countries asking for specific explanations : nutrition, genetic (another french paradox?) with a North-South gradient (higher in the North) . In OT a highest prevalence: (22%) nutrition and population different. Because of the huge increase of ESRD due to diabetes worldwide we decided to reexamine the situation in 1995 (after 6 and 4 years respectively). All the french dialysis centers (n=244 among them 12 in OT) were asked by a questionaire: total number of dialysed patients, total number of diabetics, new cases in 1995 (incidence), type of diabetes, history of hypertension and of the kidney disease, result of kidney biopsy when avalaible, type of dialysis, kidney transplantation planed, other diabetic complications. Geographic origin of the parents of the patient and where the patient spent the most part of his life, habits, to try to distinguish ethnic from environemental factors.Results: 79 %of the centers answered, total prevalence 14.3%,2313 of 16212, mainland 13,09% vs 6,9 %, 6 years ago. In overseas territory 26% vs 22% 4 years ago and 35.6% incidence for1995. Details of the data will be discussed. However the dramatic increase of medical cost of diabetic's treatment and hypertension in diabetic patients during the 10th last years is accompanied by an increase of ESRD. This must be analyzed.

2115

ALTERATIONS OF RENAL RESISTIVE INDEX (RI) DURING 3 YEARS IN NIDDM PATIENTS WITH NEPHROPATHY

H. Hosojima, K. Uchida and I. Yamamoto.
Kanazawa Medical University, Japan.

Since the resistive index (RI) obtained by intrarenal duplex Doppler ultrasonography is reflecting the status of renal vascular resistance, we reported the increased RI in NIDDM patients with nephropathy, and noted that this method is available non-invasive test for evaluating the progression of diabetic renal disease. Now, we examined the alterations of renal function and RIs during 3 years follow-up study in 96 NIDDM subjects with nephropathy (46 males and 50 females, age 60±1y) in order to evaluate the RI as a surrogate marker of diabetic nephroparthy. Mean duration of diabetes in these subjects was 14±1y. Forty subjects were treated with insulin, 45 with an oral anti-diabetic drug and 11 with diet alone. The RI was calculated from Vmax-Vmin/Vmax. Mean levels of serum creatinine, urinary albumin excretion (UAE) or RI in these subjects was 62.8±1.8 μmol/L, 233±55mg/d or 0.67±0.01 in the starting year, and then increased significantly to 73.4±5.3 μmol/L, 511.6±108.6mg/d or 0.69±0.01, respectively, after 3 years, but a mean HbA_{1c} was 9.0±0.3% and did not change.
There was increased UAE or RI in 33% or 67% of these subjects, and 7 cases who had inreased RI (>0.80) were introduced to hemodialysis during 3 years. The increments or decrements of the RI was positively correlated with those of UAE or serum creatinine in these subjects.
Thus, it suggests that the intrarenal RI may be reflecting the status of renal progression in NIDDM patients with nephropathy.

2116

CHRONIC RENAL FAILURE DURING UP TO 25 YEARS OF IDDM IN THE ERFURT DISTRICT

U.J.W. Schauer and A. Preuss, Department of Internal Medicine, Erfurt Hospital, Erfurt, Germany

The aim of the study was to find out the incidence of chronic renal failure and associated factors in IDDM within a geographically defined population. The centralized diabetes care system in the former GDR had been the basis for the almost complete registration of all diabetic patients. Development of chronic renal failure (creatinine >150 μmol/l) was evaluated by checking the original charts up to 1990 of all the 1132 patients with IDDM onset until 40 years of age in the Erfurt district between 1966 and 1988. Cumulative risk of chronic renal failure after 25 years of IDDM was 8.87 + 0.02 %, that of end-stage renal failure amounted to 3.45 + 0.02 %. Chronic renal failure developed after 14 + 5 years of IDDM at an age of 40 + 10 years. In comparison ($p<0.05$) to patients with similar age and duration of IDDM at the end of follow up (n=373) patients with chronic renal failure (n=28) showed a higher BMI (25.0 vs 22.7 kg/m²), were more often obese (21 vs 9 %) and had higher systolic blood pressure (134 vs 127 mm Hg) at IDDM onset as well as higher systolic and diastolic blood pressure during the course of IDDM. They also developed more frequently hypertension (71 vs 31 %) and proliferative retinopathy (25 vs 4 %), suffered more often from myocardial infarction (11 vs 3 %), stroke (7 vs 2 %) as well as major foot amputation (11 vs 1 %) and died with higher frequency (39 vs 8 %). In conclusion in the Erfurt district the development of chronic renal failure in IDDM followed increased body weight and blood pressure at diabetes onset and clustered with higher risk of hypertension, myocardial infarction, stroke, foot amputation, severe retinopathy and death.

2117

RENAL TUBULAR ENZYMURIA IN NON-INSULIN-DEPENDENT DIABETES (NIDDM): RELATIONSHIP TO RETINOPATHY

P.D.Chattington[a], P.Pai[b], G.P.Leese[a], A.Stevenson [c], G.M.Bell[b] and J.P.Vora[a]
[a] Department of Medicine and Endocrinology, [b]Department of Nephrology, Royal Liverpool University Hospital, Liverpool and [c] Health and Safety Executive Laboratories, Sheffield, UK.

20 years after diagnosis a third of NIDDM patients have proteinuria; but some 30% of these will have non-diabetic renal pathology. Diabetic nephropathy is correlated with the presence of retinopathy. N-acetyl glucosamine (NAG) and retinol binding protein (RBP), markers of renal tubular dysfunction, or transferrin (TF) which reflects glomerular damage, may be more specific for diagnosing diabetic renal disease than microalbuminuria (MA). 89 randomly selected NIDDM patients (mean age 60.9 [range 38 to 77] years, 32 female) collected 3 timed overnight urine samples for albumin excretion rate (UAER), and one 24 hour urine sample for NAG, RBP and TF. 49 patients [13 retinopathy] were normoalbuminuric (NA); 20 [9 retinop.] MA and 20 [10 retinop.] macroalbuminuric. Patients with retinopathy compared to those without had similar UAERs (median [range]), 58.3 [<5 to 3890] vs 10 [<5 to 3740]μg.min^{-1}; TF in MA retinopathic patients was increased to 6.4 [0.8-112] vs 0.7 [0.3-17.2]mg/mmol creatinine, $p<0.03$; NAG in macroalbuminurics with retinopathy was decreased from 2.14[1.3-5.1] to 2.42[0.9-3.0] IU/mmol creatinine, $p<0.001$, as was RBP 13.7[3.4-128] compared to 29.1[1.4-74]mg/mmol creatinine, $p<0.001$. NIDDM patients with retinopathy and MA have raised TF, while those with macroalbuminuria have lower levels of the tubular enzymes, NAG and RBP. Patients with retinopathy are more likely to have a diabetic cause of nephropathy, therefore, this would confirm that glomerular rather than tubular dysfunction is of importance in its early development. Those with macroalbuminuria and no retinopathy may have other renal pathology resulting in tubular dysfunction. The pattern of tubular enzymuria may help in defining the cause of the nephropathy.

IS RENAL BIOPSY NECESSARY IN PATIENTS WITH NIDDM?

M. Koselj, M. Kajtna-Koselj and T. Rott, University Clinical Center and Medical School, Ljubljana, Slovenia

Non-diabetic renal disease (NDRD) in NIDDM apts can alter the management and prognosis of renal disease. We retrospectively reviewed renal biopsies (RB) performed for suspected NDRD in 40 NIDDM pts, 29 males and 11 females, mean age 59,7 years, mean duration of NIDDM 5,9 years. Indications for RB were: rapidly progressive renal failure, unexplained renal failure, macrohematuria, unexpected nephrotic syndrome and acute nepritic syndrome in pts with normal or enlarged kidneys. Eight pts (20%) had only diabetic nephropathy (DN). Thirty-two pts (80%) had NDRD alone (14 pts) or in combination with DN (18 pts). Glomerulonephritis (GN) was found in 27 pts (mesangio-proliferative IgA GN and Henoch-Schonlein 11, focal necrotising and extracapillary GN 4, membranous GN 4, endocapillary postinfectious GN 2, minimal change GN 2, focal segmental glomerulosclerosis 1, membranous and mesangial GN 1, membrano-proliferative GN 1, and anti GBM GN 1 pt) Acute interstitial nephritis (AIN) had 3 pts (drug-induced 2 pts, bacterial 1 pt). One pt had fibrillary glomerulopathy and 1 pt cholesterol microembolization. Sixteen pts out of 40 were treated. Four pts with focal necrotising and extracapillary ANCA positive GN (2 pts with Wegener disease and 2 pts with microscopic polyangiitis) and pt with anti GBM GN received steroids and cytoxane, 3 pts with postinfectious GN and bacterial AIN antibiotics, 2 pts with minimal change GN steroids. In 4 pts with membranous GN-secondary, drug induced, the suspected drug was excluded and pts were cured. Two pts with drug induced AIN and acute renal failure recovered after treatment with steroids and exclusion of suspected drug Four of 6 dialysis dependent pts regained sufficient renal function. Conclusions: renal biopsy is indicated and useful in a group of NIDDM pts with an unusual clinical course. Renal biopsy findings indicated different therapy in a half of our NIDDM pts.

IGF-1 AND ERYTHROCYTE SODIUM-LITHIUM COUNTERTRANSPORT IN TYPE 1 DIABETES

A. Verrotti, M. Magri, B. Angelozzi, G. Morgese and F. Chiarelli.
Paediatric Departments, Universities of Chieti and *Siena, Italy.

It is well known that patients with systemic hypetension and diabetic children and adolescents with persistent microalbuminuria had a sodium-lithium countertransport (Na^+/Li^+ CT) activity significantly higher than healthy controls. Moreover, sometimes, raised serum IGF-1 can be concomitant of elevated Na^+/Li^+ CT in essential hypertension. In order to understand if the relationship between elevated Na^+/Li^+ CT and IGF-1 serum levels is present also in diabetic patients with persistent microalbuminuria, we studied a group of 31 (14 male and 17 female) children and adolescents with persistent microalbuminuria (defined as an albumin excretion rate >20 mcg/min) and high level Na^+/Li^+ CT activity: their age ranged from 10.4 to 19.9 years, their duration of disease ranged from 4.5 to 9.5 years; their mean HbA1c was 8.4±2.6%. The Na^+/Li^+ CT activity was higher that a control group of healthy children (0.47 mmol Li^+/L RC/h vs 0.35 mmol Li^+/L RC/h); the mean value of IGF-1 in diabetic patients was 321.1±37.9 mcg/L while in healthy controls was 329.9±53.9 mcg/L (p=ns). We found no significant correlation between Na^+/Li^+ CT activity and IGF-1 serum levels. In conclusion, in diabetic patients with persistent microalbuminuria we found high levels of Na^+/Li^+ CT activity but normal values of IGF-1. We suggest that Na^+/Li^+ CT activity is not influenced by serum IFG-1 levels in diabetic children with persistent microalbuminuria.

ANALYSIS OF FACTORS WHICH POSSIBILITY RESPONSIBLE FOR THE PROGRESSION OF DIABETIC RENAL FAILURE

K.Oi, H.Komori and H. Kajinuma. Toho University, Tokyo, Japan

In 52 NIDDM patients with renal failure, the rate of deterioration of renal function in each case was examined by linear regression analysis using the reciprocal of serum creatinine concentration versus time. It was found that the slope of the regression line differed for each case and had high coefficients of correlation(mean ± SD:r=0.973 ± 0.018). We investigated that the slope and its 10% reduction times(10% RT) as to relation to fifteen clinical characteristics such as sex, age at onset, duration of diabetes, type of treatment and several labolatory data which might be responsible for those individual change in the course of renal failure. The presense of hypoproteinemia and anemia were found the factors significantly related to the slope of the regression line. The mean slope in cases with hypoproteinemia was -2.21±0.99 and in cases with normoproteinemia was -1.16±0.63 at the start of trace($p<0.001$). In the mean 10% RT, the former was 1.8 times shorter than the latter. Similarly the mean slope in cases with anemia and in cases without anemia were -2.00 ± 1.13 and -1.20 ± 0.59($p<0.05$), respectively. In the mean 10% RT, the former was 1.4 times shorter than the latter. No other clinical data were found to be contributory. However, hypoproteinemia and anemia in the late stages of renal failure were not showed any relation to the reduction of the renal function. These suggest that hypoproteinemia and anemia may be one of the risk factors of the advancement to renal failure in the early stages of diabetic nephropaty, but it cannot be prove to have any effects by itself on the later progression of diabetic renal failure. So we need to turn our attention to the treatment.

2121

Plasma Concentrations of Immunoreactive Vascular Endothelial Growth Factor (IR-VEGF) in Diabetic Patients with Retinopathy (RP) and Nephropathy (NP)

T.WASADA, R.KAWAHARA, K.KATSUMORI, A.SATO, Y.OMORI
Diabetes Center, Tokyo Women s Medical College, Tokyo, Japan

VEGF, a secretory protein expressed in various tissues, has been suggested to be involved in the pathogenesis of proliferative RP and proteinuria in diabetic subjects. We measured plasma concentrations of VEGF using a highly sensitive enzyme immunoassay in 110 diabetic patients. Half of these patients showed measurable levels of VEGF(>15.6pg/ml). The prevalence of detectability increases in urinary albumin excretion rate (35.1% in normo-, 54.8% in micro-, 61.3% in macroalbuminuria), but not with severity of RP. Smoking caused an acute increase in plasma IR-VEGF in only 22.6% (12/53) of subjects studied. Smoking-induced elevation was more frequent in patients with macroalbuminuria compared with those with normo-or microalbuminuria (33.3% vs 16.7% or 17.6%, respectively). The magnitude of response also tended to be greater in the former than in the latter. There was no difference among groups with different degrees of RP. These findings suggest that circulating IR-VEGF is related to the progression of NP, and that smoking may contribute to this process by causing tissue hypoxia in susceptible diabetic subjects.

2122

FASTING SERUM C-PEPTIDE IMMUNOREACTIVITY IN DIABETIC PATIENTS ON HEMODIALYSIS

A. Ohno, N. Asahi, T. Sato and A. Ueki. Hachioji Medical Center of Tokyo Medical College, Tokyo, Japan.

Indicators for blood glucose control and fasting serum C-peptide immunoreactivity level (SCPR) were investigated by the cross-sectional method in diabetic patients on hemodialysis who were classified according to the type of diabetic therapy. In addition, the relationship between the changes in SCPR and in blood glucose was assessed. The subjects consisted of 133 patients with diabetes who had undergone hemodialysis. Among them, 83 undergoing dietary therapy alone were classified as group D, while 50 receiving dietary therapy plus insulin were classified as group I. SCPR, fasting plasma glucose levels (G), HbA_{1c}, and serum fructosamine levels (F) were measured in both groups. In addition, SCPR and HbA_{1c} were, as a rule, measured every 6 months. Changes in these parameters were followed for up to 4 years in 34 patients. SCPR was significantly lower, while G, HbA_{1c}, and F were significantly higher in group I than in group D. In group I, SCPR inversely correlated with the daily insulin dosage (R=-0.60). Changes in SCPR and HbA_{1c} followed pattern P (SCPR increased when HbA_{1c} increased) or pattern PS (SCPR tended to increase when HbA_{1c} increased, but the change was small or indistinct because of the short observation period) in 22 patients. SCPR can be used as an index for the initiation and cessation of insulin therapy as well as adjustment of insulin dosage. However, since SCPR often increased during poor blood glucose control, it may be preferrable to evaluate the blood glucose control at the time of measurement.

HEPATOCYTE GROWTH FACTOR AND DIABETIC NEPHROPATHY

M. Shikano, H. Sobajima*, H. Kushimoto, S. Kawashima,
Fujita Health University, Toyoake, Japan
Ogaki Municipal Hospital, Ogaki, Japan

Hepatocyte Growth factor (HGF) possesses mitogenic and morphogenic activities for renal epithelial cells. It was shown in rats that HGF acts as a renotropic factor for renal regeneration through not only paracrine but also endocrine mechanism. Recently it was also shown that HGF has a potent mitogenic activity to endothelial cell of vessel. We measured serum HGF levels in 298 diabetic patients by the ELISA kit (Otsuka, Japan) using antihuman HGF monoclonalantibodies as the solid phase and antihuman HGF rabbit polyclonal antibodies as the liquid phase. The serum HGF levels of diabetic patients were significantly higher than normal subjects (0.38 ± 0.11 ng/ml vs. 0.19 ± 0.05 ng/ml; $p<0.001$). In patients with diabetic nephropathy elevated urinary albumin or N-acetyl-d-glucosaminidase, serum HGF levels were significantly increased. We also recognized a significant relationship between HGF production and hypertension but not diabetic retionopathy or glycemic control. According to these results, HGF appears to play a role in the development of diabetic complication, including diabetic nephropathy.

KIDNEY TRANSPLANTATION ON PATIENTS HAVING DIABETES MELLITUS TYPE I (IDDM) AND DIABETES MELLITUS TYPE II (NIDDM) WITH END-STAGE RENAL DISEASE (ESRD)

C. Baptista[1], M. Bastos[1], L. Gomes[1], F. Macário[3], D. Rodrigues[1], R. Alves[3], H. Gomes[3], C. Ferreira[2], A. Roseiro[2], S. Paiva[1], L. Barros[1], L. Ruas[1], M. Carvalheiro[1], A. Mota[2], L. Furtado[2] and M. Ruas[1]. Department of: [1]Endocrinology, [2]Urology, [3]Nephrology. University Hospital of Coimbra, Coimbra, Portugal.

After Saint-Vincent Declaration, a multidisciplinary team was created for patients with diabetes mellitus and ESRD. **Aim:** to evaluate the results of kidney transplantation on IDDM and NIDDM patients with ESRD on dialysis. **Materials and methods:** A total of 618 patients with ESDR were transplanted (1980-Sep/1996). 28 of them were diabetics. Those were divided in two groups: Group I - 17 IDDM *(2.75%); 11M, 6F; mean age: 33.2; mean years of diabetes: 21.8; proliferative retinopathy: 100%; macroangiopathy: 63.6% M, 33.3% F; neuropathy: 100%; mean years of dialysis: 2.6. Group II - 11 NIDDM (1.78%); 9M, 2F; mean age: 53.0; mean years of diabetes: 14.1; proliferative retinopathy: 100%; macroangiopathy: 100%; neuropathy: 100%; mean years of dialysis: 2.7. They received a cadaver kidney and triple (AZA+P+CsA) immunosuppression in 92.9% cases and a sequential quadruple (AZA+P+CsA+ATG or OKT3) in 7.1%. **Results:** Group I- mean days of hospitalisation: 20.9; mean survival graft: 31.7 months; patients with functioning graft: 15/17; HbA1c: 8.3%; most frequent post-transplant complications: acute rejection; infections, vascular, tumours..., mortality 1/17. Group II- mean days of hospitalisation: 28.8 mean survival graft: 31.1 months; patients with functioning graft: 8/11; HbA1c: 8.2%; most frequent post-transplant complications: acute rejection; infections, vascular, tumours..., mortality 3/11. Actuarial patient survival (1995): a) non-diabetic: 1st year- 95.55%; 5th year- 90.76% and 10th year- 81.54%; b) IDDM: 1st year- 92.86%; 5th year- 92.86%; c) NIDDM: 1st year- 60%; 5th year- 60%. Actuarial graft survival (1995): a) non-diabetic: 1st year- 91.82%; 5th year- 79.58% and 10th year- 67.65%; b) IDDM: 1st year- 86.2%; 5th year- 86.2%; c) NIDDM: 1st year- 60%; 5th year- 60%. **Conclusions:** After Saint-Vincent Declaration and start of our multidisciplinary team, more diabetic patients were transplanted. Diabetics have a lower actuarial patient and graft survival than the non-diabetics ones. The NIDDM had the worst results. In the last years there was an improvement of results, so for IDDM kidney transplant is our best option. In NIDDM the decision to transplant or to keep on dialysis should be taken on a per person basis.

*3 patients received a combined pancreas and kidney transplant

2125

THE PROGRESSION OF DIABETIC NEPHROPATHY AND PHAGOCYTOSIS OF MONONUCLEAR CELLS IN NIDDM

Aleksandar Đukić[1], Lj. Bajović[1], N.N.Arsenijević[1], S.Metiljević[1], M.Jovanović[1], R.Spirić[2], T.Veljković[2], G.Samardžić[1]; 1-Dpt. of endocrinology, Medical Faculty Kragujevac, 2-Institute of diabetes Vrnjačka Banja

The aim of this study is to examine connection between different stages of diabetic nephropathy (DN) and phagocyte function of mononuclear peripheral blood cells (MN) of patients with NIDDM. In order to evaluate this connection 45 patients with NIDDM were divided into three groups:A-normal creatinine (Cr) and no macroproteinuria; B-normal Cr with macroproteinuria; C- high Cr with macroproteinuria. The groups were homogenous concerning parameters of glycoregulation, liporegulation, antidiabetic therapy, sex and age. The control group consisted of 15 healthy volunteers. All subjects were examined by method of ingestion of particles of inactivated yeast labeled with neutral-red; after these all system is labeled by acrydil-orange and analyzed by fluorescent microscopy. Percent of phagocytosis (PP), index of phagocytosis (IP) and absolute index of phagocytosis (AIP) are determined. PP are 20.48 +/- 5.42%; 22.07 +/- 7.11%; 30.64 +/- 6.90% and 24.12 +/- 9.15% in groups A, B, C and control respectively (statistically significant difference exists between groups: C vs A, p=0.0008; C vs B, p=0.006 and C vs control, p=0.0026). IP are 3.06 +/- 0.65, 3.17 +/- 0.87, 3.55 +/- 0.84 and 3.13 +/- 0.82 in groups A, B, C and control respectively ($p>0.05$). AIP are 61.10 +/- 17.91, 66.15 +/- 5.87, 107.84 +/- 41.05 and 74.17 +/- 29.41 in groups A, B, C and control respectively (A vs C, $p<0.05$). In conclusion, advanced stages of DN are connected with increasing of phagocyte activity of MN cells.

2126

ASYMPTOMATIC BACTERIURIA IN PATIENTS WITH NIDDM. HW Lee, KC Won, IH Cho, CK Lee, Hy-W Lee and IK Lee*. Yeungnam University, Keimyung University*, Taegu, Korea.

The urinary tract is a frequent site of infection in patients with diabetic mellitus. The majority of investigators have reported that the prevalence of asymptomatic bacteriuria is higher in women with diabetic mellitus than nondiabetic women. Several studies, however, report little or no difference between diabetic and nondiabetic group. Several promoters of bacteriuria have been suggested in the diabetic host, such as glycosuria, immune defence defect or autonomic neuropathy affecting bladder and urethral function.

The prevalence of asymptomatic bacteriuria was studied in 279 diabetic patients and 182 nondiabetic controls. The possible role of host factors such as glycosylated hemoglobin, duration of diabetic mellitus, cardiovascular autonomic reflex, diabetic microangiopathies was also assessed in diabetic patients with and without bacteriuria. The prevalence of asymptomatic bacteriuria was significantly higher in diabetic women than in nondiabetic controls(15.8 vs 1.5%, $p<0.001$), but not in the diabetic men. In this survey of 133 diabetic women, asymptomatic bacteriuria was more common in the older patients. E. coli was found in 70.3% of urine culture with significant growth from diabetic patients. In nondiabetic controls, E.coli was found in 2/2 (100%) cultures. Risk of bacteriuria was not related to level of glycosylated hemoglobin(HbA_1), mean duration of diabetes mellitus, diabetic nephropathy and retinopathy. Abnormalities of cardiovascular autonomic function and diabetic neuropathy were common in diabetic patients with bacteriuria than in those without bacteriuria. This results suggest that diabetic patients with abnormal cardiovascular reflex test and autonomic neuropathy appear to be at increased risk of developing bacteriuria. Further study is necessary to determined relationship between cardiovascular test of autonomic function and autonomic abnormalities in other system, especially bladder innervation.

2127

THE RELEVANCE OF KIDNEY ATHEROSCLEROSIS IN THE EVOLUTION OF KIDNEY FUNCTION IN NIDDM.
M.Maiello D.Boeri C.Martinoli G.Simoni L.Sampietro D.Storace L.Ponte C.Robaudo C.Calvi M.Cutolo A.Sulli S.Accardo and L.Derchi. University of Genoa, Genoa, Italy.

Hystomorphological aspects of renal atherosclerosis are commonly found but, in the absence of reliable and non-invasive techniques, the relevance of macroangiopathy has still to be defined. The Duplex Doppler Ultrasuonography provides data about kidney morphology and characteristics of the intrarenal blood flow up to the level of interlobar arteries. Aim of this study is to evaluate the role of the atherosclerosis of the reno-parenchymal vasculature in the kidney involvement in NIDDM. 44 NIDDM and 10 control subjects entered the study. Patients with acute kidney failure and chronic urinary tract infections were excluded. Clinical and metabolic characteristics of subjects and vascular sequelae of the disease were evaluated. (Microangiopathy: fundus oculi or fluorangiography; albumin/creatinine; video-capillaroscopy. Macroangiopathy: Doppler ultrasuonography (carotid, posterior tibial and pedidia arteries). Duplex Doppler Ultrasuonography (DDU) of the kidney: Resistive Index (R.I.) and renal volume were calculated. No correlations were found between kidney R.I. and fasting blood glucose, HbA1 and total cholesterol; HDL-cholesterol correlates negatively ($p<0.05$), Tryglycerides and uric acid correlate positively ($p<0.05$). The R.I. correlates positively with serum creatinine ($2p<0.05$) and negatively with kidney volume($2p<0.01$). An increased R.I. is significantly associated with the macroangiopathy of the lower body ($2p<0.05$), while it does not seem to be influenced by macroangiopathy of the upper body or by microangiopathy. It suggests that renal macroangiopathy is mainly responsible for the modifications of DDU and for the evolution of kidney failure in NIDDM.

2128

EFFECT OF CALCIUM - ANTAGONISTS ON BLOOD PRESSURE AND MICROALBUMINURIA IN TYPE 2 DIABETICS WITH HYPERTENSION
The Lacidipine Multi-Center Study, Diabetes Center, Hippokration Hospital, Athens University, Athens, Greece.

In order to investigate the hypotensive effect of calcium-antagonists, in Type 2 Diabetics with hypertension as well as any effect on the development of albumin excretion, we studied 136 patients, 68 males, 119 females, in 9 Diabetes Centers, with mean age 60,6± .6, diabetes duration 8,2± .6 and hypertension duration 5,1± .6 years. Thirty-five percent of the patients were treated for the first time with antihypertensive drugs. After a 2 week run-in period without antihypertensive treatment, 4mg/d of the calcium antagonist Lacidipine were given for 12 weeks. Serum lipids, HbA1c, safety tests and urinary albumin were measured at the beginning and the end of the study. Blood glucose and blood pressure were measured at each visit, i.e. at weeks 0, 1, 2, 4, 8 and 12. Both Systolic (SBP) and Diastolic (DBP) blood pressure showed a significant decrease after one week of treatment, from 167.1 to 154.5 and from 97.6 to 89.0 mmHg respectively, p<.001. Both SBP and DBP decreased progressively till the 8th week, when they were stabilized, SBP 167.1, 154.5, 151.3, 148.9, 146.1, 145.7 and DBP 97.6, 89.0, 85.6, 84.5, 82.7, 82.0 mmHg,p<.001. At the 12th week the final decrease was 12.6% for SBP and 15.9% for DBP. There were 87 subjects without microalbuminuria, Albumin ≤ 20mg/L and 14 subjects with microalbunminuria, Albumin >20 and ≤200 mg/L, while subjects with macroalbuminuria, Albumin >200 mg/L were excluded from this analysis. At the end of the 12 week treatment period with Lacidipine 18.4% of the normoalbuminurics progressed to microalbuminuria, while a greater percentage, 42.9%, of the microalbuminurics became normoalbuminurcs. The mean urinary albumin in the normoalbuminuric group increased significantly from 3.3 ±.5 to 12.8 ± 2.6 mg/L, p<.001, but remained in the normal range, while in microalbuminurics it decreased significantly from 39.7 ± 4.9 to 25.3 ± 4.8 mg/L, p<.05. **Conclusions:** Treatment of hypertensive Type 2 diabetics with the Calcium antagonist Lacidipine for 12 weeks results in: **a)** A fast, significant and sustained decrease of both Systolic and Diastolic Blood Pressure **b)** A significant decrease of the albuminuria in those with microalbuminuria **c)** Reversal to normoalbuminuria of a significant percentage of the microalbuminurics.

2129

DECREASED ACTIVITY OF CALCIUM PUMP IN SKIN FIBROBLASTS OF IDDM PATIENTS WITH NEPHROPATHY.
G. Zerbini, F. Podestà, D. Gabellini, R. Ghelardi, G. Meregalli, R. Mangili and G. Pozza. Istituto Scientifico San Raffaele, Milano, Italy.

Human essential hypertension is characterized by an abnormal cellular calcium metabolism, and a decreased activity of the calcium pump has been observed in platelets of hypertensive patients. A predisposition to essential hypertension has been suggested to underlie the development of proteinuria in IDDM patients, but whether Ca^{2+} handling may be abnormal in these patients is presently unknown. We have therefore addressed Ca^{2+} transport pathways in cultured human skin fibroblasts (HSF) from insulin-dependent patients with diabetic renal disease. Forearm skin biopsies were taken and HSF grown from 13 patients with proteinuria and from 11 age-matched normoalbuminuric patients with a comparably long duration of diabetes (26±6 vs 29±2 years, p=NS). Exchangeable cell Ca^{2+} pool, Ca^{2+} influx and Ca^{2+} efflux were measured by established tracer (^{45}Ca) techniques in subconfluent cultures of actively proliferating cells after seven passages. The exchangeable Ca^{2+} pool was comparably distributed in the above groups of patients (21.4±3 vs 22.4±3 $nmol \cdot mg_{protein}^{-1}$, p=NS). Ca^{2+} influx was lower among the patients with nephropathy, though failing to reach significance (0.68±0.07 vs 0.95±0.1 $nmol \cdot mg_{protein}^{-1} \cdot min^{-1}$, p=0.1). Finally, Ca^{2+} efflux was significantly lower in patients with proteinuria (0.09±0.01 vs 0.14±0.02 $nmol \cdot mg_{protein}^{-1} \cdot min^{-1}$, p=0.03). None of these variables was quantitatively related with HbAIc, age or duration of diabetes. These results suggest that reductions in the activity of Ca^{2+} pump may represent one more ion transport abnormality shared by essential hypertension and diabetic nephropathy. A normal exchangeable Ca^{2+} pool may reflect a parallel reduction in Ca^{2+} influx, but the mechanisms of these abnormalities remain to be seen.

RENAL BIOPSY & IMMUNOSUPPRESSIVE THERAPY IN PROTEINURIC TYPE-II DIABETIC PATIENTS.

M.G. Kibriya, A.Sayeed, H.Mahtab and A.K.Azad Khan, BIRDEM, Diabetic Association of Bangladesh, Dhaka, Bangladesh.

In proteinuric type-II diabetic subjects, absence of diabetic retinopathy (DR) or presence of erythrocyturia is usually suspicious for non-diabetic glomerulopathy. Renal biopsy in such cases is important for diagnosis and planning appropriate therapy. Aim of the present study was to evaluate the justification of renal biopsy and the role of individualized immunosuppressive therapy in clinically diagnosed cases of so-called diabetic nephropathy. Studied subjects comprise 29 (m=14, f=15) proteinuric type-II diabetic patients having erythrocyturia or absence of DR of mean age 55.07 (SD 6.36) yr. with 8.9 (SD 6.67) yr. of known diabetic duration. Renal biopsy revealed diffuse & nodular glomerulosclerosis (suggestive of diabetic nephropathy - DN) in only 8 (m=6, f=2) cases all of which also had interstitial reaction, rest 21 (m= 8, f=13) had different forms of glomerulonephritis (GN). All were treated with prednisolone with or without cyclophosphamide (including pulse doses). Intensity & duration of the therapeutic regimen were individualized according to histology, severity of disease and clinical response. Patients were followed-up for 5.4 (SD4.11) months. Proteinuria decreased from 6.69± 2.15 to 2.98±1.34 gm/24 hr ($p<0.001$) in DN group and from 5.44±3.09 to 2.18±1.69 ($p<0.001$) in GN group; serum creatinine decreased from 2.42±0.73 to 1.94±0.44 mg% ($p<0.001$) in DN group and from 2.22±1.16 to 1.83±1.00 mg% ($p<0.001$) in GN group. However proteinuria and serum creatinine at last follow-up correlated significantly with baseline proteinuria ($p=0.0031$) and serum creatinine ($p<0.001$) even in multiple regression analysis where they were adjusted for each other and other factors as well. Response to therapy was better in female compared to their male counterpart which may be related to their less severe initial presentation. We conclude that renal biopsy in selective proteinuric type-II diabetic patients is justified and individualized pathogenetic treatment may be helpful in non-diabetic nephropathy in type-II DM and early intervention should be recommended Further follow-up is going on to confirm our findings.

2131

THE EFFECT OF INTENSIVE INSULIN THERAPY ON THE PROGRESS OF EARLY DIABETIC NEPHROPATHY AND RETINOPATHY

Liu Changshan, Dong Yanhu. Deptment of Endocrinology, Weifang People's Hospital, Weifang City, Shandong Province, P. R. China (261041)

Evidence in animals and humans has suggested that the developement of diabetic chronic complications(diabetic nephropathy, retinopathy, neuropathy, ect.) is related to metabolic abnormality associated with hyperglycemia, In the clinical study, we observed the effect of the intensive insulin therapy on the progress of early diabetic complications. 16 patients with early diabetic nephropathy and 14 patients with minimal background retinopathy were randomly divided into a the intensive insulin therapy group and a placebo— controlled group. The results showed that 1. the daily administration 0. 2～1. 0 U/kg. d of biosynthetic human insulin(Actrapid, Novo Nordisk) to normalize the level of blood glucose(fasting<7. 2, 2 hours <10. 0 mmol/ L) throughout 12 week course of the experiment sharply decreased the glomerular filtration rate (clearance of ^{99}Tc) comparing with placeo group(treated group: from 140±20 to 116±11 ml/min. 1. 73 m^2, $P<0.05$; placeo group: from 138±22 to 136±16 ml/min. 1. 73 m^2, $P>0.05$); 2. Urinary albumin excretion(radioimmunoassy) was apparently decreased in the treated patients, whereas no changes was seen after placeo(treated: from 86±21 to 43±15 ug/min, $P<0.05$; placeo: from 90±11 to 83±25 ug/min, $P>0.05$)); 2. Neither the intensive insulin therapy nor placeo— controlled patients were found the statistical significant reduce in the microaneurysm counts(treated group: from 3. 6±1. 9 to 4. 1±3. 0; placeo group: from 3. 8± 2. 5 to 4. 4± 1. 8 , determined by flurorescence retino— angiography). In conclusion, intervention with the intensive insulin therapy can reduce the progress of glomerular filtration rate and urinary albumin excretion, but at least in short time, has no significant effect on the course of minimal retinopathy.

2132

CLINICAL EFFECTS OF LONG-TERM ERYTHROPOIETIN (EPO) TRAETMENT IN JAPANESE NIDDM WITH NEPHROPATHY

M Nomura, M. Ohashi, T. Nakano, M. Kakihara, Y. Yamada and H. Abe. Osaka Rosai Hospital, Sakai, Osaka, Japan.

EPO (recombinant human erythropoietin] has been used for the treatment of anemia associated with end stage diabetic nephropathy. However, there were only a few clinical data about the effects of EPO administration on amenia and renal function at more earlier stage of diabetic nephropathy before hemodialysis. In this prospective study, we have tried to investigate the long term clinical effects of EPO in NIDDM patients with anemia due to diabetic nephropathy at more early stage.

[Subjects and methods] Four Japanese NIDDM patients with anemia due to diabetic nephropathy were investigated (serum creatinine (sCr.): 2.0 ±0.4 mg/dl, erythrocyte (RBC): 285±10 x10^4/mm^3, hemoglobin: 8.6±0.7 g/dl]. EPO was administered at the dosage of 6000 units every two weeks for 96 weeks. Fasting blood sample was taken periodically and investigated the clinical effects of EPO.

[Results] After EPO administration, anemia was significantly improved [24 weeks ; RBC:328±17 x10^4/mm^3 ($p<0.01$), 96 weeks ; 343±34 x10^4/mm^3 ($p<0.05$)]. Although serum creatinine concentrations were increased in these patients, the changes were not statistically significant [24 weeks: 2.3±0.4, 96 weeks: 2.7±0.5 mg/dl, n.s.]. Mean changing rates of serum creatinine was significantly reduced than control data [- 0.0016 ±0.0010 (1/mg · dl/week) , $p<0.01$]. During this prospective study, there were no significant changes in blood pressure and blood glucose control levels.

[Conclusion] It was found that in NIDDM patients with anemia due to nephropathy, long term EPO treatment was clinically effective to improve amenia and also to attenuate the speed of deterioration in renal function.

2133

DECREASE OF URINARY ALBUMIN EXCRETION AFTER GLYCEMIC CONTROL IN DIABETES.

J.M. Poirier, B. Bauduceau, H. Mayaudon, M. Pellan, G. Prévost, G. Belmejdoub and M. Ducorps. Hôpital d'Instruction des Armées Bégin, 94160 Saint Mandé, FRANCE.

Raised urinary albumin excretion (UAE) is a marker for incipient nephropathy when comprised between 30 and 300 mg/24h. The aim of this work was to assess the influence of high blood glucose level on the rate of UAE and its evolution after glycemic control. Subjects and methods: 32 diabetic patients were included (22 M, 11 F; 13 IDDM, 19 NIDDM; mean age 51 ± 18 years, diabetes duration 8.1 ± 18 years). All patients had a poor glycemic control (fasting blood glucose level > 250 mg/dl, HbA1c > 9%) requiring short term intensive insulin therapy. The 24hour UAE was measured daily during an 11 days period. Poor glycemic control at admission was demonstrated by patients' parameters (glycemia 342 ± 102 mg/dl, HbA_1c 11.3 ± 2.3%, fructosamine 0.44 ± 0.09 mmol/l). Results : Daily measurement of UAE showed a continuous decrease until a stable level which was reached around the 8th day. A significant difference ($p<0.001$) for mean UAE rate was found between the first day (35.6 ± 61 mg/ 24h) and the last day (14.2 ± 10 mg/24h). A positive correlation was noted between the initial HbA_1c level and the magnitude of UAE's decrease ($r = 0.395$, $p< 0.02$). Comments : A long time of high blood glucose level induces an increase of urinary albumin excretion and the restoration of glycemic control allowed a decrease of UAE which becomes stable after 8 days. Thus, in diabetic patients, urinary albumin excretion rate should be interpreted with consideration of glycemic control.

2134

LOW PROTEIN DIET AND KIDNEY FUNCTION IN INSULIN DEPENDENT DIABETIC PATIENTS WITH DIABETIC NEPHROPATHY

H. P. Hansen, P. K. Christensen, E. Tauber-Lassen, A Klausen, B. R. Jensen and H.-H. Parving. Steno Diabetes Center, Copenhagen, Denmark.

Initiation of low-protein diet (LPD) in patients with varies nephropathies induces a faster initial and slower subsequent decline in glomerular filtration rate (GFR). Whether this initial phenomenon is reversible or irreversible remains to be elucidated. We performed an eight weeks prospective, randomized, controlled study comparing the effect of LPD (0,6 g/kg/24 h) with normal protein diet (NPD, 1,0 g/kg/24 h) in 29 insulin dependent diabetic (IDDM) patients with diabetic nephropathy. At baseline the patients were randomized to either NPD (n=15) or LPD (n=14) for 4 weeks. Between week 4 and 8 all patients received NPD. The following variables were measured at baseline and after 4 and 8 weeks follow-up: Dietary protein intake (DPI, estimated by the 24 h urinary nitrogen excretion, g/kg/24 h), GFR (^{51}Cr-EDTA, ml/min/1,73 m²), albuminuria (ELISA, mg/24 h) and blood pressure (BP, Hawksley random zero sphygmomanometer, mm Hg). During the investigation 14 patients in the NPD group and 12 patients in the LPD group received their usual antihypertensive treatment. Baseline data, the NPD group vs the LPD group; DPI (mean, SD) 0,9 (0,3) vs. 1,2 (0,3)($p < 0.05$), GFR (mean, SD) 92 (21) vs. 94 (21)(NS), albuminuria (geometric mean, antilog SEM) 550 (1,3) vs. 269 (1,5)(NS), and BP (mean, SD) 140/79 (17/10) vs. 135/76 (12/7)(NS). Changes in DPI (ΔDPI), GFR (ΔGFR), albuminuria (ΔUAE) and BP (ΔBP), from baseline to 4 weeks, and from 4 to 8 weeks, were compared between the LPD group and the NPD group:

	mean difference (95% CI) between LPD group and NPD group			
	0 to 4 weeks	p	4 to 8 weeks	p
ΔDPI (g/kg b. w./24 h)	-0,4 (-0,6 to -0,3)	<0,0001	0,3 (0,2 to 0,5)	<0,0001
ΔGFR (ml/min/1,73 m²)	-6,0 (-12,6 to 0,5)	=0,07	8,8 (2,9 to 14,7)	<0,005
ΔUAE (%)	-28,1 (-46,5 to -5,6)	<0,05	21,5 (-8,0 to 60,3)	=0,16
Δsystolic BP (mm Hg)	0,0 (-8,8 to 8,9)	NS	-2,5 (-12,2 to 7,2)	NS
Δdiastolic BP (mm Hg)	-3,1 (-8,3 to 2,1)	NS	-0,7 (-7,1 to 5,8)	NS

In conclusion, short-term LPD induces a reversible (hemodynamic?) reduction in GFR and albuminuria in IDDM patients with diabetic nephropathy.

2135

SECONDARY FAILURE IN NON-INSULIN-DEPENDENT DIABETES MELLITUS (NIDDM): EFFECT OF INSULIN ON RENAL FUNCTION

P.D.Chattington[a], K.Hampson[a], T.S.Purewal.[a],I.R.Jones[b]and J.P.Vora[a]
[a]Departments of Medicine and Endocrinology, Royal Liverpool University Hospital, Liverpool and [b] Arrowe Park Hospital, Wirral UK.

Some 50% of NIDDM patients fail to achieve adequate glycaemic control after 10 years on oral hypoglycaemic agents (OHA), thus necessitating insulin therapy. OHA failure patients were defined as those having an HbA_{1c}>7.2% (ref <6.2%), on maximum OHA for >1 year with C-Peptide concentrations >0.6 nM 6 mins after I mg iv glucagon. HbA_{1c}, fasting C-peptide and insulin, blood pressure (BP), morning urine for albumin/creatinine ratio (ACR) and 3 timed overnight urine collections for albumin excretion rate (UAER) [n=28], with glomerular filtration rate (GFR) and effective renal plasma flow (ERPF) [plasma isotopic clearance after single combined intravenous injection of Cr^{51}-EDTA and Tc^{99}-MAG3, corrected to 1.73m² surface area] [n=17], assessed immediately before and repeated after 3 months on insulin. HbA_{1c} improved significantly from 10.6 [0.3] mean [SEM] to 8.5[0.3]%, p<0.01. Fasting C-peptide decreased from 965 [100] vs 686 [70]pmol.l^{-1}, p<0.001; insulin increased form 12.16 [1.3] to 25.41 [9.6]mU.l^{-1}, p< 0.01. Body mass index increased from 27.3 [0.9] to 28.3 [1.0] kg.m², p<0.001. Systolic BP increased 133 [3.3] vs 138 [3.7]mmHg, p< 0.04, with no change in diastolic BP 75 [2.0] vs 77 [2.1]mmHg. ACR (median [range]) 3.2 [<5 to 390] vs 2.5 [<5 to 182]mg.mmol^{-1} and UAER at 8.7 [<5 to 3110] initially vs 6.9 [<5 to 1028]μg.min^{-1} were not significantly lower on insulin. GFR, ERPF and filtration fraction remained stable at 90.1 [6.6] vs 88.2 [7.4] ml.min^{-1}; 330 [29] vs 320 [30] ml.min^{-1} and 0.28 [0.01] vs 0.28 [0.02]% respectively. Insulin therapy produces the expected increase in BMI, serum insulin concentrations and improvement in glycaemic control. There was also the less expected increase in systolic BP. Inspite of these changes there is no alteration in renal haemodynamics or urinary albumin excretion.

2136

METABOLIC EFFECTS OF A MILD DIETARY PROTEIN RESTRICTION IN NIDDM PATIENTS WITH NEPHROPATHY

C.Takahashi,N.Ujihara,O.Tomonaga,H.Yokoyama,T.Babazono, T.Sanaka and Y.Omori.Tokyo Women's Medical College,Tokyo, Japan.

Aim of this study was to assess the effects of a short term (about 2 weeks) mild dietary protein restriction (0.8g/kg) on the renal and metabolic state in hospitalized NIDDM patients with diabetic nephropathy. **Patients & Methods:** 22 NIDDM patients (14 M/ 8 F. age 56.2±14.5y, diabetes duration 17.3±7.7y, S-creatinine 2.2±1.6 mg/dl, M±SD) were studied. 10 NIDDM patients without nephropathy (7M/3F ,age 52.2±13.7 y, diabetes duration 9±0.2y,Scr 0.9±0.2) treated without dietary protein restriction (1.45g/kg) served as controls . On admission and before discharge , 24 -hour urine samples were collected and analyzed for protein, nitrogen excretion, creatinine clearance (CCr) and nitrogen balance (NB). Serum total protein (TP),albumin(ALB), lipids (TC, TG), glycated albumin (GA)were also checked. Those data were compared between on admission and before discharge within the two groups. **Results:** Estimated protein consumption (g/kg/iw) of patients at admission and discharge were 0.93±0.25 vs 0.77±0.13,p=0.0026, but that in controls did not differ. CCr., S-cr.,U-protein did not differ in either group. TP and ALB in patients were decreased significantly at discharge,but not in controls. NB(g/day) at discharge in patients was 0.28 ±1.12 and in controls was 2.88±2.44,p=0.004, significantly lower in patients . Lipids in patients were decreased significantly. GA(%) was decreased significantly at discharge in controls, but not in patients. **Conclusion:** A protein restricted diet showed some demerits, even though the restriction was a mild and the duration was short, nutritional status should be monitored closely during a protein modified diet.

2137

PROGRESSION OF LEFT VENTRICULAR MASS DURING ANTIHYPERTENSIVE TREATMENT IN DIABETIC NEPHROPATHY

A.Sato, L.Tarnow, S.Ali*, P.Rossing, F.S.Nielsen, H.-H.Parving. Steno Diabetes Center and ^Rigshospitalet, Copenhagen, Denmark.

Increased left ventricular mass (LVM) may contribute to the increased relative mortality from cardiovascular disease in insulin dependent diabetic (IDDM) patients with diabetic nephropathy. The effect of antihypertensive treatment on LVM and systolic function was evaluated in a one year, double blind, randomised, parallel study with a long-acting calcium antagonist (nisoldipine, 20-40 mg/day) or an angiotensin converting enzyme inhibitor (lisinopril, 10-20 mg/day). Fifty hypertensive IDDM patients with diabetic nephropathy were enrolled. Three patients dropped out and 7 patients were not evaluable due to technical difficulties. M-mode echocardiography was performed and the results analyzed blinded and independently by two observers before and after treatment with nisoldipine (n=20) or lisinopril (n=20). Twenty four hours ambulatory blood pressure was measured with the A&D TM2420 device every 3 months. During the study, 24h mean arterial blood pressure was reduced from (mean(SE)) 108 (3) at baseline to 101 (2) in average during treatment in the lisinopril group and from 105 (2) to 103 (2) in the nisoldipine group (p=0.06 comparing changes in the two groups). LVM, corrected for body surface (LVMI) was comparable between groups at baseline and increased from (mean(SE)) 96 (5) to 107 (6) g/m² (p=0.007) in the nisoldipine group and from 95 (4) to 103 (5) g/m² (p=0.03) in the lisinopril group. The mean difference between the change in LVMI in the two groups were 2,9 (95% CI: -6,8 to 12,7) g/m². The prevalence of left ventricular hypertrophy rose from 18 % to 30 % during the study period. A multiple linear regression analysis revealed, that LVMI increased with higher systolic blood pressure level and declining GFR, while sex, age, metabolic control, diastolic blood pressure, urinary sodium excretion and treatment group did not contribute to explain the variation in LVMI, R^2 = 0.25. Systolic function, assessed by fractional shortening, were within normal range and similar at baseline and during follow up 42 (1) vs 41 (1) %, nisoldipine vs lisinopril, respectively. Conclusion: Antihypertensive treatment to a blood pressure level within the normal range, does not hinder a progressive rise in LVM in IDDM patients with diabetic nephropathy. The impact of more aggressive treatment should be evaluated.

2138

LOW PROTEIN DIET INCREASES INSULIN-STIMULATED GLUCOSE DISPOSAL AND ENERGY PRODUCTION RATE IN UREMIC PATIENTS.

V Rigalleau, V Blanchetier, C Combe, J Aubertin, M Aparicio and H Gin. Service de nutrition et diabétologie, hopital Haut-Lévèque, Pessac, et service de Néphrologie, hopital Pellegrin, Bordeaux, France.

Low protein diets (LPD) increase insulin-mediated glucose disposal in chronic renal failure (CRF), but the fate of the better utilized glucose and the effect on energy production rate are unknown. Using a two-step (1 and 5 $mU.kg^{-1}.min^{-1}$) euglycemic hyperinsulinemic clamp combined with indirect calorimetry, we studied the effects of a LPD (0.3 $g.kg^{-1}.d^{-1}$, supplemented with essential aminoacids and ketoanalogues) in 6 non dialized patients with chronic renal failure (Glomerular Filtration Rate: 13.6±3.1 $ml.min^{-1}$). After 3 months of diet, no significant change was observed concerning GFR, body weight, arterial pH. At the postabsorptive state, plasma glucose and insulin were significantly lower (Glucose: 4.7±0.1mmol.l^{-1} vs 5.0±0.1 before LPD, insulin 8.1±1.5 $\mu U.ml^{-1}$ vs 14.0±3.7 before LPD; both $p<0.05$) and energy production rate higher (17.16±0.67 $Cal.kg^{-1}.min^{-1}$ vs 15.72±0.48 before LPD; $p<0.05$). Insulin-stimulated glucose oxidation (3.37±0.35 $mg.kg^{-1}.min^{-1}$ vs 2.36±0.29 before LPD; $p<0.05$ at first clamp step) and non oxidative disposal (2.58±0.68 $mg.kg^{-1}.min^{-1}$ vs 1.29±0.51 before LPD at first clamp step; 5.31±0.41 vs 3.74±0.74 at 2nd step; $p<0.05$ at both steps) increased after LPD. This confirms that LPD ameliorates insulin sensitivity in CRF, even for low plasma insulin concentrations. Since energy production rate is increased by LPD, the caloric intake should be increased when protein intake is restricted.

2139

ACE-INHIBITION DURING TWO YEARS DID NOT IMPROVE U-AER IN NORMOTENSIVE MICROALBUMINURIC IDDM PATIENTS.

M Bojestig*, B E Karlberg*, and the PRIMA study group. Department of *Internal Medicine, University Hospital, Linköping, Sweden.

The aim was to investigate if a low dose of ramipril(1.25mg daily) is as effective as 5mg daily to reduct urinary albumin exretion rate (U-AER) in normotensive (diastolic blood pressure ≤ 90 mmHg) microalbuminuric (U-AER 30-300mg/24h) IDDM patients. The study was performed as a multicenter randomized placebo controlled double blind parallell group study during two years. U-AER was measured in 2 24h urinary collections every 3 month, GFR and 24h ABPM at time 0, 1 and 2 years.

Group of patients	Placebo	1.25mg Ramipril	5 mg Ramipril
Male/female (n)	14/4	13/6	14/4
Duration of diabetes	21.1	27.7	22.5
HbA1c (%)	7.4	7.6	7.2
U-AER* 0y (mg/24h)	103	109	69
U-AER* 2y (mg/24h)	95	94	81

*values is median, no differences are significant

There was no significant changes in 24 h ABPM or GFR in any group.

Conclusion: Normotensive IDDM patients with microalbuminuria and good glycaemic control had no difference in UAER progression when treated with placebo or ramipril 1.25mg or 5mg daily during 2 years. Probably, this group of microalbuminuric patients does not need Ace-inhibition.

2140

n - 3 FATTY ACID THERAPY IN DIABETIC PROTEINURIA - A CLINICAL STUDY.

C V Harinarayan*, K Ram Vijay Kumar, A Padma & PV Srinivasa Rao, Dept of Endocrinology & Metabolism, Biochemistry, Sri Venkateswara Institute of Medical Sciences, Tirupathi-517 707, Andhra Pradesh, INDIA.

Twenty four hour urine proteins were estimated when the urine culture was sterile in 36 patients ***(Group 1)*** (diabetes mellitus of 5-10 years duration) with age *50 ± 12 years (M:F = 14:12)* before and six months after n-3 fatty acid therapy (EICOSAPENTAENOIC ACID 1080 mg/day & DOCOSAHEXAENOIC ACID 720 mg/day in three divided doses. Commercial name MAXEPA). Glycemic control was achieved with insulin alone (n = 10), oral antidiabetics (n = 16) and a combination of both (n = 10). Nine were treated with ACE inhibitors, and three with calcium blockers. The mean ± SD biochemical parameters fasting and post prandial plasma glucose (FPG and PPPG - mg%), serum creatinine (SC - mg%), 24 hour urine total volume (24 TV - ml/day), 24 hour urine proteins (24 UP - mg/day), 24 hour urine creatinine (24 UC - mg/day) were *213 ± 94; 300 ± 112; 0.9 ± 0.34; 2650 ± 1045; 530 ± 600; 928 ± 447 respectively before initiation of therapy and 135 ± 68; 180 ± 88; 0.98 ± 0.5; 2394 ± 1002; 436 ± 515 respectively six months after therapy.* Forty seven percent ***(Group 2)*** (n = 17) showed a significant decline in proteinuria ($P < 0.01$) when compared to ***(Group 3)*** (n = 19) who showed a rise in proteinuria. The *mean ± SD of FPG, PPPG, SC, 24 UTV, 24 UP, 24 UC in group 2 at the time of initiation of therapy were 167 ± 57; 264 ± 94; 0.99 ± 0.33; 2740 ± 1081; 766 ± 769; 921 ± 334 and six months after therapy 146 ± 68; 191 ± 82; 1.02 ± 0.45; 2295 ± 1218; 357 ± 374; 779 ± 507 respectively.* The corresponding *values in group 3 were 254 ± 102; 333 ± 119; 0.9 ± 0.35; 2568 ± 1033; 318 ± 271; 933 ± 538 at initiation and 127 ± 69; 170 ± 93; 0.95 ± 0.56; 2483 ± 785; 506 ± 617; 1015 ± 304 respectively after six months of therapy.* There was a significant difference between Group 2 and 3 among FPG ($P < 0.01$), PPPG ($P < 0.1$) at initiation of therapy FPG and PPPG ($P < 0.01$) six months after therapy, and the fall in 24 UP ($P < 0.01$). There was a negative correlation ($P < 0.05$) between the degree of fall in 24 UP and 24 UP before initiation of therapy in group 2 only. There was no correlation between serum creatinine and creatinine clearance before and after therapy in both groups. The reduction of proteinuria by n-3 fatty acid therapy in diabetic proteinuria is complementary to glycemic control and significant when the proteinuria is mild or moderate.

2141

ACE INHIBITORS IN TREATMENT OF ADOLESCENT PATIENTS WITH IDDM AND DIABETIC NEPHROPATHY.

V.N.Sokolovskaya G.I.Sivoous, , E.A.Voichik and E.P.Kasatkina Russian Academy of Advansed Medical Studies, Moscow, Russia.

The purpose of the study was to assess the effect of ACE inhibitor Enalapril maleate in patients with IDDM on early stages of diabetic nephropathy and normal level of BP. 42 IDDM patients (13 male, 29 female, aged 11.5 - 20.9 ys) were included into the study. 35 of them had microalbumin - uria and 7 had proteinuria. All patients received 5-10 mg of Enalaprili daily during 3-6-9 months. The effect of treatment was evaluated by dynamics of microalbuminuria ("Beringer Mangheim"), HbAl blood level and BP. After 3 months of treatment with enalapril showed a decrease of urine albumin excretion and in 21 of them the urine albumin contents became normal and was normal in 75% of patients after 3 months and in 72,2% after 9 months completion of treatment. Patients who showed no changes of microalbumin-uria level after 3 months of treatment continued to receive the same dose of enalapril for 6 to 9 months. After the period of prolonged treatment improvement was achieved only in patients with decreased level of HbA1% (11.94± 0.6 vs 10.1 ± 0.4 p. > 0.05). In the group of proteinuria 6 of 7 patients showed the reduction of protinuria and 1 of them - the total absence of proteinuria after 3 months of treatment with enalapril (daily dose 5 mg.) Treatment with increased dose (10 mg. daily) o f enalalpril was continued in patients with remaining proteinuria. After the next 3 months of treatment the half of them showed the following reduction of proteinuria, the later correlated with improvement of blood HbA1% (13.2 ± 1.2 vs 10.6 ± 0.78, p > 0.05) level. BP was stable in all patients during the whole period of study. Conclusion: Enalapril is effective for treatment of patients with diabetic nephropathy with normal BP on the stages of microalbuminuria and proteinuria. Effect of treatment is better in patients with compensated carbohydrate metabolism.

2142

IS VEGETARIAN PROTEIN DIET (VPD) RENOPROTECTIVE ?

GS.Narayan, MG.Mamatha, AS.Vinaya, BS.Sudha, DV.Rama, S.Krishnamurthi, J.Srikanth, S.Nagabushan, P.Hegde, N.Nagesh, P.Ashalakshmi, S.Colaco, S.Suresh, A.Sharda and SS.Srikanta. Samatvam: Endocrinology Diabetes Center, Bangalore, India.

Dietary protein load is recognized to influence the course and progression of chronic renal diseases including diabetic nephropathy (DN). Earlier observations by ourselves and others had suggested that in addition to quantity, the quality (vegetable vs animal origin) of the dietary protein may also influence the pathogenesis and progression of DN. Urinary albumin excretion (UAE) rates (mg/24h) were measured by immunoturbidometry in 227 consecutive NIDDM subjects. The results were correlated with clinical and demographic data. Compared to vegetarians, non-vegetarians had higher UAE (X:166 vs. 205), specifically in the ODN group (858 vs. 1402). Advanced stages of DN were associated with increased diabetes duration, systolic blood pressure (SBP), and glycated hemoglobin, and tendency towards dyslipidemia (increased LDLC and TG, decreased HDLC); age at diagnosis and OHA failure had no significant associations. Conclusions: Despite VPD being potentially renoprotective and the relative predominance of vegetarianism in India, other negative influences (social deficiencies in comprehensive diabetes care - glycemic control, B.P.Control possible increased genetic susceptibility) are likely overwhelming, resulting in overall higher prevalence of advanced stages of DN in Asian Indians.

Group	NAE	IDN-1	IDN-2	ODN	P
UAE	<31	31-150	150-300	>300	
Prevalence%	22	58	10	11	
GHb %	7.8	8.3	8.1	9.1	
SBP mm Hg	137	138	143	156	0.0009
DM duration	6.1	8.0	10.2	11.0	0.012

NAE = Normal Albumin Excretion
IDN: Incipient DN
ODN: Overt DN

2143

LISINOPRIL REDUCES EXERCISE-INDUCED MICROALBUMINURIA IN NORMOTENSIVE NORMOALBUMINURIC IDDM PATIENTS

J.A. Tuominen and V.A. Koivisto. Helsinki University Central Hospital. Helsinki, Finland.

In order to study the effect of lisinopril on exercise-induced urinary albumin excretion twentysix IDDM patients with normoalbuminuria were randomized into two groups having either placebo (n=13, age 36±3 yrs, BMI 24.5±1.1 kg/m^2) or lisinopril (15 mg) (n=13, age 34±2, BMI 24.4±0.9 kg/m^2) as their treatment. Overnight and exercise-induced urinary albumin excretion rate were measured at baseline and after 1 and 2 yr treatment. Two patients from the placebo group and none from the lisinopril group developed microalbuminuria. The exercise-induced urinary albumin excretion rate diminished 46% after the first (p=0.059) and 66% (p<0.01) after the second year in the lisinopril group, but remained unchanged in the control group. Systolic and diastolic blood pressure were similar in the baseline and after 1 year, but at 2 years systolic blood pressure was 13 mmHg (p=0.03) and diastolic blood pressure 9 mmHg lower (p=0.052) in the lisinopril group as compared to the control group. Diastolic blood pressure decreased significantly at 1 and 2 years in the lisinopril group, while there was no significant change in the systolic blood pressure. At baseline, overnight albumin excretion rate correlated with HbA_{1c} (r=0.50, p<0.01) and the duration of diabetes (r=0.39, p<0.05), and systolic blood pressure correlated with both overnight (r=0.42, p<0.05) and exercise-induced (r=0.48, p<0.05) albumin excretion rate in the whole group.

In conclusion, glycaemic control and blood pressure are directly related to overnight albumin excretion rate already in normotensive, normoalbuminuric IDDM patients. Lisinopril treatment reduces exercise-induced urinary albumin excretion rate in such patients. These data suggest a protective effect of lisinopril for the development of microalbuminuria.

2144

BASAL AND AFTER ORAL METHIONINE ADMINISTRATION HOMOCYSTEINE LEVELS IN NIDDM PATIENTS. RELATIONSHIP TO MICROALBUMINURIA.

Veronelli A.,Peca M.G.,Ranieri R.,Rognoni C.,Sacchi S.,Cantatore R., Zecchini B.,Santagostini G.,Lanfredini M., Fiorina P., Craveri A.
S.Paolo Hospital. Milan. Italy.

Recent studies conferred an atherogenetic role to Homocysteine.Homocysteine has been suggested as a new independent risk factor for atherosclerosis. Aim of the study was to evaluate the relationship between Homocysteine and Microalbuminuria in NIDDM patients.In this study 33 NIDDM patients (16 males and 17 females) and 16 healthy controls (7 males and 9 females) were enrolled. We determined Homocysteine levels before and after oral administration of L Methyonine (100 mgs/kg) and microalbuminuria, HbAlc, total and HDL cholesterol, tryglicerides. All the patients were treated by hypoglicemic agents or by diet. Homocysteine plasmatic levels in fastin state (8.12 +/- 3.17 micromol/l vs 7.19 +/- 2.4 micromol/l p=ns) and after a methionine load (26.51 +/- 11.5 micromol/l vs 25.06 +/-10.76 micromol/l) did not differ in NIDDM patients versus controls. There was a significant correlation between Homocysteine levels and microalbuminuria (p< 0.005). In NIDDM patients with vascular complications presented higer homocystein levels than patients without any complications (p< 0.0001).
Homocystein could be a relevant prognostic factor warsening the progognosis in well controlled in NIDDM patients.

2145

EFFECTS OF LISINOPPRIL AND NIFEDIPINE ON THE PROGRESSION TO OVERT PROTEINURIA IN NORMOTENSIVE INSULIN DEPENDENT DIABETIC PATIENTS WITH INCIPIENT NEPHROPATHY

G. Crepaldi, Q. Carta, G. Deferrari, R. Mangilli, R. Navalesi, F. Santeusanio, A. Spalluto, A. Vanasia, G.M. Villa, R. Nosadini on behalf of the Italian Microalbuminuria Study Group in IDDM.

Microalbuminuria (MA) is observed in as high as 15-25% of IDDM patients in Europe, even in absence of arterial hypertension. It is not clear whether MA does predict overt nephropathy to the same extent when associated or not to arterial hypertension. Intervention trials on renal function in MA IDDM patients should adopt as outcome measurement the rate of decline of glomerular filtration rate (GFR). However normotensive MA IDDM patients show no change in GFR over a follow-up period of 4-10 yrs irrespective of antihypertensive teatment. In the present study we used either 1) the cumulative incidence of progression to proteinuria (albumin excretion rate-AER>250 µg/min) or 2) the rate of yearly increase in AER 50% above baseline, to study the course of renal function in 137 normotensive IDDM patients during double-blind, double dummy treatment either with lisinopril or with slow release nifedipine in comparison with placebo. 103 patients completed the 3 yrs follow-up period. Postural hypotension and hyperkaliemia did not occur in any patient. Time to event analysis indicated a reduction in the risk of progression to proteinuria of 58.1% (95% C.I.: 27.8-68.4%) in the lisinopril (p<0.02 and of 62.5% (95% C.I.: 32.5-73.4%) in the nifedipine (p<0.02) groups respectively, after adjustment for mean blood pressure, glycated hemoglobin and baseline AER. Baseline AER was 71 µg/min (range 21-230) in progressors and 73 µg/min (range 20-233) in nonprogressors (NS). The percentage of patients who showed an yearly increase of AER>50% above base line values was significantly lower in the lisinopril (14 of 34, 41%, p<0.02) but not in the nifedipine (17 of 27, 63%) than in the placebo (31 of 42, 74%) groups. Lisinopril group had significantly lower systolic values during the follow-up than nifedipine (p<0.002) and placebo (p<0.03) groups. In conclusion our data show that both lisinopril and nifedipine are effective in delaying the occurrence of overt proteinuria in normotensive IDDM patients with MA. As overt proteinuria strongly predicts end stage renal failure both treatments appear capable to prevent such complication in normotensive IDDM with MA. Lisinopril appears to improve the patterns of AER also in the range of microalbuminuria. This latter result needs to be emphasized as the patterns of AER have been suggested not be an indicator of but to contribute themselves to the progression of renal damage.

2146

LONG-TERM PICOTAMIDE, A DUAL THROMBOXANE INHIBITOR, DECREASES URINARY ALBUMIN EXCRETION RATE IN TYPE 2 DIABETIC PATIENTS WITH MICROALBUMINURIA AT REST

P. Desenzani, P. Perini, C. Mascadri, F. Manelli, M. Milani*, F. Negrini, A. Burattin, C. Cappelli, G. Romanelli, A. Giustina.
Endocrine Section, Dept. Internal Medicine, University of Brescia;* Sandoz P.F., Milano; Italy

Picotamide inhibits thromboxane-synthetase and acts as a thromboxane antagonist at the receptor level. We investigated in a randomized, double-blind, placebo-controlled trial the long-term effect of picotamide on urinary albumin excretion (UAE) at rest and induced by exercise in 30 non insulin dependent (type 2) diabetic patients normotensive (supine BP $<140/90$ mmHg) and with microalbuminuria (24-h UAE between 20 and 200 μg/min) while at rest. The subjects of our study had mean age 52.5 ± 1.6 yrs and mean BMI 28.5 ± 0.7 Kg/m^2, diabetes duration of 9.1 ± 1.8 yrs and were in fairly good glycometabolic control (HbA1c: 7.0 ± 0.8%). The patients were randomly allocated to receive for 1 year either picotamide, 300 mg, 3 tabs/day or placebo, 3 tabs/day. The patients were seen after 1, 3, 6, 9 and 12 months of treatment. At all times, BP, UAE at rest (mean of three 24-h urine samples), bood glucose, serum creatinine, serum picotamide and creatinine clearance were measured; at baseline and after 6 and 12 months all patients underwent a submaximal physical exercise for evaluation of exercise-induced microalbuminuria. After 6 months of picotamide treatment, at rest (30 ± 24 μg/min) and exercise-induced (80 ± 35 μg/min) microalbuminuria were significantly decreased as compared to the baseline (at rest: 60 ± 40 μg/min; after exercise: 250 ± 150 μg/min) and placebo level without further drops at month 12 of picotamide treatment. On placebo treatment, UAE at rest (80 ± 40 μg/min) and after exercise (170 ± 35 μg/min) was slightly, even if not significantly, increased as compared to baseline values. The effects of picotamide occurred without either significant side effects or changes in either blood pressure levels or glycometabolic control. Our study is the first, long-term, intervention trial in type 2 diabetes showing that an anti-thromboxane agent is able to dramatically decrease microalbuminuria, which in this disease is a dual marker of macro- and micro-angiopathy.

2147

COMPARISON OF THE EFFECTS OF PERINDOPRIL AND METOPROLOL ON KIDNEY FUNCTION AND ALBUMINURIA IN EARLY DIABETIC NEPHROPATHY IN IDDM PATIENTS

M. Bernas. Department of Internal Medicine and Diabetology, Warsaw Medical School, Warsaw, Poland.

The action of angiotensin converting enzyme inhibitors (ACEI) and of beta receptors blockers (beta RB) on the pathophysiological events in early diabetic nephropathy is a subject of controversy. The main question is: do the ACEI posses any specific influence on kidney function in diabetics, which is not exerted by beta RB? To explain the problem the double blind, randomised study was designed. In the study the effects of 2-8 mg of perindopril or 50-100 mg of metoprolol daily in IDDM subjects with albuminuria less than 1g/24h were measured. 30 IDDM subjects were randomised into 2 subgroups: 14 cases for perindopril and 16 cases for metoprolol and subjected to 1 year study. At the baseline and 3 times every 3 months the following observations were recorded: clinical examination, HbA1c, blood pressure (BP), daily albuminuria, glomelular filtration rate (GFR), effective renal plasma flow (ERPF), filtration fraction (FF). All IDDM subjects showed the HbA1c level <7%, did not have any additional morbidity and had free access to observes. The obtained: the mean systolic BP dropped down in the perindopril group from 151±15 to 134±10 mm Hg, in metoprolol group from 158±12 to 137±8 mm Hg, the mean diastolic BP decreased respectively from 94±6 to 78±5 mm Hg and from 93±4 to 84±6 mm Hg. The differences observed in BP decrease in both groups were not significant. Contrasting results were observed in the intensity of albuminuria. The mean daily albuminuria decreased in the perindopril group from 376±92 to 103±57 mg/24h. It did not change in the metoprolol group. Differences between both groups are statistically significant. Such functional parameters like ERPF, GFR and FF did not change significantly in the perindopril group, while they showed the tendency to deterioration in the metoprolol group. Conclusion: Both types of therapy equally reduced BP, however ACEI therapy decreased the albuminuria and contributed to the preservation of kidney function in a more visible manner than metoprolol. This outcomes are in favour of the specific ACEI significance.

2148

LONG-TERM PICOTAMIDE, A DUAL THROMBOXANE INHIBITOR, DECREASES BOTH THE URYNARY EXCRETION OF THROMBOXANE B_2 (TXB_2) AND ALBUMIN IN PATIENTS WITH TYPE 2 DIABETES

P. Desenzani, P. Perini, M. Milani*, F. Negrini, C. Cappelli, G. Romanelli, G. Davi'#, A. Giustina
Endocrine Section, Dpt. Internal Medicine, University of Brescia; *Sandoz P.F., Milano; #Unit of Hematology, University of Chieti; Italy.

It has been suggested that platelet hyperreactivity in patients with diabetes mellitus is associated with increased platelet production of thromboxane as compared to normal subjects. It has been hypothesized that this platelet activation could contribute to the pathogenesis of microangiophatic diabetic complications. In fact, recents studies have shown that in type 2 diabetes (NIDDM) the urinary excretion of TXB2 (stable metabolite of TX) is elevated with respect to normal subjects. Aim of our study was to evaluate the urinary excretion of TXB2 and albumin in 10 NIDDM normotensive patients (8M/2F) with microalbuminuria at rest treated with picotamide (300 mg tid; a new antiplatelet drug acting as antagonist of both TX-receptors and TX-synthetase) or placebo (3 tabs/day) for 12 months. At the end of the 12 month-period all the patients underwent to: 1) microalbuminuria assay at rest and after cycloergometric submaximal exercise; 2) urinary TXB2 assay (RIA; extracted from 20 ml aliquots of each urine sample on SEP-PAK C18 cartridge and eluted with ethil-acetate); 3) serum picotamide assay (HPLC). All the patients treated with picotamide showed urinary TXB2, microalbuminuria at rest and after exercise values significantly lower than the patients in the placebo group. In the whole group of patients we found: a significant inverse correlation ($r= -0.93$; $p=0.000$) between serum picotamide and urinary TXB2; a significant direct correlation between microalbuminuria after exercise and urinary TXB2 ($r=0.735$; $p=0.015$) and between microalbuminuria at rest and urinary TXB2 ($r= 0.5$; $p< 0.05$). On the basis of our data we can hypothesize that: 1) TX could be involved in the pathogenesis of microalbuminuria in diabetes; 2) the long-term efficacy and the clinical potential use of picotamide in diabetic patients with microalbuminuria at rest is due to its effective TX synthetase inhibition.

2149

ACE INHIBITORS TREATMENT REDUCES MICROALBUMINURIA LEVELS IN NIDDM.

Peca M.G., Veronelli A., Lanfredini M., Ranieri R.,Zecchini B., Sacchi S.,Rognoni C.,Cantatore R.,Santagostini G., Craveri A.
S.Paolo Hospital. Milan. Italy.

Nephropathy is a relevant cause of death in Diabetic Mellitus. Many studies have shown that the treatment with Ace Inhibitors reduces incidence of the kidney impairment throught the decrease of microalbuminuria (earliest marker of nephropathy). Aim of the study was to compare microalbuminuria levels in NIDDM patients before and after six months treatment with Ramipril (orally administrated at the dose of 1,25 mgs/day).Were evaluated 55 NIDDM patients (36 males and 19 females), 45-75 years aged, 16 of them affected by arterial hypertension, in treatment with other drugs in good control of hypertension; nobody was affected either by nephropathy or vascular diseases. Microalbuminuria was determined before and after 8 weeks and 24 weeks of treatment with Ramipril. After six months treatment was found a significant decrease in microalbuminuria (64,46 mg/dl at T0 VS 45,54 mg/dl at T6 p=0.04), this reduction being more relevant in females (64,17 vs 30,37 p=0.002) than in males (75,53 mg/dl vs 54,,78 mg/dl p=0.043). Our data would suggest that Diabetic patients with microalbuminuria request a prolonged treatment with Ace Inhibitors.

GLYCOSAMINOGLYCANS - A NEW THERAPEUTIC APPROACH FOR DIABETIC NEPHROPATHY (DN)

M.V.Shestakova, A.V. Vorontsov, L.A. Tchugunova and I.I.Dedov, National Endocrinology Center, Moscow, Russia.

The Steno hypothesis suggests that the key event in the development of DN is the loss of glycosaminoglycan (GAG) content of glomerular basement membrane, including the loss of negatively-charged heparan sulphate that impairs membrane charge-selectivity and lead to the onset of albuminuria. Experimental studies demonstrated amelioration of DN under the treatment with GAG (Gambaro,1994). The aim of our study was to evaluate the antiproteinuric effect of GAG administration in type I diabetic patients. Eighteen p-ts with good metabolic control (mean HBA1c 8.1%) were included in an open controlled GCP study: gr.1 (n=9) - with microalbuminuria 30-100 mcg/min and gr.2 (n=9) - with proteinuria 500-1500 mcg/min. We used low-molecular heparin Sulodexide (Alfa Wasserman, Italy) for 3 weeks (600 U/day i.m.). In gr.1 there was a signif. decrease in albuminuria after 2 wk of therapy (up to normal level) and it was stable after 6 wk of withdrawal. In gr.2 the signif. decrease in proteinuria was reached after 3 wk of therapy, but it quickly increased 6 wk after withdrawal. Sulodexide therapy also showed a lipid-lowering effect in gr.2 : plasma cholesterol reduced from 7.3 to 5.6 mmol/l. So GAG therapy has an antiproteinuric and hypolipidemic effects , both of which induce nephroprotection in DN. It is suggested that GAG can improve the glomerular sulfate incorporation and restore the glomerular charge-selectivity.

2151

Long and Short-acting ACE inhibitors in the management of microalbuminuric diabetics.

A.F. El-Aggan, ACMC, CAIRO,EGYPT.

Background : Microalbuminuria is a predictor of proteinuria, and a prognostic indicator of early mortality. The micoalbuminuric patients mostly have blood pressures above that of age, sex and duration matched IDDM with normoalbuminuria. Reducation of elevated blood pressure will reduce proteinuria. ACE (Angiotensin converting enzyme) inhibitors selectively normalize intrarenal blood pressure,and reduce AER. This class include short-acting and long-acting drugs. I conducted a short-term study on 15 diabetic- hypertensive patients with microalbumnuria, proteinuria. Three groups, each of 5 Patients, with same duration of diabetes and hypertension, were randomized and given either captopril, ramipril or benazepril. Glycaemic control and adequate blood pressure were maintained through the study and proteinuria was monitored at regular intervals of 3 months. The two groups on long-acting ACE inhibitors showed statistically signigicant improvement in proteinuria than the group on short acting ACE. They were superior to short-acting ACE in absence of side-effects ($P<0.001$). Long-acting ACE inhibitors do improve proteinuria better than short-acting ACE inhibitors, with minimal side effects.

2152

A PILOT STUDY OF GLYCOSAMINOGLYCANS (GAG'S) ACTIVITY ON MICROALBUMINURIA OF TYPE I DIABETIC PATIENTS

A. Popławska, M. Szelachowska, J. Topolska and I. Kinalska Department of Endocrinology , Medical School, Białystok, Poland

Nephropathy in subjects with diabetes mellitus is a major complication that leads to renal failure and death. Diabetic nephropathy ultimately develops in 30% of patients suffering from in diabetes mellitus and is initially characterized by microalbuminuria. Sulodexide is a highly purified preparation containing an endogenous -like fast moving heparin fraction (Iduronyl-Glycosaminoglycan sulphate) -60% and a dermatan fraction-40%. Fifteen out-patients with type I diabetes mellitus and microalbuminuria (mean±SEM 95.4±13.9mcg/min), were administered the glycosaminoglycan sulodexide, with the aim of investigated its influence on the rate of albumin excretion. Sulodexide (Vessel Due F-Alfa Wassermann-Italy) was given by intramuscular route with the dose of 600 Liporoteinolipase Releasing Units/day by for 21 days. At the control visits a recent anamnesis was recorded, a complete physical examination was performed, body weigh and blood pressure were measured. Two times during experiment (before and after treatment) renal function tests (creatinine clearance), hematological and coagulative parameters (blood count, APTT, fibrinogen), hematochemical parameters (creatininemia, uricemia, proteinemia, glycemia, cholesterol, triglycerides) were examined. Urinary albumin excretion was estimated six times (before, after each week of treatment, three and six weeks after end of the treatment) by immunoprecipitationes assay. All the patients completed the study. Sulodexide yielded a clear-cut and statistically significant lowering of the albumin excretion already after the first week of treatment (53,6±11.1mcg/min; $p<0.005$), the decrease was still more evident at treatment completion (26.5±6.05mcg/min; $p<0.007$) and was maintained during the follow-up period, at the end of which the mean value of albumin excretion rate was still significantly lower than at baseline (36.3±6.7mcg/min; $p<0.004$). Sulodexide short-term administration did not influance the routine hematological, hematochemical and coagulative tests contemporarily performed. Patients compliance with treatment was very good and no adverse events were ever reported. In conclusion, our study suggests that sulodexide (Vessel Due F) plays an important role in reducing urinary albumin excretion in diabetic patients with nephropathy

2153

EFFECT OF ANGIOTENSIN CONVERTING ENZYME INHIBITOR (IMIDAPRIL) ON MICROPROTEINURIA IN NON-INSULIN-DEPENDENT DIABETIC PATIENTS

S.Haisa[1], K.Asano[1], H.Himei[2], A.Kondou[2], K.Nakada[3], T.Itojima[3], Y.Mishima[4] and M.Kibata[4]. Okayama City Hospital Internal Department[1], Okayama Red Cross General Hospital[2], Okayama Saiseikai Hospital[3], National Minamiokayama Hospital[4], Okayama, Japan.

In diabetic patients, microproteinuria [urinary-albumin (ALB), transferrin (TF), β_2-microgloburin (BMG) and N-acetyl-β-D-glucosaminidase (NAG)] are markers for early renal dysfunction. We evaluated the effect of imidapril hydorochloride in blood pressure and progression of diabetic nephropathy using these urinary-proteins. In this study, 30 patients with NIDDM (non-insulin-dependent diabetes mellitus) complicated by hypertension, without severe clinical nephropathy (serum creatinine $\leq$1.2mg/dl), but with microalbuminuria, received 5~10mg orally of Imidapril from 24 to 52 weeks. They were required to revisit the outpatient clinic every 4 weeks to have their blood pressure checked, and the first urine specimen in the early morning was used to test for ALB, TF, BMG and NAG. A creatinine correction was made for microproteinuria and parametric statistics were performed using a paired t-test. Imidapril reduced both systolic and diastolic blood pressure significantly after 4 weeks of treatment, and the effect continued until the 32nd week. Also, albuminuria and transferrinuria were reduced significantly with treatment of Imidapril after 4 weeks and the effect continued until the 52nd week. The value of ALB and TF correlated well ($R=0.934$), in all of the urinary samples. No significant changes occurred in the urinary BMG and NAG levels. We also performed the renography using ^{99m}Tc-mercaptoacetyltriglycine (MAG_3) to eliminate the other renal diseases, and found that it is useful for the diagnosis of incipient diabetic nephropathy and the effective renal plasma flow (ERPF) slightly increased among early stage patients. Our study indicated that Imidapril had a proteinuria (ALB, TF)-reducing effect and might be useful for the therapy of incipient diabetic nephropathy with hypertension.

2154

BASELINE DATA FROM THE PIMAGEDINE ACTION TRIALS

J-P. Wuerth, R. Bain, T. Mecca, G. Park, K. Cartwright and the Pimagedine Investigator Group. Alteon Inc. Ramsey, NJ, USA

Baseline demographic and clinical data of two large cohorts of well defined type I and II diabetic patients with overt diabetic nephropathy and retinopathy, enrolled in the phase III pimagedine trials in the USA and Canada, are presented. Pimagedine (aminoguanidine HCl) is a potent inhibitor of non-enzymatic glycosylation and a selective inhibitor of the inducible isoform of Nitric Oxide Synthase (iNOS). Two studies, ACTION I and II, were designed to test the efficacy and safety of pimagedine in slowing the progression of diabetic nephropathy and retinopathy, and lowering morbidity and/or mortality. The ACTION I trial (**A** Clinical **T**rial **I**n **O**vert **N**ephropathy) enrolled type I diabetics between 22 and 50 years of age with overt diabetic nephropathy (estimated creatinine clearance of 0.67 to 1.50 ml/sec, based on the Cockcroft and Gault [C&G] equation, ≥ 500 mg/24 hour proteinuria). The ACTION II study recruited type II diabetics between 30 and 70 years of age with overt diabetic nephropathy of approximately identical magnitude as the type I diabetics in ACTION I (estimated creatinine clearance of ≥ 0.67 ml/sec by C&G, serum creatinine of ≥ 106.1 umol/L [males], or ≥ 88.4 umol/L [females], ≥ 500 mg/24 hour proteinuria). Study patients in both trials were required to have retinopathy by exam or history. The stage of retinopathy was determined with standardized stereoscopic fundus photography. Enrollment for ACTION I was completed on August 31, 1996 with 690 randomized patients. Enrollment for the ACTION II study was closed at 597 patients on December 2, 1996. The two populations demonstrated statistically significant differences for the following baseline parameters ($p < .05$: Mann-Whitney Wilcoxon or Fisher's exact test, two-sided): gender, ethnicity, duration of diabetes, smoking and cardiovascular history, prevalence of allergies, weight, BMI, heart rate, systolic BP, EKG findings, glycemic control, mode of diabetes therapy, renal function (GFR, C&G, and 24 hour urine creatinine clearance, corrected for body surface), proteinuria, c-peptide, ANA titers, triglyceride and HDL cholesterol levels, stage of retinopathy, and history of photocoagulation. Both cohorts exhibited surprisingly low 24 hour urinary calcium levels (mean±SD ACTION I 1.2±1.3, ACTION II 1.2±1.4 mmol/24hr) with normal serum calcium levels. These data are a unique contribution to the understanding of the epidemiology of type I and II diabetes with advanced diabetic complications.

2155

IMPACT OF CONVERTING ENZYME INHIBITION ON MICROALBUMINURIA IN NIDDM

S.MUKHERJEE, S.CHATTERJEE, S.KUMAR, MK CHHETRI
Institute of Postgraduate Medical Education and Research, Calcutta.

Overnight urinary albumin excretion rate(AER) was measured in 45 NIDDM patients having no evidence of overt proteinuria or urinary tract infection. Diagnosis of microalbuminuria was confirmed by estimation of three urine samples at one month intervals. Eight patients had microalbuminuria at presentation. There was no difference in mean age between patients with microalbuminuria and those with normal AER(46.25±11.65 years vs. 49.5±10.04 years; $p>0.05$). Compared to patients with normal AER serving as controls, microalbuminuric patients had significantly higher duration of the disease, mean arterial pressure(MAP) and glycated haemoglobin levels(17.21±2.1 years vs. 9.40±4.73 years; 123.72±5.8 mmHg vs. 101.35±14.49 mmHg and 9.33±0.23% vs. 7.67±1.37%, $p<0.001$ in all cases). 12 months' therapy with enalapril, 2.5-15 mg/day, normalized AER in two patients while microalbuminuria persisted in the remaining six; none progressed to overt proteinuria. Although significant reduction in MAP or glycated haemoglobulin occurred in one year, there was no difference in MAP or glycated haemoglobin levels between those patients in whom AER normalized and those in whom it did not; the mean duration of disease also did not differ between the two groups.
Conclusion: Enalapril therapy may delay the progression to overt proteinuria or even normalize AER in microalbuminuric NIDDM patients irrespective of age, duration of the disease, MAP or glycated haemoglobin levels.

2156

METABOLIC EFFECTS OF ISRADIPIN IN NORMOTENSIVE NIDDM PATIENTS WITH MICROALBUMINURIA

Sabuncu T., Dalmaz M., Nazlıgül Y., Vural H., Koçyiğit A., Erel Ö., Avcı Ş., Fac. of Med., Univ. of Harran, Şanlıurfa, Turkey

Several studies have suggested that ACE-inhibitors may be effective in preventing the onset of nephropathy and treatment of it in both insulin-dependent diabetic subjects and non-insulin dependent diabetic subjects. In contrast, these effects of calcium antagonists are controversial. Therefore, we aimed to evaluate the effects of isradipin, a new antihipertansive dihydropyridine calcium antagonist, on microalbuminüria, fasting plasma glucose, plasma lipids, plasma creatinin, uric acid, C-peptid, insulin, Hb A1, fructosamine, systolic and diastolic blood pressure and heart rate in normotensive patients with NIDDM. 18 subjects received sustained-release (SRO) formulation of isradipin at dosages of 5 mg once daily for 3 monrhs. After 3 months of isradipine treatment urinary albumin excretion rate (UAER) fell from 72.5 ± 40.2 to 52.9+39.5 mg/24 h ($p<0.01$). Diastolic blood pressure decreased from 85.8+4.9 to 81.9+3.0 mmHg ($p<0.05$). Other parameters were not significantly influenced by isradipin treatment. No serious clinical or metabolic side effects were observed. We therefore conclude that isradipin may be useful in regression of nephropathy in normotensive patients with NIDDM.

INSULIN-LIKE GROWTH FACTOR I PREVENTS PROGRAMMED CELL DEATH IN NEURONS.

J.W. Russell, C. van Golen, A. Parekh, J.R. Singleton and E.L. Feldman, University of Michigan, Ann Arbor, Michigan USA.

We have shown that cultured neurons undergo programmed cell death (PCD) when exposed to high glucose. Insulin-like growth factor-I (IGF-I) can prevent these changes. We are now examining the consequences of IGF-I treatment on the threshold regulators of PCD. The cysteine kinases Yama (CPP 32β) and ICE/LAP3, and the *bcl* family member *bax* propagate PCD, while *bcl*-2 and *bcl*-X_L inhibit PCD. Employing SH-SY5Y human neuroblastoma cells, we find that IGF-I rescues cells from apoptosis induced by hyperglycemia. Neuroblastoma cells were cultured in control medium (DMEM) containing 25 mM glucose, or DMEM and excess glucose, or DMEM/high glucose ± 10 nM IGF-I. At selected timepoints, cells were harvested and Western immunoblotting performed for *Yama, bax, bcl*-2, and *bcl*-X_L. Between 6 and 24 h after exposure of neuroblastoma cells to high glucose (20-150 mM excess glucose), *bcl*-2 and *bcl*-X_L protein levels are decreased, and there is increased activation of Yama and ICE/LAP3. No change was observed in the absolute level of *bax*. In the presence of hyperglycemia, IGF-I treatment sustains *bcl*-2 and *bcl*-X_L levels and suppresses the conversion of inactive cysteine kinases to their active forms, thereby blocking PCD. These results help elucidate an important pathway by which IGF-I suppresses the neurotoxic effect of neuronal stressors, and suggest dual IGF-I regulation of *bcl* family members and cysteine kinase propagation. Furthermore, these data suggest that IGF-I may have an important role in the treatment of diabetic neuropathy. These studies were supported by NIH grants K08 NS01938 and R29 NS32843.

2158

INSULIN-LIKE GROWTH FACTOR-I SIGNALING PATHWAYS IN NEURITE OUTGROWTH.

E.L. Feldman, B. Kim and P.S. Leventhal. University of Michigan, Ann Arbor, Michigan USA.

We are interested in the potential role of insulin-like growth factor-I (IGF-I) in the treatment of diabetic neuropathy. We have previously shown that IGF-I can enhance lamellipodia formation and neurite initiation. We are now investigating its role in neurite outgrowth. As part of these studies, we are characterizing the signaling pathway that mediates IGF-I's effects on neurite elongation. In our studies, we employ a cell culture model of neuronal growth, the SH-SY5Y human neuroblastoma cells. When SH-SY5Y cells were treated with IGF-I, there was a dose-dependent increase in the tyrosine phosphorylation of the type I IGF receptor (IGF-IR), and 2 MAP kinases: ERK1 and ERK2. While IGF-IR phosphorylation was immediate, maximal phosphorylation of ERK1 and ERK was not reached for 30 min and maintained for up to 4 hr. IGF-IR, ERK1 and ERK2 phosphorylation were inhibited by the IGF-IR blocking antibody, α-IR_3, while ERK1 and ERK2 phosphorylation were inhibited by a compound which specifically blocks MEK activity (PD98059). In parallel, PD98059 blocked neurite outgrowth and decreased the expression of growth cone associated protein 43 (GAP-43). Collectively these studies show that IGF-I induces a unique pattern of MAP kinase phosphorylation in neurons which results in neurite outgrowth, supporting the use of IGF-I in the treatment of diabetic neuropathy. Sponsored by R29 NS32843 and grants from the American Diabetes Association and the Juvenile Diabetes Association.

INCREASED OXIDATIVE STRESS IN EXPERIMENTAL DIABETIC NEUROPATHY

T. C. Hohman, D. Banas , M. Basso, M. A.Cotter and N.E. Cameron. Wyeth-Ayerst Research, Princeton, NJ, USA, University of Aberdeen, Aberdeen, Scotland

Recent reports that anti-oxidants restore nerve function in diabetic rats have implicated increased oxidative stress in the etiology of complications. Evidence for increased oxidative stress and/or reduced endogenous protection at the tissue sites of diabetic lesions, although suggestive, have not been consistently observed. Our aim was to validate a method for quantitating tissue levels of total (Tglut) and reduced glutathione (GSH), to characterize the effects of diabetes on these parameters and to identify possible mechanisms linking changes in glutathione levels to diabetic hyperglycemia. Tglut and GSH levels were quantitated with an enzymatic recycling assay that couples glutathione reduction to formation of the chromophore 2-nitro-5-mercapto-benzoic acid. Sciatic nerve Tglut and GSH levels were not different between 6 and 24-week old male Sprague Dawley rats (11.2±1.5 and 10.0±1.6 vs 9.9±1.2 and 8.9±1.3 nmol/mg protein), indicating that these parameters are unaffected by maturation. Six weeks of untreated diabetes induced in 19-week old rats, however, significantly reduced nerve GSH levels by 42±12% ($p<0.001$). To determine if depletion of GSH may be a consequence of increased competition for NADPH between aldose reductase (AR) and glutathione reductase, nerve glutathione levels were measured in 19-week old non-diabetic rats fed a 50% galactose diet for 6 weeks. In these animals GSH was significantly reduced by 50±17% ($p<0.001$) but was normalized within 4 days with AR inhibitor treatment (ARI-509, 10 mg/kg/day). These data link increased oxidative stress and AR activity to impairment of the glutathione redox cycle which may contributes to the etiology of nerve dysfunction in experimental models of diabetes.

2160

CYCLOOXYGENASE-DEPENDENT EFFECT OF PENTOXIFYLLINE ON NEUROVASCULAR FUNCTION IN DIABETIC RATS.

M.A. Cotter, H. Flint and N.E. Cameron. Aberdeen University, Aberdeen, Scotland UK

Pentoxifylline can improve blood rheology and tissue perfusion. The aim was to ascertain whether 2 weeks pentoxifylline (40 mg/kg) treatment could correct nerve conduction velocity (NCV) and blood flow deficits in 6 week streptozotocin-diabetic rats. Pentoxifylline is a phosphodiesterase inhibitor and could, therefore, act to potentiate the actions of vasodilator prostanoids that use cAMP as a second messenger: a further aim was to examine whether the effects were blocked by co-treatment with the cyclooxygenase inhibitor flurbiprofen (5 mg/kg). Diabetic deficits of 20.6 ± 0.9% (± SEM; $p < 0.001$) for sciatic motor and 12.1 ± 1.9% ($p < 0.001$) for saphenous sensory NCV were corrected by 56.5 ± 7.6% ($p < 0.001$) and 69.8 ± 9.8% ($p < 0.01$) respectively with pentoxifylline treatment. For motor NCV, the value remained reduced compared to that for a nondiabetic control group ($p < 0.001$). Flurbiprofen co-treatment completely abolished the improvement in saphenous NCV with pentoxifylline and markedly attenuated (52.9 ± 12.6%; $p < 0.05$) the effect on motor NCV. Sciatic nutritive endoneurial blood flow was 48.4 ± 2.2% ($p < 0.001$) reduced by diabetes. This was 50.4 ± 9.1% ($p < 0.001$) attenuated by pentoxifylline, although a 24.0 ± 4.4% ($p < 0.001$) flow deficit remained compared to nondiabetic rats. Flurbiprofen co-treatment largely (62.2 ± 11.2%; $p < 0.01$) abolished the effects of pentoxifylline on blood flow. Thus, pentoxifylline has beneficial vascular effects in experimental diabetic neuropathy which depend at least in part on products of cyclooxygenase-mediated metabolism.

2161

NA+,K+-ATPASE AND PROTEIN KINASE C ARE ALTERED IN SCIATIC NERVE FROM DIABETIC RATS.

R. Bianchi, A. Veronese, S. Savaresi and R. Bressan. Mario Negri Institute for Pharmacological Research, Milan, Italy

Experimental diabetic neuropathy, like the human form, is characterised by a decrease in Na^+,K^+-ATPase activity. Treatment of diabetic rats with gangliosides prevents or restores reduced Na^+,K^+-ATPase activity and corrects altered polyphosphoinositide turnover in the sciatic nerve. Phosphoinositide metabolism and Na^+,K^+-ATPase may be linked through a protein kinase C (PKC)-mediated step. We evaluated the effects of *in vivo* GM1 ganglioside (GM1) administration on PKC and Na^+,K^+-ATPase activities in sciatic nerves from control and streptozotocin (STZ)-induced diabetic rats. We also measured GM1 and PKC activators' effects *in vitro* on nerve Na^+,K^+-ATPase. Groups of diabetic and age-matched controls rats were injected daily with either saline or GM1 (10 mg/kg i.p.) for one month, starting two or five months after STZ. GM1 almost completely restored the drop in Na^+,K^+-ATPase in the diabetic sciatic nerves. PKC activity was slightly increased in the membranous fraction from diabetic nerves, while the cytosol fraction was unchanged. GM1 treatment resulted in a further increase in membrane-associated PKC activity, amounting to 20 and 17% respectively at three and six months. When nerve segments from untreated diabetic rats were incubated with PKC activators, homogenized and assayed for Na^+,K^+-ATPase, phorbol esters and 1,2- but not 1,3-dioctanoylglycerol restored the 30% Na^+,K^+-ATPase deficit to normal; GM1 also corrected it in a dose-dependent manner. Our data showed that diabetic nerves have reduced Na^+,K^+-ATPase activity and elevated membrane-associated PKC. GM1, which restores Na^+,K^+-ATPase, further increases PKC in *vivo*. These findings agree with *in vitro* observations that PKC activators and GM1 restored Na^+,K^+-ATPase.

2162

ISLET TRANSPLANT EFFECT ON DIABETIC NEUROLOGICAL DAMAGE: PRIMARY VERSUS SECONDARY INTERVENTION.

M.Sensi, S.Morano, G.Pugliese, AFG.Petrucci*, E.Valle*, G.Pozzessere+, V.Caltabiano#, M.Vetri#, F.Purrello# and U.Di Mario§. Endocrinology & Neurology* Departments of Rome University "La Sapienza", Endocrinology Departments of Catania# and Catanzaro§ Universities and IRCCS+, Isernia, Italy.

Neuroelectrophysiological alterations in diabetes indicate progressive nervous function failure. This study was performed to establish whether restoration of euglycemia following islet transplantation immediately after diabetes onset or after an extended period of disease can prevent or reverse neurophysiological abnormalities. Pancreatic islets (1200-1500) were injected into the portal vein of inbred Lewis rats 15 days (group A) or 8 months (group B) after induction of diabetes by streptozotocin. The rats were then followed for a total period of 12 months from streptozotocin injection. Groups of control and diabetic rats were also studied in parallel. Auditory (BAEPs) and somatosensory (SEPs) evoked potentials and metabolic parameters were measured at the beginning and at the end of the study. The metabolic parameters (blood glucose, HbA1 and body weight) in both groups of transplanted animals did not differ from those of the control group but differed significantly from those of diabetic animals ($p<0.001$). BAEP latencies (wave I, II and III) of group A were similar to those of the control rats whereas group B showed significantly altered wave I and II values ($p<0.005$ and $p<0.01$ vs control values respectively). Group A and control rat SEP conduction velocities did not vary, whereas conduction velocities of group B showed only a partial improvement since values were lower than those of control rats but higher than those of diabetic rats (significant at T5-cortex level: $p<0.05$). These results show that precocious normalisation of metabolic control by islet transplantation prevents central and peripheral neurological alterations. However, after an extended period of hyperglycemia, the beneficial effect is only partial and observable mainly at peripheral nervous system level.

2163

INHIBITION OF PHOSPHOINOSITIDE SYNTHESIS BY GLUCOSE IN RETINAL PIGMENT EPITHELIAL CELLS TRANSFECTED WITH ALDOSE REDUCTASE

T.P.Thomas, M.J.Stevens, D.R.Larkin and D.A.Greene. University of Michigan, Ann Arbor, USA.

Constitutive expression of high aldose reductase (AR) in retinal pigment epithelial (RPE) cells leads to glucose (Glu)-induced inhibition of sodium-dependent myo-inositol (MI) transport (SMIT) activity, MI-content and phosphoinositide (PI) synthesis. The *aim of the study* was to examine the effect of Glu on these parameters in low-AR expressing RPE-47, and in RPE-75 cells derived by stable transfection of the RPE-47 with AR-gene. SMIT activity was determined by measurement of [2-^{3}H] MI (1 μM)-uptake in Krebs buffer (5 mM Glu), and PI-synthesis by quantifying the PI-synthase substrate CDP-diglyceride (CDP-DG) by labeling with ^{3}H-cytidine followed by thin layer chromatography, and by liquid scintillation spectrometry. MI-content was determined by gas-liquid-chromatography. In RPE-47, Glu (30 mM) modestly inhibited SMIT activity in a time-dependent fashion, with maximum inhibition (90.2±2.7% control) reached at 12-16 h, and persisted for 5 d. The Glu inhibition was significantly higher in RPE-75 (73.6±0.8%* control at 48 h) (*$p<0.05$ vs. RPE-47). Increasing the osmolality of the MI-uptake buffer by sucrose increased SMIT activity in a dose-dependent fashion, and reversed the inhibition by Glu. In RPE-75 incubated with 20 mM Glu for 1, 2, 4 and 7 d, the average sorbitol and MI contents were respectively 1129.8±210.5% and 72.3±8.7% of that present in RPE-47. During a 72 h incubation with 15, 20, 30, and 50 mM Glu, the CDP-DG contents in RPE-47 were respectively 110.07±5.33%, 101.10±4.27%, 114.98±3.03% and 110.13±6.84% control, and in RPE-75 cells, 108.26±4.17%, 137.98±4.18%*, 135.47±3.35%* and 148.36±2.92%* control. These studies support the notion that Glu-induced MI-depletion and inhibition of PI-synthesis previously identified in certain RPE cells is consequent to their high constitutive expression of AR. The RPE-75 and RPE-47 cells may serve as suitable models for exploring the AR-related and -unrelated components of glucose-induced pathways leading to diabetic complication.

2164

THE EFFECTS OF SULINDAC ON PERIPHERAL NERVE MORPHOLOGY IN THE CHEMICALLY INDUCED DIABETIC DOG.

D Walker, RA Malik, H Anderson, TA Gardiner, and AJM Boulton. Department Medicine, Manchester Royal Infirmary, Manchester, UK, Department Ophthalmology, Queen's University Belfast, UK.

Diabetes was induced in male beagle dogs at the age of 4 months with a mixture of Alloxan and Streptozotocin. Thereafter moderate diabetes control (blood sugar 13-20mmol/l) was achieved by once daily Monotard insulin injections. 3 groups of 3 animals were studied: Control (C), Diabetic (D), Diabetic on Sulindac (prostaglandin synthesis inhibitor and in vitro Aldose Reductase Inhibitor) (DS) for 4 years. HbA1c (%) prior to biopsy was C-3.0 ± 0.6, D- 7.4 ± 0.9, DS- 7.3 ± 0.9. The Sciatic nerve was biopsied from each animal and prepared for detailed light and electron microscopy. Myelinated fibre density (no/mm^2) was not significantly different in D(4746(4414-7107)) compared with C(6354 (5951-6607)) nor did it change with treatment in DS(5760(5650-7265)). Regenerative cluster density was however marginally significantly increased ($p<0.08$) in DS (95(75-102)) v D (19 (11-50)) and C (63 (35-67)). Paradoxically, myelinated fibre and axon areas (47(42.9-66.3), 17(12-22.9)) were increased in D ($P<0.08$) compared to C (39.1 (34.2-42.5), 13.7(11.3-15.8)) without any effect of treatment in DS (47(42.9-66.3), 12.8 (9-15.2)). Unmyelinated fibre density (no.mm^{2}x10^3) failed to differ between C (148(121-155)), D (143(122-157)) and DS (139(115-153)). Axon diameter (μm) also failed to differ between C (0.65(0.58-0.65)), D (0.79 (0.69-0.82)) and DS (0.68 (0.62-0.86)). Endoneurial capillary parameters did not differ between any group for: Capillary density (no.mm^2)(C-52 (47-56), D- 58(50-81), DS- 53 (43-56)), Basement membrane area (μm^2)(C-13.8 (12.2-16.2), D-14.7 (13.6-21.9), DS- 17.2 (15.5-20.5)), Luminal area (μm^2)(C-9.5(8.7-11.6), D- 9.1 (8.6-14.5), 6.0(5.8-10)) and Endothelial cell profile no. (C-3.9(3.3-4.1), D-3.8(3.4-4.4), DS (3.8 (3.7-4.3)). The diabetic dog demonstrates only minor structural abnormalities in the peripheral nerve consistent with findings in other fully mature animals models with moderately controlled diabetes. Sulindac fails to ameliorate any of these abnormalities.

2165

ASSOCIATION OF ATP1A1 GENE POLYMORPHISM AND Na/K ATPase ACTIVITY, ISOFORMS EXPRESSION AND DIABETIC NEUROPATHY.

D. Dufayet De La Tour, D. Raccah, N. Levy, T. Coste and P. Vague. CHU Timone, Marseille, France.

The aim of this study was to characterize subunits expression and red blood cell activity of Na/K ATPase, according to ATP1A1 gene polymorphism which encodes for α1 isoform. In IDDM patients, the red blood cell Na/K ATPase activity was decreased compared to controls and more in patients with neuropathy. There was a positive correlation between red blood cell Na/K ATPase activity and nerve conduction velocity in diabetic rats and humans. A RFLP with Bgl II enzyme was described in first intron of ATP1A1 gene and was associated with diabetic neuropathy (relative risk 7.7%). In a serie of 100 IDDM patients with or without neuropathy and 100 controls, the restricted allele frequency was 0.10 and 0.09, respectively. Red blood cell Na/K ATPase activity was significantly decreased in IDDM patients with restricted allele compared to patients with unrestricted allele (237±11 vs 313±9) whereas there was no change in controls (401±12 vs 395±9). To understand the correlation between ATP1A1 gene polymorphism and red blood cell Na/K ATPase activity, we studied isoform expression in this tissue. Only α1 isoform, predominant in nervous tissue, is expressed on red cell membrane. There was a positive correlation between α1 expression and Na/K ATPase activity in IDDM patients and controls. No significant difference of α1 expression was observed between IDDM patients with or without restricted allele for a same activity. In all subjects with restricted allele, we found α1 ß1 dimers on red blood cell membrane but also ß1 subunit alone compared to subjects with unrestricted allele. These results showed an abnormality of α1 isoform in diabetic patients with restricted allele which might be due either to protein expression or degradation or binding to membrane.

BENEFICIAL EFFECTS OF ACETYLSALICYLIC ACID TREATMENT ON CENTRAL AND PERIPHERAL NEURAL RESPONSES IN DIABETIC RATS

M. Özata[1], O. Yıldız[2], S. Şenöz[2], Y. Kütükçü[3], A. Çorakçı[1], A. Aydın[3], A. Işımer[2] and M.A. Gündoğan[2]. Dept. of Endocrinology and Metabolism[1], Medical Pharmacology[2] and Neurology[3] Gülhane School of Medicine, Ankara, Turkey

The effects of acetylsalicylic acid (ASA) on nerve conduction velocity (NCV), somatosensorial evoked potentials (SEPs) and neural levels of malondialdehyde (MDA), a product of lipid peroxidation, were studied in streptozotocin-diabetic rats. ASA (100 mg/kg, in normal rat chow) was given to diabetic rats after the induction of diabetes for 8 weeks. NCV was measured from caudal nerve and SEPs were measured by stimulating via caudal nerve and recording via cortex at the 4th and 8th week during the treatment. Diabetes caused 20-30% deficits in NCV and SEPs slightly but not significantly at the 4th week. However, ASA treatment had a significant restoring effect at NCV and SEPs at the 8th week ($p<0.05$ vs.untreated diabetic rats, respectively). Diabetes caused elevation in neural MDA levels ($p<0.05$ vs. non-diabetic group), which was prevented by ASA ($p<0.05$ vs. untreated diabetic rats). Weight and the glucose levels were not influenced by ASA treatment. Our results suggest that the beneficial effects of ASA on diabetic neuropathy are not associated with the regulation of glycemia, but these effects may be related with prevention of lipid peroxidation.

2167

ARI EFFECT ON INTERLEUKIN 6 EXPRESSION AND NERVE FIBER REGENERATION.

M Kamijo, Y Takagi, S.Kon, S Makino, T Suda and M Matsunaga Department of Neurology, Hirosaki University School of Medicine Hirosaki, Japan

At the scene of nerve fiber damage, acute action of citokines, an inflammatory mediator, may have an important role to elicit the nerve fiber regeneration . To test this hypothesis, IL-6 synthesis was quantitated in axotomized sciatic nerve using bio-assay technique in streptozocin (STZ) induced diabetic rats. Furthermore, we performed RT-PCR to evaluate mRNA-IL-6 levels , confirming IL-6 synthesis in axotomized nerves. The IL-6 levels elevated from right after axotomy , was maximum at 3 days after in all three groups (normo-glycemic, hyper-glycemic and hyper-glycemic with ARI(WP-921, Wakamoto and Toyama Chemical Co. Ltd., Japan) treatment, which were 10.4+0.9 pg/mg/ww, 3.9+0.9 and 7.7+1.8 respectively. RT-PCR demonstrated IL- 6 mRNA expression in sciatic nerve tissue in all conditions but pronounced significantly less in hyperglycemia without ARI treatment. Immunocytochemicaly, ED2 positive cells (macropharges) were appeared at axotomized stump. These cells also showed positive staining with IL-6 antibody. The fequency of appearance of macropharges seemed less in hyper-glycemic condition. Myelinated fiber regeneration was quantitated using light-microscopic morphometriy. At 35 days after axotomy, regenerated fiber density was significantly reduced in hyper-glycemic condition to 32% normo-glycemia. However, fiber density was preserved to 78% normal with ARI treatment. We concluded that ARI may exert its beneficial effect on nerve fiber regeneration via activation of the IL-6 synthesis consequent on impaired recruitment of macropharges.

2168

EFFECT OF HYPERGLYCEMIA ON MITOCHONDRIAL MEMBRANE POTENTIAL OF NEURONS: LASER CONFOCAL STUDY

C.N. LIU, R.W. LI, X.H. JING, H. CAI and L.X. ZHU. Institute of Acupuncture, China Academy of Traditional Chinese Medicine,Beijing, 100700, P.R.China

Hyperglycemia and decline in contents of some neuropeptides in primary afferent neurons have been reported to be associated with the development of diabetic neuropathy. To elucidate the implications of hyperglycemia for nerve dysfunction and the associated changes in energy metabolism, we measured the mitochondria potential using laser confocal cytometric technique (ACAS 570, Meridian, USA) in single nerve cell body freshly isolated from newborn rat dorsal root ganglion (DRG) and loaded with rhodamine 123. Totally 40 small (average of 17.15±0.89μm in diameter) DRG neurons were observed in the study. The fluorescence distributed mainly around the edges of the cell , in particular in the two opposite poles of the cells.However, fluorescence intensities in the nucleus area was minimal. In some of the tested cells, the fluorescence declined gradually, in particular, when frequently shined by laser beam. In average, the fluorescence declined by the rate of 10% every 400 sec. When 30 mmol/L glucose was added into the medium of the cells, the fluorescence of the mitochondria was rapidly decreased in the majority of the cells (8/9) by 21.2±5.44-22.8±4.72 during 100-400 seconds after the addition, which returned towards the control line then, but seldom returned to the control value (the value measured before the administration of glucose). When the artificial cerebral spinal fluid (aCSF) (in volume of 20μl , same as the glucose solution) was added to the medium of the cells, no changes in the fluorescence was observed (n=7). The changes in the fluorescence was significantly difference ($P<0.05$, ANOVA) between that measured after addition of glucose and aCSF. The finding indicate that the energy metabolism in the small sensory neuron might be impaired by acute hyperglycemia.

2169

A NOVEL, HIGH SELECTIVE ALDOSE REDUCTASE (AR) INHIBITOR, NZ-314, AND ITS THERAPEUTIC MEANING.

H. Yago, Y. Nagaki, Y. Fukuda, H. Fujisawa, H. Namba, S. Morita, and S. Suehiro. Institute of Bio-Active Science, Nippon Zoki Pharmaceutical Co., Ltd., Hyogo, Japan.

To clalify the beneficial role of aldose reductase inhibitors (ARIs) in prevention of diabetic complications, we investigated the *in vitro* and *in vivo* effects of a new and highly potent ARI, 3-(3-nitrobenzyl)-2,4,5-trioxoimidazolidine-1-acetic acid (NZ-314). NZ-314 was found to possess uncompetitive and reversible inhibition *in vitro* on partially purified AR from rat lens (IC50 = 6.0×10^{-8} mol/L), from rat sciatic nerve (IC50 = 5.2×10^{-8} mol/L) and recombinant human muscle AR (IC50 = 9.6×10^{-8} mol/L) with DL-glyceraldehyde as substrate, and had remarkable improvements of motor nerve conduction velocity and sorbitol accumulation in streptozotocin (STZ)-induced diabetic rats. On the other hand, NZ-314 showed less inhibitory activity to rat kidney aldehyde reductase (ALR), which is implicated in the aldo-keto reductase superfamily as well as AR and the most important physiological role of this enzyme is metabolism or detoxication of aldehyde compounds, especially, 3-deoxyglucosone (3DG). 3DG is a highly reactive intermediate of Maillard reaction and having an important role in advanced glycation end products (AGEs) production and cytotoxicity against various type of cells. 10^{-5} mol/L of NZ-314 has no inhibitory activity on ALR with 3DG as substrate and no effects on LDH leakage from primarily cultured rat hepatocyte by the addition of 3DG, but other AR inhibitors have a strong inhibition on this detoxification of 3DG at the same doses, resulting in enhance the cytotoxicity of 3DG. These results suggest that the highly specific AR inhibitor NZ-314 will be a useful therapeutic agent for preventing and improving some diabetic complications without unsuitable side effects, and therefore, can be discriminated from other AR inhibitors.

2170

DIGITAL ELECTRON MICROSCOPIC ANALYSIS OF REGENERATING AXON CLUSTERS IN SURAL NERVE BIOPSIES.

D.A. Greene, J.H. Lillie and K.A. Sullivan. University of Michigan, Ann Arbor Michigan USA.

Diabetic neuropathy is characterized by distinct morphological features including thickening of basement membranes, axon degeneration and regeneration. Axon sprouting leads to an increased number of regenerative axon clusters; however, as the disease progresses there is an overall loss of axons. We have employed the most current digital imaging techniques in order to examine the number of regenerating axon clusters in whole nerve fascicles. Human sural nerve biopsies were assessed for EM suitability based on the degree of fixation, absence of mechanical artifacts and size (100,000 - 425,000 μm^2). Based on these criteria, the largest fascicle was selected. Thin sections were collected onto formvar coated slot grids and coated with a layer of carbon. The sections were then viewed on a Phillips CM100 transmission electron microscope equipped with a CompuStage. Digital images were captured with a Kodak digital Megaplus 1.6 camera and stored as individual tiff files. A montage of the entire fascicle was constructed and the resulting virtual image was viewed by trained EM readers. Computer assisted analysis included confirming the identification of individual axons and labeling regenerating axon clusters. A regenerating cluster was defined as two or more myelinated axons within a continuous basement membrane. Quality control was maintained by randomly assigning a sample to different readers and comparing the results. The EM readers were consistent in their analysis of the samples. It is now possible to aquire an accurate count of the total number of axons within an entire nerve fascicle and to further classify those axons into discrete populations based on relevant criteria. Supported by Hoffmann-LaRoche, Canada.

NERVE FUNCTION AND BIOCHEMISTRY IN DIABETIC PATIENTS TREATED WITH ARI-509, A NOVEL ALDOSE REDUCTASE INHIBITOR

T. C. Hohman, W.J.Bochenek, X. Meng, L. Neefe, M. Beg And The ARI-509 Development Team Wyeth-Ayerst Research , Radnor, Pennsylvania, USA

In early clinical studies, treatment effects of aldose reductase (AR) inhibitors may have been limited by the testing of doses that produced incomplete inhibition of AR in the tissue sites of lesions. To assess its therapeutic potential, ARI-509, a novel inhibitor that has been effective in experimental models of diabetes, was tested in a double blind placebo controlled study with 50 IDDM and NIDDM patients. Placebo or drug at 3 or 20 mg/day was administered for 15 to 17 days. Carbohydrates were quantitated by gas chromatography in RBC samples collected immediately prior to drug administration on alternate days and in sural nerve biopsies collected 24 h after the last drug treatment. Bilateral sural nerve conduction velocity (NCV) was assessed at baseline and on the day preceding the nerve biopsy. Mean fasting plasma glucose, HbA_{1c} and RBC sorbitol levels were not different between patient groups on the first day of the study. On the day of nerve biopsy, RBC sorbitol levels in the ARI-509 low and high dose groups were 70 and 80% lower than those in the placebo group; nerve sorbitol and fructose values were significantly reduced ($p<0.01$) by 87 and 89%, respectively, in the high dose group and by 84 and 74% in the low dose group. NCV significantly improved from baseline by 2.8±0.7 m/s ($p<0.05$) in patients receiving the 20 mg,dose but was unchanged in the other groups. The lack of effect on NCV with the low dose may have been a consequence of the slow accumulation of ARI-509 in tissues. With the 3 mg dose, nerve drug levels on day 16 were 6-fold lower than with the 20 mg dose. These results demonstrate the high potency of ARI-509 in man and suggest that both the level and duration of AR inhibition are important for improvement of nerve function in diabetic patients.

2172

REPRODUCTION OF HUMAN SYMPATHETIC LEFT VENTRICULAR REGIONAL DENERVATION IN THE STREPTOZOTOCIN-DIABETIC RAT

H. Schmid and MJ Stevens, University of Michigan, Ann Arbor, USA.

Diabetic autonomic neuropathy (DAN) is invoked as a cause of unexplained cardiac death. Our studies in patients with severe DAN using positron emission tomography and the sympathetic neurotransmitter analogue C-11 hydroxyephedrine (HED) have demonstrated left ventricular (LV) sympathetic dysinnervation with proximal hyperinnervation and impaired myocardial blood flow contrasting to distal denervation. This combination could result in potentially life-threatening myocardial electrical instability. Although the streptozotocin-diabetic (STZ-D) rat is extensively utilized as a model of diabetic peripheral neuropathy, no studies have explored its utility as a model for the heterogeneous cardiac denervation observed in man. Therefore the aim of this study was to use HED to determine the time-dependent changes in LV sympathetic innervation in nondiabetic (ND) and STZ-D rats. Changes in regional LV HED retention were assessed after 6 and 9 months. Neuronal heart imaging was performed using a bolus of 200 µCi C-11 HED injected into the femoral vein under halothane anaesthesia. After 30 min the heart was rapidly removed and the LV divided into proximal and distal sections and radioactivity was measured in each segment and corrected for decay. Results are expressed as % kg dose/g tissue/kg body weight.

Group	6 months		9 months	
	Proximal	Distal	Proximal	Distal
ND (n=4)	1.01±0.04	0.96±0.06	1.04±0.08	0.9±0.11
D (n=4)	0.92±0.02	0.64±0.02*†	0.6±0.03*	0.52±0.03*

*p<0.05 vs corresponding ND segment, †p<0.05 vs proximal segment.

In ND rats no difference in HED retention was detected in the proximal vs distal myocardium. After 6 months, compared to ND rats, myocardial HED retention had declined in the proximal segments of D rats by only 9% compared to a 33% ($p<0.05$) decrease in the distal myocardium. By 9 months, HED retention had declined in both the proximal and distal myocardial segments of the D rats by 42% ($p<0.01$) compared to the same segments in the ND rats. Therefore after 6 months of D, the pattern of sympathetic denervation of the LV partially reproduced the pattern observed in man although hyperinnervation was not observed. By 9 months, the denervation has progressed to involve the proximal myocardium. The STZ-D rat myocardium is a model to study the pathophysiology of regional myocardial sympathetic dysinnervation and to assess the efficacy of therapeutic interventions.

2173

NERVE TAURINE REPLACEMENT ATTENUATES OXIDATIVE STRESS, NERVE BLOOD FLOW AND CONDUCTION DEFICITS IN STREPTOZOTOCIN-DIABETIC RATS.

R Pop-Busui, C Vanhuysen, L Beyer, M Stevens, University of Michigan, Ann Arbor, USA.

Increased oxidative stress has been invoked in the pathogenesis of experimental diabetic neuropathy (EDN). Activation of the adenine nucleotide-linked aldose reductase (AR) pathway (generating sorbitol and fructose from glucose) may exacerbate oxidative stress in part by depleting the ß-amino acid and endogenous antioxidant, taurine. We have previously demonstrated AR-mediated taurine depletion in the sciatic nerve of the streptozotocin-diabetic (STZ-D) rat and that a 5% taurine diet which overcorrects the nerve taurine deficit and exacerbates nerve myo-inositol depletion, does not ameliorate nerve conduction velocity (NCV) slowing. The effects of selective nerve taurine replacement in EDN are unknown. We therefore evaluated the dose dependent effects of 1, 3 and 5% dietary taurine supplementation in order to explore the significance of nerve taurine depletion in EDN. Sciatic motor NCV, composite nerve blood flow (NBF) (by laser Doppler flowmetry), sciatic nerve taurine content (by HPLC) and nerve reduced glutathione (GSH) content (by fluorescence) were determined after 2 wks in nondiabetic (ND) and diabetic (D) animals and D rats given rat chow supplemented with 1% (D+1%), 3% (D+3%) or 5% (D+5%) taurine. All groups N≥6

Group	Taurine	GSH	MNCV (m/s)	Mean BP (mmHg)	Vascular Conductance (Flow/BP)
ND	3.8±0.3	0.36±0.05	57±6	125±20	1.6±0.1
D	2.7±0.4*	0.15±0.02*	44±7*	118±12	1.1±0.2*
D+1%	4.2±0.3†	0.26±0.01*†	54±8†	99±18*	1.3±0.1*†
D+3%	5.4±0.9*†	0.30±0.00†	50±6	110 ±14	1.0±0.1*
D+5%	5.7±1.7*†	0.31±0.02†	49±6	111± 6	1.1±0.1*

Nerve taurine measured as ng/mg wet wt, and nerve GSH as µg/mg wet wt.
*p<0.05 vs ND, †p<0.05 vs D.

Nerve taurine was decreased in D, replaced in D+1%, but over corrected in D+3% and D+5% rats. GSH was decreased in D, increased in D+1% and corrected in D+3% and D+5% rats. MNCV and vascular conductance was decreased in D, partially corrected in D+1% rats but uncorrected in D+3% and D+5% rats. In D+1% rats mean BP was decreased. In D rats, nerve taurine depletion may contribute to NCV slowing and NBF deficits by exacerbating oxidative stress. Correction of NCV slowing in EDN however is not an inevitable consequence of amelioration of oxidative stress.

PERIPHERAL NEUROPATHY IN VACOR-INDUCED DIABETIC RAT

T.H.Lee, H.J.Rhyu, J.S.Ahn, M.C.Lee, Y.Yamamoto*, and Y.Yasuda*, Chonnam University, Kwangju, Korea and *Tokushima Research Inst., Tokushima, Japan

Vacor-posioned patients had complained of various neurological symptoms such as burning sensation of foot, urinary retention, areflexia, and orthostatic hypotension. In animal studies, various neruotoxicities of Vacor were also reported in acute toxic phase, however, the cause of neurotoxicity is not well known. We performed electrophysiological studies including measurements of sciatic motor nerve action potential and conduction velocity in Vacor-treated Wistar rats (single oral dose of 10 or 100mg/kg), and ultrastructural studies of neuromuscular junction within the interosseous muscles of the hind foot of Vacor-treated rat (single oral dose of 80mg/kg). The results were as follows. Vacor, one week after a 10 mg/kg and 6 hours after 100 mg/kg, decreased the amplitude the compound muscle action potential with unchanged conduction velocity. Electron microscopic studies showed remarkable loss of presynaptic vesicles and swollen endoplasmic reticulum in axon terminal at 3 days after Vacor treatment. Progressive degenerative changes consisting of marked loss of presynaptic vesicles, focal disruption of membrane in the axon terminal with disappearance of the number of the damaged axon terminal appeared, and flattening of postsynaptic folds was also seen. These results suggest that degenerative changes in axon terminal at neuromuscular junction may contribute to the peripheral neuropathy developed in the early phase of Vacor poisoning.

2175

PREVENTIVE EFFECT OF CS-045 ON PERIPHERAL NEUROPATHY IN STREPTOZOTOCIN-INDUCED DIABETES RATS WITHOUT DECREASING BLOOD GLUCOSE LEVELS

J. Satoh, X.L. Qiang, M. Sagara, T. Masuda, G. Muto, Y. Muto, S. Miyaguchi, Y. Sakata, T. Nakazawa, F. Ikehata, T. Toyota. Tohoku University School of Medicine, Sendai, Japan

We previously reported that N-acetylcysteine and pentoxifylline, free-radical scavengers and inhibitors of tumor necrosis factor-α (TNF) production, significantly inhibited development of peripheral neuropathy in streptozotocin (STZ)-induced diabetes rats. In this study, we examined effect of CS-045 (troglitazone) on serum TNF activity, serum lipoperoxide and motor nerve conduction velocity (MNCV) of the tibial nerve in STZ-induced diabetic rats, because CS-045 is thought to be a free-radical scavenger. Twelve-wk-old male Wistar/Slc rats were divided into the three groups, nondiabetic control (nonDM), diabetic non-treated (DM) and diabetic CS-045-treated (DM-CS-045) and used for a 24 week experiment. Rats were considered to be diabetic when the non-fasting blood glucose levels were more than 16.8 mM (300 mg/dl) at 24 hrs after STZ injection (30 mg/kg). CS-045 (provided by Sankyo Co., Japan) was mixed with regular powder chow at a final concentration of 0.125 or 0.5 % and was given ad libitum to the rats. There is no significant difference between the blood glucose levels of DM and DM-CS-045 rats throughout the experiment. LPS-induced serum TNF activity and serum lipoperoxide levels were significantly (P<0.01) increased in DM rats compared to nonDM rats, whereas the TNF and lipoperoxide were significantly (P<0.05) suppressed in DM-CS-045 rats. At the 16th and 20th week, MNCV were significantly (P<0.01) decreased in DM rats compared to nonDM rats. However, the decreases of MNCV in DM rats were significantly (P<0.05) inhibited in DM-CS-045 rats. In conclusion, CS-045 has a preventive effect on peripheral neuropathy in STZ-induced diabetic rats regardless their blood glucose levels.

LIPID PEROXIDES IN TYPE 2 DIABETIC PATIENTS WITH NEUROPATHY

I.N. Migdalis, P. Triantafilou, K. Chairopoulos, N. Varvarigos and V. Iliopoulou. Dept. of Diabetes, NIMTS Hospital, Athens, Greece

Diabetes and its associated metabolic changes in peripheral nerves combine to cause a decrease of nitric oxide production and diminished nerve blood flow. Since lipid peroxides are thought to be formed by free radicals and may play an important role in the development of vascular disease, we have investigated the possible relationship between lipid peroxides (measured as thiobarbituric acid reacting species (TBARS)) in NIDDM patients with peripheral neuropathy. Seventy-seven NIDDM patients (39 neuropathic and 38 non-neuropathic) and 36 control subjects were studied. The neuropathy study group had significantly lower levels of TBARS, 3.5 µmol/l (2.2-5.6, 95% confidence limits) compared to controls 4.5 µmol/l (3.08-6.8), $p<0.001$ and to diabetics without neuropathy 4.9 µmol/l (3.09-8.05), $p<0.001$. No differences was found in metabolic control between the two diabetic groups. In the neuropathy group there was a negative correlation between the score for nerve dysfunction with the TBARS levels ($r=-0.42$, $p<0.01$). We conclude that in patients with diabetic neuropathy there are abnormalities of TBARS levels. Thus providing further support for the role of ischaemia in the pathogenesis of neuropathy.

2177

AN EXPERIMENTAL STUDY OF THE THERAPEUTIC EFFECTS OF THE NERVE GROWTH FACTOR ON DIABETIC NEUROPATHY IN RATS

Junhong Jia, Xueyi Ma, Shinan Yin, Donghua Tian, Guoping Yu and Huixin, Wang, Ming Zhao, 304th Hospital, Beijing, China

Objective: To study the function and morphology of nerve in diabetic rats and the therapeutic effects of NGF on it . Methods: Male wistar rats weighting 170-200g were randomly divided into three groups: G-NC; G-DM and G-NGF. The diabetes was induced in late two groups by a single dose (75mg/kg) of Streptozotocin i.p. After inducing the diabetes for two months, the NGF was administed with 200ug/kg/day im. for 1 month. Items of Observation and Results· 1 The function of nerve: 1.1. The thermal pain thresholds by tailfick testing: The thermal pain threshold value in the G-NGF was significantly decrease comparing with its before therapy and the G-DM. P<0.001. 1 2. The ability of learning and memory by water maze testing: The time that completed whole swimming journey and the number of error reaction in the G-DM and the G-NGF were similar, but much higher than that in the G-NC P<0.001 1 3. The sciatic nerve conduction velocity. In the motor nerve conduction velocity, the G-DM and the G-NGF appeared similar , but obviously slower than that in the G-NC. P<0.01. While the sensory nerve conduction velocity in the G-NGF was slower than that in the G-NC, but faster than in the G-DM. P<0.01. 2. The morphology of the nerve tissue: 2.1 The count of hippocampal pyramidal cell in the G-DM and the G-NGF were similar, but were less than that in the G-NC. P<0 01 2 2 The density of the myelinated nerve fiber axons of sural nerve:in the G-NGF was lower than that in the G-NC, but higher than in the G-DM. P<0.01 3. The substance P (SP) and neurofilament (NF) in dorsal root ganglia by the immunohistochemistry: 3.1 The positive reaction of SP in the G-DM was lower than in the G-NC, and the G-NGF was higher than that in the G-NC. 3.2 The positive reaction of NF in the G-NGF was lower than that in the G-NC , but was higher than in the G-DM Conclution: This study showed that NGF had the therapeutic effects on the rats with the diabetic neuropathy of sensory nerve.

INVOLVEMENT OF CENTRAL NERVOUS SYSTEM IN PATIENTS WITH DIABETES MELLITUS

B.N.Mankovsky Institute of Endocrinology, Kiev, Ukraine

The data regarding the disturbances of central nervous system (CNS) in patients with diabetes mellitus are controversial. We investigated time latencies of P_3, N_2, N_3 peaks of visual evoked potentials (VEP) and quantitative parameters of electroencephalogram (EEG) in 89 patients with diabetes aged 17-75 years (mean age 43.3 years, mean duration of disease 13.6 years) and 20 age-matched controls consequently divided to three differently aged cohorts (18-39, 40-59 and 60-75 years) without any overt symptoms of CNS impairment. We found that peak latencies of VEP were significantly prolonged in all cohorts of differently aged patients with diabetes compared to age-matched controls and these differences were the most pronounced in the youngest group (aged 18-39 years). VEP latencies significantly positively correlated with the age of patients, duration of disease, and severity of diabetic retinopathy. Those with diabetes had an increased EEG delta rhythm intensity and decreased intensity of alpha rhythm compared to controls. There were no correlations between VEP and EEG parameters. Thus, revealed abnormalities may reflect CNS impairment in patients with diabetes.

2179

INSULIN-LIKE GROWTH FACTOR-I (IGF-I) PROMOTES THE MYELINATION OF SENSORY NEURONS.

J.W. Russell, H-L. Cheng and E.L. Feldman, University of Michigan, Ann Arbor, Michigan USA.

IGF-I is an important neuronal mitogen and promotes oligodendrocyte directed myelination in the brain, but the effect of IGF-I on peripheral nervous system (PNS) myelination has not been previously established. E15 dissociated rat dorsal root ganglion (DRG) neurons were cultured in serum free defined medium (SFDM) containing selenium, transferrin, hydrocortisone, β estradiol, putrescine, vitamin E, defined lipids, Neurobasal Medium (Gibco), glutamate, ascorbic acid, glucose, and 10 ng/ml 2.5S NGF. Cultures free of endogenous Schwann cells were obtained by preplating and using 30 μM FUDR/uridine X 6 days. After washing, secondary Schwann cells (SSC) labeled with 10 μM immunofluorescent DiI were added to the neurons. The following culture conditions were used: 10% calf serum, SFDM ± 1-10 nM IGF-I, SFDM/ forskolin ± IGF-I. Changes in the Schwann cells were serially followed and photographed using a rhodamine cube, over 21 days. The cultures were then fixed and stained with 2% osmium and Sudan black and the number of myelinated fibers /square μm measured using a random order grid measuring system. After 24 h, the labeled SSC differentiated and extended along the axons in cultures containing serum or IGF-I, but not with NGF alone, or forskolin. SSC and axons survived well in all conditions except in the presence of forskolin. IGF-I promoted myelination of the DRG, although this was slightly reduced compared to serum treated neurons. Myelination did not occur in DRG cultures treated with SFMM alone, or SFMM/cAMP. Neuronal death was increased in forskolin treated neurons after 1 week in culture. These results imply that 1) IGF-I promotes differentiation of Schwann cells, development of basement membrane, and myelination of sensory neurons in the PNS 2) IGF-I promotes myelination independent of its effect on neuronal and Schwann cell survival, and 3) Additional permissive factors present in serum are required to induce optimum myelin production. Supported by KO8 NS01938, R29 NS32843 and grants from the American Diabetes Association and the Juvenile Diabetes Foundation International.

Neuropathy – Clinical Picture and Treatment

2180

CONDUCTION IN CORTICOSPINAL TRACT IN DIABETES MELLITUS.

P.Pacuła, J.Bojakowski, A.Petrulewicz, I.Sergiej, J.Przesmycka and A.Czyżyk. University School of Medicine, Warsaw, Poland.

The aim of the study was to evaluate the function of pyramidal tract in group of patients with long lasting diabetes mellitus associated with late complications (polyneuropathy, nephropathy, retinopathy). Conduction time was examined using magnetic stimulation of the motor cortex in 20 patient with diabetes (6 women, 14 men, duration of diabetes from 6 to 40 yrs, mean 25.1±9 (SD) and in 10 healthy control subjects. Motor responses from contralateral hypothenar abductor digti quinti (ADV) and tibialis anterior (TA) muscles were recorded and central motor conduction time (CMCT) determined by using F-wave method. Mean CMCT time for TA was prolonged to 14 ms in diabetic patients as compared with 12.6 ms in controls, $p<0.05$. In the subgroup of patients with erectile impotence (11 cases) the difference in CMCT was more marked 14.8 ms, $p=0.02$, as well as the peripheral conduction time for both TA and ADV, $p<0.01$. There was no significant correlation of CMCT with duration of diabetes. These results show impairment of conduction in corticospinal tract in diabetes and suggest that erectile dysfunction in diabetes may have central, not only peripheral origin.

2181

SUBCLINICAL NEUROPATHY IN NEWLY DIAGNOSED DIABETES.

D.J.S. Fernando, M. Fernando, Faculty of Medicine, Sri Lanka.

Nerve ischaemia resistance (NIR) is common feature of diabetic neuropathy.

We determined whether NIR was present at the time of diagnosis and the influence of glycaemic control on NIR. 420 diabetic patients (DM) mean age 43.2 SD 6.6 (280 males) who attended the clinic within 2 weeks of diagnosis and 420 age and gender matched controls (C) mean age 44.1 SD 5.7 (280 males).

Vibration perception threshold (VPT) was measured using a neurothsiometer before and after 30 minutes of limb ischaemia at diagnosis. An ischaemic index (II) was calculated (30 minute VPT/ baseline VPT) as a measure of ischaemia resistance. Peroneal motor conduction velocities were determined.

Clinical assessment was performed using a neuropathy symptom score (NSS) and a neuropathy disability score (NDS). Peroneal motor and sensory conduction velocities were assessed.

Mean VPT was higher in DM (16 SD 4.3) than in C (8 SD 3.2), p 0.01 and VPT at 30 minutes was lower (22 SD 4.1 vs 31 SD 7.2, p=0.01). II was lower in DM when compared to C (p= 0.01). II corelated with HBA1C at time of diagnosis (r=-0.60, p 0.003). Mean NDS (1.2 vs 1.4) and NSS (12% vs 14%) were similar in DM and C. Nerve conduction velocities were no different in DM (44m/sec) and C (45.2m sec). We conclude that NIR is present at diagnosis.

2182

PERIPHERAL NEUROPATHY ALTERS GAIT IN DIABETIC PATIENTS

E.C.Katoulis, M.Ebdon-Parry, H.Lanshammar, L.Vileikyte, J.Kulkarni, and AJM. Boulton. University Dept of Medicine, Manchester Royal Infirmary, Manchester, U.K.

The aim of this study was to investigate the effect of peripheral neuropathy on gait in diabetic patients. We studied four groups, each of 20 subjects, matched for age, sex and BMI: normal healthy controls, non- neuropathic controls, diabetic neuropathy and diabetic neuropathy with history of foot ulceration. For gait analysis, the VIFOR system was used. Two recordings were taken, one for each leg, in both sagittal and frontal planes. We analysed: walking speed, stance phase duration, joint angles and moment arms for the ankle, knee and hip joints, the components of the ground reaction force (GRF) vector and the ankle, knee and hip joint moments originating from the GRF vector. Two sample t-test, equal variance, was used for intergroup statistical comparisons. Walking speed was found significantly lower ($p< 0.05$) in the two neuropathy compared with the control groups. Joint angles were different in the final part of stance phase. The maximum values of the vertical and the antero-posterior components of GRF were found to be higher in the two control groups compared to the history of ulcers neuropathy group ($p< 0.01$). The maximum frontal plane ankle joint moment was significantly higher ($p< 0.05$) in the two neuropathy compared to the control groups. These alterations in gait parameters found in the neuropathic diabetic patients may be attributed to a proprioceptive deficit but other factors such as altered musculo-skeletal and soft tissue mechanics seen in longstanding diabetes complicated by neuropathy, may also be implicated. They may have clinical significance since they can increase the risk for minor trauma and ulceration.

2183

POLYNEUROPATHY INCIDENCE IN PATIENTS WITH IMPAIRED GLUCOSE TOLERANCE

D. BERKER, H. UYSAL, S. GÜLER, Z.A. ECEMİŞ, Y. ACAR and Y. ARAL. Ankara State Hospital, Ankara, Turkey.

This study is performed in order to find out the incidence of polyneuropathy in patients with impaired glucose tolerance (IGT) and in order to establish whether there is any relation between polyneuropathy and serum calcium, phosphorus, magnesium, sodium and potassium and corrected QT interval on electrocardiogram. 22 patients aged between 28 and 66 years formed the patient group and 11 subjects with normal glucose tolerance formed the control group. We have measured plasma glucose, blood urea nitrogen, serum transaminases, total, HDL-, LDL- and VLDL-cholesterol, triglycerides, insulin, calcium, phosphorus and magnesium; and calculated corrected QT interval in all cases of the study group. Polyneuropathy is assessed with electromyoneurography. The patient group had significantly higher insulin levels ($p<0.01$). We have found mild sensory polyneuropathy in 11 (50 %), and carpal tunnel syndrome in 2 (9 %) of 22 patients with IGT while only one subject (9 %) in the control group had mild sensory polyneuropathy. This difference is statistically significant. Because of this high incidence we propose that existence of polyneuropathy must be assesed with electromyoneurography in every patient with IGT. Further studies must also be planned concerning the effects of diet and drug therapy on polyneuropathy in patients with IGT.

2184

EFFECT OF TREATMENT WITH ACETYL-L-CARNITINE ON DIABETIC FOOT ULCERATION IN PATIENTS WITH PERIPHERAL NEUROPATHY: A 1 YEAR PROSPECTIVE MULTI-CENTRE STUDY.

C.A.Abbott, L.Vileikyte, S.Williamson, A.L.Carrington, A.J.M.Boulton; and the ALCAR Foot Ulcer Study Group. Department of Medicine, Manchester Royal Infirmary, Manchester, UK; and 43 other centres.

There was evidence to suggest that acetyl-L-carnitine (ALCAR) treatment improves nerve function in diabetes. The safety and efficacy of ALCAR for preventing foot ulceration in diabetic patients with peripheral neuropathy were evaluated in a double-blind, multi-centre trial. 1035 IDDM and NIDDM patients with vibration perception threshold (VPT) ≥25, ≤50V, normal peripheral circulation and no previous foot ulceration were randomised to receive either a daily oral dose of 1000 mg ALCAR (n=686) or placebo (n=349) for 1 year. The primary efficacy endpoint was incidence of first foot ulcer. Secondary parameters included VPT at the hallux and the Michigan Diabetic Neuropathy (MDN) score (sensory impairment by tuning fork, 10 g monofilament and pin prick; muscle strength; and reflexes). The incidence rate of first foot ulcers at 12 months was 6.9% (n=23) for placebo and 7.4% (n=48) for ALCAR. VPT for ALCAR and placebo were 29V (17-50V; median and range) and 28V (16-49V), respectively, at baseline, and were unchanged at 12 months (28V (5-50V) and 28V (6-50V), respectively (p>0.05)). There were no changes in MDN parameters after 12 months. The results indicate that ALCAR is non-efficacious as a preventative treatment for diabetic foot ulceration. VPT, muscle strength, reflexes and 10g monofilament scores at baseline were all significantly associated with risk of foot ulceration (p<0.01). This suggests that VPT, muscle strength, reflexes and 10g monofilament are useful predictors of future foot ulceration and may be used in clinical practice to identify high risk patients.

2185

DIABETIC NEUROPATHY: POSSIBLE NEW PATHOGENIC ASSOCIATIONS

J.J. Gagliardino (on behalf of PRAMUDIA), Argentina.

The aim of this work was to estimate the prevalence of diabetic neuropathy (N), diagnosed through the evaluation of pain and vibratory sensitivity, and its possible association with variables such as hypertension (H), dislipidemia, microvascular (retinopathy and nephropathy) or macrovascular (peripheral arteriopathy) lesions, and other clinical and biochemical parameters. For this purpose, 798 diabetic patients (49% male) assisted by 20 diabetologists from different provinces of Argentina, were randomly incorporated to a cross-sectional study using an *ad hoc* common protocol. The average prevalence of N was 35% (range 6 to 64% according to diabetes duration). The univariate analysis showed that N was significantly and positively associated with males, H, coronary disease, dislipidemia, retinopathy, nephropathy, peripheral vasculopathy, and diabetes duration. The factor analysis showed a strong link among N, retinopathy, diabetes duration, nephropathy, peripheral vasculopathy and H. The logistic regression determined the significance of the association of N with: retinopathy (adjusted OR= 4.80; 95% CI= 3.19-7.24); age (OR= 1.02 per year of age; 95% CI= 1.005-1.03), male sex (OR= 1.60; 95% CI=1.11-2.29), nephropathy (OR=2.01; 95% CI=1.16-3.49), peripheral vasculopathy (OR = 2.78; 95% CI = 1.34-5.70), diabetes duration (OR = 1.03 per year; 95% CI= 1.001-1.05), dislipidemia (OR= 1.65; 95% CI= 1.03-2.64), H (OR= 1.67; 95% CI= 1.08-2.56).The relative importance of the variables, determined by standardized coefficient ßx' (SD) was: retinopathy (0.73), age (0.34), vasculopathy (0.29), nephropathy (0.25), sex (0.25), diabetes duration (0.22), dislipidemia (0.19), H (0.18). These results suggest that the vascular component (microangiopathy and macroangiopathy), H and dislipidemia, together with the metabolic component, play a complementary role in the patogenesis of diabetic neuropathy.

2186

LACK OF EFFECT OF EVENING PRIMROSE OIL ON AUTONOMIC FUNCTION TESTS AFTER 12 MONTHS OF TREATMENT

TS Purewal [a], PMS Evans [b], F Havard [b], and JP O'Hare [c]. Royal Liverpool University Hospital[a], Liverpool, Royal United Hospital[b], Bath and University of Warwick[c], UK.

Beneficial effects of supplementation of the essential fatty acid gamolenolenic acid (GLA) have been demonstrated in both animal models, and clinically in man. At our centre all subjects enrolled in a 2 year double blind multicentre study in painful neuropathy also underwent an additional set of objective quantitative tests to assess the severity of autonomic and peripheral neuropathy. We present the results of an interim analysis at 12 months of treatment with GLA. Of 51 patients recruited, 26 were randomised to GLA 480mg/day, and 25 to placebo. Age (64.6±7.8 vs 60.5±10.1 years, mean±SD), type (9:17 vs 11:14, IDDM:NIDDM), and duration of diabetes (11.7±12.7 vs 16.2±16.2 years) were similar in each group. Compared to baseline, there were no significant changes in: Vibration perception thresholds at the hallux (GLA: 25.9±8.9 vs 24.5±11.4, placebo: 27.7±12.4 vs 23.9±13.4, normal<15 volts), Valsalva ratio (GLA: 1.79±0.49 vs 1.85±0.56, placebo: 1.61±0.6 vs 1.72±0.58, normal>1.21), RR interval variation on deep breathing (GLA: 16.30±9.35 vs 17.69±12.45, placebo: 14.76±11.16 vs 13.50±9.97, normal>15 beatsmin^{-1}), Heart rate response to standing (30:15 ratio: GLA: 1.19±0.31 vs 1.05±0.04, placebo: 1.13±0.21 vs 1.16±0.30 beatsmin^{-1}, normal>1.04), or degree of postural hypotension. We conclude that at 12 months there are no objective improvements in standard tests of severity of diabetic peripheral and autonomic neuropathy. Treatment with GLA may need to be more prolonged to show benefit, and its clinical significance may be limited.

2187

NATURAL HISTORY OF PERIPHERAL NEUROPATHY IN RELATIONSHIP TO VIBRATION PERCEPTION THRESHOLDS IN DIABETIC PATIENTS

D.V. Coppini[1], C. Weng[1], M.C. Jones[1], P.J. Young[2], A.F. Macleod[3] and P.H. Sönksen[1]. [1]Division of Medicine, St. Thomas' Hospital, London, U.K. [2]Department of Health Sciences, University of York, York, U.K. [3]Department of Diabetes, Royal Shrewsbury Hospital, Shrewsbury, U.K.

We followed up 392 diabetic patients who had a baseline diabetic clinic visit at St. Thomas' Hospital between 1982-85 for a mean period of 12 (10-14) years. All patients were reviewed in 1995. Toe vibration perception thresholds (VPT) were performed at baseline and review visits. VPT measurements are converted by our computer (Diabeta) to a 'standard deviation score' by logarithmic transformation. This corrects voltage measurements for age. We defined established peripheral neuropathy as a toe 'standard deviation score' > 1.96. Seventy-eight patients (20.4%) developed peripheral neuropathy by this criterion over a mean 12 year period, so that the calculated annual incidence is 1.7%. Fifteen patients (3.8%) developed foot ulcers (1.8%) or had an amputation (2%). Mean HbA1 over the 12 years interval was higher in patients with neuropathy (11.0 ± 1.4 vs 10.4 ± 1.4; p=0.01). Mean toe VPT in patients developing neuropathy increased from 14.2 ± 3.7 volts at baseline to 35.9 ± 9.5 volts at review and from 10.1 ± 3.7 volts to 14.2 ± 4.7 volts in the rest of the patients. Neuropathy was positively related to retinopathy at baseline (p=0.02), and to Caucasian ethnicity (p=0.02), male sex (p <0.01) and height (p=0.01).

2188

REVERSAL OF DEFECTIVE NERVE CONDUCTION WITH VITAMIN E SUPPLEMENTATION IN DIABETICS WITH PERIPHERAL NEUROPATHY

N. Başçıl, M. Bayraktar, K. Varlı, O. Gedik Department of Endocrinology and Department of Neurology, Hacettepe University Faculty of Medicine, Ankara, TURKEY.

Recent evidence has suggested that diabetic microangiopathy is associated with increased free radical induced oxidative damage. The present study has examined the effect of vitamin E, the principal modulator of free radical activity, on electrophysiologic parameters in patients with diabetic peripheral sensorimotor polyneuropathy. Two groups of noninsulin dependent diabetic patients with mild to moderate peripheral sensorimotor polyneuropathy, matched for duration of disease and metabolic control, received daily vitamin E supplementation of 900 mg and placebo, respectively, for 6 months. Fasting plasma glucose and hemoglobin A_1 (Hb A_1), postprandial plasma glucose and electrophysiologic parameters in the basal state and after 6 months of treatment were studied. Glycemic indices did not show any significant changes during the study, whereas nerve conduction improved significantly after 6 months in patients on vitamin E supplementation. The changes in the electrophysiologic parameters were obvious in the median and tibial motor nerve fibers. Nerve conduction velocity in the median motor nerve fibers (p=0.0051) and tibial motor nerve distal latancy (p=0.0284) improved significantly after 6 months of vitamin E supplementation. This study shows that defective nerve conduction in diabetics with mild to moderate peripheral neuropathy, can be reversed by pharmacological doses of vitamin E supplementation.

2189

IS VIBRATION PERCEPTION THRESHOLD MEASUREMENT REPRODUCIBLE UNDER DIFFERENT AMBIENT BLOOD GLUCOSE LEVELS AT DIFFERENT HOURS OF THE DAY ?

Taner Damci, Zeynep Osar Ersanli, Sule Beyhan, Hasan Ilkova, Mücahit Ozyazar, Ugur Gorpe and Nazif Bagriacik. Cerrahpaşa Medical Faculty of Istanbul University, Dept. of Internal Med., Div. of Diabetes and Metabolism, Istanbul, Turkey.

Vibration perception threshold (VPT) measurement by biothesiometer is commonly used in the diagnosis of neuropathy in diabetic patients. The results correlate well with the ones of electromyography. The factors known to affect VPT are age and height. Metabolic control through HbA1c was shown to have no affect on VPT measurement. It is not clear whether instantenous blood glucose levels and the hour of the day the test is done (possibly because of neuropathic edema) influence VPT recordings. To adress this question 62 diabetic patients (26 IDDM, 36 NIDDM) with mean age 48.9±13.21, diabetes duration 14.6 ± 4.27, underwent VPT examination by biotheiometer (Biomedical Instrument Co. Newbury, Ohio, USA) at different hours of the day (mainly fasting and late afternoon) right after blood was drawn for blood glucose testing and a neuropathy symptom score (NSS) questionnaire. VPT was measured at both great toes and each time the mean of three successive measurements is recorded. Statistical analyses were done in SPSS for Windows 5.0.1. using Pearson correlation coefficient, independent samples and paired samples t test where required. 34 patients had neuropathy with basal VPT measurement (>25 mvolt). Both sides of the body correlated well (r:0.90, p< 0.001). VPT significantly correlated with age (r: 0.34, p: 0.012), diabetes duration (r:0.30, p:0.02), NSS (r:0.067, p<0.001). No significant correlations were observed between VPT and HbA1c (r: 0.23, p:0.8) and instantenous blood glucose (r:-0.09, p:0.34). Change in the bloood glucose did not correlate with the change in the VPT (r:0.18, p:0.81). VPT measurements gave similar recordings in the morning and late afternoon (p: 0.35). VPT was not different in IDDM and NIDDM patients (p: 0.22). Patients having severe neuropathy (NSS >9) had significantly higher VPT values (p < 0.001) than the others. In conclusion the results of the present study show that VPT measurement is reproducible under different ambient blood glucose values at different hours of the day which confirms that it is an accurate and a rapid method of detecting diabetic neuropathy.

FIBER-SPECIFIC EFFECTS OF THE ALDOSE REDUCTASE INHIBITOR ZENARESTAT IN MILD HUMAN DIABETIC POLYNEUROPATHY.

D.A. Greene, J.C. Arezzo and M.B. Brown, University of Michigan, Ann Arbor MI and Albert Einstein College of Medicine, Bronx NY USA for the Zenarestat (FK366) Neuropathy Study Group.

Slowing of nerve conduction velocity (NCV), a hall-mark of large myelinated nerve fiber (MNF) dysfunction in diabetic polyneuropathy (DPN), is corrected by potent aldose reducatse inhibitors (ARI's), yet ARI effects on small MNF have not been well studied. In a 52-wk randomized, double-blind, placebo-controlled multi-dose clinical trial in 208 subjects with mild DPN, zenarestat (Z) (150 mg, 300 mg and 600 mg BID) dose-dependently lowered sural nerve (SN) sorbitol content 70-85% and improved a composite NCV parameter (p=0.003) ~1.5 m/sec. The diameter and the number of MNF's (per mm^2 cross-sectional area = MNF density(D)) were measured in bilateral SN biopsies obtained at baseline and 52 wk. MNFD (±SD) declined in the placebo (PL) and 150 mg BID groups (-239±197 and -175±147 fibers, respectively) and increased in the 300 and 600 mg BID groups (+168±217 and +181±281 fibers, respectively, p=0.05 adjusted for center and glycosylated hemoglobin). The MNF losses in the PL and 150 mg BID groups and MNF gains in the 300 and 600 mg BID groups were largely attributed to changes in A∂ fibers <5μm in diameter: -202±104, -50±108, +135±158 and +249±167 fibers, respectively, p=0.015. Large MNFD of fibers >5μm in diameter was unchanged in the PL and all Z groups. Thus Z, which potently lowered SN sorbitol, improved large MNF function (NCV) and specifically reversed the loss of small MNF in mild DPN. These effects of Z were equal in magnitude to those deemed clinically meaningful and detectable in epidemiological studies (Russell J.W., Karnes J.L., Dyck P.J. *J Neurol Sci* 1996; 135:114-117).

2191

FACTORS ASSOCIATED WITH FOOT VIBRATION SENSORY THRESHOLD CHANGE OVER 16 YEARS FROM DIAGNOSIS.

T.D.R.Hockaday, B.Pim and S.Dutton. Radcliffe Infirmary, Oxford, England.

Deterioration in vibration sensory threshold (VST) is related to glycaemia during the 5 years after diagnosis of diabetes: is this true 16 years afterwards? 72 diabetic patients (42 men) had foot VST assessed biothesiometrically 16 years after as well as at diagnosis aged 46 ± SD19 years as non-insulin- dependent (NID), and on 4 occasions between. After a drop from 23.2+10.0 arbitary units initially to 22.7 ± 9.9 (1 year,NS) there was a steady deterioration to 26.8 ± 11.2 (16 years,p<0.01). The 16-year VST increased with age, male sex, various measures over time of total (Body Mass Index) and central (Scapula:Triceps skinfolds) obesity (all p<0.001), as well as (p<0.05) with lower initial fasting growth hormone (GH) levels, 16 year systolic blood pressure and decreased ankle pulses as clinically detected (the two last were N.S.after controlling for the first 3 factors). Glycaemia was not a correlate, nor was it with the deterioration from diagnosis to 16 years, which was however correlated strongly with initial VST, obesity (p<0.01), age and, after controlling for these, the 16-year ankle pulses (p<0.04). The 0-10 year deterioration, after allowing for the associations with initial VST and age, was correlated with initial history of ethanol intake(p<0.01), while the 10-16 year deterioration was also associated with hepatic factors (also GH levels and systolic blood pressure). Glycaemia was not a significant determinant of VST in the later years after diagnosis of NID diabetes; differential death of the more hyperglycaemic may contribute but progressive neuropathy is possibly a 2-stage process.

2192

LONG - TERM EFFECT OF TOLRESTAT ON HEART RATE VARIABILITY IN PATIENTS WITH SEVERE OR MODERATE DIABETIC AUTONOMIC NEUROPATHY

T. Didangelos, V. Athyros, D. Karamitsos, A. Papageorgiou, G. Kourtoglou, A. Kontopoulos.

Divisions of Diabetology and Cardiology, 2nd Prop. Department of Internal Medicine, Aristotelian University, Hippocration Hospital, Thessaloniki, Greece.

Patients with diabetic autonomic neuropathy (DAN) have an increased cardiovascular mortality rate compared with diabetic patients without DAN. Heart rate variability (HRV) time and frequency domain indices are strong predictors of malignant arrhythmias and sudden cardiac death. This prospective, randomised, double-blind and placebo controlled study analysed the long-term effect of tolrestat, an aldose reductase inhibitor, on HRV time and frequency domain variables in 45 patients with diabetes mellitus (DM) and DAN. They were randomised into tolrestat (n=22) or placebo (n=23). HRV was assessed on a 2-chanel 24-hour electrocardiogram with a solid state digital recorder at months 0,3,6,9, and 12. HRV level of the 45 patients was compared with that of 20 matched patients with DM, of analogous glycemic control, without DAN and 20 healthy controls. Tolrestat, compared with placebo, had a beneficial effect on HRV level in 12/22 patients with moderate DAN. At 12th month it improved significantly ($p<0.01$) all HRV time and frequency domain indices. Despite the beneficial effect of tolrestat, the HRV indices remained less than those of controls. The patients with severe DAN (10/22) had a slight, in some indices significant, benefit. No patient at 12th month showed deterioration of HRV indices with tolrestat as seen with placebo. Tolrestat significantly restores sympathovagal interaction in patients with moderate DAN, 12 months after treatment initiation. This might contribute to the reduction of risk for malignant ventricular arrhythmias. The early detection of DAN is imperative for a successful intervention.

2193

TISSUE OXYGEN TENSIONS IN SKELETAL MUSCLE OF TYPE-1-DIABETIC PATIENTS DURING A COLD PRESSOR TEST.

V.Hofmann[1], C.Maisch[1], N.Benda[2] and D.Luft[1]. [1]Department of Internal Medicine IV, [2]Institute for Medical Biometrics, University of Tübingen, 72076 Tübingen, Germany

Background: The cold pressor test (CPT), a sympathetic stress test, leads to an increase of blood pressure, muscle sympathetic nerve activity and muscle perfusion as well. Several variables of this test may be used to assess autonomic impairment in diabetic patients. We polarographically measured changes of tissue oxygen tensions in the right anterior tibial muscle during CPT which may reflect changes of muscular microcirculation. Research design and methods: Twenty-eight type-1-diabetic patients, 18 males and 10 females, without obvious diabetic late complications (mean age 27±7 years, height 175±9 cm, BMI 22.7±2.8 kg/m^2, diabetes duration 6.8±5.1 years, HbA1c 7.5±1.9%, x±SD) and 34 normal control subjects matched for age, gender and BMI were investigated at rest and during a CPT of 5 minutes duration. Results: During CPT muscular oxygen tensions increased by more than 3 mmHg in 14 out of 28 diabetic patients and in 13 out of 34 control subjects. Mean increases did not differ between groups. Changes of oxygen tensions correlated neither to age, gender, BMI, systolic and diastolic blood pressure, duration of diabetes nor to HbA1c. The changes did correlate inversely to the respective values obtained at rest (in diabetic patients: r=-0.48, p=0.004, in control subjects: r=-0.60, p=0.001). Conclusion: In diabetic patients and control subjects with elevated muscular tissue oxygen tensions at rest there is no further increase during CPT since presumably the extent of sympathetically mediated vasodilation is limited. Basal values may be influenced by pre-test sympathetic activation which has to be taken into account interpreting test results.

2194

LONG - TERM EFFECT OF QUINAPRIL ON HEART RATE VARIABILITY IN PATIENTS WITH SEVERE OR MODERATE DIABETIC AUTONOMIC NEUROPATHY

V. Athyros, T. Didangelos, A. Kontopoulos, A. Papageorgiou, V. Skeberis, G. Kourtoglou, D. Karamitsos.

Divisions of Cardiology and Diabetology, 2nd Prop. Department of Internal Medicine, Aristotelian University, Hippocration Hospital, Thessaloniki, GREECE.

Patients with diabetic autonomic neuropathy (DAN) exhibit an increased propensity for lethal arrhythmias in comparison to patients with diabetes mellitus (DM) without DAN. This is due to increased sympathetic, reduced vagal activity or both. HRV level is a reliable tool to assess DAN. This prospective, randomised, double-blind and placebo controlled study analysed the long-term effect of quinapril, an angiotensin converting enzyme inhibitor, on HRV time and frequency domain variables in 50 patients with DAN (11 with IDDM and 14 with NIDDM). They were successfully randomised into quinapril (n=25) or placebo (n=25). HRV was assessed on a 2-chanel 24-hour electrocardiogram with a solid state digital recorder at months 0,3,6,9, and 12. HRV level of the 50 patients was compared with that of 20 matched patients with DM, of analogous glycemic control, without DAN and 20 healthy controls. Quinapril, compared with placebo, had a beneficial effect on HRV level in all patients with DAN, regardless of severity. In 13/25 patients with moderate DAN this effect was detected early, at month 3, and gradually increased until month 12. In that group quinapril improved significantly ($p<0.01$) all HRV time and frequency domain indices, mainly the parasympathetic related ones, and reduced heart rate. The patients with severe DAN (12/25) had a significant but less pronounced benefit. No patient at 12th month showed deterioration of HRV indices with quinapril as seen with placebo. Quinapril significantly restores sympathovagal balance in patients with DAN, early after treatment initiation. This might contribute to the reduction of propensity for malignant ventricular arrhythmias.

Gadolinium Enhancement of Peripheral Nerve and Muscle R1 in Human Diabetic Peripheral Polyneuropathy compared to Healthy Subjects

M.B.Damholt, P.B.Ring, H. B.W.Larson, M.Herning and J.Hilsted

Dept of Endocrinology and Danish Research Center of Magnetic Resonance, Hvidovre University Hospital, Kettegaard Allé 30, DK-2650 Hvidovre, Denmark.

The aim of this study was to examine if uptake of contrast(gadolinium enhancement) can be detected and estimated in the sural nerve in diabetic human neuropathy compared to healthy controls evaluated by magnetic resonance imaging. Kinetic models of gadolinium enhancement are used for blood flow estimation. Six type 2 neuropathic diabetic patients mean age 54 years ± 4 and 6 healthy control subjects mean age 54 years ± 8 have been studied. The diabetic patients were all classified as having severe symptomatic symmetric polyneuropathy (San Antonio - criteria). MRI was performed at 1.0 Tesla on a Siemens IMPACT MR scanner. A spin-echo sequense was employed. Power of resolution was 0.23 x 0.23 mm^2. Images of the right lower leg was recorded 15 cm proximal to the lateral malleol in an oblique slice. A oblique slice was placed in a plane allowing the sural nerve to transverse the slice perpendicular to the plane. Intially 7 recordings with variable TR was performed to allow estimation of R1. Subsequently an i.v. bolus of Gadolinium-DTPA (Gd) (0,15 mmol/kg) was given. Finally after 30 min the intial 7 recordings were repeated. The difference in R1 of the muscle before and after Gd - bolus was significantly higher in the neuropathic group, $\Delta R1$ mean 1.43 s^{-1} ± 0.7 compared to the $\Delta R1$ 0.13 s^{-1} ± 0.2 in healthy control group ($p < 0.005$). In contrast the increment in R1 in the sural nerve after Gd-bolus was higher in the healthy control group $\Delta R1$ 1.88 s^{-1} ± 1 compared to the neuropathic group; $\Delta R1$ 0.68 s^{-1} ± 0.7. ($p = 0.055$) .We conclude: 1) Gadolinium enhancement in the sural nerve can be detected and tends to be impaired in diabetic neuropathy compared to controls 2) The soleus muscle in diabetic neuropathy accumulates Gd after bolus injection compared to healthy controlls. Whether the observed differences after Gd-bolus are due to differences in blood flow,volume of distribution or Gd extration from the blood remains to be established.

2196

ELECTRICAL SPINAL CORD STIMULATION: A NEW AND EFFECTIVE TREATMENT FOR PAINFUL DIABETIC PERIPHERAL NEUROPATHY.

S. Tesfaye, J. Watt, S.J. Benbow, K.A. Pang, J Miles and I.A. MacFarlane.
Walton Hospital, Liverpool, U.K.

Conventional treatment for painful peripheral diabetic neuropathy is largely symptomatic and frequently ineffective, with unacceptable side-effects. We tested the effectiveness of electrical spinal cord stimulator (ESCS) for the management of chronic neuropathic pain not responding to conventional treatment, in 10 diabetic subjects (mean age ± SD, 51±9.3 years, mean duration of diabetes 12± 6.3 years, mean duration of neuropathy 5±2.1 years). The electrode was implanted in the thoracic/lumbar epidural space. Immediate pain relief was assessed by visual analogue scale (VAS) after connecting the electrode, in a random order, to a percutaneous ESCS and placebo stimulator. 8 subjects had significant pain relief with ESCS compared to placebo and were converted to the permanent system, with a radio-receiver implanted in the anterior abdominal wall. Significant relief of both background and peak neuropathic pain was achieved at 3 months (VAS, n=7, p=0.016), at 6 months (n=7, p=0.03) and at the end of the study (median -14 months, n=7, background pain p=0.06, peak pain p=0.03). One patient died of unrelated cause 2 months after the start of the study while continuing to benefit from ESCS. There was also an improvement ($p<0.05$) in all the 4 components of the McGill pain questionnaire at the end of the study. Exercise tolerance on treadmill also increased significantly at 3 months (p=0.015) and at 6 months (p=0.0007). Electrophysiological tests and glycaemic control were unchanged. ESCS offers a new and effective way of relieving chronic neuropathic pain and improves exercise tolerance, and should therefore be considered in those not responding to conventional treatment.

2197

CORRELATION BETWEEN PAIN SENSITIVITY AND HYPERGLYCAEMIA A CLINICOEXPERIMENTAL INVESTIGATION

AK Das, GRK Sharma, S.Ramasamy, Pondicherry, India.

The aim of the study was to assess the relationship between blood glucose levels and pain perception in 12 streptozotocin induced diabetic rats and in 16 fresh uncomplicated untreated diabetic patients before and after blood glucose control and in 10 healthy normal controls before and after meals. In rats the mean blood glucose before and after streptozotocin injection and after insulin therapy was 55.16 ± 3.23 mg/dL, 118.66 ± 14.42 mg/dL and 63.75 ± 3.26 mg/dL respectively. The corresponding tail flick latencies (in seconds) were 14.99 ± 0.64, 8.3 ± 0.42 and 12.98 ± 0.50 respectively ($p<0.001$). The corresponding tail clamp latencies were 19.17 ± 1.45, 8.88 ± 0.86 and 17.25 ± 1.32 sec. respectively ($p<0.001$). In diabetic patients the blood glucose before and after controlling diabetes was 323.37 ± 28.99 and 110.93 ± 5.48 mg/dL and corresponding ischemic pain threshold and tolerance was 12.37 ± 0.87, 30.87 ± 3.11 and 22.43 ± 1.08, 46.62 ± 3.01 sec. respectively ($p<0.001$). The blood glucose before and after meals in control was 80.10 ± 3.09 and 153.20 ± 3.06 mg/dL respectively. The corresponding ischemic pain threshold was 34.50 ± 3.16 mg/dL and 21.30 ± 1.94 sec. respectively and tolerance was 5.00 ± 2.68 and 39.20 ± 1.83 sec. respectively ($p<0.001$). It is concluded that both in experimental and clinical studies hyperglycaemia produced hyperalgesia and the latter was reversible with control of the blood glucose.

2198

DOUBLE BLIND TRIAL OF MEXILETINE ON DIABETIC PAINFUL NEUROPATHY

K. Matsuoka[1], Y. Kanazawa[2], M. Ohtake[3] and S. Kaihara[4]
A Diabetic Painful Neuropathy Study Group: Saiseikai Diabetes Center, Tokyo, Japan[1], Omiya Medical Center, Jichi Medical School, Omiya, Japan[2], Nippon Medical School, Tokyo, Japan[3], Okura National Hospital, Tokyo, Japan[4]

Acute painful neuropathy may follow either a period of unstable glycemic control or sudden normalization of hyperglycemia, and is most annoying for patients. Mexiletine (MX) is a common anti-arrhythmic agent which has been found to be useful on painful diabetic neuropathy by Dejgard in 1988. The symptomatic effect of MX was studied in a multi-center trial using 118 patients (male:76, female42, age:33-75) with painful neuropathy by double blind method after obtaining written consent. MX 100 mg tablet or placebo was given p.o., t.i.d. for two weeks. A dose finding study conducted previously has proven MX 300 mg/day to be adequate. The effect was evaluated by a 7 grade-score from "extremely severe" to "none" classified by patients. The effect was considered improved when two or more grade improvement was documented. The ratio of improvement on allodynia and shooting pain of the lower extremities was 18/43(41.9%) at the end of the 1st week while in the placebo group 8/46(17.4%) ($p<0.05$), and at the end of the 2nd week 29/55(52.7%) and 11/56(19.6%)($p<0.001$), respectively concerning numbness of the extremities, no significant effect was observed. The incidence of adverse events was not different in both groups. Objective findings, such as motor conduction velocity, vibratory perception threshold and heart beat variation remained unchanged in both groups. From the above results we concluded that MX is useful as a symptomatic agent of controlling acute pain and allodynia accompanied by diabetic neuropathy possibly through its Na-channel blocking mechanism.

2199

THE ALDOSE REDUCTASE GENE IS STRONGLY ASSOCIATED WITH DIABETIC NEUROPATHY IN PATIENTS WITH IDDM

A.E. Heesom, B.A. Millward and A.G. Demaine. Plymouth Postgraduate Medical School, University of Plymouth, Plymouth, England.

The role of the aldose reductase gene (ALR2) in susceptibility to diabetic neuropathy was investigated by analysing a microsatellite marker in the 5'end of the gene in patients with IDDM. DNA from 159 British caucasoid patients with IDDM and 102 normal healthy controls were typed for a (CA) dinucleotide repeat polymorphic marker in the 5' region of ALR2 (5'ALR2) using the polymerase chain reaction. Seven alleles (Z-6 to Z+6) were detected in the patients and controls. The patients were categorised according to the presence or absence of overt neuropathy (symptoms of pain, numbness or parathesiae in the feet and/or hands; loss of vibration and/or temperature; loss of reflexes in legs; history of neuropathic foot ulceration). There was a highly significant decrease in the frequency of the Z+2 5'ALR2 allele in patients with neuropathy - 'neuropaths' (n=78) compared to those with no neuropathy, retinopathy or microalbuminuria after 15 years of diabetes - 'uncomplicated' (n=38) (14.1% vs. 38.2% $\chi 2$ =17.3, $p<0.00001$, Pc=0.0001). There was a corresponding decrease in the frequency of the Z-2 allele in the uncomplicated group compared to the neuropaths (11.8% vs. 30.2% $\chi 2$ =9.3, $p<0.0025$, Pc=0.025). The neuropaths had an decreased frequency of the Z/Z+2 5'ALR2 genotype compared to the uncomplicated group (14.0% vs. 44.7% $\chi 2$ =13.0, $p<0.0005$, Pc=0.005, Odds Ratio 5.0). These results strongly suggest that the ALR2 or an adjacent locus is implicated in the susceptibility to diabetic neuropathy.

ACUPUNCTURE FOR THE TREATMENT OF CHRONIC PAINFUL PERIPHERAL DIABETIC NEUROPATHY: A LONG-TERM STUDY

B Abuaisha, J Borg-Costanzi and AJM Boulton. Dept of Medicine, Manchester Royal Infirmary, University of Manchester, UK.

Forty-six diabetic patients with chronic painful peripheral neuropathy were treated with acupuncture analgesia to determine its efficacy and long-term effectiveness. Twenty-nine (63%) patients were already on standard medical treatment for painful neuropathy. Patients initially received up to six courses of classical acupuncture analgesia over a period of 10 weeks, using traditional Chinese Medicine acupuncture points. Forty-four patients completed the study with 34 (77%) showing significant improvement in their primary and or secondary symptoms and in their ability to sleep at night ($p < 0.0001$ for all). These patients were followed up for a period of 13-52 weeks with 67% were able to stop or reduce their medications significantly. During the follow up period only eight (24%) patients required further acupuncture treatment. Although 34 (77%) patients noted significant improvement in their symptoms, only seven (21%) noted that their symptoms cleared completely. The response to treatment was better in white Caucasians (26/31 (84%) compared to Asians and Afro-Caribbeans (8/13 (62%), but this difference was not statistically significant. All the patients but one finished the full course of acupuncture treatment without reported or observed side effects. There were no significant changes either in the peripheral neurological examination scores, VPT or in HbA1c during the course of treatment. These data suggest acupuncture is a safe and effective therapy for the long-term management of painful diabetic neuropathy, although its mechanism of action remains speculative.

2201

EARLY DETECTION "SMALL FIBERS" NEUROPATHY IN INSULIN-DEPENDENT AND NON INSULIN-DEPENDENT DIABETIC PATIENTS

*A. Gabriele, S. Morano,*P. Rossi, *C. Froio, *A. Morocutti,*M. D'Alessio, L. Guidobaldi, R. Cipriani,*E. Valle and**G. Pozzessere. Endocrinology, *Neurology, University "La Sapienza", Rome, **I.R.C.C.S., Isernia, Italy.*

Diabetes causes widespread damage to the peripheral nervous system involving both somatic and autonomic fibers. Small nerve fibers abnormalities seem to precede large fibers involvement; nevertheless diabetic neuropathy is generally assessed with electrophysiological tests which reflect only large fibers function. Aim of this study was to evaluate the integrity of small fibers in insulin-dependent (IDDM) and non insulin-dependent (NIDDM) diabetic patients without either clinical or electrophysiological evidence of actual neuropathy. Twentyfour diabetic patients underwent neurophysiological study by means of CO2-laser induced Pain-Somatosensory Evoked Potentials (P-SEPs) and infrared TV-Pupillometry: twelve IDDM (age 33±9 years, duration of disease 15±7 years, %HbA1c 7.1±1.8) and twelve NIDDM (age 55.3±8.6 years, duration of disease 9.5 ±6.5 years, %HbA1c 6.8±1.5) without either nephropathy or retinopathy and with normal Visual Evoked Potentials (VEPs). P-SEPs following hand and foot stimulation were evaluated considering the latency of positive peak of cortical waves (P340 and P400, respectively). With regard to pupillometric exams (ISCAN, sample rate 50 Hz) we measured sympathetic (mydriatic reaction to darkness, MI) and parasympathetic (Latency, L, Amplitude, A, of light reflex) indexes. In both two groups the percentages of abnormalities of P400 and parasympathetic indexes (L and A) were 25% and 8%, respectively. In addition, the percentages of abnormalities of P340 and MI were, respectively, 8% and 42% in IDDM and 17% and 33% in NIDDM patients. Our results show an involvement of autonomic and small unmyelited somatic fibers in diabetic subjects with negative clinical and electrophysiological exams. Abnormalities mainly affect foot P-SEPs and pupillary sympathetic indexes, suggesting a length related pattern. The alterations of pupillometric parameters and P-SEPs did not correlate, indicating that somatic and autonomic nerve fibers may be differently affected by diabetic neuropathy.

2202

TREATMENT OF DIABETIC NEUROPATHY.

Strokov I., Ametov A., Smirnova V., Mjasoedov S., Balashova T., and Ivanova L. Russian Academy For Advanced Medical Studies, Ins. of General Pathology and Pathophysiology RAMN, Moscow, Russia.

The aim of this study was to compare the effect of anti-oxidant and bloker serotonin receptors for the treatment of diabetic neuropathy (DN). 94 patients with type I or type II diabetes mellitus and DN were included in this study (mean age 51,80±1,16; disease duration - 11,35±0,56 years). In all patients the expressiveness of DN was carried out with MDNS. The thiobarbituric acid reactive material was determined in the serum of all patients and in the membrane erythrocytes of the patients with IDDM as malondialdehyde (MDA). NCV was determined in the median, peroneal, sural nerves in 60 patients. 47 patients were treated with Tanacan (EGb 761, Beaufour-ipsen)-200 mg, other-Dusodril (Naftidrofuril, Byk Gulden)-120 mg during 6 weeks.

	Dusodril		Tanacan	
	before	after	before	after
MDNS	9,02±0,66	2,64±0,38**	7,73±0,36	2,74±0,28**
MDA in serum	1,07±0,08	0,68±0,04**	1,11±0,15	0,58±0,03**
MDA in membr.	1,17±0,05	1,28±0,05	1,20±0,09	0,84±0,07*
HB A1c	8,81±0,32	7,85±0,29	8,43±0,34	7,74±0,30
SNCV(normal)	81,07±27,38	114,00±30,70*	87,70±35,82	95,50±39,19
MNCV(normal)	102,45±21,2	123,10±18,85*	93,67±20,3	105,59±9,88*

* $p<0,01$, ** $p<0,001$ - compared with baseline values.

The decreased in MDA for the functional state of nerves when using drugs of different mechanism will be discussed.

2203

DOES MAGNESIUM DEPLETION PLAY A ROLE IN THE NATURAL HISTORY OF POLYNEUROPATHY IN INSULIN-DEPENDENT DIABETIC PATIENTS ? (IDDM)

W. Engelen, A. Bouten and I. De Leeuw. University of Antwerp, Antwerp, Belgium.

Chronic Mg depletion is frequently observed in IDDM and is related to an insufficient level of metabolic control. Since both conditions are also related to the development of microangiopathy and dyslipidemia a possible role in other complications like polyneuropathy (PNP) can be hypothesized. In a first study 154 IDDM (57 W + 97 M) were screened for PNP on the basis of clinical signs and symptoms supplemented by an extensive EMG exploration and repeated measurements of erythrocyte Mg (RBC Mg) were obtained. Group 1 consisted of 89 IDDM (23 W + 66 M) and presented with clear signs of PNP. Group 2 consisting of 65 IDDM (34 W + 31 M) does not have PNP. Group 1 has a higher HbA_{1c} (mean of 4 measurements, $p < 0.05$) a longer duration of diabetes ($p < 0.001$) and was older ($p<0.01$) than group 2. When each group was subdivided on the basis of low RBC Mg (< 2.3 mMol/l) Fisher's Exact Test shows a significant association between this value and the presence of PNP (p=0.0172, Odds ratio=2.389, 95% CI: 1.183 to 4.824). In a second study 23 IDDM (Group A= 14 W + 9 M) with both PNP and low RBC Mg accepted to take oral supplements of Mg during 1 year (300 mg Mg^{++} daily) and were compared to 20 identical patients (Group B = 5 W + 15 M) who did not agree to participate. In Group A 10 patients (9 W + 1 M) showed a significant improvement in the EMG data as compared to 2 patients (2 M) in Group B (Fisher's Exact Test: p=0.0193, OR = 6.923, 95% CI: 1.293 to 37.066). The patients who improved were younger ($p<0.02$) had a shorter duration of diabetes ($p<0.05$) but no differences in metabolic control was observed. The physiopathological mechanisms involved in this observation are unclear but one can speculate on an improvement of the microcirculation, a lesser oxidative stress or a better energy supply in the peripheral nervous system.

2204

THIAMINE STATUS IN NIDDM PATIENTS WITH SOMATIC NEUROPATHY

G. Jermendy, É. Noll, J. Perényi and E. Dworschák. Bajcsy-Zsilinszky Hospital, Budapest, Hungary.

Thiamine deficiency can result in neurological damage. In order to asses the thiamine status 75 NIDDM patients (age 38-74 years) and 60 age matched control subjects were investigated. Thiamine status was assessed by measurement of erythrocyte transketolase activity (αETK; normal range: 1.00-1.27). Neuropathy was evaluated by determination of both motor nerve conduction velocity (MNCV; n. peroneus) and sensory nerve conduction velocity (SNCV; n. suralis). The value of αETK was significantly higher in NIDDM patients than that of the control subjects (1.14±0.01 *vs* 1.08±0.02 x±SEM; p<0.01). Optimal levels of αETK (1.00-1.15) were observed in 45 patients (60%) whereas 26 patients (35%) were at moderate risk (αEKT 1.16- 1.27) and 4 patients (5%) at high risk (αEKT>1.27) of inadequate thiamine status. Significant difference was observed between patients with (n=23) and without (n=22) neuropathic symptoms regarding αETK (1.19±0.02 *vs* 1.10±0.01; p<0.001), MNCV (37.4±1.2 m/s *vs* 43.4±0.9 m/s; p<0.001) and SNCV (34.4±2.4 m/s *vs* 40.5±1.5 m/s; p<0.05). Short term use of benfothiamine (320 mg daily for one week) resulted in an improvement of thiamine status (αEKT 1.10±0.02 *vs* 1.01±0.01; p<0.01). Non-optimal thiamine status could be observed in some NIDDM patients with somatic neuropathy.

2205

NON-ENZYMATIC SERUM ANTI-OXIDANTS IN PATIENTS WITH DIABETIC NEUROPATHY.

JH Assink [1], RP Stolk [2], DE Grobbee [1,2], HGT Nijs [1], AF Casparie [1] and HJG Bilo [3], 1) Erasmus University, Rotterdam, 2) Utrecht University, 3) De Weezenlanden Hospital Zwolle, The Netherlands.

Evidence is accumulating that oxidative stress may play a role in the development of diabetic complications. We therefore studied the relation between nonenzymatic serum anti-oxidants (NSA's) and diabetic neuropathy (DN) in 278 consecutive patients with insulin-dependent diabetes mellitus (IDDM) (153 men ,125 women; mean age 38.1 years (SD 12.0), duration of IDDM 17.2 years (SD 10.2) HbA1c 8.2 % (SD 1.89)). DN was assessed by vibration threshold measurements (both legs and arms) and sensibility testing (legs only). DN was defined by the presence of one or more abnormal tests results. The table gives the NSA's (mean and standard error) in diabetic subjects with (91 men and 55 women) and without DN.

	DN-	DN+
α-Tocopherol (umol/l)	30.7 (7.2)	32.0 (10.9)
γ-Tocopherol (umol/l)	2.93 (1.59)	3.05 (1.99)
β-Caroteen (nmol/l)	299 (184)	370 (422)
Retinol (umol/l)	1.80 (0.48)	1.86 (0.85)
Cerruloplasmin (g/l)	0.39 (0.14)	0.37 (0.12)
Ferritin (g/l)	80.6 (70.2)*	104.0 (103.2)*
Transferrin (ug/l)	2.31 (0.39)*	2.17 (0.40)*
Uric acid (mmol/l)	0.24 (0.06)	0.25 (0.07)

Oneway Anova:* p<0.05

After adjustment for age and gender, no difference was found between patients with and without diabetic neuropathy. These results suggest that non-enzymatic antioxidants are not related to the presence of diabetic neuropathy.

Neuropathy – Autonomic

2206

PATHOGENESIS OF AUTONOMIC NEUROPATHY IN MALNUTRITION RELATED DIABETES MELLITUS

A.K.Azad Khan[1], H..Z.Rahman[2], L. Ali[1], A. Haque[1], N. S. Chowdhury[1], J.M.A.Hannan[1] and Z. Hassan[1]; *[1] BIRDEM, [2]Dept of Neurology, IPGMR, Dhaka, Bangladesh*

Autonomic neuropathy (AN) is known to be a common complication in both IDDM and NIDDM patients. Although malnutrition related diabetes mellitus (MRDM) constitutes an important class of diabetes in tropical developing countries, the prevalence and pathogenesis of AN have not yet been studied in MRDM patients. The present study was designed to explore the relation of AN with glycemic status, insulin secretory capacity and microvascular damage in MRDM subjects. Seventeen newly diagnosed MRDM (9 PDDM and 8 FCPD) along with 24 NIDDM and 21 non-diabetic Control subjects were studied. Autonomic neuropathy was diagnosed by estimating the Valsalva Ratio (VR), deep breathing test (DBT), hand grip test (HGT) and postural blood pressure test (PBPT). Glycemic status was measured by serum glucose response during a standard OGTT and by HbA_{1c}. Insulin secretory status was measured by fasting serum C-peptide and generalized microvascular damage was estimated by Transferrin-Creatinine ratio (TCR). The Control group showed no case of AN, but 14% of the total diabetic subjects showed this complication. Both DBT and VR ratio were significantly (p<0.05) lowered in patients with AN group. The abnormalities in these two autonomic function tests appeared earlier than the other two tests. PDDM patients showed considerably higher prevalence of AN compared to NIDDM subjects (FCPD 38% and PDDM 22% vs NIDDM 4%). Patients with poor glycemic control showed higher percentage of autonomic neuropathy. Fasting C-peptide levels in MRDM subgroup were much lower (p<0.0001-0.001) than the NIDDM and Control groups. indicating that both glycemic status and insulin secretory capacity may be crucial factors in the pathogenesis of neuropathy in these subjects. From the TCR data (Control-0.04 mg/mmol, PDDM - 0.10mg/mmol and FCPD - 0.06 mg/mmol) the diabetic groups were found to have higher microvascular damage in relation to Control but the three groups did not differ among themselves. It may be concluded that MRDM subjects appear to suffer from increased incidence of AN. Glycemic and insulin secretory status seems to be the most important factors in developing neuropathy in these cases and it may develop independently from generalized microvascular damage.

2207

CORRELATES OF SEVERE DIABETIC AUTONOMIC NEUROPATHY.

SA Godbole, KK Deepak, K. Kochchar, SS Srikanta, P.Shah-and N. Kochupillai All India Institute of Medical Sciences, New Delhi, India

Severe autonomic neuropathy is proposed as being predictive of mortality of diabetes mellitus (DM). We performed each of five non-invasive cardiovascular reflex tests for autonomic function (heart rate responses to deep breathing, Valsalva maneuvre, and tilting; blood pressure responses to isometric hand grip and postural change) in 23 consecutive DM patients (mean age 50.17 years; DM duration 10.9 years) and 25 age and sex matched healthy controls. Based on a standardised scoring system for autonomic dysfunction, DM patients were divided into "Borderline DAN" (B-DAN, n=12 DAN score 2-5) and "Severe DAN" (S-DAN, N=11, DAN score 5). S-DAN (vs B-DAN) was associated with increased age (55 10 vs 45 10 yr; p <0.03) DM duration (12+5.9 vs 9.6+7.4 yr), insulin treatment (63.6% vs 33.4%) and reduced nerve conduction amplitude and velocity (p <0.007 to p <0.02). There was no significant difference in fasting blood glucose and glycated hemoglobin between S-DAN and B-DAN. Thus, non-invasive testing is essential to indicate severity of DAN. S-DAN patients tend to be older, have longer DM duration and higher incidence of peripheral neuropathy.

2208

PANCREATIC POLYPEPTIDE SECRETION AND FASTING SERUM GASTRIN LEVELS IN DIABETICS WITH AUTONOMIC NEUROPATHY

J. Loba, L. Czupryniak, and M. Saryusz-Wolska. Diabetology Dept., Medical University of Łódź, Łódź, Poland.

Test meal-stimulated pancreatic polypeptide (PP) secretion is much lower in diabetics with autonomic neuropathy (AN) than in controls. It is also well established that fasting serum gastrin (FSG) levels are very high in diabetics with AN. These findings are said to result from one pathology: autovagotomy. The aim of this study was to identify the relationship of high FSG levels and blunt PP response to meal stimulus in diabetics with AN. The study subjects were 17 long-standing insulin dependent diabetics with AN (group A) and 18 well-matched diabetics without AN (group B); the latter group serving as controls. Autonomic neuropathy was tested in all the patients, using 5 common tests. FSG and PP concentrations were asessed by radioimmunologic methods. The PP secretion was evaluated for two hours on test meal ingestion and calculated as an area under curve (AUC). The mean FSG level in diabetics with AN was 134.12 ± 50.48 pg/ml compared to 82.0 ± 30.72 pg/ml in the control group ($p<0.001$). Inversely, the AUC of PP secretion values were much lower in group A than in the group B (mean 302.70 ± 72.55 vs 412.94 ± 73.65 pg/ml/2h respectively; $p<0.001$). There was also a significant negative correlation ($r = -0.5531$; $p<0.05$) between FSG and postprandial PP values in the diabetics with AN, whereas no such correlation was found in the controls ($r = 0.024$). In conclusion, high fasting serum gastrin levels in long-standing diabetics with autonomic neuropathy are accompanied by low postprandial pancreatic polypeptide secretion, and there is a negative correlation between these two phenomena.

2209

AUTONOMIC FUNCTION TESTING: MORNING OR AFTERNOON?

C. Rossi, M. Veglio, A. Grassi, M. Deandrea and D. Fonzo. Divisione di Endocrinologia, Ospedale Mauriziano, Torino, Italy

The cardiovascular tests for the diagnosis of autonomic neuropathy are usually performed in fasting conditions in the morning: however, the morning session is often unpractical in our hospital setting. The study aimed to verify if an afternoon session would lead to substantially different results. Ten patients (5 males, 5 females; 5 treated with insulin, 5 with hypoglicaemic agents, mean age 49.8 years, range 15-68) were submitted to a battery of cardiovascular tests: Deep Breathing (DB), Cough test (CT), Lying to Standing (LST), Postural Blood Pressure test (PBPT), Squatting test (SQv and SQs), corrected QT interval (QTc), Basal Heart Rate (HR). The test were performed at 8.00 AM and 2.00 PM; according to accepted criteria, each test was scored as normal (0), borderline (1) or abnormal (2). Patients with a total score >=4 were considered as affected by autonomic neuropathy . Patients abstained from drugs, insulin and from breakfast or lunch respectively. Mean glycemia was 114.9 and 128.2 mg/dl (NS) prior to the tests. No significant difference was observed in the mean results obtained for each test in the mornings and afternoons. The coefficient of variation (CV) for the repeated measures were as follows: DB 13.4%, CT 4.4%, LST 5.8%, PBPT 29.6%, SQv 6.7%, SQs 6.85%, QTc 2.0%, HR 3.0%. The scores varied in 1 patients from normal to abnormal for SQv, and from abnormal to normal in 2 patients for SQs. The mean total score was 3.9 in both occasions: one patient was considerd neuropathic in the afternoon session only (score 3 in the morning, 5 in the afternoon). In conclusion the CV for repeated measures in morning and afternoon sessions are similar to those published for repeated morning measures in the morning. Cardiovascular testing performed in fasting conditions in the afternoon do not lead to significant difference in patients classification.

2210

PATHOLOGICAL GLUCOSE TOLERANCE TEST: INCIDENCE OF AUTONOMIC SKIN'S NEUROPATHIES.

P.Költringer and F.Reisecker. Barmherzige Brüder Hospital Graz-Eggenberg, Department of Neurology, Graz, Austria.

It was the aim of this pilot study, to answer the question, if in patients suffering from pathological glucose tolerance test already autonomic skin's dysfunction can be objectivied.

30 subjects suffering from pathological glucose tolerance test since more than 2 years (group A) and 30 age-machted healthy subjects (group B) were studied for their function of autonomic nervous system in skin. Basing on the hyperthermal Laser-Doppler-Flowmetry, a method invented in 1988, it is possible to measure autonomic skin's neuropaties in routine use. The basic consideration of this new method is the fact, that a healthy autonomic nerve function reacts to hyperthermia with an increase of microcirculation after a well defined time without any severe fluctuations. In autonomic neuropathies during the perfusion increase there are severe fluctuations, defined as „Fluctuationindex" (FI) measured in percentage (normal range: ≤20%).

In group A the median of FI was 26% (IR25:11%, IR75:36%), whereas values of group B showed a median of 13% (IR25: 9, IR75:17). The incidence of pathological values (PI >20%) was 26,67% (8 of 30 patients) in group A against 0% (0 of 30 patients) in group B.

The results lead to the conclusion, that patients with pathological glucose tolerance test already develope autonomic neuropathies.

2211

THE VALUE OF COLD PRESSURE TEST IN ASSESSMENT OF SYMPATHOVAGAL BALANCE IN IDDM PATIENTS

J. Sieradzki, D. Galicka-Latała, *A. Surdacki and * J. Dubiel. Depts. of Metabolic Diseases and *Cardiology, Jagiellonian University, Kraków, Poland

Heart rate variability (HRV) offers a new method in investigating mechanisms of sudden death in diabetic patients with advanced diabetic complications. Our aim was to show the earliest changes in the balance of cardiovascular autonomic system. In 96 patients with insulin dependent diabetes (mean: age: 33.4 years, diabetes duration 10.54 years) who received insulin as the only medication and 30 healthy volunteers (mean age: 31.0 years) the following tests using short-term heart rate variability analysed by ProSciCard were performed: 5 minutes at rest (heart rate - HR-R, standard deviation - SD-R, RMSSD-R, MCR-R, sectral power at: very low frequency VLF-R, low frequency LF-R, high frequency HF-R), and 5 minutes after cold pressor test (HR-CPT, SD-RCPT, RMSSD-CPT, MCR-CPT, VLF-CPT, LF-CPT, HF-CPT). The standard Ewing battery od autonomic tests was also performed. We compared healthy group with IDDM patients without retinopathy (R0), with nonproliferative retinopathy (R1) and with proliferative retinopathy (R2). Retinopathy was assess by ophtalmoscopy.

Results: The following parameters had the highest strenght of discrimination between examined groups: **Group C vs R0:** SD-RCPT (80.68 vs 48.54ms; p=0.0004), ln HF-CPT (0.72 vs -0.10; p=0.01), ln LF-CPT/HF-CPT (-0.38 vs 0.24; p=-0.02), RMSSD-CPT (86.98 vs 40.92; p=0.0001), **Group C vs R1:** LnHF-R (-0.3974 vs -1.53, p=0.002), SDHR-CPT (80.68 vs 46.81, p=0.03), Ewing test: 0.82 vs 0.97, p=0.0002), Ln HF-CPT (0.72 vs -0.62, p=0.04), **Group C vs R2:** HR-CPT (63.57 vs 79.52, p=0.0003), RMSSD-R (60.19 vs 12.95, p=0.00001), RMSSD-CPT (86.98 vs 22.12; p=0.001), Ln HF-CPT (0,72 vs -1.10; p=0.002), **Group R0 vs R1:** ln LF-CPT (0.13 vs -0.75; p=0.001), ln LF-CPT/HF-CPT (0.24 vs -0.12; p=0.04),**Group R0 vs R2:** HR-CPT (68.59 vs 79.52; p=0.0000006), SD-RCPT (48.54 vs 28.53; p=0.0002), ln LF-CPT (0.13 vs -1.38; p=0.0000001), Ln HF-CPT (-0.10 vs -1.10; p=0.0005), ln LF-CPT/HF-CPT (0.24 vs -0.28; p=0.04), RMSSD-CPT (40.92 vs 22.12; p=0.02).

Conclusions: 1. Development of retinopathy is associated with marked changes of high frequency domain of HRV. 2. Spectral analysis of HRV detects more discret disorders in autonomic function than conventional tests.

2212

Moisture measurement of the skin
- A simple test to determine diabetic autonomic neuropathy -
S. Ota, Y. Sato and T. Toyota, Sendai, Japan.

It is very useful to measure sweating for diagnosis of diabetic autonomic neuropathy. However, there is a few simple test to measure sweating in clinical practice. Therefore, we analyzed the usefulness of moisture measurement of the skin to determine diabetic autonomic neuropathy. 28 diabetic patients and 11 healthy volunteers joined to the study. Mental sweating rate of the thumb and the first toe were measured with Kenz Perspiro OSS-100 (Suzuken, Nagoya, Japan), a devise to measure local sweating rate of patched 1 cm^2 area continuously. Sweating responses to calculation, scratch, standing and deep breathing were examined. Heart rates were also measured continuously. Moisture of the skin were measured by moisture checker (Scalar, Tokyo, Japan), a skin moisture measuring devise. Because the sweating response to deep breathing is a good test to measure autonomic function, subjects were divided into 2 groups according to the response pattern (Group A : good responders, Group B : poor responders). Skin moisture measured by the moisture checker correlated well with sweating rate measured by Kenz Perspiro OSS-100. Skin moisture of the thumb and the toe were significantly decreased in group B compared with that in group A. These results indicate moisture measurement of the skin is useful to determine diabetic autonomic neuropathy.

2213

ALTERED CIRCADIAN BLOOD PRESSURE CHANGE IN IDDM PATIENTS WITH NORMAL BEDSIDE TESTS OF AUTONOMIC FUNCTION

PJ Weston, PG McNally, H Thurston.
Dept of Medicine and Therapeutics, Leicester Royal Infirmary. UK

The presence of hypertension is an important determinant of cardiovascular risk in IDDM patients. A reduced nocturnal fall in blood pressure is a recognised abnormality in BP in IDDM patients and may be related to autonomic dysfunction. The aim of this study was to assess the relationship between circadian blood pressure change, baroreceptor-cardiac reflex sensitivity and sympathovagal balance in patients with normal bedside tests of autonomic function. 31 normotensive, normoalbuminuric IDDM patients and 31age, sex and BP matched control subjects were studied.24hour ambulatory BP was measured using the SpaceLabs 90207 system and circadian change in BP assessed by Cusums analysis. Heart rate and blood pressure variability was assessed,using spectral analysis, from data recorded non-invasively using the Finapres system. The α index, a measure of overall baroreflex gain was assessed from the frequency domain data. There was a significant reduction in high frequency power of heart rate variability in the IDDM group (Mean $\pm$ SEM: 22 ± 3.1 vs 33 ± 3.1 NU $p < 0.002$). In addition, BRS was significantly reduced in the IDDM group (9.7 ± 3.7 vs 18.5 ± 4.7 ms/mmHg $p < 0.001$). Sympathovagal balance (the ratio of low frequency to high frequency power) was increased in the IDDM group (4.6 ± 0.55 vs 2.9 ± 0.52 $p < 0.002$). IDDM patients showed a significant reduction in circadian variation of blood pressure (Cusum Derived Circadian Alteration of Magnitude: CDCAM=15.4 ± 5.7 vs 25.6 ± 7.3 mmHg $p < 0.003$). There was a significant negative correlation between sympathovagal balance and CDCAM ($r = -0.5$ $p < 0.05$). Reduced circadian change in blood pressure is seen in IDDM patients with normal bedside tests of autonomic function and may be due to an increased sympathetic predominance. This would increase cardiovascular risk amongst IDDM patients.

2214

Evaluation of skin vasoconstrictor responses to deep breath in diabetes by using laser Doppler flowmetry

Yoshimasa Aso, Toshihiko Inukai, Yoshihiro Takemura
Koshigaya Hospital, Dokkyo University School of Medicine, Koshigaya, Japan

To elucidate peripheral sympathetic neuropathy in patients with diabetes, we measured the vasoconstrictor responses to deep breath in the feet of 51 non-insulin-dependent diabetes mellitus (NIDDM) and 20 healthy control subjects, using laser Doppler flowmetry. Subjects whose skin temperature was less than 32°C were excluded from our study because a skin temperature of approximately 34°C is an optimal temperature to detect skin vasomotor reflexes to deep breath by laser Doppler flowmetry.

Vasoconstrictor responses to deep breath in the big toe of diabetic patients were significantly reduced compared with healthy controls (26.8±20.0% vs. 48.3±18.5%, P<0.0001). In NIDDM patients, the percent vasoconstriction was positively correlated with diabetes duration, median motor and sensory nerve conduction velocity, coefficient variation of R-R interval on electrocardiogram at rest and postural fall in systolic blood pressure, and inversely correlated with vibratory perception threshold. Vasoconstrictor responses to deep breath in diabetic patients with progressive retinopathy or overt nephropathy were significantly decreased than in those with no retinopathy or normoalbuninuria. These results suggest that vasomotor reflexes to deep breath in the lower limb of diabetic patients is markedly impaired and decreased in parallel with others diabetic neuropathy or diabetic microangiopathy, and that measuring of vasoconstrictor responses to deep breath by using laser Doppler flowmetry is a novel and useful tool for detecting peripheral sympathetic failure in diabetes.

2215

DECREASED PARASYMPATHETIC TONE IN YOUNG IDDM PATIENTS.

C.Saloranta, K.Tahvanainen, M.Lipsanen-Nyman, T.Kuusela and H.Åkerblom. The Children's Hospital, University of Helsinki, Helsinki, Department of Clinical Physiology, University of Tampere, Tampere, and Department of Applied Physics, University of Turku, Turku, Finland.

Cardiac autonomic dysfunction is associated with diabetic complications such as nephropathy and retinopathy, and may carry an increased risk of mortality. Using new methods to study cardiac autonomic function an early detection of cardiac autonomic dysfunction is possible. To evaluate the cardiac autonomic function in young diabetic patients we studied 7 (4M/3F) insulin-dependent diabetic and 10 (5M/5F) healthy control subjects aged 14.2 ± 1.3 yr (mean $\pm$ SEM, range 8.1-18.0 yr) and 13.9 ± 0.9 yr (8.6-18.0 yr), respectively. The diabetic patients had a duration of diabetes of 5.1 ± 0.8 yr (1.5-7.3 yr) and HbA_{1c} of 9.6 ± 0.6 % (8.0-12.5%). Heart rate and blood pressure variabilities were registered at rest for 5 min in the supine position, and analysed by power spectral analysis (CAFTS, Medikro Oy, Finland). In addition, conventional tests including the Valsalva, handgrip, and tilt table test were performed. At rest, diabetic patients had decreased heart rate variability in terms of root mean square of successive differences of RR intervals (RRI RMSSD; 42 ± 8 vs 89 ± 19 ms, $p < 0.05$), total power of RRI intervals (TP-RRI; 1952 ± 570 vs 6789 ± 2034 ms^2, $p < 0.05$) and RRI variability in the respiratory band (HFP-RRI; 1076 ± 295 vs 5042 ± 1819 ms^2, $p < 0.05$) compared to healthy controls. During the tilt table test, a decreased acceleration index (19 ± 2 vs 31 ± 3 %, $p < 0.05$), and brake index (13 ± 2 vs 27 ± 5 %, $p < 0.05$) was seen in the diabetic subjects. All these abnormalities reflect mainly an impairment in the parasympathetic tone. There were no differencies in blood pressure variability, Valsalva or handgrip tests between the groups. In conclusion, an easily performed registration of resting heart rate variability reveals autonomic abnormalities even in young IDDM patients. The dysfuntion is seen in parameters mainly reflecting parasympathetic tone.

2216

QUANTITATIVE ASSESSMENT OF DIABETIC AUTONOMIC NEUROPATHY BY ACCELERATED PLETHYSMOGRAPHY

N.Ueda, T.Aoki, T.Yamaguchi, K.Kosugi and Y.Shimizu. Osaka Police Hospital, Osaka, Japan.

AIM It is well known that accelerated plethysmogram (APG) is useful for assessing peripheral circulation. In this study, we attempted to evaluate diabetic autonomic nervous dysfunction by the difference (APGD) of APG index (APGI) between before and after cold water stress test .

SUBJECTS Fifty thee healthy volunteers as control group NC (age 54.3± 7.2yr), age-matched 48 diabetics without neuropathy as group DMN- (age 55.4±8.9yr, duration 5.3±3.4yr, HbA1c 8.4±2.6%), and age-matched 46 diabetics with neuropathy as group DMN+ (age 56.2±8.6yr, duration 13.6± 4.2yr, HbA1c 9.2±1.8%) were enrolled into the study.

METHOD First, the subjects were sitting during 5 minutes, and then APGI were measured from the right second finger , using APG-200 (Misawa Co. Ltd.) that automatically calculates APGI from plethysmogram. Second, their left hand was kept dipping in cold water (3℃) and APGI was acquired in the same way. The differences of APGI between before and after cold water test were calculated as APGD.

RESULTS There was no significant difference between NC and DMN- in APGD, but APGD in DMN+ was significantly lower than the other two groups. APGD significantly correlated with coefficient of variation of ECG R-R intervals (CV) in diabetics ($r=0.58$, $p<0.001$). There was significant reverse correlation between APGD and diabetic duration ($r=-0.42$, $p<0.003$). After one month strict blood glucose control of diabetics with relatively short duration (less than 5 years), APGD significantly increased (10.8±5.4 vs 28.7±6.3%, $p<0.01$), but CV did not significantly changed.

CONCLUSION This study shows that APGD is useful to estimate autonomic nervous dysfunction in peripheral circulation and its improvement after strict blood glucose control in diabetics.

2217

DETERIORATION OF CARDIOVASCULAR AUTONOMIC FUNCTION OF DIABETIC PATIENTS IN TWO YEARS .

D.T.Karamitsos, T.P.Didangelos, A.K. Koumaditis, V.G. Athyros, G.I. Kourtoglou.

Diabetes Center, Hippocration Hospital , Thessaloniki ,Greece.

Autonomic neuropathy sometimes carries a poor prognosis and increased risk of mortality from sudden death. The aim of this study was to clarify the natural history of autonomic neuropathy in diabetic patients. Methods: We studied 30 diabetic patients, 8 IDDM and 22 NIDDM, with mean duration of diabetes of 17.3 years (range 10-41) and mean age 54.3 years(range 26-65). Patients aged more than 65 years old or those with overt nephropathy or heart disease were excluded from this study. The HbA1c(%) remained actually unchanged during the study period and was 9.3±0.27(se) the higher and 8.9±0.27 the less(p=NS). We used the apparatus Monitor ONE NDX that helps to perform deep breathing test { Expiration /inspiration ratio(E/I R), standard deviation of R-R(SD), mean circular resultant of vector analysis(MCR), } Valsalva manoeuvre and the changes of R-R (postural index) from lying to standing. We also observed the postural hypotension. All the parients had two or more of the tests abnormal. Results: Deterioration was observed in all the tests performed comparing the baseline with two years. E/I index from 1.073±0.0006(se) in 1.043±0.005, $p<0.0001$, SD from 26.6±2.3 in 17.9±1.9, $p<0.0001$, MCR from 12.6±1.64 in 8.23±1.39, $p< 0.0002$, Valsalva index from 1.3±0.03 in 1.2±0.03, $p< 0.0001$, postural index from 1.12±0.02 in 1.05±0.01, $p<0.0001$ and postural hypotension (mmHg) from 26.2±2.1 in 36.7±2.1, $p<0.0001$.The E/I ratio deteriorated statistically earlier than the other tests. Conclusions: Definite and statistically significant differences in the various tests of cardiovascular autonomic function in all the patients appear in two years of follow up. The E/I ratio is considered as the most sensitive test because it can detect the deterioration of autonomic function earlier. Although the clinical significance of these changes is difficult to be estimated, our findings emerge for early detection and treatment of autonomic neuropathy.

2218

CAN ACUTE INDIRECT COOLING BE USED TO ESTIMATE PERIPHERAL AUTONOMIC NEUROPATHY?

A. Ugarph, K. Brismar, B. Fagrell and G. Jörneskog. Department of Endocrinology and Diabetology, and Department of Internal Medicin, Karolinska Hospital, Stockholm, Sweden.

Easy non-invasive methods are desired to estimate peripheral autonomic nervfunction. The aim of this pilot study was to examine if an acute indirect cooling-test can be used to diagnose peripheral autonomic neuropathy in diabetic patients. Thirteen patients (5 women) with diabetes duration 16±9 years were examined (age 52±16 years; mean±SD). Five patients had no central autonomic neuropathy, while 4 had suspected and 4 had clear signs of central autonomic neuropathy. Eight patients had clinical signs of peripheral autonomic neuropathy (dry skin, loss of hair, impaired sweating). Eight healthy controls (25-65 years) were also examined. The skin microcirculation at the pulp of the left great toe was measured by laser Doppler fluxmetry (LDF) before and during cold exposure of the right hand for 90 s in icewater (4-6°C). LDF was measured in arbitrary units (AU). In 7 patients and 5 controls the skin microcirculation was simultaneously measured at the pulp of the left thumb and at the pulp of the left great toe. Before cooling, LDF in the left great toe was similar (ns) in patients (65±53 AU) and controls (42±24 AU). During cooling, LDF decreased ($p<0.05$) to 35±21 AU in the controls, while LDF in the patients was unchanged (62±47 AU). However, in 4 patients without autonomic neuropathy LDF decreased ($p<0.05$) during acute cooling. LDF in the left thumb decreased ($p<0.05$) during cooling in all patients and controls. In conclusion, in diabetic patients with central autonomic neuropathy reflective vasoconstriction was lost in the contralateral foot, but intact in the contralateral hand and in patients without autonomic neuropathy. Consequently, acute indirect cooling of the hand seems to be a useful method to investigate peripheral autonomic neuropathy in the feet.

2219

A MODIFICATION OF THE 30:15 AUTONOMIC FUNCTION TEST-EFFECT OF SQUATTING

N.Tentolouris, N.Katsilambros, A.Linos, E.Stamboulis and K.Papageorgiou. 1st Department of Propaedeutic Medicine and Neurologic Department, University of Athens, Greece

The classical 30:15 autonomic function test consists of the measurement of the RR cardiac intervals at the 30th and 15th cardiac beats immediately after standing up from the lying position. The present study deals with similar measurements (30:15) after resuming the standing position following a two-minute interval during which examined persons remained squatting. In order to investigate this, 105 diabetic persons (type 1: n=55; type 2: n=50) as well as 32 controls, serially matched (by age and sex) were examined. They underwent the standardized battery of the 5 Ewing tests and also the squatting test (SqT). Autonomic neuropathy was diagnosed if 2 of the 5 Ewing tests were abnormal. There were 40 diabetic persons (DP) without (AN-) and 65 with autonomic neuropathy (AN+). Sensitivity (S), specificity (Sp), positive (PPV) and negative predictive value (NPV) of the classical 30:15 (Clr) and SqT ratios (SqTr) are shown on table along with 95% confidence intervals (CI):

	Clr		SqTr	
	%	95% CI	%	95% CI
S	60.31*	51-69	68.25*	59-77
SP	54.36[1]	45-63	77.50[1]	77-78
PPV	44.70[2]	38-57	82.26[2]	74-79
NPV	69.13*	60-77	60.78*	51-70

(*: $p>0.05$, [1]: $p=0.0005$, [2]: $p<0.0001$)

The coefficients of variation were 6.91 and 6.94% for Clr and SqTr, respectively. The passage from squatting to the standing position caused greater tachycardia than the classical lying to standing test in all subjects. Until 15th beat all DP showed a similar response to heart rate. At the 30th beat, although the heart rate of AN- and controls was restored, AN+ continued to have tachycardia. The resulted low SqTr clearly indicates parasympathetic dysregulation. So, the greater cardiac stress after squatting seems to unmask an underlying parasympathetic damage to a greater degree than the classical test. Conclusions: 1) The proposed SqTr can discriminate between AN- and AN+ DP to a greater extent than the Clr. 2) SqTr gives information on parasympathetic activity.

2220

THE VARIABILITY OF THE PHOTOPLETHYSMOGRAPHIC SIGNAL - A MEASURE OF AUTONOMIC NEUROPATHY

M. Nitzan, A. Babchenko, S. Turivnenko and B. Khanokh. Jerusalem College of Technology, Jerusalem, Israel.

The heart rate and the arterial blood pressure show spontaneous low frequency oscillations, which are associated with the sympathetic nervous system activity. Similar fluctuations were also found in the photoplethysmographic (PPG) signal, which measures the tissue blood volume increase during systole. The latter depends on the compliance of the arterioles, which is affected by the sympathetic nervous system. The aim of the study was to compare the PPG signal variability in diabetic patients to that in non-diabetic subjects. The PPG signal was measured simultaneously on the index fingers of both hands of 16 non-diabetic and 7 diabetic patients. None of the diabetic patients showed clinical manifestations of neuropathy. The correlation coefficient of the PPG signal amplitude between the right and the left hand was 0.87 ± 0.08 for the non diabetic subjects, while four out of the seven diabetic patients had correlation coefficients of 0.47 – 0.75. The low correlation coefficient is probably due to autonomic neuropathy. The difference in the PPG amplitude between the two fingers was $9.4 \pm 10.2\%$ for the nondiabetic subjects, while four of the diabetic patients showed differences higher than 40%. In conclusion, the PPG variability provides a potential means for the assessment of the sympathetic neuropathy.

2221

AUTONOMIC NEUROPATHY AND HYPERTENSION IN INSULIN-DEPENDENT DIABETES MELLITUS: THERE IS A RELATIONSHIP

P.Kempler, I.Barna, A. Marton, É.Kádár, K.Keresztes, Zs.Hermányi, Á.Fazakas, P.Vargha and R.de Chatel. I.Dept. of Medicine, Semmelweis University, Budapest, Hungary.

Follow-up studies revealed poor prognosis of autonomic neuropathy (AN) in diabetic patients. Silent myocardial ischemia / infarction and major arrhythmias are thought to be most important in this respect. However, factors leading to increased mortality of AN have not been definitely identified up to now. Aim of our study was to evaluate a connection between AN and blood pressure in 32 patients with IDDM (mean age: 37,8 ± 12,7 ys, mean duration of diabetes: 17,9 ± 10,1 ys, males: 5, females: 27). The five standard reflex tests of cardiovascular autonomic function were applied. Twenty four hours blood pressure monitoring (ABPM) was performed by Meditech ABPM 02 device. Severity of AN was characterized by the number of abnormal reflex indices on patient and correlated significantly with systolic ($p<0,001$) and diastolic ($p<0,01$) hypertensive time indices as well as with systolic ($p<0,01$) and diastolic ($p<0,05$) hyperbaric impact (mmHgxh). Analysing the relationship between ABPM parameters and the five autonomic tests separately, a significant correlation was found with two tests only, 30/15 ratio and Valsalva ratio - both tests reflect mainly parasympathetic function. These data suggest that a relative sympathetic overactivity due to predominantly parasympathetic neuropathy might be responsible for the higher ABPM indices observed. Severity of AN correlated also with microalbuminuria ($p<0,001$.) Autonomic neuropathy as well as microalbuminuria were independently associated with hypertension. Severity of AN did not correlated significantly with diurnal blood pressure indices. Conclusion: autonomic impairment and hypertension seems to be associated in IDDM. Hypertension itself may contribute to the poor prognosis of autonomic neuropathy.

SKIN BLOOD FLOW RESPONSE TO HEATING DURING A 75-g oGTT IN HEALTHY INDIVIDUALS

P. Tsapogas, N. Tendolouris, I. Ioannidis, I. Kalliteraki*, D. Nikolakopoulos*, I. Tsigeridis, and N. Katsilambros. First Department of Propaedeutic Medicine; and *Department of Experimental Pharmacology; Athens' University Medical School, Athens, Greece.

Capillary blood flow response to a thermal stimulus is expected to be affected by glucose intake, since systemic catecholamine secretion occurs after administration of the substance. During a 75-g oGTT of ten right-handed and overnight fasted healthy volunteers, we recorded the capillary blood flow on the left forearm using Laser-Doppler flowmetry (Periflux model 4001, Perimed Ltd, Sweden) and raising the local temperature to 44^0 C for three minutes, at 0, 30 and 60 minutes (EXP1). We repeated the same procedure on a different day using water instead of glucose solution (EXP2). Three double-peaked curves were obtained for each individual on each experiment. Peak flow absolute values (APF) and areas under the curve (AUC) were significantly decreased in EXP1 as compared to EXP2. In EXP1, Friedman Two-way ANOVA revealed a significance of $p=0.02$ for AUC values, and a $p=0.06$ for APF values, while it failed to show any correlation in EXP2. Repeated measures ANOVA (MA) of APF revealed a significance $F=0.059$ in EXP1 but no significant correlation in EXP2. MA of AUC showed a trend for decrease ($F=0.083$) in EXP1, and no change in EXP2. Recovery of blood flow to baseline was faster in the second and in the third curve. No difference was noted in the percentages of changes of the peak flow rates over baseline levels as well as in the time elapsed from baseline to peak flow. Thus, in healthy individuals, glucose load results in a decreased capillary blood flow response to short and acute thermal stimuli in healthy individuals.

2223

DIVERGENT DEVELOPMENT OF AUTONOMIC AND PERIPHERAL SOMATIC NEUROPATHIES IN NIDDM

JP Töyry, JVS Partanen, LK Niskanen, EA Länsimies, MIJ Uusitupa. Kuopio University Hospital, Kuopio, Finland.

There is no information on the mutual occurrence and the development of autonomic and peripheral somatic neuropathies based on long-term follow-up of patients with NIDDM. We studied a representative group of patients with newly diagnosed NIDDM (n = 133, aged 45-65 yr) at baseline and 5 and 10 years later. Parasympathetic autonomic neuropathy was diagnosed on the basis of conventional criteria for heart rate variability during deep-breathing (E/I ratio $\leq$ 1.10) and sympathetic autonomic neuropathy on the basis of fall in systolic blood pressure ($\geq$ 30 mmHg) while changing from supine to standing. Polyneuropathy was diagnosed on the basis of both clinical criteria (pain and paresthesias) and electrodiagnostic studies (nerve conduction velocity and response-amplitude values). We investigated the relation between the changes in autonomic function values and electrodiagnostic values, and the relation between occurrences of autonomic neuropathy and somatic peripheral polyneuropathy. Altogether 36 patients died during the follow-up and 78 patients completed the study on autonomic nerve function tests and electrodiagnostic tests for polyneuropathy. When the study ended, the number of patients with parasympathetic autonomic neuropathy was 61.3 % of those with polyneuropathy and 66.7 % of those without. Likewise, the number of patients with sympathetic autonomic neuropathy was not different in those with polyneuropathy (21.9 %) and those without (26.5 %). The worsening of parasympathetic and sympathetic autonomic function values was not related to the worsening in sensory or motor nervous function with time. **In conclusion**, the development of autonomic and peripheral somatic neuropathies are divergent in patients with NIDDM suggesting different pathopysiological processes for these neuropathies.

2224

LASER DOPPLER BLOOD FLOW IN IDDM PATIENTS BEFORE AND AFTER PANCREAS TRANSPLANTATION

N. Eberl , S. Dachauer, W. Piehlmeier and R. Landgraf, University of Munich, Germany

To investigate the effect of a long-term glucose normalization on peripheral blood 74 IDDM patients with severe secondary complications were studied: **Group A** (n=10): patients on the waiting list for pancreatic-renal grafting (age 39.7±4.3 yrs, duration of diabetes 24.1±3.2 yrs, duration of dialysis 47.9±46.6 m, Hb 10.0±2.8 g/dl, HbA1c 7.0±0.9 %); **Group B** (n=41): patients after successful simultaneous pancreas and kidney transplantation (age 41.9±7.8 yrs; duration of diabetes 29.2±5.4 yrs, duration of dialysis 41.8±23.3 m, posttransplant 59.7±46.4 m, Hb 13.5±1.8 g/dl, HbA1c 4.6±0.7 %) ; **Group C** (n=23): posttransplant patients with functioning kidney graft, under insulin therapy (age 42.3±9.3 yrs, duration of diabetes 29.1±8.7 yrs, duration of dialysis 33.4±24.5 m, duration of renal graft functioning 83.4±56.7 m, Hb 12.8±2.0 g/dl, HbA1c 6.7±1.0 %). Data were compared to 19 control persons (**Group D**): age 30.6±11.5 yrs, HbA1c 3.7±1.4 % (mean±SD). Laser Doppler blood flow was measured in supine position on the dorsum of the foot using Periflux 4001 Master, Perimed AB, Sweden. Skin temperature was very similar in the groups at room temperature of 22±2° C. Basal blood flow was calculated as mean of 2 min measurement. After arterial occlusion by a cuff with 240 mmHg for 3 min maximum hyperemia was assessed. The biological zero flow was subtracted from measured values. Blood flow on the middle finger was measured before and during 30 seconds of a cold pressure test by putting the contralateral hand into ice water. Veno-arteriolar response was assessed by calculation of the decrease of blood flow on the foot after reaching standing position using a tilting table. Basal blood flow was lowest in Group B (5.0±3.4 Perfusion Units) and Group D (6.1±3.2 P.U.) followed by Group C: 9.3±6.9 P.U. and Group A: 14.7±11.2 P.U. With the exception of the comparison between Group B and D all groups differed significantly ($p<0.05$). Maximum post-occlusive increase was highest in Group D with 569±300 %, followed by 338±290 % in Group B; Group C: 194±250% ($p<0.01$ vs. all other groups); Group A: 149 ±200%. Decrease in blood flow during cold pressor test was highest in Group D with 67±20 %. Group C 31±30 %, Group B 30±16 %, Group A 18±20 % ; D vs A,B,C $p<0.001$). The veno-arteriolar response was similar in all groups. These data suggest that long-term glucose normalization has a positive influence on several functional parameters of microcirculation.

2225

QUONTITATIVE EVALUATION OF CARDIOVASCULAR AUTONOMIC REFLEXES FOR DIABETIC COMPLICATIONS.

Y. Ohtsuka, N. Yabunaka, S. Takayama and H. Noro.
Hokkaido University School of Medicine, Sapporo, Japan.

In order to clarify the relationship between diabetic complications and cardiovascular autonomic nervous functions, cardiovascular autonomic reflexes in diabetic patients were quantitatively evaluated by means of a deep breathing test and active postural change test with the Finapres (a method of non-invasive continuous blood pressure measurement). It revealed that both sympathetic and parasympathetic nervous system in the diabetic patients were deteriorated. The coefficient of variation of the pulse rate (CV-PR) during deep breathing in the sitting position and the time required for the recovery of blood pressure (Δ Time) in the active postural change test showed significant differences between the patients with major diabetic complications (retinopathy, peripheral neuropathy or nephropathy) and healthy subjects. Moreover, the critical point for the appearance of each complication was about 2% for CV-PR and about 30 sec for Δ Time. The present method enables the separate examination of sympathetic and parasympathetic nervous functions of patients by quantitatively evaluating their cardiovascular autonomic reflexes, which appears to be useful for detecting complications and investigating of correlations between autonomic nervous function and both somatosensory and peripheral circulatory functions.

2226

IMPAIRED MICROVASCULAR RESPONSES TO GLUCOSE IN FRUCTOSE-INDUCED DIABETIC RATS.

C. Renaudin, E. Michoud, M. Lagarde and N. Wiernsperger. Diabetic Microangiopathy Research Unit, LIPHA - INSERM U352, Insa-Lyon, France.

Abnormal reactivity of resistance vasculature may contribute to the pathogenesis of diabetic microangiopathy, inducing alterations in regional haemodynamics. The purpose of our study was to determine whether microvascular responses to elevated blood glucose and insulin, mimicking the postprandial state, are impaired in a model of type II diabetic rats. Studies were conducted on 3-months fructose (10 % in drinking water/FRU)-treated rats and age-matched controls. Intravital microscopy was used to examine diameter changes of arterioles (< 40 µm) in spinotrapezius muscle of fasted, anesthetized rats, before and 15, 30, 45 and 60 min after glucose infusion (1.5g/kg; i.v.) or NaCl 0.9 %. Blood glucose and insulin levels were determined before and 10, 40 and 70 min after infusion. FRU rats were hyperglycemic (7.5 ± 0.4 mM vs 6.6 ± 0.3 mM for control rats, $p < 0.05$) and hyperinsulinemic (184 ± 23 UI/ml vs 88 ± 11 UI/ml for control rats, $p < 0.01$) in the basal state. Intravenous glucose infusion produced a peak of glycemia and insulinemia which returned to basal in control rats at 40 min, but not in FRU rats. NaCl infusion did not modify arteriolar diameter. After intravenous glucose infusion, an arteriolar vasoconstrition was observed (14 % at 30 min vs NaCl, $p < 0.05$) in control rats but not in FRU rats. In contrast, glucose infusion produced an arteriolar vasodilation (15 % at 30 min vs NaCl, $p < 0.05$) in FRU rats. Our results indicate that in FRU rats, there is a lack of vasoconstriction in microvascular responses to intravenous glucose infusion. This impaired vasoconstriction could result in hyperperfusion and subsequent microvascular damage which might contribute to the development of diabetic microangiopathy.

2227

CARDIOVASCULAR EFFECT OF DIABETIC AUTONOMIC NEUROPATHY.

Jamal Ara. Co-Author: Zahir Khan
Jinnah Postgraduate Medical Centre

AUTONOMIC NEUROPATHY, a late complication of Diabetes Mellitus, also effects CVS. In 1995 an outpatient based prospective study was designed to see this effect in Diabetic patients at JPMC diabetic clinic,Karachi.First 100 adults (50 male 50 female)diabetics for more than 5 years were selected, 45 were IDDM and 55 were NIDDM. Follow-ingparameters were recorded.On ECG heart rate changes (RR-interval)during deep breathing(48%) Immediate response to standing (41%) and Valsulva maneuver(26%). Fall in systolic blood pressure on standing (12%)and an increase in diastolic blood pressure by sustained handgrip(8%). And accord-ingly these patients were divided into four groups. All tests normal (44), mild neuropathy with only one test abnormal(28), definite neuropathy with more then one test abnormal(29) and denervated heart with any one test reflecting sympathetic damage and another test showing parasympathetic damage (10). The results suggest that Diabetic Autonomic neuropathy effects CVS.in a large number of diabetics and is directly related to the age and duration of the disease. Simple bedside non-invasive tests are important for early detection and control of this complica-tion.

2228

IMPROVEMENT OF NUTRITIVE CAPILLARY BLOOD FLOW DURING INTRAVENOUS C-PEPTIDE INFUSION IN IDDM PATIENTS

T. Forst, T. Kunt, T. Pohlmann, P. Kann, M. Löbig, M. Engelbach, J.Beyer and A. Pfützner. Dept. of Internal Medicine and Endocrinology, University Mainz and Lilly Deutschland, Bad Homburg, Germany

It is postulated that C-peptide substitution increases blood flow, oxygen uptake and capillary diffusion capacity in forearm muscle in IDDM patients. The purpose of the present study was to investigate total skin microvascular blood flow and nutritional capillary blood flow during C-peptide administration in the feet of IDDM patients. Eight male IDDM patients without severe secondary complications (age 29 - 45 years, duration of diabetes 2.5 - 40 years) participated in this investigation. Following a randomized double-blind crossover protocol, C-peptide (8 pmol/kg/min) or placebo (0.9 % NaCl) were infused intravenously for 60 min. Observation parameters, measured after 0, 15, 30, 45, 60, and 90 min, were capillary blood flow at the toe nailfold (CBV; television-microscopy), total skin blood flow at the pulp of the toe (LDF; laser-doppler-flux), blood pressure, blood sugar and plasma C-peptide levels. In the verum arm, C-peptide levels increased directly after start of injection to reach a maximum of 6.6 ± 1.0 ng/ml after 45 min, but remained below 0.5 ng/ml during placebo treatment. No significant difference was found in CBV between the two treatment periods at baseline (C-peptide 150 ± 6 nm/s ; NaCl 148 ± 8 nm/s). In parallel with the increase in C-peptide levels, a significant increase in CBV was observed ($p<0.05$), reaching a significant difference in CBV between C-peptide and NaCl after 45 min of infusion (C-peptide 164 ± 7 nm/s; NaCl 136 ± 5 nm/s; $p<0.001$). LDF signal slightly decreased during NaCl infusion and remained unchanged during C-peptide infusion. The results were not biased by changes in systemic haemodynamic parameters (blood pressure; heart rate). Our findings suggest that there is a change in the distribution of microvascular blood flow during C-peptide administration, which may be important in the development of microvascular complications in IDDM.

2229

THE RELATIONSHIP BETWEEN DURATION OF DIABETES AND AUTONOMIC NEUROPATHY.

D.J.S. Fernando, M. Fernando, Faculty of Medicine, Colombo, Sri Lanka.

Onset of many diabetes complictions such as retinopathy and peripheral neuropathy is related to duration of diabetes. We determined the relationship between cardiac autonomic denervation (CAD) and duration of disease in 171 diabetic patients with CAD, 1000 patients with retinopathy and 500 patients with neuropathy attending the national diabetes centre, National Hospital, Sri Lanka and Faculty of Medicine Colombo. Autonomic function was assessed using standard cardiovascular reflex tests. Sensorimotor neuropathy was assessed using biothesiometry and electrophysiology. Retinopathy was assessed by fundus examination. There was no correlation betweer duration of disease and the presence of autonomic neuropathy or any of the cardiovascular reflex tests (p 0.19). No significant differences were observed in CAD in subgroups of patient with diabetes for 1-5 years (21%), 6-10 (27%) years, 11-15 (28%) years, 15-20 years (22%). The prevalence of peripheral neuropathy ($p=0.01$) and retinopathy ($p = 0.01$) were significantly higher in those with a longer duration (10 years). Mean duration of diabetes was similar among those who had CAD and those without CAD ($p=0.6$) Duration of diabetes was not related to onset of CAD but was related to onset of neuropathy and retinopathy.

DIFFERENTIATED ANALYSIS OF PLETHYSMOGRAPHY IN DIABETES MELLITUS

H.Ueda[1,2], K.Suzuki[1], H.Ohyama[1], K.Ohnishi[1], K.Nobunaga[1], T.Miyauchi[1], Y.Ohyama[1], M.Ohishi[1] and H.Taniguchi.[3]

[1]Department of Diabetes and Endocrinology, Kobe Mahoshi Hospital, [2]Second Department of Internal Medicine and [3]Department of Metabolism and Community Health Science, Kobe University School of Medicine, Kobe, Japan

[AIM] Disorder of peripheral blood flow is an important problem in diabetes mellitus, as it is said to be responsible for its complications. In the present study we assessed the usefulness of differential calculus analysis of plethysmography in diabetes mellitus.

[SUBJECTS & METHODS] Plethysmography was done in 40 control subjects, and 52 diabetics whose average age was 61.8 years and average duration of diabetes was 7.1 years. Plethysmogram was taken at both forefingers using the system composed of recording part and analyzing program (FUKUDA DENSHI Co.,Ltd., Tokyo, Japan). Obtained plethysmogram was successively differentiated as much as five times and arbitrary parameters of each portion of the plethysmogram were set up. The effect of autonomic blocking agents was also studied in healthy subjects.

[RESULTS] Each parameter of the differentiated plethysmogram was negatively correlated to age. Twice differentiated plethysmogram was revealed a lower response in subjects taking β-blocker in healthy subjects. No significant difference of the parameters was observed between diabetics and control subjects in terms of the effect of the modality of treatment and control state of blood glucose. In diabetics aged over fifty years with complications parameters of plethysmogram were lower than those without complications.

[CONCLUSION] Differentiated plethysmography seems to become an indicator of diabetic complications irrespective of modality of treatment and blood glucose level.

2231

PROGNOSTIC SIGNIFICANCE OF CORRELATION BETWEEN PERIPHERAL NEUROPATHY AND CARDIAC AUTONOMIC NEUROPATHY IN NIDDM

M. K. Bhatnagar and P. Guha, Lady Hardinge Medical College, New Delhi, India.

Fifty one cases of NIDDM were examined for the Peripheral Neuropathy (PN) and Cardiovascular Autonomic Neuropathy (CAN). Clinical scoring method of Valk-et-al was adopted for evaluation of PN and bed side clinical tests advocated by American Diabetic Association were performed to detect CAN. Mean age of the patients was 52.2 years and mean duration of Diabetes was 7.4 years. Peripheral Neuropathy was present in 56.7% cases of which 27.4% had mild, 19.6% moderate and 9.8% had severe neuropathy. Cardiovascular Autonomic Neuropathy was present in 23.1% cases. Statistical analysis showed that PN score had a strong positive Correlation with CAN score (0.7113, $p < 0.0001$). Peripheral Neuropathy correlated best with Postural hypotension test (0.6273) followed by 30:15 ratio (0.6233), hand grip test (0.4938) and deep breathing test (0.4937). No correlation was found with resting heart rate and Valsalva maneuver. The severity of symptoms of PN demonstrated a significant rise in the number of test positive for CAN. This positive correlation can be explained on the basis of similar pathogenic mechanism involving Microvascular function defects. We conclude that the presence of severe Peripheral Neuropathy in NIDDM indirectly indicate presence of Cardiovascular Neuropathy and therefore these patients are at a increased risk of Sudden Cardiac death.

2232

RENAL TRANSPLANTATION: A CURE FOR DIABETIC GUSTATORY SWEATING

J.E.Shaw, C.A.Abbott, R.Gokal and A.J.M. Boulton. Dept of Medicine, Manchester Royal Infirmary, Manchester, UK

Gustatory sweating (GS) is very common in diabetic nephropathy, and complete resolution after renal transplantation has recently been reported in a few cases. We studied patients who had undergone renal transplantation for diabetic nephropathy to determine how common the phenomenon is. 31 subjects were questioned about gustatory sweating and had an assessment of neuropathy at a mean (range) time after transplantation of 36(2-108) months. 20/31 reported gustatory sweating prior to transplantation and in 11/20, GS completely disappeared post-transplantation. A further 3/20 noted partial improvement. In 1 subject who reported improvement, sweating in response to food was measured before and after transplantation by measuring the increase in weight of absorbent dressings. Prior to transplantation, GS was 9.3mg/cm^2, falling to 1.5mg/cm^2 post transplant. There were no differences between improvers and non-improvers with regard to age at transplantation, diabetes duration or type, sex, sympathetic function or post-transplant creatinine or immunotherapy. There was a trend towards worse somatic neuropathy in the improvers, as measured by the median (IQR) vibration perception threshold (38V(23-47) vs 16V(8-49)) and modified neuropathy disability score (8(6-10) vs 2(0-9)), but these differences did not reach statistical significance. Although GS is common in nephropathy, complete or partial resolution occurs in 70% of patients undergoing renal transplantation. The mechanism of this change remains unclear, but the observation indicates that aberrant nerve regrowth is untenable as a cause of GS.

2233

COEXISTENCE OF AUTONOMIC NEUROPATHY AND MICROANGIOPATHY IN DIABETIC SUBJECTS

N.Tentolouris, Ph.Philippides, G.Lazana, M.Micha, A.Linos, E.Kitsou, B.Alevizou and N.Katsilambros. 1st Department of Propaedeutic Medicine and Neurologic Department, Athens University Medical School, Athens, Greece

The purpose of the present study was to investigate whether microangiopathy (retinopathy or microalbuminuria) is associated with autonomic neuropathy (AN) in diabetic subjects. For this purpose data from 101 diabetic persons (type 1: n=57; type 2: n=44) were analyzed. The battery of the five standardized autonomic function tests (Valsalva test, deep breathing test, heart rate and blood pressure responses from lying-to-standing position and handgrip test) was used. Retinopathy was assessed using the criteria of the Hammersmith protocol. Microalbuminuria was measured by RIA in 3 separate urine collections. Values in the range of 30-299 mg/24-hrs were considered as abnormal. No case exceeding 299 mg/24-hrs was observed. No person had hypertension, clinical and/or ECG findings of coronary heart disease and no one received medications other than antidiabetic drugs. Logistic regression analysis controlling for sex, age, type and duration of diabetes, AN, smoking, blood pressure, HBA_{1c} and type of treatment, showed that the risk for retinopathy significantly increases with AN (odds ratio: 3.66, p=0.03) and systolic blood pressure (odds ratio: 2.44, p=0.02). No other significant association was observed. Several potential explanations could be offered of a common etiopathogenetic mechanism for AN and retinopathy and/or that AN may predispose to the development of retinopathy. No such conclusion can be drawn about microalbuminuria. In addition, we confirmed the association between systolic blood pressure and retinopathy. Thus, the strong association of AN with retinopathy possibly indicates a common etiopathogenetic mechanism or that AN may be a risk factor for retinopathy.

2234

RELATIONSHIP OF AUTONOMIC DIABETIC NEUROPATHY AND PROSTAGLANDIN E1 RESPONSE IN IMPOTENT DIABETIC MEN

M. Reljanović, G. Roglić, F. Coce, P. Pavković, N. Car and Ž. Metelko. Vuk Vrhovac Institute, Zagreb, Croatia

The aim of the study was to explore the relationship of autonomic diabetic neuropathy (ADN) and response to intracavernosal application of prostaglandin E1 (PGE1) in impotent diabetic men. It is assumed that ADN does not play an important role in the erection response to PGE1 application and that it is mainly influenced by the vascular status of the penis. We examined 71 diabetic patients (18 Type 1, 53 Type 2), median age 51.5 years, median diabetes duration 9.5 years.All patients were assessed by the standard battery of cardiovascular tests (ProSciCard system) of which 6 tests of R-R interval were evaluated (coefficient of variation at rest, power spectrum at low and mid frequency bands in the supine position, mean circular resultant during deep breathing, max/min 30:15 ratio, and Valsalva index) as well as fall in systolic blood pressure on standing. All patients were tested by intracavernosal aplication of PGE1 starting with 10 ug and increasing up to 40 ug until sufficient erection for intercourse was achieved (positive reaction). During this procedure 54 patients achieved sufficient erection. The number of pathologic autonomic function tests correlated significantly with the response to PGE1 (Gamma statistic=-0.321, p=0.03). However, when age, diabetes type, diabetes duration and number of pathologic tests were entered in a logistic regression model with the positive or negative reaction to PGE1 as the outcome variable, none of the regression coefficients quite reached statistical significance at the 95% level (age B=-0.08,p=0.19; duration B=0.06, p=0.23; type B=-0.19, p=0.86; number of pathologic tests B=-0.32, p=0.09). Only 11% of the variance in the outcome variable was explained by the selected set of predictors. However, possibly through its' relation to variables not measured in this study, the significant correlation and the p-value of the autonomic tests regression coefficient (close to the conventional level of 0.05) indicate that it is likely that a higher number of pathologic autonomic tests is related to a negative response to PGE1.

EFFECT OF METABOLIC CONTROL ON PROGRESSION OF DIABETIC AUTONOMIC NEUROPATHY

Gupta RC, Jain A, Gupta N
J.L.N. Medical College, AJMER, INDIA

The role of strict metabolic control in the treatment of established diabetic autonomic neuropathy remains an important but controversial issue. The DCCT report has shown delay in onset and retardation in the progression of complications of diabetes in all groups of diabetic patients by intensive and meticulous glycemic control. 50 patients of diabetes mellitus (both IDDM and NIDDM) were selected with typical symptoms, signs and positive bed side tests of autonomic neuropathy. All the patients were followed for three months during which strict metabolic control was achieved by routine treatment with oral hypoglycaemic agents and/or insulin, simply by change in their previous treatment dosages and better attention to diet and physical activity. 22% patients showed significant improvement in symptoms of autonomic neuropathy. 42% showed partial improvement and 36% patients did not show any improvement. Improvement in objective test score was significant in 18%, partial in 46% and insignificant in 36%. Improvement in neuropathy did not correlate with HbA1C levels. 36% patients did not show any subjective or objective improvement in autonomic neuropathy inspite of good glycaemic control as indicated by normal HbA1C levels in them.

2236

BLADDER DYSFUNCTION IN DIABETIC MEN WITH AUTONOMIC NEUROPATHY. A.Z.Ibrahimov.Azerbaijan medical university,Baku,Azerbaijan Republic.
The aim of this study was to examine the functional state of urinary bladder in men with IDDM Three groups of subjects were examined:gr.1-healthy men(n=7);gr.2-5 men with IDDM without autonomic neuropathy(AN) and gr.3- 6 IDDM patients with AN.Mean age of three groups and average duration of IDDM in gr.2 and 3 were practically same.Diabetic AN was diagnosed with battery of tests(Valsalva,deep breathing,active ortostatic test,heart rate variation in rest).The bladder function was assessed with uroflowmetry, retrograde cystometry and profilometry of urethra.All diabetic patients(gr.2 and 3) had reservoir disorders:decrease of detrusor tonus(gr.1-1,65+-0,140;gr.2-0,95+-0,144;gr.3-0,95+-0,121; p<0,001);increase of threshold sensibility to fill(gr.1-144+-12,4 ml,gr.2-282+-62,5 ml,gr.3-326+-36,4 ml,p<0,001)and increase of the maximal bladder volume(gr.1-286+-13,3 ml,gr.2-733+-66,3 ml,gr.3-897+-98,8 ml,p<0,001).Empty disorders was revealed in gr.3.Diabetic men with AN had decrease maximum(Qm)and average(Qa)urinary flows(Qm-13,98+-1,92 ml/sec,Qa-7,2+-1,45 ml/sec, p<0,01),increase voiding time(52+-8,5 sec,p<0,01 flow time(49+-8,4 sec,p<0,05)and time to peak flow(18,0+-4,11 sec,p<0,05).Thus,diabetes mellitus leads to reservoir dysfunction of bladder. Diabetic autonomic neuropathy results in reservoir-empty disorders of urinary bladder.

Cardiovascular Reflexes in Children and Adolescents with Insulin Dependent Diabetes Mellitus

Authors: Isis Mohamed Ghaly, Nermin Salah, Fadia Mahmoud, Mona Hafez, Mona Attieya, Sonia El Saiidy, Diabetic Endocrine Metabolic Pediatric Unit, Children Hospital, Cairo University.

Objective: To assess the usefulness of specific cardiovascular reflex test (CVRs) in children and adolescents with IDDM and to estimate the prevalence of cardiovascular reflex abnormalities among young IDDM patients.

Abstract: The study included 100 young IDDM patients. Their age ranged from 4,42 to 30.25 years (mean 12.53 ± 4.5) of whom 55 were males and 45 females. Five non-invasive CVR tests namely HR-deep breathing mean, HR 30/15 ratio, valsalva ratio, blood pressure, response to standing and hand grip tests were done to detect cardiac autonomic neuropathy. The 5th percentile for 42 non-diabetic children (age and sex matched) was chosen as the lowest limit of normal for the tests. In 100 patients who had the full battery of investigation, 49% showed abnormality; 24% one test abnormal, 13% two tests abnormal and 12% three tests abnormal. None of our patients showed abnormality in four or five tests at the same time. 28% of diabetic patients showed abnormalities in HR-DRm, 20% in the 30/15 ratio and the hand grip test, 13% in the valsalva ratio and only 5% in the postural blood pressure difference. Symptoms of autonomic neuropathy was present in 37 patients (37%), 27 of which had abnormal cardiovascular reflexes. Autonomic neuropathy symptoms was highly related to the results of CVRs. The results of this study also showed that CVRs was highly related to age of the patient (P value - 0.001), accordingly age dependent indices would be needed in children. Also duration of illness was related to results of CVRs (P value = 0.005). Sex did not show any difference between those with normal or abnormal reflexes. Glycemic control as assessed by mean HBA,C showed significant relation to CVRs.

2238

THE EVALUATION OF ESOPHAGEAL MOTOR DISORDERS IN IDDM

M.Graur,G.Botnariu and M.Rusu;University of Medicine,Iasi,Romania

Esophageal motor abnormalities are an early sign of neuropathy in diabetic patients. Early diagnosis and treatment are essential. The clinical symptoms, which are correlated with radiological, manometric and scintigraphic data, may diagnostiċ esophageal motility disorders. Twenty patients with an over 5 year insulin dependent diabetes presenting clinical signs of episodic esophageal syndrome – dysphagia, retrosternal chest pain, heartburns, esophageal reflux – has been investigated. Contrast esophagogram has been used for excluding an ulcer, cancer, hiatal hernia and resected stomach in these patients. Esophageal manometry studies entailed the recording of esophageal peristalsis, lower esophageal sphincter (LES) pressure, and swallow response. Esophageal sequential scintigraphy (ESS) with choloidal ^{99m}Tc – labeled liquid bolus – was used for calculating total and segmental esophageal transit time and residual radioactivity. A 90% correlation index between the manometric changes and prolonged esophageal transit time was found, thus confirming the sensitivity of ESS. The mean pressure in LES was 20.5±8.1 mmHg, and an incomplete swallow relaxation was found in 5 patients. Within the esophageal body, the manometric studies have revealed the absence of deglutitive contractions in the distal esophagus, segmental contractions, multiple pressure peaks in response to a single swallow. With ESS, a prolonged esophageal transit time, especially in the distal esophagus (11.5± 1.3sec, normal 8.5±1.5sec) with TE_3 10.1±1.3sec (normal 7.6±0.8sec) was recorded. The use of ESS, a cheap and reproductible technique, as a screening test for early diabetic neuropathy is suggested.

DIAGNOSTICS OF THE AUTONOMIC DIABETIC NEUROPATHY IN CHILDREN.

V.Mirza-Zadeh,A.Eiudova and G.Achmedov. Diabetic centre of Baku, Azerbaijan Medical University, Baku, Azerbaijan Republic.

Autonomic diabetic neuropathy (ADN) is well known complication of Diabetus melitus (DM). But a diagnostics of this complications in children have not worked out up to now.The aim of our investigation was elaborating of a simple and reliable method for revealing autonomic disorders of children with DM. It was investigated 116 practically healthy children and 48 with IDDM(age from5to 15 years old). It was carried out, the following tests on children:Valsava maneuver; deep dreathing test;HR variations in supine resting position(50 intervals RR); HR response to standing up(30 intervals RR after standing up).The investigations showed impossibility of the conducting the Valsava test in the majority of children under 10 years old.On the base of the other test data, we elaborated the complex ECG-index that is the sum of differences of maximal and minimal RR of the three tests. The index more than 410 should consider as normal one, less than 350 as patology. All the others indicies are the border ones.ADN was diagnosed in 15 children with IDDM from 48 investigated ones(31 6,7%). Thus, it was elaborated a simple method of ADN diagnostics in the children.

HYPERINSULINEMIA AND ESOPHAGEAL MOTILITY DYSFUNCTION IN PATIENTS WITH SCHISTOSOMIASIS AND DIABETES MELLITUS

Hassan Rizk and N. Gad El-Hak. Mansoura Faculty of Medicine, Mansoura, Egypt.

In this study patients with hepatosplenic schistosomiasis and DM were studied for esophageal motility and serum insulin level. It comprised 30 patients and 7 control normal subjects. Patients were classified into: (a) Group with DM (b) Group with hepatosplenic schistosomiasis (with and without ascites). (c) Group with both hepatosplenic schistosomiasis and DM. There was significant decrease in LES pressure in patients with Type 1 or Type 2 DM. compared to the control group (P 0.016). There was significant decrease in the velocity and distal amplitude of peristalsis in hepatosplenic schistosomiasis with ascites compared to control group (P= 0.021 and 0.043 respectively). Also, significant increase in the percent of the retrograde waves in hepatosplenic schistosomiasis with ascites and DM compared to hepatosplenic schistosomiasis without ascites (P= 0.034). There was significant decrease in percent of full relaxation of LES in hepatosplenic schistosomiasis with DM compared to DM. There was significant decrease in the LES pressure in hepatosplenic schistosomiasis (with and without ascites) with DM compared to the control group (P= 0.014). There was significant elevation of insulin levels in hepatosplenic schistosomiasis with ascites than without ascites (P=0.032).The study revealed significant positive correlation between insulin level and LES pressure in hepatosplenic schistosomiasis (without ascites) with DM & highly significant negative in hepatosplenic schistosomiasis (with ascites) with DM . There was highly significant positive correlation between insulin level and mid amplitude in hepatosplenic schistosomiasis without ascites & significant positive correlation with proximal amplitude in hepatosplenic schistosomiasis with ascites We concluded that ascites decreases LES pressure ,velocity, distal amplitude of peristalsis and the percent of primary peristalsis. DM decreases LES pressure, combined DM & Bilharziasis produce more abnormalities than each disease alone. Hyperinsulinemia in those patients increases proximal and mid amplitudes of peristalsis and percent of tertiary peristalsis and increases LES pressure in absence of ascites.

2241

EFFECT OF NITRATES AND CALCIUM CHANNEL BLOCKERS ON AUTONOMIC REFLEXES IN NIDDM PATIENTS

R.Garg, K.K.Deepak and N.Kochupillai. All India Institute of Medical Sciences, New Delhi, India.

Effect of nitrates and calcium channel blocking drugs on cardiovascular autonomic reflexes was studied in ten NIIDM patients who were newly detected to have hypertension (HT) and ischemic heart disease (IHD). Five standard tests for autonomic reflexes were performed before starting isosorbide dinitrate (10 mg 6 hourly) and nifedipine (10 mg 8 hourly). The tests were repeated after 2 days. The results were as follows. 1. Rise in diastolic blood pressure (DBP) on isometric hand grip (Mean±SD in mmHg): 18.4±15.3 (pretreatment) Vs 9.8±7.3 (on treatment), (p=0.05) 2. Fall of DBP on 70 degree head up tilt (mean±SD in mmHg): 5.4±9.8 (pretreatment) Vs 9.8±8.0 (on treatment), (p<0.05). 3. Expiratory inspiratory ratio (on deep breathing), Valsalva ratio, 30:15 ratio & systolic blood pressure response on head up tilt as well as DBP response to cold immersion didn't change significantly. However, the overall autonomic status, as assessed by Ewing's score, worsened from 4.80±2.70 (pretreatment) to 5.80±2.04 (on treatment), (p<0.05). Thus calcium channel blockers and nitrates, given together, can cause significant worsening of autonomic reflexes in NIDDM patients with HT and IHD.

2242

MULTIPLE-SITE GASTROINTESTINAL MOTILITY DISORDER IN DIABETIC AUTONOMIC AND SENSORY NEUROPATHY

T.T. Várkonyi, Cs. Lengyel, A. Rosztóczy, A. Fehér, P. Kempler*, T. Fazekas, T. Wittmann and J. Lonovics. 1st Dept. of Medicine, A. Szent-Györgyi Med. Univ., Szeged, and *1st Dept. of Medicine, Semmelweis Med. Univ., Budapest, Hungary

The aim of this study was to determine the pattern of motor dysfunction at different levels of the gastrointestinal (GI) tract in patients with long-standing diabetes mellitus (DM) and to evaluate the influence of autonomic and sensory diabetic neuropathy on GI motility. *Methods*: 17 diabetic patients were studied (duration of DM: 20.6±3.3 years, BMI: 26.1±1.6, age: 53±3.7 years, mean±SE). GI motility was investigated by means of manometry. The motilities of the pharynx, upper and lower esophageal sphincters, esophageal body, stomach, and external and internal anal sphincters were measured. To determine the severity of autonomic neuropathy, five standard cardiovascular tests were performed and a score was calculated. The sensory nerve function was studied with a Neurometer (Neurotron Inc., Baltimore MD), using constant sine wave transcutaneous nerve stimulation. *Results*: The mean autonomic score of the patients was 5.6±0.5 and all had increased current perception thresholds at 2 kHz and 250 or 5 Hz (median nerve: 3.57±0.49, 3.20±1.07 and 2.21±1.07; peroneal nerve: 5.64±1.02, 4.77±1.26 and 4.12±1.27 mA, respectively). The presence of an esophageal body dysfunction of varying severity was detected in all patients (17), while abnormalities of lower esophageal sphincter relaxation were observed less frequently (11). Ano-rectal motility disturbance was found in 13 patients. There was an impaired gastric motor function in 12 cases, 7 of these involving the absence of a migrating motor complex phase III, i.e. diabetic gastroparesis. Analysis of the motor functions tested revealed at least three concomitantly impaired regions in most patients (14). *Conclusions:* High frequencies of pathologic esophageal body, gastric and ano-rectal motility parameters were found in diabetic patients with moderate autonomic and severe sensory neuropathy. The data confirm the hypothesis that a multiple-site motility disorder is present in long-standing DM. The observed coexistence of long-term DM, diabetic neuropathy and GI motility disorders emphasizes the necessity for further clinical and experimental investigations in this field.

2243

FACTORS DETERMINING THE 24H BP PROFILE IN NORMOTENSIVE IDDM AND NIDDM PATIENTS

V. Spallone, M.R. Maiello, E. Cicconetti, A. Barini, S. Gambardella and G Menzinger. Endocrinology, Tor Vergata University; Biochemistry, UCSC, Rome, Italy

To evaluate the relative influence of clinical data, autonomic neuropathy (AN), and albuminuria on 24h blood pressure (BP) profile in IDDM and NIDDM, we studied 43 IDDM (age: 40±11, duration: 18±9 yr), and 31 NIDDM (age: 53±6, duration: 14±7 yr) normotensive non-proteinuric patients. Cardiovascular AN, 24h BP, and urinary albumin excretion rate (UAE) on simultaneous urine collections timed day and overnight were measured. IDDM patients with AN showed lower day-night difference in systolic (ΔsBP: 3±9 vs 9±5%, p<0.01) and diastolic BP (ΔdBP: 8±10 vs 15±5%, p<0.01) than those without AN. Microalbuminuric IDDM patients had higher night BP (119±16/74±6 vs 107±12/64±7 mmHg, p<0.01), and lower ΔsBP (2±17 vs 8±6%, p<0.05) and ΔdBP (6±11 vs 14±7, p<0.01) than normoalbuminuric IDDM patients. In NIDDM patients with AN, ΔdBP was significantly lower than in those without AN (4±8 vs 10±4%, p<0.05), while no difference was found in relation to the presence of microalbuminuria. In IDDM patients ΔsBP and ΔdBP were related to cardiovascular tests and to autonomic score, index of tests impairment (r= -0.56, p<0.0001), but also to night UAE (r=-0.44, p<0.01). In NIDDM patients both ΔdBP and ΔsBP were related only to cardiovascular tests and to autonomic score (r=-0.50, p<0 005). We performed a stepwise regression analysis including sex, age, body mass index, smoking, diabetes duration, HbA_{1c}, serum cholesterol, autonomic score, and night UAE as independent variables, and ΔBP or 24h BP as dependent variables. We found that in IDDM autonomic score and night UAE were the variables of primary importance for ΔsBP and ΔdBP, while HbA_{1c}, cholesterol, body mass index, and diabetes duration were all related to 24h BP. In NIDDM autonomic score was the major determinant not only of ΔsBP and ΔdBP, but also of 24h BP. In conclusion, in both IDDM and NIDDM normotensive patients the day-night variation in BP is dependent on autonomic function. In IDDM the strong relationship between AN and nephropathy does not allow a full discrimination of their relative role. In NIDDM the weaker relationship between BP and albuminuria makes more easily detectable the influence of AN on 24h BP pattern.

2244

THE USEFULNESS OF RADIOPAQUE MARKER (KG-S10) TO EVALUATE THE DIGESTIVE TRACT MOVEMENT IN NIDDM.

M.Ikeda, T.Watarai, M.Iida, K.Utsumi, T.Mori, M.Kubota, Y.Yamasaki, and M.Hori. Osaka University, Osaka, Japan.

AIM : Diabetic gastroenteropathy is speculated to induce postprandial hyperglycemia in diabetics. The aim of this study was to access the usefulness of radiopaque maker, KG-S10, and to elucidate impaired digestive tract movement in patients with NIDDM. METHODS : KG-S10 is a gelatin capsule including 20 pellets of polyvinyl chloride rings (4.5×1.0mm). The KG-S10 was given orally just before intake of a test meal to 12 patients with NIDDM who had a symptomatic diabetic gastroenteropathy (age 75±9 yrs ; duration of DM 20±3 yrs; HbA_{1c} 9.2±1.3%). The serial abdominal plain radiograms were taken until the marker could not be detected by radiography. The markers were counted at 7 parts on the abdominal radiograms. RESULTS : Diabetics showed a shorter calculated segment passing time(hour) in stomach (1.4±0.6vs.4.1±2.5), longer times in upper small intestine, pelvic part of small intestine, ascending colon, transverse colon, and descending colon (3.3±2.3vs.1.9±1.7, 8.3±10.4vs.5.7 ±4.7, 10.2±8.0 vs.6.6±5.3, 9.4±7.9vs.6.6±5.3, and 21.1±21.2vs.6.6± 3.1, respectively) , and comparable time in sigmoid colorectum (5.9±5.8vs.5.9 ±5.8), as compared with those of healthy subjects. The patients with constipation had a longer segment passing time in colon than the patients without constipation. No adverse effect was observed except X-ray radiation on abdomen. CONCLUSION : The KG-S10 makes it possible to quantitatively and less-invasively evaluate the movement at each digestive tract part through stomach to rectum without specific facilities. Compared with healthy subjects, NIDDM with symptoms of diabetic gastroenteropathy showed shorter segment passing time in stomach and longer times in upper small intestines and in the subsequent parts, which might worsen postprandial hyperglycemia.

2245

24-H-BLOOD PRESSURE BEHAVIOR WITH INCREASING AUTONOMOUS NEUROPATHY OF THE CARDIOVASCULAR SYSTEM

N.Lotz, J.Vortherms and R.Petzoldt, Herz- und Diabeteszentrum NRW, Bad Oeynhausen, Germany

Autonomous neuropathy of the cardiovascular system (ANP) is connected to a high cardiovascular mortality rate. The present study examines secondary changes in blood pressure behavior, in relation to the severity of ANP, using 24-hour ambulatory blood pressure monitoring (ABPM). 94 type I and type II diabetics with a mean diabetes duration of 22±10 years ($\bar{x}$±SD) and without pre-existing antihypertensive medication or ouvert nephropathy underwent ABPM, with statistical attention being paid for the first time to the actual time of falling asleep, as well as a standardized test battery for ANP (heartbeat variation at rest, heart rate analysis, deep respiration and the Ewing test). With an increase in the number of pathological ANP tests (group 1 to 5), the proportion of non-dippers (<10% blood pressure day/night drop) increased from 29 via 40, 58, 70 to 73%. The systolic day and night mean values differed significantly in group 1 from those in group 5 (132±9 vs. 135±17 and 116±10 vs. 130±10 mmHg respectively; $p<0.05$), as did the subsiding reduction in pulse rate at night (-24±12 vs. -14±9 bpm; $p<0.005$). The ANP degree of severity did not correlate with the duration of diabetes, but with metabolic quality (HbA1c), existing retinopathy and peripheral sensitive neuropathy ($r>0.34$; $p<0.001$). ANP can lead to an increase in blood pressure and pulse rate at night, indicating principal damage to the parasympathetic nervous system. Long term, the predominance of adrenergic stimulation could be partly responsible for cardiac damage with diabetes mellitus. The occurrence of ANP seems more likely to be linked to metabolic control than to the duration of diabetes. Regarding secondary prevention with existing diabetic ANP, importance should be attached to thorough diagnosis, a consistent reduction in blood pressure, restoration of physiological dipping, as well as optimum metabolic control, in order to lessen the cardiovascular risk to these patients.

2246

HYPERGLYCAEMIA SLOWS GASTROINTESTINAL MOTILITY IN PATIENTS WITH DIABETES MELLITUS

M. Burgstaller, K. Haß, H. Kasper and B.Allolio, Department of Internal Medicine, University of Würzburg, D 97080 Würzburg, Germany

It has been supposed that gastric emptying time is affected by blood-glucose-concentration. We measured the effect of different blood-glucose-concentrations (glc) on gastric emptying (GE), gallbladder motility (GBM) and small bowel transit time (SBTT).

10 patients with diabetes mellitus were tested (8 IDDM, 2 NIDDM; 2 women, 8 men; age 38.2y (28y-56y), HbA1c 7.6%+/-1.25, duration of diabetes 15.8y in mean). Using glucose-clamp-technique (Biostator) glc was 5.5mmol/l during one and 14mmol/l during the other test and an observation period of 4 hours postprandial each. GE was measured by ultrasound using antral cross sectional area. GBM was determined by ultrasound using maximal area in longitudinal axis. SBTT was measured by breath hydrogen analysis. Test meal was a solid-liquid-multicomponent meal of 1692kJ plus 20g lactulose.

In analyses of multivariance GE was delayed significantly when glc was 14mmol/l ($p<0.05$; emptying time about 180min postprandial with glc=5.5mmol/l vs. 240min with glc=14mmol/l). Postprandial GBM was different ($p<0.001$), especially refilling was slower with glc=14mmol/l. SBTT also was significantly different ($p<0.01$): SBTT was about 95min with glc=5.5mmol/l vs. about 135min with glc=14mmol/l.

These results demonstrate a strict dependence of the described parameters of gastrointestinal motility on blood glucose in patients with diabetes mellitus. Reducing postprandial blood glucose, f.e. by using a short acting insulin analogue, could be an alternative to prokinetic drugs, which often fail especially in long time treatment of gastroparesis diabeticorum.

(partly supported by Institut Danone für Ernährung, Munich, Germany)

2247

BAROREFLEX DURING AN ORTHOSTATIC TEST (SQUATTING) IN DIABETIC PATIENTS WITH CARDIAC AUTONOMIC NEUROPATHY

A.J. Scheen, M. Marchand, G. de Fooz, J. Juchmes and P.J. Lefèbvre. Division of Diabetes, Nutrition & Metabolic Disorders, CHU Sart Tilman, B-4000 Liège, Belgium.

We studied the influence of diabetic cardiac autonomic neuropathy (CAN), assessed by decreased respiratory arrhythmia during deep breathing, on the baroreflex during an orthostatic test. Changes in mean arterial blood pressure (MAP) and heart rate (HR) were measured continuously with a Finapres^R device (Ohmeda, USA) during an active orthostatic test (successively 1 min standing; 1 min squatting; 1 min standing) in three groups of subjects similar for sex, age, height and body weight : 41 healthy controls, 32 diabetic patients without CAN (R-R E/I : 1.32 ± 0.02) and 23 diabetic patients with CAN (R-R E/I: 1.07 ± 0.01). In initial standing position, HR was higher ($p < 0.01$) in both diabetic groups (87 ± 2 and 92 ± 3 min^{-1}, respectively) than in controls (79 ± 1 min^{-1}). In squatting position, MAP increase was greater ($p < 0.01$) in diabetic patients with CAN. After standing up, diabetic patients with CAN were characterized by a greater (39 ± 2 mm Hg, $p < 0.05$ *versus* 31 ± 1 in controls and 32 ± 2 in diabetic patients without CAN) and more prolonged ($p < 0.02$) drop in MAP and by a markedly decreased reflex tachycardia (10 ± 1 min^{-1}, $p < 0.0002$ *versus* 20 ± 1 min^{-1} in controls and 19 ± 2 min^{-1} in diabetic patients without CAN). The baroreflex gain calculated during the hypotension phase (HR increase/MAP drop, expressed in beat/mm Hg) was markedly dampened in diabetic patients with CAN (0.27 ± 0.03, $p < 0.0001$) when compared to that of diabetic patients without CAN (0.74 ± 0.10) and that of controls (0.75 ± 0.08). In conclusion, non-invasive beat-to-beat monitoring with the Finapres^R device during a squatting test allows to clearly demonstrate major disturbances in the baroreflex of diabetic patients with cardiac autonomic neuropathy.

2248

INSULIN PER SE MODIFIES GASTROINTESTINAL SENSORY RESPONSES TO DUODENAL DISTENSION IN NORMAL SUBJECTS.

Th. Lingenfelser, W. M. Sun, R. Kadow, U. Hotovy, M. Ewald, J. Dent. Klinikum Amberg, Germany, and Royal Adelaide Hospital, South Australia.

Recent studies have demonstrated that in healthy individuals physiological hyperglycaemia (~10mM) modulates visceral sensations arising from the gastrointestinal tract. Concurrent hyperinsulinaemia may be the putative mediator of this phenomenon. The present study investigated the effect of physiological changes in blood insulin concentration on the perception of duodenal distension in 7 healthy volunteers. Measurements were performed during normoinsulinaemia (50pM) and mild hyperinsulinaemia (300pM) in randomized order and cross-over fashion, i.e. hyperinsulinaemia-normoinsulinaemia (H/N) vs. normoinsulinaemia-hyperinsulinaemia (N/H). Gastrointestinal sensory responses were evaluated at baseline and after repetitive proximal duodenal distension which was performed with a non-compliant ultrathin bag during phase I activity. Intrabag volumes increased by 4 mL at each distension step (from 12 to 48 mL), which lasted 2.5 min in 10 min intervals. Perception of duodenal distension was scored from 0=no perception to 6=pain. Gastrointestinal sensations were assessed using a visual-analogue scale after each distension. Perception threshold for duodenal distension was lower during hyperinsulinaemia: 18.7±1.5/20.0±1.6 (H/N) vs. 22.7±2.4/18.6±1.2 (N/H); $p<0.05$. At all intrabag volumes perception of duodenal distension was higher during hyperinsulinaemia, e.g. at 48mL: 5.7±0.2/4.7±0.5 (H/N) vs. 4.8±0.3/5.5±0.2 (N/H); $p<0.05$. The gastrointestinal sensation fullness was experienced more intensively during hyperglycaemia, e.g. at 48 mL: 10.8±5.3/7.5±4.4 (H/N) vs. 12.2±5.6/17.0±7.6 (N/H); $p<0.05$), hunger less intensively, e.g. at 48 mL: 3.2±1.9/20.0±8.3 (H/N) vs. 10.8±6.5/2.5±1.6 (N/H); $p<0.05$. Physiological changes in blood insulin concentration have a major impact on the gastrointestinal sensory responses to duodenal distension in healthy individuals.

2249

IMPAIRED BLOOD PRESSURE RESPONSE TO STANDING IS ASSOCIATED WITH DIMINISHED DIURNAL BLOOD PRESSURE INDICES IN IDDM

A. Marton, P.Kempler, I.Barna, K.Keresztes, É.Kádár, Zs.Hermányi, Á.Fazakas, P.Vargha and R.de Chatel. I.Dept. of Medicine, Semmelweis University, Budapest, Hungary.

Cardiovascular reflexes are essential in the diagnosis of autonomic neuropathy. Blood pressure (BP) responses to standing and sustained handgrip (SH) reflect mainly sympathetic function. However, there are no data whether changes in BP during standing and SH are related to diurnal variations of BP and to hypertension itself or not. To evaluate these connections 60 patients with IDDM (mean age: 40,7 ± 14,2 ys; mean duration of diabetes: 20,4 ± 12,1 ys) were studied. The five standard reflex tests of cardiovascular autonomic function were applied. Twenty four hour long blood pressure monitoring (ABPM) was performed by Meditech ABPM 02 device. Decrease of systolic BP after standing correlated significantly positively with systolic ($p<0,01$) and diastolic ($p<0,05$) diurnal BP indices that is higher diurnal indices were associated with higher increase or diminished fall of systolic BP after standing. Mean casual BP values were 122,7±3,9/78,5±10,9 mmHg while mean ABPM values were 116,6±15,7/73,9±11,2 mmHg. The degree of orthostatic hypotension correlated significantly negatively ($p<0,05$) with higher casual systolic BP not as with systolic ABPM values. No significant correlations were found with SH test. Conclusions: impaired BP response to standing is associated with diminished diurnal BP variations in IDDM. ABPM is suggested to perform in patients with orthostatic hypotension and vice versa: "non-dippers" should be screened for postural hypotension. Impaired BP regulation to standing as well as diminished diurnal BP indices may contribute to poor prognosis of autonomic neuropathy in IDDM.

THE EFFECT OF EUGLYCAEMIC HYPERINSULINAEMIA ON GASTRIC EMPTYING IN IDDM

M.-F. Kong, P.E. Blackshaw, P. King, I.A. Macdonald, A.C. Perkins and R.B. Tattersall. Queen's Medical Centre, Nottingham, U.K.

Hyperglycaemia (blood glucose~15mmol/l) delays gastric emptying in both normal subjects and in patients with diabetes but whether hyperinsulinaemia has an effect remains debatable We looked at the effect of two different levels of hyperinsulinaemia, with concomitant euglycaemia, on gastric emptying in 7 male patients with IDDM None had evidence of autonomic neuropathy. Mean diabetes duration was 14.6±10.7 years and mean HbA_{1c} was 6.9±0.7%. After an overnight fast the subjects were infused with insulin, at 40mU/m^2/min on one occasion and at 80mU/m^2/min on the other, with 20% glucose given simultaneously to maintain euglycaemia. Steady-state glucose infusion rate was ensured before the subjects ate a meal consisting of a pancake (labelled with 3MBq non-absorbable ^{99m}Tc) and milkshake (labelled with 0.33 MBq non-absorbable ^{111}In-DTPA), providing 400 kcal (57% carbohydrate) Gamma-scintigraphic images were then obtained at 20 min intervals for the next 3-4 hours to quantify gastric emptying. There was no difference in the solid t_{50} or the liquid t_{50} between visits (132.5±10.0 min v 124.0±9.6 min for solid and 34.3±7.1 min v 38.6±6.0 min for liquid respectively, $p>0.05$, paired t-test). CCK and GLP1 hormone responses were similar ($p>0.05$, ANOVA for repeated measures) following the meal on the two occasions. Thus our data show that there is no effect of the two different levels of hyperinsulinaemia on gastric emptying of a solid and liquid meal in IDDM subjects.

2251

MEALTIME SC INSULIN INJECTION CAUSES ORTHOSTATIC HYPOTENSION IN DIABETIC AUTONOMIC NEUROPATHY DESPITE ADAPTATION TO PROLONGED ORTHOSTATISM.

F.Porcellati, P.Bottini, S.Pampanelli, A.Baccarelli, F.Santeusanio, P.Brunetti, and G.B.Bolli. University of Perugia, Perugia, Italy.

To assess whether the therapeutic prandial subcutaneous (sc) insulin injection, or the meal *per sè*, has appreciable haemodynamic effects in patients with diabetic autonomic neuropathy (DAN) adapted to prolonged orthostatism, 11 patients without DAN (DAN-), 6 with DAN but no orthostatic hypotension (DAN+OH-), 6 with DAN and OH (DAN+OH+) and 6 nondiabetics (N) were studied on 4 occasions (S1-S4) at 2 week intervals. In all studies subjects remained seated for 2 hours before, and for 3½ hours after 0.2 U/kg insulin injected sc 30 min prior to ingestion of a standard mixed meal (in N no insulin was injected) (S1). In S2, all subjects fasted (diabetics had 0.15 mU/kg/min insulin infused to prevent ketosis). In S3 (diabetics only) meal, but no sc insulin was given (i.v. insulin as in S2). In S4, all subjects had sc insulin but glucose was infused to maintain euglycaemia. In S1, mean blood pressure (MBP) did not change neither in DAN-, nor in N due to simultaneous *increase* in forearm peripheral vascular resistances (PVR) by 4.23± 0.03 mmHg/ml/100ml/min. In contrast, in DAN+OH- and DAN+OH+, MBP decreased between 60-210 min by 9.7±0.07 and 12.4±0.08 mmHg (patients experienced symptoms of faintness), because PVR *decreased* by 5.21±0.03 and 6.38 ±0.05 mmHg/ml/100ml/min ($p<0.05$ vs DAN-). Plasma noradrenaline (NA) increased to 2.17±0.04 nmol/l in DAN-, 2.62±0.06 nmol/l in DAN+OH-, but only to 1.33±0.05 nmol/l in DAN+OH+ (N 1.76±0.03 nmol/l, $p<0.05$). In S3 MBP did not decrease in DAN-, whereas it decreased by 4.55±0.03 mmHg in DAN+ without changes of FVR. In S4, MBP did not change in N and DAN-, but it did in DAN+ as in S1. Thus, in DAN+ prolonged adaptation to orthostatism does not prevent the haemodynamic effects of therapeutic hyperinsulinaemia which unmasks overt or latent defects of NA release. The meal *per sè* may contribute to decrease in MBP, likely by reducing splanchnic vascular resistance.

2252

GASTRIC EMPTYING IN INSULIN-DEPENDENT DIABETES MELLITUS: LONG-TERM EFFECTS OF CISAPRIDE VERSUS PLACEBO.

G. Stacher, G. Schernthaner, M. Francesconi, H.-P. Kopp, H. Bergmann, G. Stacher-Janotta, M. Frank, P. Hopmeier nad U. Weber. Psychophysiology Unit, Dept. of Surgery, Depts. of Biomedical Engineering & Physics and Nuclear Medicine, University of Vienna, Vienna; Depts. of Medicine I and Clinical Chemistry, Krankenanstalt Rudolfstiftung, Vienna; Rehabilitationszentrum der Pensionsversicherung der Arbeiter, Alland; Austria.

In many patients with insulin-dependent diabetes mellitus, slow gastric emptying makes the delivery of ingesta into the small intestine and the time of their absorption unpredictable. Hence, insulin is administered at inappropriate time points and poor glucose control ensues. Prokinetic agents were found to accelerate emptying, but controlled studies in long-term effects are scarce. We investigated the effects of 10 mg cisapride QID for 8 weeks, as compared to placebo, on gastric emptying and glucose control under random, crossover, double-blind conditions. Ten males and 13 females, age 25-67 years (median (M) 45 yr), Body Mass Index 19.0-32.8 kg/m^2 (M 23.9 kg/m^2), illness duration 3-48 yr (M 20 yr), completed the study. None took other drugs affecting gastrointestinal function. Emptying of a radiolabelled semisolid 1168 kJ meal was recorded before and after 8-weeks' drug intake as well as after a 4-week wash-out followed by another 8-weeks' drug intake. At the study's start, 14 of the 23 patients had a delayed emptying, their residual radioactivity (RRA) 50 min after meal ingestion exceeding 48 healthy subjects' mean RRA+1.5 SD, i.e. 73.2 %. Of these 14 patients, 7 had cardiovascular autonomic neuropathy (CANP) as compared to 1 of the 9 with normal emptying. Cisapride accelerated emptying in 8 of the 14 patients with delayed and 7 of the 9 with normal emptying. Emptying was enhanced by cisapride in 11 of the 15 patients without CANP, but only 4 of the 8 with CANP. In those without CANP, the RRA 120 min after meal ingestion was 19.0 %±3.4 SE following cisapride and 24.3± 2.4 % following placebo; in the patients with CANP, these figures were 30.5±9.5 % and 30.6±7.5 %. Glycemic control as revealed by glycosylated hemoglobin was unaffected by cisapride. Conclusion. Cisapride intake over 8 weeks tended to accelerate gastric emptying in patients without but not with CANP, and had no effect on glucose control.

2253

POSTURAL STABILITY IN DIABETIC NEUROPATHY: IS IT A DEVICE FOR EARLY DIAGNOSIS ?

M.Farinelli*, L.Baratto*, E. Betti*, P.Morasso*, R.Capra*, V.Rubino*, G.Spada*, P. Spigno*, A.Corsi, F.Menozzi, P. Ubaldi, M.A.Comaschi
Dpt. of Int. Med. - Diabetes Unit "La Colletta"Hospital Genoa Italy
*Center of Rehabilitation Bioengineering - University of Genoa

Our previous papers have shown that diabetic patients affected by peripheral neuropathy show a typical postural pattern, charactherized by mean sway speed, paths and areas much higher than in normal subjects and not neuropathic diabetics. Altogether, the speed diagrams of the sway show frequent "escapes" from the mean values, and this shape seems to be related only to sensitive defect.
In the present work insuline dependent diabetic patients have been studied, in order to define if the lack of the postural stability is an early symptom of an asymptomatic neuropathy. Twenty patients (13 F, 7 M) and ten healthy subjects (6 F, 4 M) have been submitted to stabilometry by postural platform, Nerve Conduction Velocity, Vibration Perception Threshold by biothesiometer, Neurological Examination performed by a single neurologist to avoiding intra-observers variability, Autonomic Nervous System Functional Evaluation by DB, PH, VR beside methabolic common parameters control. The data of patients are shown in the table. Our results suggest that stabilometric parameters seems to be more sensitive than VPT in discriminating neuropathic patients.

	Normal subjects	Not Neuropathic Diabetics	Neuropathic Diabetics
Age	32 ± 10	37 ± 12	45 ± 6
Sway Path (mm)	139 ± 28	142 ± 24	203 ± 46
Sway Area (mm^2)	168 ± 77	172 ± 105	251 ± 57
Mean Velocity (mm/sec)	18 ± 3.6	21 ± 5.8	49 ± 23
Nerve Conduction Velocity	Normal	Normal	Abnormal
VPT (Volt)	5 ± 2	10 ± 2	15 ± 4
Neurological Examination	Normal	Normal	Abnormal
Autonomic Test	Normal	Normal	30% Abnormal
Duration of Desease (years)		12 ± 6	19 ± 4

2254

SLOWER, NOT FASTER, GASTRIC EMPTYING OF SEMISOLID MEAL IN NON-INSULIN-DEPENDENT DIABETES MELLITUS THAN IN HEALTH.

A. Festa, A. Holzäpfel, C. Schneider, G. Stacher-Janotta, H. Bergmann, G. Schernthaner, G. Stacher. Psychophysiology Unit, Dept. of Surgery, and Dept. of Biomedical Engineering & Physics, University of Vienna; and Dept. of Medicine I, Krankenanstalt Rudolfstiftung, Vienna, Austria

In patients with recently diagnosed as well as with more longstanding non-insulin-dependent diabetes mellitus (NIDDM), the gastric emptying of liquids and solids has been reported to be faster than in healthy subjects. Others, however, found gastric emptying in NIDDM patients either not to differ from the one in healthy individuals or, in a substantial number of cases, to be delayed. The present study was carried out to shed more light on this controverse but, for therapeutic consequences, important topic. Thirteen patients (7 females and 6 males; age 44-68 years, median (M) 56 yr; Body Mass Index (BMI) 22.9-41.3 kg/m^2, M 27.1 kg/m^2; NIDDM duration 1-23 yr, M 5 yr) took part. The gastric emptying of a semisolid meal (1168 kJ) as well as of 250 ml 10 % dextrose solution (420 kJ) was studied scintigraphically at 1-week intervals. A single-headed gamma camera and a correction procedure for posterio-anterior movement of gastric contents were employed. The patients emptied the semisolid meal significantly ($P<0.001$) slower than 55 healthy subjects, the mean residual radioactivity (RRA) in the stomach 50 min after ingestion being 73.3 %±18.0 SD versus 54.0±13.3 %. After the semisolid meal, the RRA in 5 of the 13 patients was greater than the healthy subjects' mean RRA ± 2 SD, i.e., >80.6 %. Two patients had a RRA slightly lower (48.2 % and 40.8 %, respectively) than the healthy subjects' mean RRA. The glucose solution was emptied slightly faster by the patients than by 11 healthy subjects (age 23-52 yr, M 34 yr; BMI 19.4-33.7 kg/m^2, M 22.2 kg/m^2), the mean RRAs 30 min after drinking amounted to 59.0±10.7 % vs 68.1±15.1 %. In the patients, the RRAs for the semisolid meal and the glucose solution were correlated with neither the blood-glucose levels before the emptying studies nor with the levels of glycosylated hemoglobin indicative of glycemic control. Conclusions. The gastric emptying of semisolids but not the one of liquids is slower in patients with NIDDM than in healthy subjects and both are unrelated to actual blood-glucose levels and glycemic control.

2255

BAROREFLEX SENSITIVITY IN NORMAL AND IMPAIRED GLUCOSE TOLERANCE AND NIDDM

J. Gerritsen[1,2], B.J. TenVoorde[1], J.M. Dekker[2], L.M. Bouter[2] and R.M. Heethaar[1].
[1] Dept. of Medical Physics and Informatics, [2] EMGO Institute, Fac. of Medicine, Institute for Cardiovascular Research *Vrije* Universiteit, Amsterdam, Netherlands

The deep breathing expiration-inspiration difference in heart rate (EI-value) is used to diagnose diabetic autonomic neuropathy. Easily overlooked is the fact that this EI-value is largely caused by respiration-induced changes in blood pressure (BP, mmHg), which may differ among persons. However, baroreflex sensitivity (BRS, ms/mmHg) is an estimate of the change in heart rate caused by these BP variations and possibly a more sensitive parameter of autonomic function than conventional EI-values, which has recently been claimed to be the case in IDDM. Therefore BRS-estimates and EI-values were studied in relation to glucose tolerance in a population based study. Subjects (50-74 yr-old) were categorized (after two OGTTs) as normal (NGT, n=199), impaired glucose tolerant (IGT, n=125), newly diagnosed diabetes (NDM, n=62) or known diabetes (KDM, n=46). RR-intervals (ms) and systolic BP (SBP, Finapres®) were recorded in supine position during spontaneous breathing (3 min) and during deep breathing at 6/min (1 min). BRS_{spont}, $BRS_{6/min}$ (both transfer function gain), $\Delta SBP_{6/min}$ (absolute changes in SBP) and $EI_{6/min}$ were calculated in a narrow frequency band around 0.1 Hz, including only those spectral points having a squared coherence $\gamma^2>0.5$.

Group	BRS_{spont}	$BRS_{6/min}$	$\Delta SBP_{6/min}$	$EI_{6/min}$
NGT	7.1 ± 4.2	9.1 ± 4.6	19.2 ± 8.9	177 ± 98
IGT	6.1 ± 3.6 #	8.3 ± 4.7	18.6 ± 12.6 #	155 ± 97 #
NDM	5.2 ± 3.4 *	7.6 ± 4.1 †	18.1 ± 7.4 †	146 ± 98 †
KDM	5.3 ± 2.6 †	7.5 ± 3.9 †	16.9 ± 7.7	132 ± 89 *

given are mean ± SD; different from NGT group with * $p<0.01$, † $p<0.05$, # $p<0.1$

BRS_{spont} was significantly lower than $BRS_{6/min}$ (paired t-test, $p < 0.0001$). After transformation, analysis of variance showed that, adjusting for age and gender, BRS_{spont} ($p=0.04$), $BRS_{6/min}$ ($p=0.05$) and $EI_{6/min}$ ($p < 0.01$) decreased with decreasing glucose tolerance while ΔSBP only showed a trend ($p=0.07$). However, BRS did not show a stronger association with glucose tolerance than EI-values did.

SEX DIFFERENCES IN THE RELATIONSHIP BETWEEN THE QT INTERVAL AND DIABETIC COMPLICATIONS IN IDDM PATIENTS

M.Veglio, M. Borra, P. Cavallo-Perin, LK Stevens and The EURODIAB IDDM Complications Study Group, London, UK

QT interval prolongation is thought to be a risk factor for mortality. We examined the relationship of corrected QT (QTc) prolongation with Ischemic Heart Disease (IHD), nephropathy, and retinopathy in people with IDDM. QT intervals were measured and corrected for heart rate in 3147 patients from EURODIAB, which was a study of 3250 men and women from 31 clinics across Europe. IHD was defined by ECGs which were Minnesota coded, nephropathy was assessed using albumin excretion rate (AER), which was measured centrally from a single 24 hours urine collection, and retinopathy was assessed by centrally graded retinal photographs. Mean QTc was 0.412s in men and 0.422s in women ($P<0.001$), and QTc was positively related to HbA1c and age. Therefore all subsequent analyses were adjusted for these confounding factors. In men the mean QTc for those without IHD was 0.410s and was 0.423s for those with IHD ($P<0.001$). In women these values were 0.422s and 0.429s ($P<0.01$). Thus the relationship between QTc and IHD was stronger in men than in women ($P<0.05$ for the interaction). A similar pattern was seen for nephropathy. For men mean QTc for those with AER < 20 mcg/min was 0.411s, for those with AER 20-200 mcg/min was 0.413s and for those with AER > 200 mcg/min 0.418s ($P<0.001$), and the equivalent figures for women were 0.421s, 0.425s and 0.425s ($P<0.08$) ($P<0.09$ for the interaction). Ther was no relationship between retinopathy and QTc in men or women. We show that Qtc is higher in women than men, and the relationship of Qtc with IHD and nephropathy is not as strong in women as in men. Further studies need to be performed to determine the importance of Qtc and it's impact on mortality in both men and women.

DISTURBANCES OF HEART RATE VARIABILITY AND SPATIAL AND CIRCADIAN QTc INTERVALS IN DIABETIC PATIENTS WITH CARDIAC AUTONOMIC NEUROPATHY

Cs. Lengyel, A. Thury*, T.T. Várkonyi, I. Ungi*, K. Boda**, T. Fazekas and M. Csanády* , 1st and *2nd Departments of Medicine and **Dept. of Medical Informatics, A. Szent-Györgyi Medical University, Szeged, Hungary

Increased cardiac mortality due to ventricular arrhythmias has been demonstrated in diabetic patients with cardiac autonomic neuropathy (CAN). The aim of this study was to evaluate the disturbances of heart rate variability (HRV) and spatial and circadian QTc intervals in diabetics with CAN. *Patients and methods:* CAN was assessed by means of five standard cardiovascular reflex tests. 8 healthy controls and 18 insulin-treated diabetics (7 CAN- [score$\leq$1] and 11 CAN+ [score$\geq$2]) were studied. 24-h HRV parameters (mNN, SDNN, SDNNi, SDANN, rMSSD and pNN50; and low-frequency [LF], high-frequency [HF] and total power [TP] spectra) were calculated. The QTc interval dispersion (QTc-d) was defined as the longest *interlead* difference of the standard 12-lead ECG. QTc intervals during a sampling period of 6 s were analyzed from the Holter ECGs every hour and the diurnal fluctuation of QTc was characterized by a circadian index generated by a custom-made computer program. One-way ANOVA and Scheffé's test were applied for statistics. *Results:* No differences in HRV indices and QTc intervals were found between the control and CAN- groups. The two diabetic groups (*CAN- vs CAN+*) differed significantly in SDNN, SDNNi, SDANN, rMSSD, pNN50, HF, LF and TP, but there was no difference in mNN. The circadian fluctuation of QTc was diminished in the CAN+ group. Moreover, CAN+ diabetics displayed an increased QTc-d relative to the CAN- subset. *Conclusions:* 1) CAN+ diabetics exhibit an enhanced spatial inhomogeneity and a depressed temporal variability of the ventricular repolarization (QTc) time; 2) CAN+ diabetics have decreased non-spectral and spectral HRV parameters.

2258

CLINICAL BENEFIT OF THE SPECTRAL ANALYSIS AND ITS SEGMENTAL INTEGRATION TO ASSESS THE AUTONOMIC NERVE FUNCTION IN DIABETIC PATIENTS

H. Himei, T. Matsuoka, Y. Kawanishi, T. Kajitani and M. Ogata. Okayama Red Cross General Hospital, Okayama-700, Japan

The clinical usefulness of simultaneous guantitative assessment of sympathetic and parasympathetic function by spectral analysis using the maximum entropy method (MEM) was evaluated. ECG tracings were obtained from 235 normal individuals and 776 patients with diabetes mellitus, and R-R interval variations over 100 beats were subjected to spectral analysis using an MemCalc 1000. In normal individuals, segmental integration in the high frequency range (HF) was increased significantly by deep breathing and was well correlated with other parameters of parasympathetic function based on R-R interval variation. Parasympathetic activation by deep breathing was associated with sympathetic activation, as indicated by a significant increase of segmental integration in the low frequency range (LF). Compared to normal individuals, patients with sympathetic dysfunction had a smaller resting LF segmental integration value. In this diabetic group, segmental integration also showed a significatly smaller increase upon deep breathing. In both normal individuals and diabetic patients, segmental integration values decreased with ageing. In patients with obvious diabetic neuropathy, both the HF and LF segmental integration values were reduced at rest and only increased slight upon deep breathing. In conclusion, HF and LF segmental integration values obtained by MEM spectral analysis of R-R interval variation were correlated well with other parameter of sympathetic and parasympathetic nerve function. In particular, LF segmental integration may be of clinical value for assessing sympathetic function in patients with diabetes mellitus.

2259

CARDIAC AUTONOMIC NEUROPATHY IN DIABETIC PATIENTS UNDER HEMODIALYSIS THERAPY FOUND BY POWER SPECTRAL ANALYSIS OF 24 HOUR R-R INTERVAL

J. Y. Lee[1] , M. Kodama[2], I. Nakahara[2], M. Hori, Y. Yamasaki[2]
[1]Higashi Osaka Hospital, [2]Osaka University School of Medicine, Osaka, Japan

AIM: Diabetics under hemodialysis showed poorer prognosis and more frequent episodes of sudden death than non-diabetics under hemodialysis.

METHODS: In order to analyze the poor prognosis, we detected episodes of arrhythmia and evaluated cardiac autonomic nerve functions in hemodialysed diabetics without peripheral neuropathy (HD group), age-matched diabetics without peripheral neuropathy nor autonomic neuropathy (NN group), and age-matched diabetics with symptoms of autonomic neuropathy (AN group). The averaged (± SEM) low frequency (LF; 0.03-0.15Hz) and high frequency (HF; 0.15-0.4Hz) components, which represent cardiac sympathetic nerve function and parasympathetic function, respectively, were calculated from 24 hour RR-intervals by means of power spectral analysis for 24 hours (24h: 8h-8h), daytime (12h-18h), and midnight (0h-6h).

RESULTS: HD group showed significantly lower 24h-LF (41 ± 16 vs 322 ± 83 msec2, $p<0.05$) and 24h-HF (51 ± 8 vs 162 ± 34 msec2, $p<0.05$) than NN group, which were comparable to those of AN group (27 ± 8 for 24h-LF and 43 ± 9 for 24h-HF). Daytime (12h-18h) averaged sympathetic function (LF) was significantly lower in HD and AN than that in NN group (36 ± 15, 29 ± 6, 340 ± 98, respectively). Midnight (0h-6h) averaged para-sympathetic function (HF) was significantly lower in HD and AN than in NN group (56 ± 17, 47 ± 12, 200 ± 40, respectively). The episodes of arrhythmia were comparable among HD, NN, and AN groups.

CONCLUSION: In spite of non-symptoms of autonomic neuropathy, hemodialyzed diabetics showed impaired cardiac autonomic functions comparable to those of diabetics with symptomatic autonomic neuropathy, which might result in their poor prognosis.

2260

POWER SPECTRUM ANALYSIS OF R-R INTERVALS UNDER 24-HOUR HOLTER ELECTROCARDIOGRAM IN PATIENT WITH NIDDM WHO DEVELOPED INCREASED BLOOD PRESSURE AT NIGHT

N.Asahi, T. Sato, A. Ohno, and A. Ueki
Hachioji Medical Center of Tokyo Medical College,Tokyo, Japan

[Objective] The mechanism of an abnormality in diurnal variation of blood pressure seen in patients with diabetes mellitus was studied by means of power spectrum analysis of R-R intervals under 24-hour Holter electrocardiograms. [Subjects and Methods] The subjects were 69 in-patients with NIDDM. Each patient wore a portable noninvasive automatic blood pressure meter and were administered a Holter electrocardiogram at about 2:00 p.m. Based on their 24-hour blood pressure pattern, the patients were classified into three groups: a first group in which blood pressure decreased at night (the decreased group), a second group in which blood pressure flattened at night (the flattened group) and a third group in which blood pressure increased at night (the increased group). The R-R intervals obtained from Holter electrocardiogram were analyzed every 512 seconds by means of fast Fourier transformation to draw a power spectrogram. In some patients urine was divisionally sampled during the day and at night to measure catecholamine. [Results] The coefficient of variation (CV) of R-R at rest in the increased group was 1.7%, and 1.2% in the flattened group, both of which were lower than the CV R-R of the decreased group at 2.6%. The excretory amount of catecholamine in the urine of the increased group decreased during the day and at night in comparison with that of the decreased group. In the decreased group, low frequency (LF) was superior during the day and high frequency (HF) was superior at night under the power spectrum. In the increased group, both the LF and HF components decreased, and some patients actually showed very few HF components. [Discussion] Increased blood pressure at night seen in patients with diabetes mellitus is profoundly associated with the level of autonomic disorder. Especially, in consideration of the results of the power spectrum of R-R intervals, the disappearance of any change in the vibrational amplitude of the maximum frequency as well as the disappearance of the HF components alone could be associated with the disappearance or reversal of diurnal variations in blood pressure. It also is possible that increased blood pressure at night might be attributable to parasympathetic hypoactivity rather than sympathetic hypoactivity, taking their mechanisms into account.

2261

MYOCARDIAL PERFUSION, ECG-INDICES AND CARDIAC REFLEX TESTS IN NEWLY DIAGNOSED AND LONG-TERM IDDM

M. Meier[1,2], O. Schnell[1,2], D. Muhr[2], M. Weiss[3], M. Haslbeck[1,2], K. Tatsch[3], E. Standl[1,2];[1]Diabetes Research Inst. and Third Med. Dept., Schwabing City Hospital, Munich; [2]Diabetes Research Inst., Munich; [3]Dept. of Nuclear Med., University of Munich, Germany

Myocardial perfusion of 20 newly diagnosed and 40 long-term IDDM patients without clinical evidence for coronary artery disease was assessed with a Tc-99m-methoxy-isobutyl-isonitrile (Tc-99m-MIBI) scintigraphy with regard to ECG-based indices (PQ segment, QRS complex, QT and QTc interval). Global and regional (anterior, lateral, posterior, septal and apical) mean tracer activities were grouped into a myocardial uptake score (MU-score: 1-6). Five cardiac reflex tests were performed to assess cardiac autonomic neuropathy (CAN). None of the diabetic patients demonstrated significant myocardial perfusion defects (MU-score > 3). In newly diagnosed IDDM, QRS-complex correlated with global ($p < 0.05$) and posterior ($p < 0.01$) 99mTc-MIBI uptake. QTc interval was related to global ($p = 0.02$), posterior ($p < 0,05$) and septal ($p < 0.05$) 99mTc-MIBI uptake. In long-term IDDM, a correlation between apical 99mTc-MIBI uptake and QTc interval was observed ($p < 0.05$). One patient (5 %) with newly diagnosed and 17 (42.5 %) patients with long-term IDDM demonstrated ECG-based CAN (≥ 2 abnormal reflex tests). No significant differences in global and regional myocardial Tc-99m-MIBI uptake, PQ segment, QRS complex, QT and QTc interval were observed between diabetic patients with and without CAN. The study demonstrates that CAN in IDDM patients without clinical evidence for coronary artery disease occurs in the absence of myocardial perfusion defects. In this group, ECG indices are not strongly related to myocardial perfusion.

2262

QT DISPERSION IN PATIENTS WITH CARDIAC AUTONOMIC NEUROPATHY DURING INSULIN - DEPENDENT DIABETES MELLITUS.

K. Wanic, W. Dynowski, E. Kozek, D. Galicka - Latała and J. Sieradzki. Department and Clinic of Metabolic Diseases - Jagellonian University, Cracow, Poland.

Patients with diabetic cardiac autonomic neuropathy are particullarly at risk of sudden death as the result of ventricular arrythmias. Our objective was the measurement of QT and QTc dispersion and the assesment of influence of cardiac autonomic neuropathy on QT and QTc dispersion in patients with insulin - dependent diabetes mellitus. Patients were tested for cardiac autonomic neuropathy using ProSciCard system. We carried out four tests: resting pulse, deep breathing pulse, Ewing test, Valsalva maneuwer. QT interval was measured manual on the basis of 3 tests on each of 12 - lead ECGs. We studied 44 patients (23 men, 21 women) in which 21 with cardiac autonomic neuropathy (14 men, 7 women) and 23 without cardiac autonomic neuropathy (9 men, 14 women). Mean QTc interval by Bazett's formula in the group with cardiac autonomic neuropathy was $0.4099 \sqrt{sek} \pm 0.0300$ and was significantly higher than in the group without cardiac autonomic neuropathy ($0.3767 \sqrt{sek} \pm 0.0294$) ($p < 0.001$). The QT dispersion is the difference between the maximum and minimum QT across the 12 - lead ECG. QT dispersion in the group with cardiac autonomic neuropathy was statistically higher than in the group without cardiac autonomic neuropathy (mean $0.0511 \text{ s} \pm 0.0159$ vs $0.0319 \text{ s} \pm 0.0104$; $p < 0.001$). In the group with cardiac autonomic neuropathy QTc dispersion was significantly statistically higher (mean $0.0620 \sqrt{sek} \pm 0.0219$ vs $0.0501 \sqrt{sek} \pm 0.0134$; $p < 0.05$). Our result show higher QT and QTc dispersion in patients with cardiac autonomic neuropathy which can be the reason of higher risk of ventricular arrythmias.

2263

Cognitive Function in NIDDM Patients before and after Glycemic Adjustment

M. Mussell, W.Hewer, F. Rist, *B. Kulzer, *K.H. Bergis
Central Institute of Mental Health, Mannheim, Germany
*Research Institute of the Diabetes-Academy, Bad Mergentheim, Germany

Several studies have found cognitive impairment in Type II -Diabetes subjects (DS). However, data are not consistent on all accounts. This study was conducted to determine cognitive impairment in DS with neuropsycholoical methods. We hypothesized that glycemic state and diabetic late complications affect cognitive performance.

54 DS inpatients (58,8 ± 6,0 years) were compared at admission (t1: GHb 13,3 ± 1,6%; FPG 205,4 ± 40,1mg/dl) and after glycemic correction, mainly by insulin (t2: GHb 11,6 ± 1,3%; FPG 111,2 ± 17,8mg/dl), with 30 age-matched non-diabetic controls, tested in the same interval of 14 days. Cognitive function was assessed on memory, learning, processing speed and reaction time in a focused-attention task. Scores of depression and intelligence, relevant variables of diabetes and general health status were controlled.

First results of ANOVA show: reaction time is prolonged in DS ($p<.01$), they reproduce fewer words ($p<.05$), and recall fewer words from immediate memory ($p<.01$) than controls. In the two latter tasks DS decline from t1 to t2 ($p<.05$). DS with the greatest reduction of FPG (237,1 ± 27,3 to 97,1 ± 9,5mg/dl) show a decrease in reproduced words ($p<.05$). DS with microangiopathic and neuropathic late complications reproduce fewer words ($p<.05$) and have a lower intelligence score for abstract reasoning ($p<.05$) than those without late complications.

Cognitive impairment in DS were found primarily in the encoding of new information and in reaction time. According to our data late complications have important impact on cognitive performance. The impact of FPG on performance is seen as a transient effect of metabolic adaptation. The results of the 3-month follow-up study may confirm these findings. Information on neurophysiological processing is expected from the data of evoked potentials.

2264

The evaluation of the frequency of asymptomatic central diabetic neuropathy in insulin dependent diabetic children with auditory, visual and somatosensorial evoked potentials.

S. Mıkla, A. Aydın, N. Uzun, C. Fıçıcıoğlu, M. Arapoğlu, E. Adal. University of Istanbul, Cerrahpaşa Medical Faculty, Deptartment of Pediatrics, Istanbul, Turkey.

To investigate the frequency of asymptomatic diabetic encephalopathy, we examined the somatosensorial (SEP), visual (VEP) and auditory (BAEP) evoked potentials in insulin dependent diabetic children whose visual, auditory and somatosensorial functions were normal. 36 diabetic patients, 21 female, 15 male and 10 normal children at the same age and sex were included in the study. Diabetes duration varied between 6 months and 11 years (average 4.6 ±2.6 years), with average control of disease (HbA1C: %10.97± 4.02) and ages varied between 6 years and 17 years (average 11.1 ±3.24 years). Supraspinal (central) somatosensorial conduction was normal whereas median nerve (wrist-C7: $p<0.001$, wrist -scalp: $p< 0.001$) and tibial nerve (ankle -scalp: $p<0.05$) SEP latencies were significantly delayed as compared to control group.

Right eye, left eye and intraocular VEP (P100) latencies were also significantly delayed as compared to control group (for each one $p<0.001$).

Evaluation of auditory pathways by BAEP revealed normal latencies at I., II., and III. waves, however IV. wave latencies (right $p<0.001$, left $p<0.05$) and V. wave latencies (right: $p<0.05$, left: $p<0.001$) were found to be delayed. Interpeak latencies were also delayed between I-V (right: $p<0.05$, left: $p<0.001$) and between I-III (left $p<0.05$).

Age, sex, duration and control degree of diabetes did not correlate with SEP, VEP or BAEP abnormalities.

Perjpheral SEP pathology was found in 13 patients (36.1%), central BAEP pathology in 14 patients (39%) and VEP abnormalities were seen in 9 patients (25%) whose somatosensorial , auditory and visual functions were intact, respectively. 17 patients (47.3%) had either abnormal BAEP or abnormal VEP results.

These electrophysiological results revealed that 47.3% of the patients included in this study had asymptomatic central encephalopathy and 39% of the patients had asymptomatic peripheral sensorial neuropathy unrelated to age, sex, duration and control degree of diabetes.

2265

CENTRAL MOTOR INVOLVEMENT IN TYPE I DIABETIC SUBJECTS: A NEUROPHYSIOLOGICAL STUDY.

L.Pisano, C.Suraci, M.Giuliano, M.G.Pennafina, *M.T.Desiato, *C.Ianni, *M.G.Palmieri and *M.D. Caramia. Divisione di Malattie del Ricambio, Ospedale S.Eugenio, *Clinica Neurologica, Università Tor Vergata, Roma, Italy

The aim of this study is to evaluate, in a group of type 1 diabetic patients, most without clinical symptoms of neuropathy, the presence of neurophysiological signs of peripheral and central nervous system involvement. Thirtyone well compensated patients (HbA1c<6,5% ; aged 18-45 years ; duration of diabetes 1-20 years) were enrolled in the study. The following neurophysiologic tests were performed: surface neurography of median and tibial nerves, "near nerve" sensitive neurography of sural nerve; Motor Evoked Potentials (MEPs) to magnetic brain Trans-Cranial Stimulation (TCS) through a regular coil applied on the scalp at optimal positions for hand and foot motor areas; sudomotor palmar responses to electric median nerve, brain TCS and cervical roots stimulation (skin test). Significant differences between controls (25 healthy age-matched subjects) and diabetics in the excitability threshold of MEPs (THR lower limbs=56.3±6.8 vs 70.6±12 % - $p<0.001$; THR upper limbs=39.4±3.6 vs 48.9±9.1 % - $p<0.001$), but not in the central conduction time (CCT lower limbs=12.7±1.2 vs 13.4±2.7 msec; CCT upper limbs=5.6±0.8 vs 6.1±1.2 msec) were found. Twenty-two subjects had a mixed, mainly axonal, neuropathy in the lower limbs and 4 in all four limbs. MEP parameters showed, in the lower limbs, increased THR in 11 patients and prolonged CCT in 5 patients. Motor central involvement for the upper limbs was found in 16 patients lacking sign of peripheral neuropathy: increased THR was detected in 12 patients and prolonged CCT was found in 4 patients. The skin test was absent in 12 diabetics, 3 of whom without peripheral involvement. Five out of nine patients, suffering from diabetes for less than three years, presented signs of polyneuropathy and involvement of central motor pathways, whilst three out of nine had only a pathologic skin test. The present study shows a subclinical central motor involvement in some patients with was not correlated with the occurrence of peripheral neuropathy, possibly suggesting a distinguished pathophysiology responsable for central and/or peripheral involvement.

HEART RATE VARIABILITY AND MORTALITY. THE ARIC STUDY

JM Dekker, RS Crow, AR Folsom, P Hannan, DP Liao, EG Schouten, CA Swenne, Inst. For Research in Extramural Medicine, Vrije Universiteit Amsterdam, The Netherlands

Low HRV is a marker of sympathetic predominance, and is associated with mortality risk in patients with heart disease. We studied the predictive value of HRV in the Atherosclerosis Risk in Communities Study, a prospective study of 16,000 men and women, aged 45-64, using a case-cohort design.

At baseline, in 1987-1989, 2-minute rhythm strips were recorded. HRV was determined in a random sample of 900 subjects without CHD, and in all deaths through 1993 (423). Subjects were categorized according to the tertile-distribution in the random sample. Relative rates of total- and cause-specific mortality, and 95% confidence intervals, were computed using Poisson regression for case-cohort design, adjusting for age, race and field center. For cancer analyses, subjects with a history of cancer were excluded.

Subjects with low HRV had an adverse cardiovascular risk profile and higher risk of mortality from all causes (see table). The associations could not be attributed to other risk factors, or to prevalent diseases. These results suggest low HRV may be an indicator of poor general health.

HRV	All causes	CVD	cancer	other
SDNN\# cases:	423	134	162	89

CARDIAC SYMPATHETIC DYSINNERVATION IN DIABETES: AN EXPLANATION FOR ENHANCED CARDIOVASCULAR RISK?

MJ Stevens, DM Raffel, DM Wieland, MA Pfeifer and M Schwaiger. University of Michigan, Ann Arbor and Southern Illinois University School of Medicine, Springfield, USA.

Regional cardiac sympathetic hyperactivity predisposes to malignant arrhythmias in non-diabetic (ND) cardiac disease. Conversely, cardiac sympathetic denervation predicts increased mortality in severe diabetic autonomic neuropathy (DAN). Diabetic patients however experience proportionally greater cardioprotection from β-blockade. We propose that in diabetes, regional cardiac denervation may induce regional sympathetic hyperactivity and ischemia which may act as a focus for chemical and electrical instability. We have used positron emission tomography and C-11 hydroxyephedrine (HED) to explore regional changes in cardiac sympathetic neuronal density and tone and N-13 ammonia to measure regional changes in myocardial blood flow (MBF) at rest and after intravenous adenosine (140 µg/kg/min) in diabetic patients with and without DAN. Cardiac scans were performed in 10 diabetic control subjects without DAN (DAN-), 9 subjects with DAN (4 mild and 5 severe) and 14 healthy subjects. 40% of DAN(-)subjects had abnormalities of cardiac HED retention. In mild DAN, only distal inferior left ventricular (LV) tracer defects were observed but in severe DAN, defects also involved the distal and proximal anterolateral walls. Absolute tracer retention was paradoxically increased by 63% ($p<0.05$) in the proximal segments of severe DAN subjects compared to the same segments in mild DAN subjects (60% $p<0.05$ greater than ND subjects) while distally tracer retention was decreased in these subjects by 42% ($p<0.05$). No washout of tracer was observed in the proximal segments, consistent with normal regional tone but increased sympathetic innervation. Coronary flow reserve was decreased only in severe DAN subjects who achieved only 49% ($p = 0.0004$) and 51% ($p = 0.01$) of the values measured in ND and DAN(-) subjects, respectively. Reduction of myocardial vascular resistance on adenosine infusion during severe DAN subjects was identical to DAN(-) subjects in the distal denervated myocardium, but was markedly blunted in the proximal hyperinnervated segments, where vasodilation was attenuated by 35% ($p = 0.04$). Diabetes may result in LV sympathetic dysinnervation with proximal hyperinnervation complicating distal denervation. The hyperinnervated segments also demonstrate elevated vascular resistance. These findings could result in potentially life-threatening myocardial electrical instability and explain the enhanced cardioprotection from β-blockade in these subjects.

2268

IODINE-123-METAIODOBENZYLGUANIDINE IMAGING AND CORONARY ARTERY DISEASE IN PATIENTS WITH NIDDM.

K.Kamado, S.Gorogawa, A.Kuroda, T.Morozumi, S.Nanto, M. Nagata , T.Shimonagata*, and M.Fukuchi**.Kansai Rosai Hospital, *Osaka Prefectural General Hospital, and **Hyogo College of Medicine, Hyogo, JAPAN

It has been reported that abnormality in I-123 metaiodo benzylguanidine (MIBG) uptake is closely related to sympathetic nerve dysfunction in diabetics . But, in some cases, asymptomatic coronary artery disease is coexisted in abnormal MIBG accumulation . In this study ,the patients with non-insulin dependent diabetes mellitus (NIDDM) is undertaken to examine the relationship between abnormality in MIBG uptake imaging and coronary artery disease.We compare the H/M ratio of MIBG between 68 NIDDM patients (Group N, male:36,female:32, Age 62+/-6 y.o.) and 7 non diabetic patients (Group C, male:5,female2, Age 60+/-10 y. o.). We studied a coronary angiogram in 37 NIDDM patients who had abnormality of MIBG imaging (Group NA, male:17cases, female: 20cases, Age:65.6+/-8.6 y.o.). (1)The group N had a lower H/M ratio than those in group C(3.1 +/-0.3 vs. 2.74+/-0.42, $p<0.05$). (2) In group NA, 7 cases had detected more than 75 % stenosis of coronary arteries (Group A), 12 cases had 25% or 50% stenosis (Group B) and remains 18 cases are normal coronary angiogram (Group C). We found that the more severe stenosis of coronary artery, the lower the H/M ratio, but not significantly ((A) 2.38+/-0.52, (B) 2.38+/-0.54, (C) 2.66+/-0.32, (A)vs. (C), $p = 0.11$, (B) vs.(C), $p=0.06$). Group A were patients with asymptomatic myocardial ischemia. And 2 cases of them had decreased MIBG uptake in corresponding to areas perfused by severe stenosis of coronary arteries. In conclusion, the H/M ratio in diabetics tends to lower than those in non diabetic patients . But, if we will find abnormality of MIBG uptake imaging in diabetics, we must role out asymptomatic coronary artery disease.

2269

LEFT VENTRICULAR MASS AND MYOCARDIAL SYMPATHETIC INNERVATION IN TYPE I DIABETICS WITH AUTONOMIC NEUROPATHY.

M. Pellegrinotti, S. Frontoni, #V. Spallone, *A. Giordano, *V. Rufini, $S. Grego, @G. Testa, *L. Troncone and S. Gambardella - Diabetology and #Endocrinology, University "Tor Vergata"; *Nuclear Medicine and $Cardiology, UCSC, @San Camillo Hospital, Rome, Italy.

Myocardial uptake of 123 I- metaiodobenzylguanidine (MIBG) is decreased in type I diabetics (IDDM) with autonomic neuropathy (AN). Moreover, we previously demonstrated increased left ventricular mass (LVMI) in diabetics with autonomic neuropathy. Aim: to investigate the impact of diabetic AN on LVMI and its relationship to circadian rhythm of blood pressure (BP), and on myocardial sympathetic innervation in normotensive IDDM. We studied 8 IDDM, 4 with autonomic neuropathy (AN+) and 4 without (AN-) (cardiovascular tests), basally and after 6 months of evening treatment with an α-blocker (doxazosin). patients underwent 24-h BP measurement, M-mode echo- cardiographic recording, planar scan and single-photon emission tomography with ^{123}I-MIBG and ^{99m}Tc-MIBI to assess myocardial sympathetic innervation and perfusion. The two groups were comparable for all the main clinical characteristics. Before drug administration, BP although similar in the two groups during the day, was significantly higher in AN+ during the night (Δ mean BP AN-: 8.9±1.5 vs AN+:-5.3±1.7, $p<0.05$). LVMI was in the normal range in both groups and slightly, but not significantly increased in AN+. Posterior wall was significantly increased in AN+ (AN-: 7.4±0.2 vs AN+: 8.7±0.5 mm, $p<0.03$). The heart/mediastinum uptake ratio of 123 I-MIBG (H/M) was significantly reduced in AN+ (2.04±0.1 vs AN-: 2.34±0.1, $p<0.04$). H/M significantly correlated with autonomic score ($r^2=0.6$, $p<0.05$), deep breathing ($r^2=0.8$, $p<0.005$), orthostatic hypotension ($r^2=0.6$, $p<0.05$). Preliminary results suggest that doxasin treatment decreases LVMI (basal: 109.3±9.8 vs 6 month: 97.9±5.1 g/m^2, $p<0.05$) and increases Δ mean BP (basal: -5.3±1.7 vs 6 month: 5.5±2.5, $p<0.05$). In conclusion, 123 I-MIBG allows to detect sympathetic innervation abnormalities in diabetic neuropathy, which in turn may play a role in determining those myocardial abnormalities largely known to be involved in the pathogenesis of sudden deaths.

2270

SENSITIVITY OF HEART SCINTIGRAPHIC IMAGING USING (123 I) MIBG COMPARED TO EWING TESTS IN CARDIAC AUTONOMIC NEUROPATHY IN DIABETES

E. Cosson, H. Mayaudon, M. Ducorps, J.F. Gaillard, G. Prévost, M. Pellan, G. Belmejdoub and B. Bauduceau. Hôpital d'Instruction des Armées Bégin, 94160 Saint Mandé, FRANCE

Cardiac autonomic neuropathy is a frequent complication of diabetes leading to resting tachycardia, postural hypotension, painless myocardial ischaemia, rhythm disturbances and sudden cardiac death. The aim of the study was to evaluate in a diabetic population the sensitivity of two exploration modes of autonomic neuropathy in diabetics : the Ewing tests which are, at present time, the reference method and the (123 I) meta-iodo-benzylguanidine (MIBG) single photon emission computed tomography (SPECT) which evaluates the cardiac sympathetic innervation. Patients and methods : 9 male insulin-dependent diabetes mellitus patients were studied. Mean age was 40.7 ± 15 years and diabetes duration was 10.8 ± 6 years. None had hypertension or macroangiopathy as demonstrated by patient's history, clinical examination, rest and exercise electrocardiography and ambulatory blood pressure monitoring. The complications observed were background retinopathy in 2 patients, incipient nephropathy in 3 and a peripheral neuropathy in 4 patients. Ewing tests, i.e. Valsalva maneuver, beat to beat heart rate variation during deep breathing and standing, blood pressure response to standing and to sustained handgrip, were performed. The results were considered as pathologic when the score was over 2. After injection of 10 mCi (123-I) MIBG, planar imagies were realized at times 1, 2 and 4 hours and SPECT imagies after 2 hours. The heart/mediastinum uptake ratio was calculated. Results : We noted abnormalities of planar imagies in 3 patients, SPECT imagies in 1, and both in 1 patient. None was positive for EWING tests. Conclusion : although MIBG SPECT will explore only the sympathetic innervation, these preliminary findings suggest that this technique could be more sensitive for the evaluation of cardiac autonomic neuropathy. Nevertheless cost and lack of disponibility of this technique should limit its use.

2271

HEART RATE VARIABILITY DURING EUGLYCEMIC, HYPERINSULINEMIC CLAMP IN OFFSPRING OF NIDDM PATIENTS AND CONTROL SUBJECTS

T.Laitinen, I.Vauhkonen, L.Niskanen, J.Hartikainen, E.Länsimies, M.Uusitupa and M. Laakso. Dept. of Clinical Physiology and Nuclear Medicine and Dept. of Medicine, Kuopio University Hospital, Kuopio, Finland

Sympathetic activation has been considered as a link between insulin resistance, hyperinsulinemia and hypertension. However, little is known about the association between insulin sensitivity and autonomic regulation as well as the effect of acute hyperinsulinemia on cardiac sympathovagal balance. The aim of this study was to investigate the effects of insulin sensitivity and insulin infusion on heart rate variability (HRV) during euglycemic, hyperinsulinemic clamp study. We studied 35 non-diabetic offspring of non-insulin dependent diabetes (NIDDM) patients and 14 controls. The probands were chosen from a 10-year follow-up study of patients with well-characterized NIDDM according to their fasting C-peptide level (selected from the both ends of the distribution) and from control subjects to form three groups: group with parental history of insulin resistant NIDDM (phR, n=18), other with parental history of insulin sensitive NIDDM (phS, n=17) and a control group with parental history of normal glucose metabolism (phN, n=14). In phR-group whole body glucose uptake (M-value) was lower than in phS- and phN-groups (7.5±2.4 vs 10.1±1.9 and 11.3±3.1 mg/kg/min, $p<0.05$). In the pooled population M-value correlated with low frequency (LF, $r=0.34$, $p<0.05$) and high frequency (HF, $r=0.29$, $p<0.05$) spectral components of HRV. In all groups heart rate increased significantly during insulin infusion. In phR-group insulin infusion increased also total power of HRV (from 2695±414 to 3804±590 ms^2, $p<0.01$) and LF/HF ratio (from 2.19±0.30 to 4.11±0.81, $p<0.01$) and decreased power of HF spectral component (from 391±66 to 276±42 ms^2, $p<0.01$), whereas in other groups changes in HRV were non-significant. In conclusion, insulin resistance was associated with decreased cardiac vagal activity. Exogenous insulin changed cardiac autonomic balance toward sympathetic predominance. In addition, HRV-response was modulated by the parental history of the NIDDM phenotype.

2272

AUTONOMIC NEUROPATHY IN INSULIN DEPENDENT PATIENTS ASSESSED BY SPECTRAL HEART RATE VARIABILITY ANALYSIS

D.Galicka-Latała, A. Surdacki*, J. Dubiel* and J. Sieradzki. Depts. of Metabolic Diseases and *Cardiology, Jagiellonian University, Kraków, Poland

In diabetic patients with advanced diabetic neuropathy heart rate variability (HRV) is known to be depressed. To evaluate the pattern of cardiovascular autonomic dysbalance 96 insulin dependent patients (mean age: 33.4 years, diabetes duration 10.54 years, treated only with insulin four time a day) and 30 healthy volunteers were studied. The following short-term heart rate variability (HRV) measures were assessed by a computer assisted technique (ProSciCard, Linden, Germany): standard deviation (SD), coefficient of variation (CV), root mean square successive difference of RR intervals (RMSSD), expiration/inspiration ratio, MCR, Valsalva ratio (VR), max/min R-R ratio on standing. Absolute and relative (%) spectral analysis HRV power in 3 standard frequency bands: VLF (0.01-0.05 Hz), LF (0.05-0.15Hz), HF (0.15-0.50 Hz) was assessed by Fast Fourier Transform. We compared healthy group with IDDM patients without retinopathy (R0), with nonproliferative retinopathy (R1) and with proliferative retinopathy (R2). **Results:** The following parameters had the highest strenght of discrimination between examined groups: **C vs R0:** Ln ratio LF/HF (-0.55 vs0.33; p=0.001), RMSSD (60.19 vs 39.55 p=0.04), **C vs R1:** LnHF (-0.40 vs -1.52; p=0.002), Ln total power (1.69 vs 0.51; p=0.03), **C vs R2:** LnVLF (0.41 vs -1.23; p=0.001), LnLF (0.25 vs -1.96; p=0.0006), LnHF (-0.40 vs -1.74; p=0.002), Lntotal power (1.69 vs -0.39; p=0.00004), RMSSD (60.19 vs 12.96; p=0.00001), HR (69.92 vs 84.35; p=0.03). **Conclusions:** 1. The gradually more pronounced difference between the diabetic patiens with retinopathy and control group seems to be inseparably connected with the degree of diabetic complication. 2. As compared to time domain measures, spectral analysis seems to be more precise in differentiation diabetic patients without complications from control group.

2273

HOLTER SPECTRAL ANALYSIS : A TECHNIQUE WITH A FUTURE FOR CARDIAC AUTONOMIC NEUROPATHY ASSESSMENT IN DIABETES

M. Pellan, B. Bauduceau, X. Chanudet, H. Mayaudon, M. Ducorps, N. P. Chau, P. Larroque. Hôpital d'Instruction des Armées Bégin, 69 avenue de Paris, 94160 Saint-Mandé, FRANCE.

The frequency of diabetic cardiac autonomic neuropathy (DCAN) is probably underestimated and its assessment is still based on Ewing tests. New techniques could help to earlier and easier detection. Patients and methods: 30 patients with insulin-dependent diabetes were studied, 20 males and 10 females, aged 20 to 66 years (mean : 38.1 ± 11 yrs). None of these patients had a cardio-vascular treatment. The five Ewing tests have been performed for each patient by the same operator, in standardized conditions, the results beeing expressed as a score from 0 to 1 for each maneuver. Heart rate variability (HRV), which reflects autonomic control, has been studied by spectral analysis of 24 hour continuous ECG record (ECG Holter Elatec, HRV Software, Ela Medical, France). Spectral analysis was performed using a nonparametric method by calculation of Fast Fourier Transform values (FFT). A particular study was done for day time (sympathetic tract prevalent) and night time (parasympathetic tract prevalent). Results: a severe DCAN (total score >2) was detected in 5 patients. A significant correlation (p<0.001) has been found between total score of Ewing tests and FFT values, showing a depressed heart rate variability (HRV) in case of DCAN. The correlation is especially apparent between night FFT and the parasympathetic tests : Valsalva maneuver (r : 0.603), heart rate response to deep breathing (r : 0.664) and heart rate response to standing up (r : 0.448). In opposition, the correlations of FFT with other maneuvers (sustained handgrip, BP response to standing up) have a borderline statistical significance.
Conclusion : the 24 hour continuous ECG record appears to be a relevant technique in diabetic patients for the detection of DCAN and may help in coronary heart disease. Spectral analysis of ECG Holter is a simple method which does not require the patient's contribution as it does in Ewing tests. But it is now necessary, by the mean of large studies, to define reliable criteria for DCAN quantization in spectral analysis.

2274

THE CIRCADIAN ASSESSMENT OF HEART RATE VARIABILITY IN DIABETIC SUBJECTS.

S. Teshima, Y. Tanaka, Y. Fujimoto, K. Narasaki, H. Ochi, T. Ikeda, and C. Shigemasa: Tottori University, Yonago, Japan.

The aim of this study was to investigate the circadian rhythm of heart rate variability (HRV) and to evaluate its clinical significance in diabetic subjects. One hundred and thirty-six diabetic patients and forty-eight non-diabetic subjects underwent 24 hour ambulatory ECG monitoring. HRV was evaluated hourly using the spectral variables of total frequency (0.01-1.00 Hz: TF), low frequency (0.04-0.15 Hz: LF), high frequency components (0.15-0.40 Hz: HF), and LF/HF ratio. The mean TF, LF, and HF for 24 h were significantly lower (p<0.0001) in diabetic subjects than in controls (21.7±8.5ms vs. 29.4±6.2ms, 11.2±5.0ms vs. 15.9±4.3ms, and 7.9±3.5ms vs. 10.3±2.9ms; respectively). The mean LF/HF ratio for 24 h was lower in diabetic subjects than in controls, but the difference does not reach statistical significance (1.46±0.48 vs. 1.60±0.40, p=0.08). The midnight (1:00am-6:00am) / daytime (1:00pm-6:00pm) ratio (N/D ratio) of TF, LF, or HF does not show any differences between diabetic subjects and control subjects. The N/D ratio of LF/HF ratio was higher in diabetic subjects than in controls, but the difference was not statistically significant (94±27% vs. 88±30%, p=0.10). During the daytime the mean LF/HF ratio was significantly lower in diabetic subjects than in control subjects (1.47±0.48 vs. 1.72±0.58, p<0.02). We concluded that parasympathetic TF and HF were significantly lower throughout 24hr period, while the sympathetic LF/HF ratio was significantly lower only in daytime, suggesting that sympathetic nervous function analyzed by the HRV should be evaluated by the day-time recordings of Holter monitoring in diabetic subjects.

2275

CARDIAC AUTONOMIC DYSFUNCTION IN LONG-STANDING TYPE-I-DIABETES WITH AND WITHOUT NEPHROPATHY

J. Meinhold, E. Wessel and P.T. Sawicki; Dept. of Metabolic Diseases and Nutrition, Heinrich-Heine-University, Düsseldorf, Germany

The increased mortality risk in type-I-diabetic patients has repeatedly been linked to cardiac autonomic neuropathy (CAN). CAN may contribute to myocardial electrical instability and an increased risk of sudden death. We have studied CAN in 66 consecutive patients with type-I-diabetes (>10years duration). 24 had no diabetic nephropathy, 19 incipient and 23 overt nephropathy (diabetes duration 21, 32, 31 years; HbA1c 7.4%, 7.4%, 8.0%; hypertension was present in 5%, 25%, 96%; mean values). A cohort of 184 healthy subjects served as control group. Standardized assessment of CAN was performed with short-term spectral analysis (Variapulse TF3), spectral power was used as an index of autonomic activity in two frequency-areas. In the low-frequency area (0.06-0.15 Hz) which mainly represents sympathetic activity, spectral power was predominantly reduced in patients with nephropathy (incipient: median 138 ms^2 [upper;lower quartile: 80;335], overt: 43 ms^2 [18;229]) in comparison to patients without nephropathy (457 ms^2 [275;713]) and controls (521 ms^2 [197;1000]; p<0.0001). In the high frequency area (0.15-0.50 Hz) which is considered as an index of vagal activity, diminished spectral power was observed in all patients (no nephropathy: 462 ms^2 [267;1078], incipient: 144 ms^2 [59;337], overt: 88 ms^2 [30;234]) as compared to controls (707 ms^2 [273;1476]; p<0.0001). These results suggest that longstanding type-I-diabetes is associated with CAN and that its pattern differs depending on the stage of nephropathy. Patients without nephropathy show an impaired neural function with a predominantly vagal damage. Patients with incipient and overt nephropathy show a considerable loss of both vagal and sympathetic activity. These results probably explain the higher risk of sudden death in patients with diabetic nephropathy.

BONE LOSS IN INSULIN DEPENDENT DIABETES MELLITUS PATIENTS WITHOUT DIABETIC NEPHRTOPATHY

E.Goliat, K.Ostrowski, W.Marusza, A.Lipińska and J.Przedlacki. Medical Academy of Warsaw, Warsaw Poland.

Insulin-dependent Diabetes Mellitus (IDDM) is thought to be one of risk factors for secondary osteoporosis - diabetes osteopathy. The aim of the study was to assess the bone mineralisation in diabetes type I patients in age< 40 years old. The examined group consisted of 99 patients (45 women and 54 men), with IDDM without diabetic nephropathy and without another risk factors for osteoporosis. The control group consisted of 113 healthy controls matched for age, sex, weight, height and calcium diet. The evaluation of bone mineral density (BMD) was performed with the LUNAR DPX-L apparatus in the AP projection for lumbar part of vertebral column (BMD L2-L4), left femur neck (BMD-neck) and total skeleton (BMD-total). Bone tissue metabolism was evaluated with the aid of some biochemical tests. The results were related to: sex, age in which IDDM was diagnosed, duration of IDDM, and metabolic control of diabetes. In patients with IDDM the BMD and Z-score were significantly lower when compared to healthy subjects ($p<0.001$), for all measured points. Bone loss was higher in diabetic men then diabetic women. For all patients bone loss was higher when diabetes appeared before 21 years of age. BMD seems to be dependent to duration of IDDM and metabolic control of IDDM. In IDDM patients a higher level of: total serum hydroxyproline ($p<0.05$), hydroxyproline in 3 hours and 24 hours urine collection ($p<0.01$) and urine calcium in 3 hours morning collection ($p<0.05$) were found. One the most important bone loss patomechanism in IDDM seems to be a dominance of bone resorption over bone formation. The proof to it are biochemical results of bone markers and the presence of statistically important correlation coefficients between these parameters and BMD and Z-score in IDDM patients.

2277

Bone changes in patients with insulin - dependent (type I) diabetes mellitus

L.Koeva, H.Bohchelian, A.Klisarova, L.Pranchev and L.Svrakova Clinic of Endocrinology, Department of Radiology, Department of neurology, Medical University, Varna, Bulgaria

The aim of the study is to evaluate bone changes in patients with insulin-dependent diabetes. We studied 60 healthy subjects and 112 diabetics (mean age-31,3±8,9 years, BMI-24,5±2,4 kg/m^2, sex-ratio M/F- 44/68). Patients were subdivided into 2 groups matched for age, gender and BMI: group 1-60 diabetics with poor control of diabetes and chronic diabetic complications; group 2-52 diabetics with good control without complications. Patients were subjected to a clinical examination, bone densitometry, spinal radiography, electromyography, bone scintigraphy, investigation of vibration perception threshhold, doppler ankle/arm systolic pressure, microalbuminuria, blood level of calcium, phosphorus, alkaline phosphatase. Bone mass density (BMD) is lower in type I diabetics than in controls (0,405±0,020 vs 0,520±0,025g/cm^2). BMD is lowest in patients with poor control and chronic complications-diabetic foot, retinopathy, neuropathy, nephropathy. A positive correlation between the degree of neuropathy and BMD reduction is found. The estimated frequency of osteopenia in group 1 and 2 is 33,4% vs 23% and for osteoporosis 24,2 % vs 12,4%. Insulin-dependent diabetics reveal lower BMD than healthy subjects. Reduction of BMD is more frequent and is positively correlated with diabetic control and complications- diabetic foot, neuropathy, retinopathy, nephropathy. Index of Tc99-MDP fixation in foot bone scintigraphy is higher in group 1 and is correlated with decrease of BMD. Bone densitometry could be one of prognostic tools for assessment and prevention of diabetic foot.

2278

LIMITED JOINT MOBILITY IN SUBJECT WITH INSULIN DEPENDENT DIABETES MELLITUS.

N. Saka, G. Alper, R. Bundak, F. Darendeliler, H. Günöz, Endocrinology Unit, Department of Pediatrics, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey

The frequency of limited joint mobility (LJM) was investigated in 104 (55 girls, 49 boys) insulin dependent diabetic patients and 82 (35 girls, 47 boys) control subjects. In diabetic patients, mean age was 12.4 years (range: 3.6-28 years) and mean duration of diabetes was 4.5 years (range: 2 months - 16 years). LJM was observed in 32 patients (30.7 %) and 2 (2.4 %) control subjects. Mean age of patients with LJM was 15.6 ±4.4 years while that in patients without LJM was 10.9±3.9 years ($p< 0.001$). Mean duration of diabetes in patients with LJM was also longer than in those without LJM (6.7±4.4 years vs 3.5±2.3 years, $p< 0.001$). LJM was related with age, puberty and duration of diabetes. In patients with LJM, 64.5 % have a duration of diabetes greater than 5 years, 94 % of them were older than 10 years of age and 87 % were pubertal. No relation was found between LJM and sex, HbA1c and height and weight SDS and microvascular complications. In conclusion, duration of diabetes, age, and puberty were important factor influencing joint contractures.

2279

BONE METABOLISM IN IDDM PATIENTS WITH INCIPIENT AND OVERT DIABETIC NEPHROPATHY.

P.Ponťuch, J.Payer, Z.Killinger, E.Tošerová. Teaching Hospital, Bratislava, Slovakia

We investigated the bone metabolism in IDDM patients with low-range normoalbuminuria and high-range microalbuminuria or proteinuria. We studied 25 patients (age<55yrs, females with regular menstruation): Group A (n=18, AER<10 µg/min), Group B (n=7, AER 100-1000 µg/min, serum creatinine<150 µmol/l)). Serum parathormone (PTH) and osteocalcin (OC) were assessed by RIA, serum bone alkaline phosphatase (ALP-B) and tartrate-resistant acid phosphatase (ACP-TR) by photometry. The groups A and B did not differ in diabetes duration (medians: 21vs22yrs), HbA1c (7.1vs 8.2%), creatinine (80vs95µmol/l). There was a difference between two groups in ALP-B ($p<0.05$)(380vs560 nkat/l). No significant difference was found in PTH (0.01vs0.2 ng/ml), OC (9.6vs13.7 ng/ml) and ACP-TR (160vs174 nkat/l), although the values were slightly increased in group B. We conclude that slightly increased bone turnover expressed mainly by biochemical parameters of bone formation occurs in nonazotaemic IDDM patients with proteinuria.

2280

THE EFFECTS OF CHRONIC PANCREATITIS AND DIABETES MELLITUS ON BONE AND MINERAL METABOLISM.

R. Shires, JM Pettifor, G Moodley, CM Schnitzler. University of the Witwatersrand, Johannesburg, South Africa

Chronic pancreatitis (CP) due to alcohol has become common in urban black South Africans and often causes diabetes. We examined bone histomorphometry and the biochemical changes in 13 black male patients, aged 27-55, with alcohol-induced chronic pancreatitis - 6 diabetic(D) and 7 nondiabetic(ND). Serum Ca,P,Mg, PTH, vitamin D metabolites, osteocalcin, testosterone, leukocyte ascorbic acid, urine Ca and hydroxyproline were compared to those of 12 healthy controls(C) or available control data. Transiliac bone biopsies following tetracycline double-labelling were obtained for histomorphometric analysis and compared to those of 26 age-matched healthy controls(C) for static measurements, and to 8 controls for the dynamic data. TBV (% trabecular bone vol/total vol), TbTh (trabecular thickness), OTh (osteoid thickness) and EDe (erosion depth) were all significantly reduced in CP and the D (diabetic) subgroup vs C (see Table).

	TBV(%)	TbTh(μm)	OTh(μm)	EDe(μm)
C(n=26)	21.2(12.4-32.8)	164(122-242)	10(4.1-16.1)	8(4.8-13.1)
CP(n=13)	13.3(5.8-35.3)^c	94(58-302)^a	8.5(3.1-10.3)^e	5(4-11.4)^c
D(n=6)	9.9(5.8-19.0)^c	87(58-107)^b	5.8(3.1-10.3)^d	4.7(4-6.2)^d
ND(n=7)	18.3(8.1-35.3)	97(82-302)^c	8.8(4.4-11.9)	5.7(4.4-11.4)

Results are median (range). ^{a}p<0.0001; ^{b}p<0.0002; ^{c}p<0.005; ^{d}p<0.02; ^{e}p<0.04 vs C. In ND,however, only the TbTh was significantly reduced. There were more haemosiderin laden macrophages/mm^2 bone marrow in CP: 8(0-140)vs C:0.5(0-26), p<0.005. Leukocyte ascorbic acid levels were subnormal in 10 subjects. There were no differences in Ca, P,Mg, PTH and osteocalcin between groups. 25OH vitaminD (nmol/l) was reduced in CP (33.8±5.0, mean ± SEM) and D(25±4.5) vs C(54.4±3.7), p<0.005 for both. 1,25$(OH)_2$D (pmol/l) was reduced in D alone (52.8±7.8) vs C(95±4.4), p<0.03. In conclusion, CP patients have reduced TBV, TbTh, OTh, and EDe, consistent with low bone mass and turnover, especially in the diabetic subgroup. Apart from diabetes, other contributing factors include alcohol, poor nutrition, vitamin C deficiency and dietary Fe overload.

2281

Increased uptake of ^{99m}Tc - tetramethylene phosphonic acid in sacroiliac joints of adolescents with diabetes mellitus.

O.V.Remizov[1], T.L.Kouraeva[1], E.S.Mach[2], O.V.Pushkova[2], L.N.Denisov[2] and V.A.Peterkova[1]. [1]Endocrinology Research Centre, [2]Institute of Rheumatology, Moscow, Russia.

A wide range of musculoskeletal syndromes have been described in association with IDDM. The aim of this study was to investigate the status of the sacroiliac joints (SIJ) in adolescents suffering from IDDM.22 diabetic patients (12 boys,10 girls; mean age 13,8 ± 1,3 yrs.,range12-16 yrs.) were divided into 3 groups. Group 1: 6 patients without limited joint mobility (LJM),with diabetes duration from 1 to 2 yrs.(mean 1,6 ± 0,5 yrs.).Group 2A: 7 patients without LJM, with diabetes duration from 6 to 10 yrs.(mean 7,9 ± 1,4 yrs.).Group 2B: 9 patients with LJM, with diabetes duration from 6 to 12 yrs.(mean 8,2 ± 1,9 yrs.). 9 age- and sex- matched healthy adolescents were studied as controls. SIJ were investigated using scintigraphy with ^{99m}Tc-tetramethylene phosphonic acid (5 MBg/kg.). The parameter for measuring joint activity was a ratio of peak SIJ to peak sacrum counts (SIJ index). **Results** (means ±SD): The diabetic patients showed increased SIJ uptake (mean SIJ left index 1,44 ± 0,20 , mean SIJ right index 1,44 ± 0,20) in comparison with controls (mean SIJ left index 1,19 ± 0,32, mean SIJ right index 1,25 ±0,20;p< 0,05).The mean SIJ index in group 2A and in group 2B had the same value (mean SIJ left index 1,43 ± 0,21,mean SIJ right index 1,42 ± 0,21 and mean SIJ left index 1,44 ± 0,22,mean SIJ right index 1,42 ± 0,21; respectively) that's why group 2A and group 2B were combined. Comparing group 1 and group 2 (A,B) we found to diminished of the increased SIJ index in group 2 (A,B) (not significant) and inversion ratio SIJ left / SIJ right index (p< 0,01).**Conclusion:** This study shows that the adolescents with IDDM frequently have increased uptake of ^{99m}Tc - tetramethylene phosphonic acid in SIJ, and it could be a radiological sign of subclinical sacroiliitis. These results are preliminary and need further observation .

2282

BONE METABOLISM IN THE PATIENTS WITH NON-INSULIN DEPENDENT DIABETES MELLITUS :EFFECT OF INSULINTHERAPY

Kanae Shimizu, Masato Matsushima, Michihiko Maruyama, Rimei Nishimura, Keiko Asao, Hironari Sano, Naoko Tajima. Department of Internal Medicine (III), The Jikei University School of Medicine.

Because of the controversy findings so far published in the patients with non-insulin dependent diabetes mellitus (NIDDM), we assessed bone mineral content (BMC) and bone metabolism in 17 NIDDM patients (10 males and 7 females) and healthy controls matched for sex and age (±2 years). We selected NIDDM patients who were very poorly controlled due to insulinopenia and considered to require insulin therapy. First, BMC was compared in lumber vertebrae and in separate parts of body, using dual energy x-ray absorptiometry (DEXA) between the cases and the controls. Second, calcium and vitamin D metabolism were examined in NIDDM patients before and after 3 months of insulin therapy with the comparison with those in the controls. No significant differences in the bone mass was found between the cases and the controls. In terms of bone metabolism, the serum level of 1,25(OH)2vD among the patients was significantly lower than that in controls. With the improvement of glycemic control, moreover, the level of 1,25(OH)2vD and serum calcium elevated significantly by insulin therapy. From these observations, we concluded that hyperinsulinemia might cause the bone increase in NIDDM patients and that insulinopenia may cause the bone decrease through a deficit of 1,25(OH)2vD.

2283

BONE MINERAL DENSITY (BMD): CORRELATION WITH METABOLIC CONTROL AND VIT D RECEPTOR GENE POLYMORPHISM (VDR) IN IDDM

O.M.Hauache, M.Lazaretti-Castro, A.C.Ramalho, I.Kunii, T.S.Kasamatsu, L.F.Hayashi, S.A.Dib, J.G.H.Vieira. Escola Paulista de Medicina - UNIFESP, São Paulo, Brazil.

Among the genetic factors related to the development of osteoporosis, a possible causal association with VDR may exist. Literature reports low BMD in IDDM population and our aim was to verify the correlation of BMD values with glycemic control and with presence of different vitamin D receptors genotypes. In this way, 78 patients with IDDM were studied (45M, 33F, 23.3 ± 5.5 years old, median of 21 years). Mean age at diagnosis of IDDM was 12.0 ± 3.9 years (median of 13 years), mean duration of the disease was 11.3 ± 5.9 years (median of 10.5 years). None of these patients had any other disease or condition that could interfere in bone mass. Fasting blood was drawn for the measurement of ionized calcium, HbA1, creatinine and for DNA analysis. DNA was extracted from peripheral leucocytes and amplified by PCR. PCR products were digested by the *Bsm*I restriction enzyme and genotypes were detrmined by agarose gel electrophoresis. Isolated urinary albumin was also measured. BMD at lumbar spine and femoral neck was evaluated by a LUNAR DPX densitometer (DEXA). Statistic analysis was performed by using Student t test and Pearson correlation test. The VDR distribution was: 33.3% bb (26/78), 50% Bb (39/78) and 16,7% BB (13/78). Patients with bb genotype disclosed a higher BMD at femoral neck and lumbar spine when compared to BB genotype (p = 0.02). Bb genotype was also associated with a better lumbar spine BMD than BB (p = 0.01). A negative correlation between BMD at both sites and urine albumin loss was observed. No significance was found when comparing HbA1 and urine albumin levels among the different genotype groups. Duration of disease was significantly lower in the BB genotype group (median of 7 years) than in the bb patients (median of 12 years). These results suggest an independent influence of VDR (besides metabolic control and duration of the disease) in BMD in IDDM patients.

2284

OXYDEVITE AS A METHOD OF EFFECTIVE DIABETIC OSTEOPOROSIS THERAPY.

N. S. Salakhova and A. A. Bakhadirova. 2ND Tashkent State Medical Institute. Tashkent, Uzbekistan.

The purpose of this issue is to study the influence of $1_{\alpha}-$ oxivitamine D_3-oxydevite on bone tissue mineralization process in diabetic osteoporosis. Active metabolite of vitamin D_3-oxydevite was used for 45 insulin−dependent diabetes mellitus (IDDM) patients and 78 non−insulin−dependent diabetes mellitus (NIDDM) patients. The existence of osteoporosis was evaluated clinically: by a dynamics of bone pains, a capacity of motive activity; by results of rentgenogramme of feet bones and rentgendensitymetric data. Treatment using oxydevite had been carried out during 6 months. For the starting period it was prescribed during 2−4 weeks with a dosage of 0.5−2 mkg/a day, and thereafter during 6 months with a dosage of 0.25−1 mkg/a day simultaneously a calcium gluconat with a dosage of 1−1.5 g/a day. In a month after treating IDDM and NIDDM patients, there were signs of a clinic improvement, expressed by lessening of pains in bones, increase of number of motions, increase of ability to work. An increase in mineralization of bone tissue was noted when it was applied not less than 3 months ($P<0.02$). After 6 months of treatment, mineral saturation in bones of IDDM patients was increased 1.9 times ($P<0.001$), and in bones of NIDDM patients 1.3 times ($P<0.002$). Thus, the treatment using oxydevite should be carried on with a dosage of 0.25 up to 1 mkg/a day with combination of calcium preparations up to 1.5 g/a day, continuously during 3 up to 6 months. Analysis of the results proves that when using oxydevite for IDDM and NIDDM as per the said scheme a clinical improvement can be noticed after one month, and increase of mineralization of bone tissue according to rentgendensitymetric data can be observed only after 6 months.

BONE MINERAL DENSITY OF THE CALCANEUS MEASURED BY ULTRASOUND DENSITOMETRY IN DIABETIC NEUROPATHY

[a]EB Jude, [b]IM Hodgkinson, [a]P Selby, [b]JE Adams and [a]AJMB Boulton. [a]Manchester Diabetes Centre, [b]Dept of Radiology, University of Manchester, Manchester, UK

Diabetic patients are known to develop osteoporosis. We have previously demonstrated that bone mineral density is lower in the lower limb of diabetic patients with neuropathy. Ultrasound has recently been suggested to give information regarding the bone structure as well as bone mass. We therefore conducted a study using ultrasound to assess the calcaneus in diabetic patients with and without neuropathy. Control (C), diabetic patients without neuropathy (D) and diabetic patients with neuropathy(DN) were matched for age, sex, type and duration of diabetes (6 per group). All patients had ultrasound of the heel using CUBA clinical (McCue ultrasonics); measurements of the os calcis including broadband ultrasound attenuation (BUA) and velocity of sound (VOS). There was no significant difference in BUA or VOS between C vs D or D vs DN; although it was lower in diabetic subjects. However, the difference in BUA between C (102 $\pm$ 8.9 dB/Mhz) and DN (78.9 $\pm$ 17.9 dB/Mhz) was significant ($p<0.05$). This indicates that in addition to influencing bone mass diabetic neuropathy may have an effect on bone architecture.

2286

The Evidence for Uncoupling between Bone Formation and Resorption in NIDDM Patients

SUZUKI,K.,TAGUCHI,Y.,ISHIDA,H.,SEINO,Y., JAPAN

Diadetes mellitus has been known to be chronically associated with abnormal calcium(Ca) metabolism and bone mass reduction. To clarify the nature of metabolic bone disorder in NIDDM, alterations in mineral metabolism and biological markers of osteoblast/osteoclast were studied. Age matched 99 male NIDDM patients and 55 non-diabetics were compared. Serum level of intact osteocalcin(i-OC) in NIDDM(3.4±1.7ng/mℓ) was significantly lower than that of non-diabetics(5.9±1.8ng/mℓ)($p<0.01$). Serum level of intact-PTH (i-PTH) in NIDDM(20.4±3.4pg/mℓ) was significantly lower than that of non-diabetics(29.1±3.0pg/mℓ)($p<0.01$). There were no significant difference in serum Ca and calcitonin levels. Level of serum tartaric acid-resistant acid phosphatase (TRACP) in NIDDM(11.0±1.2U/l) was significantly higher than that of non-diabetics(10.0±0.9U/l)($p<0.01$). There were positive correlation between i-PTH and i-OC ($p<0.01$). However, there was no clear correlation between i-PTH and TRACP or between i-OC and TRACP. In NIDDM, therefore, bone formation is thought to be decreased due to the reduction of osteoblastic function, meanwhile bone resorption increases. The absence of correlation between i-OC and TRACP suggests the uncoupling between bone formation and resorption. The positive correlation between i-PTH and i-OC may suggest that the reduction in serum i-PTH level reflecting reduced parathyroid function might be a causative factor of decreased osteoblastic function.

2287

DOES IMPROVEMENT OF METABOLIC CONTROL INFLUENCE THE MARKERS OF BONE TURNOVER IN DIABETIC PATIENTS?

T.Miazgowski, E.Mamos and S.Czekalski. Department of Endocrinology and Metabolic Diseases, University School of Medicine, Szczecin, Poland

Some recent data suggest that intensification of treatment in patients with insulin-dependent diabetes mellitus (IDDM) may alter bone metabolism, as expressed, amongst the others, by a significant decrease of markers of bone formation. The aim of study was to evaluate the effects of improved glycemic control of diabetes assessed by serum HbA_{1c} on some markers of bone turnover: osteocalcin (OC), total alkaline phosphatase (ALP) as well as pyridinoline (PYD) and deoxypyridinoline (DPD) crosslinks in patients with long-standing IDDM. Serum OC was assessed by RIA (Incstar Corporation) and ALP by enzymatic method. PYD and DPD in urine were assessed by EIA (Metra Biosystems). The study was performed on 50 patients (23 F, 27 M), aged 38.4 ± 9 years and mean duration of IDDM 16.7 ± 8 years. OC, ALP, PYD, DPD and HbA_{1c} were measured at the baseline and in 6-month intervals during 3 years. The improvement of metabolic control was achieved by dietary advices, increased physical activity and the intensification of insulin therapy. At the baseline mean HbA_{1c} was 8.4 ± 1.2% and significantly decreased to 7.5 ± 1% after 1 year ($p<0.0005$), 7.3 ± 1.3% after 2 years ($p<0.0001$) and 7.2 ± 1.2% after 3 years from the baseline ($p<0.0001$). The diminution of HbA_{1c} was not accompanied by marked changes of markers of bone turnover during 3-year follow-up: at the end, OC decreased by 0.42 ± 1.7 ng/ml and DPD by 0.17 ± 1.5 nM/mMcreat; PYD increased by 0.63 ± 5.3 nM/mMcreat and ALP by 10 ± 41 IU/l, and all the values were within normal range. There was no significant correlation between markers of bone turnover or between HbA_{1c} and particular markers. Moreover, the markers were not correlated with age, sex or duration of IDDM.

In conclusion, the improvement of metabolic control in IDDM patients does not influence markedly the bone metabolism, frequently altered in diabetes, assessed by markers of bone formation and bone resorption. We also conclude that the interpretation of results obtained from repetitive measurements of markers of bone turnover is difficult and warrants further studies.

2288

EFFECT OF OBESITY ON BONE DENSITY IN PATIENTS WITH NIDDM AND INCREASED CORTISOL LEVEL.

I. Trznadel-Morawska, J. Sieradzki and P. Olszanecki Department of Metabolic Diseases, Jagellonian University, Cracow, Poland

In NIDDM associated with obesity the density of bone is only mildly altered Protective factors include hyperinsulinism, insulin resistance, insulin-like growth factors, slow bone turnover. Cortisol accompanying obesity is a resorptive factor **Aim of the study:** 1) assessment of bone density in NIDDM with obesity and increased cortisol. 2) assessment of the effect of androgenes (metabolites) on bone density. 3) assessment of the effect of diabetes normalization on bone density. **Material and methods:** 44 patients with NIDDM treated with insulin (n=31) or orally (n=13). Bone density was measured by ultrasound with Lunar (USA). The patients were divided into a group without osteoporosis I (- 1≤ Tscore < 1), risk II (-2 ≤ Tsc <-1) and with osteoporosis III (Tsc <-2). Body weight was assessed according to BMI. Biochemical determinations: cortisol, endogenous insulin (in orally treated NIDDM), 17-ketosteroids, 17-ketogenic steroids in Tscore groups **Results:** Group III had the highest BMI (mean=30.1 SD=4,68) and cortisol level (mean=22.2 SD=9.73). In group I and II 17-ketosteroid level (mean=37.4 SD=10.95, mean= 41.1 SD=19.71) was higher than that in group III. Endogenous insulin was highest in group I (mean=10.5 SD=3.77). Significant correlations were noted: negative SOS with cortisol (r=-0.30, p<0.05) and positive SOS with insulin (r=0.80, p<0.05). BUA with 17-ketosteroids (r=0.44, p<0.05) **Conclusions:** The lowest bone density in NIDDM with the highest body weight and increased cortisol, as well as correlations between cortisol, SOS and BUA suggest that in these patients the balance between protective and resorptive factors is impaired. The lowest 17-ketosteroid level in patients with the lowest bone density, obesity and the correlation between 17-ketosteroids and BUA may indicate a reduced anabolic effect of androgenes in this group The highest level of endogenous insulin in patients with NIDDM and normal bone density and obesity confirms its contribution into bone protection.

2289

AMINOGUANIDINE TREATMENT INCREASES BONE MINERAL DENSITY IN STZ INDUCED DIABETIC RATS.

Y.Katayama, T.Soulis*, M.E.Cooper*, E.Seeman*, N. Nagata‡, T.J. Martin and D.M. Findlay†. St. Vincent's Institute of Medical Research, *Austin and Repatriation Medical Centre, Melbourne, †University of Adelaide, Adelaide, Australia, ‡National Defense Medical College, Saitama, Japan.

Osteopenia is a recognised complication of long term diabetes mellitus. Advanced glycation endproducts (AGEs) are believed to contribute to chronic diabetic complications in various sites. Aminoguanidine (AG) is a potential therapeutic agent to prevent diabetic complications which acts to inhibit AGE formation. We have previously reported that there is accelerated accumulation of collagen AGEs in bone tissue in STZ induced diabetic (DM) rats *in vivo* and altered osteoblastic cell function *in vitro*. These findings suggest that advanced glycation may play a role in diabetes related osteopenia. In the present study, we evaluated the effects of diabetes and AG treatment on AGEs formation and bone mineral density (BMD) in STZ (55mg/kg) DM rats with and without treatment of AG (1g/l in drinking water). In addition, a group of DM rats were rendered euglycaemic by insertion of insulin silastic implants (DI). Plasma glucose and glycated haemoglobin levels were increased in DM but not in DI rats and were not affected by AG treatment. In the DM rats, the BMD of femora was significantly reduced by 37% (control, 0.45±0.02 vs. diabetic, 0.28±0.01g/cm^3, mean±SEM, p<0.01). AG treatment significantly attenuated but did not normalise the reduced BMD in DM rats (0.38±0.03 g/cm^3, p<0.05 vs DM). DI rats had BMD levels similar to control rats (0.44±0.02g/cm^3). Levels of Plasma Bone Gla Protein, a marker of bone formation, were reduced in diabetic rats (control, 24.8±2.4 vs diabetic, 10.7±0.6ng/ml, p<0.001) and were not influenced by AG treatment (8.8±0.7ng/ml). Levels of urinary deoxypyridinoline, a marker of bone resorption, were reduced in diabetic rats (control, 3.2±0.3 vs diabetic, 0.6±0.1nmol/day, p<0.001) and were not influenced by AG treatment (0.5±0.1nmol/day). Immunohistochemistry revealed increased AGE staining in tissues from DM rats which was reduced by AG treatment. These data suggest that diabetic osteopenia may be related to AGE accumulation in bone and that AG may have a therapeutic role in preventing osteoporosis in this population.

DIABETIC TREATMENT REGIMENS AND BONE REMODELING

P.D.Ragonesi,M.Dantes,G.Ragonesi,M.T.Taddei.Department of Internal Medicine,San Carlo Borromeo Hospital,Milan,Italy.

The influence of diabetic treatment regimens on bone remodeling is still object of debate.In our study bone mineral density,calcium regulating hormones(PTH,vitamin D metabolites), bone turnover markers(bone GLA protein,deoxypyridinoline) and glucose metabolism parameters(fasting glucose,HbA1c, C-peptide)were measured in 93 NIDDM males (48 on glyburide, 45 on insulin)and in 45 controls with normal renal and hepatic function.

	GLYBURIDE (G)	INSULIN (I)	CONTROLS(C)
25OH-D (ng/ml):	7.1 ± 5.1 a	22.5 ± 9.1	21.9 ± 10.3
1,25OH2-D(pg/ml):	29.7 ± 7.6	28.4 ± 4.0	29.4 ± 4.3
PTH (ng/ml):	63.4 ± 22 b,c	52.9 ± 19	50.7 ± 21
BGP (ng/ml):	7.1 ± 1.7 d	6.8 ± 2.6 d	14.1 ± 3.8
D-Pyr (pmol/ml):	17.3 ± 1.9	17.9 ± 2.8	18.1 ± 3.6
BMD (mg/cm2):	395 ± 60 e	397 ± 58 f	441 ± 71

a:p 0.001 vs I,C; b:p 0.01 vs I; c: p 0.006 vs C; d:p 0.001 vs C ; e:p 0.01 vs C; f: p 0.02 vs C.

In conclusion,treatment with glyburide can only be associated with an acclerated vitamin D metabolism.It is possible that the reduction of 25OH-D levels depends on a high conversion rate to the active form,as a consequence of PTH-stimulated increase of 1-alpha-hydroxylase activity,but BMD values are similar in patients taking glyburide or insulin. On the other hand,the occrrence of extremely low BGP levels in all diabetic patients reflects a decrease in osteoblastic activity,which can explain the osteopenia in these patients.

2291

INTERLEUKIN-6 PRODUCTION BY OSTEOBLAST-LIKE CELLS IS INCREASED BY ADVANCED GLYCATION ENDPRODUCTS.

M. Takagi, S. Kasayama, T. Yamamoto,* T. Motomura, K. Hashimoto, B. Sato, S. Okada* and T. Kishimoto. Departments of Medicine III and Pediatrics*, Osaka University Medical School, Osaka, Japan.

Advanced glycation endproducts (AGEs), which result from nonenzymatic reactions of glucose with tissue proteins, have been shown to accumulate on collagen derived from cortical bones of diabetic or aged-animals. In the present study, we examined the effects of AGEs on the production of bone-resorption cytokines by human bone-derived cells and mouse osteoblastic MC3T3-E1 cells. AGEs stimulated the release of IL-6 but not of IL-11 in the culture supernatants from human bone-derived cells. The IL-6 release was inhibited by sodium salicylate, TLCK, TPCK and probucol, known as the inhibitors of the transcription nuclear factor-κB (NF-κB) activation. Electrophoretic mobility-shift assays revealed that NF-κB was activated in the nuclear extracts from the bone-derived cells treated with AGEs. The protein kinase A inhibitor Rp-8-Br-cAMP suppressed the AGEs-stimulated IL-6 production and NF-κB activation. Enhanced IL-6 production and NF-κB activation by AGEs were also observed in MC3T3-E1 cells. These results suggest that AGEs modulate bone remodeling by stimulating the production of IL-6 in osteoblast-like cells, probably *via* activation of NF-κB. Protein kinase A may be involved in AGEs-stimulated NF-κB activation.

2292

INFLUENCE OF METABOLIC CONTROL ON PTH SECRETION IN PATIENTS WITH DIABETES MELLITUS. F.J.A. Paula, C.M.M. Lanna, G.M.G.F. Paccola and M.C. Foss. School of Medicine of Ribeirão Preto - São Paulo University, Ribeirão Preto, SP, Brazil

Previous studies have shown that increased urinary calcium, phosphorus and magnesium excretion occurs in diabetes mellitus (DM) and have suggested that patients with DM have lower bone mineral density. The objective of the present study was to determine PTH secretion under basal conditions and stimulated during EDTA infusion (30 mg/kg/h) in patients with good and regular metabolic control (Group GR-HbA_1 < 8.5%) and in poorly controlled patients (Group P-HbA_1 > 10%). Blood samples were collected at 10 min intervals during the basal period (30 min) and for 2 h during EDTA infusion for the determination of ionic calcium, PTH (intact molecule), glycemia and Mg. The study was conducted on 8 normal subjects (HbA_1 group M = 4.2 ± 0.2%), 8 GR diabetics (HbA_1 = 7.3 ± 0.4%) and 8 P diabetics (HbA_1 = 13 ± 1%). Glycemia was significantly higher in group P at all times studied (range: 13.2-15.8 mmol/l vs. 6,1-7,9 mmol/l for the GR group). Basal Ca^{++} levels were lower in group P (1.19 ± 0.01 mmol/l) both compared to the normal group (1.22 ± 0.01 mmol/l) and to group GR (1.24 ± 0.02 mmol/l). During EDTA infusion PTH levels were slightly higher in group GR than in the normal group and significantly higher than those of group P (e.g.: + 40 -normal group = 86.9 ± 20 vs GR = 110.2 ± 12.8 vs P = 49.3 ± 5 ng/l). Mg levels for the control group were slightly higher than those for the GR group and significantly higher than those for the P group. We conclude that DM patients with poor metabolic control present disorders of PTH secretion, a change that is particularly important if we consider that calcium ion levels are lower in these patients. This alteration may be related to a higher frequency of osteopenia among diabetics.

Complications – Experimental and Pathogenesis

2293

OXIDATIVE DAMAGE TO MITOCHONDRIAL DNA AND ITS RELATIONSHIP TO DIABETIC COMPLICATIONS.

S. Suzuki, Y. Hinokio, M. Hirai, M. Chiba, A. Hirai, Y. Sato and T. Toyota. Third Department of Internal Medicine, Tohoku University School of Medicine, Sendai 980, Japan.

In order to explore role of oxidative stress-induced DNA damages on the pathogenesis of diabetic complications, we investigated mitochondrial DNA (mtDNA) mutations and 8-hydroxydeoxyguanosine (8-OHdG) contents in the muscle of 16 NIDDM patients and 7 normal subjects. mtDNA 5778bp (8214-13991) deletion was identified in the muscle of the diabetics and the normal subjects. The percentage of the deleted mtDNA [ΔmtDNA (%)] was much higher in the muscle of the diabetic patients (12.2±9.5) than the normal subjects (1.71±1.68, $p<0.01$) . 8-OHdG/dG (10^{-5}) was also much higher in the muscle of the diabetic patients (38.8±20.8) than in the normal subjects (8.6±7.8, $p<0.005$) . ΔmtDNA (%) was highly correlated to 8-OHdG content (r=0735, $p<0.0001$) . 8-OHdG/dG was significantly proportional to duration of diabetes and hemoglobin A1c. ΔmtDNA and 8-OHdG/dG in the muscles of the diabetic patients with nephropathy and chronic renal failure, were significantly higher than those in the diabetics with macroalbuminuria, microalbuminuria or normoalbuminuria. ΔmtDNA and 8-OHdG/dG in the muscles of the diabetics with proliferative retinopathy were significantly higher than those in the diabetics with simple retinopathy or without retinopathy. Oxidative stress causes conversion from dG to 8-OHdG. Because the mtDNA5778bp deletion covered areas coding ND3-ND5 in complex I, the deletion might cause a reduction in mitochondrial oxidative phosphorylation capacity and contribute to the pathogenesis of diabetic complications.

2294

EFFECT OF DIABETES MELLITUS ON ADENOSINE AND ADENOSINE DEAMINASE (ADA) ISOENZYMES: ADA_1 AND ADA_2 IN BLOOD

B. Kopff, M. Kopff, K. Szosland, J. Drzewoski. Medical University of Łódź, Military Medical University of Łódź, Poland

The aim of the study was to evaluate energetic metabolism by assessment of concentration of adenosine (the most important product of ATP degradation). Also the activities of isoenzymes of adenosine deaminase (ADA): ADA_1 and ADA_2 were assessed- both of them are responsible for degradation adenosine to inosine. The subjects were 38 people suffering from diabetes and being treated with insulin. As a control was group of 19 patients without previously recognized IGT or DM. The levels of adenosine were estimated using photometric method and the activities of isoenzymes due to Giusti & Galanti method. It was found that the concentration of adenosine was significantly higher in the group suffering from diabetes than in control group ($p=0.01$). The same was found estimating activities of extracellular ADA_1 ($p=0.02$) and ADA_2 ($p=0.002$). There was not significant difference in the activities of intracellular ADA_1 ($p=0.15$). There was a significant correlation between concentration of adenosine and HbA1c among diabetic subjects ($p=0.02$). Almost the same correlation was found between activity of ADA_2 and concentration of adenosine ($p=0.03$)

Conclusion: It can be postulated that the increased degradation of high energetic phosphates observed among patients suffering from diabetes can be responsible (among other factors) for the development of long-term complications.

2295

ABNORMAL MARKERS OF FREE RADICAL ACTIVITY IN CHILDREN & ADOLESCENTS WITH INSULIN DEPENDENT DIABETES MELLITUS

T.A Elhadd, A. Hill, S.A. Greene and J.J.F. Belch. Ninewells Hospital and Medical School, Dundee, United Kingdom.

Oxygen free radicals are highly reactive substances that is capable of inflicting injury to cell membranes if not adequately scavenged by antioxidants. The metabolic disturbances in diabetes may favour generation of excess free radicals and this might be associated with reduced anti-oxidants activity. Recently the injurious effect of free radicals has been implicated in pathogenesis of diabetic angiopathy, however this has not been well studied in young people with diabetes. Low levels of reduced glutathione (GSH), and plasma thiol (PSH) may reflect excess free radical generation and a depleted anti-oxidant reserve. We have found reduced levels of plasma thiol (PSH) and red cell glutathione (GSH) in 51 children, adolescents and young adults with IDDM (22 males & 29 females), mean age ± SD 14.8 ± 3.4 years, duration of diabetes 6.8 ± 4.5 years, and HbA1c of 8.7 ± 1.5%; (none had any clinical evidence of complications), compared with 21 healthy normal controls matched for age and sex (11 females & 10 males). In the diabetic cohort the GSH and PSH levels were 1266.73 ± 201.89 µmol/l & 458.14 ± 38.34 µmol/l vs 1403.26 ± 277.81 µmol/l & 486.75 ± 69.73 µmol/l in the control group, reaching statistical significance of $p< 0.02$ and $p<0.03$ respectively, Student t-test. We have previously shown significant abnormalities of vascular reactivity in the same study group and this result suggests a possible role of free radicals in pathogenesis of diabetic angiopathy which might start very early in the course of childhood diabetes.

2296

THE DETERMINATION OF ERYTHEOCYTE ALDOSE REDUCTASE LEVEL WITH ELISA IN PATIENTS WITH DIABETES MELLITUS

Liu Changshan. Deptment of Endocrinology, Weifang People's Hospital, Weifang City, Shandong Province, P. R. China (261041)

Using a modification of the procedure ofsalting out and DE− 52, hydroxylapatite, sephadex− G100 chromatography, aldose reductase was purified to homogeneity from bovine testis. Female New Zealand white rabbits were subcutaneously injected with purified enzyme mixed 1:1 with complete Freunds adjuvant to prepare antiserum. The antibody was purified from serum by a 33% ammonium sulphate precipitation and DEAE− cellulose column chromatography, antibody was linked with Horseradish Peroxidase by sodium periodate oxidation method to prepare antibody− HRP. Approximately 1 ml of blood was hemolyzed immunoassay. In the antibody− sandwich ELISA, antibody was first immobilized on plastic plate to capture antigen, following a second antibody conjugated to HRP. The level of aldose reductase in 22 patients and 10 nondiabetic subjects was determined with the assay method , the results showed that: 1. The level of enzyme was significantly increased in diabetic patients compared with normal subjects (8.37±3.46 vs 3.23±1.16 ng/g Hb, $P<0.01$). 2. The level of enzyme varied approximately 5− fold in diabetic patients and 3− fold in nondiabetic controls, respectively. 3. In patients, the level of enzyme was apparently correlation with fasting plasma glucose level ($r=0.67$, $P<0.05$), but there were not relationship in normal subjects ($r=0.11$, $p>0.05$). 4. There were not statistically correlation between the level of aldose reductase and sex, age, duration of diabetes. Inclusion , quantiative determination of erythrocyte aldose reductase level with ELISA provided an useful mothod in the evaluation on the efficacy of aldose reductase inhibitors, and in the study on the relationship between the polyol pathway and diabetic chronic complications.

2297

TYPE 1 (IDDM) DIABETES MELLITUS AND SERUM TOTAL ANTIOXIDANT CAPACITY (TAC)

E Petruzzi, P Pinzani, E Mannucci, CM Rotella, M Serio, and M Pazzagli

Clinical Biochemistry and Endocrinology Unit, Dept of Clin Pathophysiology ; Instit of Gerontology and Geriatrics; University of Florence - ITALY

In diabetes mellitus, a sharp reduction of antioxidant defences and an increased production of serum free radical seem to coexist *(Cross CE et al, Ann Intern Med 107: 526-45, 1987)*. For this reason there is increasing interest in the study of mechanisms of antioxidant protection against free radical-induced injury and in the identification of suitable biochemical parameters for the measurement of the Total Antioxidant Capacity (TAC) in body fluids. Several methods have been proposed for the assessment of TAC, including that based on enhanced chemiluminescence *(Whitehead TP et al, Anal Chim Acta 266:265-77, 1992)*. This technique is calibrated with TROLOX and assay results are expressed as µmol L^{-1} of Trolox. This procedure implies the determination of TAC both on whole serum (WTAC) and on its deproteinated fraction (DPTAC), obtained by ultrafiltration, using a Centrifree MS-1 micropartition system (Amicon Massachusetts). We have measured WTAC and DPTAC in two subject groups: i) 15 young Type 1 (IDDM) diabetic subjects (Mean±SD= 30±3.5 yr), affected by medium-term Diabetes Mellitus, in a good metabolic control, evaluated on the basis of HbA_{1c}% (Mean±SD=5.9±1.3%) and of fasting glycemia (Mean±SD=146±34 mg/dL); ii) 16 age- and sex-matched healthy control subjects (HS). Results (Mean±SD) in IDDM were: WTAC =204±137 µmol/L^{-1} and DPTAC=82±30 µmol/L^{-1}; in HS were: WTAC=366±145 µmol/L^{-1} and DPTAC=204±116 µmol/L^{-1}. Statistical analysis showed a significant difference ($p<0.01$) between IDDM and control subjects both in WTAC and DPTAC values. The significanly reduced WTAC and DPTAC in IDDM subjects may be due to an increased free-radicals production. It may be due, at least in part, to the reduction of circulating vitamin E induced by insulin *(Quinones-Galvan A et al, Metabolism 1996, in press)*. As the good metabolic control of our IDDM patients resulted unable to prevent the serum TAC reduction, it remains to verify the role that a supplementary antioxidant therapy may have in the treatment of Type 1 (IDDM) Diabetes Mellitus.

2298

HGH AND IGF-I IN DIABETES MELLITUS.

P.Born, P.Olbert, P.Wallisch, R.Lorenz, P.Bottermann.
II.Med.Klinik, Klinikum r.d.Isar; Technical University of Munich, Munich, Germany.

Introduction: The role of human growth hormone (HGH) and insulin-like growth factor-I (IGF-I) in the pathogenesis of diabetic late complications is under discussion for long. Therefore we investigated these paramemeters in IDDM- and NIDDM-patients at different stages of the disease.
Subjects and methods: HGH and IGF were measured in 11 IDDM patients without complications (group A: 8m,3f;age:27 +/-6 years; mean diabetes duration:4.9 years), in 9 NIDDM patients with diabetic microangiopathy (B:6m,3f;39+/-16; 19.8),in 47 IDDM adulescents (C:29m,18f;13+/-3;6.9)and 113 age adapted controls (D:44m,69f;44+/-18) as well as in 21 NIDDM patients with peripheral arterial occlusive disease (PAOD) (E:14m,7f;72+/-6;17.4), in 10 NIDDM with microangiopathy (F:6m,4f; 67+/-8;10.2),in 9 NIDDM without complications (G:5m,4f;57+/-14;2.4),in 9 non-diabetics with PAOD stage IIb-IV (H:7m,2f;62+/-7) and in 62 ageadapted controls (I:20m,42f;62+/-8) applying a radioimmunoassay.
Results: The levels of HGH(ug/ml) / IGF-I(ng/ml) were: A:3.0/234 (HbAlc:10.6);B:3.1/162 (8.7);C:2.7/295 (8.6), D: 3.1/212 (5.2);E:1.3/119 (7.9);F:2.3/127 (8.8); G:1.5/ 142 (8.2);H:2.3/127 (5.3);I:2.6/175 (5.4). IGF-I was significantly ($p<0.05$) reduced in all diabetic groups and in the PAOD-controls. HGH levels did not differ significantly. There was no correlation between IGF-I and HbAlc.
Conclusion: IGF-I is reduced in all diabetics more pronounced in the presence of late complications.

2299

HYDROXYL RADICAL MEDIATES N^{ε}-(carboxymethyl) lysine (CML) FORMATION FROM AMADORI PRODUCT

R. NAGAI, K. Ikeda, T. Higashi, H. Sano, Y. Jinnouchi, K. Matsumoto and S. Horiuchi Department of biochemistry, Kumamoto university school of medicine Kumamoto, Japan

Free radical generation has been postulated to play a role in atherogenesis. Recent immunological studies demonstrated the presence of N^{ε}-(carboxymethyl) lysine (CML)-modified proteins in several tissues and their increase in aging as well as age-enhanced diseases such as diabetic complications and atherosclerosis. Since CML formation from glucose-protein adducts or fatty acids needs oxidation, it is thought as a biomarker of glycoxidation or lipid oxidation product in vivo. However, the mechanism of CML formation is not well known. In the present study, to examine effects of radical oxygen species on CML formation from an Amadori product, CML generated from glycated HSA was measured by the immunochemical method using anti-CML antibody. Our glycated HSA prepared by 7 day's incubation with 1.6 M glucose and DETAPAC contained undetectable level of CML. Incubation of the glycated HSA with 0.4 mM $FeCl_2$ for 1 hour lead to CML formation at a detectable level. The CML formation was enhanced dose-dependently by addition of hydrogen peroxide, but significantly inhibited by catalase or mannitol. Superoxide anion generated by the xanthine/xanthine oxidase system or hydrogen peroxide itself failed to produce CML from glycated HSA. In addition, superoxide dismutase had no effect on this process. These data indicate that hydroxyl radical generated by Fenton reaction between Fe^{2+} and hydrogen peroxide might play a major role in CML formation.

SERUM LEVELS AND "IN VITRO" PRODUCTION OF CYTOKINES IN INSULIN-DEPENDENT DIABETIC PATIENTS (IDDM). N.T. Foss, R. Nahas, C. Melli, C.L. Silva and M.C. Foss. School of Medicine of Ribeirão Preto - São Paulo University, Ribeirão Preto (SP), Brazil.

The aim of this study was to evaluated the capacity of immunocellular response in IDDM patients by the determination of cytokines (IL1, IL2, IL4, IL6 and αTNF) levels in the serum and in PMNBC cultures supernatant. PMNBC from 37 IDDM patients were cultured in the presence of LPS (10 μg/ml) and IFNγ (50 U/ml) during 24 hours. Lymphoproliferation assay was developed in the presence of PHA (20 μg/ml) during 72 hours, and was measured by 3H-thymidine incorporation. The serum and supernatant cytokines (IL1, IL2, IL4, IL6 and αTNF) were measured by Elisa assay. The data of the IDDM group were compared with those of a control group of 10 normal individuals. The IL1 and αTNF levels were elevated in serum of IDDM patients (6.0 ± 0.3 and 139.1 ± 4.7 ng/ml) when compared with the normal subjects (0.7 ± 0.02 and 38.9 ± 2.9 ng/ml, respectively). However, the IL1 and αTNF levels in the cultures supernatants (67.0 ± 6.6 and 61 ± 4.2 ng/ml) of normal subjects were significantly higher than those in IDDM patients (21.2 ± 2.3 and 25.0 ± 1.2 ng/ml). Serum and supernatant levels of IL2 from the control group were markedly higher (30.2 ± 0.3 and 45.2 ± 4.0 ng/ml) than those from IDDM patients (16.7 ± 0.7 and 17.9 ± 1.8 ng/ml). In contrast, IL4 levels in the serum (27.7 ± 1.0 ng/ml) and in the supernatant (41.6 ± 2.1 ng/ml) of IDDM patients, were elevated compared to the control group values (3.2 ± 0.1 and 14.3 ± 2.6 ng/ml). The elevated serum levels of IL1, αTNF and IL4 observed in IDDM patients suggest that mechanisms of macrophage activation are developed following the course of the diabetes, but the macrophage response can be negatively controlled by the IL4 action. The lower production of cytokines in PMNBC cultures of IDDM patients compared to normal response may suggest a impaired macrophage capacity of defense against infection.

2301

LIPOIC ACID TREATMENT DECREASES NEURAL TUBE DEFECTS IN FETUSES OF DIABETIC RATS.

R. Potashnik, N. Ayalon, M. Khamaisi, A. Wiznitzer, and N. Bashan. Dept. of Clinical Biochemistry, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel.

Increased oxidant stress is suggested to play a pathogenic role in diabetic embryopathy. Supplementation of vitamin E to pregnant diabetic rats has been shown to prevent fetal malformations. In this study we evaluated the effect of α-lipoic acid (LA), a potent antioxidant, shown to exert therapeutic effects in various conditions associated with increased oxidative stress, including diabetic complications. Female Sprague-Dawly rats (n=57) recieved a daily i.p. injection of LA (30 mg/kg body weight), beginning at first day after matting, for 17 consecutive days. Diabetes was induced by streptozotocin (65 mg/kg body weight i.p) on the 6th day after matting (n=43). Mean maternal blood glucose on the 17th day of gestation was 496 ± 56 and 525 ± 30 mg% in vehicle and LA treated diabetic rats, respectively, $P>0.1$. The prevalence of neural tube defects (NTD) was reduced by LA treatment, from 26% in fetuses of vehicle treated diabetic rats (n=201) to 12% in LA treated group (n=177) ($p<0.05$). Crown rump length (CRL) was reduced in fetuses of streptozotocin-induced diabetic rats (1.69 ± 0.35 cm Vs. 2.07 ± 0.17 cm in control), but was unafected by LA treatment. We conclude that LA has the ability to reduce fetal dysmorphogenesis in diabetic rats, probably by its anti-oxidant capacity.

2302

SIALIC ACID IS DIMINISHED ON THE SURFACE OF CIRCULATING IMMUNO-COMPETENT CELLS IN TYPE II DIABETES

M. Vanhaeverbeek, D. Brohee, P. Piro and P. Neve. Lab. Exp. Med., CHU Vesale, Free University of Brussels, Belgium.

Sialic (N-acetylneuraminic) acid NANA, plays an important role in cell-to-cell recognition; studies done on red blood cells in diabetic patients give contradictory results for NANA concentration on their membrane. The aim of the present study is to evaluate NANA on the membrane surface of circulating immuno-competent cells of type II diabetic patients. 30 patients are compared to 28 non-diabetic patients(consecutive recruitment). Circulating mononuclear cells are isolated by centrifugation. NANA is studied by two different methods. First, surface negative charges are globally estimated by agglutinability after action of polybrene, a positive charged molecule and expressed as % agglutinated cells; secondly, CD_3 (T- lymphocytes), CD_{19} (B- lymphocytes) and CD_{14}(monocytes) subpopulations are marked with limulus polyphemus (horse-shoe crab) agglutinin - a lectin from the sialic group - coupled to flurorescein-iso-thio-cyanate - and studied by flow cytometry; the fluoroscence is expressed as the median channel of the studied subpopulation. Wheat germ agglutinin (triticum vulgare) a lectin from the N-acetyl-glucosamine group - is used as internal control ; parametric tests are used. Agglutinability (47.3 % versus 39 % - $p = 0.0009$), CD_3 limulus fluoroscence (LF) (22.3 versus 12.6 - $p < 0.0001$), CD_{19} LF (35.8 versus 17.2 $p < 0.0001$) but not CD_{14} LF (48.8 versus 44.9 NS) are significantly diminished in diabetic patients. Results are not significant for triticum vulgare. Agglutinability is significantly predicted by CD_3LF, CD_{19}LF and CD_{14} LF (multiple linear regression, $R^2 = 0.356$, $p < 0.0001$). Diabetes and acute phase reaction (APR) (identified by serum CRP> 1 mg/dl) are independent and significant determinants, with interaction, for CD_3 LF, CD_{19} LF but not CD_{14} LF, while diabetes interacting with APR is the only significant determinant for agglutinability - $p < 0.001$ - (two-way ANOVA) We conclude that sialic acid is diminished on the surface of both T and B lymphocytes in type II diabetic patients. This fact must be interpreted in the context of defence problem encountered in diabetes.

2303

EFFECTS OF EPALRESTAT ON THE GLYCATION OF ERYTHROCYTE MEMBRANE PROTEINS

Y. Kokubun, Y. Hayashi, M. Matumura, R. Uchida, R. Sato, M. Okamoto, N. Ogiwara, M. Kawakatu, T. Murakami, A. Asaoka, and Y. Arakawa. 3rd Department of Internal Medicine, Nihon University School of Medicine, Tokyo, Japan.

It has been reported that fructose promotes the Maillard reaction, causing the late reaction product to be accumulated. We administered the aldose reductase inhibitor, epalrestat, to streptozotocin (STZ)-induced diabetic rats to determine its inhibitory effect on the glycation of erythrocyte membrane proteins. The glycation of erythrocyte membrane proteins was determined according to the method of Miller et al. by measuring the radioactivity of each [^{3}H]- labeled protein band on SDS-PAGE. The results obtained in our experiments showed that the sorbitol content of red blood cells in the epalrestat-treated diabetic rats (STZ+E) was reduced ($p<0.05$) compared with that of untreated diabetic rats (STZ), and that the glycation of erythrocyte membrane proteins was significantly inhibited in the epalrestat-treated group. The inhibition was evident in erythrocyte spectrin (bands 1, 2) after 4 wk-long administration ($p<0.05$, STZ+E vs. STZ) and in all bands after 6 wks ($p<0.001$, STZ+E vs. STZ). These findings suggest that aldose reductase inhibitor tends to suppress the accumulated levels of sorbitol in diabetic animals and the elevation of the Maillard reaction.

2304

IN VITRO PRODUCTION OF GRO-α IN NON-INSULIN DEPENDENT DIABETES MELLITUS (NIDDM) RATS.

N. Aoki, M. Fujimoto, Y. Ohno. Department of Medicine, Kinki University School of Medicine, Osaka-Sayama, Osaka 589, Japan.

It is widely assumed that susceptibility of diabetic patients to bacterial infection is caused by dysfunction of neutrophils in them. Not only neutrophil function, but also chemotactic factors for leucocytes, are important in defense against infections. Therefore we focused in this study on Gro-α, an intrinsic chemotactic cytokine for neutrophils produced by rat mononuclear cells. We studied *in vitro* production of Gro-α in the OLETF (Otsuka Long Evans Tokushima Fatty) rats, a model of NIDDM, in comparison with that in control rats. Materials and Methods: Peripheral blood and spleens were obtained from the OLETF rats and LETO (Long Evans Tokushima Otsuka) rats, a non-diabetic control strain. Peripheral mononuclear cells (PMC) and spleen cells (SC) were cultured with or without stimulants (10 μg/ml of lipopolysaccharide, LPS or 10 ng/ml of interleukin-1, IL-1) for 5 days. Culture supernatants were collected at 1, 3 and 5 days after incubation. Gro-α concentration in the supernatants was measured using ELISA kits. Results: 1. Gro-α concentrations in IL-1-stimulated PMC and SC were as low as those in unstimulated cultures. There was no significant difference in IL-1-stimulated Gro-α production between the OLETF and LETO rats. 2. Gro-α levels were significantly higher in LPS-stimulated cultures than in unstimulated or IL-1-stimulated cultures of PMC and SC obtained from both the OLETF and LETO rats. LPS-induced Gro-α production by PMC and SC was lower in the OLETF rats than in the LETO rats at 1, 3 and 5 days after incubation. Conclusion: Production of Gro-α, an intrinsic chemotactic factor for neutrophils, by spleen cells of diabetic rats was decreased significantly compared with that in non-diabetic control rats. Reduction of Gro-α production may be one of the causes of susceptibility to infections in diabetics.

2305

CARBOXYMETHYLLYSINE (CML) IS INCREASED IN SERUM OF CHILDREN AND ADOLESCENTS WITH IDDM

T.J. Berg[1], P.A. Torjesen[1], J.T. Clausen[2], K. Dahl-Jørgensen[1], H.-J. Bangstad[1], H. Vogt[3], and K.F. Hanssen[1], Aker Diabetes Research Centre[1], Aker University Hospital, Oslo, Novo Nordisk A/S[2], Denmark and Akershus Central Hospital[3], Norway.

Advanced glycation endproducts (AGEs) are heterogenous protein modifications probably involved in the pathogenesis of diabetic late complications. The relative importance of the different AGE structures is not known. The glycoxidation product CML can be formed from early glycation products. CML was recently shown to be the dominant AGE in vitro and in human lens proteins. CML is also increased in skin collagen of patients with diabetes.

Aim: In the present study we investigated whether the serum levels of CML in adolescent diabetic patients were different from normal subjects. **Methods:** We also compared the serum levels of CML as measured by monoclonal anti-CML antibodies, to the serum levels of AGEs (pAGEs) measured by polyclonal antibodies made from rabbit immunized with AGE-RNase. 19 female and 19 male IDDM patients aged 14±3.2 (mean±SD) years, mean duration 5 (range 0.5-15) years, were compared with 13 normal female and 13 normal male subjects aged 16±1.7 years. HbA1c was 9.6±2.2 in the diabetic group. **Results:** The serum levels of CML and pAGEs were significantly elevated in the diabetic group when compared to controls; CML: 1,08 (0.82-1.37) (median, 95% CI) CML-BSA units vs. 0.70 (0.56-0.97), $p<0.03$, and pAGEs: 6.6 (5.8-7.3) AGE-BSA units vs. 5.5 (4.6-6.4), $p<0.01$, respectively. A significant correlation ($r=0.76$, $p<0.001$) was found between the serum levels of CML and pAGEs in the diabetic group but not in controls ($r=0.17$). No association was found between the Amadori product HbA1c and CML ($r=-0.02$) or pAGE ($r=0.35$, NS). Neither CML nor pAGEs were associated with age, sex or diabetes duration.

Conclusion: The serum levels of CML are increased by 50% in young patients with diabetes. As suggested by in vitro studies, the source of CML does not seem to be an Amadori product.

EFFECTS OF PIOGLITAZONE ON Ca^{2+} HANDLING IN CARDIOMYOCYTES OF DIABETIC RATS

M.Kume, T.Miwa, M.Kanazawa, Y.Notoya, J.Hayashi*, K.Yamaguchi*, K.Akagawa* and T.Hayashi. Tokyo Med. Coll., Kyorin Univ.*, Tokyo, Japan.

Introduction: We have shown that contractile function impaired in diabetic myocardial cells at the 15th IDF Congress. The aim was to demonstrate intracellular mechanisms of diabetic myocardial cell dysfunction and effects of pioglitazone (PGZ). **Method:** Seven male Sprague-Dawley rats aged eight weeks were injected with 60 mg/kg of streptozotocine intraperitoneally. Three of them were treated with PGZ (30 mg/kg/day). At 14 days after streptozotocine injection, both PGZ treated (group P) and untreated (group D) rats were sacrificed and the heart was quickly excised. Myocardial cells were isolated using collagenase, then loaded with acetoxymethyl ester of Indo-1 at a concentration of 5 μM for 15 min at 37 ° C. Control myocardial cells were prepared from six normal rats (group N). Cells stimulated with electrical pulses (0.25 Hz, 350 mV, 6 msec duration) were monitored continuously in high resolution video system. Intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) was measured at 33 msec interval using ARGUS-50/CA system (Hamamatsu Photonics, Ltd.). $[Ca^{2+}]_i$ was evaluated as fluorescence intensity ratio of 405/480 nm of whole cell fluorescence images, which were obtained simultaneously from a cell exposed by a exciting light of wavelength at 350 nm, visualized by an intensified CCD camera, and stored in an imaging processor. We analyzed velocity of increase (VCa) and time constant of decrease (τ) of $[Ca^{2+}]_i$ changes during myocardial cell contraction and relaxation. **Result:** VCa was reduced in group D (5.80 ± 0.48 sec^{-1}) compared from group N (6.82 ± 0.56 sec^{-1}). Impaired VCa was recovered in group P (7.60 ± 1.30 sec^{-1}). τ in group D was larger than that in group N (584 ± 30.4 vs 475 ± 34.4 msec). In group P, τ became small to 559 ± 12.5 msec. **Conclusion:** These findings suggest that reduced contraction and delayed relaxation observed in diabetic myocardial cells could depend on the impairment of $[Ca^{2+}]_i$ handling, and PGZ may improve dysfunction by smoothing the movement of $[Ca^{2+}]_i$.

THE 1,5-ANHYDRO-D-GLUCITOL PLASMA LEVEL AND HbA_1c CONCENTRATION IN HEALTHY SUBJECTS.

M.Dworacka,K.Szczawińska,H.Winiarska,D.Zozulińska* and S. Kuczyński.Karol Marcinkowski University of Medical Sciences in Poznań.*Internal Medicine and Diabetology Department of F.Raszeja Hospital.Poznań,Poland.

1,5-Anhydro-D-glucitol (AG) - glucose analogue was reported in human plasma by Pitkanen first in 1972.AG level of diabetic patients is lower than in healthy humans and is probably associated with hyperglycemia and glucosuria,reflects metabolic compensation in 1-2 days before examination.From these properties,AG is proposed to be an useful marker of glycemic control in diabetic patients.The aim of our study was to establish the mean plasma AG level of normal subjects and to analyze the link between AG and HbA_1c in these subjects.32 healthy subjects (fasting plasma glucose 4,7 ± 0,6 mmol/l,creatinine concentration in plasma 91,1 ± 8,8 µmol/l):12 woman and 20 men in the mean age of 46,9 ± 16,2 years,range:16-76 were investigated.Plasma AG concentration was determined using enzymatic method based on pyranose oxidase (pyranose:oxygen 2-oxidoreductase) and HbA_1c was assayed according to the immunoenzymatic method (DAKO kits).The mean level of AG was 168 ± 39 µmol/l,range: 129-206 µmol/l.Any correlation between AG level and HbA_1c was observed.Summarizing AG level could be an undependent on HbA_1c values,index of glycemic control.

VENOUS ERYTHROCYTE COLUMN WIDTH IS INCREASED IN TOE CAPILLARIES OF DIABETIC PATIENTS

M Lombardi, B Fagrell and G Jörneskog.
Karolinska Hospital, Stockholm, Sweden.

A maldistribution of blood from skin capillaries to subpapillary vessels through arteriovenous shunts has been demonstrated in the toes of diabetic patients. This may lead to an increased postcapillary venous pressure causing dilation on the venous side of the capillary. The aim of the present study was to investigate if the capillary diameter (erythrocyte column) is wider in diabetic patients than in healthy subjects. Fiveteen patients with type 1 diabetes (age: 30±8 years), and 15 age and sex matched controls were investigated. Nine of the patients had short diabetes duration (3±2 years) and no complications, while 6 patients had diabetes since 14±12 years and microangiopathy. Skin temperature and toe blood pressure were similar in patients and controls. Single skin capillaries of the big toe were investigated by videophotometric capillaroscopy and the erythrocyte column width was determined at 6 standardized levels (3 arterial and 3 venous). Ten measurements were performed at each level and mean±SD values for the arterial and venous parts were calculated. A small but insignificant increase was seen on the arterial side in the patients (9.3±1.6 µm; controls: 9.0±1.8 µm). The venous part was wider (p=0.02) in the patients (11.9±1.4 µm) than in controls (10.9±1.8 µm), mainly due to an increase in the patients with microangiopathy (12.4±1.4 µm). The results of the present study show that the venous part of skin capillaries is dilated in the diabetic foot, which further supports the hypothesis of blood passing through arteriovenous shunts resulting in a decreased ratio between pre- and post capillary pressures, leading to a reduced blood flow through nutritive capillaries. These functional disturbances may be of importance for the development of neuropathy and chronic foot ulcers in the diabetic foot.

DETERMINATION OF GLYCATED ALBUMIN BY ENZYME-LINKED BORONATE-IMMUNOASSAY (ELBIA)

K. Ikeda[1,2], Y. Sakamoto[2], Y. Kawasaki[2], T. Miyake[3], K. Tanaka[3], T. Urata[4], Y. Katayama[5], S. Ueda[1] and S. Horiuchi[2]

[1]Department of Urology and [2]Biochemistry, Kumamoto University School of Medicine, Japan [3]Research Institute, Nacalai Tesque, Japan [4]Department of Clinical Pathology, Showa University School of Medicine, Japan [5]Laboratory of Clinical Chemistry, National Cardiovascular Center Hospital, Japan

A new affinity method for quantification of glycated albumin by an enzyme-linked boronate-immunoassay (ELBIA) was established. ELBIA was based on the interaction between boronic acids and cis-diols of glycated human serum albumin (HSA) trapped by anti-HSA antibody coated on a microtiter plate well. We first examined the feasibility of the conventional boronate affinity method. In the conventional method, 8.1 to 18.9% of nonglycated standard albumin nonspecifically binds to the boronate affinity column whose values are regarded as column-blank. Therefore, in the present modified affinity chromatographic method, this column-blank was subtracted from the apparent glycated albumin values to obtain the correct one. The accuracy of ELBIA was evaluated by comparison with this modified affinity chromatographic method. Correlation coefficients of 0.995 (n = 22) and 0.991 (n = 6) were obtained for ELBIA versus the modified affinity chromatographic method for measurement of glycated standard albumin and albumin fractions purified from human sera, respectively. The correlation line for all measurement was $y = 0.996x + 0.846$ (n = 28, r = 0.993). Thus, glycated albumin values determined by ELBIA exactly correspond to those determined by the modified affinity chromatographic method, suggesting that ELBIA reflects the in vivo situation of albumin glycation. Furthermore, we developed a fully automated ELISA system for ELBIA, which allows the multiple, rapid and precise measurement of glycated albumin. In this fully automated system, the intra-assay CV was 3.7% (n = 92) and the inter-assay CV was 4.2% (n = 5). The glycated albumin value of normal subjects was 5.26 ± 0.96% (n = 110, mean ± SD). Further clinical study using ELBIA showed that the correlation line of glycated albumin versus stable-HbA1c was $y = 2.904x - 9.783$ (n = 470, r = 0.876).

CAPILLARY PRESSURE IN SUBJECTS WITH FASTING HYPERGLYCAEMIA

Shore AC, Morris SJ, Stockman AJ, Tooke JE.
Institute of Clinical Science, University of Exeter, Exeter, U.K.

In support of the haemodynamic hypothesis which proposes that raised capillary pressure and flow are instrumental in the pathogenesis of microangiopathy, capillary pressure is elevated in IDDM patients with microalbuminuria but not in those of equivalent disease duration without evidence of microvascular disease. In contrast capillary pressure is not raised in NIDDM. The prolonged period of metabolic disturbance preceding NIDDM is known to be associated with abnormalities of microvascular function. This study investigated whether this prediabetic phase was also accompanied by abnormalities of capillary pressure. Subjects with fasting hyperglycaemia (FH), defined as individuals with fasting plasma glucose in the range 5.5 to 7.7 mmol/l on two separate consecutive occasions, were recruited from the general population and groups at risk of diabetes e.g. gestational diabetes, family history of diabetes. 21 subjects with FH and 21 age sex and menstrual status matched healthy volunteers (13 male) were investigated. Capillary pressure was measured by direct cannulation of finger nailfold capillaries using a resistance based servo-controlled system. The two groups did not differ in systolic or diastolic blood pressure or skin temperature. Capillary pressure was not different between the two groups (16.9±3.5 controls v 18.0±4.4 mmHg FH, p=0.46). Thus capillary pressure does not appear to be elevated in the prediabetic state.

2311

ANTIBODIES AGAINST IN VITRO GENERATED AGE: SPECIFICITY AND APPLICABILITY TO ASSAYS FOR *IN VIVO* AGE.

J.T.Clausen, M.Christensen, I.Skovsted, S.B.Mortensen,O.J.Bjerrum and M.Wilken. Novo Nordisk A/S, Bagsvaerd, Denmark

Most immunoassays for advanced glycation endproducts (AGE) are based on antibodies prepared against *in vitro* generated AGE. Also the majority of assays are of the competitive type, using *in vitro* AGE as tracer/competing antigen. This means, that the final specificity of these assays depends solely on *in vitro* AGE different from the *in vivo* material, that one would analyse. Often, *in vitro* AGE has been prepared by letting protein and sugar react under conditions, that due to differences in eg. the concentration of trace amounts of metal ions, pH, oxygen tension and temperature result in variable products. The aim of our investigation was to compare poly- and monoclonal antibodies prepared against a panel of *in vitro* AGE's. The *in vitro* AGE's included preparations made by incubating proteins (KLH, BSA, lysozyme, RNAse and PPD) with various sugars (glucose, glucose-6-P, fructose and ribose) and by defined chemical modifications of proteins (methylglyoxal-, carboxymethyl-, glyoxal-, GOLD, MOLD and pentosidine). Each AGE was characterised by aminoacid analysis to determine the degree of modification and, where possible, the chemical nature of the modified aminoacids. Ribose BSA containing per mole 48 modified lysines of which one was CML, served as reference material. The detection limit for this compound was in ELISA about 1ug/ml. Our results show, that despite the fact that conditions during protein/sugar incubations vary, carboxymethylated lysine (CML) is by far the most abundant epitope recognised by the raised antibodies. Nevertheless, competitive ELISA's using these antibodies with various *in vitro* AGE's as coating antigen, show differences in the relative response for the different AGE's. The conclusion is, that although the specificity of most AGE antibodies is CML, the final assays using these antibodies may differ in their capability to recognise *in vivo* AGE. Thus thereis an urgent need for standardisation of AGE immunoassays.

2312

SERUM 8-HYDROXY-GUANINE LEVELS ARE INCREASED IN DIABETIC PATIENTS

C.S.Shin, B.S.Moon, J.J.Koh, D.J.Park, K.S.Park, S.Y.Kim, H.K.Lee, C-S.Koh, S.J.Park and M.H.Chung, Seoul National University College of Medicine, Seoul, Korea

Production of reactive oxygen species are increased in diabetic patients and the oxidative damage may contribute to the development of diabetic microangiopathic and macroangiopathic complications. This study was performed to investigate whether the serum levels of 8-hydroxyguanine (8-OHG), as an indicator of oxidative damage to DNA, was elevated in diabetic patients. Forty-four diabetic patients (41 NIDDM and 3 IDDM) were matched by age for 33 healthy controls. Serum 8-OHG levels were measured by high-pressure liquid chromatography. Diabetic patients had significantly higher mean concentrations of 8-OHG than controls (5.23 ± 4.25 vs. 0.98 ± 0.84 pmol/ml, $p<0.01$, t-test). Among diabetic patients, those with advanced nephropathy (n=11, serum creatinine levels >1.2 mg/dl) had significantly higher 8-OHG levels than the other non-azotemic patients (7.26 ± 4.09 vs. 4.11 ± 4.02 pmol/ml, $p<0.05$, t-test). The 8-OHG levels tended to be higher as the retinopathy progressed in diabetic patients. However, there was no significant correlation between the level of 8-OHG and age, HbA1c, duration of diabetes and creatinine clearance. In conclusion, the diabetic patients showed greater oxidative damage to DNA and such changes might contribute to the vascular complications of diabetes.

2313

LENS LIPID PEROXIDATION AND HEAVY METAL ACCUMULATION IN DIABETIC CATARACTOUS AND CLEAR LENSES

Erel O., Koçyiğit A., Alçelik T., Avcı Ş., Aktepe N, Fac. of Med., Univ.of Harran, Sanlıurfa, Turkey

Relationship between lens lipid peroxidation and heavy metal accumulation was investigated in 15 diabetic cataractous lenses and 6 clear lenses. Lens malondialdehyde (MDA) concentration which is the product of lipid peroxidation was measured by colorimetric method. Lens Cu, Fe, Cr, Ni, Pb, Mn, Sb and Zn concentrations were measured by electrothermal atomic absorbtion spectrometer. In diabetics, lens MDA concentrations were higher about three times than control group. Accumulation of Cu, Fe, Cr, Ni about six times, Pb, Mn about four times, Sb and Zn about twice times were higher in diabetic cataractous lenses than clear lenses. Significant correlation between Zn, Cr, Mn, Pb and MDA concentrations was determined ($p=0.001$ $r=0.66$, $p=0.005$ $r=0.59$, $p=0.05$ $r=0.44$, $p=0.05$ $r=0.42$ respectively). No significant correlation between Cu, Fe, Ni, Sb and MDA concentrations. Very high concentrations of latter group elements in diabetic lens may suggest that accumulation of heavy metals in diabetic lens is prior process than lens oxidation, and it may be accelerate lens lipid peroxidation.

2314

THE EFFECT OF HYPERGLYCEMIA AND DIABETES ON METHYLGLYOXAL AND ITS DETOXIFICATION PATHWAYS

PAUL J BEISSWENGER*, Allison Touchette and Scott Howell, Dartmouth Medical School and Dartmouth-Hitchcock Medical Center, Lebanon, NH 03756 USA

The reactive α dicarbonyl, methylglyoxal (MG) has been postulated to produce diabetic complications as a direct toxin and as a precursor for advanced glycation end-products (AGEs). Levels of MG are regulated by rates of production from glucose and the detoxification pathways to D-lactate (glyoxalase) and acetol (aldose reductase). To address factors that determine tissue levels of MG and the activity of degradative pathways we have measured MG, D-lactate and acetol in plasma by HPLC. We measured these compounds in 25 IDDM subjects with minimal complications (<15 yrs duration), 40 NIDDM subjects with normal renal function, and 20 non-diabetic controls. Glycemic control was determined by HbA1c and glucose determination. MG and D-lactate levels were significantly elevated in diabetic subjects relative to controls. (see table below)

mean± SD	MG (nM)	D-lactate (μM)
NIDDM (n=40)	221.8±43.6	12.3±5.9
IDDM (n=25)	215.3±61.9	13.3±6.0
Control (n=20)	154.6±30.6*	8.7±4.7#

* p=<0.0001
\# p=0.03

We also found a highly significant association between plasma MG concentrations and glucose levels in NIDDM ($r=0.74$, $p=0.0003$) and IDDM ($r=0.35$, $p=0.04$) indicating that glycemic control is an important determinant of MG levels. D-lactate and acetol showed no relation to glycemic control. We found no correlation of MG and its degradation product D-lactate in NIDDM ($R=0.12$, $p=0.62$) or IDDM ($R=0.24$, $p=0.17$) when compared with non-diabetic controls who showed a significant relationship ($R=0.49$, $p=0.07$), while acetol showed a significant inverse relationship with MG ($r=0.56$, $p=0.001$). These studies indicate elevated MG in diabetes and that levels of MG, but not its degradation products D-lactate and acetol, are directly related to the level of glycemic control. Acetol and MG demonstrate a reciprocal relationship suggesting that different factors regulate their levels in diabetes.We also show that MG undergoes predictable detoxification to D-lactate in non-diabetics but degrades to a variable degree in diabetes, suggesting that acquired or genetic factors may modify MG detoxification. Understanding the activity of this pathway in diabetic individuals may help to predict their degree of risk for diabetic complications.

2315

DEPRESSING EFFECT OF EXOGENIC AND ENDOGENIC COMPOUNDS ON SERUM GLYCATION IN DIABETES

N.I.Verbovaia and E.A.Lebedeva. State medical University, Samara, Russia

The assessment of few substunces impact on nonenzymatic glycation process in diabetes was undertaken in vitro and in vivo experiments. Substrate was obtained by incubation of human serum albumin in 5% water solution (HSA) with 44 mM/l glucose for 20 days, t=+1-+2°C. Fructosamine concentration (FA) by tetrasolium nitroblue method was 273,3±6.6 mkM/l. Addition of serum of healthy persons and IDDM patients in amounts of 50% of the total volume decreased FA to 19,0±1,3 mkM/l and 22,6±0,57 mkM/l (p<0,001) respectively. Serum heating didn·t alter it properties. Physiological concentrations of thermostable substunces of uric acid 600 mkM/l, arginin 170 mkM/l, creatinine 150 mkM/l added to solution of HSA and glucose 17mM/l decreased FA from 38,8±5,8 mkM/l to 12,8±5,2 mkM/l (p<0,01). We proposed, that aminogroup compounds could join with glucose, precluding its binding to body proteins, decreasing glycation. To prove this preposition Bucarban (0,075 g/kg, n=9, gr.1) and Glibutid (0,01 g/kg, n=9, gr.2) were administrated to alloxane diabetes rats for 1 month. FA fell from 7,7±0,2 to 5,7±0,2 mkM/l (p<0,001) in gr.1 and from 7,6±0,1 to 5,4±0,1 mkM/l (p<0,001) in gr.2, showing effects of this common drugs on glycation

2316

GLYCOXIDATION AND LIPOXIDATION PRODUCTS IN RED BLOOD CELL MEMBRANES IN POORLY CONTROLLED DIABETES.

T.J. Lyons, J.R. Requena, C.W. Fountain, A.J. Jenkins, C.M. Perez, D. Gates, K.L. Hermeyer, L.P. King, J.W. Baynes and S.R. Thorpe. Medical University of South Carolina, Charleston and University of South Carolina, Columbia, U.S.A.

Background: Increased blood glucose levels and oxidative stress result in the formation of glycoxidation and lipoxidation products in proteins and phospholipids. These products may be implicated in the pathogenesis of the chronic complications of diabetes. Red blood cell (RBC) membranes are readily available, have a relatively long life span and contain both lipids and protein, hence may be a useful source of markers of both glycoxidation and lipoxidation.

Aims: To establish if markers of glycation (fructose-lysine (FL)), glycoxidation (carboxymethyllysine (CML)) and lipoxidation (carboxymethylethanolamine (CME)) are detectable in RBC membranes, and if levels of these markers differ between subjects with poorly controlled diabetes and non-diabetic controls.

Methods: Thirteen subjects with diabetes (HbA1c >8%, normal renal function) and matched non-diabetic control subjects were studied. Levels of FL, CML, and CME were measured in RBC membranes by gas chromatography/mass spectroscopy.

Results: mean (standard deviation)

	diabetes	controls	t-test
fasting glucose mg/dl	232(114)	78(9)	p=0.0004
HbA1c %	10.6(2.3)	5.7(0.6)	p=0.0001
FL/lysine mmol/mol	12.2 (8.0)	4.3 (2.7)	p= 0.008
CML/lysine mmol/mol	0.20(0.07)	0.21(0.06)	p>0.05
CME/ethanolamine mmol/mol	0.31(0.54)	0.18(0.16)	p>0.05

RBC membrane FL and HbA1c correlated , r=0.57, p<0.01.

Conclusions: FL, CML, and CME are detectable in RBC membranes. FL levels are increased in diabetic vs non-diabetic subjects, and correlate with HbA1c. Levels of CML and CME do not differ between diabetic and non-diabetic subjects. This study provides no evidence of increased oxidative stress in diabetes.

2317

EFFECT OF DIABETES MELLITUS AND OXIDIZING AGENTS ON HUMAN RED BLOOD CELL ENZYMES ACTIVITY.

K. Szosland, I. Zavodnik, E. Krajewska, L. Zavodnik and M. Bryszewska. Medical Academy of Łódź, University of Łódź, Poland

The aim of the study was to measure the parameters of enzymatic activities of membrane acetylcholinesterase (AChE) and cytosolic glutathione peroxidase (GSHP) from red blood cells of diabetic patients and upon the influence of oxidative stress. The membrane AChE activity was measured by the spectrophotometric method of Ellman et al, the GSHP activity in cell haemolysates as the rate of exogenous GSH oxidation according to the method of Romos-Martinez. The maximal enzyme reaction rate of AChE was (17.2 ± 0.8) μmol acetylthiocholine/ml packed cells/min (n=11) for diabetic cells vs. (13.1 ± 0.8) μmol acetylthiocholine/ml packed cells/min (n=14) (p<0.02) for control erythrocytes. For GSHP the enzymatic reaction rate was (11.9 ± 3.0) μmol GSH/ml packed cells/min in diabetic cells in comparison to (13.9 ± 3.9) μmol GSH/ml packed cells/min in controls (p<0.05). The cell exposure to the oxidative agent t-butyl hydroperoxide (tBHP) significantly changed the parameters of enzyme activities. The maximal AChE reaction rate increased but substrate affinity decreased up to tBHP concentration of 0.1 mM for diabetic cells and 0.4 mM for control ones. For higher oxidant concentrations both the maximal AChE enzymatic reaction rate and Michaelis-Menten constant decreased. The GSHP maximal reaction rate increased and substrate affinity decreased up to tBHP concentration of 1.5 mM. The susceptibility of red blood cell membranes from diabetic patients to oxidative stress was much higher than of control erythrocyte membranes. It can be postulated that the alteration of erythrocyte enzymes activity in diabetes is a result of the constant oxidative stress in this disease which can be responsible for the development of long-term complications.

NEW STRATEGY FOR TREATING THE DIABETIC HYPOXIA : PREVENTION OF HEMOGLOBIN-AGE FORMATION

T. Kawamura, T. Maruyama, T. Akira, M. Sugiura and N. Nakamura. Central Research Laboratories, The Green Cross Corporation, Osaka, Japan.

In the pathologic mechanisms underlying diabetic neuropathy, a role of endoneurial hypoxia, as well as impaired polyol pathways, is recently stressed. However, in the model of streptozotocin-induced diabetes, the endoneurial blood flow (eBF) , which plays a pivotal role in tissue oxygen supply (tOx), remains at the range enough to preserve the anaerobic glycolysis of the sciatic nerve, although the nerve conduction is already disturbed 3 weeks after the diabetic operation. We thus postulated that the dysfunction, not the mass (flow), of the oxygen carrier protein, hemoglobin is problematic at such earlier time points. A positive correlation between eBF and tOx, as seen in non-diabetic rats, was disturbed in the diabetic conditions. This was backgrounded by an impaired capacity of oxygen release from diabetic erythrocytes. The decreased oxygen half partition pressure (P50) was likely to be a crucial factor for limited oxygen supply to the peripheral nerves. The P50 values are generally influenced by the level of the 2,3-DPG in erythrocyte, however, in the diabetes, this may not be the case. The raised level of 2,3-DPG does not necessarily function to elevating P50 values. This is caused by a dysfunction of the diabetic hemoglobin. In the present study, we demonstrated that the dysfunction of the oxygen carrier protein is attributed to the advanced glycation end products (AGE) of hemoglobin, Hb-AGE, rather than the glycation of the carrier protein, HbA1C, and that a novel aldose reductase inhibitor, SG-210, if orally administered for 2 weeks, alleviates the formation of Hb-AGE for improved the tissue oxygenation. A clue may thus be provided for medication of the diabetic neuropathy.

2319

THE ERYTHROCYTE SORBITOL LEVELS CORRELATE WITH BLOOD GLUCOSE LEVELS AND DIABETIC COMPLICATIONS

R.Hayashi, Y.Itoh, N.Hayakawa, T.Mokuno, S.Kato, K.Uchimura, M.Kotake, M.Itoh, A.Nagasaka, T.Fujita, and R.Shinohara. Fujita Health University. Toyoake, Aichi, Japan.

Abnormal polyol metabolism may contribute to the development of diabetic complications. Previous reports on the roles of sorbitol in diabetic patients provided contradictory results probably due to the poor reproducibility of sorbitol assay methods. We devised an improved sorbitol assay and investigated the relationship between sorbitol levels in erythrocytes and glycemic control indices and diabetic complications, and also evaluated the effect of aldose reductase inhibitors on the sorbitol level. Erythrocyte sorbitol concentrations were measured as follows: The washed erythrocytes were mixed with NaOH and ZuSO4, followed by centrifugation. Two ml of the supernatant was added to 2.0ml Tris-HCl buffer containing 10mM EDTA, 2U/ml sorbitol dehydrogenase and 12.5mg NAD, and incubated at 37℃ for 30 min. The NADH thus formed was measured at an excitation wavelength of 366 nm and an emission wavelength of 452 nm.

Fasting sorbitol levels were 67.1±36.3nmol/gHb in NIDDM patients, 95.0±60.8nmol/gHb in IDDM patients, and 38.5± 8.1nmol/gHb in normal individuals. Positive correlations were noted between the fasting blood glucose and sorbitol levels, and between the HbA1c and sorbitol levels. Sorbitol levels did not correlate with the 24h Ccr, microalbuminuria, tibial nerve MCV or ECG R-R100 values. Treatment with aldose reductase inhibitors for one month induced a decrease in the sorbitol levels. Thus, this assay method makes it possible to measure erythrocyte sorbitol with good reproducibility and to elucidate the relation between the diabetic condition and sorbitol levels.

2320

RELATION BETWEEN EARLY GLYCATION PRODUCT AND ADVANCED GLYCATION END PRODUCT ON ERYTHROCYTE MEMBRANE PROTEIN AND HEMOGLOBIN.

Z. Makita, S. Kuwajima*, K. Yanagisawa, T. Atsumi, K. Tsutida, S. Obara, H. Miyoshi, N. Yoshioka*, and T. Koike. Internal Medicine II, Hokkaido Univ. School of Med., and Sapporo city Hospital*, Sapporo, Japan

Protein glycation mainly consists of two sets of reaction in vivo, early reversible and advanced irreversible glycation. Few reports are available concerning comparisons of levels of early and advanced glycation products in vivo. We made use of a radioimmunoassay to detect early glycation and an ELISA for advanced glycation, we assessed the amount of early glycation product (EGP) and advanced glycation end product (AGE) in erythrocyte membrane protein (EMP) and Hb in diabetic (DM) and non-diabetic control subjects (C). The levels of early EGP in EMP were 48.4±2.5 (nmole glucitollysine/mg proteins) in C, and 79.4±13.1 in DM (P<0.001) while levels of EGP in Hb were 4.1±1.4 (nmole glucitollysine/mg Hb) in C and 7.5±2.1 in DM (P<0.001). The levels of AGE in EMP by ELISA were 22.5±7.7 (AGE Units/mg proteins) in C, and 70.7±51.8 in DM (P<0.001), and the levels of AGE in Hb were 3.8±1.2 (AGE Units/mg Hb) in C, and 12.3±2.1 in DM (P<0.001). To investigate the large differences in levels of AGE in EMP and Hb between DM and C compared to EGP, we estimated the the levels of AGE in samples with several proteins (EMP, Hb, albumin) incubated with glucose, fructose, fructose-3-phosphate (F-3-P) or intermediate substance 3 deoxyglucosone (3-DG). The formation of AGE was dramatically increased by incubation with F-3-P and its decomposition products 3-DG, compare to the incubation with glucose or fructose. The AGE inhibitor aminoguanidine effectively inhibited AGE formation by 3-DG. These findings demonstrate that even under the same metabolic conditions the extent of EGP and AGE differs depends on proteins and the extent of AGE dramatically increases in DM patients, although EGP in DM patients remain increases little.

GLICATED γ-GLOBULINS: A NEW PARAMETER FOR METABOLIC CONTROL OF DIABETIC SUBJECTS?

A. Lapolla, D. Fedele, R. Aronica, M. Battaglia, M. Garbeglio, M D'Alpaos, R. Seraglia and P. Traldi.
Istituto di Medicina Interna, Università di Padova, Padova, Italy.

The knowledge of the glycation level of γ-globulins in diabetic subjects can be relevant either for the disease control or for its possible relationship with immunological impairment. Consequently the development of specific methods for the determination of such levels is of high interest. Stimulating results have been achieved by matrix assisted laser desorption/ionization mass spectrometry (MALDI/MS), which allows to determine the molecular weight of intact proteins with an accuracy in the range 0.1-0.01%. Fourteen badly controlled diabetic patients [**A**] (mean age ± SD 63 ± 7 years, mean disease duration 12 ± 8 years, mean fasting plasma glucose (FPG) 20.8 ± 4.5 mmol/L, mean furosine 0.47 ± 0.07 μg Fur/mg prot, mean HbA_{1c} 10.9 ± 2.0%), eight well controlled diabetic patients [**B**] (mean age 60 ± 12 years, mean disease duration 13 ± 9 years , mean FPG 8.0 ± 1.2 mmol/L, mean furosine 0.33 ± 0.03 μg Fur/mg prot, mean HbA_{1c} 7.2 ± 0.5%) and eight normal controls [**C**] (mean age 57 ± 9 years, mean FPG 5.5 ± 0.3 mmol/L, mean furosine 0.22 ± 0.02 μg Fur/mg prot, mean HbA_{1c} 5.5 ± 0.4%) were examined. For these subjects the molecular weight of human serum albumin (MW_{HSA}) and γ-globulin (MW_γ) were determined by MALDI and compared with those of genuine, non-glycated proteins. HSA shows mean mass increase (ΔM_{HSA}) of 1491 ± 624 Da for **A**, 321 ± 82 Da for **B** and 76 ± 48 Da for **C**. In the case of γ-globulins ΔM_γ values of 2516 ± 1120 Da, 1128 ± 339 Da and 581 ± 347 Da have been found for **A**, **B** and **C** respectively. The observed mass increase (ΔM_{HSA} and ΔM_γ) must be related to a number of glucose molecules condensed on the proteins. The plots ΔM_γ *vs* FPG, furosine, HbA_{1c} and ΔM_{HSA} result linear, with correlation indexes of 0.754, 0.641, 0.832 and 0.869 respectively. These results show that by MALDI an easy determination of γ-globulins glycation levels can be achieved. Their relationship with other metabolic control parameters suggests its use in the same field and suggests to undertake investigations on its possible relationship with immunological impairment.

2322

QUANTIFICATION OF CROSSLINE™ IN SERUM AND ERYTHROCYTE MEMBRANE PROTEIN IN DIABETIC SUBJECTS

M. Yamaguchi, K. Nakano, G. Hasegawa, H. Shigeta, Y. Kitagawa, N. Nakamura, H. Obayashi, I. Fukui , M. Kondo and K. Ienaga. First Dep. of Int. Med, Kyoto Pref. Univ. of Med, Kyoto, Japan. IBAS, Nippon Zoki Pharm. Co. Ltd, Hyogo, Japan.

Recent studies have suggested that advanced glycation endproducts (AGEs) play an important role in the pathogenesis of diabetic complications. Crossline is a novel AGE-product which has both crosslink and fluorescence similar to AGE-proteins *in vivo*. Although the accumulation of AGEs in specific tissue might explain the role of this compounds for the deterioration of diabetic complications, we need more pragmatical strategy for the evaluation of glycation, the most important events in the development of diabetic complications. Now we developed high performance competitive ELISA system for the determination of crossline. The aim of this study was the cilinical evaluation of this crossline assay system in diabetic patient; the relationship between serum level <S> or values in erythrocytes membrane proteins <M> of crossline and glycemic control or diabetic complications. Serum samples or erythrocyte membrane fractions were collected from 69 NIDDM patients and 21 normal subjects as control. Glycemic control was evaluated by measuring HbA1c and diabetic retinopathy was assessed by ophthalmologist. <S> and <M> of crossline were positively correlated with HbA1c, r=0.312 (p<0.05) and r=0.427 (p<0.01), respectively. In patients with retinopathy, however, <M> of crossline significantly increased (p<0.01) independently to HbA1c levels, although no relation was observed between HbA1c levels or <S> of crossline and diabetic retinopathy. These results suggested that 1) serum levels of crossline reflect diabetes controls, 2) crossline levels in membrane also correlated to glycemic control and would be possible indicator or predictor of diabetic complications such as retinopathy.

Complications – Clinical Problems

2323

HYPEROSMOLAR HYPERGLUCEMIC NONKETOTIC COMA, CLINICAL EXPERIENCE IN HOSPITAL 25 IMSS MONTERREY, N.L. MEXICO.

C. Lozano-Peña, V. Guibovich, J. Ocotla and A. Reyna.

We analized the cases of patients with hyperosmolar hyperglucemic coma in Hospital 25 IMSS, Monterrey N.L. México; in the period January 1993 - December 1995. They were 406 hospitalized patients with diabetes type II, 20 out of all with hyperosmolar coma: 3 cases associated with ketoacidosis, 17 hyperosmolar hyperglucemic nonketotic coma (HHNC): 1 case in 1993, 7 in 1994 and 9 in 1995. 7 Out of 17 patients were women (41%) and 10 men (59%). The mean age was 67 years (44 - 87), with mean duration of diabetes: 12 years (2 - 30 years), only 3 cases with recent onset of diabetes. 9 patients in treatment with oral hypoglucemiants agents (54%), 2 with insulin (11%), 1 with diet alone (6%) and 5 without treatment (29%). Precipitating causes: 6 cases due to pneumonia, 2 urinary infection and 2 gastroenteritis, one case due to pancreatitis (6.6%), 1 due to stroke (6.6%), 1 due to surgery stress (gastrectomy) (6.6%), and 1 due to chemotherapy (6.6%) and 7 cases with unknown etiology. The mean initial glycemia was 1043 mg/dl (+/- 443). The mean corrected serum sodium was 163 mEq/lt. (+/- 24). the mean osmolarity was 378 mOsm/lt (+/- 52). 9 patients died (53%), mostly due to complications: sepsis (3 cases), ARDS (2 cases), pulmonary thromboembolism (2 cases) and acute myocardial infarction (2 cases). In conclusion, HHNC is a infrequent complication but severe in the diabetic patient type II, mostly in that patient with inadecuate control of diabetes and delay in medical assistance, precipitating by infection or acute stress. Poor prognosis is seen in advanced age, severe hyperglycemia, hypernatremia, hyperosmolality, severe acidosis and developing some complication. Th adequate treatment with insulin, potassium and liquids improve the prognosis.

2324

TREATMENT OF CHRONIC ERECTILE DYSFUNCTION WITH TRANSURETHRAL ALPROSTADIL IN DIABETIC AND NONDIABETIC MEN.

P. C. Norwood, F. E. Kaiser, W. E. Nolten, D. S. Schalch, V. A. Place, A. P. Spivack, D. E. Stephens, P. Y. Tam, N. Gesundheit and the VIVUS-MUSE Study Group, Menlo Park, CA.

Erectile dysfunction is a common problem in diabetic men. Previous short-term studies have shown that alprostadil delivered by a transurethral system produces erections and restores sexual intercourse. We have now studied the clinical safety and efficacy of MUSE® (alprostadil) delivered by this system over a 3-month period in diabetic and nondiabetic men. 1511 patients (age: 30-84; mean 62) with organic erectile dysfunction (mean duration: 4 yrs) were enrolled in a prospective, double-blind, placebo-controlled trial. Patients self-administered transurethral alprostadil (125, 250, 500, and 1000 µg) in the clinic; those achieving an erection sufficient for intercourse (996 patients) were randomized to home therapy with either active drug or placebo. Diabetes was present in 240 patients (39 insulin-dependent; 196 non-insulin-dependent; 5 unspecified). Key results are shown in the table below. In patients who responded at home, approximately 7 of 10 active drug systems resulted in sexual intercourse. Adverse effects, other than penile pain, were uncommon in the group as a whole. 88% of patients completed the 3 months of home treatment. Transurethral alprostadil is well tolerated and can restore erections and sexual intercourse in both diabetic and nondiabetic men with chronic erectile dysfunction.

% Reporting Intercourse on:	Active	Placebo	p-value
Overall	64.9	18.6	<0.001
Diabetic	64.3	21.1	<0.001
Nondiabetic	65.0	17.7	<0.001

2325

ENDOTHELIN-1 AND ATRIAL NATRIURETIC PEPTIDE IN DIABETIC PATIENTS WITH HYPEROSMOLAR HYPERGLYCEMIC SYNDROME

Y.-J. Lee, S.-J. Shin, J.-F. Hwang, T.-J. Hsieh and J.-H Tsai. Kaohsiung Medical College, Kaohsiung, Taiwan

To investigate whether endothelin-1 (ET-1) and atrial natriuretic peptide (ANP), potent vasoregulatory peptides with diverse actions, are enrolled in the pathophysiology of patients with severe decompensated hyperglycemia and dehydration. Plasma and urinary ET-1 and ANP immunoreactive substances were measured in 16 diabetic patients with hyperosmolar hyperglycemic syndrome (HHS) by specific radioimmunoassays. Plasma and urinary ET-1 levels (7.0 ± 4.1 pg/ml and 890 ± 130 ng/g Cr, respectively) were significantly higher in HHS patients in the acute phase, and after recovery, plasma ET-1 (3.6 ± 0 7 pg/ml) returned to normal range (3.4 ± 1.3 pg/ml), while urinary ET-1 level (2,360 ± 680 ng/g Cr) was still increased in HHS patients than that of the control group (260 ± 30 ng/g Cr). Plasma ANP level of patients with HHS was not significantly different during acute (22.0 ± 5.2 pg/ml) or recovery stages (22.1 ± 3.6 pg/ml) from that of control subjects (18.4 ± 2.5 pg/ml). In contrast, urinary ANP excretion was significantly higher in acute stage of patients with HHS (323 ± 100 ng/g Cr) than that of control subjects (48 ± 3 ng/g Cr), and after recovery, urinary ANP level (86 ± 10 ng/g Cr) was not significantly different from that of controls. Serials follow up of plasma and urinary vasoactive peptides and clinical manifestations showed that plasma ET-1 level was significantly correlated to the plasma angiotesin I, blood urea nitrogen, and creatinine concentrations. Our results demonstrated that plasma ET-1 may be involved in the blood pressure homeostasis and renal synthesized ET-1 and ANP contributed to the maintenance of the tubular functions in state of dehydration induced by severe hyperglycemia.

2326

Diabetes mellitus and hormone replacement therapy: risk-benefit situation

S.A.Popkov, E.I.Sokolov, T.P.Morosova

MMSI, Moskow, Russia.

Clinical experience has shown that hormone replacement therapy (HRT) is effective in relieving climacteric symptoms as well as in preventing osteoporosis and cardiovascular disease. These diseases are known as the main causes of morbidity and mortality among women with diabetes mellitus. The purpose of this study was to evaluate the possible risk factors of application HRT in women with non-insulin dependent diabetes. We examined carbohydrate and insulin change, lipid metabolism and blood coagulation in women receiving Divina for a year. Metabolic changes indicate that Divina acted beneficially not deteriorating the course of diabetes mellitus (P<0,001).

2327

DECOMPENSATION IN 633 ECUADORIAN DIABETICS

C. Orellana, M. Pérez and J. Robalino. Diabetes Ecuadorian Foundation (FED). Quito- Ecuador.

We wanted to know the frequency of ketosic hyperosmolar decompensation (basal blood glucose 300 mg/dL + cetonuria), non ketosic hyperosmolar decompensation (basal blood glucose > 600 mg/dL without cetonuria) and hyperglyemic decompensation (basal blood glucose > 150 mg/dL or > 200 mg/dL two hours post-prandial) in patients with diabetes of five cities of Ecuador. It was a descriptive study that used an univariate/bivariate analysis, Data Base and Quattro softwares. We found 14.6% of hyperosmolar decompensation (ketosic and non ketosic) in insulin dependent diabetes mellitus patients in contrast of 53.6% of hyperglycemic decompensation ($p < 0.01$). In non insulin dependent diabetes mellitus patients we observed 6% of non ketosic hyperosmolar decompensation in comparation with 47.8% of hyperglycemic decompensation ($p < 0.01$). Oriental area of Ecuador had 80% of total decompensation, coast area 51.5% and mountain area 48.5%. We conclude that hyperglycemic decompensation is more frequent than ketosic/non ketosic decompensation. Finally, we thought that percenteges obtained in this study were alarming.

2328

QUANTITATIVE EVALUATION OF SCLEREDEMA DIABETICULUM

A. Ota, H. Sato, and N. Saito. St. Marianna University School of Medicine, Kawasaki, Japan.

Diabetic scleredema is diffuse edema with sclerotic changes of the posterior neck in patients with diabetes mellitus. We applied a new apparatus equipped with a suction device (Cutometer SEM575) to measurement of skin elasticity for quantitative evaluation of the skin lesions. Thirty-nine diabetic patients were measured using this device. The value of skin elasticity (VSE) in patients over ten years in diabetic duration was lower than that under ten years in diabetic duration. VSE in patients with diabetic retinopathy and diabetic neuropathy was lower than that in patients without these complications. VSE ($71.3 \pm 11.1\%$) in patients with scleredema diagnosed clinically was lower than that ($83.3 \pm 11.1\%$) in patients without scleredema, therefore sclerotic changes in the skin were indicated quantitatively. Histopathological examination confirmed the diagnosis of diabetic scleredema. Skin elasticity measurement using a suction device was useful for quantitative evaluation of diabetic scleredema.

2329

HEMODIALYSIS(HD)-INDUCED HYPERKETONEMIA IN DIABETIC PATIENTS

I. Saito[1], K.Mizuno[2]. [1]Dept. of Internal Medicine, Kashima Hospital, Iwaki, Japan, [2]Dept. of Internal Medicine, Odaka Municipal Hospital, Odaka, Japan.

Aim: Recentry, we have found that hyperketonemia(HK) occurred in hemodialysed diabetic patients. Thus the aim of this study was to address the mechanism(s) by which HK is caused in those patients.

Methods: We studied 31 diabetics and 15 non-diabetic patients(N). Of diabetic patients 15 were on good control(G), and 16 on poorly controlled(P). HD was performed using glucose-added bicarbonate dialysate, and either heparin or nafamostat mesilate(FUT) was used as an anticoagulant during the dialysis. Plasma glucose(PG), 3-hydroxybutyrate(3OHBA) and free fatty acid(FFA) were measured before and after HD.

Results: Although 3OHBA remained unchanged after HD in groups N and G, it increased significantly in group P($p<0.01$), irrespectively of use of heparin or FUT. Plasma FFA also elevated only in group P($p<0.01$). In group P the percent change in plasma FFA was significantly smaller in the patients performed HD with FUT than that in those with heparin($p<0.05$). In addition, the percent change in plasma 3OHBA was significantly correlated with the percent change in plasma FFA in group P performed heparin-used HD($r=0.58$, $p<0.01$). Such relationship was not found in either group N or G.

Conclusions: These findings strongly suggest that glucose-added bicarbonate HD using either heparin or FUT as an anticoagulant is able to evoke hyperketonemia in poorly controlled diabetic patients on HD.

2330

IRON DEFICIENCY ANEMIA IS ASSOCIATED WITH GASTRIC AUTOIMMUNITY IN INSULINDEPENDENT DIABETIC PATIENTS (IDDM)

C. De Block, L. Van Gaal, I. De Leeuw, University of Antwerp, Antwerp, Belgium

Previous studies have shown a high prevalence of anti-parietal cell-antibodies (PCA) in IDDM. This condition can induce chronic atrophic gastritis and elevated levels of gastrine accompanied with iron malabsorption, and hypochromic anemia. In a series of 29 IDDM patients (11 male, 18 women) with increased titers of PCA (> 1/20 dilution) 41% had a gastrine level > 100 ng/l and 45% showed significantly lower circulating iron levels (<50 µg/dl). Twelve patients (4 m, 8 w) with high gastrine levels had a peripheral hematogram typical for hypochromic, microcytic anemia (41%) that could be normalized with parenteral iron injections. This group (A) was compared to a second group (B) consisting of 121 PCA negative IDDM patients (71 m, 50 W) with the same age distribution. In group B only 6.6% showed elevated gastrine ($p<0.0001$) and 19% had low iron levels ($p<0.01$). Anemia was present in 16% of the patients but only 14 had hematologic evidence of iron deficiency. As compared to group A, a significant higher incidence (Fisher exact test: $p=0.0085$, Odds ratio: 4.023, 95% CI: 1.560-10.371) of iron deficiency anemia looks to be present when PCA titers are elevated. All the patients with anemia were explored in order to find other potential etiologies. For this reason 2 cases of Biermer anemia and 1 case with auto-immune hypothyroidism were excluded from group A. In group B, 1 folium deficient anemia and 4 normochromic anemias of various origin were excluded. Since there is some doubt about the influence of the level of metabolic control on iron levels, 103 serum iron levels were correlated with the corresponding HBA1c taken at the same moment. The correlation coefficient ratio was 0.057 (p value of 0.56) indicating a complete lack of correlation. In conclusion it looks important in practice to keep gastric auto-immunity in mind as a frequent cause of iron deficiency in the presence of hypochromic anemia in IDDM. The ionic form of iron and the way of administration can be important to maintain a normal hematopoiesis in this kind of patients.

Anemia in Non-Uremic Diabetic Patients

Yun YS., Cha BS., Song YD., Lim SK., Lee HC., Hahn JS., and Huh KB., Korea

Anemia is a frequently noted disorder in diabetic patients. So, we evaluate the causes and characteristics of anemia in diabetics without uremia(creatinine clearance rate $\geq$ 30 ml/min/m^2). Total 192 patients (M:F=73:119, 14 IDDM and 178 NIDDM) with disease duration of mean 10.5 $\pm$ 7.4 years, were investigated. In order to analyze the causes of anemia, serum iron, total iron binding capacity, ferritin, vitamin B_{12}, and folate levels were measured and if necessary, serum erythropoietin(EPO), Coombs' test, serum haptoglobin, bilirubin, peripheral blood smear, and bone marrow studies were taken in 69 cases. Serum EPO levels were measured in 20 non-diabetic anemic patients as a control.

Serum hemoglobin(Hb levels were mean 11.1 $\pm$ 1.1g/dl with 180 mild anemic(Hb 9-12 g/dl) and 12 moderate anemic (Hb 6-9 g/dl) patients. Erythrocyte indices were normocytic in 134 (69.8%) out of 178 patients, macrocytic in 42 (21.8%), and microcytic in 16 (8.3%). The Hb levels were negatively correlated with diabetic duration (r=-0.21, p=0.03) and the amount of albuminuria(r=-0.39, p=0.01). The evaluable causes of 69 anemic patients were iron deficiency(21.7%), chronic disorders(18.8%), folate deficiency(4.3%), vitamin B_{12} deficiency(1.4%), hemolytic anemia(1.4%), aplastic anemia(1.4%), however causes were not explained clearly in 35 (51.0%) patients. Serum EPO levels of patients with unexplained anemia were mean 17.1 $\pm$ 8.0 mU/ml, which were significantly lower than that of non-diabetic anemic patients(144.9 $\pm$ 108.0 mU/ml, p<0.01). Blunted EPO response to anemia was noted in patients with diabetes showing unexplained anemia.

In conclusion, causes of anemia were not interpreted clearly in many diabetics patients. Insufficient EPO response may play some roles to unexplained anemia in non-uremic diabetic patients.

2333

ANALYSIS OF DIABETIC KETOACIDOSIS AND HYPEROSMOLAR NONKETOTIC COMA CASES

Nilgün Güvener M.D., Alper Gürlek M.D. and Olcay Gedik M.D. Hacettepe University Faculty of Medicine, Division of Endocrinology, Ankara, Turkey

In this retrospective study, diabetic ketosis, ketoacidosis (DKA) and hyperosmolar nonketotic coma (HNKC) cases were analysed in a 15 year period (1980-1995). Of 82 cases evaluated, 47 of them fulfilled the criteria for DKA, 23 cases for diabetic ketosis and the remaining 12 cases for HNKC. Of 47 cases with DKA, 66% had juvenile onset (<30 years) type I diabetes, 14.9% had adult onset (≥30 years) type I diabetes and the remaining 19.1% had NIDDM (Non insulin dependent diabetes mellitus). Of patients with diabetic ketosis, 78% had NIDDM, 13 % had juvenile onset, 4.3% had adult onset type I and 4.3% had secondary diabetes. All cases with HNKC were diagnosed as having NIDDM. Ketoacidosis was found to as initial clinical presentation in 13.4% of cases. In the whole group, the most common precipitating factor was infection (32.9%). Omission of insulin therapy (9.8%), trauma (4.9%), myocardial infarction (2%) and cerebrovascular accident (1%) were other precipitating factors. In 25.6% of patients, the cause of ketoacidosis was unknown. As to DKA cases, urinary tract infection in two patients (4.3 %), hypoglycemia in five patients (2.1%), thrombophlebitis in one patient (2.1%) , acute renal failure in two patients (4.3%) and for diabetic ketosis cases, hypoglycemia in 4 patients(17.3%) and sepsis in 2 patients(8.7%) developed as a complication during the treatment. In HNKC cases, sepsis, brain edema, thrombophlebitis and mesenteric vascular disease were seen in one patient (8.3%) for each. Mortality rates for DKA, diabetic ketosis and HNKC cases were 6.4%, 8.7% and 33.3% respectively. The data suggest that DKA and HNKC are still major problems in diabetic patients despite the advance in diagnosis and treatment.

Limited Joint Mobility and Respiratory Function Tests in Children with Insulin Dependent Diabetes Mellitus

N.Demirel, C.Fıçıcıoğlu, H.Çokuğraş, A.Aydın. University of İstanbul, Cerrahpaşa Medical Faculty, Department of Pediatrics, İstanbul ,Turkey.

Limited joint mobility (LJM) is an early complication of insulin dependent diabetes mellitus (IDDM) and it is also associated with the increase in the frequencies of complications observed in long term IDDM.Published data regarding the respiratory function tests performed in patients with IDDM having LJM were conflicting . 60 patients with IDDM were included into the study to evaluate the relationship between LJM and respiratory function tests.These patients were separated into two groups as LJM (+) (n:32) and LJM (-) (n:28) .The weight, height and HbA1c values did not differ significantly between these two groups.The age of the patients and the duration of diabetes were significantly higher in LJM (+) group (p<0.01).

Respiratory function tests were performed with spirometer for all patients in both of the groups. Despite the significantly low levels of FVC observed in LJM(+) group

(LJM(+) mean±SD: 88.3±18.01, LJM(-) mean±SD: 104.3±9.07) (p<0.05), no difference was found considering FEV1 for both of the groups (LJM(+) mean±SD: 77.25±19.6, LJM(-) mean±SD: 87.25±19.02) (p>0.05).Results of the function tests in LJM(+) patients was correlating well with a restrictive type of respiratory disorder.

It is well known that diabetes can cause changes in collagen metabolism .LJM is shown to be related to changes in collagen metabolism. Collagen is also important for the architecture and the functions of lung . Our data support the view that LJM and restrictive type of respiratory dysfunction occur together.

EVALUATING SEVERITY OF ACUTE COMPLICATION OF DIABETES IN KOREA BY USING APACHE III SCORING SYSTEM

S.J. Yoo, J.H. Yoo, J.H. Han, K.H. Song, H.S. Son, B.Y. Cha, K.W. Lee, H.Y. Son and S.K. Kang, Catholic University Medical College, Seoul, Korea

As an acute complication of diabetes, diabetic ketoacidosis(DKA) and hyperglycemic hyperosmolar state(HHNS) need intensive care in an early stage of disease, because of relatively high mortalities. To evaluate the expected mortality of acute complication of diabetes, we enrolled 154 patients(87 male, 68 female, mean age 50±20 yr) who need intensive care unit from March, 1986 to March, 1995. We used APACHE III as an objective grading methods of disease severity and mortality and ADA criteria as a diagnostic tool for DKA and HHNS. The overall mortality of 154 patients was 20.1%(31/154). Ther were significant difference in BUN(46.6 ± 28.0 vs 32.0 ± 18.7 mg/dl), age(59.3±20.0 vs 43.3 ± 18.2 yr), duration of diabetes(7.4±7.2 vs 4.6 ±5.1 yr) and APACH III score(69.9 ± 24.9 vs 44.8 ±11.7) between death group(n=31) and survival group(n=123)($p<0.05$). The mortality of DKA(n=106) was 20.7%, while that that of HHNS(n=48) was 18.8%. The difference of APACH III score between both groups was not significant($p>0.05$). Logistic regression analysis about the relationship between APACH III score and risk of death revealed the equation: $\log_n R/(1-R) = 0.04314 \times (\text{APACH III}) - 3.488$. According to this equation, the estimated risk of death was over 50% at the point range 80-85 and over 95% at 140-145. APACH III scoreing system could be a useful guideline to predict and to evaluate the outcome and it would be valuable in clinical decision making and proper management of acute diabetic complication.

FAILURE TO DETECT THE MALIGNANCY IN POOR-CONTROLLED DIABETICS WITH HIGH LEVEL OF TUMOR MARKERS

H.Ohfusa,K.Nishizawa,Nagano Red Cross Hospital,Japan

To elucidate the reliability of the tumor markers (TMs) for detection of the malignancy in diabetics, serum CEA(EIA), CA19-9(RIA) and DUPAN-2(EIA) were determined in 74 patients(M:42,54.8 y.o.,F:32,53.0 y.o.) with 62 NIDDM and 12 IDDM. In 17(23 %) of patients, TMs were in high value. Mean of HbAlc level was 11.7 %. Mean of serum CEA was 41.7 ng/ml, CA19-9 was 74.7 U/ml, and DUPAN-2 was 910 U/ml. The frequencies of high level of TMs were 16/17(94 %) in CEA,14/17(82 %) in CA19-9 and 3/17(18 %) in DUPAN-2. Both high CEA and CA19-9 was 11/17 (65 %), and all of high TMs was 3/17(18 %). By various studies: gastrofibersopy,colonofiberscopy,ERCP,US and CT, 3 of all diabetics(5 %) beared some malignancies were diagnosed.They had progressive gastric cancer(GC),sigmoid cancer and both GC and multiple colon cancers. All of the patients suffered from these cancers had both high CEA(153 ng/ml) and CA19-9(99 U/ml). But none of patients had high level of DUPAN-2 and no liver and billiary tract metastasis. Whereas,in diabetics beared no malignancies, all of TMs changed in lower values accompanied with the improvement of BS control(HbAlc:12.2 - 9.7 %,CEA:10.4 - 3.4 ng/ml,CA19-9:67.4 - 35.4 IU/ml,DUPAN-2:910 - 413 U/ml)

These results suggest that in poor BS controlled diabetics, serum CEA,CA19-9 and DUPAN-2 have a tendency to be in high value and variability with BS level. Then, these TMs should not be reliable to detect malignancies.

2337

INVESTIGATION 230 CASES OF KETOACIDOSIS DURING A 6 YEAR PERIOD

Zs. Gaál, K. Ésik, P. Pataki, Zs. Papp, B. Valenta.
Department of Internal Medicine IV., Nyíregyháza, Hungary

The aim of this study was to gather data about diabetic ketoacidosis morbidity and mortality and to investigate the diagnosis and the treatment. 230 adults were treated with diabetic ketoacidosis (DKA) during a 6 year period from 1989 to 1995 from an area with a population of 350 000. All these diabetics were treated in the same department and their medical records were reviewed retrospectively. The average age of the patients was 48 year (18-78) with a 1,52:1 ratio of men and women. 69 DKA repeatedly occuring episodes were treated in 16 patients (11men, 5 women). The following reasons for DKA were found: infection was proved in 56 cases (24,3 %), newly diagnosed diabetes was in 20 cases (8,6 %), pancreatitis was in 8 cases (3,5 %), myocardial infarction and stroke was in 4-4 cases (1,8-1,8 %)- other reasons in 31 cases and in 107 cases (24,3%) it was not possible to identify the reason. Of the 230 DKA cases 12 patients died which represent a 6,08 % morbidity. Their avarage age was 61 year (41-78). Most patients were admitted to the department from an emergency ward.The diagnosis of DKA was often made too late. These diabetics spent an avarage 3,7 hour in the emergency ward. During this time they received an average 1,3 l infusion and often unnecessary bicarbonate treatment.During the first 24 hours the patients received an average 5,7l infusion and 56 U insulin in the department.DKA still have a high morbidity and mortality . It is important to educate on the first first symptomes of DKA especially to those who had recurring DKA. The patients with recurring DKA often need psychological support as well. The use of glucometers and urine test strips could help to diagnose DKA at an earlier stage.In conclusion the results suggest that, better education of the patients and the medical staff could reduce morbidity and mortality of DKA.

DIABETES MELLITUS AND MITRAL VALVE PROLAPSE

H.Kahraman, Ö. Yılmaz, F. Tanyeri, M. Başkol
Ondokuz Mayıs University, Samsun, Turkey

Mitral valve prolapse (MVP) is the most common cardiac valvular anomaly ethiopathogenesis of which is not known. Mitral valve prolapse can occur as a primary anomaly, and it can also be detected during the course of some systemic diseases. It is suggested that autoimmune mechanisms may play a role in the ethiopathogenesis of mitral valve prolapse, but it is not known whether diabetes mellitus plays a role in MVP. For this reason, we planned this study to determine the prevalence of MVP in both type I and type II diabetic patients. One hundred three patients (35 male, 68 female) whose mean age is 47 years are taken in the study. Seventy six of the patients had type II diabetes, 27 had type I diabetes. Patients who had autoimmune, metabolic and heart diseases that can influence MVP were excluded. Sixty volunteering normal subjects without any diseases were taken as control group. Two-dimensional M-mode colour Doppler echocardiography was applied to all patients after physical examination and routine laboratory analysis were made. Mitral valve prolapse was diagnosed when one or both of the mitral valves deplaced back in to the left atrium more than 3 mm in systole. Mitral valve prolapse was detected in 3 (5%) of control group and 13 (12.6%) of 103 diabetic patients. Prevalence of MVP was higher in diabetic patients but the difference was not statistically significant ($p>0.05$).

2339

DIABETIC KETOACIDOSIS IN ENDOCRINOLOGY DEPARTMENT, HOSPITAL 25 IMSS, MONTERREY, N.L. MEXICO.

C. Lozano-Peña, V. Guibovich and F. Hinojosa.

We analized the cases of Diabetic Ketoacidosis (DKA) in the period January 1993 - December 1995. There were 496 hospitalized diabetic patients in that period of time in the Departament of Endocrinology, 121 with diabetes type I and 375 with type II; 72 patients with DKA, 29 cases in 1993, 24 cases in 1994 and 18 cases in 1995. We found only 26 charts, the remainder were not included in our study, because they were not found. Out of 26 patients, 11 were men (42%) and 15 were women (58%), mean age was 36 years (13 - 59), 22 patients with diabetes type I (85%), 4 patients with diabetes type II (15%). The evolution of diabetes, was about 10 years in average. Only 1 patient with recent diagnosis. In relation to previous treatment before the admission to hospital:12 patients required insulin intermediate twice a day (46%), 4 patients with insulin intermediate once a day in morning (15%), 5 patients with combined insulin (rapid and intermediate) twice a day (19%) and 3 patients taking only oral hypoglucemiants (12%). Precipitating factors like infections were the most frequent, were 11 cases (42%): 6 urinary infection and 4 respiratory infection, 1 periodontal abscess. Digestive etiology 2 cases (8%): 1 secundary to digestive bleeding and 1 due to acid-peptic syndrome; 2 cases (8%) due to inadecuate treatment for diabetes and suspension of insulin, 3 cases (11%) due to inadecuate diet; 1 case (4%) due to myocardial infarction and 7 cases (27%) with unknown precipitating factors. 11 patients developed complications: 5 cases (45%) due to hypokalemia, 2 cases (18%) with pneumonia, 1 case (9%) with myocardial infarction, 1 case (9%) pulmonary thromboembolism, 1 case (9%) acute renal failure, 1 case (9%) hypoglycemia. There were 3 died patients (12%), 2 due to myocadial infarction and 1 case due to metabolic encephalopathy and pneumonia. In conclusion the education of diabetic patients about the disease and complications, is the keystone for preventing DKA.

2340

FREQUENCY OF THYROID DYSFUNCTION IN TYPE 2 DIABETIC PATIENTS.

A.T. Herskovits and T. Chajek-Shaul, Western Galilee Hospital-Nahariya and Hadassah Hospital - Jerusalem, Israel.

To assess the prevalence of thyroid disease in type 2 diabetes (NIDDM) we used the sensitive TSH assay. The study population consisted of 319 patients, 189 females(F) and 130 Males(M), aged 37-83, with HbA_1C less than 10%, normal kidney and liver function and no clinical signs of thyroid disease. The patients with abnormal TSH were assayed for FT_4, TT_3, thyroid antibodies. Thyroid dysfunction was diagnosed in 15.7% (50 patients) with a much higher prevalence in females: 24.9%F, 2.3%M. The commonest diagnosis was subclinical hypothyroidism (11.6%F, 0.8%M), followed by hypothyrodism (6.9%F, no males), subclinical hyperthyroidism (4.2%F, 0.8%M) and hyperthyroidism (1.6%F, 1.5%M). All 5 hyperthyroid patients had T_3 toxicosis. Thyroid antibodies were detected in 11/31 patients. Conclusions: 1)Thyroid function should be screened routinely in NIDDM patients (especially in women) to detect the frequent asymptomatic thyroid dysfunction. 2)Further study is currently performed to confirm the association between NIDDM and T_3 toxicosis.

2341

KETOACIDOSIS IN NATIVE AMERICAN APACHES WITH NON-INSULIN DEPENDENT DIABETES MELLITUS

J. Krakoff, C. Wilson, and D. Ghodes. Indian Health Service, United States Public Health Service

Background: The Native American Apache as with other Native American groups have high rates of non-insulin dependent diabetes mellitus while insulin dependent diabetes mellitus is rare. Diabetic ketoacidosis in this population would be expected to be unusual but when present has been attributed to acute alcohol use. A retrospective chart review was undertaken to look at the incidence and characteristics of ketoacidosis in this population. Methods: Cases of diabetic ketoacidosis were identified at the Mescalero and White Mountain Apache reservations. Retrospective chart reviews were used to confirm the acidosis and determine the influence of alcohol. Alcohol use was considered recent if included in the history of present illness as a contributing factor; a lifetime history of alcohol use was considered present if recorded as a problem in the past medical history. Results: We found seventeen patients out of 727 diagnosed diabetics who had episodes of diabetic ketoacidosis. All were at least three-quarters or greater Native American heritage. The mean age was 41+/-14 (mean +/-SD). The patients were predominantly male (88%), with a body mass index of 24.9kg/m2+/-4.4. Recent alcohol use was noted in only 27% of presentations while lifetime use of alcohol was noted in 94% of cases. Conclusion: Diabetic ketoacidosis is not unusual occurring in 2.3% of known diabetics in this Native American population of Apaches. Recent alcohol use was less common than expected despite high rates of lifetime alcohol use. Diabetic ketoacidosis is a significant complication this NIDDM population and the role of alcohol needs to be further delineated.

2342

THE IMPORTANCE OF MONITORING THYROID AUTOANTIBODIES IN ADULT IDDM

K.Vondra,J.Vrbíková,B.Bendlová,I.Šterzl and V.Zamrazil, Inst. of Endocrinology, Prague, CR

To evaluate a clinical revalence of thyroid autoantibodies(Th-AAb) we assessed antibodies to thyroglobulin(TgA,RIA) and to microsomes (MsA,ELISA) in 50 patients at diagnosis(Dg) of IDDM (25years) and repeteadly during 8 years follow-up.
Results: At Dg incidence of TgA and MsA(0%,8%)in men(M) was in normal range, while in female(F) both TgA(8%) and MsA(15%) were increased. During follow-up Th-AAb prevalence signif.increased: in F we found TgA in 33% and MsA in 67% as compared to 31% and 56% in M. Th-AAb first detected in the first 5 years had a marked tendency to persist in contrast to those first detected after 5 years. Depending on the nature of Th-AAb the patients were divided.

	M:F%	TSH mIU/l	Pathological US
TGA++,MsA++	7:33	5.4+1.2 x	100% x
TGA-,MsA++	21:28	3.2+0.8	86%
TgA+,MsA+	43: 6	2.5+0.7	28%
TgA-,MsA-	29:33	2.5+0.7	12%

++persisting +sporadic -negative US ultrasonography x $p < 0.001$ TSH 1:2,3,4 US 1:3,4
Conclusions:Th-AAb monitoring revealed:1)an unexpected high prevalence of autoimmune thyroid disease(AITD) in adult IDDM early after Dg. 2)high prediction of the clinical relevant forms of AITD was associated with Th-AAb detected within the first 5 years and which persisted. 3)Neither a sporadic Th-AAb appereance observed later nor negative findings were associated with AITD.

2343

INTENSIVE CARE OF PATIENTS WITH DIABETES KETOACIDOSIS M.Dudás, I.Fazekas and I.Iványi. Department of Internal Medicine,Gyula,Hungary

The authors working at a department of internal medicine specializing in diabetology surveyed the data of the patients with hyperglycaemic ketoacidosis treated between 1991-1995.74 patients'94 episodes justified hospitalization during that period.The average age was 51,7(8-84)yrs.The patients had had diabetes for 7,8(9 months-36yrs)yrs on average.25 relapses occured in 10 cases.The most frequent reasons precipitating them were enteral infection (25,5%) and respiratory infection(23,4%).In the case of 29 patients(30,8) along with other factors,the failures of dieting also contributed to acute metabolic disorders.On admission the level of consciousness was closely related to the increase in bloodsugar and urea nitrogen level as well as the decrease in the ph level of capillary blood.The first specific step taken was administering salt solution(1191 ml on average in the first hour) parenterally.In the majority of the cases fast-affecting insulin (Lilly Humulin R,Novo Actrapid HM) was administered by means of infusion pumps or,in the other cases,low-dosage intravenous and intramuscular infections.The authors emphasized the importance of potassium supply.They tried to avoid agressive and quick acidosis correction during the treatment.Despite the application of the latest therapies,relatively high mortality (15,9%)was brought about by chronic statuses lasting for several days then.

2344

MELAS BROKED OUT 24-YEARS LATER AFTER ONCET OF IDDM -AN UNUSUAL AUTOPSY CASE-

T. Nonogaki, Y. Yoshimura, H. Inoue*, M. Takahashi,* T. Ibi*, Y. Hashizume, K. Sahashi* and S. Aoki. Dept. of Pathology, *Neurol. Section and **Institute for Med. Sci. of Aging, Aichi Medical University, Aichi, JAPAN**

A typical mitochondrial(mt) myopathy, encephalopathy, lactic acidosis and stroke-like episodes(MELAS) syndrome is sometimes accompanied by insulin dependent diabetes mellitus(IDDM). The objective of this presentation is to disclose a relationship between both diseases. **Case Report**: A 55-year-old female died of pneumonia followed by unconsciousness due to high blood sugar levels(831 mg/dl) and a severe stroke-like episode. Family history was unequivocal. After the birth of the patient's second baby at age 27, she began suffering from IDDM. As a result insulin therapy was needed, but the DM control was extremely poor because of fluctuating marked increases in blood sugar. From age 51, she started to suffer from hearing loss which finally led to deafness. At age 53, her husband noticed changes in her personality, and she complained of visual disturbances(cortical blindness). At this time, a limb muscle biopsy demonstrating abundant ragged-red fibers and an mtDNA analysis revealing a heteroplasmic A-3243-G transition of tRNA confirmed the mt disease. **Autopsy Finding**: The macroscopic findings of the brain showed marked ventricular enlargement (dominant to the occipital portion) with a softening of the cortex. The pancreas showed remarkable atrophy and amyloid depositions among islets of Langerhans. The microscopic findings comfirmed the mt disorder, scar stage of IDDM and diabetic nephropathy. In conclusion, this case indicates that age-related accumulation of the mutant mitochondrias between each tissue over a period of 24 years is clinically important to the onset of the symptoms and occurrence of MELAS and seems related to long-termed IDDM.

2345

DIABETIC KETOACIDOSIS IN TRIPOLI. THE CAUSES AND OUTCOME OF 100 CONSECUTIVE CASES

A A Lakhdar and S Elhabroush,
The Diabetes Centre, Tripoli, Libya

To describe the characteristics, causes and outcome of patients with diabetic ketoacidosis we collected the following data on 100 consecutive admissions. Male/female ratio was 51/49, their mean age 30.6 ± 15.5 years, duration of diabetes 8.7 ±7.7 years, age at diagnosis 23.7 ±14.7 years, body mass index 22.6 ± 5.4, insulin treated 73%, tablet treated 5% and 22% were new cases of diabetes presenting with diabetic ketoacidosis. Arterial pH 7.12 ± .14 and serum bicarbonate 7.8 ± 4.0. Causes of diabetic ketoacidosis were insulin omission 41%, inappropriate medical advice 3%, infection 13%, including one case presented with diabetic ketoacidosis and pulmonary tuberculosis, non-infection illness 3% and undetermined 39%. Mortality was 2%. BMI was significantly higher among females than males (24.5 ± 6.3 vs 20.9 ± 3.4). $P < 0.001$. The number of underweight subjects was significantly higher among males than females (20/51 vs 6/49). $P < .01$. There was a trend among males to omit insulin more than females (25/51 vs 16/49) NS. The low mortality rate is noted. The data suggests many of the cases of diabetic ketoacidosis are avoidable, especially those caused by insulin omission. Measures required for prevention include a considerable need for education for patients, health professionals and the general public.

2346

BREATHING PATTERN AND RESPIRATORY MECHANICS IN INSULIN-DEPENDENT DIABETES MELLITUS.

A.Fabbri, G.Misuri, I.Iandelli, M.Filippelli, R.Anichini, R.Duranti, A.Sanna, G.Scano, F.Innocenti, and G.Seghieri. Diabetes Unit and Dpt. of Respiratory Physiopathology, Spedali Riuniti, Pistoia, Section of Pneumology, Dpt. of Internal Medicine, University of Florence, Fondazione Don C.Gnocchi, Florence, Italy.

The interaction between the presence of insulin-dependent diabetes mellitus (IDDM) and the performance of inspiratory muscles has, so far, been scarcely studied. To better focus this topic we evaluated 6 IDDM patients with a stable and good metabolic control (HbA1c repeatedly < 7.2% in the previous 12 months), without smoking history, or without microvascular complications (somatic or autonomic neuropathy, retinopathy or nephropathy), as compared to a sex-and-age matched group of 6 non diabetic individuals. In each subject we measured pulmonary volumes, the arterial blood gases, time and volume components of ventilation such as tidal volume (VT), respiratory frequency (Rf), and mean inspiratory flow (VT/Ti), pleural pressure swings (Pplsw), dynamic compliance (Cldyn), and the transdiaphragmatic pressure (Pdi). We also evaluated the maximal inspiratory pressure (Pplsn) during the sniff manoeuvre. No difference was measured in pulmonary volumes, as well as the arterial blood gases, Pplsn, Pdi and the breathing pattern, between diabetic patients and controls. In contrast IDDM patients were characterised by a lower Cldyn, a higher Ppslw%Pplsn (a measure of respiratory effort), a higher (Pplsw%Pplsn)/VT (a measure of neuroventilatory coupling of the respiratory pump), and a greater tension time index [(Pplsw%Pplsn)(Ti/TTot)]; ($p<.05$ for all). Finally Cldyn tended to be inversely related to (Pplsw%Pplsn)/VT ($r=-0.62$). In conclusion in IDDM patients, even if in good and stable metabolic control and exempt from clinical evidence of microvascular complications, despite a normal respiratory muscle strength and gas exchange, we observed an increase in both respiratory effort and neuroventilatory coupling, due to a significantly increased elastic load

2347

EFFECTS OF SNK-860 AND AMINOGUANIDINE ON GLUCOSE-INDUCED IMPAIREMENT OF HUMAN NEUTROPHIL KILLING

T. Kawamura, K. Suzuki, A. Kanai, T. Uno, H. Matsumae, T. Sano and N. Sakamoto, Chubu Rosai Hospital, Nagoya, Japan

The aim was to elucidate the mechanism for glucose-induced impairment of neutrophil killing and to examine effects of SNK-860 (SNK), an aldose reductase inhibitor (ARI) and aminoguanidine (AG). Lucigenin-enhanced chemiluminescence (CL) to fMLP as respiratory burst and metabolites were measured in neutrophils after incubation with glucose (G), SNK (10μM) and AG (10μM). (1) Changes in CL: Both D- and L-G inhibited CL in a dose dependent fashion (40mM D-G: 65±3%, 40mM L-G: 72±3% of 5mM D-G, mean±SE, n=7). SNK and AG improved CL decreased by 40 mM D-G (40mM D-G: 66±2%, +AG: 72±3%, +SNK: 70±2%, $p<0.05$ vs 40mM D-G, +AG+SNK: 80±2%, $p<0.05$ vs +AG, $p<0.01$ vs +SNK, n=12), while SNK and AG had no effects on CL decreased by 40mM L-G. (2) Changes in metabolites: Sorbitol levels increased by 40mM D-G (0.246±0.023 n=8, $p<0.001$ vs 5mM D-G 0.141±0.017 nmol/10^7cell) was normalized by SNK (0.155±0.021), but not AG (0.252±0.029). However, fructose production (1.04±0.20 nmol/10^7cell/h) increased by 40mM D-G was decreased by SNK (0.70±0.12) and AG (0.71±0.14), respectively. Both AG and SNK had no effects on glycolytic intermediates.

Our results indicated that SNK improved decreased CL by blocking increased polyol pathway activity, while AG worked through different metabolic mechanisms from the inhibition of glycation. It seems likely that AG and ARI may be effective for the prevention of susceptibility to infection as well as the prevention of microangiopathy in diabetic patients.

2348

DIABETES MELLITUS AND DEEP VEIN THROMBOSIS

TAIN C.G., LIU J., NANJING GULOU HOSPITAL OF MEDICAL COLLEGE OF NANJING UNIVERSITY, NANJING, P.R. CHINA

The main aim of this study was to research what is the morphological changings at early stage of deep vein (D.V.) on experimental diabetic rats, and the relationship between deep vein thrombosis (DVT) in hind limbs and diabetes, as well as whether the plasma level of PAI-1 is the risk factor to the DVT with diabetes. Induced male Sprague-Dawley diabetic rats were randomized into three groups: diabetic, diabetic with insulin and controls, and maintained for twelve weeks. Blood samples were taken for t-PA, PAI-1 determination. D.V. together with muscles were isolated from hind limbs to study the vascular lesions and the development of thrombosis. The results of this study showed (1) PAI-1 activity was elevated in diabetic rats and daily insulin treatment restored it to control level. (2) Endothelial lesions and smooth muscles proliferation of deep vein significantly enhanced in diabetic rats ($p<0.01$). (3) A negative correlation was found between plasma levels of PAI-1 and t-PA ($r=-0.69$, $p<0.001$). From this study, could we also pay more-attention to DVT with diabetes in clinical future?

2349

SELECTED MARKERS OF INFLAMMATORY RESPONSE IN PATIENTS WITH TYPE I DIABETES AND LATENT FOCUSES OF INFECTION.

M.Sobieska*, D.Zozulińska, K.Wiktorowicz* and B. Wierusz-Wysocka. Poznań Diabetic Center, *Laboratory of Cellular Immunology, Academy of Medicine in Poznań, Poland

Disturbances in inflammatory response play an important role in the pathogenesis of diabetes and its late complications. The aim of the study was to assess selected parameters of acute phase reaction in patients with type I diabetes and present focuses of inflammation. The study was performed in a group of 15 patients, 8 male and 7 female, aged 21-48 years, mean diabetes duration 5.2±3.6 years, who suffered from chronic purulent tonsillitis and/or peridental abscesses. Mean HbA_{1c} in the study group was 9.84±1.04 %. 15 type I diabetic patients matched for age, sex and metabolic control were used as controls. We evaluated: serum concentration of alpha-1 acid glycoprotein (AGP) and alpha-1 antychymotrypsin (ACT) (rocket immunoelecrophoresis according to Laurence) and the profile of their glycosylation (affinity immunoelectrophoresis with concanavalin A according to Bog-Hansen). The results of glycosylation profile were expressed as reactivity coefficients. We noticed markedly higher concentration of AGP and ACT in patients with chronic focuses of inflammation in comparison with control subjects (AGP: 1.38±0.02 vs 0.94±0.05 g/l, $p<0.05$, ACT: 0.55±0.18 vs 0.37±0.02 g/l, $p<0.05$). We also observed significant differences in glycosylation profile in these patients. AGP-RC and ACT-RC values were much higher in patients with focuses of inflammation when compared with the control group (AGP-RC: 1.19±0.14 vs 1.08±0.06, $p<0.05$, and ACT-RC: 3.44±0.53 vs 2.83±0.23, $p<0.05$). The results obtained in this study might indicate, that the presence of latent focuses of infection exacerbates a chronic inflammatory process in patients with diabetes. AGP and ACT and their glycosylation profile seem to serve as good laboratory indicators which confirm the presence of infection.

2350

THE PREVALENCE AND TREATMENT OF DEPRESSION IN ADULTS WITH DIABETES. M.Sheikman,M.D.,University of Massachusetts,Worcester,MA,U.S.A.

According to current controlled studies,the prevalence rate of major depressive disorder in patients with diabetes varies from 8.5% to 27.3%. Depression was found to have a more malevolent course in diabetic patients who have a greater relapse rate than in depressed,but physically healthy, population. The severity of depression correlates strongly with many symptoms of diabetes. In our previous studies depression has been found to be associated with an increased rate of complications of diabetes. In many patients depression significantly impaired diabetic management. In the group of 78 patients with serious chronic macrovascular and microvascular complications of IDDM and NIDDM 11 patients presented symptoms of depressive disorder,such as depressed mood,loss of energy,sleep disturbance,diminished abilities to concentrate,feelings of worthlessness and inappropriate guilt,2 patients had recurrent thoughts of death and one had suicidal ideations. Depression is a common accompaniment of chronic painful diabetic neuropathy. Treatment with antidepressants is indicated in these patients and is found to be successful in many cases. Some of the tricyclic antidepressants,despite showing effective antidepressant effect,were associated with worsening of diabetes producing hyperglycemia. The monoamine oxidase inhibitors were found to have a tendency to exaggerate hypoglycemia and lead to weight gain. Serotonin-selective reuptake inhibitors were found to reduce blood glucose level and could be considered as a treatment of choice for diabetic patients with depression. This group of antiderressants may lead to improvement in both depression and glucose control not causing significant impairment in alertness. Serotonin-specific reuptake inhibitors (fluoxetine,sertraline and paroxetine) cause fewer troublesome side effects,such as anticholinergic side effects and sedation,than the tricyclic and tetracyclic drugs,and are also safer when taken in overdose as compared to the tricyclic drugs. Sertraline has the least effect on cytochrome CYP2D6 activity in human liver microsomes and less effect in increasing the blood level of other medications with which combined and may be safer to use in diabetics than either fluoxetine or paroxetine.

2351

SERUM INTERLEUKIN-8 LEVEL IS INCREASED IN TYPE I DIABETIC PATIENTS

K.Wiktorowicz*, D.Zozulińska, M.Sobieska* and B. Wierusz-Wysocka. Poznań Diabetic Center, *Laboratory of Cellular Immunology, Academy of Medicine in Poznań, Poland

Endothelial derived Interleukin-8 (IL-8) is a strong stimulator of polymorphonuclear neutrophils (PMN). Previously we have shown, that in diabetes unstimulated PMN are activated and their response to stimuli is decreased. The explanation of this might be very interesting for pathogenesis of late diabetic complications. The aim of the study was to evaluate serum IL-8 concentration in type I diabetic patients. The study was performed in a group of 42 patients, aged 19-43 years, 25 female and 17 male with mean duration of disease 10.8±8.2 years and HbA_{1c} 7.6±0.8 %. IL-8 level was estimated with the use of the ELISA test. We noticed significantly higher serum IL-8 level in diabetic patients in comparison with healthy subjects (160.29±34.81 and 39.93±4.96 pg/ml, respectively, $p<0.0001$). The results might indicate, that active inflammatory process plays an important role in the pathomechanism of late diabetic complications.

2352

RELATIONSHIP OF PERIODONTAL POCKET DEPTH WITH VIT-C LEVEL AND GLYCAEMIC STATUS.

AR Chowdhury, K Jahan, NG Banik, S Sultana and AK Azad Khan. BIRDEM, Diabetic Association of Bangladesh, Dhaka, Bangladesh.

To assess the relationship of glycaemic status (HbA_1C) and serum Vit-C(mg/dl) level with periodontal pocket depth (PPD), 54 NIDDM (duration 1-5 yr) and 54 non-diabetic (ND) patients were studied. Among the NIDDM subjects, 40 were on OHA+diet and 14 were on insulin. The relationship of PPD with Vit-C and HbA1C is shown in the table.

			Periodontal Pocket depth		
			<3 mm	3-5 mm	>5 mm
Vit-C	<0.6	NIDDM	3 (5.55%)	23 (42.59%)	1 (1.85%)
		ND	5 (9.25%)	15 (27.77%)	---
	0.6-2.0	NIDDM	7 (12.96%)	20 (37.03%)	---
		ND	15 (27.77)	19 (35.18%)	---
HbA_1C	<6%		1 (1.85%)	8 (14.81%)	---
	6-10%		8 (14.81%)	25 (46.29%)	1 (1.85%)
	>10%		1 (1.85%)	10 (18.51%)	---

The results showed the number of patients is higher in NIDDM than ND with PPD >3mm when the Vit-C level is <0.6mg/dl. Among NIDDM subjects greater PPD is observed when the Vit-C level is low and HbA1C level is higher. Follow-up of larger group of patients is going on to confirm this result.

2353

MYCOTIC COMPLICATIONS IN PATIENTS WITH INSULIN DEPENDENT DIADETES MELLITUS.

G. Sokolova,P.Silnizkiy,A. Mirsabalaeva and N.Vorokhobina E.Volkova Russian Centre For Deep Mycosis & the Department of endocrinology, Medical Academy of postgraduate studies, St.Petersburg,Russia

We examined 200 patients with IDDM (51 men & 149 women aged 18-68),the duration of disease 2-17 years.Mycological,serological,immunological examination of patients was carried out. 28 patients (14.3%) with IDDM had candidiasis:3 patients - candidosis-chronic mucocutaneus candidosis (CMC),10 -with oral candidosis,8-with esophageal candidosis,1 -with intestinal candisosis, 1 -with gastric candidosis,12-with vaginal candidosis,1-with candidal balanoposthitis & 2 - with candida sepsis.In patients with different forms of candidosis the T-supressor count was low,T-helper/T-supressor index was increased.Good control of IDDM after insulin treatment & short-term courses of antifungal therapy led to quick remission of candidosis. These data show the dependence between decompensated IDDM and different forms of candidosis / exept CMC/.

2354

ORAL HEALTH IN INSULIN DEPENDENT DIABETES MELLITUS (IDDM)

A.M. ANDRADE, M. ANTONY, T.M.G.O. SILVA, M.L. TEREZAN, C. VINAGRE, G.B.CASTRO and M.B. GOMES. STATE UNIVERSITY OF RIO DE JANEIRO, RIO DE JANEIRO, BRAZIL.

The aim of our study was to evaluate the oral health status of IDDM patients (pts). For this purpose, 55 pts (26 male) aged 21.4 ± 7.5 years, with diabetes duration of 7.5 ± 6.3 years, were submitted to oral soft tissue inspection and palpation, dental probing, complete radiographic dental examination (periapical and byte-wing), salivary flow (SF) measure, and determination of DMFT (decayed-missed-filled teeth) index, plaque index, gingival index, periodontal pocket depth, loss of attachment and alveolar bone loss. By means of those periodontal parameteres, it was determined the presence of gingivitis (GV) or periodontitis (PO) in each of 4 sites per tooth and the pts were classified as having gingivitis and/or periodontitis levels I to IV respectively when they had 1-25%, 26-50%, 51-75% or 76-100% of sites affected. Statistical analysis was done by Mann-Whitney and Kruskal-Wallis (one way Anova), and univariate regression. Data were expressed in mean (SD) or median (range). The most frequent alterations of oral soft tissues were enlargement of sub-mandibular salivary gland in 12 pts (21.81%) and labial dryness in 4 pts (7.27%). The DMFT index was 10 (0 - 27). The correlation coefficient between DMFT and age was $r = 0.63$ $p < 0.001$. Salivary flow was 1.1 ± 0.6 and there was xerostomy (SF <1.0 ml/min) in 20 pts (36,4%), having no correlation with blood glucose. The most frequent periodontal alterations were GV level IV in 18 pts (32.7%) and GV level I in 12 pts (21.8%). PO associated with GV was noted in 16 pts (29%). We observed 64.7 ± 37.6 and 6.7 ± 18.8 sites affected by GV and PO respectively. No correlation was found between diabetes duration and % of sites affected by GV or PO. Age > 25 years was associated with % of PO affected sites ($p < 0.0007$), but not with the % of GV sites. In conclusion, our study has observed a great percentage of sites affected by periodontal disease in IDDM patients, and a significant correlation between age and the prevalence of caries and of periodontitis.

2355

PATTERN OF MUCO-CUTANEOUS YEAST INFECTION IN DIABETES - A STUDY ON 460 CASES AT BIRDEM

R.B. Zaid, J.M.A. Hannan, M.A. Sayeed, M.N. Islam, H. Begum, T. Sarkar and H.M. Khan. *Bangladesh Institute of Research and Rehabilitation in Diabetes, Endocrine and Metabolic Disorders (BIRDEM), Dhaka, Bangladesh*

It is recognized that patients with diabetes have increased risk of muco-cutaneous yeast infections. To characterise the yeast infections in diabetes according to their anatomical structure invaded, sex, age, duration of diabetes and glycaemic status, we have investigated 460 diabetic patients at dermatology department of BIRDEM. Based on microscopy and culture, Candidial intertrigo 47.8%, C. paronychia 23.5%, C. nail 9.6%, C. vulvovaginitis 6.7%, Pityriasis versicolor 6.7%, C. balanitis 2.6%, Oral candidiasis 2.2%, Perianal candidiasis 0.7% was diagnosed. Pityriasis versicolor ($p<0.5$) and oral candidiasis ($p<0.01$) were significantly higher in male whereas candidial paronychia was significantly higher ($p<0.001$) in female. Vulvovaginal candidiasis was very high below 40 yrs of age ($p<0.001$) whereas C. paronychia ($p<0.02$) and C. intertrigo ($p<0.05$) was high above 40 years of age group. Candidial vulvovaginitis clearly showed higher frequency ($p<0.001$) in newly detected diabetes (<1 month duration) than old diabetic group (>5 years duration). Accepted range of glycaemic control (<10 mmoll/L 2 HBG) showed lower frequency of C. vulvovaginitis and C. nail than who had hyperglycaemia ($p<0.01$). The rest perianal candidiasis and C. balanitis failed to show any relation with sex, age, duration of diabetes and glycaemic status.

2356

DENTAL PATHOLOGY IN DIABETIC PATIENTS: ABSENCE OR LOSS OF TEETH

R. Hernández, N. Cédola, E. Caride, E. Pereyra and E. Olivera. CENEXA, (UNLP-CONICET), C. Posgrado Clínica Nutrición y Endocrinología, F. Cs. Médicas, C. Periodoncia, F. Odontología, UNLP, La Plata, Argentina.

The objective of this work was to investigate possible differences in the number and topography of tooth loss in diabetic patients (DPs) relative to patients that were nondiabetic (NonDPs). We studied DPs voluntarily presenting themselves at the general odontologic services of the public subsector plus, for each one of them, two NonDPs who were selected at random among those seeking services on the same date of registration. Our sampling thus consisted of 44 DPs and 89 NonDPs; each patient was evaluated by both an odontologist and a diabetologist through the use of an *ad hoc* protocol designed by them, with the sex distribution being similar between the two groups (male DPs and NonDPs, 32% and 34%, respectively). The median age was 44.5 years for the DPs and 49 years for the NonDPs. The distribution according to the type of diabetes among the DPs was the following: IDDM, 18%; NIDDM, 59%; insulin-requiring, 16%; gestational diabetes, 2%; and diabetes of as-yet-unidentified nosology, 5% of the cases. Some 61% of the PDs had had their conditions diagnosed fewer than 10 years earlier. With respect to dental status, the DPs exhibited a significantly higher incidence of tooth loss than the NonPDs, with 44% of the former having missing teeth as opposed to only 26% of the latter ($X^2 < 0.000001$). The affected teeth showing a difference in representation among the two groups that was significant at a level of $p < 0.0005$ were as follows: (a) upper jaw: incisors, left canine and secondary premolar, and right lateral incisor and primary premolar; (b) lower jaw: left premolar and secondary molar and right canine, primary molar, and secondary molar. Whereas the greater tooth loss in the DPs would be a consequence of the higher frequency of vascular lesions in those patients, the difference in the topography of their dental pathology relative to that of the NonDPs could be attributed to the specific characteristics of the blood supply between the two sectors of the jaw.

2357

FATAL GASTRIC MUCORMYCOSIS IN A YOUNG IDDM PATIENT

JEP,Oliveira; D,Douek; NC,Leite; V,Panaim; CS,Oliveira; L,Zajdenverg and A,Milech -Division of Nutrition and Metabolic Diseases University Hospital Clementino Fraga Filho-UFRJ- Rio de Janeiro- Brazil

Gastric Mucormycosis is a rare complication of diabetic ketoacidosis. We present a case of a 17 years old patient with IDDM since age 11. Five days before admission she experienced epigastric pain, dyspnea and fatigue. On admission, she had diffuse abdominal pain, drowsiness, dehydration, pallor, tachycardia and tachypnea. Blood glucose was 450 mg/dl, BUN 21 mg/dl, creatinine 0.8 mg/dl, hematocrit 27%, Wbc 29,600/mm3. Arterial blood pH was 7.2, p02 92 mmHg, pC02 12.7 mmHg, HC03 3.2 mEq/l. Urinalysis disclosed glucose ++++ and ketones +++. Treatment with insulin, IV fluids and eletrolytes was started, with marked improvement of the ketoacidosis that, however, recurred on the 8th day. At that time, she had severe epigastric pain worsened by foods, fever (38.5 C) and leukocytosis. Three days later, the pain improved, but a 5 cm tender epigastric mass was noticed. An abdominal ultrasound scan revealed gastric wall thickening. A gastroscopy showed a 10 cm ulcer on the greater curve, with infiltrated margins and covered with fibrin. The bottom of the ulcer was irregular and blood was oozing. Biopsies revealed Zygomycete fungi. Treatment with amphotericin B was started up to a cumulative dose of 325 mg. However, on the 32nd day, she had a massive upper gastrointestinal bleeding which ultimately caused her death. This case suggests that gastric Mucomycosis should be included in the differential diagnosis of upper gastrointestinal hemorrhage complicating diabetic ketoacidosis.

2358

CLINICO-BIOCHEMICAL AND RADIOLOGICAL FEATURES OF TROPICAL CALCIFIC PANCREATITIS AND EARLY FIBROCALCULUS PANCREATIC DIABITES PATIENTS

Z. Hassan[1], H. Rahman[2],L. Ali[1], N.S. Chowdhury[1], M. Hasan[2], A.K. Azad Khan[1]
[1]Research Division, BIRDEM; [2]Dept of Gastroenterology, IPGMR, Dhaka, Bangladesh

The exact relationship between tropical calcific pancreatitis (TCP) and fibrocalculous pancreatic diabetes (FCPD) is still unclear. Earlier data on late FCPD cases suggest that exocrine pancreatic damage *per se* may not be the only factor leading to diabetes in FCPD patients. As a part of an attempt to clarify the issue the serum(S) levels of fasting and postprandial glucose, C-peptide and insulin (by ELISA) and lipids were estimated in 25 TCP and 10 early FCPD cases (age in yrs: 22±6 in TCP vs 25±6 in FCPD, M±SD). ERCP was done in 15 TCP and 9 FCPD cases. FCPD subjects showed normal to near normal BMI (19.58±2.73; M±SD) which was almost similar to TCP subjects (18.23±2.73). Compared to TCP, the FCPD patients had about 1.4 times higher fasting S glucose (TCP: 4.51±1.02, FCPD: 6.19±2.00, mmol/l, M±SD), 2 times higher postprandial S glucose (TCP: 6.85±2.25, FCPD: 15.14±2.85), about 2 times less fasting S C-peptide (TCP: 0.51±0.17, FCPD: 0.29±0.18, nM, M±SD), 1.5 times less postprandial C-peptide (TCP: 1.15±0.52, FCPD: 0.77±0.41), about 1.3 times less fasting S insulin (TCP: 60±21, FCPD: 46±24, pM, M±SD), 1.6 times less postprandial S insulin (TCP: 212±109, FCPD; 130±75) levels. Analysis of C-peptide-glucose and insulin-glucose ratios revealed the marked differences between the two groups (C-peptide-Glucose, M±SD: Fasting - 0.12±0.05 in TCP vs 0.05±0.03 in FCPD, t=4.91, $p<0.001$ and 2 h postprandial - 0.20±0.13 in TCP vs 0.06±0.04 in FCPD, t=3.30, $p<0.002$; Insulin-Glucose, M±SD: Fasting - 14.46±7.10 in TCP vs 8.33±5.27 in FCPD, t=2.80, $p<0.01$ and 2 h postprandial - 35.68±23.00 in TCP vs 9.35±6.74 in FCPD, t=3.46, $p<0.001$). Although the absolute levels of C-peptide and insulin in FCPD showed insulin secretory capacity, the ratiosl reveal that their capacity of increasing insulin secretion to combat hyperglycemia is almost nil. Subjects showing mild, moderate and severe changes of chronic pancreatitis in ERCP were 0, 1(7%) and 14 (93%) respectively in TCP and 0, 0 and 9 (100%) respectively in FCPD Groups. Conclusions: a) Malnutrition is not the cause but probably a consequence of diabetes in FCPD and b) Neither the onset nor the severity of diabetes in FCPD follow a straightline relationship with the degree of ductal damage.

2359

STUDY OF PLASMA INTERCELLULAR ADHESION MOLECULE-1(ICAM-1) LEVELS IN PATIENTS WITH NIDDM

Y. Kishitani, Y. Ohno, A. Nishimura, N. Aoki.
Second Department of Internal Medicine, Kinki University School of Medicine, Osaka-Sayama, Osaka 589, Japan.

Intercellular adhesion molecule-1(ICAM-1) is an adhesion molecule belonging to the immunoglobulin superfamily group which can bind lymphocyte function associated antigen-1(LFA-1). ICAM-1 has a role of lymphocyte activation and immunological modulation, and plasma ICAM-1 levels have been reported to increase in autoimmune diseases. On the other hand, ICAM-1 expression is increased on the surface of endothelial cells in human atherosclerotic lesions and supposed to have a role in the development of atherosclerosis. In this study, we examined plasma ICAM-1 levels in patients with NIDDM, and compared with those in normal subjects. We also studied the difference of ICAM-1 levels between the patients with or without diabetic microangio-pathic complications. Plasma ICAM-1 levels were measured using commercial ELISA kits. Plasma ICAM-1 levels were significantly higher in NIDDM patients than in normal subjects. In NIDDM patients, plasma ICAM-1 levels were significantly correlated with fasting plasma glucose and HbA1 levels but not with any of serum total cholesterol levels, serum triglyceride levels, and ages. Plasma ICAM-1 levels were significantly higher in NIDDM patients with microangiopathy than in NIDDM patients without microangiopathy. In NIDDM patients with diabetic nephropathy, plasma ICAM-1 levels were significantly correlated with the amount of urinary microalbumin but not with 24 hour creatinine clearance. In summary, plasma ICAM-1 levels may be related to the progression of diabetic microangiopathy in NIDDM patients.

SERUM LEVELS OF ZINC AND COPPER IN NEWLY DIAGNOSED MALNUTRITION RELATED DIABETES MELLITUS SUBJECTS

A.M.S. Alam[1], L. Ali[2], A.K. Azad Khan[2], A. Gowsami[1], S. Sattar[1]. *[1] BIRDEM; [2]Dept of Chemistry, University of Dhaka, Dhaka, Bangladesh*

Changes in serum (s) levels of Zn and Cu have been reported in diabetes mellitus and the elements have also been implicated in the etiopathogenesis of various types of diabetes and its complications. In the present study the serum levels of Zn and Cu were measured in 21 newly diagnosed malnutrition related diabetes mellitus (MRDM) subjects under 30 years of age [fibrocalculus pancreatic diabetes (FCPD) 13 and protein deficient diabetes mellitus (PDDM) 14] along with 29 NIDDM patients in the same age group. Fifteen nondiabetic subjects with BMI <19 were included, which served as a matched Control for PDDM cases. Fasting serum values Zn and Cu were measured by atomic absorption spectrometry. Serum values of Zn and Cu [Median (Range), μmol/l] in Control subjects were as follows: Zn 15.9 (13.14-55.34) and Cu, 19.19 (10.85-86.08). As compared to Control the NIDDM subjects showed similar S Zn [24.01 (9.93-88.7)], but both PDDM and FCPD groups showed significantly higher values of SZn [35.02 (6.30-69.41), $p<0.05$ and 31.75 (22.17-41.75), $p<0.01$ for PDDM and FCPD respectively). In cases of S Cu all the 3 diabetic groups showed significantly higher values compared to Control [NIDDM 31.51(16.83-57.3), $p<0.001$; PDDM 28.79 (11.01-43.12), $p<0.04$; and FCPD 29.26 (20.14-58.07), $p<001$]. The Zn-Cu Raios were significantly lower in NIDDM and PDDM subjects (Median value; 0.776 and 0.961 respectively) compared to Control (1.025) and FCPD (1.145) patients. The results suggest that Zn and Cu may have a role in the etiopathogenesis and progression of diabetes in MRDM as well as in NIDDM subjects. The details of this role remain to be elucidated.

2361

ANTI-HEV (HEPATITIS E VIRUS) SEROPREVALANCE IN DIABETIC PATIENTS

H.Kahraman, M. Günaydın,F. Tanyeri, B. Özer, F. Furtun
Ondokuz Mayıs University, Samsun, Turkey

Hepatitis E virus (HEV) causes epidemic outbreaks of enteral hepatitis in Asia and Africa. It is responsible of acute non-A, non-B viral hepatitis (NANBVH) in the underdeveloped countries, and in general population, anti-HEV is very high. Socioeconomic and educational status of the country are very important risk factors for HEV infection. Although it is not known which systemic disease constitutes a risk factor, anti-HEV seroprevalance has been investigated in different patient groups, except in diabetics. Therefore, we designed this study to evaluate the prevalence of HEV infection in our diabetic patients. Ninety six diabetic patients (40 men, 56 women) were included in this study protocol. Liver function tests were determined and chronic complications of diabetes were examined. Seventy four healty persons (38 women, 36 men) without any diseases were taken as a control group. Serum samples of both groups were investigated for IgG antibody to HEV with ABBOTT ELISA kit. Anti-HEV (IgG) seropositivity is found in 7 (7.3%) diabetic, 4 (5.4%) nondiabetic patients. There was no difference between patient and control groups.

Aim : TRACE ELEMENTS AND DIABETIC COMPLICATION

Authors : *M.W. Tsang, **P.L. Leung, *K.M. Chong and [+]D. Desmond
*United Christian Hospital, ** City University, [+]Queen Mary Hospital, Hong Kong

Method : Controlled comparative study. 106 patients were recruited. 68 are diabetes and 50 are normal health control. Hair samples from the occiput were cut and the hair ashes were prepared for trace elements analysis by inductivley-coupled plasma (ICP) emission spectrometer model : Shimadz ICPQ-1012. 27 from the study group and 28 from the control group also had their blood and RBC Zn and Cu analyzed.

Result : Table I

	Study group (58)	Control group (48)	P value
Age	38.38 ± 10.06	34.12 ± 9.07	0.283
Hair Mg++	83.38 ± 76.70	86.49 ± 9.26	0.255
Hair Zn++	136.86 ± 49.53	139.94 ± 31.93	0.01
Hair Ca++	1101.16 ± 930.68	1070.55 ± 72.43	0.006
Hair Fe++	22.44 ± 11.39	27.58 ± 12.33	0.311
Hair Cu++	6.05 ± 2.43	8.60 ± 5.49	0.04

Table II - RBC Zn / RBC Cu

	Study (27)	Control (28)	P
RBC Zn	167.77 ± 23.21	168.06 ± 22.63	0.565
RBC Cu	9.97 ± 2.48	10.75 ± 1.93	0.772
Serum Zn	12.02 ± 1.89	11.47 ± 1.23	0.008
Serum Cu	18.14 ± 3.18	16.75 ± 2.87	0.254

Conclusion : There were statistical significant differences in Zn++, Cu++ and Ca++ in hair of diabetes, as compared with normal control. There was also statistically difference in serum Zn++ in diabetes as compared with normal. No statistical difference was found in Mg++ both in hair and in red blood cell (RBC) in the study and control group. In conclusion, we proved that hair analysis study with ICP spectrometry was useful in trace elements analysis of hair, and it confirmed our previous study with X-ray spectrometry of low Cu++ in diabetes and its application. However, we cannot find any association between diabetic complications and Mg^{2+} or $Zinc^{2+}$.

2363

DIABETES MELLITUS AND HEPATITIS C VIRUS INFECTION

H.Kahraman, E. Özyılkan, G. Kesim, F. Tanyeri, M. Günaydın, Ş. Dabak
Ondokuz Mayıs University, Samsun, Turkey

Serum transaminase levels of patients with diabetes mellitus are frequently evelated. This is often atributed to fatty infiltration of the liver without further investigation. Indeed, hepatitis C virus (HCV), as well as the other hepatotrophic viruses, may be responsible for the increase in serum transaminase levels. Therefore, we designed this study in order to determine whether the HCV seroprevalance is increased among our diabetic patients. Two hundred thirty two diabetic patients (100 male 132 female) were investigated. The mean age of patients was 51 years (range 17 to 80 years). Liver function tests were performed for each patient. HCV antibodies (anti-HCV) were investigated with third generation enzyme-linked immunosorbant assay (ELISA) (Organon Teknika). Twenty seven patients (11.6%) were found to be anti-HCV positive. In this group, serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels were 131.96±161.86 U/L and 97.33±80.55 U/L, respectively. ALT and AST levels of the anti-HCV negative patients were 41.05±58.11 U/L and 40.91±46.86 U/L. Serum transaminase levels (ALT, AST) of the anti-HCV positive diabetic patients were higher than those with anti-HCV negative ones, and this differences were statistically significant ($p<0.001$). There was no difference of being anti-HCV positivity among type-1 vs. type-2 diabetics and insulin users vs. nonusers ($p>0.05$). Similarly, it was also found that age and body mass index didn't affect anti-HCV positivity ($p>0.05$). There was correlation between anti-HCV positivity and previous operations and/or blood transfusions ($p<0.05$). Anti-HCV prevalance varies between 0.3% and 1.8% among healthy population in Turkey. The prevalance we have found among our diabetic patients (11.6%) is higher than average values for Turkey. For this reason, if serum transaminase levels of diabetic patient are elevated different reasons other than hepatosteatosis must be considered.

2364

SERUM TNF α LEVELS AND DIABETIC COMPLICATIONS IN NIDDM PATIENTS

S. NISHIMURA, J. SATOH and T. TOYOTA, SENDAI, JAPAN

TNF α has a wide range of biological activities and it is important to clarify the role of TNF α in diabetic complications. In animal model we already reported that in vivo TNF α productivity was significantly enhanced in long-term hyperglycemia and N-acetylcysteine suppressed the increased TNF α production, and inhibited the development of peripheral neuropathy. In this study, we examined serum TNF α levels in NIDDM patients and analyzed relationships between the TNF α levels and diabetic complications. Subjects were 150 NIDDM patients (age 62.1 ±12.0, range 19-81) and sex- and age-matched 150 non-diabetic healthy controls who were not associated with malignancy, infection, allergy and autoimmune diseases and not taking steroid and other anti-inflammatory drugs. Serum TNF α was measured by the sensitive ELISA kit. Serum TNF α levels were significantly higher in NIDDM patients (3.15±1.62 pg/ml) than in controls (1.76±1.61 pg/ml) ($P<0.001$). In the NIDDM patients, the TNF α levels were significantly correlated with age ($r=0.19$, $P<0.05$), duration of diabetes ($r=0.23$, $P<0.005$), serum Cr levels ($r=0.47$, $P<0.001$), urinary protein levels ($r=0.23$, $P<0.01$), severity of retinopathy ($r=0.25$, $P<0.01$), and severity of hypertension ($r=0.25$, $P<0.01$) and slightly with motor nerve conduction velocity, but not with sex, BMI, fasting blood glucose levels, HbA1c, total cholesterol, HDL-cholesterol and triglyceride levels. The results indicate that secondary increased TNF α under chronic hyperglycemic state may participate in the development of the diabetic complications.

HCV INFECTION PREVALENCE IN TURKISH DIABETIC POPULATION

F.Salman(1), K.Karşıdağ (1), İ.Satman (1), N.Dinççağ (1), M.Sargın (1), A.M.Şengül (1), A.Ökten (2) and M.T.Yılmaz (1).
(1)Diabetes Education Center, Inst.For Exp Med, and Division of Diabetes, Istanbul Faculty of Medicine, (2)Department of Gastroenterohepatology. Istanbul University Istanbul-TURKEY

In the present study, we investigated the effect of several epidemiological and clinical factors on prevalence of the hepatitis C virus (HCV) infection in patients with diabetes mellitus. The study included 61 Type 1 (36 males/25 females, mean age 17.1±7.4 years and mean diabetes duration 3.2±2.2 years) and 101 Type 2 (61 males/40 females, mean age 57.7±11 years and mean diabetes duration 10±8.4 years), totally 162 diabetic patients. Results were compared with 0.8-1 % prevalence rate in healthy blood donors screened for HCV. Relationships between HCV infection and several parameters, including age, sex, history of blood transfusion and/or alcohol use, type of diabetes, duration of diabetes, modes of therapy (oral antidiabetic drug/insulin), regulation of glycaemia and presence of long-term diabetes complications and liver functions were evaluated. None of the Type 1 diabetes patients showed HCV seropositivity. However, this frequency in Type 2 cases was found to be 5.9 % (6/101). Serum levels of AST, ALT, alkaline phosphatase and gamma-glutamyl transpeptidase increased in all HCV (+) patients. 5 of these were diagnosed as having chronic liver disease (4 with chronic active hepatitis and 1 with decompensated liver cirrhosis) confirmed by liver punction biopsy and/or laparoscopy. Moreover, of the 6, three patients revealed HCV positivity. We could not define any relationship between HCV infection and mode of diabetes therapy, diabetes duration, type of diabetes and history of alcohol use or blood transfusion. These findings have indicated that HCV infection is more prevalent among diabetic patients than in normal population, HCV positive diabetic patients have a higher risk of chronic infections possibly due to immune system defects commonly seen in diabetes, and finally increased liver enzymes might always not indicated hepatosteatosis, in patients with diabetes HCV infection should also be probable.

2366

MATURITY ONSET DIABETES OF THE YOUNG

Clinical characteristics
Dr. Al- Mahroos G.M. Al-Mahroos
Arabian Gulf University Bahrain

Maturity onset diabetes of the young is genetically determined disorder. We studied 173 individuals in 11 families with MODY . The aim of the study is to find the clinical characteristics of this condition. NIDDM was diagnosed in 129 patients. 20 patients diagnosed before the age of 25 years, and 6 patients before the age 10 years. Two patients presented with Ketoacidosis . 6 patients developed proliferative retinopathy. 4 patients developed nephropathy of whom 2 progressed to chronic renal failure . On conclusion ketoacidosis though rare but it may occur if the diagnosis is delayed , severe microvascular complication occurred in patients with persistent hyperglycaemia but genetic predisposition may have a role in our patients.

2367

HIGH PREVALENCE OF DIABETES MELLITUS AMONG PATIENTS WITH PNEUMOCOCCAL BACTEREMIA.

J.M.A. van Ampting, K.P. Bouter, R.J.A. Diepersloot, B.P. Overbeek, P.M. Netten and D.W. Erkelens. Bosch Medical Center, Den Bosch, Laboratory for Public Health, Diakonessen Hospital, Utrecht, St Antonius Hospital, Nieuwegein, University Hospital, Utrecht, The Netherlands.

Streptococcus pneumoniae is an important pathogen causing pneumonia, bacteremia and meningitis in adults as well as in children. Infection is a significant cause of morbidity and mortality in patients with diabetes mellitus (DM). In this study we report a retrospective survey of all patients with pneumococcal bacteremia hospitalised in five non-university hospitals in the Netherlands during 1993-1995. The records of patients with DM were analysed. Pneumococcal bacteremia was diagnosed in 177 patients (96 men and 81 women, mean age 60.1 ± 22.5 years). Chronic obstructive pulmonary disease, malignancy and DM were the three most common risk factors (31.3, 21.5 and 19.8% respectively). All except one of the 35 patients with DM (19 men and 16 women, mean age 68.8 ± 12.3 years) had type II diabetes. DM was diagnosed (W.H.O. classification) at admission in 7 of the 35 patients. Eight patients were on insulin therapy, 16 patients used oral hypoglycaemic drugs. Nephropathy (proteinuria) was present in 40%, retinopathy and clinical signs of neuropathy in 11.4% each of the diabetic patients. Length of the hospital stay was 24.0 ± 24.4 days in patients with DM and 21.6 ± 22.4 days in non diabetic patients. Three diabetic patients (8.6%) and thirteen (9.2%) other patients needed artificial ventilation. In-hospital mortality was 28.6% among patients with DM and 23.2% in patients without DM. It is concluded that in this retrospective analysis DM is the third most common risk factor in patients with pneumococcal bacteremia. A discussion covering the issue of pneumococcal vaccination for patients with DM is therefore warranted.

2368

MICROVASCULAR COMPLICATIONS IN AFRICAN AND INDIAN SUBJECTS WITH DIABETES OF LONG DURATION

A Amod, AA Motala, MAK Omar, FJ Pirie, E Gouws*. Diabetes Unit, Department of Medicine, University of Natal, and *Centre for Epidemiological Research of the MRC, Durban.

A retrospective study was undertaken to assess the development of microvascular complications (retinopathy and nephropathy) in 219 [132 African (B); 87 Indian (A)] patients with duration of diabetes >10yr, who were attending the diabetes clinic at the King Edward VIII Hospital. Retinopathy was evaluated by findings at annual fundal examination. Markers of nephropathy included persistent dipstix proteinuria, hypertension (HT), abnormal serum creatinine or glomerular filtration rate (GFR). Glycated Hb and blood glucose levels were also examined. Of the 219 patients, 172 were classified as NIDDM(B:A =96:76) and 47 as IDDM(B:A =36:11). The mean age of onset was later in Africans than in Indians, both for IDDM ($p < 0.05$) and NIDDM ($p < 0.01$). For IDDM, the prevalence of retinopathy was 53.2% (B=55.6%; A=45.5%); persistent proteinuria was present in 23.4% (B =25%; A =18.2%). Hypertension was found in 34% and was more prevalent in Africans (41.7%) than in Indians (9.1%) ($p < 0.05$). Onset of retinopathy occurred earlier in African (156 mth) than in Indian (216 mth) patients ($p < 0.05$). For NIDDM, the prevalence of retinopathy was 64.5% (B = 68.8%; A 59.2%) and that of persistent proteinuria 25% (B =30.2%; A =18.4%). Hypertension was found in 68% and was more prevalent in Africans (B vs A; 84.4 vs 47.4%; $p < 0.01$). Onset of retinopathy ($p < 0.05$) and hypertension ($p < 0.01$) was earlier in African than in Indian subjects. Comparison between IDDM and NIDDM showed that the prevalence of HT ($p < 0.01$) and abnormal GFR ($p < 0.01$) was higher in NIDDM patients. Retinopathy (n = 219) was significantly associated with duration of diabetes ($p < 0.001$) plasma glucose ($p < 0.05$) and HbA_1 ($p < 0.01$). This study has shown that as in other population, microvascular complications are common in Indian and African patients with long-standing diabetes.

METHICILLIN RESISTANT STAPHYLOCOCCUS AUREUS CARRIER STATUS IN DIABETIC PATIENTS. M.Calvagno, M.Burgos, J.Alvariñas, A.García and G.Burlando, Servicio de Nutrición, Hospital Tornú, Argentina.

Objective: Knowing the importance of methicillin resistant S.aureus (MRSA) in diabetics, to study the frequence of MRSA carrier status in a sample of diabetic patients and compare it against a non-diabetic subjects sample.

Methods: During one year period (June 1995 to June 1996) we study the presence of MRSA carrier status in 40 IDDM and NIDDM patients (20 out-patients; 20 in-patients); diabetes duration of over 10 years. Diabetic in-patients were matched to a in-patients non-diabetic control group (sex and age). In all of them we performed a nasal test to determine the carrier status. For out-patients was requiered a period of over a year without any hospital internation.We excluded in any case patients receiving anti-MRSA in the month of testing. Statistical analysis: Fisher Exact Test.**Results**:Comparing diabetics against non-diabetics, we found:

	IN-PATIENTS		
	Carriers		Non-carriers
Diabetics (n=20)	6 (30%)		14 (70%)
Non diabetics (n=20)	0 (0%)		20 (100%)

Fisher Exact Test: p=0.02

In Diabetics, dividing in out and in-patients ve found:

	DIABETICS		
	Carriers		Non-carriers
Inpatients	6(30%)		14(70%)
Outpatients	1(5%)		19(95%)

p=0.09.

Conclusion: MRSA carrier status was more frequent in diabetic inpatients than in non-diabetics.In diabetics, frequency maybe higher among inpatients.

EVIDENCE ON COMPLICATIONS AND RISK FACTORS FROM NATIONAL DIABETES MANAGEMENT NETWORK IN POLAND.

J.Taton for medical and B. Lyholm for statistical teams.
Department of Internal Medicine and Diabetology, Warsaw Medical School, Poland. Novo Nordisk, Disease Management Systems, Copenhagen, Denmark.

As an integrate part of a newly established national network for managing diabetes care, we assessed the prevalence of late complications and risk factors using the DiabCare BIS. The goal was to establish a long term quality circle and to decrease the prevalence of complications. Data were assessed in a randomly selected population (n = 1271) covering all 12 region in Poland. Data were entered, analysed and published using the latest computer technology, by the central diabetes clinic in Warsaw in close co-operation with the regional participants. The establishment of the baseline description revealed the following findings on the St. Vincent targets (data are presented as %no / %yes / %missing), blindness 95.7 / 3.2 / 1.1, MI/CABG/Angioplasty 97.3 / 1.5 / 1.1, cerebral stroke 98.6 / 0.3 / 1.1, ESRD 97.8 / 0.6 / 1.6, amputation above ankle 97.6 / 0.7 / 1.6. amputation below ankle 98.1 / 0.1 / 1.9.The following were reported on the prevalence of smoking (data are presented as %no / %yes / %missing) 77.8 / 21.2 / 1.1 while the prevalence of alcohol consumption was reported as 94.5 / 4.2 / 1.3. The results proves the ability of the network to monitor and highlight problems in diabetes care in Poland. The data will be further analysed in order to explain dependencies between risk factors and complications in Poland. Secondly while the next phases of the project will secure the monitoring and continuous improvement of diabetes care.

2371

STAGE-SPECIFIC DEGENERATION OF GERM CELLS IN THE SEMINIFEROUS TUBULES OF NON-OBESE DIABETIC MICE

S. Sainio-Pöllänen[1,2], K. Henriksén[2], M. Parvinen[2], O. Simell[1] and P. Pöllänen[2]. Depts. of [1]Pediatrics and [2]Anatomy, Univ.of Turku, Turku, Finland

The reasons for fertility problems in IDDM are largely unknown. The aim of the present study was to evaluate the role of autoimmunity-associated phenomena in the testis as a possible cause to the derangement in spermatogenesis. **The** stage-specific apoptosis of germ cells in the insulitis-**phase of prediabetes** was quantified in the testis of non-obese diabetic (NOD) mice. **The seminiferous epithelium** of normal BALB/c and NOD mice **contained cells positive in *in-situ*** end labelling (ISEL) of DNA. ISEL-positive **(+) germ cells formed** clusters in the seminiferous epithelium of the NOD mice **in striking difference** to the seminiferous epithelium of the BALB/c mice, **which contained only** individual ISEL+ cells. ISEL+ cells were present in the **basal and luminal compartments** of the epithelium. Ultrastructural analysis **confirmed that the cells were** undergoing apoptosis. The ultrastructurally apoptotic **cells included** spermatogonia, spermatocytes and spermatids. In cytological squash preparations of segments of **seminiferous** tubules of 17 to **20-week-old NOD** mice **the number** of ISEL+ **cells/mm tubule** was lower in **segments representing** stages I-II of the seminiferous epithelial wave but had **increased markedly** in stages III-IV thus exceeding clearly the number of **ISEL+ cells** in the BALB/c mice. The numbers of ISEL+ cells/mm tubule in the **other** stages were similar in the two strains of mice. Analysis of ^{32}P-3'-end **labelled** DNA from the testes showed that the BALB/c mice had relatively more DNA fragmentation than the NOD mice. These data suggest that autoimmune insulitis in the NOD mice is associated with abnormal stage-distribution of apoptosis in the seminiferous epithelium, resulting in derangement of spermatogenesis.

2372

COMPARISON OF METABOLIC STATUS AND DIABETES COMPLICATIONS IN THREE POPULATIONS

S.Colagiuri, M.Layton, T.Palu, R.Colagiuri, Z.Hussain. Prince of Wales Hospital, Randwick, Australia.

Some data suggest different patterns and rates of complications in different populations. This study compared the metabolic status and complication rates in 3 different populations - urban non Aboriginal Australians, non urban Aboriginal Australians and Tongans living in Tonga. The assessment protocol included physical examination, measurement of HbA_{1c}, microalbuminuria and lipids, and eye examination through dilated pupils. Data were collected on a total of 971 Non Aboriginal Australians (NAA), 143 Aboriginal Australians (AA) and 195 Tongans (T). The findings were compared to the NAA after separately matching AA and T groups with NAA for age, gender and duration of diabetes. Overall mean (SD) age was 57 (9) y and mean duration of diabetes was 8 (8) y. Results are shown in the Table.

	NAA	AA	Tongans
BMI > 27	66%	74%	81% #
Smoking	41%	62% *	32% #
Hypertension	14%	30% *	47% #
Coronary Disease	23%	31%	17%
Chol (Mean SD)	5.7 (1.4)	5.6 (1.2)	5.3 (1.1)
HbA_{1c} (Mean SD)	8.3 (1.8)	8.2 (1.9)	9.8 (1.9) #
Microalbumin	31%	63% *	72% #
Retinopathy	44%	46%	57% #
Neuropathy	14%	22%	31% #
PVD	10%	11%	9%
Foot Ulcer	1%	5% *	4%
Amputation	0%	1%	8% #

* Significant difference NAA v AA: # Significant difference NAA v Tongans.

This study confirms different rates of metabolic abnormalities and diabetes complications in different populations after matching for age and duration of diabetes. Tongans had the poorest diabetes control and the highest complications rates. Microalbuminuria was more common in both AA and T compared with NAA.

2373

THE CAUSE AND TREATMENT OF SEXUAL DISFUNCTION IN DIABETIC MEN.

N.Vorokhobina ,P.Silnizkiy , E.Aref'eva and G.Sokolova, I.Churina.The Department of endocrinology, Medical Academy of postgraduate studies, St.Petersburg,Russia

Serum fasting levels of luteinizing hormone (LH),follicle-stimulating hormone (FSH),prolactin (Prl),testosterone (T) were measured in 230 diabetic men. 51% of patients with IDDM aged 18-50 had sexual disfunction & low basal T level,elevated basal Prl level in serum.After good metabolic contol of diabetes by insulin serum fasting concentration of Prl & T in diabetic men aged 18-36 became normal, in men with IDDM aged 36-50 with good control of diabetes serum T remained lowered & Prl-elevated. In these patients improvement of sexual function & hypothalamic-pituitry-gonadal axis disorders can be maintained by relatively small doses of Parlodel & treatment with Sustanon -250.Diabetic patients showed no increase of pituitary LH & FSH after administration of Gonadotropin-Releasing-Hormone & low increase of T after administration of chorionic gonadotropin.

2374

RISK FACTORS FOR THE INCIDENCE OF LATE VASCULAR COMPLICATIONS OF NIDDM: 15-YEAR FOLLOW-UP

J.Kopczyński, D.Janeczko and A.Czyżyk
University School of Medicine, Warsaw, Poland

In assessing the contribution of cardiovascular risk factors and that of diabetic millieu to vascular complications in NIDDM, their incidence in surviving patients may overcome some problems created by mortality data. From the follow-up examination of 1329 out of 4420 NIDDM patients followed for 15 years (1973/74 - 1988/89), the incidence of micro- and macrovascular complications (proteinuria & nephropathy, symptoms of leg vascular disease, ischaemic heart disease [IHD], and cerebrovascular events) was estimated and related to the levels of base-line risk variables using logistic regression. For new cases of proteinuria & heavy proteinuria, hyperglycemia was the common predictor (alongside diastolic hypertension, smoking and overweight);hyperglycemia and glycosuria were among significant predictors of leg vascular complications (with duration of diabetes, smoking, male sex, diastolic hypertension, and proteinuria). On the other hand, systolic hypertension and male sex prevailed among factors predicting both IHD (with high cholesterol, and overweight), and stroke. The data confirm the higher involvment of diabetic millieu in micro- than macrovascular incidents, with diabetic foot placed in between.

2375

SEXUAL DYSFUNCTION IN DIABETIC MEN

Dr N Sudhakar Rao,Dr Y Purnanandam and Dr C Sekhar, Department of Endocrinology, Gandhi Medical College,Andrology Centre,Hyderabad,India

The study was carried out to establish a protocol for investigating and treatment of Sexual Dysfunctions in Diabetic Men.20 Diabetic men with Sexual Dysfunction were studied in the last 2 years.They were investigated as per Protocol devised by the team.This involves a structural interview of both partners, Complete Physical Examination, Psychiatric assessment and following Clinical tests were carried out a)Bulbocavernous Reflex b)QST of vibration sense c) Intra Cavernous Injection (ICI) with papaverine d) Nocturnal Penile Tumescence and Rigidity assessment(NPTR) e) Dynamic Infusions Cavernosometry&Cavernosography(DICC) f) Hormonal profile. All had abnormal ICI response, QST Vibration, sensation was abnormal.The NPTR study revealed 4(20%)with Psychogenic impotency and 16(80%)with organic impotency.DICC was done in 6 patients where surgery was contemplated.Findings on DICC includes Dorsal vein,Crural & Urethral leaks. 3 Patients had Penile Implants & 4 took ICI rest were treated conservatively.The study showed that organic impotency is more commoner than psychogenic impotency compare to previous studies.

2376

Glycemic control ,growth and complications in children with insulin-dependent diabetes mellitus

K.Izumi, M.Hoshi, S.Kuno, G.Okuno, Y.Yamazaki, G.Isshiki and A.Sasaki. Osaka Childhood and Juvenile Diabetes Mellitus Study Group, Osaka, Japan

The influence of glycemic control on growth and on the development of complication in diabetic children was studied. The subjects of the study were 408 children with insulin-dependent diabetes mellitus (IDDM), who were enrolled in a Summer camp program for diabetic children in Kinki District, Japan from 1972 to 1990. Many of the children had high mean levels of HbA1, regardless of age. The height and weight were below the standards for the respective ages in many children, indicating the retardation of growth. However, S.D. scores for height and weight and other physical indices were not related to the mean levels of HbA1. By contrast, the prevalence of diabetic retinopathy was related to an elevated mean level of HbA1, but that of albuminuria was not. Serum cholesterol levels were higher in children with higher mean levels of HbA1, but serum triglycerides appeared not to be related to glycemic control. The incidence of retinopathy during the observation period closely related to the degree of the mean levels of HbA1, but that of albuminuria did not. During these observation period for five years in average ,their SD score of height and weight, body mass index, Rohrer index and percent desirable weight did not changed; their insulin roquirement, Hb A1, systolic blood pressure, serum cholesterol level and the incidence of relinopathy incrcased year by year. Also intensive insulin therapy and selfmonitoring of blood sugar were used recetly much more.

2377

MALE SEXUAL DYSFUNCTION IN IDDM
INCIDENCE-DIAGNOSIS AND TREATMENT

H.K.Penninckx,M.D.,Endocrinology,St Jozef kliniek,Vilvoorde,Belgium.

Impotence is a common problem among male diabetics.Demonstrate the exact etiology is of importance to the therapy .102 young IDDM male patients ,with a mean duration of diabetes for 11 years have been evaluated.They have been followed for 10 years .At onset patients were between 19 and 36 years old,15 of them showing impotence (15 %).After 10 years 92 patients were available for follow up,among them 34 (37 %) with impotence.Using arterio,evoked potentials of the Pudendal nerve, cavernosography and Prostin TM intracavernous,the main reasons for impotence were classified as follows: neurogenic n=12(35 %), vascular n=5 (15%) combined vascular/neurogenic n=9(26%),medication n=4(12%) psychogenic n=4(12%).Comparison of those 20 who acquired impotence and those having maintained normal sexual functions (n=58) will show a good correlation with regard to parameters usually considered related to diabetic control.The mean glycosylated hemoglobin during 10 year follow up was 7,4%(4,5-6,1%) in those with normal sexual activities and 9,4 % in the impotence group(n=20).At onset 11 men showed microalbuminuria,1 macroalbuminuria and 5 developed microalbuminuria during the observation period.It was of importance to find 2 impotent diabetics without microalbuminuria after 10 years,classified as psychogenic.The efficacy of treatment in those accepting therapy is good:7 refused,11 men are regularly injecting Prostin TM with good results ,4 patients had vascular repair with good evidence in 2 of them, 6 men took advantage of a penile prosthesis,3 are using a vacuum erection device.Trazodon TM was prescribed to 3 diabetics without organic disease. Sexual disturbances based on organic deficiencies were correlated with diabetic control.It is worth establishing the right cause of the organic disease in order to provide the patient with adeqaute treatment.Severe diabetic control might result in prevention of sexual disturbances.

2378

MICROVASCULAR AND ACUTE COMPLICATIONS IN THAI IDDM PATIENTS

C. Deerochanawong, P. Kornthong, S. Ngawngamrat et al. Diabetes unit, Department of Medicine, Rajavithi Hospital, Ministry of Public Health, Bangkok, Thailand.

The incidence of IDDM in Thailand was quite low and the reports of diabetic complications in Thailand were largely from NIDDM. To study the prevalence of microvascular and acute diabetic complications, and their relation to duration of diabetes and glycaemic control, a cross-sectional study was done in diabetic clinic of Rajavithi Hospital, the tertiary governmental hospital in Bangkok. During the year 1995, there were 2,978 diabetic patients who attend the diabetic clinic regularly (more than 2 visits a year). Forty six patients were IDDM (31 females and 15 males). The prevalence of IDDM in our diabetic clinic was 1.5%. The mean ± SD age of 46 IDDM patients was 29.3 ± 7.4 years (range 14-47). Mean ± SD duration of diabetes was 9.8 ± 7.2 years (range 1-26). Onset of diabetes varied from 5 to 34 years (mean ± SD = 19.7 ± 7.0). Prevalence of hypertension was 13.0%. Normal HbAic by enzyme immunoassay (2.6-4.9%) was found in 8.7% of the patients. Mean ± SD of total cholesterol, triglyceride and HDL-cholesterol were 5.4 ± 1.6, 1.3 ± 0.7 and 1.3 ± 0.5 mmol/L respectively. For the regimen of insulin usage, 67.4% used twice daily of insulin injection, 23.9% used one injection of intermediate acting insulin and 8.7% used multiple insulin injection regimen. Mean daily dose of insulin was 43.6 ± 22.9 units per day. An albumin excretion rate of 30-300 mg/24 hr and higher than 300 mg/24 hr were found in 17.4% and 15.2% respectively. The prevalence of all retinopathy was 34.8% (background diabetic retinopathy 19.6% and proliferative diabetic retinopathy 15.2%). Of all patients 23.9% reported one or more severe hypoglycemic attack during the last 12 months and 10.9% reported hospital admission for ketosis over the same peroid. Microvascular and acute complications were clearly related to duration of diabetes and glycemic control. In this study, HbAic above the lowest quatiles (> 6.5% or > mean + 4SD) was significantly increase the risk of microvascular complications.

2379

FACTORS RESPONSIBLE FOR SEXUAL IMPOTENCY IN DIABETES MELLITUS: BIRDEM EXPERIENCE

H.S. Ferdous, F. Pathan, T. Ahmed, N.B. Bhowmik and D. Hossain. *Bangladesh Institute of Research and Rehabilitation in Diabetes, Endocrine and Metabolic Disorders (BIRDEM), Dhaka, Bangladesh*

Autonomic neuropathy is one of the disgraceful complications of Diabetes Mellitus. Most of the time management is unsatisfactory. Eighty six diabetic subjects complaining of sexual problems were studied in the Endocrine Out-patient clinic, BIRDEM. Their mean age was 48.93±0.99 years. Among them 37 (43%), 36 (42%) and 13 (15%) were found above 50, 41-50, below 40 years of age respectively. Mean duration of diabetes was 6.54±0.66 years. 16 (22%), 21 (24%) and 46 (54%) subjects had diabetes more than 11, 6-10 and less than 5 years respectively. Overall glycemic status by HbA_1c was 7.5%. On clinical examination peripheral vascular disease, peripheral neuropathy were revealed in 10 (12%) and 30 (35%) subjects respectively. Psychiatric component was elicited in 45 (52%) subjects. Mean serum prolactin was 147±10 mmol/ml with above 100 mmol/ml in 59 (67%) and less than 100 mmol/ml in 27 (31%) subjects. Mean testosterone level was 5.03±0.20 ngm/ml. 44 (51%), 17 (20%) and 25 (29%). Subjects were treated with dietary modification, insulin and oral hypoglycemic agent respectively. Not only neurological but also hormonal deficiency, vascular and psychiatric components should be borne in mind while dealing with sexual impotency in diabetes mellitus.

2380

Volkov I.E.[1], Logachev M.F[2]., Kuznetzova L.A[1]., Stotikova O.V[1]., Cygancova S.A[1].
Russian Republican Children's Hospital, Moscow [1] &
Pirogov Russian State Medical University, Moscow [2].

Glycemic control and complications in paediatric type I diabetes mellitus patients in Russia.

In 1996 296 paediatric patients with type I diabetes mellitus (IDDM) were referred to the National Diabetes Reference Service. 4% were referred from Moscow, 30.7% were referred from Moscow region. Age of patients varied between 2 and 16 years (25% 2-6 y.o.; 32,7% 7-11 y.o.; 42,3% 12-16 y.o.). 5,4% of patients had newly diagnosed IDDM; 72.9% of patients were diagnosed 1-5 years ago; 15.2% were diagnosed 6-10 years ago and 6,5% more than 10 years ago. All patients received human recombinant insulin preparations according intensive treatment regimen.

The average level of HBA1c was 11.06±0.12%. We observed lipodistrophy in 61.5% of patients; retinopathy in 7,1%; neuropathy in 5,7%(detected by examination and electro-myography); Mauriac syndrome in 4,4%; liver problems in 4,7%; limited joint mobility in 8,4%; cataract in 5,7%; nephropaty in 6,7% (detected by increased urine albumin excretion and changes in glomerular filtration rate); hart problems in 0.67%; lipoid necrosis in 1%.

We conclude that poor glycemic control is responsible for high complication rates in our patients.

2381

EPIDEMIOLOGY OF DIABETES MELLITUS IN MOSCOW DISTRICT (CHILDREN REGISTER DATA).

V.A.Loseva, A.V.Dreval and Yu.A.Redkin, Moscow Regional Research Clinical Institute, Moscow, Russia.

Recently all high developed countries show a pronounced rise in the number of cases of insulin-dependent diabetes mellitus (IDDM) including children's population. Only limited studies concerning epidemiology of diabetes mellitus have been published in the native scientific literature. For example, there is none of corresponding information about population of Moscow district. The present study reflects the degree of distribution of the disease and its complications among the Moscow district children. Observation of 430 children with IDDM (322 from newborn to 14 years of age, and 108 teenagers from 15 to 17 years old) showed a high percentage of diabetic patients: 25.79 of 100000 children studied, and 42.08 of 100 000 teenagers). Sensory neuropathy (11.64%), retinopathy (7.69%) and cataracts (2.88%) were the main complications in children, while retinopathy (17.66%) and sensory neuropathy (16.89%) prevailed in teenagers including some cases of diabetic foot. In all age groups the above complications were more frequently seen in girls. On our evidence the average level of microalbuminuria (MAU) forms 33.82±7.22 mg/l in children with the disease duration >3 years, while 32.34% of children examined had a microalbuminuric stage of diabetic nephropathy. When evaluating healing IDDM in children of Moscow district 8.0% glycosilated hemoglobin was revealed in 4.64 % of children with IDDM,; 8.0-12.0% in 30.61% of children, and >12.0% - in 64.74 % of children's patients.

2382

EVALUATION OF PENILE VASCULAR SYSTEM IN DIABETIC PATIENTS WITH ERECTILE DYSFUNCTION

T. Kaplancan(1), P. Kadıoğlu(2), K. Karşıdağ(3), İ. Satman(3), N. Dinççağ(3), A. Kadıoğlu(1), M.T. Yılmaz(3).

(1)Department of Urology (2)Division of Endocrinology, Cerrahpaşa Medical Faculty, and (3)Institute for Experimental Medicine, Diabetes Research Unit, and Division of Diabetes, Istanbul Medical Faculty, Istanbul University, Istanbul-TURKEY

Patients with diabetes have often erectile disorders. The pathogenesis of these disorders are complex and at present the exact mechanisms are not known. 199 of 1242 patients with erectile dysfunction were diagnosis to be diabetes mellitus (DM) and evaluated. 168 had (84.4 %) (Group 1) DM before admittance while the remaining 31 (15.6 %) (Group 2) had been diagnose on routine chemistry profile for erectile dysfunction. Mean duration of type 1 DM (n:146) and type 2 DM (n:22) were 82.1±58 and 80.1±76 months respectively, no statistically significant could be confirmed between duration's of this two groups ($p>0.05$). Among 82 patients evaluated by color Doppler ultrasonography, 33 had (40.2 %) arterial insufficiency, 15 had (18.3 %) caverno-venous incompetence, while the remaining 9 had (14.1 %) normal penile vascular system. The most frequent component of erectile dysfunction was observed to be arterial insufficiency (42.4 %) and mixed type (43.8 %) impotence in group 1 and 2 respectively. In conclusion, detailed evaluation of vascular damage observed in diabetic patients which plays a crucial role in pathogenesis of neurogenic and vascular complications can be successfully imaged.

2383

THE EFFECT OF DISTANCE FROM HEALTH CARE CENTRE ON COMPLICATION RATES IN THE EURODIAB IDDM STUDY

J. Holloway, J.H. Fuller and The EURODIAB IDDM Complications Study Group, EURODIAB, Dept of Public-Health, University College London, WC1E 6BT, UK.

Access to health care affects the risk of developing IDDM complications and may depend on distance from health care centre. We report findings from EURODIAB, a cross-sectional complications study of 3250 subjects with IDDM from 31 European centres. Participants were grouped according to distance from the clinic (<10km (group 1), 10 -20km (group 2), 20-50km (group 3), 50-100km (group 4) and 100km + (group 5)). There were no significant differences in age, HbA_{1c}, or systolic blood pressure between the distance groups or between the sexes. More people were referred to the clinic with complications from the groups living farthest away (54% and 44% in groups5 and 4 versus 27% in group 3 and 23% in groups 1 and 2 p = 0.00001), a distinct trend which was the same for both men and women. This measure was internally valid when comparing referral rates with other complication variables found at examination. Prevalence of cardiovascular disease showed a similar trend with a higher percentage of events found in participants living farthest away from the clinic (16 % in group 4 and 5 combined, and 7% 11% and 9% in groups 3 2 and 1 p= 0.01) although this was not demonstrated as clearly in men as women (p = 0.01, p=0.007). Proliferative retinopathy showed the same trend (18% in group 5 versus 10 % in group 1 p=0.1) but was significant only in men (19%, 16%, 9%, 7% and 10% p=0.03); as was neuropathy (42% in group 5 versus 31% and 29% in groups 2 and 1 respectively p = 0.02). A similar pattern was seen with macroalbuminuria (albumin excretion rate ≥200 µg/min) (12% and 11% in group 5 and 4 versus 8% in groups 1, 2 and 3) but was not significant for either sex. There was no association between distance and microalbuminuria (17%, group 5,21%,23% 21% and 22% p= 0.7) or background retinopathy (42% group 5, 47%,47%,44%, and 47% p=0.7). In conclusion, high rates of severe complications at presentation suggest that those living farthest away may experience delays in diagnosis, but, when seen by a specialist, they receive the same standard of care as those living near the clinic.

2384

LONG TERM COMPLICATIONS AND SEXUAL DYSFUNCTIONS IN MALNUTRITION RELATED DIABETES MELLITUS.

A.Majumder and D.Ganguly, S.S.K.M. Hospital, Calcutta, India.

Malnutrition related diabetes mellitus(MRDM) comprises 35%(94 cases)of the diabetic population at our centre. Prevalence of peripheral neuropathy is very high (65.9%) and a good number (28%) occurs in the initial 5 years of diabetes. Incidence of retinopathy(23.4%), nephropathy(21.3%) & hypertension(21.3%) increases with duration of diabetes. Retinopathy and nephropathy occur in the initial 5 years, emphasising a need to evaluate it from the begining of diabetic life. A subset of patients (4 cases) did not have any of these complications even after 20 years of diabetes. Impotency was detected amongst 16 male (30%) patients, out of a total of 52, where neurogenic cause was 75% as evidenced by good response to intracavernosal injection of papaverine and presence of cardiac autonomic dysfunction. Secondary amenorrhoea among 20 female(47%) patients out of total 42, had a negative correlation with body mass index. Secondary amenorrhoea due to a functional defect at hypothalamo-pituitary axis, as evidenced by low FSH & LH Level and reversion following improvement in body weight.

2385

METABOLIC CONTROL AND PREVALENCE OF MICROVASCULAR COMPLICATIONS IN YOUNG PATIENTS WITH DIABETES.

BS.Olsen, AK.Sjølie, B. Thorsteinsson, S. Pramming, Knut Borch-Johnsen, HB. Mortensen and The Danish Study Group for Childhood Diabetes. Department of Paediatrics, Glostrup University Hospital, Denmark

Danish nationwide investigations (1987, 1989) have previously demonstrated unsatisfactory blood glucose control in unselected young diabetic patients. The purpose of the present survey was to study the prevalence of microvascular complications in a cohort of children participating in both previous nation-wide investigations and their association to HbA_{1c}. In 353 patients (50.1% of the inception cohort) we were able to collect urine, blood samples, a standardized questionnaire, fundus photo's (with central reading) and a standardized physical examination. Mean age was 20.6 ± 3.3 years and mean diabetes duration 13.2 ± 3.2 years. HbA_{1c} (normal range 4.3 - 5.8, mean 5.3%) and urine albumin excretion rate (AER) (upper normal limit (95%): 20 µg/min) in at least two timed overnight urine collections were analyzed centrally. Average HbA_{1c} was 9.7 ± 1.7% (mean ± SD). Males had significantly ($P<0.015$) higher values than females. Eighty-eight percent of the children (n= 309) were treated with three or more daily insulin injections. Mean daily insulin dose was 0.92 ± 0,25 ie/kg/24 h. Retinopathy was present in 60% and was associated long diabetes duration, high HbA_{1c}, diastolic blood pressure and AER (all $p<0.01$) while subclinical neuropathy (VPT by biothesiometry >10 V) was found in 30% and was asso-ciated to male gender, age, duration, linear height and retinopathy (all $p<0.01$). Microalbuminuria (>20-150µg/min) and nephropathy (>150µg/min) was found in 9 and 3.7%, respectively and was positively correlated to diastolic blood pressure ($p=0.009$) and retinopathy ($p<0.001$). Microvascular complications are frequent in children and teen-agers with IDDM. Only 38 of the patients had HbA_{1c} below 8%. Despite intensive efforts by health care providers current treatment of diabetes in young people is unsatisfactory.

2386

IMPOTENCE IN ETHIOPIAN DIABETIC MEN. SEYOUM B. ADDIS ABABA UNIVERSITY, ADDIS ABABA, ETHIOPIA.

Prevalnce of impotence was assesed among 292 consecutive diabetic men attending the Tikur Anbessa Hospital diabetic clinic. The mean age was 41.4 years (range 18-86 years). One hundred fortynine (51.6%) were type I and 143 (49%) were type II patients. The mean duration of diabetes was 9.9 years and 37.7% have known long term diabetic complications. The overall prevalence of impotence was 48.7%. The mean duration of impotence was 3.5 years. In the majority impotence startd after the diagnosis of diabetes mellitus however in 3.7% impotence occured before the diagnosis of diabetes mellitus. Many of the patients (79.1%) have never complained to physicians and 59.2% of the patients do not know that impotence Is the complication of diabetes mellitus. All but 10 patients (7.5%) have not lost libido. Impotence is significantly higher in Type II as compared to Type I patients (94/143 versus 40/132 $x^2 = 33$ $P < 0.001$) and in patients with complication than without (76/104 versus 54/159 $x^2 = 34.1$ $P<0.001$). The mean duration of diabetes mellitus is significantly higher in patients with impotence than without impotence (12.3 years versus 8.1 years $P<0.001$). We conclude that impotence is a common and significant problem in our diabetic men and we recommend further study to asses its social and psychiatric inpacts.

2387

DIACOMP: A GLOBAL STUDY OF IDDM COMPLICATIONS

T. Orchard, K. Borch-Johnsen and A. Fapohunda on behalf of the DIACOMP investigators, Unversity of Pittsburgh, Pittsburgh, USA

The WHO sponsored Diamond Study is an international study of childhood onset insulin-dependent-diabetes mellitus, which has fostered the development of a number of sub-projects with particular foci to address important questions about IDDM. The DIAmond COMPlications Study (DIACOMP) is the most recent of these sub-projects. The rationale for this study is based on the observation of diverse cause specific mortality experience in IDDM across the world. Considerable variation by ethnicity and/or geographic location of micro and macrovascular complications is likely to underlie these mortality patterns. DIACOMP is designed to explore variation in IDDM complication rates and risk factors.

The study is being organized on two levels at present. Level I is a survey of all identified cases in the registries. The second level, which will start after completion of level I survey will be a brief physical examination and measurement of proteinuria (Micral II®, Boehringer Mannheim) and HbA_{1c} (DCA 2000 Analyzer®, Bayer Diagnostics) along with a more detailed questionnaire. Survey forms will be translated into the local language and then back translated to English to validate the translation. Both Diamond and Non-Diamond centers are participating. Diamond populations have (by definition) a short duration (5-14 years), while the Non-Diamond centers will provide longer duration experience (15-24 years). Twenty-two centers (14 Diamond centers and 8 Non-Diamond centers) have registered from Asia, Europe, North, South and Central America, and Australia. Three Workshop/Training Sessions have been held in Copenhagen, San Francisco and Vienna in April, June, and August 1996 respectively. Eleven centers have had their local protocols approved and 11 have completed clinical training for level II (7 have completed both steps). Centers will start data collection in early 1997. An updated progress report will be presented.

2388

PREVALENCE OF SEXUAL DISORDERS IN A SELECTION-FREE DIABETIC POPULATION (JEVIN)

R. Schiel and U.A. Müller; University of Jena Medical School, Department of Internal Medicine II, Jena, Germany

There is extensive clinical literature on sexual disorders among diabetic patients, but a paucity of studies on their prevalence in selection-free populations. In the present trial (JEVIN) 90% of all insulin-treated diabetic patients (IDDM/NIDDM n=127/117) aged 16-60 years and living in the city of Jena (100,247 inhabitants) were studied: Each subject underwent a structured interview followed by a clinical and laboratory examination. The prevalence of sexual disorders was 32% in IDDM and 46% in NIDDM male patients. Patients with sexual disorders were older (IDDM 47.5±9.8 vs 37.7±11.6, p=0.0004; NIDDM 53.4±4.3 vs 49.4±8.2 ys, p=0.04) and had longer diabetes duration (IDDM 23.1±13.8 vs 13.5±11.1, p=0.001; NIDDM 12.4±7.5 vs 8.4± 5.8 ys, p=0.03), but there were no significant differences ($p<0.05$) between the groups as regards HbA1c, BMI and insulin dose/kg body wt. The prevalence of diabetes long-term complications in men with vs without sexual disorders: IDDM/NIDDM: retinopathy 65/53% vs 50/ 18% (p=0.34/0.03), neuropathy (assessed according to Young et al.) 58/48% vs 9/34% (p=0.001/0.47), nephropathy 65/50% vs 12/36% (p=0.001/0.45). In addition all the patients completed standardized questionnaires according to Bradley et al./Lewis et al. to assess quality of life/treatment satisfaction and one question concerning sexual disorders. The quality of life of IDDM patients with sexual disorders was lower than that of patients without sexual disorders (42.2±11.4 vs 54.2±8.5, p=0.0005), but there were no differences ($p<0.05$) in NIDDM patients. In women the prevalence of sexual disorders was 18/42% in IDDM/NIDDM.

2389

FAMILIAL CLUSTERING OF IDDM COMPLICATIONS IN THE DCCT.

J. Lachin, S. Genuth, P. Cleary, R. Spielman and the DCCT Research Group. The George Washington University, Rockville, MD, U.S.A.

Of 1441 DCCT subjects, 372 had 467 first degree relatives with diabetes. Retinopathy (R) was assessed in relatives using ETDRS score and nephropathy (N) using albumin excretion rate (AER). All analyses were adjusted for treatment group of the DCCT proband, gender, age, body weight, duration of diabetes and HbA1c. Complete data was available for 241 relatives (52%) of 217 DCCT subjects. Familial aggregation was evaluated by comparing the prevalence of R and N in relatives of DCCT probands positive (+) vs negative (-) for R or N. In the DCCT secondary intervention cohort there was an increased risk of severe R (ETDRS ≥ 47, or clinically significant macular edema, or laser Rx in either eye) among relatives of R+ probands vs R- probands [odds ratio OR 3.1, 95% confidence interval C.I. 1.2 - 7.8, $p < 0.05$]; and an increased risk of N (AER > 40 mg/24hr) in relatives of N+ vs N- probands (odds ratio OR 5.4, 95% CI 2.2 - 13.7, $p<0.001$). In the DCCT primary intervention cohort, there was no increase in risk of any R (≥ 1 microaneurysm or worse) in relatives of R+ probands and there were too few events to assess the risk of N. Clustering of severity (level) of R or N was measured by determining the correlations of log ETDRS and log AER among probands and relatives, adjusting for number of family members. For R, the parent-child correlations were significant, but the sib-sib were not. For N, no correlations were significant.

Intrafamilial Correlations of Severity

	Retinopathy (R)			Nephropathy (N)		
	INT	CON	Comb	INT	CON	Comb
Parent-child	.311*	.344*	.327*	.090	.188	.138
Sib-sib	.000	.148	.060	.176	.000	.107

*p < 0.01; INT=Intensive Rx, CON=Conventional Rx, Comb=combined cohort adjusted for treatment group

Conclusions: The DCCT provides the first evidence, to our knowledge, for increased risk of severe R in relatives of R+ probands, and for intrafamilial clustering of the severity of R. We confirm the risk of N among relatives of N+ probands.

PS 62
Education for People with Diabetes

2390

EVALUATION OF DIABETIC FOOTCARE EDUCATION.
E.Göker, C.E. Hoff, J. Dooren and K. Bakker. Spaarne Hospital, Heemstede, The Netherlands.

Introduction: In reducing the rate of limb amputations in diabetics, which is one of the targets of the St Vincent Declaration (SVD), patient education plays an important role. The aim of this study is to determine the success of our footcare education program as advised in the SVD. **Methods:** Patients (P) who visit the foot clinic for the first time are given information orally by the podiatrist and referred to the patient information-centre for video-instruction (AV) and brochure (B) on footcare. A questionnaire, concerning general information, knowledge and practice questions was sent to all new patients in 1994 (n=179). 140P(78%) were eligible. For every patient a "knowledge-score" (KS) and a "practice-score" (PS) was calculated. The student-*t*-test was used for the statistical analysis. **Results:** 67P(48%) received AV+B, 15P(11%) AV, 25P(18%) B and 33P(23%) no information (N). The KS and PS were: AV+B 72% and 63% resp. vs. N 55% and 61% (KS $p<0.05$); AV 69% and 67%; B 67% and 58%. P from the group AV+B who read diabetic magazines had higher KS and PS scores than non-readers (76% and 66% vs. 62% and 52%; KS and PS, $p<0.05$). P with only elementary education had a lower KS than P with higher schooling (54% vs. 73%, $p<0.001$). P with visual/physical handicap vs. no handicap, PS 57% vs. 64%, $p<0.05$. **Conclusion:** Only 47% of the patients followed a complete education program on footcare. This group scored a significant higher knowledge-score compared to patients without information. Evaluation of education programs is useful, as proposed by the SVD.

2391

EVALUATION OF AN EDUCATIONAL PROGRAM: "HOW TO TREAT MY DIABETES"
Salazar S., Arguedas C. Intern Medicine Hospital México, San José Costa Rica.

Introduction: "Education of the diabetic patient is not part of the treatment, it is the treatment itself" (E. Joslin 1927). In 1993 the DCCT study showed the value of educational programs to reach a desirable metabolic control. In 1988 began in Germany the educational program: HOW TO TREAT MY DIABETES", we started the same program in 1994.

Objective: To evaluate the educational intervention with a graded test.

Methods: The program consist of four modules: Self monitoring, Diet, Foot Care and Exercise, was taught to a group of no more than ten patients, using a rotafolio, 2 hours a day, two days a week for two weeks. Randomly we took 100 patients who had attended the program and ask them to take a test before and after the educational program, according with the results we grouped them in three categories: **A** from 80 to 100; **B** from 60 to 79; and **C** those bellow 60 points.

Results:

	BEFORE	AFTER
A	13%	56%
B	18%	38%
C	69%	6%

Conclusions: After the educational program patients tend to increase knowledge about their disease. We think this program is easy to teach and permits its objetive evaluation trough a graded test.

2392

VIDISA(means in spanish HEALTHY DIABETIC LIFE)

E. Cotto and M. Rivera. Cayey Primary Medicine Center Cayey, Puerto Rico

Ussually in our health settings the diabetic patient does not participate actively in the management of their condition. They are told about the importance of education, exercises and nutrition but it seems that nobody has the time to tell them how to do it. The main goal of our project was to give the participants an opportunity to do and to learn how to manage their own condition by participating in a structure program that offered exercise, breakfast according to the personal needs monitoring of blood glucose before exercises and the opportunity to know for the first time the results of the HBA1c. The program promoted the adquisition of basic management skills for the daily life. The patients were selected from our pharmacy profiles, evaluated by our medical team and nutritionist. They attended a three month-three day out of the week sessions. All the activities were complemented with an educational experience. Evaluation of the intervention was base on tests on cardiovascular endurance, strengt, flexibility, coordination and a comparison of two glycated hemoglobin. Results of this evaluation showed improvement in all areas, including up to 35% improvement in the HBA1c test. VIDISA is now a support group organized to help the diabetic patient of our community

2393

THE VALUATION OF EFFICIENCY OF THE EDUCATION PROGRAM FOR IDDM PATIENTS

Yu. A.Redkin, A.V.Dreval and I.V.Misnikova. Moscow Regional Research Clinical Institute, Moscow, Russia.

The aim of our investigation was creation of the education program for patients with IDDM and valuation of its efficiency. During 1995 in endocrinology clinic was educated 41 persons with IDDM. The education was conducted under the 14-day structured program (about 40 hours). The control group included all patients IDDM found in endocrinology clinic in the same period. The increase of a level of knowledge of IDDM patients is revealed as in main, as in control group (from 71.04 till 93.36 %, $p < 0.05$ and from 70.55 till 90.90 %, $p < 0.05$ accordingly). In main group was significant decrease of levels 24h main blood glucose level and main amplitude glucose fluctuation level ($p<0.05$). In control group the similar tendencies are revealed. At comparison control and main groups the significant distinctions are revealed only in quantity of days, conducted by patients in clinic (30.85 and 23.95 days accordingly, $p < 0.05$). Thus, the education permits to reach that effect, as the usual hospitalisation in endocrinology clinic, but in shorter terms, that makes it economically expedient.

2394

PSYCHOLOGICAL CHARACTER OF POORLY MOTIVATED DIABETICS

K.Nunoi, N.Shinohara and Y.Togawa.
St.Mary's Hospital, Kurume, Japan

To improve motivation, psychological characteristics of poorly motivated diabetics (PMD) was investigated. Subjects were consecutive 217 diabetics who attended 2 weeks education program. Motivation level was discussed and rated into 10 by the multidisciplinary team members including psychologist. PMD defined as 6 or lower point was 45(21%), and most of them had barriers; psychological (73%), pysiological (58%) or social (33%) problems. Motivation level was significantly predictive to patient's attitudes 2 years later. Psychological aspets of PMD was compared with general diabetics.General health questionaire revealed neurotic in 65% of PMD. The egogram pattern of PMD was obviously deviated, and frustrated, self-centered, superman and poor adaptation type were 3-10 times more frequent than general population. The tree test (a drawing of tree with fruits) of PMD revealed more frequently abnormal as compared with general diabetics;opened top of the trunk (3.5 times) may indicate poor perspective, narrow trunk (4.2 times) may indicate low confidence, cut of trunk line (3.9 times) may indicate non-selfintegration. Evaluation of motivation level and psychological approach to poorly motivated diabetics is necessary for education.

2395

THE EFFECT OF HOME VISITING PROGRAM ON BLOOD GLUCOSE CONTROL IN DIABETIC CHILDREN IN IRAN

Rajab .A , Sadegian.H.A, IRAN

This is a quasi - experimental research carried out in order to evaluate "the effect of home visiting program on blood glucose control in diabetic children " in Tehran (1995). 45 diabetic children and thier families participated in this program in two groups: the visit group (23 patients) and control group (22 patients) . The average age of patients was 9.3 (7-12) years.The parents' Knowledge about diabetes and glycated hemoglobin (G.Hb) was measured in the two groups in pre- test stage . glycated hemogolobin checked every 3 months. this method was followed - up for one years . In addition, the practice of the visit group was measured and compared . Data were gathered by questionnair and check list format . colorimetric technique was employed to measure glycated hemoglobin. Data Analysis showed that parents' Knowledge about diabetes had Increased (P less than 0.05) According to the results of paired T - test , practice in visit group had increased from 35.2 percent to 79.8 percent ($p < 0.0001$). In this research , long - term diabetic control was evaluated by measurement of glycated hemoglobin(non diabetic Range 2.5 - 4%). in visit group, glycated hemoglobin in pre- test was 6.5 ± 1.5 percent and decreased to 5.5 ± 1.1 percent in mid - way test ($p < 0.0001$) The rate of G.Hb was decreased in post-test After one year to 4.6 ± 1 percent (p less than 0.0001) wilcoxon test indicated that the number of Hypoglycemic shock was decreased . ($p< 0.05$) . Based on results obtained in this study, It is recommended that home visit can be used as a basic and essential approach to control and prevent the chronic diseases possibly developed due to diabetes. with appropriate patients' education and follow - up we have been able to obtain a better control and prevention of complications .

2396

ESTIMATION OF STANDARD OF KNOWLEDGE OF PATIENTS WITH DIABETES MELLITUS ON FOOT SELF-CARE.

A.Z.Ibrahimov,O.T.Ibrahim-zade,I.J.Aliyeva.
Azerbaijan medical university,Baku,Azerbaijan.

The aim of this investigation was to determine the initial standard of knowledge of diabetics on foot self-care. There were 30 patients examined during this investigation using the questionnaire prepared by the group taking up the problem of Diabetic Foot in the Azerbaijan National Committee of SVD.This form contains 15 questions with 4 answers for each.In that way, maximal possible value was 60 points.The average value received by patients was 25+-1,6 points that means that more than half of accomplishments were wrong.The standard of knowledge on foot self-care didn t depend on sex of patients (24,7+-3,29-men;27,8+-1,84-women,p>0,05).The correlation between age and standard of knowledge on foot self-care as well as that between duration of disease and standard of knowledge wasn`t determined.Persons with higher educational index had a higher standard of knowledge on foot care(28,0+-3,21)than that persons with lower educational index(19,9+_2,22,p<0,05). The group having took an amputation of lower limb revealed higher standard of knowledge on foot care(31,9+-1,79,p<0,001).These results show that diabetics began to interest with information on foot self-care **only** after the appearance of. such problem as diabetic foot syndrome.Every patient must take a training course on foot self care as soon as diabetes will be revealed.

2397

LONG TERM EFFECT OF A STRUCTURED OUTPATIENT EDUCATION PROGRAMME IN IDDM - A 6 YEAR FOLLOW-UP

B. Semlitsch, D. Goritschan, H. Zapotoczky, G.A. Brunner, A. Siebenhofer, and T.R. Pieber. Dep. of Internal Medicine, University Graz, Austria.

Aim: We evaluated the long term effect of our structured outpatient diabetes teaching and treatment programme (DTTP) for intensive insulin therapy (IIT) in IDDM patients.

Methods: 3 and 6 years after the DTTP all patients, who participated between 6/1989-6/90 in the programme, were invited for a follow-up visit. Out of 123 patients 13 subjects (12%) could not or did not want to take part in the follow-up. However, patients or their relatives were contacted by telephone to get basic information about their status. 2 (2%) patients died and 2 were lost for follow-up.

Results: 106 patients (86%) (57 female, age: [mean±SD] 44±12 years, diabetes duration: 20±11 years) completed the follow-up after 6 years.

	Baseline	3 years	6 years
HbA1c (%)	8,4±1,9	7,4±1,2***	8,3±1,5 ns
Severe hypoglycaemia (n/year)	0,49±1,33	0,16±0,44***	0,22±0,54***
BMI	23,3±3,0	23,7±3,0**	23,8±3,1***

*ns=not significant, **p<0.01,***p<0.001 vs. Baseline*

Daily insulin dosage remained unchanged (0,57±0,19 IE/kg body weight vs. 0,55±0,17 after 6 years, ns). 98 (93%) of the patients continued with IIT over 6 years. The number of daily insulin injections (2,5±1,0 vs. 4,5±1,2, p<0.001) and use of regular insulin (39±18% vs. 55±18%, p<0.001) increased significantly compared to baseline. A high frequency of daily blood sugar monitoring (3.5/day) was maintained by the patients over 6 years.

Conclusion: 6 years after participation in the structured patient education programme frequency of hypoglycaemia was considerably reduced, whereas the improvement of metabolic control after 3 years could not be maintained. These results clearly indicate the need of a continued patient education with an „expert programme for IIT" in IDDM patients.

2398

PATIENT EDUCATION BASED ON DIABETES EDUCATORS' POINT OF VIEW

Tuula-Maria Partanen, Department of Nursing Science, University of Kuopio, Finland)

The aim of this study was to clarify the diabetic patient education based on diabetes educators' point of view. The data for this study were collected by a unstructured questionnaire from 56 diabetes nurse in Finland. The data were analysed mainly qualitatively using content analysis. According to the answers the main targets for patient education were self management and support of every day life. Other targets were good diabetes control and good quality of life. About 80 % of participants felt being able to deliver good patient education. Supporting factors for succesfull patient education were adequate time, good co-operation of the treatment team and personalities of educator like experience and enthusiasm. About 20 % felt being insufficient in patients education. Things behind were lack of time, few contacts with other diabetes educators like Medical Doctors and weaknesses in the skills and knowledge of the instructors. The participants wanted to develope their skills in patient education by increasing recources (mainly more time), contacts and co-operation with other diabetes educators and train themselves as well as try new education methods. Further research are needed in evaluating good patient education.

2399

INFLUENCE OF PATIENT EDUCATION ON GLYCEMIC CONTROL IN DIABETIC PATIENTS IN TURKEY

G Erdoğan, S.Güllü, N.Başkal, N.Kamel, A.R.Uysal. Ankara University Medical School, Endocrinology and Metabolic Disease Dept., Ankara,Turkey

We evaluated the efficacy of an eight-day structured patient education program in Turkish non-insulin dependent diabetic subjects. Two hundred and fifty NIDDM patients participated the education program in our outpatient diabetes teaching unit. Patients were interacted by a diabetic education team both one - on - one and in classes. Fifty of these patients completed the program. data is covering this group. Mean age was 53 ± 10 years and duration of diabetes was 8.2 ± 4.2 years. All of them were on diet and on drug treatment either with insulin,insulin plus oral agents or only oral agents.The fasting plasma glucose (FPG), postprandial two hour glucose(PPPG),and HbA1c levels were evaluated just before and at least six months after the completion of the education program FPG levels fell from 10 1± 4 mmol/L to 7.1 ± 2.9 mmol/L ($p< 0.01$) and PPPG levels decreased from 13 ± 4.9 mmol/L to 10 ± 3.9mmol/L ($p<0.01$).HbA1c levels also declined (6.4 ± 1 vs 8.7 ± 2%, $p<0.001$). Although 38% of these patients had low education levels (primary school or less), they showed significant improvement in their glycemic controls with the structured education program. As mentioned, only 50 of 250 patients completed the full education program. The reason for this ratio (20% of all participants) was the low socio-economic and cultural status of the patients. Other striking data was that the most of the diabetics who dropped from the program were living in other areas of the country and visitted our outpatient clinics for a short period. In conclusion,these results indicate that under-education of the patients with NIDDM is a major health problem also in Turkey. This teaching experience with an educated diabetes team seems highly satisfactory and may be a helpful model in improving the glycemic control and life quality of diabetics. In order to increase the number of participants to such courses, education programs, including the educators and patients should be organized throughout the whole country.

2400

EDUCATION AND TREATMENT OF DIABETIC PATIENTS WITH CHRONIC ISCHEMIC HEART DISEASE IN GEORGIA.

R.Kurashvili, N.Asatiani, M.Dundua and M.Natsvlishvili. Diabetes Center of Georgia, Tbilisi, Georgia.

The aim of the present study was to assess treatment and education efficacy in NIDDM patients with chronic coronary heart disease (CCHD).32 patients with NIDDM were observed (mean age 59.4yrs; diabetes duration 12.7yrs; body weight -84.5kg; mean heigh 168±8.4cm). 8 patients had MI in the anamnesis, CCHD diagnosis was confirmed by the specific changes on the ECG. 21 patients had arterial hypertension. Most patients had decompensated DM (HbA1c-11,2±0,32%), hyperinsulinism (fasting IRI 23.4±3.4mmol/l), hypertriglyceridaemia (2.85±0.33 mmol/l), elevated VLDL - CH levels (1.34±0.12 mmol/l). All patients took a 4 - day course of education at the Diabetes School, attention was mainly paid to dietary recommendations (low saturated fat content), physical activity and self - monitoring (peripheral vessel palpation, BP - measurement, cardiac angina episode registration).Patients were treated with antidiabetic,antianginal, hypotensive and antihyperlipidaemic drugs. Repeated examination 6 months later revieled decrease in frequency and intensity of anginal attacks, BP normalization. 8 patients stopped smoking. Body weight normalization tendency was observed (mean 77.2kg). HbA1c levels dropped to 8.1±0.2% ($P<0.001$), IRI content decreased insignificantly (22.1±3.1 mmol/l), TG and VLDL- CH levels also dropped 15.2±0.26 mmol/l and 0.7±0.12, respectively,$P<0.01$) The results demonstrate that education improves quality of life and metabolic control of the patients,thus helping them to live with DM and CHIHD.

2401

THE EFFECT OF A LONG-TERM EDUCATIONAL PROGRAMME FOR BLIND DIABETICS ON THE LEVEL OF METABOLIC EQUALIZATION.

E.Bandurska,M.Zabłocki,U.Tarasiewicz,B.Falkowska,E.Aksamit. Olsztyn Diabetes and Metabolic Disseases Center,Olsztyn,Poland.

Every year in Poland 400 diabetes sufferers either with poor sight or completely blind is registered. The main problem of patients who turned blind is adaptation to the new situation,problems with independent living,injection of insulin and conducting self-control.**Aim**:evaluating efficiency of the long-term educational programme for blind suffering from diabetes.**Methods**: Two models of complex influence on patients have been introduced.The former is group education conducted in groups of 20 patients and repeated twice a year.It covers basic information concerning diabetes,self-control,interventional actions and using the Novo Pen injector.The latter model is repeated every three months,one-day observation in a room for daily-basis patients,which is combined with an individual educational programme and evaluation of metabolical equalization.Having undergone the programme,patients switched to using acoustic Novo Pen injector.After 6 and 24 months the level of patients' knowledge was checked with a test containing 10 questions and with application of 1-5 point scale.The state of metabolic equalization was also tested,by means of evaluating the average glycemia,concentation of HbA1c and the dosage of insulin.**The results of research**:The level of patients' knowledge has increased after 6 months by 33% and after 12 months by 41%.The average glycemia has lowered from 253 mg% to 168 mg%, after 2 years-down to 126 mg%.The concentration of cholesterol has decreased from 258,7 mg% to 240,8 mg% after 24 months.At the same time there was an increase in the fractions of HDL from 48,7% to51,7%,HbA1c from 10,1% to 8,5%.The daily dose of insulin was reducted from 58,1 units a day to 35,9 units a day.A positive body weight reduction has been observed.BMI has lowered from 30,1 to 27,7.**Suggestions**:In blind patients suffering from diabetes,it is possible to reach metabolic equalization by means of complex education with use of acoustic insulin injectors.In this way patients may become independent,further complications can be hindered and diabetes treatment costs can be lowered.

2402

Surveying The Trained Diabetic Educators in the State of Bahrain

Kawther Al-Taitoon, Diabetic Clinical Specialist, Lecturer
College of Health Sciences

The main aim of this survey study was to assess the "Trained Diabetic Educators" (Nurses); identify barriers; specific needs and wants.

The method was carried out by sending a circular to all the Trained Diabetic Educators to meet at the College of Health Sciences were surveyed self administered questionnaire in June, 1996.

The results showed that out of the 100 Trained Diabetic Educators only 43 responded from privit and government health sectors all over Bahrain.

The age ranged from 24 to 40 years old. As for sex there were 88% females and 12% males. The duration since completion of the diabetic course ranged 1-4 years and all stated that they benefited from the course. The majority were able to implement what they have studied; develop their teaching/learning package and media. The barriers included no time; shortage of staff, no chance; no support; not accepted by their leaders; and priority to other responsibilities.

However, though 81% perceived that their supervisors are interested in diabetic education, yet they were approached only one time that suggests a thought rather than act from both sides. Around 47% attempted to develop diabetic team in their working area but were suppressed by their supervisors. The view regarding the "Diabetic Course" was positive and suggested to extend the period of the course; the clinical hours and project, work. The plan or specific needs and wants is to establish diabetic educational TV program; establish diabetic team and carry out research projects.

In conclusion the survey pointed out deficits and strengths which gave directions for further planning diabetic education and improving communications between the Trained Diabetic educators and their supervisors.

2403

EFFECT OF EXERCISE THERAPY ON AEROBIC THRESHOLD IN PATIENTS WITH NIDDM

H. Fujinuma, R. Hirano, T. Hoshino, T. Asakura, T. Yamazaki, H. Seino, H. Kikuchi, and R. Abe. Ohta Nishinouchi Hospital, Koriyama, Japan.

The main aim of the study is to evaluate effects of exercise therapy and improvement of carbohydrate metabolism, such as HbAlc and FPG, on aerobic threshold (AT).

Methods

285 patients with NIDDM are subjected. At the beginning of their educational hospitalization, the patients were subjected to an exercise load test on a bicycle ergometer, and AT was determined by analyzing breath samples. They underwent more than two weeks (mean 3.4 weeks) of exercise therapy one hour each day under the direct supervision of the exercise physiologists, then AT was again determined at the time of discharge from the hospital. The results were compared with those of a control group without exercise therapy.

Results and Conclusion

Oxygen uptake ($\dot{V}O_2$) at AT was significantly increased in male patients in 30's, 40's and 50's. The values increased from 14.7 ml/min/kg before exercise therapy to 16.3 ml/min/kg posttherapy, 15.1 to 16.1, and 14.0 to 14.8, respectively, in each group. No statistically significant increase was noted in 60's, while the value increased from 13.0 to 13.7. There was also a significant increase in power (work rate; WR) at AT after the therapy. The same tendency was observed in female patients. No changes were noted in $\dot{V}O_2$ and WR at AT in the control group. There was a significant improvement in HbAlc in both groups. However, the improvement rate of HbAlc was not statistically correlated with that of $\dot{V}O_2$, nor that of WR at AT. The term of exercise therapy was significantly correlated the improvement rate of $\dot{V}O_2$ at AT ($r=0.229$), and that of WR ($r=0.314$)($P<0.001$).

It was demonstrated that three to four week exercise therapy during educational hospitalization improved aerobic capacity and QOL of patients.

EVALUATION OF KNOWLEDGE FOR DIABETES EDUCATION PROGRAM IN DIABETES NUTRITION CENTER, SURABAYA, INDONESIA

A.Pranoto, A.Tjokroprawiro, A.Sutjahjo, S.Murtiwi, L.B.Soeharjono, H.Tandra, and Hendromartono, Diabetes and Nutrition Centre, Dr.Sutomo Hospital, Airlangga University School of Medicine, Surabaya - Indonesia

ABSTRACT: Education program was regularly done every month in Diabetes Nutrition Center, Dr.Sutomo Hospital, Surabaya Indonesia. The goal of the program is to help patients with diabetes gain the knowledge and skills that enable them to care for themselves and to develop the attitudes that will enable them to make behavioral changes. The educators form the basis of the team approach to diabetes education. The team is consisted of Internists, nutritionist, psychiatrist, and nurses. The topics of education program are To understand Diabetes, Foot Care, Diabetes and Nutrition, and Psychological aspect of Diabetes. The education group was maximally 15 patients and the program was given one topic every week until four weeks. The education on 1996 has already conducted every month started on February to August 1996 with total coverage of 77 persons. Pre-test evaluation revealed 55.05 ± 20.77 and the post-test was 74.92 ± 21.11 with ($p < 0.05$). The evaluation proves that the increment of knowledge among participant is successfully achieved. This program is supported by Diabetes and Nutrition Center, Surabaya, Indonesia and also funded by IDF Eli Lily Fund 1995-1996.

2405

CURRENT STATUS AND PROBLEMS IN INITIAL INSTRUCTION FOR INJECTION TECHNIQUE WITH INSULIN PEN-INJECTOR

T. Asakura, S. Nozaki, H. Seino, R. Abe. Ohta Nishinouchi Hospital, Koriyama, Japan.

The main aim of the study is to investigate instruction items and duration required for the initial instruction for the use of insulin pen-injector.

Subjects and Methods

Subjects were 62 patients (M/F=41/21) with NIDDM aged 55.1 ± 12.0 years (M ± SD). After the first injection, subjects injected insulin 9 times by themselves with careful attention to the following 7 skills: 1) being able to identify the name and unit of insulin, 2) shaking an NPH preparation more than 10 times, 3) sterilization of cartridge rubber cap, 4) void injection, 5) sterilization of the injection site, 6) correct injection, and 7) removing a needle 5 seconds after injection. Then, nonperformance rate of each skill was calculated.

Results and Conclusion

The nonperformance rate in each skill increased with increasing the age of the subjects; 4.9%, 8.0% and 13.8% in groups (40's, 50's and 60's), respectively. It decreased with increasing the number of injections, 15.5%, 6.7% and 4.0% in the 1st to 3rd, 4th to 6th, and 7th to 9th injections, respectively. In fifteen patients (M/F=7/8, 58.5 ± 12.3 years of age) who had have a tendency to forget to shake the NPH preparation more than 10 times, a sticker "Shake more than 10 times" was used as a reminder. The nonperformance rate decreased to 6.0% after using the sticker, in comparison with 82.7% before using it.

As conclusion, it is necessary to give a practical training to elderly patients for a long period. In addition, since the nonperformance rate decreased with increasing the number of injections, it is essential for medical staff to assist the patients for a long duration until they master the technique satisfactorily. Since there are many patients who do not remember the name and unit of insulin and who forget to shake the NPH preparation, it is important to use stickers to instruct them properly.

2406

DIABETES PATIENT AND COMMUNITY HEALTH EDUCATION/ TRAINING PROGRAMS IN A DEVELOPING COUNTRY

A.S.Vinaya, GS.Narayan, MG.Mamatha, BS.Sudha, DV.Rama, J.Srikanth, S.Nagabushan, N.Nagesh, S.Krishnamurthi, S.Colaco, A.Sharda, and SS.Srikanta. Samatvam: Endocrinology Diabetes Center, Bangalore, India.

Beginning 1993, we have designed and implemented a variety of structured group health education (ED)/ training (TR) programs in various parts of Karnataka State, tailored to the specific needs [diabetic patients (PT) and families (FM) vs. general public (PU); ED/TR only vs. ED/TR plus medical screening (MS) and treatment (MT)] and capabilities [literary and motivation levels; English vs. regional languages; urban vs. rural] of the recipient population. Thus far we have conducted 48 programs, each providing for 50-850 people. Some important features of the programs include (a) 100% voluntary free professional service (specialist doctors, counselors, dietitians, social workers); (b) Multiple educational techniques and audiovisual aids (lectures, discussions, nutrition demonstrations); (c) Structured syllabi and course content (Diabetes teaching guide-100 pages; Diabetes introductory booklet - 14 pages]; (d) Efficient adaptation of local resources (under a tree, village school, health center, marriage hall, industrial sites, hotels etc.); (e) Vigorous anti-smoking, anti-alcohol, prudent diet-predominantly vegetarian and physical fitness campaign; (f) Medical screening (Height, body weight, spot blood glucose, BP check) and medical treatment (drug adjustment, follow up) to the extent possible in rural/poor situations. Conclusion: India projected to bear world's largest burden of diabetes by 2010, needs to urgently and systematically implement the positive health care experiences of volunteer organizations, like ours.

PROGRAM	RECIPIENTS	DURATION	ACTIVITY
Diabetes Self Care Intensive (12):	PT, FM	8 hrs	ED+TR+/-MS+/-MT
Diabetes Self Care Basic (28):	PT, FM	2-4 hrs.	ED+TR
Diabetes Awareness (5):	PU, PT	2-4 hrs.	ED+TR+/-MS
Diabetes & Heart Awareness (3):	PU, PT	2-4 hrs.	ED +TR +/-MS

KNOWLEDGE OF RISKS/BENEFITS OF HORMONE REPLACEMENT THERAPY IN PERIMENOPAUSAL DIABETIC WOMEN

P.H. Davies, R. Streeton and A.H. Barnett. Department of Diabetic Medicine, University of Birmingham, Birmingham Heartlands Hospital Diabetes Centre, Birmingham, UK.

200 consecutive female patients in our diabetic clinic completed a questionnaire concerning their own knowledge and beliefs about post-menopausal hormone replacement therapy (HRT). 185 questionnaires were returned (91%). 75 of these women were likely to be perimenopausal (defined as aged between 45-65 years). 69 patients (92%) said they were menopausal/approaching the menopause and 21 (28%) were taking HRT. 27% had never heard of HRT. Of those that had heard of HRT, 47% had received information about HRT from a doctor, 36% from media sources and 33% from friends or relatives. Of these, only 36% thought they had been given adequate information. Only 55% felt able to answer any questions of possible risks and benefits of HRT. Of those who answered, response rates agreeing with the following statements were as follows: "HRT is safe in diabetes":- 37%; "HRT improves diabetes":- 15%; "HRT improves blood cholesterol levels":- 20%; "HRT reduces risk of brittle bones (osteoporosis)":- 83%; "HRT worsens blood pressure":- 17%; "HRT increases the chance of heart disease":-12%; "HRT increases the risk of cancer":- 37%. Our survey, in a patient group who regularly receive health promotion advice and in whom the impetus for HRT may be greater than the general population, reveals a poor awareness of HRT, a perception of inadequate information and a perception that HRT is not safe in diabetic women.

2408

"HOLISTIC" VERSUS "BLOOD SUGAR" COUNSELLING IN DIABETES

BS.Sudha, GS.Narayan, MG.Mamatha, AS.Vinaya, DV.Rama, S.Krishnamurthi, J.Srikanth, S.Nagabushan, P.Hegde, N.Nagesh, A.Sharda and SS.Srikanta. Samatvam: Endocrinology Diabetes Center, Bangalore, India.

Complex behavioral factors are responsible for translation of diabetes self care knowledge into positive self care practices, which are crucial for better metabolic control and improved health in diabetes (and other interactive chronic non-communicable disorders). In order to evaluate the clinical effectiveness of the comprehensive health education and training program being provided at our diabetes center for the last two years, we have evaluated selected health behavior of 121 subjects, (structured questionnaire, and personal interview , 76 no insulin, 45 on insulin; male 63, female 58, diabetes duration 10 y). Medical management, introduction to and increased compliance with UGM, SBGM and exercise, were associated with improved BP and glycemic control. 70 % of the obese people lost an average of 4 kg, where as the remaining could not lose or gained weight. About half of the counseled subjects discontinued consumption of deleterious food and addictive substances. Conclusion: Multifactorial nature of diabetes and associated degenerative disorders, make comprehensive health counseling mandatory; further innovations in counseling strategies and patient empowerment are crucial.

EVALUATION OF A FIVE-DAY STRUCTURED TEACHING PROGRAM FOR DIABETIC PATIENTS - A ONE YEAR EXPERIENCE

T. Tankova, G. Dakovska, P. Kozlovski, D. Koev, I. Atanassova, N. Aslanova and M. Karapeeva, Clinical Centre of Endocrinology, Sofia, Bulgaria

The aim of the present study was to evaluate the effect of a five-day structured teaching program for diabetic patients one year afterwards. 101 insulin-treated diabetic patients,of mean age 35.4±11.1 years and mean duration of the disease 10.0±7.9 years, who had passed the program were followed up at reeducation one-day sessions 6 months and one year later. There was a significant increase in the overall quality of life (score 52 after six months and 51 after one year, resp., vs 41 before education, $p<0.01$), due to reduction in depression (4.0 after one year vs 5.1 before education, $p<0.01$) and anxiety (4.97 vs 7.63, $p<0.001$), and increase in well-being (13.8 vs 12.1, $p<0.05$) and energy (9.63 vs 8.78, $p>0.1$).The metabolic control improved significantly, judging by HbA1 level (from 9.1% to 8.0% after six months and 7.8% after one year, $p<0.05$). There was a significant increase in diabetes-related knowledge at the end of the five-day program (81% vs 52%, $p<0.01$), being maintained unchanged 6 months (80%) and one year (79.5%) later.The patients carrying sugar with them increased dramatically 6 months after education (from 4% to 89%), this percentage being slightly reduced a year aftewards (82%). There was a significant rise in the number of patients keeping a log book - from 16% to 72% after six months and 66% a year later. The rate of severe hypoglycaemia decreased from 0.15 to 0.06cas/pat/yr, ($p<0.01$) after one year and the rate of diabetic ketoacidosis fell from 0.30 to 0.14 cas/pat/yr ($p<0.01$). These results demonstrate that structured patient education improves the quality of life of diabetic patients and their metabolic control and significantly reduces the rate of acute complications, and we consider reeducation as absolutely necessary to maintain this beneficial effect of education.

2410

ASSESSMENT OF EDUCATIONAL EFFECTS ON NIDDM PATIENTS.

H-F. Tu, J-H. Juang*, S-H. Ma, M-T. Huang, C-H. Kao, Chang Gung College of Medicine and Technology, and *Division of Endocrinology and Metabolism, Chang Gung Memorial Hospital,Taipei, Taiwan, R.O.C.

Lifestyle modification consisting of diet combined with aerobic exercise can be effctive in diabetes control and reduction of macrovascular complications.

An experimental design was conducted to evaluate the effects of diet and exercise education. We studied 8 NIDDM patients at our metabolic clinic. They were assigned into the experimental (N=4) or control (N=4) group at random. Our 2-month intervention included 2 times of educational sessions with instruction on nutrition, exercise, and behavioural modification strategies to the experimental group. They were encouraged to adhere the protocal and record their diet and exercise.

There was statistically significant different in the change of daily calories between 2 groups (-150±127 vs +388±116 Kcal/day, $p<0.05$). Improvement was observed in diabetes knowledge, attitude, behavior, glycosylated hemoglobin levels, and serum lipid levels in experimetal group. In conclusion, diet and exercise education are effective in diabetes control and reduction of macrovascular risk factors.

2411

DEVELOPMENT OF PATIENT SATISFACTION WITH DIABETES EDUCATION QUESTIONNAIRE

E.C.Y.Kan and P.W.H.Lee. University of Hong Kong, Hong Kong

The assessment of patient satisfaction has become an important concern in the evaluation of health services and diabetes education is no exception. This study describes the process and outcome of the development of an instrument, ***Patient Satisfaction with Diabetes Education Questionnaire (PSDEQ)***. The PSDEQ aims to measure patients' satisfaction with diabetes education provided by diabetes nurses in the local setting. The process of item generation and content validity testing will be reported. Pascoe (1983)'s definition was used as the working definition of patient satisfaction. Patient satisfaction is defined as a health recipient's reaction to salient aspects of the context, process and result of his service experience. Generation of domains and items from the empirical and conceptual sources was then completed. 100 diabetic patients were interviewed upon their completion of the education sessions to identify all characteristics they regarded as important to the rating of satisfaction. Satisfaction statements were generated from the data. Conceptually, review of the definitions and standards of quality diabetes education was conducted and items were also generated on this focus. Together with those generated from the patient interviews, 38 items assessing 5 domains were generated. The domains covered communication content, nurse's attributes & behavior, relationship, convenience & accessibility and perceived outcome. A seven point Likert Scale was adopted. Content validity was assessed by 5 experienced diabetes nurses and diabetologists and 5 patients. 25 items were finally retained after modification and elimination by criteria of irrelevance, ambiguity, and undesirable similarity. Further testing on validity and reliability of the instrument will be done by administering the instrument to 150 subject samples from two local Diabetes Centers. Item-scale correlation, with an acceptable Cronbach alpha coefficient set at 0.70, will be done to examine the internal consistency. Factor analysis will be used to confirm the expected factor structure and how these factors underlie the set of items. Evaluating service using the PSDEQ will help to identify specifically the instances satisfying or dissatisfying to the patients. The findings will enable the planning of service more focused to the patients' needs and improving patient satisfaction.

2412

THE EFFECTS OF DIABETIC EDUCATION PROGRAM ON DIABETIC CONTROL.

L-C. Shih, J-H. Juang, S-H. Hsieh, W-T. Lu, K-H. Yeh, H-S. Lin, S-J. Lin, J-D. Lin, H-S. Huang and M-J. Huang. Division of Endocrinology and Metabolism, Department of Internal Medicine, Chang Gung Memorial Hospital, Taipei, Taiwan, R.O.C.

Education for diabetic patients is important for their glycemic control. To evaluate the effects of diabetes education, we studied 57 inpatients who were admitted to our diabetic unit during Jan-Feb,1995. Fifteen items were assessed which included knowledge on diabetes and its complications, diet, exercise, medications and foot care. Of each item, score 1, 2, 3 and 4 represented poor, partial, complete understanding without action, and complete understanding with action. Patients were assessed before and after 1-2 weeks of educational program. Their mean score improved from 16.2±3.3 to 39.4±4.4 ($p=0.0001$) after education. The mean glycohemoglobin (HbA1c) decreased from 10.6 ±2.5 % to 8.7 ± 1.8 % ($p=0.0001$) at outpatient clinic follow-up. The improvement in education scores was correlated with the decrease of HbA1c levels ($r=0.32$, $p=0.02$). In conclusion, our inpatient education program improves not only patients knowledge but also their glycemic control.

2413

IMPACT OF EDUCATION ON GINGIVAL INDEX IN DIABETIC AND NON-DIABETIC SUBJECTS. Z.Stolarza, S.Goldstein and C.González, Servicios de Nutrición y Odontología, Hospital Francés, Buenos Aires, Argentina.

Objective: To determine the impact of an odontologic educative plan on the oral clinical status in diabetics, and to compare this effect vs a non-diabetic sample.**Methods**: We studied 15 diabetic patients (group I) and 16 non diabetic subjects (group II); each patient in a group was randomly alocated in one of two subgroups; in the first one (subgroup A), they received programmed information on the appropiate bucal care methods, reinforced in a weekly contact, during three months. In the second subgroup (subgroup B), just a general information was brought, without a particular reinforcement.The oral clinical status was qualified through gingival index (Löe and Silness, modified) at the beginning and at the end of the study (month 3) for each patient. Metabolic control was evaluated by HbA1c. Statistical analysis: One tailed Fisher Exact Test; X^2 (Yates correction) and non-parametric ANOVA. **Results**: In both groups, gingival index improvement was more frequent and stronger in subgroup A (in Group I -diabetics-, $p=0.028$; in group B -non-diabetics- $p=0.029$). No between groups difference was found. HbA1c improved significantly in subgroup A diabetics.**Conclusions**: In patients under this educative plan (both diabetics and non diabetics) gingival index was significantly reduced (improved) in comparison with non educate subjects. May be of great interest to persist in this kind of educational work to prevent further bucal complications in diabetic patients.

2414

KNOWLEDGE AND COMPLIANCE OF HYPOGLYCEMIC AGENTS IN DIABETIC PATIENTS IN TAIWAN.

S-C. Niu, J-H. Juang*, K-W. Chen*, C-C. Liao and H-S. Huang*. Department of Pharmacy and *Division of Endocrinology and Metabolism, Chang Gung Memorial Hospital, Taipei, Taiwan, R.O.C.

To know patient's knowledge and compliance of hypoglycemic agents (HA), we studied 104 diabetics (46 males and 58 females) by questionnaire. Eighty-seven patients were non-insulin-dependent (NIDD) with mean (±SD) age of 58±14 years and 17 patients were insulin-dependent (IDD) with age of 20±9 years. Fifty-four (52%) patients had additional medications other than HA. Most (90%) patients knew the action of HA they were using. However, only 53% of patients completely followed doctor's prescription. The most common cause of poor compliance was forgetfulness. There were 25% of patients experienced side effect(s) of HA. The most common side effect was hypoglycemia. Patient's knowledge, compliance and the occurrence of side effects of HA were not significantly different between IDD and NIDD. In NIDD, patients with complete compliance had better HbA1c (10.0±2.1 vs. 11.3±3.1 %, P<0.05) as compared with those without. In conclusion, poor compliance of HA is common in our diabetic patients and it is related to patient's glycemic control.

2415

EVALUATION OF A COMBINED EDUCATION/CLINICAL-EXAMINATION PROGRAM FOR NIDDM PATIENTS.

I.J.M. van den Arend, R.P. Stolk, B.P. Bakker and A.J.P. Schrijvers. Department of Health Sciences, Utrecht University, The Netherlands.

An increasing amount of evidence suggests that patient education for people with diabetes should be an integral part of effective disease management. In this study, an education program for NIDDM patients, including basic self-care skills, basic physiology of diabetes and its complications was performed as part of an extensive clinical examination by a diabetes nurse, dietician, ophthalmologist and podiatrist. We evaluated the effect of this program on knowledge, self-care behaviour, disease perception, metabolic control and body mass index. Data was collected upon entry to the program, immediately following the education sessions, and after 6 months (follow-up). Metabolic control was assessed by glycosylated hemoglobin (HbA1c). Self administered questionnaires were used to assess patients knowledge, self-care behaviour and disease perception.

The study group consisted of 96 patients, of which 54% was female, treated by a general practitioner. At baseline the mean age was 64.5 years (SD 8), duration of diabetes 5.5 years, (SD 4.8) and mean Hba1c was 9.3% (SD 2.5). Self-care behaviour and disease perception improved after the program (for all dimensions $p<0.05$). The mean score for knowledge (range 1-23) changed from 8.5 at baseline to 12.4 and further to 13.6 at follow-up ($p<0.001$). Moreover, the patients showed an improvement of metabolic control after following the program. This effect was maintained, although it leveled off during the next six months (mean HbA1c decreased from 9.3% at baseline to 8.9% $p< 0.05$ to 9.1% in the follow-up). The percentage of patients with the poorest metabolic condition (Hba1c>10%) decreased (from 28% at baseline to 21% in follow-up, $p<0.001$). The body mass index decreased from baseline (28.7) to follow-up (28.2, $p<0.005$).

These results indicate that a combined education/clinical-examination program is able to improve both self-care behaviour and metabolic control in NIDDM patients. These improvements endured after the completion of the program, which suggests that it initiates lasting changes in the way patients handle their disease.

2416

EVALUATION OF A STRUCTURED 5-DAY EDUCATIONAL PROGRAMME FOR INTENSIVE INSULIN THERAPY.

J.L. Selam, V. Jullien, F. Elgrably, P.Y. Traynard, G. Slama, Hotel-Dieu Hospital, INSERM U. 341, Paris, France.

There is a clear consensus for improving glycemic control in most IDDM patients, but not on the methods to attain these goals, e.g. advanced (re)educational programmes or intensive DCCT-like outpatient follow-up. We retrospectively evaluated the impact at 1 year of a 5-day inpatient structured educational programme designed to help compliant IDDM patients with standard diabetes education to attain near-normoglycemia with the least consequences on hypoglycemias and quality of life. The programme included interactive sessions on treatment goals, injection techniques, diet and insulin adjustment, and early recognition and management of hypo and hyperglycemias. Quality and frequency of subsequent out patient follow-up were kept unchanged i.e. conventional visits every 3-4 mo. Seventy-three IDDM patients aged 42 ± SD 10 years, with diabetes duration 18 ± 10 years, were consecutively recruited. Most self-management indicators improved, the most significant differences being in the number of daily glucose testings (3.8 ± sem 0.4 vs 4.6 ± 0.2 at 0 and 12 mo), use of a log book (58 vs 88 % of the patients) and of an appropriate technique of injection (46 vs 80 % of the patients). Diabetes control indicators improved slightly though significantly : HbA1c 9.2 ± 0.3 % vs 9.0 ± 0.3, frequency of severe hypoglycemias 74 ± 28 per 100 pt-year vs 26 ± 12 i.e. the number of patients with satisfactory control (HbA1c < 8 % and no severe hypoglycemia in the last year) increased from 6 to 18 % ($p < 0.03$). Six of the 14 items of a DCCT-adapted quality of life questionnaire were scored significantly better at month 12 than at month 0. In conclusion, our results suggest that intensive diabetes management limited to a 5-day educational programme is able to improve patients attitudes and quality of life but has only modest long-term effects on diabetes control limited to a reduction of severe hypoglycemias.

2417

A study of syringe and lancet disposal practices among diabetic patients in a Singapore diabetes center

G CHANG, S RAHAYU, W TEO, C H LEE, TOA PAYOH HOSPITAL, SINGAPORE

The correct disposal of insulin syringes and lancets is an important issue because of the potential for accidental needle-stick injury. However, syringe and lancet disposal is often an area poorly understood by patients, and practices vary. We therefore conducted a study to better understand the practices adopted by insulin and blood glucometer users in Toa Payoh Hospital Diabetes Center. A questionnaire was applied to a group of 75 diabetic patients (39 males, 36 females). All 75 were using insulin, and 72 monitored their blood glucose regularly.The mean age of the group was 49 years, and 39% had glycated hemoglobin below 9% (NR 4.6 - 6.4%). 21% did not have any formal education, 40% had primary school education, 33% had secondary school education, the rest had vocational, pre-university or university education. 84% had monthly household incomes more than US$ 600. 55 patients (73%) were using insulin syringes, while 20 patients (27%) were using insulin pen-injectors. 79% of the patients were personally responsible for disposing of their syringes, needles and lancets, the remaining 21% depended on family members to take care of this task. 99% did not break the needle off the syringe prior to disposal. 95% recapped their needles. Only 5% put their used needles and syringes into a puncture-resistant container, 53% put these items in a plastic bag prior to disposal into the dustbin or rubbish chute, and 41% threw the used items directly into the dustbin or chute. For lancets, 26 patients (36%) did not bother with capping, throwing used lancets directly into the bin, whereas 21 (29%) collected the lancets first into a plastic bag before disposing of the bag into the bin. Only 4% got rid of used lancets using a puncture-resistant container. 6 individuals (8%) reported experiencing needle-stick injury. No needle-stick injuries occurred to household members. After the questionnaire, the patients were re-educated on syringe and lancet disposal safety issues. 89% of them resolved to use a puncture-resistant container in future, and 4% decided to use the safe-clip disposal device. We conclude that health professionals responsible for diabetes education programs should teach patients the correct ways to dispose of insulin syringes and lancets, and alert them to the potential dangers of needle-stick injury.

2418

BIBLIOTHERAPEUTIC PROGRAM FOR PEOPLE WITH DIABETES.
S.K.GOEL REGIONAL INSTITUTE OF EDUCATION, BHUBANESWAR.

In this study, 50 patients from Rural India were selected.They were not having adequate psychological adjustment with this disorder and were undergoing stress. The main aim of this study is to conduct a need oriented training program and evaluate through the gain in understanding and change in attitude before and after the training. Another aim was to investigate the misconception and superstition held by Indian families. Case history was collected for each patient. A questionnaiare was prepared to assess their knowledge about this matabolic disorder, the effect of this problem in their families and social circle, treatment with special diet, regular exercise, etc. A systematic training program was conducted by supplying bibliotherapeutic materials, counselling different members of family, providing information services, group discussion, etc. The pre and post test results, feedback questionnaire and also verbal feedback in an open session revealed significant gains made by the patients. Bibliotherapy proved to be an excellent mode of communication. The idea behind this procedure is to provide patients with information about diabetes in the hope of changing their attitudes, dietary habits, etc. The effectiveness of the program could be judged from the fact that the revisits of the patients are gradually increasing and message is reaching the unreached and the patients are improving by this innovative method. The author is hopeful that such training programs would go a long way, especially in India where there is an acute shortage of human and financial resources.

FAMILY EDUCATION PROGRAM FOR THE HOSPITALIZED DIABETIC PATIENTS
M.Morimoto, H.Fukumoto and E.Kawabata : Dept.of Met.& Endocr. Shiga Medical Center For Adults Diseases ; Moriyama Shiga, Japan.

Patient education is the fundamental factor in the treatment of diabetes mellitus. Also education for patient's family seems to be indispensable to keep patient in well controlled codition.We assessed the role of family of diabetic patients on diabetic control. In 1995 we started the family education program for hospitalized patient's family. The program consists of five lessons: (1) What is Diabetes, it's etiology, symptoms, complications and treatment. (2)Nutrition and health. (3) Dietary cure of diabetes. (4) Planning of dietary menu. (5)Prevention and care for hypoglycemia. Care of insulin injection, if necessary. Sixty-three were invited to this program. 48 were partner of the patients, 14 were child, and one mother. The comments of the attendants to this program were: (1) it was very good time to consider how to do something better next day, (2) to recognize the necessity to cooperate with patient, (3) to obtain the knowledge of nutrition, (4) to correct the misunderstanding on diabetes, and so on ; while patients says that they were encouraged by family, that can easily get the help or support than before, that the condition of surroundings for cary out diet are improved. Mean HBA_{1c} of patients was improved from 8.5% on admission to 6.8% at discharge, and kept this value or below for 9 months, whereas in the case of 59 patients(age and metabolic state are matched) admitted before this program, mean HBA_{1c} was improved from 8.7% on admission to 6.7% at dischage, and exceeded this value after 5 months. Namely the duration of good control after discharge was doubled. These facts suggest that cooperation of family is indispensable for diabetic control and also family education is very important facter in the treatment of diabetes mellitus.

2420

UTILIZING FOURTH GRADE STUDENTS TO INCREASE DIABETES AWARENESS

P.Villas, University of Texas System Texas-Mexico Border Health Coordination Office, Edinburg, Texas, USA

This project was originated by the Texas-Mexico Border Diabetes Registry Project (TMBDRP) to determine if fourth grade students were a suitable group to assist the TMBDRP register persons with NIDDM, raise awareness about the diabetes problem and delivering a diabetes message. Since NIDDM is found in epidemic proportions along the Texas-Mexico border of south Texas, it was determined that delivery of a NIDDM prevention message to as young a population as possible was important. The school pilot program was initiated with 1701 fourth graders from four school districts. School administrators and teachers cooperated with the project and were eager to assist since they themselves knew relatives and friends with NIDDM. Data from the project revealed that 916 out of 1701 fourth grade students who took part returned the diabetes enroll form as instructed and 808 forms out of the 916 were completed by persons with NIDDM. The 54% return rate indicated that closer attention to instructions needed to be followed by all involved. Results from the pilot program revealed that fourth graders are a suitable group to receive a diabetes message and they can responsibly assist in the enrollment of their relatives with NIDDM into the Diabetes Registry. Individual school campus responsibility for the return of all enrollment forms will be included in a planned future project which will involve 20,000 fourth grade students. It is estimated that at least 10,000 persons with diabetes will be added to the TMBDRP database as a result of the larger effort.

2421

SPECIFIC INSTRUCTIONS GAVE REDUCTION OF LIPOMAS AND IMPROVED METABOLIC CONTROL IN DIABETIC CHILDREN.

I. Franzén and J. Ludvigsson. Department of Pediatrics, University Hospital, Linköping, Sweden

Many diabetic children develop lipomas at the injection sites despite active education. The aim of our study was to see whether a specific instruction scheme lead to reduced lipomas, and if HbA_1c then decreased. First we examined 96 diabetic children and adolescents, aged 4-19 years (mean 12.6), with a diabetes duration of 1 month - 17 years. They all had multiple insulin therapy. 35 patients (27 boys and 8 girls) had lipomas, and they got traditional education in injection technique. After a three month run-in period 20 of these children with lipomas, 17 boys and 3 girls, were randomized into either a control group (C), who got further conventional advice, or into an experimental group (E). In addition to advice the E patients received a formal injection scheme which could be put on the injection area of the stomach, plus a diary for follow-up of their injection practice. Another 3 months later the area of lipomas was registered. HbA_1c was determined before and after the intervention (normal range <5.4%).
The E group got a more pronounced and frequent reduction of lipomas then the C group. The total lipoma area in the E group decreased from 107.6 cm^2 to 40.8 cm^2 ($p=0.07$), but was constant in the C group (89.9 resp. 82.2 cm^2). HbA_1c decreased in 9/10 E patients (mean went from 7.9% to 7.0%;), but only in 3/10 C patients (8.0% resp. 8.1%) ($p<0.001$). In both groups a decrease in HbA_1c was correlated to reduced lipomas ($p=0.07$).
We conclude that quite simple but distinct instructions may reduce lipomas and improve metabolic control in diabetic children and adolescents.

2422

BENEFIT OF IN-PATIENT DIABETES EDUCATION TO GLYCEMIC CONTROL

Feng-Hsuan Liu, Kuei-Lai Huang, Chih-Hung Chen and Bie-Yu Huang. Division of Endocrinology and Metabolism, Department of Internal Medicine, Chang Gung Memorial Hospital, Kee Lung, Taiwan, R.O.C

It is a consensus that education is important in the management of diabetic patients. In our division, out-patients have educator and dietitian consultations using food models at their initial visit and subsequent visits if random blood glucose is higher than 11 mmol/L. In-patients have educator and dietitian educations, chi-kong exercise instruction, and daily diet with calculated calories. In this study, we investigate whether short-term admission for diabetes education improves glycemic control in those out-patients with poor sugar control. During July 1995 to June 1996, 53 non-insulin dependent diabetic out-patients (19 male and 34 female) were admitted for sugar control. The mean age, disease duration and body mass index was 58 ± 11 yrs, 8 ± 4 yrs and 23 ± 3 % in male patients; 60 ± 8 yrs, 11 ± 5 yrs and 26 ± 6 % in female patients. At admission, 51 % of them admitted irregular medication, all of them had higher daily calorie intake (38 ± 10 Kcal/kg body weight in male patients; 30 ± 11 Kcal/kg in female patients) and imbalance nutrition (carbohydrate 47 ± 10 %, protein 16 ± 3 %, fat 37 ± 14 % in male patients; 49 ± 9 %, 16 ± 3 %, 33 ± 7 %, respectively in female patients). Their mean of HbA_1c was 10.4 ± 1.7 %. After short-term admission (8 ± 4 days), HbA_1c level decreased to 8.9 ± 1.7 % ($p<0.05$ by paired Student's t-test) in 2-3 months while their dosage of oral hypoglycemic drugs were not increased In conclusion, diabetes care must repeat and repeat till patients can fuse these concepts and skills into their daily life. The diabetes educators and dietitians play important roles in the follow-up work.

2423

WHEN IS IT TIME TO RE-EDUCATE OUR PATIENTS? Sulway, M.J., Diment, A.D. and Harris, G., Royal North Shore Hospital, Sydney Australia.

Since the development of the Bodylink™ Teaching System we have been evaluating its long-term use in our adult I.D.D.M. programmes which are designed to improve understanding of and adapting to diabetes. The D.C.C.T which was conducted over an 8 year period has raised the question of long-term educational 'support' for patients. To investigate this reinforcement issue we analysed evaluation data on programme cohorts immediately before, after and at 6,12,18 and 36 month intervals on a 34 item questionnaire developed to assess both theoretical and behavioural, practical "skill" issues of diabetes management. A subset of course participants had three pre-course and three post-course HbA_{1c} measurements taken.

RESULTS. "Knowledge" scores - means ± S.D. (max. score = 34)

Whole group (n=259) Pre-course = 13.6 ± 5.2
Immed.Post-course = 28.3 ± 2.8

(a)	6 months	(n=71)	=	23.8 ± 4.7
(b)	12 months	(n=53	=	21.5 ± 3.2
(c)	18 months	(n=50)	=	19.8 ± 3.8
(d)	36 months	(n=38)	=	17.2 ± 4.4

Pre x (a) (b) (c). All significant at 0.001 level
(d) Not quite significant at 0.05.

Post x (a) (b) Not significant
(c) Significant at 0.05 level
(d) Significant at 0.001 level.

HbA_{1c} (means, n=56) Pre-course/post - 8.6% to 7.3% ($t = 4.32$ $P<0.001$).

These data indicate that knowledge scores having initially doubled, declined at a steady rate over the study period (3 years). It appear that between 2 - $2^1/_2$ years this "decay" shows there is now no difference between pre-course levels and follow up. On this basis we recommend some "formal" re-education between $2^1/_2$-3 years as an adjunct to the clinical and self-managed maintenance of the observed HbA_{1c} trends.

2424

DIABETIC EDUCATION : ASSESSMENT OF COMPLIANCE

P. Ushabala, A. Padma, G. Parvati and P.V. Rao.
Diabetes Education and Treatment Center and
Nizam's Institute of Medical Sciences, Hyderabad, India.

Compliance and metabolic control were ascertained in 13 diabetics (group A) attending education program of a University Hospital for first time, and in 20 (group B) and 28 (group C) diabetics who attended 10.9 ± 4.4 and 28.5 ± 8.7 similar programs respectively. Education Score (3.9 ± 2.2 in A, 6.7 ± 1.8 in B, 7.5 ± 1.5 in C /max 8) and Self-Care Score (4.1 ± 2.6 in A, 6.5 ± 0.9 in B, 6.5 ± 1.3 in C / max 7) were better in groups B and C. But, BMI (kg/m^2 22.4 ± 3.2 in A, 23.9 ± 2.6 in B, 24.2 ± 3.3 in C) and blood glucose in fasting (mg/dl 132.1 ± 48.7 in A, 119.6 ± 37.6 in B, 126.2 ± 30.8 in C) or at random (mg/dl 177.6 ± 43.6 in A, 194.9 ± 59.8 in B, 195.7 ± 72.9 in C) were similar in all. Self reported glycemic control (chi^2 4.6 n.s.) and diet adherence (chi^2 3.8 n.s.) were also not different among 3 groups. Monitoring of body weight, blood or urine glucose, GHb, lipids, ECG or fundus were not more frequent in group B or C. Elicited responses for poor compliance and control were inapt application of information (59.0%), inadequate education (27.9%), unrealistic treatment goals (23.0%), unawares of accompanying diseases (23.0%), uncommunicative health care team (19.7%) and limited resources (11.5%).

WESSEX MULTIPROFESSIONAL COURSE IN DIABETES CARE. EDUCATION OF DIABETES CARERS BY FELLOW PROFESSIONALS

A.P.Brooks, N.Baker, J.Braithwaite, D.Clements, S.Cradock, S.Doyle, A.Grundy, D.Jones and L. Worrall, Royal Hampshire County Hospital, Winchester, England (U.K.)

Good quality Diabetes Care is delivered by professionals from several disciplines working together as a multiprofessional, patient centred team. The Wessex Multiprofessional Course in Diabetes Care (W.M.P.C.D.C.) provides education of these professionals by their own Health Care colleagues. We aim to teach knowledge, practical skills, motivational techniques, coping mechanisms, and teamwork theory. The course is in 4 parts: a pre-course learning package, including learning activities in a course handbook; a 5-day intensive teaching block with 14 seminars, 4 practical workshops, and feedback sessions; a work based project done over 3 months; and a residential weekend to report on projects and discuss aspects of adult learning and team working. In 1995 and 1996 20 professionals, 10 podiatrists, 7 nurses, 2 dietitians, and 1 Prison Medical Services Nurse, have attended. In an evaluation questionnaire 75% found the precourse learning package and 66% the multiprofessional interaction in the 5 day block very useful, but 66% criticised one topic heavily, which has been withdrawn. Each presentation was scored (1-5, high) with mean values as follows: content 4.3, presentation 4.3, interaction 4.2, teaching aids 4.1, and relevance 4.3. The residential weekend was very valuable in understanding the roles patients and professionals play. The W.M.P.C.D.C. is a good model for multiprofessional education, which is important in trying to deliver good Diabetes Care.

2426

SUPPORTING PROGRAMME FOR EDUCATORS IN POLAND.

M.Tracz and A.Czyżyk. University School of Medicine, Warsaw, Poland

A diabetes educator to be successful must be skilled in the teaching-learning methods and in process of planning, implementing and evaluating of local education programmes.The aim of this report was to identify the problems of educators and to develop a supporting programme for educational teams. Forty two educators (14 doctors and 28 nurses), aged 22-56 yrs, who has been working with diabetics 0.5-20 yrs (9.15±6.47, mean±SD) from different diabetes centres, participated in first step of the programme (3-day training course). All participants answered a 34-item questionnaire to evaluate their activity in the field of the patient education. The nurse's knowledge about diabetes was assessed by means of a multiple choice test with 20 questions at the beginning (A) and the end (B) of the course. The main barriers to the patient education were: the lack of the appreciation of the education by another medical staff, lack of formal programmes and financial problems. A significant improvement of nurse's knowledge was observed, global score changing from (A) 45.5±13.1 to (B) 70.7±9.6 ($p<0.001$). Next, all teams had to develop and implement own teaching programmes. As a result of 3-day training after 3 months, 18 of 19 local educational programmes for diabetics were implemented and evaluated with 237 of patients with diabetes involved. Conclusion: A first step of a long-term programme for the educators was very effective in the increase of motivation of educators and in the process of developing of local teaching programmes.This course was sponsored by the Eli Lilly Fund of the International Diabetes Federation.

INTERNATIONAL EXCHANGES IN DIABETES EDUCATION :E Baumer Diabetes clinic Vienna Austria, M Schlaeppi Unité de diabétologie, Lausanne Switzerland and the Red Bus 1996 Global Medical Conference Project Group, USA. Representants from 23 varying countries attended the 2nd annuel GMC in Indiana USA.which incorporated models of patient care and the setout of varying training courses available throughout the world. During this Conference along with the sharing of ideas and experiences many friendships were made. The participants were then the guests of Eli Lilly at the 23rd American Association of Diabetes Educators Annual meeting in New Orleans. The Diabetes Educators from the following countries: Austria, Switzerland, Slovania, Croatia, Philippines, Aruba, Jamaica and Puerto Rico decided to create an International working group The first meeting of the "RED BUS PROJECT " working group was held with the objective of deciding exactly what the future plans were and who would be responsible for specific tasks. It was decided to open this group to all Diabetes Educators interested in the aims of international exchange. The main aims of this group are, to continue the International friendships and contacts made during the GMC, share and work together on research programs, encourage participation at future conferences, and the composition of joint written articles, abstracts and posters. The first project was the creation of this poster which would be an opportunity for as many representatives from the 1996 GMC to display their own personal gains, describe the work being done in their own countries and to explain their intentions with regards to future research studies between thier own and other countries. This poster shows a map of the world encircled by a Red Bus with pages of text attached to thier varying countries by ribbons indicating the knowledge and interest shared by each of the diabetes educaters. As Diabetes educators change thier roles from a source of all knowledge to that of disease managers they are also having to change the way they practice diabetes education, One very important way to obtain this new role is by sharing the experiences of other trained diabetes educators. Therefore the continuation and availability of these international educator conferences is very important in the ever changing domain of diabetes education.

POST GRADUATE TRAINING IN DIABETOLOGY : RSSDI ACCREDITED PROGRAMS.

P.V. Rao
on behalf of the National Accreditation Committee for Diabetology.
Nizam's Institute of Medical Sciences, Hyderabad, India.

To impart competence among primary care physicians in managing diabetes up to secondary level, Research Society for the Study of Diabetes in India (RSSDI) empowered National Accreditation Committee for organizing post graduate training programs. The program contents were uniform and comprehensive in the format of Continuing Medical Education, Workshop, Update, Panel Discussion, Open Forum, Post Graduate Course, Annual Scientific Meeting, Conference, Advanced Course or National Symposium. Since May 1995 in 18 months period, 31 programs were conducted in 13 Indian states including 5 Post Graduate Courses at teaching hospitals from South, North, East and Western regions of India. RSSDI designated post graduate training activity of 287 credit hours for these diabetes education programs - 14 for 5 credit hours each, 4 for 8 hours each, 7 for 10 hours each, one for 15 hours and 5 Post Graduate courses for 20 hours each. On average, each program benefited about 102 (45-325) clinicians and 3158 participants were trained for 6409 clinician-training-days over 52 program days for 6 hours a day. RSSDI accredited post graduate training in diabetology was effective in ensuring active participation of primary care physicians to facilitate coordinated diabetic health care system in the country,

PRACTICAL DIABETES MANAGEMENT FOR FAMILY PRACTITIONERS

S.J.Meltzer, J.F.Yale, A.B.Belton and T.A.Harmathy. McGill University, Montreal, Canada

The purpose of this program is twofold; to increase the diabetes knowledge and management skills of family physicians and to foster a collaborative working style between the local Diabetes Education Centre and key family physicians in the community. The program was developed under the auspices of the Canadian Diabetes Association and the Association Diabète du Québec with support from industry. A needs assessment supported addressing practical management issues in the care of the patient with diabetes. A 20 module manual was developed highlighting different aspects of diabetes management, with 10 modules considered "core". A handbook for the team teaching the program was developed, but the method of teaching was left to the discretion of the local group. It was expected that the local endocrinologist or other interested physician, the nurse educator and the dietitian would teach the program together. Three Diabetes Education Centres in various settings, ie teaching hospital, small urban setting were asked to pilot the program. Some centres indicated some difficulty in deciding who was to teach what and how to team teach when the participants were physicians and some of the teachers were not. The participants and the team teaching the program were asked for evaluations. Results of the pilot programs showed that more information was needed on nutrition and some refinement of the insulin initiation module was needed. The participants indicated an increased respect or trust in the Diabetes Education Centre and stated that they would refer more patients. Criteria for the selection of centres to host the program were developed. The first roll out of the program in the fall of 1996 resulted in 14 programs across Canada and 115 participants. Interest in the program has been very high, already a waiting list has formed both for new centres as well as for the original centres to repeat. Evaluations are being conducted at the finish of each program and will also be conducted after a 6 month interval. Results of these evaluations will be discussed in the presentation as well as the use of this program material in other related areas. Early results indicate that this program will be successful in addressing the education needs of family practitioners as well as encouraging better collaboration with the Diabetes Education Centres.

2432

DIABETES EDUCATORS TRAINING : INDONESIAN EXPERIENCE,

Sidartawan Soegondo*, Imam Subekti*, Soesilowati Soerachmad*, Aris Wibudi, Slamet Suyono*. * : Diabetes and Lipid Center, Faculty of Medicine, University of Indonesia/Ciptomangunkumo Hospital, ** : Sumber Waras Hospital, Jakarta. *** : Ridwan Meuraksa Military Hospital, Jakarta.**

Estimated Indonesian diabetic population in the year of 2020 will be up to 4 million, while there will be only 40 endocrinologists. As an anticipation of the forthcoming problems, Diabetes and Lipid Center through its Diabetes Information Center in Jakarta has conducted the diabetes educator trainings in 1992 and every year there after, and holding to the theme : *trying to live as a diabetic*. The first training was attended by 18 doctors, 19 nurses, 13 dietitians and 3 lay people from 20 hospitals. The hospitals are only allowed to send their participants to this training as one team. This course consisted of lectures, workshops, role play, learning by doing , case studies, problem solving and interactive learning. The system used in this course is a modification of the Steno Diabetes Center Course in Diabetology, education material given are modification of the DTTP program of Prof. Berger , Dusseldorf and Body Link from Australia. The second basic and the first advance courses in 1995 were co-sponsored by The Education Foundation of the IDF with participation of 14 specialists,17 GP's, 19 nurses, 18 dieticians, from 28 hospitals and 19 cities. The 3rd basic course in 1996 was held together with the 2nd advance course with 28 doctors , 30 nurses, 23 dietitians, 2 from pharmaceutical companies, from 31 hospitals (12 cities). All together there are now : 87 doctors, 100 nurses, 61 dietitians and 5 lay people , from 61 hospitals scatered in 23 cities in 15 provinces (from 27 provinces in Indonesia). At this moment some of these educators are doing their work in special diabetes education clinics. In Jakarta itself there are now 12 diabetes education clinics . The activities of these clinics will be reported in more detail.

2433

DIABETES MINI-RESIDENCY FOR HEALTH PROFESSIONALS: EFFECT ON KNOWLEDGE, ATTITUDES AND BEHAVIOR CHANGE. K. Berkowitz, L. Anderson, R. Panayioto, D. Ziemer and D. Gallina. Grady Health System, Emory University, Centers for Disease Control, Atlanta, GA, USA.

The aim of this study is to assess the impact of a diabetes mini-residency for health professionals on knowledge, attitudes and behavior change toward diabetes and its treatment. The one-week mini-residency is held in the Grady Health System Diabetes Unit in Atlanta, Georgia. The format includes lectures, interactive sessions, and case study presentations. There are 3 hours of clinical observation with diabetes team members, including nurses, dietitians, podiatrists and inpatient educators. Over the 13 month study period, 125 health professionals completed pre- and post-test questionnaires (79%) assessing knowledge and attitudes. Participants were asked to write 3 self-behavior change goals to be implemented into their practice within a 3 month period. Knowledge was assessed by a 40-item multiple choice questionnaire designed to reflect the content of the course. Attitudes toward diabetes and its treatment were measured by five subscales of the Diabetes Attitude Scale which assess attitudes toward: need for special training (α =.80), control and complications (α =.55), patient autonomy (α =.58), team care (α =.77), and impact of diabetes on patients lives (α =.59). Differences were found in pre-post knowledge scores (26.2 vs. 34.2, $P < .0001$). Attitudes were more positive after the course for each of the following subscales: need for special training, patient autonomy and team care ($P < .0001$), with a positive trend for the control and complications scale ($P < .02$). Most behavior change goals were in the areas of education (53%) or diabetes management (36%). Forty six percent of participants reported their 3 month goal completion; 67% of goals were > 50% achieved. Many goals were unrealistic, represented multiple goals or were unmeasurable. This study demonstrates that attitudes can become more positive after a mini-residency. Whether such changes will translate into behavior changes is not known and will need further study. Goal setting is not intuitive and may require structured training.

2434

DIABETES SELF-CARE REGIMEN SIMULATION AS A COMPONENT OF HEALTH PROFESSIONAL TRAINING. *BP Brackenridge, Learning Prescriptions, Phoenix, Arizona, USA.*

In caring for patients with diabetes, professionals make many recommendations for daily living. Although the recommended actions are known to be helpful in controlling diabetes, patients often do not implement the advice they receive. Although extensive research in the behavioral sciences describes a variety of reasons for such behavior, many health care providers persist in characterizing such "noncompliance" as a failure on the patient's part. Such "blaming of the patient" is not productive and may impair the health professional's ability to enter into a respectful therapeutic alliance with the patient. To help professionals gain insight into some of the practical and human reasons behind regimen nonadherence, the author includes a simulated diabetes self-care regimen in the educational design of an international training program which she conducts. Based on principles of experiential and discovery learning, the regimen simulation requires professionals to follow a diabetes meal plan, take three saline injections and four blood glucose tests daily, exercise, and keep a self-care record for a period of three days. Adherence data for 1015 professionals who have taken part in the simulation are comparable to adherence data reported for diabetes patients. The simulation impacts diabetes-related attitudes of participants, as measured by a sub-set of questions from the Michigan Diabetes Research and Training Center's Diabetes Attitude Survey for Professionals.

2435

DIABETOLOGIC IN-SERVICE EDUCATION FOR HEALTH PROFESSIONALS OF NON-DIABETOLOGICAL WARDS. E. Schipani, A. Piaggesi, F. Campi, F. Baccetti and R. Navalesi. Cattedra di Malattie del Metabolismo, Università di Pisa, Pisa, Italy.

To test the efficacy of in-service requalification interventions, we carried out a course on general knowledge on diabetes (GKD), bedside monitoring of blood glucose (BMG), insulin preparation and administration (IPA), diagnosis and treatment of hypoglycemic crises (DTH), hospitalization-related problems (HRP), to 171 health professionals (HP) of non-diabetological departments of our hospital. Knowledge before and after the course was evaluated with a multiple-choice questionnaire, while skills were evaluated with specific operational checklists. HP were compared with a group of non-trained colleagues (CG). Global knowledge on diabetes after the course, gathered from the percentages of correct answers in each questionnaire, significantly improved (61.82±23.64% vs 31.18±20.00%; $p<0.001$); separated analysis of different areas evidentiated improvements in GKD ($p<0.01$), BMG ($p<0.01$), IPA ($p<0.05$), and DTH ($p<0.05$), but not in HRP. Professional skills profiles of HP were significantly ($p<0.001$) better than those of CG, for BMG, IPA and DHT. Linear regression evidentiated a significant ($p<0.001$) correlation of skills and knowledge after the course either for BMG ($r2 = .49$), IPA ($r2 = .53$) and DTH ($r2 = .61$). The course produced a significant improvement of knowledge and skills on specific diabetologic items among participants.

2436

DOCTORS & STUDENTS KNOWLEDGE ABOUT DIABETES MELLITUS. D.J.S. Fernando, Colombo Medical Faculty, Sri Lanka.

We determined the level of knowledge on diabetes mellitus among final year medical students non specialist hospital doctors and general preactitioners from the Faculty of medicine, Colombo, National Hospital Sri Lanka, College of General Pratitioners of Sri Lanka. 120 randomly selected final year medical students (group A), 90 non specialist hospital doctors from the outpatient department and diabetic clinics (group B) and 80 general practitioners who attended a CME meeting (group C). A previously validated MCQ paper of 10 questions which assessed knowledge of diabetes on diagnosis, management, insulin therapy, dietery advice screening for complications management during acute illness and management of emergencies was administered to all subjects. The mean score were 53% SD 12.3 for A, 51% SD 14.3 for B and 52.3% SD 10.7 for C. Deficiencies were shown in diagnosis (34%A, 30%B, 40%C), management of non insulin dependent diabetes (35%A, 40%B and 45%C), Management during an acute illness (50%A, 58%B, and 54%C), Insulin therapy (59%A, 65%B, 60%C), Use of oral hypoglycaemics (45%A, 60%B and 55%C). Medical students had one lecture on diabetes in their 3rd year. Medical officers had no in service CME while general practitioners had attended lectures on diabetes sponsored by pharmaceutical industry. Knowledge required to manage diabetes mellitus is inadequate among medical students, hospital doctors and general practitioners.

2437

INJECTION-MEAL-INTERVAL: WHAT DO DIABETOLOGISTS RECOMMEND TO THEIR PATIENTS?

H. Overmann and L. Heinemann; Dept. of Metabolic Diseases and Nutrition, Heinrich-Heine-University Düsseldorf, Germany

In order to evaluate which suggestions diabetologists gave their patients regarding handling of the injection-meal-interval (IMI), we submitted a single-page questionnaire to the 72 hospitals organised in the "Working Group Structured Diabetes Therapy" in Germany. 55 (77 %) of the hospitals responded. In 16 hospitals (29 %) patients were recommended to keep a fixed IMI of 15 (0, 30) min (median (range)). The recommended minimal IMI was 0 (-10, 15) min and the maximal IMI 45 (20, 60) min. In the other 39 hospitals (71 %) patients were trained to use a flexible IMI. The suggested limits for the IMI was a minimal interval of 0 (-30, 15) min and a maximal of 45 (15, 120) min. The conditions influencing the length of the chosen time interval were evaluated by crossing: pre-prandial glycaemia 95 % YES/3 % NO, time of day 41 % YES/59 % NO, physical exercise 51 % YES/49 % NO, amount and type of meal 75 % YES/25 % NO, situation 85 % YES/15 % NO. In 18 (32 %) of the 55 hospitals a differentiation between patients with diabetes mellitus type I and type II with respect to the IMI was done. Answers to the question: "From which source do you have your information about the IMI?" were: literature 64 %, colleagues 56 %, textbooks 53 % and original articles 24 %. In 45 questionnaires other sources or comments were mentioned, "own experience" was named 24 times (53 %) and experience of the patients 9 times (20 %). This study shows, that the recommendations of experienced diabetologists regarding the injection-meal interval vary considerably.

2438

ASSESSMENT OF BASIC KNOWLEDGE RELATED TO THE MANAGEMENT OF DIABETES AMONG GENERAL NURSING STAFF (GNS).

Setia S, Shah P, All India Inst of Med. Sc., New Delhi, INDIA.

We observed that inadequate knowledge among general nursing staff (GNS) could explain a considerable number of problems related to the management of diabetes. To assess the knowledge of one of the premier hospital's GNS, we administered a questionnaire to 94 nurses. Only 39% of the nurses felt that they were confident in judging the type of diabetes, 39% whether patient needs insulin life long and, 47% regarding insulin formulations with different concentrations. 67%, 57% and 53% felt they were confident about their knowledge regarding type of insulin (according to the duration of actions), different syringe scales and diagnosis of hypoglycaemia (HG) respectively. However, only 31/94 stated that they could treat a patient having HG very confidently by themselves and only 2/31 knew the proper management of a patient found in the state of severe HG (unconscious). 56/94 thought they knew well how to prevent HG but 25 of these 56 subjects indicated inappropriate management of a diabetic who vomited immediately after insulin and food. 31%, 41%, 45% and 91% of the nurses felt: insulin should not be injected by diabetics themselves, should not be injected in adipose tissue, plain and lente insulin should not be mixed and patient should take meal immediately (no gap) after insulin injection.

Conclusions: A large section of general nursing staff have inadequate information and ill founded confidence regarding diabetes management issues. Continued medical education of nursing staff regarding diabetes management is urgently required.

2439

PERCEPTION AND KNOWLEDGE OF DIABETES MELLITUS AMONG NURSES WORKING IN A GENERAL HOSPITAL

M. Millán, MT Valverde, L. García-Pascual, F Urbano, S. Cano, E. Esquius and M. Balsells. Hospital Mútua Terrassa (Spain).

Nurses play a key role in providing education for individuals with diabetes (DM). This study was conducted in order to assess perception and knowledge of DM among nurses of our Centre. With permission from the authors (Drass et al,Diabetes Care, 1989), three adapted (translation and back translation) questionnaires: Demographic data (DQ), Perception (PQ) and Basic DM Knowledge (DKQ) were distributed to nurses who voluntarily participated in the study. The Centre is a 575-bed teaching hospital. An average 20% of inpatients admitted have the diagnosis of DM. The questionnaires were answered by 131 out of 320 (43%) staff nurses, 45% of them reported having attended a DM trainning course at least once, 37.8% had a family member or friend with DM and 46.5% felt themselves competent in caring for diabetic patients. DKQ was score 24.4±8 (54% correct). DKQ score was better in nurses working in the Endocrinology ward and those having a family member or friend with DM. DKQ score was not realted to previous attendance to a DM trainning course ($p<0.05$). Perceived and actual knowledge of DM were positively related ($r=0.37$; $p<0.01$). The study revealed that knowledge of DM among nurses of this Centre: needs to be improved although, its perception is satisfactory. Furthermore, these results, could be helpful in designing appropriate trainning programmes.

2440

INSTRUCTING NURSES ABOUT DIABETOLOGY

M.L. Martí[(1)], Z. Stolarza [(2)], C.A. Markmann [(3)], D. Fox [(3)] and S. Lapertosa. [(1)] University of Bs.As., [(2)] H. Francés, [(3)] H. María Curie. Buenos Aires, Argentina.

178 Nurses were evaluated pre and post two days course about physiology, physiopathology, clinics and therapy of Diabetes Mellitus performed at Buenos Aires City and Corrientes City (Argentina). A multiple choice questionnary was given to them. The questionnary was the same pre and post course and contained 15 questions: 5 about Physiology and Physiopathology, 5 about Clinics and 5 about Treatment. Each good answer gave 1 point for the evaluation score. Statistical analysis was performed through T student test. The punctuation media at the pre-course evaluation was 11.77 and 41% of the students answered at least 13 questions. The punctuation media post-course was 12.77 but 65.1% of the students answered at least 13 questions. The difference between these two figures was statistically significant ($P < 0.001$). A high proportion of bad answers in the pre-course evaluation was in those questions about therapy. In two Argentine cities, the two days course for instructing nurses about Diabetology seems to be good in the sense of improving knowledge on Diabetes Mellitus. Therapeutical aspects must be focused specially.

2441

IMPACT IN THE MANAGEMENT OF D.M. TYPE II AMBULATORY PATIENTES BY A MULTIDISCLIPLINARY HEALTH TEAM.

D.Gonzalez-Barcena, A.Correa, A.Ibarra, A. Muñoz and M.Jimenez. Hosp. Esp. Centro Medico La Raza. IMSS Mexico D.F. (02990).

In the northeastern region of Mexico City the Mexican Institute of Social Security (IMSS) during six months in 1996 registered 23,216 patients with Diabetes Mellitus type II. With the object to implement the ambulatory management of Diabetes a team of Health Care Professionals (25 Family-Physicians, 22 Nurses, 21 Social-workers, and 9 Dietitians) was integrated, from 11 Medical Family Clinics of this area belongs to IMSS who were motived for the treatment of diabetic patients. After obtaining a consensus of the team about D.M. concepts and treatment. a group of 2036 ambulatory diabetic patients were selected; All of them with no more than 5 years of diagnosis, with persistent hyperglucemia in spite to eleveted glibenclamide and/or insulin administration. All patients recieved individual education in DM (diet, exercise, drugs, complicactions, etc) and were follow-up every week during two months in each clinic.A total of 1976 patients were able to evaluated at 2 mo showed excelent metabolic control and minimal doses of hypoglycemiant or insulin. Results:

	0	2 months	
FBS	237	122	
(mg/dl)	n=1976	n=1976	
Glibenclamide	25	7.5	0
(mg/day)	(n=1973)	(n=667)	(n=1126)
Insulin	35	20	0
(U/day)	(n=183)	(n=102)	(n=81)
Hb1Ac (%)	9.41	7.72	

These patients have been follow-up by 8 months and maintened this good control. These results emphasize the importance and the benefit of the multidiciplinary team for managment of DMII.

DIABETES WORKSHOP FOR FAMILY PHYSICIANS

PRASANNA KUMAR K M, MALA DHARMALINGAM, ARAVIND S R, AND MUNICHOODAPPA C. M.S.R.MEDICAL COLLEGE , BANGALORE.India

AIM : TO CONDUCT DIABETES WORKSHOP TO IMPART MANAGEMENT SKILLS AND FORMULATE AN IDEAL PROGRAMME FOR DIABETIC WORKSHOP IN FUTURE.

MATERIALS AND METHODS : 5 diabetes workshops were held in different parts of Karnataka a South Indian State and interested family physicians registered in the year 1995 - 96. The workshop was for 2 days over the week end covering all topics of practical importance like OHA, Insulins, Monitoring, Diet & Exercise as group discussions and Etiology and classification, complications, pregnancy and diabetes as lectures. The knowledge was imparted by diabetologists and related specialists. The workshop initially consisted of 3 lectures and 7 group discussions. A pre post assesment were done and impression regarding workshop documented. The mean pre assesment mark 51.7% $\pm$ 14.4 and post assesment was 61.4% $\pm$ 17.4, T=2,995, DF=48,(P<0.001) Impression regarding the workshop 74% prefered group discussions 87% opined duration was ideal while 11% opined duration is short. All participants opined that content and arrangement was good.
The ideal number of deligates for a workshop should be 30-40 group discussion should be more ideal duration should be 1 1/2 days over the week end. This type of workshop increase level of knowledge in diabetes among family physicians.

2443

Nursing staff's understanding of diabetes in Northeast Zaire.

J.T. Burdon. Centre Médical Evangelique, Nyankunde, Zaire.

Diabetes is an important medical problem seen at the Centre Médical Evangelique (CME) accounting for up to 5% of all adult medical admissions to the hospital. It is the nursing staff who are responsible for the initial diagnosis, treatment and daily supervision of these patients. In order to improve the quality of care CME offers patients with diabetes a questionnaire was sent to all 70 nurses employed at the hospital to assess their level of understanding about diabetes. 41 (59%) nurses returned a completed questionnaire. 36 (88%) understood diabetes to be a disorder of glucose metabolism but only 23 (56%) knew the normal range for blood glucose. Knowledge of the clinical features of hyperglycaemia, hypoglycaemia and severe ketoacidosis was generally poor. The majority of respondants understood that long-standing diabetes can compromise the eyes and cardiovascular system but knowledge of other complications was poor. There was a significent minority (34%) of respondants who considered that traditional/local medicine may be able to provide a permanent cure for diabetes. Knowledge of the various treatment options was good e.g 68% of respondants could give appropriate advice on a diabetic diet; but no respondant could provide a satisfactory treatment plan for the management of severe ketoacidosis. The majority (61%) of respondants considered diabetes a difficult condition to treat. Many of the nurses working in Northeast Zaire have been trained at the nursing school linked to CME and the responses generated by this survey probably reflect the level of healthcare received by many diabetic patients in the region. This survey shows the need for continuing medical education for nursing staff at CME and in the region if the level of care for diabetic patients is to be improved in Northeast Zaire. Of particular concern is the poor understanding of the treatment of severe ketoacidosis. This complication carries a high mortality in Africa and although lack of resources may be partly to blame this study suggests that a lack of education of the health-care team may also play a role. The introduction of standard treatment plans for ketoacidosis may help to improve the management of this complication.

EDUCATED P.H.C. TEAMS - THE BASIS FOR SUCCESSFUL DIABETES TREATMENT

Prašek M, Pavlić-Renar I, Pibernik-Okanović M, Rogić M, Metelko Ž. Vuk Vrhovac Institute for Diabetes, Endocrinology and Metabolic Diseases.

For the past 3 years we have been organizing continuous education courses for primary health care physicians and registered nurses. The courses have been held twice a year, whereas in 1996 they are held 4 times a year, due to increased interest. An examination board of the Medical Faculty administers exams for the course participants, who then obtain a no.1 category licence for autonomous follow-up of NIDDM patients. The courses include lectures and round-table discussions, and practical work with a diabetes care team. Training of educators is carried out through work with small groups by means of meta-plan system and patient interviews. The training programme also includes the acquisition of skills required for self-monitoring and administration of pen injections. Since 1993, 172 primary care physicians and nurses from Croatia have completed the course. The final exam consists of both oral and written (test of 20 questions) form, together with comments on three examples of self-monitoring diaries. The results of the courses of continuous medical education are the active involvement of primary care physicians in the follow-up of NIDDM patients, founding of 22 new clubs of diabetic patients and the organization of educational courses for NIDDM patients in each GP team.

CHILDRENS KNOWLEDGE OF DIABETES. AGE-RELATED GOALS, GUIDELINES AND EVALUATION METHODS.

L.Povlsen, K.Dyrløv, B.Iversen, M. Pramming and S. Sander. Paediatric Department, Glostrup County Hospital, Copenhagen, Denmark.

It is essential, that children with diabetes are ensured a continual learning process, adjusted and adapted to educational level, abilities and psychological development. This gives probability for improvement in the childs accept and regulation, thereby creating an increased quality of life, despite diabetes. The purpose of the present study is to define age-related goals for both practical abilities and knowledge of diabetes for children and young people, aged between 6 and 17 years. The investigation is undertaken by an interdisciplinary team consisting of teachers, psychologist and diabetes nurse specialists, attached to the childrens department. Detailed guidance material has been made for both children and parents to show, how the practical responsibility and theoretical insight in diabetes can gradually be transferred to the child. Furthermore the objectives have been used to develop an interview guide to ensure a broad evaluation of the knowledge and practice of the children. The evaluation is carried out from a structured interview by the teachers, while the family is informed of the results by the diabetic nurse specialists, who also assess the need for further teaching activities. A pre-pilot investigation was carried out with 10 children. The preliminary results generally show, that most children have adequate knowledge of diabetes, but that the material provides a good instrument to reveal areas, where there is a further need for teaching.

2446

BEHAVIORAL MEDICAL TREATMENT IN NIDDM IS MORE EFECTIVE THAN AN EDUCATIONAL PROGRAM: RESULTS OF A RANDOMIZED TRIAL

K.H. Bergis, B.Kulzer, P. Imhof, N. Hermanns and H. Reinecker[2].Diabetes-Akademie Bad Mergentheim (FIDAM), [2] Universität Bamberg, Bad Mergentheim, Germany

Objective: In a randomized, prospective trial (MEDIAS II), sponsered by the German department for research and technology (BMFT, now BMFB), we testet, whether two newly developed behavioral medical programs are more effective than an evaluated structured treatment and teaching program for NIDDM (Group A; 4 lessons) on hyperglycemia, dyslipoprotinea and obesity. The behavioral medical programs were designed to enhance selfmanagement abilities to cope with the demands of the diabetes treatment (eating behavior, physical activity, home monitoring of urine glucose, diabetic foot care). One of the two treatments was performed as a group-treatment (Group B, 12 lessons), whereas the other program (Group C; 12 lessons) was designed to individualise the therapeutical approach by six single lessons. **Methods:** 193 type II diabetes patients were recruited, fulfilling following criteria (age 40 - 65 years, no insulin treatment, stimulated C-peptide >0,8 nmol/l; BMI > 26,7 kg/m²; no known psychiatric diagnosis, no cognitive impairment). These patients (age: 55,6 ± 6,3 years; diabetes duration 6,6 ± 6,2 years; BMI 32,1 ± 3,9 kg/m²) were randomised. At baseline (t1) i.e. glycemic control (GHb), triglycerides, total cholesterol, HDL-cholesterol and body weight were determined. The crucial evaluation (t5) was the course of these parameters 15 months after baseline.176 patients could be examined at t5 (drop-out rate 8,8%). **Results**:

Parameter	Group A		Group B		Group C	
	t1	t5	t1	t5	t1	t5
GHb %*	9,5 ± 2,5	9,7 ± 2,4	10,3 ± 2,7	9,3 ± 2,9	9,9 ± 2,4	9,5 ± 2,3
Triglyc. mg/dl*	207 ± 131	225 ± 150	206 ± 122	181 ± 102	207 ± 101	203 ± 190
Chol. mg/dl	231 ± 43	230 ± 39	233 ± 45	225 ± 42	237 ± 50	230 ± 37
HDL mg/dl	47,7 ± 14	45,4 ± 14	50,5 ± 22	47,4 ± 11	47 ± 12	44 ± 11
BMI kg/m²*	32 ± 3,5	31,5 ± 3,9	31,8 ± 3,9	30,9 ± 3,6	32,7 ± 4,2	31,9 ± 4,2

*Significant differences (<.05) between group A and B; no significant differences between group B and C (T-Tests or Man-Whitney-Test). **Conclusion**: The study demonstrated that a selfmanagement orientated behavioral medical approach (group B) is significantly more successful regarding the improvement of glycemic control, triglycerides and obesity than the educational program (Group A). Surprisingly a more indivualised approach (group C) had no further advantage.

2447

EDUCATIONAL METHODOLOGIES: AN ANALYSIS OF CHAOS
A 10 YEARS REVIEW OF PATIENT EDUCATION LITTERATURE

S. Jacquemet, M. Grazia-Albano, Ph. Sudre, J-Ph. Assal
Division of Therapeutic Education for Chronic Diseases, Geneva University Hospital - Switzerland

Rationale: The therapeutic role of patient education has been widely documented in chronic diseases in general and diabetes in particular. Despite the awarness, limited progress is made in the field of educational methodologies and implementation of patient education programmes in diabetes care. We were interested to review papers dealing with patient education and to analyse which educational methods were described. **Methods:** We investigated a period of 10 years (1986-1996) using MedLine. *Key-words* were 1-«Patient Education (PE)», 2-«Diabetes Mellitus (DM)» and 3-«Randomised Trial (RT)». **Results:** A total of 9'111 articles were found on PE out of which 964 were on DM and PE (11%). A total of 57'400 were dealing with DM out of which 964 were on DM and PE (2%). Samples from the 964 DM and PE were taken: they spoke mainly about general concepts and role of education and its effect. We therefore tryed to analyse the studies which were structured in a scientific way and used the key-words [«Randomised Trial (RT)» and DM and PE]. Out of the total 964 papers on DM-PE, only 49 were RT (5%). Out of those randomised trials, 12 (25%) did not describe the randomisation. We therefore selected the 37 remaining papers where RT was clearly presented and analysed which educational methodologies was described: *no paper* described a meaningful and pertinent educational methodology used by the autors. Papers came from a total of 25 different medical journals out of which 14 (56%) used reviewers. Finally 2/3 of papers showed a positive effect of patient education, 1/3 of autors could not show any effect. **Conclusions:** 1-Diabetes is not any more the leading disease for patient education (11% of papers on PE). 2-In the field of diabetes research only 2% of papers deal with PE. 3-There is a dramatic absence of description of precise educational methodologies even in papers with scientific reviewers... This situation has urgently to be improved in order to analyse which educational methodologies are responsible for the outcome either positive or negative of those clinical studies. Therapeutic education deserves the same scientific methodological approach as that used for the study of any pharmacological agent.

2448

ALTERNATIVES TO ENHANCE SURVIVAL SKILL'S KNOWLEDGE

F. Nieves-Rivera, L. González-Pijem and L.N. Navarro. UPR, School of Medicine, San Juan, Puerto Rico.

In 1993 the need to explore alternatives to enhance diabetes education became one of our priorities. We developed a revised diabetes survival skill's program which consisted of 1-2 hours/day/wk sessions with audiovisuals. Among the skills covered by this program were: diabetes pathophysiology (DP), injection technique (IT), insulin kinetics (IK), glucose (GM) and ketone monitoring (KM), sick-days management (SDM), glycated hemoglobin (A_{1c}), and hypoglycemia (HYPO). A questionnaire was developed to ascertain for changes these interventions may have made. The latter was mailed to 143 patients with IDDM followed at the University Pediatric Hospital Diabetes Clinic between 1976-96. The data were grouped in patients diagnosed before 1993 with their parents (G-I) and those diagnosed afterwards (G-II). At the time of this submission 20 families have returned (12 in G-I and 8 in G-II) the questionnaire. Of these, we found: 74% of G-I answered correctly the GM questions *vs* 87% from G-II, both groups answered (100%) correctly questions about KM and IT, ≈ 1/2 answered correctly the SDM questions (58% and 62%, G-I and -II), questions regarding IK were answered correctly in 72% of G-I *vs* 68% of G-II, 92% of G-I and 88% of G-II answered correctly questions about DP, questions about A_{1c} were answered correctly by 88% from G-I but 69% of G-II, the lowest percentage was obtained for HYPO management where 17% of G-I and 25% of G-II answered correctly. In summary, patients diagnosed after 1993 and their parents, followed in our clinics, have continued accruing survival skill's knowledge as before. There was persistent lack of knowledge in hypoglycemia and sick-day management. We conclude that a more extensive survey is warranted to ascertain if above results can be extended throughout the population followed.

2449

EDUCATING DIABETIC PATIENTS: THE HAITIAN EXPERIENCE

N. Charles-Larco, Fhadimac, Port-au-Prince, Haiti

Diabetes can not be well controlled without education. Everywhere, educational programs are established to inform diabetic patients and their relatives. However, if the program is not adapted to the local customs and tabous, the goal of prevention and good control will never be reached. At Fhadimac, we have started an educational program since 1989 where the information is delivered daily in creole (language used by all Haitians) by a trained nurse, using posters adapted to the haitian reality, and person-to-person mean of communication for illiterate patients. The diabetics admitted to our popular clinic must attend all the classes and are periodically reevaluated on their knowledge. Well-trained patients inform others during group sessions. The final objective is to take away and diminish the impact of some of the ancestral concepts of our culture like the one of chronic diseases that doesn't exist. The patient doesn't know that he has the most important role in the good control of his diabetes. Furthermore, Diabetes at an early stage is silent, painless and doesnt render the patient inactive. Therefore the patient doesn't see any reason to refrain his urges. In conclusion, these methods of education are very demanding and ask for a constant and adapted follow-up; however the results are longlasting and efficient because we have seen a decrease in acute complications in patients coming to Fhadimac.

2450

EDUCATION CAPS CONTRIBUTION FOR YOUNG DIABETICS LIFE

A. ABID, S. BLOUZA, F.AENNABI, K. KHELIFI, A. BEN MANSOUR and K. NAGATI

TUNISIAN ASSOCIATION (ATD), Tunis, TUNISIA.

The aim of this study is show the education effect on young diabetic behaviour and life. It concerned two young diabetic groups controlled in the same clinical center (INN) group I (n=41) educated in ATD young diabetic caps and group II (n=59) did not recieve this structured education. The mean age and diabetes duration are respectively 14.1 ± 3.4 and 5.3 ± 3.4 in group I and 13.4 ± 5.4 and 2.9 ± 3.0 in group II. Our results show that patient knowledges according diet and self monitoring are significatively better in groupI than in group II. Patients in group I perform more frequently self urinary (85.5 %) and blood glucose monitoring (19.5 %) than patients in group II (55.9 % , 6.7 %) $p < 0.0001$. They adapt better there insulin doses (75.6 %) and take more regularly their monitoring note book (68.0 %) than patients in group II (38.0 % , 44.0 %) $p < 0.0001$. The mean hospitalization number and duration were significatively reduced in group I (3.0 ± 2.1 , 23.4 ± 13.9 days) compared to group II (8.6 ± 2.6 , 107.5 ± 53.3 days) $p < 10^{-5}$, $p < 10^{-7}$,delayed statural growth decreased from 40.6 % to 26.0 % in group I and increased from 33.3 % to 53.3 % in group II (p=0.04). School success is better in group I than in grou II. These results indicate that education improves diabetes control, self monitoring quality, statural growth and reduces the duration of hospitalisation and fees and regularly fill in their note book (68.0 %).

2451

Evaluation of Out-patient Group Consultation for Children and Teenagers with Diabetes and Their Parents.

Doctor Agne Lindh, dietician Carina Samuelsson, diabetes-nurse Annica Wiik, Childrens- and youthclinic, Borås Hospital, Sweden

Backgroud: Since 1992 we carry on with outpatient group consultation in our clinic. The aim is that the families meet eachother and learn from eachother. Each time we talk about different subjects in order to gradually build up the knowledge of diabetes. We have done this evaluation to find out if this consulting is a good pedagogic method to pick up knowledge about diabetes.

Method: 52 children/teenagers participated in this evaluation. Together with Bengt Pettersson (educationist from the University of Gothemburg) we constructed a questionnaire with 17 questions. In the questionnaire we had medical, practical and dietquestions. If the children´s age was less than 7 years the parents filled in the form. If the children were between 7 and 12 years the children and parents together filled in the form. The teenagers filled in the form by themselves. The children and parents have without preparation filled in the form at two occasions. The first occasion was directly before group consultation and the second occasion was 3-5 months later at an ordinary visit. We gave the answers of the questions on the group consultation by playing a game.

Results: We found that the knowledge of diabetes was high from the beginning. 62% of the participants got a better result at the second test compared to the first. The families had the highest score on the practical questions, secondly the medical questions and thirdly the dietquestions. The result of the study indicates that outpatient group consultation is an useful method to pick up knowledge about diabetes.

2452

Club activity experience in motivating teenagers, suffering from diabetes,for study.

N.Goustova, Moscow Diabete Assotiation, Fund "Yours", Moscow, Russia.

The aim of program: to imprjve live of teenagers suffering from diabetes.
Participants: 30 teenagers and young people aged 14-20.
Duration of the program: 1 year, steps of the program - monthly.
The way of realization of the program:
- collective and individual meeting on diabetes control with an instructor of the program (doctor - diabetologist),
- execution of constant self-control along with keeping a self-control register,
- games, compeninions and tests in diabetes issues.
Results of the program:
-Kept self-control register befor participation in the competition-77%
constantly - 43% from time to time - 57%
-Keeping self-control register after participanion in the program-91%
constantly - 48% from time to time - 52%
-Participanion in the competition improved my life - 75%
-Improved their competence in diabetes issues - 51%
-Received additional information - 67%
-Would like to participate in continuation of the program - 75%

2453

Diabetology Course for Students in their last year of Medical School

Bragagnolo Julio C., Traversa Mercedes. División Diabetología
Hospital de Clínicas "José de San Martín". Buenos Aires, Argentina.

To improve the diagnostic and therapeutical approach on diabetic patients of the next medical school graduates, we set the following special goals: 1) To extend the knowledge of diabetes to students in their last year of medical school, offering a nonobligatory course. 2) To establish, by means of a pre- and post-course evaluation, the impact of this diabetology course on the acquisition of new information. The course was attended by 108 students, evaluated before and after each diabetology course, developed in 1995 and 1996. The program included: diagnosis of Diabetes Mellitus, methods of metabolic control (self-monitoring, laboratory), management of the Oral Antidiabetic Agents, management of insulin in IDDM and NIDDM, management of acute complications, detection of chronic complications. It was a two-day course. Pedagogical resources applied were 20-minute information presentations for descriptive programs, and dynamic approach Workshops, encouraging participation by the presentation and the resolution of prevalent clinical cases in diabetological practice. The same evaluation method was applied before and after each course. It consisted of a multiple choice and semistructured questionnaire with 11 questions: 4 on diagnosis, 2 on NIDDM therapy, 2 on IDDM therapy, 1 on acute complications, 2 on chronic complications. The general average of correct answers was 56 % before the course and 74 % afterwards, with a statistically significant difference of $p < 0.003$ (paired samples t-test). These results suggest the need to emphasize the development of diabetology programs intended for medical students, as an essential complement of the study program, apparently insufficient for the currently required approach to the care of diabetic patients.

2454

Educational and Support Groups for Type II Diabetes

J. Diamond and T. Lavie, Maccabi Health Fund, Herzlia Israel.

The goal of such groups is to improve self-management skills in Type II diabetes Type II diabetes is a chronic disease requiring life-style changes as the foundation of all treatment. Most patients are treated by a primary physician, who usually doesn't have the time or specialised knowledge to deal with life-style changes such as dietary discipline, the importance of physical activity, foot care, etc. Coming to terms with a way of life that has daily limitations is a constant battle and the emotional needs must be given on-going support. Maccabi's National Diabetic Centre has written a program for group support and education. Each course has six two-hour sessions and is counselled by a diabetic educator or nurse and a dietician, allowing adequate time for discussion. During the past two years, seven groups have taken place, including 80 participants, in the Herzlia Diebetic Centre. The following results are from 30 participants taken from the first four groups: Average HbA1 was 10.76% (4-7%) before the course and dropped to 9.42% after a period of between 6-12 months. 42% of all participants were exercising before the course and it rosé to 75% on follow-up, 6-12 months later. 25% of participants smoked before the course and after 6-12 months, only 17% continued to smoke. 47% lost weight on follow-up. A questionnaire given at the end of the course showed participant satisfaction and 80% expressed that the course was a help to them in managing their diabetes. A renewed sense of confidence motivated them to consider the importance of life-style changes. 98% agreed that they would recommend the course to a diabetic friend. Group meetings for diabetics are an important tool in meeting the emotional needs of living with a chronic disease. The use of guided discussions, allowing integration of theoretical material, must be applied by the educators. Flexibility and assessment must be used in order to determine to what extent the academic material is being understood, thus allowing necessary changes in the program.

2455

CHEF COMPETITIONS - AN INITIATIVE TO COMBINE HEALTHY EATING PRINCIPLES WITH FINE DINING.

J.Stockdill, K.Hegan, J.Duff and K.Brouard. Diabetes Life Education, Public Health Service, Healthlink South, Christchurch, New Zealand.

Recent consumer trends are to choosing foods lower in fat and salt and higher in fibre. People are eating more meals away from home and are dependent on public food establishments for an increasing proportion of their food and nutrition. Eating out often creates a barrier to compliance for those with specific dietary requirements, or those with a desire to follow healthy guidelines when dining away from home.

Diabetes is predicted to affect more than 173,000 New Zealanders by the year 2010 and cardiovascular disease is currently responsible for 44 % of deaths in New Zealand. Almost half of the population is overweight. The authors believed it was time to highlight the need for healthy eating to the industry and to influence hospitality and catering Chefs' attitudes about healthy eating and the methods they prepare food. Creating a supportive environment by making healthy choices easier and more accessible will encourage people to make better choices more consistently and thereby influence their overall health and future disease risk.

A new initiative of Diabetes Life Education in Christchurch, New Zealand, was sponsorship of a Healthy Fare category in the 1996 Canterbury Salon Culinaire. These are annual competitions for Chefs run by the Christchurch Polytechnic and supported by the industry.

On a national level, Diabetes Life Education and the National Heart Foundation of New Zealand co-sponsored a similar event in the 1996 New Zealand Culinary Fare. Participants were required to prepare a main course and sweet that met the criteria of being low in fat, sugar and salt.

This is the first time in New Zealand that health agencies have been involved in such competitions.

Work is proceeding in extending this initiative. Results and outcomes will be presented.

2456

DIABETES "TEACHING GUIDES" VERSUS "MAGAZINES": NEED FOR A DEVELOPING COUNTRY ?

GS.Narayan, AS.Vinaya, MG.Mamatha, BS.Sudha, DV.Rama, S.Krishnamurthi, J.Srikanth, S.Nagabushan, P.Hegde, N.Nagesh, S.Colaco, S.Suresh, P.Ashalakshmi, A.Sharda and SS.Srikanta. Samatvam: Endocrinology Diabetes Center, Bangalore, India.

As part of a non-profit volunteer group involved in diabetes education and care, since 1987 we have continued to improvise and disseminate a variety of low cost self-care health educational materials [cyclostyled leaflets; printed booklets and books; structured diabetes "teaching guides" (a. "Diabetes: the answer is in your hands", 100 pages, English; b. "Diabetes - an introduction" - 14 pages, local languages); quarterly news letter/ "magazine" ("Challenge", 8 pages, English)]. Based on the recipients' (patients and families) responses to our publicational activities, and in comparison with responses to diabetes magazines, books etc., published from time to time by other Indian and International individuals/ organizations, we currently place emphasis predominantly on "teaching guides". The third edition of our teaching guide: (a) has been enriched with full chapters devoted to other, but critically interactive health problems (BP, dyslipidemia, smoking, heart disease, obesity and alcohol), highlighting a "holistic", rather than a "blood sugar" approach to total diabetes care. Simplicity (non-scholarly), clarity of expression, lack of ambiguity/ vagueness in the specified instructions and consistent format are qualities of good educational material. Conclusion: From a socio-economic point of view, inexpensive "teaching guides" (one-time; amenable for mass distribution) are more relevant and utilitarian to the current Indian society, rather than unstructured and fragmented diabetes "magazines" (periodicals).

2457

EDUCATIVE ACTIVITY IN A COMPLEX DIABETOLOGICAL CARE ORGANIZATION: FEASIBILITY OF A DIVERSIFIED INTERVENTION.

A. Girelli, A. Cimino and U.Valentini.
Diabetes Department, Spedali Civili, Brescia, Italy.

Educative intervention needs to be diversified due to the variability of diabetic patient type and the consequent complexity of diabetological care organization. In Brescia, our model provides three different levels of intergrated assistance. 1st level: territorial nurses/GP; 2nd level: diabetological centre; 3rd level: hospital. Aim of this study is to demonstrate the feasibility of a diversified educative intervention in this model of assistance. We report here the 1995 data. 1st level: *receivers:* NID patients in absence of complications, with steady metabolic control; *aim:* diet information (correction of main errors) and feet (prevention of lesions); *operators*: nurses, GP; *methodology*: traditional lessons;3620 interventions. 2nd level: *receivers*: NID, NID obese and ID patients; *general aim*: informative/therapeutic education for specific aims; *operators:* diabetological equipe; *methodology:* traditional lessons and/or interactive didactics; individual or groups; monothematic or courses. 1013 individual interventions; 803 individual diet-therapy interventions; educative group activity (10-15 patients each): monothematic meetings (18 dedicated to foot care; 7 to diet); courses: 6 for NID patients recently diagnosed; 4 for obese NID patients and 4 for NID patients treated with insulin were realized. 3rd level: hospital activity in specific outpatient clinics, in day hospitals and with inpatients. *Receivers*: NID/ID patients at the beginning of disease; NID and ID patients with specific needs; ID adolescent patients transferred from pediatric divisions; pregnant diabetic patients; patients with gestational diabetes; *general aim:* therapeutic education; *operators*: diabetological equipe; *methodology*: single or group interactive didactics. 121 individual interventions; 27 individual courses for ID-NID outpatients; 735 for inpatient and 407 for outpatient alimentary education and diet-therapy interventions; 89 courses for pregnant patients and 6 courses for ID patients were realized. For each intervention (at 2nd and 3rd level) there is a verification (theoretical or practical; with interview and/or questionnaire; evaluation of behaviour; clinical parameters). If, we believe, education is a necessary therapy, it cannot be carried out occasionally or simply because we have sparing time. It is necessary to project management planning of educative activity specific for each reality. Our experience demonstrates the feasibility of a diversified educative intervention in a complex model of diabetological care organization. This model guarantees the realization and permits evaluation of efficent education, satisfying modern criteria for resource rationalization.

A PRESENTATION OF THE NEW SWEDISH BROCHURE
"GOOD FOOD FOR CHILDREN - FOOD FOR CHILDREN WITH DIABETES"

B.Karlström, M.Eliasson and Bengt Vessby. The Nutritional Board of the Swedish Diabetes Association, Stockholm, Sweden.

In 1996 the Nutritional Board of the Swedish Diabetes Association published a new brochure, for children with diabetes, in the age group 1-14 years and their parents. As indicated in the title the message is suitible also for healthy children. The brochure visualises the message how to obtain a balanced diet for children with diabetes in a simple way and consist of 36 pages and about 70 pictures. Headlines included in the brochure are: The plate model, the plate model shows the proportions of foods to include in the main meals. Menus for the three different age groups. What to consider when children have diabetes. Physical activities. What to do when children refuses to eat. Sickness: colds, infection and illnesses.
Foods for pick-nick and parties. Sweets and ice cream.
What is carbohydrate. What to drink. Nutrition labeling.
The brochure ends with about 40 recipes of dishes that Swedish children often appreciate.
The Nutritional Board of the Swedish Diabetes Association hopes that this brochure will be a toool not only in families having children with diabetes but also to other people who will meet these children, i.e. teachers and nursery staff, to increase the knowledge of nutrition and diabetes.

HOW MANY HOURS ARE NEEDED TO TEACH PATIENTS TO MASTER THEIR TREATMENT ? AN INTERNATIONAL SURVEY

S. Jacquemet, A. Maldonato, D. Halimi, J-Ph. Assal
Division of Therapeutic Education for Chronic Diseases, Geneva University Hospital
WHO Collaborating Center - Switzerland

Rationale: Thousands of diabetes centers provide education of patients. Strangely enough even if different curricula are available, no clear data exist regarding the number of teaching hours necessary for therapeutical education of patients. This question is adressed by health care providers (HCP) as well as by health policy makers, medical insurance and hospital administrators. **Methods:** At time of several scientific reunions which all delt with patient education, participants were asked to fill a questionnaire which was asking two questions for type I and type II diabetes: how many hours are needed for the initial education for a newly diagnosed patient and how many hours during the first year follow-up. Participants were asked to define the minimum indispensable number of hours as well as the recommended time for education. **Results:** 419 participants answered the questionnaire (304 MD, 74 RN, 23 RD, 18 Psycho.). Participants originated from 46 different countries but the majority of them came from Occid. Europe (70%). ***Minimum indispensable hours*** *(mean +/- SD)*: Type I Diabetes: *Initial education*: 7.3 +/- 6 hours; *First year follow-up*: 9.2 +/- 7. Type II Diabetes: *Initial education*: 5.2 +/- 5 hours; *First year follow-up*: 7.0 +/- 6. As far as the ***recommended number of hours*** are concerned participants usually agreed to increase the minimal number of hours by about 70%. The analysis of the recommended hours showed little non-significant differences between doctors and nurses. Psychologists and specialists in education recommended 2 more hours than the average for each clinical situation. The coefficent of variation was in the order of magnitude of 79%. This certainly highlights the heterogeneity of the group of HCP on one side and of the great variability of the educational process on the other. **Conclusions:** This investigation has focused on the average number of hours needed for educating patients without diabetic complications in order to help them to self-manage their treatment. Based on those figures HCP may recommend to the appropriate health decision makers the number of hours needed for therapeutic education. These data may also help to better tailor the educational curriculum of patients.

EFFICACY OF INTENSIVE GROUP EDUCATION PROGRAM ON METABOLIC CONTROL OF DIABETES IN TURKEY

E. Özer, A.M. Şengül, M. Sargın, F. Salman, S. Gedik, K. Karşıdağ, N.Dinççağ, İ. Satman, Ş. Karadeniz and M.T. Yılmaz. Diabetes Research Center, Diabetes Education Unit, Institute for Experimental Medicine and Division of Diabetes, Istanbul Medical Faculty, Istanbul University, Istanbul-TURKEY

In this study, we aimed to investigate the efficacy of intensive group education program on metabolic regulation. Totally 38 patients who were not taken education before, 12 type 1 diabetics (mean chr. age: 34±10 yrs, diabetes duration: 9.6±9.5 yrs) and 26 type 2 diabetics (mean chr. age: 59±7 yrs, diabetes duration: 8.7±5.3 yrs) were included. All patients took a two days diabetes education program including definition and types of diabetes, diet planning, exercise, therapy with OAD and insulin, home monitoring, symptoms and prevention of acute and chronic complications, foot-skin-tooth care and special conditions related to diabetes for 14 hours totally 10 hours practical and 4 hours theoretical. All topics were given as 30-60 minutes theoretic and/or practical lessons to groups composed of 8-10 patients. A questionnaire including 24 questions were given to check the diabetes knowledge of patients at the beginning and after course. Answers were scored as +1 for right, -1 for false and 0 for empty replies. The values of blood pressure, body mass index (BMI), glycemia, HbA_{1C}, blood lipids 3 months before, at the beginning and at 3nd, 6th, 12th months after education were compared. No difference was observed between metabolic parameters and BMI values before and after education. In contrast HbA_{1C} levels were found to be significantly lower at 3rd, 6th, 9th months than the levels at entry ($p< 0.001$, $p<0.001$, $p<0.05$ respectively). But, improvement in HbA_{1C} was not lasted at 12th month. Compared to entry, diabetes knowledge level at 12th month was increased significantly ($p<0,0001$). No association was noticed between BMI and clinical findings with education. We concluded that intensive group education is effective on metabolic control up to 9th months, but to achieve good continuous knowledge in long-term, the education program should be repeated in regular intervals.

2461

COMPARISON BETWEEN TWO EDUCATIONAL APPROACHES IN OBESE NIDDM PATIENTS

M. Petkova[1], M. Vladimirova[1], M. Protich[1], G. Genchev[2]. 1. Diabetes Center, Sofia, Bulgaria, 2. Medical Faculty, Sofia, Bulgaria

Weight reduction and normalisation improve the cardiovascular risk profile in cases of obese Type II diabetic patients. However, the majority of these patients experience certain difficulties in changing their eating habits and fail achieving calorie reduction. That is why the educational approach is very important in these cases. The aim of the study was to assess in a comparative way the effects of two educational approaches: a) 3-day-food-records (two working days and one Sunday) and b) traditional informative education on: food intake, BMI, glucose control and lipids. Sixty obese Type II diabetic patients were randomized to receive training in a 3-day-dietary-records educational program (group I) or in a traditional informative method (group II). Their mean age was 52.1±6.4 years and the duration of diabetes was 9.2±7.3 years. The first method included three times (at the beginning, after the 3rd and after the 6th month) dietary records analysis and reinforcement of the prescriptions. The second method included only the recommendations reinforcement for the same intervals. Fasting triglyceride, total serum-cholesterol, HbA_{1c} and weight were also measured three times. Significant differences were found between group I and group II concerning the percentage of energy derived from total fat (28.7±4.8% vs 37.5±7.6%); BMI (26.8±4.1 kg/m^2 vs 28.8±1.8 kg/m^2); HbA_{1c} (8.8±2.7 % vs 6.6±0.4%). Conclusion: Education based on the 3-day-dietary-records approach is simple, time saving and effective in weight reducing programs in obese Type II diabetic patients.

2462

DO WE REALLY HELP DIABETIC PATIENTS TO LEARN HOW TO MANAGE THEIR TREATMENT ? AN NEW EVALUATION METHODOLOGY FOR INTERACTIVE LEARNING TECHNIQUES

S. Jacquemet, A. Lacroix, A. Golay, J-Ph. Assal
Division of Therapeutic Education for Chronic Diseases, Geneva University Hospital - Switzerland

Rationale: When Health Care Providers (HCP) teach patients, experience shows that they tend spontaneously to inform them about the disease rather than to help them to acquire self-management skills for their daily treatment. The concept of therapeutic education implies that HCP master educational skills which should help patients to *learn* how to treat themselves. We therefore developed an new evaluation methodology in order to quantify how much information and how much learning skills are involved during courses to patients. **The evaluation scale:** This validated tool is divided in 6 intermediate steps distributed from level «1» = pure information, to level «6» representing the most active level of learning. These evaluation scales took into account : 3 dimensions: 1) the interpersonal dynamics between teacher and patients, 2) the mental level of activity of the learners (patients) and 3) how HCP used the therapeutic knowledge when it had to be transfered to patients. **Methods:** This evalution scale was used for the educational follow-up of 15 HCP (6 RN+9 MD). The same course was videotaped weekly during 3 consecutive weeks. After the educational analysis of the course with the evaluation scale, a 45 minutes training was provided to each HCP. **Results:** Initial evaluation showed that HCP favoured information (mean of the 3 dimensions), score 2.9+/-0.1 SD. After those 2 supervisions the score rose significantly to 3.6+/-0.1 SD ($p<0.01$). This change documented that HCP had acquired educational skills which favoured the learning process of patients. Compared with nurses, results of physicians were significantly lower ($p<0.05$) showing that doctors tend to provide more medical information than to really help patients to acquire new therapeutic skills. **Conclusions:** This evaluation tool provides **1**-an objective and reliable system to evaluate the educational methodologies of courses to patients; **2**-it offers objectives ways for continuing education of the health care team involved in patient education; **3**-the use of this scale offers ways to analyse and compare which educational strategies are used between centers. Since patient education is a therapeutic approach such a scale may be used locally and to evaluate these new competences in patients' care.

2463

WRITTEN HEALTH EDUCATION MATERIAL SUPPORTING SELF-CARE OF IDDM DIABETICS

S.Kähönen, M. Perälä and M. Torvinen. Jyväskylä University, Jyväskylä, Finland.

Written material is important in patient education in self-care with in insulin dependent diabetes mellitus (IDDM). The purpose of this study was to find out how the IDDM guidebook is used and how it should be developed to support its users as well as possible. This study analyzed how the characteristics of the booklet were related with in its use, what kind of opinions and ideas the patients had of it and what kind of role it had in the process of becoming ill and self-care. In the study 4 diabetes nurses and 12 insulin diabetics were interviewed. The interviews were taped and written according to identified themes. In the first stage of the analysis the material was examined deductively according to the themes and subthemes. The frequencies of the similarities and differences of the opinions were then searched. In the second stage the material was examined inductively. The main results are related to the meaning of the guidebook for the patients in their process of becoming ill. The information of the booklet is of great significance for the patients who are just taken ill. The layout and illustrations and use of colours motivate to study the booklet but do not forward learning. Information about the balance of the therapy was the most central aspect for the elaboration of the content. Those patients who have had diabetes for longer periods solve their problems relating to the illness on the basis of their own and other diabetics' earlier experiences. The goal of the nurses and the patients in the treatment is common: good self-care. The nurses used the booklet to support the consultation especially in the early stages of illness. The use of the booklet of diabetics depends on their need of information, learning strategy, self-care motivation, individual characteristics, stage of illness as well as on other information available and the characteristics of the booklet. The booklet supports self-care by providing information to the patients. The booklet is also used by the family members of the patients from whom the patients get the most social support. The nurses give information as well as psychological support to the patients. Getting diabetes creates a crisis. In this situation the meaning of a booklet with relevant information is to help the patients to accept their illness and to put good self-care into practice.

Keywords: diabetes booklet, self-care.

2464

INTENSIVE DIETICIAN EDUCATIONAL SUPPORT CAN POSITIVELY INFLUENCE METABOLIC CONTROL IN NIDDM.

I.Nosari, M.L.Maglio, A.Bonalumi and G.Lepore. Diabetes Unit, OO.RR. Bergamo, Italy

The aim of the study was to evaluate the short(2), middle(4) and long term (12months) metabolic effects of two different educational Dietician-Patient approaches. 42NIDDM (25M,17F, age37-66yrs) were randomly assigned to two groups, balanced for age,BMI and disease duration:A(12M,9F, age48.2±12.4, BMI 27.2±3.2,diabetes duration 10.6 ± 6.4 yrs, 14 treated by oral hypoglycemic agents(OHA), 7 only by diet) and B (13M,8F, age49.5±11.1, BMI 27.2±4.4, diabetes duration 9.4±7.3, 14 treated by OHA,7 only by diet). *Group A* patients were allocated to a simple dietary instructions *support* by a dietician at the onset of the study and after 2 months. *Group B* patients were asked to fill an elaborate form, with questions about caloric intake,life style, food habits,"wrong believes"and more common quality and quantity mistakes, aimed to prepare a suitable personalized diet.The dietician checked patient's knowledges and behaviour correcting mistakes till the end of the study, every 15 days for the first 4 months and 30 days for the following 8 months(*intensive protocol*). BMI, HbA1c, fasting blood glucose level, total and HDL Cholesterol (HDL-Chol), triglycerides (Tg), serum Uric acid (Ua) (0,2,4 and 12 months) were evaluated.Group A: No tested parameters change occurred after 2 months; a significant fasting blood glucose(170±49 vs 257±43mg/dl, p< 0.01) and HbA1c(8.3±0.8vs9.7±1.4%,p<0.01)reduction occurred after 4months.Fasting glycemia decrease was also maintained after 12 months (201.8±42.6,p<0.005).Group B:Tg (216 ±62 vs296.1±91mg/dl,p<0.05) and Ua(4.1±1.0 vs5.1±1.1mg/dl,p<0.05) were reduced after 2 months, 4 months (Tg 187±62, Ua 4.3 ± 1.0, p<0.05) and all study long (12 months) (Tg 212.2±81.7, Ua 4.4 ± 0.67,p<0.05). Fasting blood glucose levels (183±55 vs234±72, p<0.05) and HbA1c (8.4±0.7 vs 9.8 ± 2.1, p<0.05) were also significantly reduced after 4 months. HDL-Chol levels increased after 12 months (53.3±15.5 vs 43 ±11[4 months] and vs 41±13 mg/dl [baseline], p<0.05). Comparing the groups, Ua after 2 months (B 4.1±1.0, A 5±1.0 mg/dl, p <0.05) and Tg after 12 months (B 212.2± 81.7, A 280.8±79.6mg/dl, p <0.05) were significantly modified.The *intensive protocol* caused an important Tg and Ua reduction, with an HDL-Chol increase. The caloric intake did not significantly vary to cause a weight loss.Therefore, these changes are mainly due to a modified behaviour and are suitable to reduce the cardio-vascular risk in NIDDMs, even if a remarkable charge of human resources was employed.

2465

CAN MAGAZINES ABOUT DIABETES SELF CARE CHANGE BEHAVIOR PATTERNS AMONG READERS?

A.Keegan, American Diabetes Association, Alexandria, Virginia, USA

To the best of my knowledge, scientific research has not been conducted to pinpoint the effect of magazine reading on behavior. There are simply too many variables to account for, including the personality profile of the reader, exposure to other media, exposure to other sources of medical information, contact with health care providers, and comprehension of material presented. Even when the material is fully comprehended by a reader, it does not necessarily follow that he or she will act on the recommendations offered, especially when the matter under discussion is self care, and the means to that end entail sacrifice and lifestyle changes. In this session, the methods publishers and editors use to assess reader involvement, including subscription renewals, letters to the editor, responses to advertising, and feedback from experts in the field will be discussed. The magazine staff at the American Diabetes Association's Diabetes Forecast has experimented with other methods as well, including reader opinion surveys, contests, and rewards of books or subscriptions, to increase its impact on the health of its readers. There have been successes (hundreds of readers did initiate an exercise program following a contest) and failures (less than half a dozen readers took up our challenge to quit smoking cigarettes).

2466

A TEACHING TOOL ON INSULIN ACTION

M. Burgess, St Vincent's Private Hospital, Melbourne, Australia

A tool was developed to help insulin-using patients achieve a greater understanding of insulin action, dosage and timing of administration in accordance with blood glucose profiles. A secondary benefit has been in nurse education programmes. Blood glucose readings and times are graphed. Fine overhead transparencies, colour coded to correspond with short, intermediate and long acting insulin (Novo Nordisk and Eli Lilly codings) are placed over the chart on the exact times of insulin administration, extending over onset, peak action and duration in hours. Episodes of hyperglycaemia and hypoglycaemia are examined in relation to dosage. The tool may be used on overhead transparencies and projector when group teaching. A pre-requisite to the use of the tool is that the person is adequately educated to recognise the factors which may affect blood glucose (diet, exercise, illness, stress, insulin dosage, drugs, injection sites) and accurate blood testing techniques. The tool was offered to 404 insulin-using patients, 242 (59.9%) elected to use it; 162 (40.1%) declined due to age, underlying illness or preferred the doctor to adjust their doses. Of the 211 nurses (6.6% students,93.3% registered) using this tool, 73.6% classified it as very good, 21% as good, 5.2% fair. This device was used by 59.9% of all insulin using patients successfully. It can be used by any insulin-using patients on any regimen.

A LOCAL SUMMER CAMP IN JAPAN: CHANGES OF GLYCEMIC CONTROL AND INSULIN THERAPY OF IDDM CHILDREN AND ADOLESCENTS DURING 11YEARS

T.Seguchi, T.Okeda, T.Noguchi, I.Katsuragi, H.Sakino K.Tsuda, M.Fukuda, Y.Ishibashi, K.Adachi, K.Sato, S.Yamashita and T.Sakata, Oita Medical University, Oita, JAPAN

The Oita summer camp for diabetic children and adolescents has been maintained since 1986. Clinical records including glycemic control, duration of diabetes, body weight, number of daily insulin injections, dosage of insulin, severe hypoglycemic episodes and diabetic complications were evaluated in 67 camp attendants between 1986, 1991and 1996. Incidence of single daily insulin injection was 35.7% in 1986, but that of 2 times daily injection was 64.3% in 1986, 68.8% in 1991 and 12.0% in 1996 ($p<0.05$, for each vs 1996). Incidence of 4 times injection was 0% in 1986, 31.2% in 1991 and 88.0% in 1996 ($p<0.05$). Average HbA1c level decreased from $10.0\pm1.8\%$ in 1986 to $8.8\pm1.9\%$ in 1996 ($p<0.05$). Decrease in number of severe hypoglycemic episodes during the summer camp was dependent on number of daily insulin injections, *i.e.*,4 times injection was superior to 2 times injection ($p<0.05$). Changes in Kaup index, Rohrer index and body mass index were not significant between the years. Introduction of the pen system for insulin injection was found to be a main cause to enable those young campers to maintain good diabetic controls.

2468

EFFICACY OF CALORIE COUNTER FOR GUIDANCE TO EXERCISE THERAPY IN DIABETICS

R. Todo, Y. Doi, C. Sato, J. Kitaguchi, C. Fudamoto, K. Morinishi, M. Katsura and M. Ikebuchi. Osaka National Hospital, Osaka, Japan.

Aim: Calorie counter has an advantage to determine not only number of walking steps but also consumption calorie levels during exercise and total consumption calorie levels. In the present study, we investigated usefulness of calorie counter for guidance to exercise therapy in diabetics. Methods and Subjects: Enrolled were 67 patients who were admitted to our hospital to receive education program for diabetes mellitus. In the group with calorie counter (n=44), patients carried calorie counter, whereby the consumption calorie levels during exercise and the total consumption calorie levels were determined to calculate daily calorie valances every day. Six months after discharge, questionnaire survey was performed to review the degree of understanding about exercise therapy of continuity, compliance status, plasma glucose levels and alterations of body weights . Results: 1.Even after discharge, most of the patients in the group with calorie counter positively employed exercise therapy and continued it. (89% vs 65%, $p<0.01$ by chi-square test) 2.The group with calorie counter attained more favorable trend toward maintenance of reduced body weights and controlling plasma glucose levels than the group without calorie counter. Conclusion: Incorporation of calorie counter into exercise therapy of diabetics was evidenced to be effective in enhancement of recognition of significance, continuity and positive attitudes toward exercise therapy.

2469

FIRST BLACKSEADIAB SUMMER CAMP FOR CHILDREN WITH DIABETES. M. Mota, K. Koprivarova, Z, Anestiade, E. Panteleeva, E. Toma, C. Panus, C. Ionescu-Tirgoviste. Diabetes Centre, Craiova, Romania.

The **BlackSeaDiab Working Group** was created with a view to promoting an exchange of experience in the field of diabetes care between the 12 countries surrounding the Black Sea in which the ethnic, social and cultural heterogeneity explains the great difference in the systems of health care. The first BlackSeaDiab Summer camp which took place in Breasta, Craiova in Romania between 10 and 20 July 1996 included 80 children with diabetes from three countries: Romania (59), Moldova (11) and Bulgaria (10). Mean age was 13 yrs. (range 7-18 yrs.); sex distribution - 38M/42F; mean duration of diabetes - 5 yrs. (range 1-9 yrs.). Before and after the camp, a score assessing the quality of diabetes care comprising a knowledge questionnaire, self monitoring, no. of injections/day, glycosuria, blood glucose and the glycated Hb. values was calculated for each participant. The maximum score possible was 40. The scores obtained at the beginning (stated in no particular order with a view to maintain confidentiality) for the three centres were : 34 (very good), 28 (good), and 17 (poor). The content of the programmes was categorised into three groups: (1) basic education programme; (2) recreation and sports programme and (3) social programme. Safety was completely ensured by following camp rules, permanent supervision and provision of translation. The main conclusions of this regional European Diabetes Summer Camp were: a) a large variability was noted with regard to the level of education and the qualities of treatment and metabolic control among the groups; b) in the low level group, an impressive improvement was noted at the end of the programme with regard to knowledge and treatment. In the group with the poor score at entrance, an improvement was noted from 17 to 24. An unexpectedly high level of enthusiasm was noted in the participants with regard to both the giving and the receiving of information, self-monitoring materials and the acceptance of a higher number of injections. Of the 16 receiving 2 injections per day, only 6 remained at the end. c) camping appears to have the best cost-benefit ratio d) camping standards should include special considerations for the different cultural backgrounds of campers if the participants are drawn from different ethnic groups.

2470

DIABETES CAMP AS MEANS OF EDUCATION FOR CHILDREN WITH IDDM

V. Serban, M. Holospin, M. Serban and I. Velea, University of Medicine and Pharmacy, Timisoara, Romania

Since 1992, the Foundation Cristian Serban from Timisoara has been organising every year summer camps for diabetic youngsters. A number of 71 children and teenagers aged between 7 and 22 years from 20 districts of Romania attended it last year. The diabetic team aimed at: a) enhancing self-esteem, independence in injections and blood testing; b) providing informal diabetes education (practical lessons, three-times a day self monitoring and adjustment of insulin doses); c) screening for microvascular complications (fundoscopy, Micral-test); d) improving short and long-term glycaemic control; e) providing education for diabetes care providers. The mean blood glucose values decreased significantly ($p < 0.05$), while daily insulin requirements slightly increased during the camp. The levels of HbA1c (chromatographic method) were 9.5% for all the participants, higher for the age group 15 - 22 years (10.7%) then for prepubertal children (9.12%). Home blood glucose monitoring equipment is available in 49.3% of these children, only urine strips in 26.7% of them, while 24% have neither glucose nor urine testing possibilities at home. As much as 29.5% of the children had Micral values $\geq$ 20 mg/l in two urine specimens and 11.2% had at least one microaneurism at fundoscopy, all of them with poor glycaemic control (HbA1c beyond 10%). We believe that diabetes camps are useful as means of medical education .

2471

"REAL LIFE" EXPERIENCE WITH IDDM DURING SUMMER CAMP. LESSONS TO BE IMPLEMENTED IN IDDM EDUCATION PROGRAMS.

R. Ofan, A. Galatzer, E. Sprecher, O. Kalter, Z. Flexer, P. Vardi, and M. Karp SCMCI, Petah Tikva, Israel

Our aim was to demonstrate that summer camps (SC) for children and adolescents with diabetes provide significant psychosocial benefits in terms of self-empowerment, improved attitudes towards diabetes, increased sense of responsibility and feelings of adequacy. Summer camps are highly recommended for IDDM youth as they enable camp activity under professional medical supervision. As a result of six years of cumulative experience in organizing and operating sleep-away camps for diabetic youth aged 9-16 years, we present our concept of a summer camp whose primary goals are fun and interaction with other children and counselors with diabetes; where there is no formal diabetes education, but rather education in "real life" using problem-solving methods. In order to evaluate the impact of this type of camp we compared 37 diabetic children attending SC with 21 not attending. An ATT-39 (Diabetes Attitudes and Adjustment Scale), which measures adaptation to illness, degree of positive attitudes and emotional adjustment to diabetes, and degree of alienation from society was administered to each child individually, without parental assistance, during a regular out-patient visit. Our preliminary results, based on chi-square analyses, show that young IDDM subjects who have attended SC show significantly better adaptation to their illness, have more positive attitudes towards diabetes and an increased sense of responsibility toward their condition when compared to those who have never participated in such activity. In conclusion, participation of young people with IDDM in summer camps using problem-solving methods of education is highly recommended and should be officially included as part of any diabetes education course curriculum; moreover, we propose that the medical team's participation in SC should be considered as an integral part of diabetes education work by the health care system.

2472

DAY CAMPS FOR MASS DIABETES HEALTH EDUCATION AND CARE : SOCIAL EXPERIMENTS IN A DEVELOPING COUNTRY.

BS.Sudha, AS.Vinaya, GS.Narayan, MG.Mamatha, BS.Sudha, DV.Rama, J.Srikanth, S.Nagabushan, N.Nagesh, S.Krishnamurthi, S.Colaco, A.Sharda, and SS.Srikanta. Samatvam: Endocrinology Diabetes Center, Bangalore, India.

We [Health Care Team: HCT] have designed, standardized and implemented [through local sponsors [LS] collaboration], a voluntary, structured, 8 hours weekend (third Sunday of the month), intensive health education and self care training program for people and families, titled "Diabetes Self Care Intensive" [DSCI]. DSCIs have been provided at different urban and rural parts of the state of Karnataka and neighboring regions, upto a distance of 500 kms from our center (outreach program). A. Design [HCT]: (i) Creating syllabus and course content; (ii) Development of teaching and audiovisual aids [Diabetes teaching guides: English - 100 pages, local languages - 14 pages; 35 mm slides (n=220); modular lectures and group discussions (n=12); video tapes (n=3); health survey and multiple choice questionnaires; display posters (n=20)]; (iii) Model diabetes lunch, recipes and nutrition exhibits; (iv) minimal health screening (spot blood glucose, BP, ideal body weight), and (v) individual counseling. B. Implementation [HCT + LS]: (i) Requests from LS (Lions, Rotary, Medical Associations); (ii) Camp operations manual/ check list (4 pages) mailed out to LS 2 months in advance, followed by meeting and correspondence with LS representatives; (iii) Publicity, fund raising, printing, catering and other facilities organized by LS; (iv) HCT volunteers (doctors, nurse educators, dietitians, social workers) travel to and conduct the day camp at the outreach site; (v) Follow-up referral to specialized centers, as per need and stimulation of local programs. C.Results: (i) Camps conducted (1994-96; n=13); (ii) IDDM + NIDDM, 50-850 patients per camp; (iii) Education and training standards tailored to recipients capabilities and needs (literacy economics, motivation). Conclusion: A volunteer day camp movement has been successfully implemented for outreach community diabetes care, in a developing country with high disease burden.

2473

INTERNATIONAL CAMPS FOR JUVENILES WITH DIABETES 1987-1995

W. Hüpfl and M. Hüpfl, Austrian Diabetes Organisation, Vienna, Austria

Our aim was to organize camps for hitherto unprovided-for juvenile diabetics (over 16), in order to provide these generally overprotected individuals with a valuable experience away from home, yet in a safe environment where their independence and self-confidence in the areas of therapy and social contacts would be able to grow. We started 10 years ago with a large educational, medical and dietetic team, thus guaranteeing optimal care. A total of 186 juveniles came from 22 countries and three continents and used English as the language of communication. Sport, arts and crafts, the culture, history and sights of the host country and an exchange of experiences relating to treatment methods from the countries represented comprised the programme. The medical support and mutual supply of information led to a successful learning process for all, notable improvements in therapy owing to the relaxed atmosphere, motivation for improved diabetes management, promotion of international dialogue, improved English and a lessening of cultural prejudice. The success of the camps should be a motivating factor for other European countries to do likewise. The setting-up of self-help groups in both, Third World and Eastern European countries, could be stimulated by inviting juveniles and occasionally physicians from them to participate free of charge.

LIFESTYLE INTERVENTION IN PEOPLE WITH INSULIN-DEPENDENT DIABETES MELLITUS (IDDM)

J Mann, T Perry and N Lewis Barned, Department of Human Nutrition, University of Otago, Dunedin, New Zealand

Sixty one subjects participated in a randomised trial to determine whether a lifestyle intervention programme could further improve glycaemic control and lipoprotein mediated risk of cardiovascular disease in patients with insulin-dependent diabetes, amongst whom home blood glucose testing and insulin regimes had already been optimised. Subjects were randomised to a programme which involved intensive dietary advice and a programme of physical activity (Group 1) or routine surveillance (Group 2). After the 6 month randomised trial, Group 1 were followed for a further 6 months, with no further advice and Group 2 were given intensive advice similar to that received by Group 1 during the formal trial. Nutrient intakes, maximal oxygen consumption, weight, blood pressure, glycated haemoglobin, lipids and lipoproteins were assessed throughout the trial and follow-up period. During the 6 months trial, in Group 1 saturated fatty acids decreased significantly from a mean of 16% to 12% total energy ($p<0.001$) and carbohydrate plus monounsaturated fat increased from 55% to 60%. Protein intake remained relatively high at 17% total energy. These changes were sustained during the 6 month follow-up period. Some changes occurred in Group 2 during the trial but saturated fat only decreased to 12% during the 6 month follow-up period when they received intensive dietary advice. LDL cholesterol showed a small (0.2 mmol/l) statistically significant ($p<0.001$) fall between recruitment and randomisation. The improvement was sustained in Group 1, but not in Group 2 until they were given intensive advice in the post trial phase. Changes in HbA1 mirrored those in LDL cholesterol, average improvements of 0.6% ($p<0.01$) being observed with intensive advice. The lifestyle intervention programme resulted in modest changes in diet and exercise habits, sufficient to produce some improvement in glycaemic control and lipoprotein mediated risk of coronary heart disease over and above the benefits induced by optimising insulin regimes and home blood glucose monitoring. However despite intensive education nutritional targets were not met. More innovative approaches will be necessary to achieve the full benefit of lifestyle treatments.

2475

REPORT ABOUT PSYCHOLOGICAL AND SOCIAL APPROACHES BY PATIENTS USING CONTINUOUS SUBCUTANEOUS INSULIN INFUSION (CSII)

M.Reinhold and E. Austenat; Diabetes Institut Berlin, Germany

CSII is since 10 years a safe and well known insulin delivery therapy,but still very seldom.The question is :Do the diabetics or the diabetologist fight against this intensifed insulin therapy? We asked 279 diabetics (142 female,137 male) by self-assessment questions. **Basic data:** age 34,9 years, diabetes duration 15,3 years, CSII treatment time 3,4 years. **Psychological fields:** *1.part:* pump user expections before CSII versus theire experiences with insulin pump. *2.part:* Does the self-esteem change under CSII?*3. part:* Do the users find a pronounced difference in quality of metabolic control,different egos and possibilities in active handling of this chronical disease? **Results:** most of the pumpusers are employes (55% male, 71% female) between 20 and 40 years (85% male, 81 female) with a diabetes duration between10 - 20 years (41% male, 27% female).For the decision to switch from discontinuous insulin delivery to pump therapy 46% need in middle 5,1 weeks.1. part: Flexibility: 6,8%expectation – 53% achieved, indepance from watch: 74,2% expectation – 57,7% achieved 2. part: 77,4% feel more independent,76% more liberal,68,1% more sense of responsibility, 42,7% more independent,36,6% more selfconfidens.3. part: better blood glucose 84,2% expectation – 52,0% achieved.Assessment of blood glucose quality: much better (24,9%), better (64%) same (10,3%), worse (0,8%)very bad (0%); improvement of HbA1/1c:: 84,2% expectation – 53,8% achieved.Assessment of HbA1/1c: much better (22%), better (60,2%) same 15%), worse (2,8%) very bad (0%).Body feeling:much better (15,4%), better (47,6%) same 34,6%), worse (1,6%)very bad (0,8%);Psych. feeling: much better (12,3%), better (34,3%) same (47,9%), worse (4,7%)very bad (0,8%).Other details will be demonstrated. **Summary:** The pump therapy is well accepted because it is a great advantage for the users.Body-psychological- and metabolic effects are better under CSII,if patients get the most possible professional support by diabetologists.

2476

ARE DOCTORS AND DIABETES PATIENTS READY TO COOPERATE?

G.Freimane, I.Rasa and R.Ligere, Latvian Diabetes Association, Riga, Latvia.

Cooperation and partnership between diabetes patient and doctor is one of the preconditions for the successful treatment of diabetes. Successful cooperation between diabetes patient and doctor is hindered by insufficient knowledge of diabetes patients about their ilness and limited possibilities of selfcontrol as well as their turn of a mind -- conviction that only doctor is responsible for their health. Doctors are not ready for the partnership with their patients either both for subjective (psychological) and objective reasons: there is insufficient number of endocrinologists in Latvia which results in their overload, they are insufficiently trained to educate diabetes patients; internists and family doctors are completely unprepared to solve problems connected with treatment of diabetes. Doctors view patients only as a material of their work and not as partners. Latvian Diabetes Association (LDA) turns a great deal of attention to improvement of partnership between diabetes patients and doctors by improving the patients' knovledge of their ilness, trying to raise their self confidence, informing doctors endocrinologists and other medicine professionals about different aspects of diabetes. To improve the cooperation between doctors and diabetes patients, LDA recommends: to create well structured, understandable for different target groups of patients educational program; to advance the knovledge of doctors about diabetes; to reach an understanding that selfcontrol equippment should be paid by state; to advance the psychological preparedness of doctors in creating a partnership relations with patients; to advance the creation and adoption of programs about the diabetes patients' education for doctors endocrinologists, internists and family doctors.

2477

PANIC DISORDER AND DEPRESSION IN INSULIN DEPENDENT DIABETES MELLITUS

Vladimir Diligenski, Zorica Čaparević, Nada Kostić, Svetlana Jelić, Gradimir Bojković
Department of Psychiatry KBC "Dr Dragiša Mišović", Belgrade, Yugoslavia

Panic disorder with concomitant depression becoms to be frequent in patients with insulin dependent diabetes mellitus. 25% with panic disorder and 41% depresed was found in the study of 44 patients with diabetes mellitus acording to th DSM IV clasification of mental disordes. Most frequent symptoms were shortness of breath (dyspnea), trembling or shaking, sweating, fear of doing something uncontrolled, early awaiking, loss of interest or pleasure in activities, excessive guilt, fatigue or loss of energy, decreased appetite. 81% had common panic disorder and depression, so it was necessery to make good psychological assesment and consequent psychotherapy and psychopharmacological treatment. The prognosis of insulin dependent diabetic patients with panic disorder and depression is unsatisfied becouse these patients could not rich good glycemic control and complications are very frequent (especially polyneuropathy and angiopathy). The complications were found in 96% in this group.

2478

PSYCHOSOCIAL IMPACT OF TYPE 1 DIABETES ONSET IN A COHORT OF DIABETIC PATIENTS.

J. Ubeda, M. Maria, C. Durán, E. martín and J.M. Pou. Dpt. Endocrinology and Nutrition Hosp. Sta. Creu i S. Pau. Autonmous University of Barcelona. Spain.

The psychopatological impact of diabetes onset was analyzed in a group of type 1 diabetic patients (IDDM). Forty five IDDM patients were studied in the first month of their diabetes onset The mean age was 26 ± 6 years, 66,6 % were men and 33.3 % women. Social and psychological impact of the diabetes were evaluated by three test: V.S (social events), Beck-Pichot and H.G.Q. Golberg.

Results: It was observed in V.S. study that 84 % of patients considered satisfactory their social situation without any adverse social events, 73.3 % had good adaptation to the new situation of diabetes onset, 93.2 % and 90 % manifested a great family and social support. In the Beck-Pichot test, it was demonstrated anxiety crisis in 9 % of patients and moderate anxiety in 11 %, (Normal range scale 0 to 9), serious and moderate depression symptoms was manifestated in 7 % and 13 % of patients (Normal range score: 0 - 11). In Golberg test, general psychopathological manifestations was observed in 47 % of all patient group (Normal modified scale 0 - 14). A very good correlation was observed between Golberg (general psychopathological manifestations) and Beck tests (anxiety and depression) ($r=0.78$, $p < 0.001$ and $r=0.82$, $p < 0.001$, respectively) and no correlation with V.S (social events of life).

In conclusion, the Beck-Pichot and Golberg test demonstrated an important psychopathological manifestations in patients at the onset of the type 1 diabetes although they did not detected any problems in their social events.

2479

DO DIABETICS NEED PSYCHIATRIC EVALUATION FOR THE GOOD QUALITY OF LIFE?

Bostancı A., Özyazar M., Keser N., Doksat.MK, Görpe U.,Damcı T.,Ersanlı Z., Bağrıaçık N. Cerrahpaşa Medical Faculty-ISTANBUL

The aim of our study is to evaluate the pysiciatric status in patients with well(HbA1C<%6,fasting blood glucose<%120) and poorly(HbA1C>%8,fasting blood glucose>%140) controlled diabetes.150 patients(70 female,80 male,mean age 45.3±13.6) are evaluated psychiatrically by using SCID-OP(Structered Clinical Interview for DSM III-R-outpatient).Depression degree was calculated by using Hamilton depression scala. The parameters that we observed also included age,sex,marital,social,economic status,number of stillbirths,degree,duration type and therapy of diabetes, associating psychiatric and organic disorders caused by diabetes and the presence of diabetes and psyciatric disorder in 1st degree relations.

The frequency of psychiatric disorder in the past was %21.3, depression at present was %30.7,depression and anxiety at present was %15.3, psychotic symptoms at present was %2 respectively.Among the patients with anxiety 5 had panic attacs with agorophobia, 28 without agorophia, 10 of them had obsessive compulsive disorder,15 had generalized anxiety disorder , 5 had social phobia and 4 had simple phobia.When correlated to each other, significant correlations have been found between the group with depression and degree of diabetes($p<0.05$) and proffesion distribution($p<0.05$); between the group having depression and anxiety with treatment of diabetes($p<0.05$) and between the group of anxiety disorders with sex($p<0.05$.

So, we emphasize that in order to manage diabetics appropriately pysciatric analysis should be kept in mind for the good control of diabetes.

2480

Gender Equity in Swedish Diabetes Care: the Patient Perspective.

Gåfvels MC, Jonsson PM
Depts of Public Health Sciences, Karolinska Institute and University of Umeå and LUCD, Karolinska Hospital, Stockholm, Sweden.

As perception is the step that psychologically precedes response and action, the patients´ subjective experience of diabetes mellitus, and the care they receive, is an issue of great importance.
A number of studies in Sweden indicate gender differences in sickness perception, sickness impact, experienced quality of life and satisfaction with care among diabetic patients. A population-based study in northern Sweden (Gåfvels et al) showed that diabetic women worried most about symptoms and future complications, while men were more troubled by the regulated life-style imposed by the disease. Depression and anxiety, in combination with a low general well-being and a high subjective sickness impact, are found to be more common in diabetic women than in men (Wredling et al). Gender differences in perceived health, such as that women are less satisfied with their health status and physical capacity, are also found (Jonsson et al). Regarding experience of diabetes health care, more women than men reported dissatisfaction with the way they were met and the accessibility and service they were offered (Jonsson et al). Women in hospital care were less satisfied with their doctor-patient relationship and reported a greater dissatisfaction with the treatment and the time for discharge than did men (Östlin et al).
We suggest that, because of a different sickness perception and subjective sickness impact, due to gender-based or biological differences, men and women have different needs and expectations of diabetes care. The model of practising diabetes health care today may suit men better than women.

2481

DIABETES EMPOWERMENT SCALE (DES): A MEASURE OF PSYCHOSOCIAL SELF-EFFICACY

R Anderson, J Fitzgerald, M Funnell, and C Feste, University of Michigan, Ann Arbor, Michigan, USA

The Diabetes Empowerment Scale (DES) is a 34 item questionnaire developed to measure the psychosocial impact of a patient empowerment program. The empowerment program is a six-session (2 hours each) group education program focusing on psychosocial issues related to living with Diabetes Mellitus (DM). The DES has eight subscales: assessing satisfaction, setting goals, solving problems, emotional coping, managing stress, obtaining support, motivating oneself, and making decisions. The overall reliability of the DES is .94. Subscale reliabilities (Chronbach's coefficient α) ranged between .57 and .85. To provide evidence of validity the pre/post empowerment program change score for patients on the DES was compared with their change scores on independent measures of positive and negative attitude toward having diabetes (Correlations of .65 and -.51 respectively, p <.001), and glycosylated hemoglobin levels (Correlation =.31, p = .03). Also, baseline DES scores were correlated with the patients' self-reported comfort asking questions of their doctor (.29, p =.02), and self reported positive adjustment to DM (.50, p <.001). Test/retest reliability was determined by comparing the scores of the control group on the DES from baseline and at six weeks. The test/retest correlation was .79 (p <.001). These findings provide evidence that the DES is a valid and reliable measure of diabetes-related psychosocial self-efficacy. The DES is suitable for clinical assessment and program evaluation.

2482

PSYCHOEMOTIONAL STRESS AND TYPE 1 DIABETES : THE POINT OF VIEW OF PATIENTS

M.R ABABOU and A. OUASSIF, Diabetes center, Casablanca, Morocco.

Chronic patients relate frequently their health problems to stressful events. In this study - using a questionary - we compare the point of view of type 1 diabetic patients, (50 patients, 23 male 27 female, ranging in age from 15 to 25 years mean : 22,5 years; duration of diabetes between 1 and 10 years mean duration : 4,6 years) and the point of view of a control group (50 patients with acute chirurgical illness, 28 male, 22 female, same range of age) about : 1 - psychoemotional stress in every day life. 2- stressful events and onset of disease. We also ask diabetics about : 3 - relation between stress and metabolic control. The results show 1- number of psychoemotional stressful events in diabetic patients was higher than in control group (44 versus 15); different types of stressful events were reported: death in the family, problems with divorce or separation, legal problems, difficulties with family members, school and job problems. 2- 70% diabetics patients and only 26% control patients said they have lived stressful events before illness onset ($p<10^{-4}$). 3- 25 diabetic patients said that stress impairs metabolic control producing hyperglycemia alone (20 patients) or hyperglycemia and ketonuria (5 patients). These data suggest the importance of educating type 1 diabetic patients about relation between stress and their disease.

2483

MULTIDISCIPLINARY BOARDING IN EDUCATION OF THE DIABETIC CHILDREN AND ADOLESCENT , PSYCHOLOGICAL ASPECT

L. Pelegrina A. Rivero M. Ciambella and R. Varela. Notti Hospital, Mendoza, Argentina

It describes a modality of interdisciplinary attention that emphasized the psychoterapeutic boarding to identify the psychological aspects that interfere in the education process and in the treatment. It was worked with 150 diabetic children and their families Their ages are of 6 to 15 years from june 1994 of until july 1995 It was realized a psychological evaluation that was formed of individual and familiar interview,proyectives, graphic and verbal tests. Of the material to extract graphic statistical as holding to the theorist postulates. The results to which arrive:the psychological characteristics were in a 100 % depressive elements of the personality and dependence- passivity ; in a 80 % impulses auto-heteroagresives and negation of the sickness and in minor percentage 60 % difficulty in the acceptance of the limits and to be integrated to the group of even. As soon as the parents the 74 % label to the sons as the" poor thing" and a 20 % as alone" to be diabetic", the remainder see to the sons in normal manner. Fit into to spotlight that to measure that the treatment advances, these psychological characteristics have improved in a 80 %. This permits us to conclude that the interdisciplinary boarding permits advances in the boy and the family.

2484

THE THIRD VERSION OF THE DIABETES ATTITUDE SCALE (DAS -3)

R Anderson, J Fitzgerald, L Gruppen, and M Funnell, University of Michigan, Ann Arbor, Michigan, USA

The purpose of this study was to improve the psychometric properties and clinical relevance of the Diabetes Attitude Scale (DAS). The DAS is a general attitude scale that can be used to compare diabetes-related attitudes of nurses (RN's), physicians (MD's), dietitians (RD's), and patients. Content validity was assured by having the new items for the DAS-3 generated by a panel of 22 diabetes experts (including physicians, nurses, dietitians, social workers, and patients) at the University of Michigan. A total of 210 new items were generated. A modified Delphi process was used to reduce the list to 17 new items. The 17 new items and 18 clinically relevant and psychometrically sound items from the previous DAS were combined to create the DAS-3 with 35 items. The DAS-3 was then completed by 531 RN's, 567 RD's, 320 MD's, and 378 patients with diabetes (Total n=1796). The revised subscales (along with their Chronbach α's) are: need for special training to treat Diabetes Mellitus (DM) .67; seriousness of Type II DM .80; value of tight glucose control .72; psychosocial impact of DM .65; and patient autonomy .76. These subscale reliabilities are significantly (p<.0001) better than the two earlier versions of the DAS. The validity of the DAS-3 is further supported by the finding that specialists in treating diabetes had significantly (p < .0001) more positive (as defined by the expert panel) attitudes than nonspecialists on all five DAS-3 subscales. The DAS-3 is a valid and reliable general measure of diabetes related attitudes that can be used to compare the attitudes of different groups (e.g. patients, health care professionals) and for program evaluation.

2485

DIABETES & STRESS: THE FORGOTTEN LINK

W. Colina-Pineda and L. Colina-Bracho. Carabobo's State Diabetes Association. Valencia. Venezuela.

As part of our program "Consciousness of Being", patients and relatives (150n) have praise since 1987 the benefit of regular practice of Mental Exercises (muscular relaxation, deep breathing and visualization). To evaluate the objetive /subjective impact of these experiences we did a 20min. - early morning practice, randomly choose 30 non-trained patients and made measurements in glycemia, pulse, systolic/diastolic pressure and changes in physical and emotional complaints. The group A, with hypertension(61yrs.age, 10yrs.DM evolution) and oral treatment had a glycemia derease 22mg/dl, pulse decrease 06rpm,a systolic increase15 mmHg, no change in diastolic pressure. The group B,with out hypertension(54yrs., 08yrsDM) and oral treatment had glycemia decrease24mg; pulse, systolic& diastolic with no change.The groupC,without hypertension(22yrs,05yrs DM) and insulin treatment had glycemia decrease 69mg, pulse decrease 02rpm, systolic decrease12mm, diastolic decrease 19mm.Of all groups, 20% had physical complaint (75%improved)and 60% had emotional moan(85% improved). This short-term result expose the usefulness of Mental Exercises to get a well being state, condition that seem related with - moderate glycemia decrease. We do recommend Mental Exercise, as daily therapeutic tool in the diabetic treatment.

2486

ASSESSMENT OF DIABETES-RELATED DISTRESS IN IDDM vs.NIDDM INSULIN TREATED PATIENTS

G. Roman, Diabetes Center & Clinic, Cluj-Napoca, Romania

The study intended to identify the levels of diabetes and insulin treatment-related distress. **Patients**: 86, IDDM-66,NIDDM insulin treated-20, mean age-37.06 ± 18.23years, duration of DM-7.74 ± 6.03 years, number of injections/day-2.5 ± 0.98, with the same education. **Method.** Psychometric instruments have been used: PAID-test (Problem Areas In Diabetes Survey-H.Polonsky) and a structured interview assessing insulin treatment-related emotional distress. **Results.** The general PAID-score, was 50.44 ± 21.12, higher in NIDDM than IDDM patients (57.1 ± 13.27 vs 48.42 ± 17.03).As serious problems were reported the diabetic complications (63.6% IDDM vs 70% NIDDM) and the guilty feeling when the diabetes management was not followed (54.51% IDDM vs. 40% NIDDM). The insulin requirement for the well being status, was recognized by 70% of IDDM patients vs. 30% of NIDDM patients; 42.42%IDDM and 40%NIDDM patients are dissatisfied with the meal and insulin regimen.The acceptance of the disease and the treatment, was present in 48.48% IDDM vs. 60% NIDDM patients. Among them, 71.42% IDDM and only 28.5% NIDDM patients were worried about the future. In spite of the worry about complications,41.86% are not satisfied with the diabetes regimen, a possible obstacle for a good care.There is a significant relationship between emotional distress and worry about complications. **Conclusions.** Insulin treated patients, especially NIDDM patients, have a high level of distress, the main problem being the future complications. A small number of NIDDM patients recognised the necessity of insulin; even if the majority of them are concerned about complications; they hardly agree with the meal and insulin regimen.The negative reaction towards insulin therapy is an obstacle for a good metabolic control; it is need to provide education according to psycho-emotional identified problems. The IDDM patients, have a higher acceptance of insulin regimen and meal planning, to avoid diabetic complications. PAID- test could be useful for an efficient education and treatment approach.

2487

GENDER DIFFERENCES IN QUALITY OF LIFE AMONG PERSONS WITH DIABETES MELLITUS IN S INDIA. Madhu K, Veena S and Sridhar GR*. Andhra University and *Endocrine & Diabetes Centre, Visakhapatnam, India

We have studied the quality of life (QOL) using diabetes quality of life measure employed in the DCCT. The scoring was done according to the modified method of Jacobson et al (1994), where raw scores were converted into 100 point scale, with 100 representing the highest possible score (ie best quality of life). The random selection of patients (n:227; 144 men, age 49.22 +/-10.78 years, duration of diabetes 5.4 +/-4.88 years; 83 women; age 49.22+/-10.78 years, duration of diabetes 6.28+/-5.67 years), was done from three Diabetes clinics of Visakhapatnam. The women had a consistently poorer score (ie worse QOL) than men on all aspects in quality of life -- satisfaction core (62.17+/-7.5 in men; 59.14+/-6.84 in women; p<0.01), social and diabetes worry (26.94+/-5.77 in men; 24.17+/-6.31 in women; p<0.01) and total quality of life score (174.15+/-20.19 in men, 166.47+/-15.72 in women; p<0.01). Women as a group felt their health was poorer compared to other women of their age group. In summary, we have shown that women with diabetes scored lower on quality of life score, compared to men with diabetes.

2488

VALIDATION OF THE DIABETES-39 DISEASE SPECIFIC QUALITY OF LIFE INSTRUMENT IN DANISH, FINNISH, NORWEGIAN & SWEDISH

A Lloyd, M Keech and JG Boyer. Glaxo Wellcome, Greenford, UK.

Measurement of health-related quality of life is increasing in importance for assessing patient perception of therapy and for evaluating interventions and care programmes. The Diabetes-39 has recently been developed in English for use in all people with Type 1 or Type 2 diabetes - whether managed with insulin, oral agents or diet alone. Due to differences in culture, attitude and perception, the properties of any quality of life instrument must be assessed separately for each translation of the instrument. This study evaluated the reliability and validity of new translations of the Diabetes-39 into Danish, Finnish, Norwegian and Swedish. Translation was by a process of two forward and one backwards translations: an accepted methodology. Patients enrolled in a clinical trial of a novel antidiabetic agent were asked to complete the Diabetes-39 at baseline and after three and six months of the study. The SF-36 generic quality of life instrument was also administered. Psychometric evaluation of baseline responses was performed. 467 patients completed evaluable questionnaires at baseline: 68 in Denmark, 180 in Finland, 118 in Norway and 101 in Sweden. The translations of the Diabetes-39 were found to be reliable and valid and their psychometric performance was consistent with the original, US English, version. Internal reliability of the instrument's five scales (Diabetes Control, Anxiety and Worry, Social Burden, Sexual Functioning, Energy and Mobility) was supported by Cronbach's alpha of >0.7 for all scales in all countries (range 0.78-0.93). The results of other psychometric tests confirmed the validity of the translations: definite scaling error occurred for less than 1% of assessments; construct validity, assessed by intercorrelating scales of the Diabetes-39 and correlation with the scales of the SF-36, was consistent with *a priori* expectations. The Diabetes-39 is now validated for use in patients in these countries.

2489

BULIMIA DIABETICA

L. William-Olsson, Swedish Diabetes Organization, Stockholm, and University of Umeå, Umeå, Sweden.

Main aim: To help diabetes care teams prevent, identify, and handle bulimia among patients with IDDM, and to develop psychotherapy methods. **Background:** In one psychologist's practice, 40% of clients suffered from eating disorders, responding well to psychosocial support and information; those with IDDM and bulimia did not: some requested psychotherapy. Bulimia prevalence in IDDM was 6% in one report, agreeing with the author's experience of people with IDDM, but higher than commonly expected. In individual psychotherapy sessions, clients with IDDM described their compulsive eating and purging as extremely shameful. They hid these habits from doctors and nurses, often even from family members. **Methods:** Twenty group meetings were held in Swedish cities, with a total of 300 participants (persons with IDDM and members of diabetes care teams). ***Bulimia diabetica*** was suggested as a descriptive term for the syndrome under discussion. **Results:** During the meetings, persons with IDDM described how they, from the time of onset of the disease, had been taught to weigh all their food (and themselves), initially achieving near-normoglycaemia; in later years, their FBG concentrations were low, levels of glycated haemoglobin high. Strenuous efforts were made to keep body weight low through physical exercise and hyperglycaemia with glucosuria. Since eating caused anxiety, they withheld insulin. Some kept to a strict regimen of training, vomiting, and expectorating. **Conclusion:** Diet teaching may be a risk factor for eating disorders. Bulimia is frequent in IDDM, though often hidden; thus prevalence can be underestimated.

2490

PSYCHOLOGICAL IMPACT OF ISLET CELL ANTIBODY SCREENING.

A. Galatzer, E. Green, R. Ofan, H. Ben Zaken, Z. Josefsberg, N. Wientrob M.Karp and P.Vardi, SCMCI, Petah-Tikva, Israel.

The purpose of this priliminary study was to evaluate the psychological impact of Islet Cell Antibody (ICA) screening and its results on at risk individuals and their family members. ICA+ individuals were identified through a large scale screening program conducted at our institute. The sample consisted of 9 families in whom 10 youngsters with ICA+ were identified. The 7 boys and 3 girls ranged in age from 6 to 18 years (mean age 11.8 median age 10 years). Both parents participated in the study. Eight diabetic youngsters (mean age 15.2 median age 16) as well as 9 healthy sibling were also included in the study. (One family had 2 diabetic children and in two families one of the parents was diabetic). Reactions to positive results of ICA were assessed by a structured questionnaire and with the Impact of Events Scale (IES). The IES was answered twice : within a week from the disclosure of the ICA+status and 3 months later. Although mothers' reactions on the IES were higher than that of the fathers ,no significant difference was found between parents.

Impact of events scores at diagnosis and three months later

	Intrusion		p	Avoidance		p
parents	14.6 ± 6.2	7.1 ±3.5	.004	16.6 ± 8.2	11.3 ±5.5	.04
diabetic	4.3 ± 2.1	2.0 ±1.0		3.6 ± 2.2	3.6 ±1.9	
ICA+	7.5 ± 1.7	3.5 ±1.4		2.0 ± 1.3	1.0 ±0.7	

The results suggest that learning one's ICA+ status induces significant anxiety especially in parents of ICA+ youngsters. Although this initial anxiety is diminished over time, it still remains quite high after 3 months. Although preliminary, these results highlight the importance of maintaining sensitivity to the impact of ICA screening upon the entire family.

2491

COMMITMENT TO SELF-CARE AND METABOLIC CONTROL AMONG IDDM PATIENTS

M. Toljamo and M. Hentinen. University of Oulu, Oulu, Finland.

The aim of the study was to assess the relationship between commitment to self-care and metabolic control among adult patients with diabetes in Finland. The data were collected from 213 patients (age ≥ 17 year) using questionnaires. The response rate was 75 %. Most of the respondents (63 %) were on flexible insulin therapy (>3 injections per day or an insulin pump). According to the results, the patients had no problems with their insulin treatment, though they had some problems observing the diet. A fifth of them (21 %) ate daily whatever they wanted without thinking of the nutrient content of the food. Many (82 %) mentioned some difficulties with evaluation of the food consistency. 39 % did not monitor their blood glucose regularly, and a tenth of the patients did no monitoring at all. In spite of this, SMBG was not perceived as being problematic. Altogether, 48 % of the patients did not mention any difficulties in their daily care, but reported more problems related to special situations, such as attending parties. The mean of glycosylated hemoglobin as a measure of metabolic control was 8.1 % (sd 1.94). The patients who had had diabetes for a longer time had poorer GHbA1c ($r=.23$, $p<0.001$) than the others. Those with good metabolic control (under 8.0 %) reported better observance of diet regimens than those with poor metabolic control ($p<0.001$). There was no statistically significant relationship between metabolic control and SMBG, exercise, or insulin treatment. Nevertheless, although if the patients evaluated themselves to be active and responsible in the care no response was seen in metabolic control in this population. In conclusion, the results suggest that patients with diabetes can have better metabolic control with commitment to the observance of diet regimens than to the other aspects of diabetes care, although there are many other variables relating to metabolic control as well.

2492

PROSPECTIVE STUDY ON QUALITY OF LIFE IN IDDM PATIENTS AFTER PANCREATIC-RENAL GRAFTING

S. Lippert, W. Piehlmeier and R. Landgraf, University of Munich, Germany

To investigate the effects of successful combined pancreas and kidney transplantation on quality of life (QOL) a prospective study was performed. Therefore a multi-dimensional questionnaire was mailed twice in 1989 and 1995 to all patients in the transplantation program in a single transplantation center. In 41 IDDM patients data of both evaluations were available: **Group A** (n=12): patients on the waiting list for transplantation in 1989, meanwhile successfully pancreas and kidney grafted: age 40,7±9,6 yrs, duration of diabetes 28.3±4,7 yrs, duration of dialysis 46,7±20,2 m, time posttransplant 3,8±1,7 yrs. **Group B** (n=15): patients after successful simultaneous pancreas and kidney transplantation at both evaluations (age 44,1±9,6 yrs; duration of diabetes 29.3±5,1 yrs, duration of dialysis 31,2±22,1 m, time since transplantation 8,7±1,8 yrs. **Group C** (n=14): posttransplant patients with functioning kidney graft and under insulin therapy at both evaluations: age 45,2±7,2 yrs, duration of diabetes 34.1±10,1 yrs, duration of dialysis 32,5±37,2 m, duration of renal graft functioning 9,3±2,2 yrs. Questions for satisfaction with different aspects of QOL were answered using a rating system from 1 (very dissatisfied) to 5 (very satisfied). Means ± SD were calculated for each item separate for each group and both evaluations respectively. For testing significance of intraindividual changes the Wilcoxon signed ranks test for paired samples was performed. In **Group A** a marked improvement of QOL scores was observed in 7 of 9 different aspects of QOL (f.e. physical capacity: 1995 3.1±1,4 vs.1989: 2.1± 0,8 ;partner relationship:1995: 4.3±0,9 vs. 1989: 3.9± 1,5 ; sexual activities: 1995: 2.8±1,5 vs. 1989: 1.9±1,1) , in two items values remained stable. However with respect to overall QOL a significant improvement was observed (1995: 3.8±0,6 vs. 1989: 2.5±0,9 ; $p<0.05$). **Group B** also showed an improvement in 5 aspects of QOL plus in overall QOL (1995: 4.3±0,7 vs. 1989: 3.8±0,9), but this was insignificant. In 4 aspects (mental capacity, family life, number of friends, leisure time activities) the satisfaction deteriorated. Patients in **Group C** remained exactly or nearly stable in all aspects of QOL (f.e. overall QOL 1995: 3.7±0,6 vs. 1989: 3.9±0,8). These data indicate an additional positive influence of pancreatic grafting on QOL when compared to single kidney transplantation in diabetics.

2493

EQUIVALENCE OF THE PAPER-AND-PENCIL AND THE COMPUTERISED ADMINISTRATION OF THE WB-Q AND THE DTSQ.

F. Pouwer, F.J. Snoek, R.J. Heine, and H.M. van der Ploeg. Vrije Universiteit, Amsterdam, the Netherlands.

To monitor well-being and satisfaction with treatment in patients with diabetes, the St Vincent Declaration recommended the use of two instruments, the Well-being Questionnaire (WB-Q) and the Diabetes Treatment Satisfaction Questionnaire (DTSQ). It is argued that clinical practice benefits from computer-assisted administration of both questionnaires. Aim of the current study was to investigate whether the paper-and-pencil assessment and the computerised assessment of the WB-Q and the DTSQ can be considered equivalent. One hundred and five patients with diabetes, treated at the outpatient clinic of the Academic Hospital of the Vrije Universiteit (Amsterdam), were invited to take part in the study. A randomised crossover design was employed. Seventy six patients completed both a personal computer and a paper-and-pencil version of the WB-Q and the DTSQ in a randomised order, with a mean interval of 7 days. Mean age was 48.1 years (sd 17.9), 61% was female. Data suggest that the traditional paper-and-pencil questionnaire and the computerised version of the WB-Q and the DTSQ can be considered equivalent according to criteria formulated by the American Psychological Association. The scales showed high test-retest correlations and the means, dispersions, kurtosis and skewness were found to be approximately the same in both versions. In both ways of assessment, the WB-Q Depression scale and the WB-Q Energy scale proved to be sensitive for carry-over effects, resulting in better well-being scores at the second measurement (one week later). Although even 58% of the subjects reported that they had rarely or never used a personal computer, 99% of the subjects found the questionnaires (very) easy to complete on the personal computer. It is concluded that norms and cutting scores obtained from paper-and-pencil assessments can be used in computerised versions of the WB-Q and the DTSQ.

2494

IMPEDIMENTS TO DIABETES CARE IN PRIVATE MEDICAL PRACTICE IN A DEVELOPING COUNTRY.

S Goenka, P Shah, J Lobo, T Patel, A Sood, KS Reddy, N Delhi, India.

Background: Medical care is not state funded for most citizens in India. Most diabetics are followed with private medical practitioners (family physicians, specialists).
Aim: In order to plan a diabetes education module for patients and to explore for issues not addressed in KAP surveys. ***Study subjects:*** 20 private medical practitioners at their clinics in different areas of Delhi, and different educational levels and 20 diabetics followed up in private medical practice. ***Design:*** a cross-sectional, multiple, free flowing, friendly, guided interviews (mean: 3 hours per interview). ***Results:*** **Doctors believe** that the impediments to effective diabetes care are: 1. patients perception that diabetes is curable (20/20); diabetic tablets and insulin are addictive to the body (20/20); should be avoided as far as possible (19/20); faith in alternative system medicine (20/20); patients getting lost after first few consultations; patients reluctance to spend $6 for fundus examination. AND 2. problems at practice: inadequate continued medical education including lack of awareness of basic skills of insulin injection technique; unawareness regarding adverse effects of oral hypoglycaemic agents (4/20); unaware of retinal and feet check-ups (4/20); prescription of overdose and multiple sulphonureas; prescription of alternative system of medicine (4/20) [with a belief in its effectiveness (2/20), or sheer fear of loss of patients (2/20); inadequate time ("can't spend more time with a fees $0.2-$0.5 per patient"). **Patients believe** that there is no relation of DM to obesity (16/20); or CHD (19/20); diabetes can disappear on its own (19/20); diabetes can be cured if properly treated (20/20); people who do not eat sugar need not test for diabetes and its control (19/20); one cannot have high BP if one is feeling fine (6/20); alternative system medicine are effective (17/20) [should not be taken with oral hypoglycaemic agents (8/20)/ can be taken (9/20)]; unaware of incurable blindness (retinopathy) (18/20) associating poor DM control with spectacles ; take an extra oral drugs when one eats more than usual (6/20).
Conclusions: an understanding of the patients' and their health care providers' constraints and beliefs have been uncovered.

2495

DIABETES RELATED DEPRESSION IN YOUNG INSULIN DEPENDENT DIABETES MELLITUS (IDDM) PROBANDS

R. Shobana, P. Rama Rao, A. Ramachandran, S. Rajkumar.

Diabetes Research Centre and M.V. Hospital for Diabetes, Madras, India.

The study was aimed at comparing factors of depression in children with IDDM, their normal siblings and normal controls. The IDDM samples consisted of 74 boys and 76 girls, their normal siblings 21 boys and 23 girls,the normals controls 51 boys and 58 girls. The normal controls were drawn from neighbouring schools. All subjects were in the age group 7 - 18 years. All groups were matched for relevant demographic variables. Kovac's children depression inventry was used to measure depression scores. The data were processed using 3*2 factorial analysis of variance followed by one-way analysis of variance and t tests. None had scores diagnostic of depression. But within normal range of scores on depression factors the IDDM probands were significantly less depressed, lower in negativemood, ineffectiveness, anhedonia, and negative self-esteem than the normal controls (P=0.001). Results indicated that the IDDM children had developed good coping devices and made psychologically healthy adjustments. It is to be noted that IDDM probands and their parents had the advantage of diabetes education programme and counselling.

2496

TREATMENT SATISFACTION IN 657 TYPE 1 DIABETIC PATIENTS.

U. Bott, I. Mühlhauser, H. Overmann and M. Berger. Clinic of Metabolic Diseases and Nutrition, Heinrich-Heine-University Düsseldorf, Germany

Assessment of Treatment Satisfaction is an integral part of the evaluation of new treatment strategies. However, there are no validated measures taking account of individual treatment goals in order to help tailor treatment strategies to individual patient needs.

In a population-based study, a treatment satisfaction scale (TSS) was validated in 657 adult IDDM patients (41% women, age 36 ± 11 years, diabetes duration 18 ± 11 years, HbA_{1c} 8.0 ± 1.5%; mean ± SD). The TTS comprises 20 items: patients rate the desirability of 10 different treatment goals (e.g. stability of blood glucose, diet flexibility, avoidance of mild or severe hypoglycaemia) on a 6-point Likert scale and, accordingly, the degree of satisfaction with the achievement in these treatment goals. The product of both ratings provides a preference-weighted treatment satisfaction score. TSS score was moderately associated with HbA_{1c} ($r = -.22$; $p < .001$) and quality of life ($r = .42$; $p < .001$). Patients with more than two episodes of mild hypoglycaemia / week ($p < .001$), those with HbA1c values above 9% ($p < .001$), patients with late complications ($p < .05$) and patients living alone ($p < .01$) perceived less treatment satisfaction. Kind of insulin therapy was not associated with treatment satisfaction. ANOVA revealed a two-way interaction between treatment goals and insulin therapy on treatment satisfaction ($p < .01$). Patients with unrealistic treatment goals (aiming at good and stable blood glucose levels but at the same time intending to avoid frequent self-monitoring, to avoid even mild hypoglycaemia and to conceal their disease from other people) achieved the lowest scores under intensified insulin therapy. Patients with realistic goals (categorisation by cluster analysis) achieved the highest scores when intensively treated. Unrealistic treatment goals were more frequent in patients with a low social status and patients with conventional insulin therapy ($p < .001$).

The TSS is a valid instrument to assess preference-weighted treatment satisfaction. High scores do not necessarily indicate a good treatment. Assessment of individual treatment goals may be helpful to identify motivational deficits and to tailor individual treatment strategies.

2497

SMBG measurements in unstable diabetics do not correlate well with their HbA1c

Y. Sato, S. Ota and T. Toyota, Sendai, Japan.

Measuring SMBG and HbA1c are useful methods to estimate long-term glycemic control in diabetic patients. However, the correlation of the SMBG and HbA1c measurements in unstable diabetic patients is not clear. Therefore, we compared the theoretically predicted HbA1c values from SMBG measurements and the measured HbA1c values in unstable diabetics. Subjects were 5 IDDM patients. They made SMBG measurements 3 times or more every day, however their blood glucose measurements fluctuated very much. The calculated mean of the SMBG measurements of a day was assumed to be the mean blood glucose of the day. HbA1c had been indicated theoretically to be proportional to the weighed mean of the blood glucose for 120 days. The weighed mean of the blood glucose was calculated using the calculated daily mean blood glucose for 120 days. The relationship of the measured HbA1c values and the calculated weighed means were then analyzed. There were no correlation between the measured HbA1c and the calculated weighed mean of blood glucose in all subjects. Therefore, we concluded that the calculated mean of blood glucose of a day from SMBG measurements was not a correct measure of the real mean of blood glucose of the day in unstable diabetics.

2498

PATIENT AND DOCTOR'S PERCEPTION OF DIABETIC CONTROL

S. Robinson[a], J. Kidd[b], C. Tydeman[b], A. Robinson[a], P. Chong [a], T. Marteau[b] and R. Elkeles[a] Unit of Metabolic Medicine St Mary's Hospital[a] and Unit of Psychology Applied to Medicine Imperial College School of Medicine[b], Norfolk Place, Paddington, London, W2 1PG

We aimed to study patients' perception of their diabetic control. 133 patients agreed to participate in the study. Patients perceived a mean level of diabetic control on a scale of 0 (poor) to 7 (well controlled) was 4.7±1.6 (mean±SD) when HbA1c was 8.0±1.5. Patients who perceived their health as poor had higher HbA1c than those who perceived their health as excellent (9.2± 2.1 v 7.7± 1.5 %, $p<0.01$). Patients who perceived their control as good also perceived better general health ($p< 0.001$). Perceived diabetic control was negatively correlated with HbA1c at the beginning and end of the study ($r = -0.39$ and $r =-0.41$ $p<0.0001$). Patients describing themselves as well controlled were better controlled. They were also more satisfied with their consultation. Doctors perceived consultations with these patients as more satisfactory and thought the patients would be more likely to comply. Patients complying with advice on weight perceived their general health and diabetic control to be better after three months. However patients perception of compliance did not correlate with improvement in HbA1c. In conclusion patients are good at perceiving their own control and this correlates with wellbeing. Doctors perception of compliance and actual compliance may be at variance.

2499

QUALITY OF LIFE OF THE PATIENTS WITH DIABETES MELLITUS AND ITS INFLENCE FACTORS

Fan Li-Feng, Huang yu-rong, Li Hai-yang. Department of Endocrinology, General Hospital of PLA, Beijing China, 100853

The aim of this paper was to investigate the influence factors of the quality of life.

Material and Methods: There were 143 patients with diabetes mellitus, based on WHO diaghosis standard. Investigation table included 156 questions (3 aspects) in total. The content of quality of life cocsisted of 14 items, covering physiological, psychological, social function and Living conditions.

Results and Discusstion: The results showed that mang abnormal changes of quality of life were found in the patients with diabetes mullitus . Among them the decrease of memory and lack of attention concentration were the most obvious . And less important changes were abnormal emotional reactions, reducing of entertainment activities, social adaptation and work ability . The age, degree of aducation, condition of the illness, complications, social and family background have effects on the quality of life.

GLYCOSILATED HAEMOGLOBIN CORRELATES WITH COGNITIVE FUNCTION IN PATIENTS WITH INSULIN DEPENDENT DIABETES MELLITUS

M. De Angelis. G. Calabrese, T. Sciarma*, S. Frizza*, C. Cantoni*, M. Massi Benedetti and M.Piccirilli*
Dipartimento di Medicina Interna e Scienze Endocrine e Metaboliche;
*Istituto di Malattie Nervose e Mentali Università di Perugia. Italy.

This study investigates the correlation between the glyco-metabolic control of Diabetes and Cognitive Function (CF) in patients with Insulin Dependent Diabetes Mellitus (IDDM) younger than 50 years and without any primary and secondary illness. IDDM patients were between 20 and 50: schooling ≥5 years; onset of disease before the age of 35: no concurrent diseases that could justify cognitive deficits as hypoglycemia before and after test, alcohol abuse, uremic and hepatic encephalophaty, thyroid disfunction. In all the patients a brain computerized tomography (CT) and E.E.G. were negative. CF were analyzed using a battery of neuropsychological tests for the following intellectual functions: memory, attention, visuospatial analysis, language, praxia, perceptual recognition, "frontal function", visuomotor coordination (Raven's CPM 47, WAIS digit span, Corsi cubes, prose memory, Rey's Figure A, WAIS digit symbol, Wisconsis card-sorting, Buschke-Fuld verbal learning, Benton Judgement of Line Orientation, Grooved Pegboard test A and B, Stroop test, phonological fluency, sematic fluency). Performance was compared with the normative data from control subjects equivalent in age and education. The patients with highest HBA1C had the highest compromission of CF. This result introduces a new and not very analyzed problem in the communication amongst the doctor, his staff and the patients: 1) The patient may have difficulty in learning what the doctor and his staff teach. 2) the doctor and the staff may be frustrated and distort the education of the patient Since education is generally considered the most important form of therapy, its alteration represents a serious damage for these young patients.

2501

TYPE 2 DIABETES AND ITS INFLUENCE ON THE PATIENTS' PSYCHOLOGICAL WELL-BEING.

M.Ravnik-Oblak, Al.Oblak and V.Urbančič-Rovan. University Medical Centre Ljubljana, Slovenia.

The aim of the study was to evaluate the influence of type 2 diabetes on the quality of patients' life from the psychological point of view. 100 type 2 diabetics (average age 59.6 yrs, average duration of diabetes 11.5 yrs, 50 on oral therapy and 50 on insulin), attending our out-patient diabetes clinic, participated in the study. The patients who were divided into groups regarding age, sex, level of education, diabetes duration, therapy, metabolic control, and presence or absence of chronic complications answered the ATT 39 questionnaire which serves for the appraisal of the patient's adaptation to diabetes. According to these results, our patients are well adapted as it can be deduced from the positive direction of the score of the total 39-item scale and of its parts. Interestingly, more than 75% of the patients gave identical answers to 1/3 of the questions. Positive influence of the regular education of our patients was shown, as the majority of them feel capable of coping with their illness, are cooperative, and in 99% establish good relationship with their therapist. In general, we have not found any statistically significant differences between the groups concerning the studied parameters, although replies by males, younger patients and patients with shorter diabetes duration tended to be more positively oriented. The illness was more stressful to the insulin-treated patients and to those with advanced chronic complications. The latter have, expectedly, reconciled themselves with every-day measures necessary for control of their diabetes.

We conclude that diabetes is not inevitably associated with poor psychological or physical feeling. Probably, education of patients as well as good relationship between the patient and the therapist play an important role.

2502

PERSONALITY PROFILE OF INSULIN NON DEPENDENT DIABETICS

N .D. Jokic, G . S. Pudar and I.M . Hercigonja-":Zvezdara" University hospital, Belgrade, Yugoslavia

The psychosocial structure of NIDDM patients is of great importance for the education and the achieving of satisfying therapeutic effects. The psychosomatic model of approaching internal diseases is also applied to diabetes mellitus. 21 persons ,11 female [f] and 1o male [m] had participated in this research. Psychiatric interviews had been accomplished with each patient, as well as EPQ- Eysenck test which considers 4 personality features: P- psychoticism [rigidity], E- extravertness, N- neuroticism [emotional instability] and L- longing for social acceptance. Eysenck differentiates the characteristics of 4 classical temperaments: sanquinic, melancholic, choleric and phlegmatic. In total score , our patients had: P values 9,17% lower, E values 3,71% higher, N values 11,17% higher and L values 20,77% higher than normative values. The single analysis of each test result gives the following picture: 7 melancholics [5f, 2m], 7 sanquinics [4f, 3m], 5 cholerics [1f,4m] and 2 phlegmatics [1f, 1m]. There is no statisticaly important difference between groups [Fp=1,014, p=0,412 , p.>0 ,05] and sexes [Fp=0,364, p=0,782, p.>0,05].,tested by ANOVA. The longing for social acceptance is remarkably increased.

2503

THE GLUCOCARD MEMORY 2 BLOOD GLUCOSE ANALYSER. AN EVALUATION OF ITS ANALYTICAL PERFORMANCE.

W. G. John. Clinical Biochemistry Department, The Royal London Hospital, Whitechapel, London. E1 1BB. UK.

The Diabetes Complications and Control Trial demonstrated for the first time the beneficial effect to the diabetic patient of good glucose control. It has been shown that self glucose monitoring is of central importance in achieving good glycaemic control. The Glucocard Memory 2 glucose meter (A. Menarini Diagnostics, Florence, Italy) is a new meter designed for patient and clinic use; it uses a biosensor strip which utilises glucose oxidase to estimate blood glucose. Analysis is initiated by the application of blood, which is introduced into the strip by capillary action. Performance was investigated by using either fresh blood, blood collected into EDTA or Fluoride Oxalate. Imprecision was assessed by 20 repeat measurements of samples. Linearity was investigated by measuring glucose (in triplicate) in a mixture of whole blood samples with a low and a high glucose concentration. Samples analysed on the Glucocard Memory 2 were additionally analysed for glucose using a hexokinase method on a main biochemistry analyser (ILab 900). Results demonstrate good precision throughout the analytical range of the meter, typically 4.5% CV at a glucose concentration of 1.2 mmol/L (22 mg/dL) and 3.0% CV at a concentration of 10.0 mmol/L (180 mg/dL). The analyser was found to be linear (y = 1.00x - 0.32; r = 1.00) throughout the quoted analytical range (1.1 - 33.4 mmol/L; 20 - 600 mg/dL). Good correlation was demonstrated (y = 1.1x - 0.5; r = 0.99) between the Glucocard Memory 2 (y) and the hexokinase reference method (x). Haematocrit ranging from 35% to at least 68% had no significant effect on the result obtained, this meter can confidently be used with paediatric samples. The ease of use of this meter (especially the ease of sampling) and its excellent analytical performance will result in this meter becoming an important new tool in self monitoring, and because of the sampling process will play an important role in the diabetic clinic.

2504

HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH INSULIN-TREATED DIABETES MELLITUS IN SUDAN

M.N. Elbagir, M.A. Eltom, E.O. Mahadi, K. Wikblad and C. Berne. Department of Internal Medicine, Uppsala, and College of Health and Caring Sciences, Falun, Sweden, and Endocrinology and Diabetes Center, Omdurman Teaching Hospital, Sudan

To determine health-related quality of life (HRQL) in people with insulin-treated diabetes mellitus in Sudan, a total of 89 patients aged 25-55 years and with ≥ 5 years diabetes duration was studied. HRQL was measured with a 68-item questionnaire from the Medical Outcomes Study. Late diabetic complications were assessed, and haemoglobin $A1_c$($HbA1_c$) was measured to assess the metabolic control. Of the patients (m=36; f=53), only 13.5% had good metabolic control ($HbA1_c$ < 7.5%). These patients rated their HRQL as worse than patients with poor metabolic control ($HbA1_c$ > 10%). However, the latter were significantly younger, had shorter diabetes duration, and were free from late complications. Overall, 49.4% of the patients had one or more of the late diabetic complications. These patients rated their HRQL significantly lower when compared with patients without complications. Older age and the presence of late diabetic complications were the most important predictors for HRQL. The results indicated that self-rated HRQL in this group of patients is generally low. Improving diabetes knowledge and the metabolic control since early in the course of the disease, will not only retard the development of late complications, but will certainly improve the HRQL of these patients.

2505

PSYCHOSOCIAL WELLBEING OF THE DIABETIC; THE DIFFERENCE BETWEEN THE IDDM AND NIDDM DIABETICS

Marja-Leena Keskinen, Sociology, University of Turku. Turku, Finland.

The study examines the wellbeing of the diabetic, the differences in psychosocial factors between IDDM and NIDDM, the self-image and life control and compare the characteristics of IDDM diabetics and heart diseases type A and NIDDM and type B. Teory: a model considering the quality of life on human being as a whole, symbolic interaction, coherence feeling and self-image. The material of the empirical part was collected in 1992 by a questionnaire, aged 16 and 64,in Turku. Analysing methods were the factor and the wariance analysis. Conclusions: Psychosocial factors differences were found in social life situation, health factors, working-life factors, knowlegde level of the one's illness and life control. Social and psychosocial coping on IDDM is significally better than that of NIDDM. The IDDM diabetics have a stronger self-image and better life control. The prominent characteristics were autonomy, balance, sociability, courage and energy. Long-term illness develops character. It seems that diabetes is a high-living-standard and way-of-life illness. It is easier to prevent NIDDM than IDDM by changing way-of-live.

2506

ASSESSMENT OF GENERAL AND DIABETES SPECIFIC FEARS IN INSULIN REQUIRING ADULT DIABETIC PATIENTS.

E.D. Mollema[1], F.J. Snoek[1,2], L.M. Bouter[1], R.J. Heine[1,3], H.M. van der Ploeg[2]. [1]EMGO Institute, Vrije Universiteit, [2]Department of Medical Psychology, Vrije Universiteit, [3]Department of Internal Medicine, Vrije Universiteit Hospital, Amsterdam,The Netherlands.

Literature suggests that anxiety disorders occur more often among people with diabetes than in the general population. Aim of this study was to assess both general and diabetes-specific fears in diabetic patients. General fear was measured by the STAI-DY-2, a questionnaire referring to trait anxiety. Other measures included were diabetes-specific: the Diabetes Fear of Injecting and Self-testing Questionnaire (D-FISQ), which was developed to measure the degree of fear of self-injecting and fear of self-testing of blood glucose, and the Dutch version of the Hypoglycemia Fear Survey (HFS). Also, patients were asked how concerned they were about having (further) diabetic complications. A sample of 266 insulin requiring adult diabetic patients (50% ♂, 72% type II) filled in these questionnaires. Intercorrelations between the questionnaires are as expected, ranging from .41 to .66 (P<.001). Results show that 49 (18%) patients (27♂, 39 type II) have one or more high scores on the measures; almost half (23) of this group obtained multiple high scores. Fourteen patients scored ≥ 2 s.d. above mean on the trait-anxiety scale. On the specific questionnaires, respectively 13 and 14 (9♂) patients scored in the top 5% on fear of injecting & fear of self-testing. 14 patients had scores ≥ 2 s.d. above mean on the HFS. Twenty patients were "always" worried about complications. Fear of injecting and fear of self-testing seem to be different phenomena as highscorers overlap in only 7 cases. Patients scoring high on trait anxiety often also show diabetes-specific fears (12 out of 14 cases). However, a large number of high scorers (35, 71%) had (multiple) high scores on specific diabetes fears, but showed no elevated trait anxiety. A high prevalence of anxiety was confirmed in this study, demonstrating the psychological burden of diabetes and underscoring the importance of psychological assessment in diabetes care.

2507

ASSOCIATIONS AMONG DIABETES SELF CARE PRACTICES AND ILLNESS-SPECIFIC HEALTH BELIEFS: DIFFERENCES BY DISEASE AND TREATMENT TYPE.

J. Stennett and S.Boyages. Westmead Hospital, Sydney, Australia.

This study aimed to examine whether associations among illness-specific health beliefs and self care practices varied among different diabetes patient groups. The sample comprised 107 patients recruited from the diabetes centre, and was divided into three groups on the basis of patient diagnosis and treatment type: Type I patients undergoing conventional insulin therapy (n=27), Type I patients undergoing intensive insulin therapy (n=38), and tablet treated Type II patients (n=42). Self care practices and illness-specific health beliefs, including diabetes self efficacy, diabetes locus of control, and hypoglycemic fear, were assessed using self report instruments completed by patients during a routine visit to the diabetes centre. Analysis of the reliability and validity of the health belief measures supported their use in Australian patient groups. Factor analyses of the diabetes self efficacy and diabetes locus of control scales revealed the multidimensionality of these constructs, and supported an examination of associations among the components of these health beliefs and diabetes self care practices. Analysis of variance procedures comparing group means on the self care scales suggested that patient groups differed only in their diet self care ($p<.05$) and glucose monitoring ($p<.05$), with conventionally treated Type I patients reporting the most positive self care in these areas. Between group differences were also observed on several of the health belief scales. Intensively treated Type I patients demonstrated greater confidence in their ability to manage their treatment demands ($p<.05$), less fear of hypoglycemia ($p<.05$), and were less likely than other groups to consider medical professionals ($p<.05$) and others' support ($p<.05$) as essential for maintaining their health. As hypothesised, correlational analyses revealed that associations among health belief scales and self care practices differed among patient groups. Findings support a more complex conceptualisation of the structure of illness specific health beliefs, and suggest potential targets for interventions aimed at improving self care practices in different patient groups.

2508

KNOWLEDGE, ATTITUDE AND PRACTICE OF KHARTOUM DIABETICS IN RELATION TO THEIR DIABETIC STATE.

EI DAW MUKHTAR AND FAWZIA HALIM, FACULTY OF MEDICINE, UNIVERSITY OF KHARTOUM, SUDAN.

Diabetes mellitus with its concomitants has become a major health problem in the Sudan. The aim of this work is to assess patient disease related knowledge and practice and study patient attitude towards their disease condition. Two hundreds middle aged alert and ambulatory diabetes were randomly chosen. Most patients were illiterate. A structured questionnaire with closed end questions was used to obtain patient knowledge about his disease state, complications, diagnostics tests and management. Further information were obtained about daily activity, hygienic measures, reaction to disease and dietery intake. The level of knowledge and practice was poor. Most patients accepted their disease state. Patient compliance depends on his cooperation and understanding of his disease. Illiteracy may account to the lack of knowledge. This is not being helped by fragmented information given to them. The general acceptance of this disease suggest lack of appreciation of the problem. This coincided with faulty dietary practice. This study calls for urgent measures to establish patients' education programs.

2509

A DEVICE FOR RECORDING INSULIN USAGE IN DIABETIC PATIENTS WITH VISUAL IMPAIRMENT.

M. Burgess, St Vincent's Private Hospital, Melbourne, Australia.

Insulin delivery systems (pens) and 'talking' blood glucose meters allow greater independence for the visually impaired diabetic, however a means of recording insulin usage in order to calculate how much insulin is left in a 300 unit pen cartridge was needed. A small unit was devised consisting of 3 horizontal rods with 5 unit graduations secured inside the lid of a Novopen 3 case. Each rod has a small marker which is progressively moved to the right (in multiples of 5 units) to a total of 95 units each rod. When all markers on the 3 rods are moved to the extreme right, the cartridge is spent. Built in to the mechanism is a 15 unit excess allowing for patient error. Where 2 insulin pens are used they are identified with Braille or a tactile material such as Velcro to differentiate between insulins. Extensive education is needed in the precise and safe use of the talking meter and the insulin pen. A studyof 404 insulin-using patients was conducted; 62 (15%) were visually impaired, 35 (8%) were using insulin pens and needed assistance with dose recording. Trials involving nursing staff and patients were conducted over 2 years. All device users maintained their independence.

RELIABILITY OF THE SPANISH VERSION OF THE DIABETES QUALITY OF LIFE.

M. Millán, M.D Millán*, A. Sastre**, M. Balsells, J. Reviriego**. Hospital Mútua de Terrassa. Universidad de Barcelona*. Lilly**. Spain.

Results of the Spanish version of Diabetes quality of life (Sv-DQOL), evaluated in 105 diabetic patients from Terrassa (Spain) have been published recently. Our aim was to assess the reliability of the Sv-DQOL in the whole country and to find out about differences according to sex, age, diabetes duration and place of residence. From all the Spanish regions, 874 diabetic patients (mean age 43.5 y, 48% men, mean diabetes duration 10.2 y and 95% insulin-treated) answered the questionnaire and 496 of them, answered the retest. Sixty percent defined themselves as IDDM and 40% as NIDDM. Reliability was assessed for: Internal consistency (Cronbach's α) and Test-retest by Pearson's correlation. Globlal Cronbach's α was 0.88 and 0.84, 0.76, 0.8 and 0.68 for Satisfaction, Impact, and Worry: Social and Diabetes-related subscales. The test-retest correlations were in the 0.52-0.81 range ($p<0.001$). Except for Social worry, quality of life was better in the youngest group (16-25 y) than in the oldest (56-69 y) ($p<0.001$). Diabetes-realted worry was higher in women than men ($p<0.01$) and Social worry was higher in patients with longer diabetes duration ($p<0.05$). No inter-regional differences were found. The Sv-DQOL is highly reliable for both IDDM and NIDDM. The absence of inter-regional differences suggests it could be useful in other Spanish speaking countries.

2511

DIFFERENCES BETWEEN AFRICAN-AMERICAN AND CAUCASIAN PATIENTS IN SELF-REPORTED FUNCTIONAL HEALTH STATUS

F. Whitehouse, P. Williams, D. Kahkonen,and D. Nerenz, Henry Ford Hospital/Henry Ford Health System, Detroit, MI, USA

We obtained data on functional health status in a sample of 415 patients with either NIDDM or IDDM using the RAND SF-36 survey. Scores on the eight SF-36 dimensions were compared for African-American (N=129) vs. Caucasian patients(N=73) with NIDDM. (Too few African-American patients with IDDM were available for analysis.) Median scores were lower for African-American patients on all dimensions; these differences were statistically significant for Physical Functioning, Social Functioning, Role-Physical, Pain, and General Health. Logistic regression methods were used to adjust for potential demographic or clinical confounding variables. After adjustment for these variables (e.g., duration of disease, age, gender), significant differences only remained for Physical Function. We conclude that apparently large differences between racial groups may reflect the influence of a complex mix of clinical and demographic factors, but that a residual effect of race remains in at least one SF-36 dimension after adjustment for other factors.

2512

THE VALUE OF PREDICTIVE TESTS FOR FAMILIES WITH IDDM

C. Roby and V. Collins. International Diabetes Institute, Melbourne, Australia

Before widespread clinical predictive testing for IDDM occurs, it is important to study the impact of testing on family members and to identify their concerns. The aim of this study was to gather qualitative data about the value of predictive testing for adults and children when a family member has IDDM. Two leaders ran five focus groups with a total of 31 participants (males=9, females=22) from three diabetes services in Melbourne. Answers to prepared questions were tape-recorded and responses categorised. Groups:- 1. Teenagers with IDDM (n=9); 2. Young adults with IDDM (n=6); 3. Young parents with IDDM (n=6); 4. Older parents with IDDM (n=3); 5. Parents of children with IDDM (n=7). In addition, data from telephone interviews of siblings of children with IDDM (n=5) were used in the study. A broad range of views were given, and some common themes were identified including 1. The value of predictive tests is limited as prevention is presently not possible; 2. However, many indicated they would modify lifestyle in an attempt to prevent or delay onset; 3. There is no value for young children in knowing test results, but anxiety could be reduced for some adults and parents, raising the issue of children's right to decide; 4. For most, a false negative result was not as devastating as a false positive; 5. Insurance companies and employers should be denied access to results. The study provided valuable insights into the way predictive tests are viewed by a range of family members. The impact of test results on individuals and their relationships, the complexity of handling risk statistics, and the range of associated ethical issues requires that pre and post counselling protocols are established. Quantitative studies are now needed to assess possible uptake of testing, and to plan specialised services.

2513

KNOWLEDGE, SEVERITY BELIEFS AND HELP SEEKING BEHAVIOURS: NIDDM COMPARED WITH NON DIABETICS.

+P.L. Dunning and *M. Martin. +St. Vincent's Hospital and *Deakin University, Melbourne, Australia.

Appropriate self care, seeking treatment early and regular screening can limit diabetic complications. They depend on the person having the appropriate knowledge a belief that diabetes is serious and that they are vulnerable to its effects. A cross sectional survey using a self completed questionnaire was undertaken to determine knowledge about diabetic complications, if subjects considered diabetes to be serious and how long they would wait before seeking help for chest pain. Subjects were randomly selected from a) the hospital diabetic Outpatient Department (NIDDM n =50) and b) non diabetics from a suburban general practice (non DM n = 51). 46% NIDDM and none of the non DM had received formal diabetes education in the six months preceding the study 78% of NIDDM were able to list at least one complication compared with 35% of non DM. Both groups considered diabetes to be a serious disease and 48% of NIDDM believed they were likely to develop a complication particularly eye disease. Females were more likely than males to seek treatment within 30 minutes for severe chest pain, ($p<0.05$). The NIDDM group were more likely to seek treatment than non-DM, ($p<0.05$). There was no significant relationship in NIDDM between seeking treatment immediately for chest pain and diabetic treatment, duration of diabetes or age. Reasons for not going to the doctor included work commitments; hoping the problem would resolve; fear; not to worry the doctor and cost. NIDDM have a good knowledge of diabetic complications, believe diabetes to be serious and are likely to seek help quickly for chest pain. Non DM consider diabetes to be a serious disease but have limited knowledge about it complications.

2514

EVALUATION OF AN ENHANCED ELECTROCHEMICAL GLUCOSE METER SYSTEM BY DIABETICS AND NURSES AT THREE CLINICAL SITES

D. Parker, C. Kilo, J. Baum, J. Joynes and B. Pistone. West County Internal Medicine, St. Louis, MO; Abbott Northwestern Hospital, Minneapolis, MN; Denver VA Medical Center, Denver, CO; Bayer Corporation, Elkhart, IN, USA.

The performance of enhancements in the Glucometer ELITE® blood glucose monitoring system; including a 30 second reaction time, 1.11 to 33.3 mmol/l assay range, 20 result memory, temperature compensation and improved ergonomics; were evaluated in the hands of 61 diabetics and 3 nurses. Each participant assayed controls and fresh capillary bloods on new and current ELITE® meters. Capillary plasma glucoses and hematocrits were done by study site laboratory staff using appropriate handling care. The 61 diabetics and 3 nurses, using 9 meters, obtained CV on three controls that ranged from 3.3 to 4.6% and 3.1 to 4.3%, respectively. Replicate analyses on 119 fresh capillary bloods at the three sites, by the 64 testers, had a CV of 4.7%. For three comparative methods (Abbott Vision and Hitachi 911 hexokinase, and Beckman CX3 glucose oxidase methods), combined regression statistics were:

Analyst	n	Regression	Syx (mmol/l)	r	Bias
Diabetics	116	y = 0.96x + 0.13	1.02	0.978	(-) 4.6 %
Nurses	116	y = 0.95x + 0.12	0.82	0.985	(-) 4.0 %

Nurses had 100% of blood glucoses within 20% of laboratory results and diabetics had 97.4% within 20% of laboratory results. In comparisons of new ELITE to current system by nurses and diabetics at the three sites, result ranges were; n = 38 to 42, slopes of 1.02 to 1.06, y-intercepts of -0.58 to 0.03 mmol/l, Syx of 0.38 to 0.78 mmol/l, r =0.988 to 0.997 and biases of -1.2 to 1.5%. Both diabetics and nurses had 100% of new ELITE glucoses within 12% of current ELITE results on bloods and controls. The new ELITE system compared well to laboratory and current ELITE glucose results. The 61 diabetics and 3 nurses at the three sites found the new Glucometer ELITE® to be attractive, ergonomically improved, precise, accurate, convenient and easy to use.

2515

Self-management of young diabetics in reality.

P.Jarosz-Chobot*, D.W.Guthrie†, R.L.Jackson‡
E.Otto-Buczkowska*, B.Malanowicz*
* Silesian Academy of Medicine, Katowice, Poland
† University of Kansas, Wichita, USA
‡ Diabetes Treatment and Research Center, Wichita, USA

To determine, whether young diabetics follow the most important rules of diabetes educational programs as forgetting "carrying sugars" and insulin shots in their daily life, the analysis using 263 simple and anonymous questionnaires was performed. The study involved 183 IDDM children from Kansas-USA (76 boys, 107 girls) and 80 IDDM children from Silesia-Poland (36 boys, 44 girls) of mean age 12,95±2,65, mean IDDM duration 4,77±3,15 years, mean HbA1c 8,52±1,9%. We found: (1) 78,85% of all IDDM children carry something to treat or prevent hypoglicaemia, more girls than boys, and more American than Polish ones ($p<0,01$). (2) Only 59,92% IDDM children carry "soluble sugars" (no statistically significant differences between sexes and nationalities). (3) No correlation between "carrying sugars" and age, metabolic control, number of glycaemia measurements, forgetting insulin injections and kind of insulintherapy. (4) Duration of diabetes was not correlated with carrying "sugars" whereas was correlated with carrying "other food" ($p<0,05$). (5) 53,4% children never forget insulin injections. (6) Forgetting insulin shots was correlated with IDDM duration in boys group, with increasing level of HbA1c in all children group, with the intensive insulin therapy in girls and Polish groups ($p<0,01$ in all cases). Conclusions: (1) Young diabetics more often forget their insulin injections than carrying "sugars". (2) Older girls with longer IDDM duration and worse metabolic control check their glycaemia less frequently and forget the insulin injections more often.

2516

QUALITY OF LIFE FOLLOWING CHANGE IN DIABETES THERAPY

M.Pibernik-Okanović, S. Szabo and Ž. Metelko, Vuk Vrhovac Institute, Zagreb, Croatia

Twenty-eight subsequently recruited diabetic persons who were switched from oral hypoglycemic agents (OHA) to insulin therapy (Group 1), were compared with 28 persons who remained on OHA (Group 2) with respect to quality of life issues. The samples were matched according to sex (13 males and 15 females), age (63.3 ± 7.83 in Group 1 vs 60.8 ± 10.1 yrs in Group 2), duration of disease (11.5 ± 6.2 vs 9.4 ± 6.1 yrs), education and family status. The World Health Organisation Quality of Life Questionnaire (WHOQOL) was used to assess the individual quality of life initially and after a two-month follow-up period. T-tests were used to compare the two groups' quality of life indicators. Initially, Group 2 gave higher ratings, indicating better quality of life with respect to overall quality of life (t= -1.945 p=0.05), physical health (t= -2.412 p=0.02) and level of independence (t= -2.939 p=0.05), while no differences were found with respect to the psychological, social and personal beliefs domain. After the follow-up period the groups were comparable in all quality of life aspects excepting the level of independence which remained higher in patients who continued with oral therapy (t= -3.469 p=0.01). Observing changes inside the groups, no differences were registered in Group 2 during the follow-up period, while patients who changed their therapy to insulin significantly improved some psychological quality of life determinants (Negative feelings; t=-2.77 p=0.01) and improvement in the whole psychological domain was almost significant (t=-1.87 p=0.07).
From the holistic point of view, assessing quality of life when undertaking therapeutic interventions is justified.

2517

PREDICTORS OF DIABETES-RELATED QUALITY OF LIFE.

E. Mannucci, G. Bardini, V. Ricca* and C.M. Rotella. *Section of Metabolic Diseases, Division of Endocrinology; and *Unit of Psichiatry, University of Florence, Italy.*

The present study is aimed at evaluation of the impact of demographic and clinical features on diabetes-related quality of life. A consecutive series of 480 diabetic patients (81 IDDM, 399 NIDDM; 250 F, 230 M), aged 18-70 yrs (m±sd 53.1±13.3), with a duration of diabetes of 10.2±8.7 yrs, Body Mass Index 27.2±4.9 kg/m^2, HbA_1c 7.4±1.6 %, was studied. Quality of life was measured using a recently developed questionnaire, the Well-being Enquiry for Diabetics (WED), investigating four different domains: physical symptoms (WED-S), diabetes-related psychological distress (WED-D), mental health (WED-M), and practical impact (WED-I). Multivariate analysis was used to detect the specific contribution of each variable to quality of life. Type of diabetes did not appear to interfere with total and subscale WED scores. Among patients with NIDDM, those receiving insulin treatment showed lower WED scores (meaning worse quality of life), particularly in the WED-S and WED-I subscales. Both in NIDDM and IDDM, female patients resulted to have a worse diabetes-related quality of life ($p<0.05$) than males. An inverse correlation was observed between Body Mass Index and WED-D ($p<0.01$), WED-I ($p<0.05$), and WED total ($p<0.05$) scores. Age and duration of diabetes were directly correlated ($p<0.01$ and $p<0.05$, respectively) to WED-S. At multivariate analysis, an inverse correlation was found between WED-S scores and HbA_1c. In conclusion, female sex, insulin treatment (in NIDDM only), higher age, and longer duration of disease are all predictors of worse diabetes-related quality of life. Overweight is also capable of affecting quality of life, determining a greater diabetes-related physiscal impairment (WED-I) and psychological distress (WED-D). Finally, HbA_1c does not appear to correlate with overall quality of life (WED total), but is significantly affected by mental health (WED-S).

2518

WHAT SIGNIFICATION HAS THE DIABETES DISEASE FOR THE CHILDREN AND THEIR PARENTS ?

E. Löwstedt, Pediatric Clinic, Borås, Sweden

The Pediatric Clinic in Borås has a group center for diabetic children and adolescents. The intention is that one patient group with the same diagnosis shall meet. In may - 95 an evaluation of the activity started and has been carried out as one pedagogic part and one psychological, which the latest is described here.
Method: Material is collected by interviews with children,adolescents and parents that regulary participate in the group center. Totally 30 randomised interviews have been carried out.**Results:** The moment of falling ill has a vital importance for how the child and the parent react on the disease initially. The factors that contribute to this is the chronological age, individuell mature, develepment phase and life- and familysituation. The same factors contribute that the signification of the disease vary. Parents and the adolescents with diabetes have private admissions about what has cause the disease. Especially among the mothers of the diabetic children there are guilt problems connected to this, that is experienced as all from manageable to seriously handicapping. In normal crise processes the mothers have used the group center in a terapeutic way. The value of the group for the smallest children appears to be learning by imitating. This has in many cases had a great practical importance in their own handling of injection.
Conclusion: The group center appears to have a subjective appreciated terapeutic effect on the mothers. Since the study confirms what previous research has presented, that the mothers of children with diabetes show different symtoms of anxiety, should this form of parental treatment be a good indirect help for the children. Differential diagnostics should however be applied more in an early stage to separate children and parents in normal crise processes from those who need more individual treatment. As cronics often have an unnecessarily large identity of illness, the pediatrics should act for not giving the children this to early. For that reason the group center should primarly have an practical approach to the child before puberty. That goal is reached in the effect of learning by imitating.

2519

PSYCHIATRIC MORBIDITY AND METABOLIC CONTROL IN DIABETIC PATIENTS

J. Mousleh, Iacovides, J. Yovos, L. Karagianni, , K. Fountoulakis, K. Kazakos, A. Vlachoiannis, Ch. Ierodiakonou.
C: Department of Psychiatry and Diabetes Center of Aristotelian University of Thessaloniki.
AHEPA General Hospital of Thessaloniki, Greece.

Psychiatric morbidity and especially depression is believed to be an important aspect of Diabetes Mellitus (DM).The prevalence of depression in DM is reported to vary between 8.5% to 27.5%.Thirty-nine patients (20 males and 19 females) suffering from DM entered the study. Their age was 44.41±15.7 years (range 18-70), BMI values were 25.55±3.56 (range 17.91±32.46), and the duration of illness 8.58±7.56 years (range 1.5-33). Sixty-Four percent of them were overweight, 60.6% were insulin dependent and 68.57% were well controled. Their HbA1c was 7.7%±1.72% (range 3.7±-11%) and their glucose level was 204.31±88.55mg% (range 81.454). GHQ -28 and Beck Depression Inventory (BDI) were used for psychometric evaluation. Stepwise Multiple Linear Regression Analysis (SMLRA) was used for the analysis of data. The least squares method was used to draw the Regression line in bivariate scatterplots, to search for non- linear relationships. From SMLRA results it seems that C dimension of GHQ correlates with HbA1c, D dimension of GHQ correlates with glucose levels and management of DM ane BDI correlates with HbA1c, managenent of DM and BMI. Bivariate scatterplots, however showed a non-linear relationship between depression and DM. Depression, measured either by BDI or D dimension of GHQ seems to correlate weakly with management of DM when HbA1c values are under 10% or glucose levels under 250mg% . However, beyond these values the increase in depression is impressive

2520

A WALKING GROUP - ITS ROLE IN THE MANAGEMENT OF NIDDM

*K.E Young, The Royal Melbourne Hospital, Victoria. Australia.

The benefits of regular exercise for people with NIDDM is well documented. However, motivating individuals with NIDDM to do so can be a challenge particularly as they are often older and may have other conditions interfering with their ability to exercise. To address these factors a supervised, weekly walking group was set up. The aims of the group were: 1) to provide a safe, supportive environment where people with diabetes may enjoy the benefits of exercise and 2) to encourage and equip the individual with the skills to incorporate exercise into their diabetes management plan. The route chosen took approximately 45 minutes to complete. Random blood glucose tests (RBG) were performed and feet inspected prior to walking and on return. Morning tea, a popular part of the program, was provided after the walk. The group consisted 10 males and 6 females. Mean age was 65 years (range 45-76) and duration of diabetes was 5.3 years (range 1-20). 8 subjects were treated with diet alone, 8 with oral hypoglycaemic agents. Mean individual attendance rate over 12 months was 77%. Mean weight at commencement was 85.7kg. Weightloss occurred with 13 subjects (range 0.3 - 5.2kg), weight gain occurred with 3 subjects (range 0.3 - 2.9 kg).Mean weightloss for the group was 1.2kg. Mean HbA1c fell from 7.6% to 7.3% with 75% showing an improvement. Blood glucose results (mmols/L) are summarised below.

Pre Walk	RBG Range	Mean Pre walk	Mean Post walk	Mean Drop	Hypos
N = 37	3.6 - 5.4	4.7	4.2	0.5	4
191	5.5 - 9.9	7 .7	4.8	2.9	21
92	10.0 - 14.9	11.5	7.0	4.5	3
17	>15.0	16.7	13.1	3.6	0

In conclusion, the benefit of walking, as a group exercise, was demonstrated by improvement in short term blood glucose and positive trends for HbA1c and weight control. The incidence of hypoglycaemia (10%) reinforces the need to test RBG before and after exercise. High attendance rates and increasing membership highlight the importance of social interaction as a motivating factor for incorporating exercise into a diabetes management plan.

2521

PSYCO AND SOCIAL PROFILE OF THE ELDERLY DIABETIC.

L.Zagury, Instituto Estadual de Diabetes e Endocrinologia, Rio de Janeiro, Brasil.

The purpose of this study was to raise the psyco and social profile of the type I and II elderly diabetic belonging to the Brazilian middle class and from 60 to 65 ears old. To accomplish this an assessment containing 45 objective questions, which after proper validation, whose applied to 83 individuals of both sexes. The data were computed trying to verify the percentage of incidence of each one of the raised itens. The middle class elderly diabetic profile revealed, in the great majority, a person that, in accordance to medical literature, accepts badly the modifications imposed by diabetic treatment (57%). On the other hand, does not present difficulty in learning (94%), more physical problems that make him/here incapable (chewing-92%; hearing-57%; seeing-80% or seringe use-91,5%) cares for his personal independence, does not feel abandoned by his family(86%), lives, most the time, with his consort(56%) and the treatment does not substancially compromises his monthy butget (53%).

2522

EFFECT OF ACUTE TEMPERATURE INCREASE ON HYPOGLYCEMIC EPISODES

M.Sargın, N.Dinççağ, L.Oktay,Z.Sağlam,F.Salman,A.Şengül,Ş.Karadeniz, F.Sargın, S.Salman, K. Oktay, S.Seçkiner, G.Aydın, S.Gedik, İ.Satman, M.T.Yılmaz Institute for Experimental Med., Diabetes Research Unit and Division of Diabetes, Istanbul Medical Faculty, Istanbul University, Istanbul-TURKEY

In this study, metabolic parameters of 31 IDDM patients (F/M, 12/19,mean age: 14.1 ±2.4) used to living in warmer temperatures(20-23°C) and joined to a diabetes camp held at a higher environment (36-39°C) were observed for 10 days and compared with 13 IDDM camp attenders (F/M, 6/7,mean age: 15.6 ±4.0) originally living in this hot area. Although similar isocaloric diet and same exercise-insulin program were applied before and during the camp, there was a significant difference in number of hypoglycemic episodes between patients from warmer and living in hot regions; 78/14 (p=0.02) . The difference was particulary remarkable in first 48hrs;64/14 (p=0.00). Patients from warmer regions were evaluated in two groups based on ages: Gr.I; <15yrs old (n:16) and Gr. II; ≥15yrs old (n:15). When number of hypoglycemic episodes observed in first 48hrs (20/3, p =0.00) and following days(44/11, p=0.00) were compared, we found that attacks in the first 48 hrs were high in both groups. Evalution of insulin requirements have shown that in Gr.I precamp insulin dose $0.77IU.kg^{-1}.day^{-1}$ decreased in first 48hrs;0.63 (p=0.01) and reached approx. to initial value at the end;0.74. However, in Gr.II insulin requirement decreased from 0.73 at initial to 0.54 at 48hrs (p= 0.00) and to 0.49 at the end. Although pre and postcamp BMI were closed to each other in both groups; findings of acute increase in incidence of hypoglycemic episodes along with rapid decrease in insulin requirements in first 48hrs have suggested that the main reason for this among patients from warmer regions was rapid insulin action due to acute increase in temperature during camp. Furthermore, we concluded that smaller children adapted to the environment easier than older ones.

2523

COMPREHENSIVE EVALUATION OF THE FACTORS RESPONSIBLE FOR SELF-MANAGEMENT OF DIABETES.

ADR Mackie, EJ Rowley, DF Clarke and JL Day, Ipswich Diabetes Centre, Ipswich, UK.

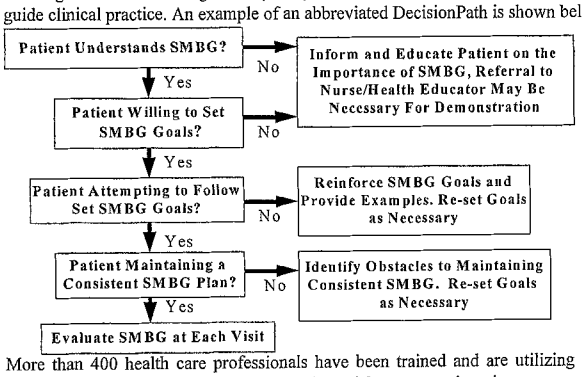
Sucessful self-management of diabetes is dependent on a wide range of beliefs, attitudes and, to a lesser extent, basic knowledge and/or demographic factors. All require assessment if educational needs of patients are to be determined and met. A well validated questionnaire, (41 questions) previously shown to assess these factors in insulin treated subjects and one newly developed for non-insulin treated subjects (54 questions; Cronbach alpha 0.78} were applied to consecutive attendees (253 insulin treated, age 18-74; 203 non-isulin treated, age 28-75) at routine diabetes clinics over a six week period. Factor analysis was performed on the responses of 202 (insulin treated) and 139 (non-insulin treated) subjects and regression coefficients of individual questionnaire and factor scores against HbA_1 determined. Nine factors (Eigen values 5.72 - 1.18), namely effect on lifestyle, self efficacy, weight concerns, benefits of treatment, targets, confidence/coping, general emotional adjustment, food concerns, and barriers to treatment in insulin treated and five factors (Eigen values 10.2 - 1.87), lifestyle, benefits to treatment, barriers to treatment, self efficacy and targets in non-insulin treated subjects emerged from this analysis. Weight concerns ($p<0.05$), targets ($p<0.001$), general emotional adjustment ($p<0.05$), barriers to treatment ($p<0.01$) and total questionnaire score ($p<0.05$} in insulin treated and lifestyle ($p<0.05$) in non-insulin treated subjects were significantly correlated with HbA_1. The variation in number of subjects (5 - 55%) scoring low for separate factors indicate that the questionnaire may be able to distinguish individuals well adapted to certain factors, though not to others. The questionnaire scores provide an overall estimate of the educational process and should enable education to be directed to meet specific needs of individuals and provide explanation of reasons for failing to meet glycaemic targets.

2524

PSYCHOSOCIAL ASSESSMENT GUIDELINES FOR PEOPLE WITH DIABETES IN THE PRIMARY CARE SETTING.

S. Sundem, R. Mazze, G. Simonson, R. Bradley, and G. Castle. International Diabetes Center, Minneapolis, MN, USA.

A survey of primary care practices showed that adherence issues are frequently noted in medical charts as an obstacle to adequate diabetes care. This is documented as patient refuses treatment, SMBG, dietary plan or exercise. This is explained by patient confusion about diabetes and its management, provider limited time and a general lack of intervention strategies available in a primary care setting. In this project, guidelines for adherence assessment and improvement were developed using the Staged Diabetes Management (SDM) format which relies on DecisionPaths to guide clinical practice. An example of an abbreviated DecisionPath is shown below.



More than 400 health care professionals have been trained and are utilizing these DecisionPaths. Recognizing limited psychosocial resources in primary care, this approach focuses on four readily attainable diabetes management variables: medication, food plan, SMBG and exercise. It encourages patient behavior change by re-education, setting specific targets with the patient, frequent re-assessment of goals (with re-setting goals as needed) and close follow-up.

DETERMINING DIABETIC TREATMENT REGIMENS BASED UPON SOCIOCULTURAL HABITS OF KENYANS

J.Suren and K.Rennie, Kikuyu Hospital, Nairobi, Kenya.

In order to develop therapeutic regimens compatible with the Kenyan lifestyle, the lifestyle had to be identified and the insulins and oral agents placed appropriately to mealtimes. Eighty diabetic and nondiabetic patients waiting at the Eye Unit clinic were interviewed to determine food choices and quantities with frequency and timing of meals. Combining the action, peak, and duration of insulins and oral agents, we developed treatment regimens that were compatible with the Kenyan socio-cultural habits. Fitting the treatment modalities into the lifestyle has made adherence easier and maintaing good control more possible.

2526

EFFECTS OF ETHNICITY ON METABOLIC CONTROL DURING THE FIRST SIX YEARS OF NIDDM. TME Davis, CA Cull, RR Holman and RC Turner for the UKPDS Study Group, Diabetes Research Laboratories, Oxford, UK.

Changes in metabolic indices were evaluated in 3,319 patients with NIDDM recruited to the UK Prospective Diabetes Study (UKPDS) at diagnosis and followed for 6 years. All patients had 3 months' dietary therapy initially and then other treatments were randomly allocated. 2,720 (82%) were White Caucasian (WC), 331 (10%) were Indian-Asian (IA) and 268 (8%) were Afro-Caribbean (AC). After adjusting for age, BMI and HbA_{1c} at randomisation, there were no significant ethnic differences in the change in HbA_{1c} over 6 years (ΔHbA_{1c}; P=0.1). However, in those who were obese (>120% ideal body weight) at randomisation, ΔHbA_{1c} was greater in IA and AC than WC patients (means 0.59%, 0.68% and 0.27% respectively; P=0.02). Significant interactions between ethnicity and allocated treatment were present in ΔHbA_{1c} in obese patients, with metformin-treated AC patients having the greatest improvement in ΔHbA_{1c} (-0.72%) compared to the other 15 ethnicity-treatment combinations (range -0.20% to 1.38%; P=0.03). Significant differences in serum lipids were also found in AC patients who had the greatest increase in ΔHDL-cholesterol adjusted for age, BMI and fasting serum HDL-cholesterol at randomisation (0.13 vs 0.03 and -0.03 mmol/L in WC and IA respectively; P<0.0001). In summary, these data suggest that obese AC and IA patients have greater progression in glycaemia than WC. However, obese AC patients treated with metformin show the best glycaemic response to any allocated treatment in the three major ethnic groups in the UKPDS. AC patients have the most favourable change in serum lipids over 6 years of NIDDM.

2527

STANDARDS OF QUALITY OF HEALTH CARE IN DIABETES IN NORTH SPAIN: A DIABCARE-BASED ANALYSIS OF 3646 PATIENTS.

G.Villar,I.Goicolea,A.Mancha,J.Vazquez.Hospital de Cruces.Spain

Several reports have proven that the incidence and progression of diabetic complications may be reduced by early surveillance and treatment and, on the other hand, by risk factor control.The aim of the study was to evaluate and compare the quality of diabetic care (QC)between the different outpatient specialized diabetic units in Cruces Hospital Health Area in the Community of Pais Vasco, Spain through DiabCare-based analysis of 3646 diabetic patients. This health area have about 400.000 inhabitants, and include 1 main hospital, and 4 specialized diabetic clinics (7 endocrinologists provide the whole specializad diabetic care for the community in these centers). Data collection was in DiabCare Basic Information Sheet, made in 1995 in diabetic patients older than 14 years. Differences in QC between hospital treated or outpatient clinics treated patients were analyzed with the Chi-square test and Mantel-Haenzelt test for trends. Data are expresed as means+/-SD and range. Results: There were 620 patients (17%) with type 1, and 3026 (83%), with type 2 diabetes mellitus. Mean age was 58,6±13 years. Female / male ratio was 52,5 / 47,5%.

Process of care (%):	GLOBAL	HOSPITAL	OUTPATIENT CLINICS	P
Hb A1C	91	98,6	87,2 (83,8-95,7)	<0,0005
Educational activities	34,4	71,9	19,5 (11,3-41)	<0,0005
Glycemic control	52	81,5	41,5 (36-47)	<0,0005
Ophtalmoscopy	85,5	99,4	78,5 (74,1-87,1)	<0,0005
UAE analysis	68,3	92,5	56,1 (17-88,5)	<0,0005
Blood pressure	97,9	99	97,4 (91,6-100)	<0.0005
Lipids	87,8	97,4	82,9 (70,9-98,2)	<0,0005
Smoke inquiry	76,6	76,1	76,9 (60,3-94,2)	NS

High blood pressure was known in 27%(10-44), hypercholesterolemia in 25%(17-37), hypertriglicerdemia in 20,5%(13-35), and 20,3%(7-35) smoked. Poor glycemic control (Hba1c A1c>7,5%) was present in 64%(62-69), diabetic nephropathy in 32,3%(26-55), and rethinopathy in 41,7%(39-45). Blindness affected 3,3%, stroke 5,3%, limb amputations 2,3%, renal failure 0,8%, and ischaemic heart disease 8,9%. We conclude that specialized diabetic care can be ameliorated, although there are great differences between the diverse outpatient units and hospital practice. Nevertheless, prevalence of cardiovascular risk factors was lower than expected.

2528

MANAGEMENT OF DIABETES IN INNER-CITY PATIENTS: THE GRADY MEMORIAL HOSPITAL EXPERIENCE.

L.S. Phillips, D.C. Ziemer, I. El-Kebbi, and D.L. Gallina. Emory University School of Medicine, Atlanta, GA.

African-Americans have increased prevalence of diabetes, and increased risk of complications; inner-city patients face additional problems due to limited resources. The Grady Diabetes Unit provides high-volume care (~1,000 new patients a year) for patients who are predominantly African-American (87%) and poor (54% have incomes below U.S. Federal Poverty Levels), with low health literacy skills (inadequate in ~50%). In 4,886 new patients, 88% had NIDDM, and 73% were obese; 34% of 578 patients had renal damage at first presentation. Our management utilizes a team approach (nurse-providers, dietitians, podiatrists, and physicians), with stepped intensification of care (diet, oral agents, insulin). In 563 patients who returned for visits at 2, 4, and 6 months, HbA1c fell from 9.3% to 7.5% ($p<0.001$). Moreover, use of pharmacologic agents decreased: in 1,156 obese patients, 71% were using such therapy at presentation, but only 54% at 6 months. Since our patients report difficulty in understanding food exchanges, we initiated a randomized controlled comparison between an exchange diet (ADA) and a "healthy choice" diet (HC) which focuses on food choices and moderation of intake without emphasis on portion sizes or weight loss. The 311 ADA and 375 HC patients were indistinguishable in weight, obesity, gender, duration of diabetes, and HbA1c. The groups exhibited comparable weight loss (36% of ADA lost at least 5 lb, vs. 30% of HC; p=NS), and fall in HbA1c at 6 months (from 9.9% to 7.9% in ADA, vs. 9.3% to 7.6% with HC; p=NS); there was also no difference in lipids or BP, or use of pharmacologic agents.

Conclusions: Stepped care with a team approach constitutes an effective paradigm for management of inner-city patients; a healthy choice diet is easier to teach than an exhange diet, and metabolic outcomes are similar. Flexibility in therapy can help overcome barriers to effective care.

2529

CSII-THERAPY: IMPROVEMENT OF GLYCEMIC CONTROL WITHOUT A LONGTERM INCREASE OF HYPOGLYCEMIA

H.J. Schreckling and K.H. Bergis. Diabetesklinik Bad Mergentheim, Bad Mergentheim, Germany

Objective: The DCCT observed 62 hypoglycemic episodes (assistence required) and 16 episodes of coma or seizure per 100 patient-years in the intensive therapy group. We tested if CSII-therapy would reduce the frequency of hypoglycemia compared with DCCT results. **Methods:** 250 IDDM-patients were requested to answer a standardized questionnaire for quality-management 15 months after the beginning of CSII-therapy. This questionnaire includes questions about hypoglycemia-frequency und insulin dosage. Furthermore the patients were invited to return a blood sample for determination of glycemic control (Ghb, affinity-chromatography, mean of non-diabetics 5,5 ± 0,5%). 148 patients (age 37,8 ± 12,9 years, diabetes duration 16,9 ± 9,2 years) returned questionnaires and blood samples (drop out-rate 40,8%). **Results:** Glycemic control improved considerably from Ghb 10,7% before CSII - therapy to Ghb 7,9%. The daily insulin dosage was reduced from 56,5 ± 23,4 insulin units to 49 ± 17 insulin units. Overall 32,8 hypoglycemic episodes (assistence required) and 12,3 comas per 100 patient-years occured. Within the observation time the patients reported a decline in the frequency of hypoglycemia. In the first three months 70,2 hypoglycemic episodes and 29,7 comas per 100 patient-years occured; in the following three months there was a reduction to 67,5 and 18,9 events respectively, and in the 9 months there after this rate dropped to 17 hypoglycemic episodes and 5 comas per 100 patient-years. 20 patients reported hospitalisation caused by hypoglycemic episodes. **Conclusion:** In spite of a marked improvement in glycemic control and reduction of insulin-dosage there was overall an unexpected low incidence of hypoglycemia compared with the intensive-therapy-group of DCCT. After the initial adaptation to the new therapy conditions, the relativly high incidence of hypoglycemia in the first six months dropped markly. As a long term perspective CSII-therapy will not inevitably increase negative side effects like hypoglycemia.The incidence of severe hypoclycemia is even less than DCCT-data indicate.

2530

THE METABOLIC CONTROL IN CHILDREN AND ADOLESCENTS WITH TYPE 1 DIABETES IN KRASNOYARSK REGION.

Osokina I., Manchouk V.
Institute for Medical Problems of the North,
Krasnoyarsk, Russia.

We examined 142 patients with type 1 diabetes, aged 2-19 years, with a diabetes duration from 1 to 12 years. The degree of glycemic control was estimated with the help of glycosylated hemoglobin (HbA1c). HbA1c was measured by a HPLC method (normal range 4,5-7,0 %). 57 patients (40%) were in better control (HbA1c < 8,5%), with significantly lower diabetes duration ($p<0,001$), more frequent daily blood glucose monitoring ($p<0,02$) and more injections/day in comparison to children and adolescents (n=85, 60%) in poorer control (HbA1c >8,5%). In group with low diabetic control complications were revealed more frequently. After 5 years 34,5% patients had microalbuminuria, retinopathy was diagnosed in 38%. The education and intensive treatment diabetes allowed to achive higer degree metabolic control.

2531

THE EFFECT OF EVALUATION BY PATIENTS ON THE PROCESS OF ANNUAL REVIEWS IN DIABETIC CARE.
A.K.Baksi, P. Singhal and T. Dean. St. Mary's Hospital NHS Trust, Isle of Wight, U.K.
Objective To assess the effect of evaluation carried out by patients on the process of annual reviews in diabetic care and to measure the degree of patient satisfaction. Design Patients attending the clinic for annual reviews were given a leaflet explaining what to expect at the consultation. They were invited to complete an evaluation questionnaire anonymously at the end of the consultation. The process of annual reviews carried out was audited during a four week period. The results were compared with an audit of 100 conseecutive annual reviews before the onset of the study. Main outcome measures - Indicators in the process of annual reviews and patient satisfaction ratings. Results Indicators relating to the examination of blood pressure, feet, eyes and metabolic control showed a significant improvement as a result of evaluation by patients. Indicators for clinic urine tests, ser um cholesterol and microalbuminuria did not reach an adequate standard. Conclusion Audit by patients improves the quality of annual reviews and it is also a tangible expression of patient empowerment

BLACKSEADIAB: REGIONAL EUROPEAN INFORMATION NETWORK AIMING AT A BETTER DIABETES CARE IN THE COUNTRIES OF THE BLACK SEA REGION. E. Stanciu, C. Ionescu-Tirgoviste, S. Pruna, S. Bejan, G. Rachiteanu, I. Cazacu and I. Mincu. Clinic of Diabetes, Institute "N.C. Paulescu", Software ITC, Bucharest, Romania.

The **BlackSeaDiab Working Group** was created in view to promote in the 12 countries surrounding Black Sea the objectives of the St. Vincent Declaration and of the Acropolis Affirmation. Ethnical, cultural and economic heterogeneity gives a unique opportunity to know the specific problems related to diabetes care in the participating countries. The project will provide the informational support required by the **BlackSeaDiab Action Project**. The solution sought had to facilitate an extension of the network from a minimal level up to a top level, with the smallest costs. A two stage solution has been adopted. In the present stage, an INTERNET compatible network (protocols, application interfaces) is realised using existent physical communication channels, with limited INTERNET access. In the second stage, the network will be developed to use high speed communication channels, with total INTERNET access from any point of the network. The architecture of the system is a *modular* and *open* one. This means that the architecture is compatible with and can be easily integrated into existing information systems and networking environments. Each module is in fact a **National BlackSeaDiab network Section** and is composed of a central node connected by different types of links with a number of local nodes. The access to all these nodes will be accomplished from access points. The scope of the project ranges from routine diabetes care to diabetes research. A wide range of software applications will be developed such as: patient monitoring, programs for the assistance of the clinical research regarding various aspects of diabetes mellitus, epidemiology, education and treatment, statistical analysis of information recorded in data bases, etc. In view to attend such objectives the main instrument is creation in each participating country a **BlackSeaDiab Registry of Diabetes**, which will allow to obtain: accurate prevalence and incidence of both IDDM and NIDDM patients; continuos up-date regarding the presence of chronic complications; mortality data; main demographic and socio-economic date related to the quality of diabetes care.

EVALUATION OF A DIABETES ADVISORY SYSTEM IN ADOLESCENTS

O.K. Hejlesen[1], M. Rix[2], S. Andreassen[1], A. Lange[2], J. Schaarup[2], E. Østergaard[2], U. Andersen[2], R. Hovorka[3] and D. Cavan[3]. Dept. of Medical Informatics[1], Aalborg University. Aalborg Hospital[2], Denmark. St. Thomas' Hospital[3], London, UK.

The aim of this pilot study was to evaluate insulin adjustment advice by a Diabetes Advisory System in adolescents. 19 unselected adolescents, 12-16 years of age with diabetes duration > 1 year, were randomised into 2 groups, matched according to sex, age and HbA_{1c}. The study period was 3 months with intensified contact in the first month and a follow up period of 2 months. In the first, second and fourth week all patients collected data on meals, insulin doses and 4 daily blood glucose measurements for 3 consecutive days. The patients had insulin doses adjusted in the first, second and fourth week. In the target group the insulin adjustments were exclusively based on the advice from the system. Adjustments in the control group were based on the departments routine principles. HbA_{1c} was measured in the first week, just prior to the initial data collection, and after 3 months. 6 patients were excluded for different reasons and the study ended up with 5 patients in the target group and 8 patients in the control group. When comparing HbA_{1c} at the beginning and at the end of the study, no significant difference was seen neither in the target group (HbA_{1c} 9.6% to 9.0%) nor in the control group (HbA_{1c} 9.4% to 9.1%). However, in the same period a marginally significant mean reduction in insulin dosage was seen in the target group (0.82 to 0.72 U/kg, $p = 0.06$), but not in the control group (0.98 to 0.97 U/kg). This reduction in insulin dosage in the target group was reflected in a marked reduction ($p = 0.09$) in number of measured hypoglycaemias (< 3.5 mmol/l) from 0.41 to 0.07 attacks per day. The pilot study suggests the Diabetes Advisory System being a safe tool for insulin dose advice in adolescents obtaining as least as good a result as the traditional setting.

EXPERIMENTING WITH THE SYSTEM OF THE QUALITY CARE CONTROL IN POLAND

J.Tatoń for medical and B.Lyholm for statistical teams
Department of Internal Medicine and Diabetology, Warsaw Medical School, Poland. Disease Management System, NovoNordisk, Copenhagen, Denmark.

Exploiting the fact, that diabetes care in Poland is based on a uniform structured system, the network of 11 regional and 1 central centers for quality control was inbuilt into it. Each regional center was formed as a group of 3-4 spontaneously interested in quality control diabetologists. Such centers was equipped with standardised hardware, Polish version of the Diabcare chart, statistical programmes and modest operational budget. Central center function as the organizer, scientific planner, statistical analyst. The main goal of this system were: measurement of the St. Vincent Declaration targets for whole country, production of objective data for regional comparisons in the relation to local potential and investments. The system was able to produce the respective data in the randomly selected representative group of 1271 of IDDM, which were validated and analysed accordingly to the Diabcare chart 12 areas of interest. The clinical characteristics of the studied population, the biochemical parameters including HbA1c, the parameters assessing the life style, morbidity due to chronic complications, educational activities and performance of diabetes care providers were determinated as aggregated outcomes for the whole country and separately for 11 regions. The average age at the group was 34.0 ± 10.3 years, diabetes mellitus duration 13.0 ± 9.35 years, BMI 23.6 ± 3.04 kg/m^2, systolic blood pressure 126 ± 17.2 mm Hg, diastolic 78.5 ± 9.12 mm Hg, HbA1c 7.99 ± 1.72%, total cholesterol 191 ± 41.5 mg/dl, triglycerides 108 ± 73.7 mg/dl; percentages of smokers was 21.2%, alcohol users 4.2%, morbidity due to retinopathy 37%. The differences between regions were very significant and were connected with the local quality of care indexes. Conclusions. The system used revealed the average level of quality and strong regional differences calling for action and investments. It also proved to be useful for measuring the distance from the St. Vincent targets.

2535

IMPLEMENTATION OF SPECIALIST RECOMMENDATIONS BY PRIMARY CARE PHYSICIANS

V.Fong, S.Colagiuri. Prince of Wales Hospital, Randwick, Australia.

Specialist annual review clinics have been developed to assist general practitioners (GPs) to care for their diabetic patients. This study was undertaken to determine the implementation by GPs of recommendations made as a result of attendance at our Diabetes Complication Screening Clinic (DCSC) which is part of the Shared Care Program conducted with the local GP Division. Follow up and implementation by GPs of recommendations made at the DCSC were reviewed in patients reattending after 1 year. Written recommendations on management of diabetes, complications and atherosclerosis risk factors, are made by an endocrinologist, diabetes educator and ophthalmologist. 134 patients attending over a 10 month period who had previously attended the DCSC one year previously were assessed for implementation of recommendations. In addition, benefits/deterioration from implementation/lack of implementation of glycaemic and dyslipidaemia management recommendations were made, based on comparisons of initial and follow up HbA_{1c} and lipid profile results. A total of 128 recommendations were made in 71 of the 134 patients related to diabetes control, dyslipidaemia, hypertension, obesity, microalbuminuria, renal impairment and referral to diabetes educator, dietician, podiatrist, ophthalmologist & vascular surgeon. The annual frequency of GP diabetes-specific visits ranged from 0 to 10, with a mean of 3.9. 62.5% of recommendations made at the DCSC were implemented. 73.9% of the recommendations for glycaemic control were implemented with a benefit in 35.3% and deterioration in 50% where recommendations had not been implemented. 77.8% of recommendations for management of dyslipidaemia were implemented with a benefit in 28.6% and deterioration in 25% of those where implementation had not occurred. The lowest implementation rates were recorded for referrals to other diabetes health professions: diabetes educator,dietician & podiatrist. Overall implementation of recommendations made to GPs from DCSC is satisfactory but could be improved. To address the 37.5% failure to implement recommendations, greater patient and GP participation and education about the service and recommendations are being trialed. Written recommendations are being provided and explained to patients and GPs are being encouraged to undertake a clinical attachment at the DCSC.

2536

EVALUATION OF A DIABETES ADVISORY SYSTEM

Andreassen S, Hejlesen OK, Frandsen NE, Petersen T, Sandø SH, Cavan DA and Hovorka R, Aalborg University, Aalborg, Denmark, Sønderborg Hospital, Sønderborg, Denmark, Odense University Hospital, Odense, Denmark, St. Thomas Hospital, London, UK.

A double blind clinical trial was conducted to evaluate advice on insulin dose adjustment, generated with the help of a decision support system. The study was conducted on 12 IDDM patients admitted consecutively to Sønderborg Hospital due to poor metabolic control. On admission, the patients were maintained for about 4 days on an intensive regimen with 8 daily measurements of blood glucose and 8 daily injections of soluble insulin. Typically on the fourth day they were switched to a regimen with 3 daily injections of soluble insulin and one injection at night of intermediate-acting insulin. After a further 4 days they were discharged with this regimen. 6 patients were assigned randomly to the target group and 6 to the control group. The advice on insulin doses during the period with 4 daily insulin injections was generated by an experienced diabetologist at Odense University Hospital for the patients in the control group and by the diabetes advisory system for the patients in the target group. The clinician in charge of the patients at Sønderborg Hospital did not know the source of the advice. 2 month after the patients were discharged, HbA1c was measured. For the patients in the target group HbA1c was improved by 1.9% ± 2.9% (mean ± sd), from 9.4 ± 1.4% to 7.5 ± 1.0%. For the patients in the control group HbA1c was improved by 0.9% ± 1.4% (mean ± sd), from 8.1 ± 1.4% to 7.2 ± 0.9%. Although the patients in the target group thus seemed to achieve larger improvements in HbA1c than the patients in the control group this was not statistically significant due to the small sample size (p=0.24). In conclusion, advice generated by the system seems to be safe and of a quality comparable to advice from an experienced diabetologist.

2537

COMPLICATIONS IN TYPE 1 DIABETICS ARE CAUSED BY ELEVATED BLOOD GLUCOSE LEVEL: RESULTS FROM AN AUSTRIAN CENTER.

G. Kacerovsky-Bielesz, M. Kacerovsky, I. Pecnik, H. Hohenecker, I. Palkovic and W. Grossmann, I. Med. Hanuschkh., Inst. f. Statistik Univ. of Vienna, Vienna, Austria

Aim: The aim of the study is to estimate the risk of the development of complications, depending on the metabolic balance (measured by HbA1c ≤ 6.1), kind of treatment and duration of the illness.

Methods: 177 type 1 diabetics treated in our center were selected at random. 72 were treated from the beginning, 105 started 7.1 a (sd 10.5) after the onset. The 177 pat. (1405.3 pat. years), age of onset 27.0 a (sd 13.0), duration of illness 14.9 a (sd 11.7), present age 41.8 a (sd 14.8); 45% have conventional (KT), 55% intensive therapie (IT). HbA1c: KT = 7.8%, IT = 7.9%, severe hypoglyc. KT = 4.7/100 pat. years, IT = 11.7/100 pat. years; 37.8% have HbA1c < 7%; 53.3% have no microvascular complications. In the group treated from the beginning n = 72, duration of illness = 8.1 a(sd 5.6), HbA1c KT = 7.2%, IT = 7.2%; 46% have Hba1c < 7%; 78% have no complications. All of them took part in our training and attended the outpatient clinic at least 4 times yearly (BG self-control, therapy adjustment)

Results: After 1/2 year with a level of HbA1c > 7.0% the risk for complications rises to 2.4 times as opposed to a level < 7%. Depending on the duration of the illness 0.67 is the risk for the first 5 years, 2.45 between 5-10 years, 3.12 after 15 years. 0.85 / 5.53 / 2.57 for retinopathy respectivly. 1.04 / 7.58 / 3.12 for neuropathy. Only 13% have nephropathy (too little data for statististical analysis). For patients treated in our center from the onset the equivalent risk is only half.

Conclusion: This study shows like many other studies (DCCT, Kroc, SDIS, Steno, Oslo etc.) that the long term complications are directly related to the elevated blood glucose level. HbA1c level of 15% above the normal seems to have little risk for developing late complications together with a rate of hypoglyc. as low as possible. It is very important to start at the onset with an optimal therapy. This is the most important point of the study. The duration of illness plays only a role in cases of poor control of the metabolic balance. Not the type of therapy but the results are important.

2538

FEASIBILITY OF AN INTRANET-SOLUTION FOR DIABETES DISEASE MANAGEMENT IN A ROUTINE HEALTH CARE ENVIRONMENT

S.Kottmair, K.Gerlach, J.Lederer, D.Westphal, A.Kaeding and K.Piwernetz.
DiabCare Office, Munich, Germany.

Progress in achieving higher levels of primary health care quality depends crucially on the implementation of structured care procedures on the basis of standardised documentation and guidelines. This applies as well to organisational as to medical quality. Aim of the project is to demonstrate the feasibility of an intranet solution respecting the aforementioned features thus providing the health care team with useful and effective support in the management of diabetes. The disease management module is organised cascade-like where the user starts from a general top level proceeding to levels of greater details. Documentation according to standardised data sets (DiabCare Diabetes Data Set, Care Card Diabetes) is imbedded into structured routine procedures which may be tailored to the individual needs of a specific health care setting. Whenever necessary the user may request reference to generally accepted guidelines and knowledge bases via easy to use hypertext links. Documented data are transferred in anonymised form to a central data base where evaluations are carried out with respect to watchdog rules, patient centred benchmarking, and the DiabCare quality indicators. This intranet solution is realised in standard html-technique and therefore widely independent of the users technical prerequisites. It could be demonstrated that the described system is technically feasible and faces wide acceptance among health care practitioners because of its easy and intuitive way of use, its flexibility, as well as its referral to commonly accepted standards and guidelines. A disease management module implemented as an intranet solution contributes to the structuring of routine health care procedures according to standards and guidelines thus providing the basis of quality management in primary health care.

2539

GENDER EQUITY IN SWEDISH DIABETES CARE: A REVIEW

P.M. Jonsson, C. Gåfvels and J. Östman. Dept. of Public Health Sciences and Dept. of Medicine, Karolinska Institute, and Dept. of Public Health Sciences, University of Umeå, and LUCD, Karolinska Hospital, Stockholm, Sweden.

Gender differences in the utilization of health services may be explained by differences in the epidemiology of disease and accompanying need of services or by differences in the expected safety, effectiveness and cost-effectiveness of medical interventions. However, gender differences may also reflect care providers' knowledge and attitudes or differences in the accessibility of services to males and females. Such differences may indicate gender inequity in health care and may adversely affect the quality of care. In 1995 the Swedish government appointed an expert committee to analyse gender equity in health care, and diabetes care was selected as one of the fields for review. The aim of the review was to explore the performance of diabetes care in Sweden from a gender perspective. The review was based on published data on health care utilization, metabolic control, patient satisfaction, quality of life, and mortality.

The registered level of use of inpatient care with the diagnosis diabetes mellitus is identical for the sexes before the age of twenty, while males use more inpatient care between twenty and seventy-five years of age. Young and middle-aged diabetic females receive more outpatient care than diabetic males, which is mainly explained by females' use of services at gynaecology clinics and community health centres. Data from two counties show no gender differences in metabolic control, but no comparisons are available on a national level. Studies of patient satisfaction indicate less satisfaction among diabetic females. Females also have reported poorer quality of life than males. Results from the Diabetic Incidence Study in Sweden indicate higher excess mortality in young and middle-aged diabetic males than females. A follow-up study of individuals identified in the Surveys of Living Conditions show that diabetic females with low socioeconomic status have higher excess mortality than diabetic females with high socioeconomic status, while the social class gradient is less prominent among males. - More research is needed to explain gender differences in patient satisfaction, quality of life, and mortality. Monitoring the impact of gender should become an integrated part of quality management in diabetes care.

2540

The therapeutic reality of type II diabetes

Prof. Dr. M. Siebolds · Katholische Fachhochschule Nordrhein-Westfalen, Fachbereich: Gesundheitswesen · Cologne / Germany

In spite of all improvements that have been made in diagnosis, drug therapy and education, the therapeutic results obtained with many type II diabetics are lamentably poor in the light of the St. Vincent Declaration. Against this background, it appeared useful to examine the problem using an integrative research approach, i.e. qualitative group interviews validated by individual interviews. All the professional categories involved in therapy were interviewed: 200 general practitioners, 90 hospital-based doctors, 110 diabetes advisors and nurses, 15 care-givers from the out-patient services and 15 from old retirement homes and 20 old age type II diabetes patients.

- The most significant problem in diabetic management is the inability of health-care professionals to motivate the diabetic patient to take responsibility for his disease and act in a way that promotes his own health. (None of the people interviewed was familiar with any motivation theory or its practical application).
- All those interviewed agreed that the full potential of somatological therapy cannot be realised as long as diabetic patients cannot be motivated and as long as therapy is so poorly integrated into the everyday situation of the patient.
- Interviewers were asked to estimate the potential therapeutic success; general practitioners said 0 to 15 per cent, hospital-based doctors said 20 to 60 per cent!
- 75 per cent of the general practitioners interviewed, but only 25 per cent of the hospital-based doctors, asked whether purely somatological therapy goals are truly significant targets and quality parameters for patients.
- Only 10 per cent of those asked were familiar with the NIDDM Policy Group recommendations.
- The perception of health-care professionals is coloured by frustration, resignation and underrating.
- Nursing staff in old retirement homes and out-patient services complained about the lack of interest on the part of general practitioners in coordinating the care they give diabetic patients with the care given by the nursing services. Also, neither general practitioners nor hospital-doctors are familiar with the early demential deterioration processes that occur not uncommonly in elderly diabetic patients.
- Diabetes advisors and nurses agreed that it is ultimately neither possible nor sensible to attempt weight reduction through diet or any form of nutritional intervention in chronically obese elderly diabetics.
- Patients do not feel that diabetes is one of their really important problems in life.

The study identified three factors which cause diabetic therapy of the elderly to fail:

1. The fundamentally reduced ability of the diabetic patient to manage his disease competently and on his own responsibility. This could be due to early demential processes which makes both patient education and self-management impossible.
2. The amount of freedom to make changes that elderly type II diabetics allow to those treating them. Care-givers generally tend to assume that the diabetic wants to improve his diabetes. This is the basis on which they offer therapeutic help. Care-givers almost never try to establish a real dialogue with the patient as an equal and respected individual as a framework for deciding what the patient actually wants to do about his diabetes and what degree of change he thinks could be possible.
3. The various institutions that care for diabetics on a day-to-day basis often have completely different ideas about therapy. In general, none of the parties concerned tries to coordinate therapy with the care given by another party. There is often a serious lack of understanding of other treatment systems, and this makes appropriate and sensible cooperation between the systems possible.

2541

AN AUDIT OF STRUCTURE, PROCESS AND OUTCOME OF CARE OF THE DIABETIC CLINIC NATIONAL HOSPITAL SRI LANKA.

M. Fernando, D.J.S. Fernando Colombo Medical Faculty, Sri Lanka.

We audited the structure, process and outcome of care at the Diabetic clinic National Hospital, Sri Lanka. A previously validated MCQ paper of 10 questions which assessed knowledge of diabetes on insulin therapy, dietary management, management during acute illness and management of emergencies was administered to all patients. The function of the clinic was assessed using previously validated audit care record forms. Diabetes knowledge among patients, waiting times, bypassing of local institutions, availability of diagnostic equipment, screening activities and time spent per consultation was assessed. The clinic had a daily attendance of 186 patients who were seen between 0800 to 1200 hours. A single medical officer spent 2.14 minutes per patient. No screening was performed. There were no facilities to examine patients or for patients to sit while consulting the doctor. The diabetes knowledge score was 15.06SD 3 from a maximum of 40. 43% had bypassed a local institution. Reasons for bypass included non availability of drugs and the expectation of quality care at NHSL. Patients spent a mean of 1.5 SD 0.7 hours travelling to the clinic and waited a mean 1.56 SD 0.4 hours to see the doctor and 1.3 SD 0.12 hours to obtain drugs. We concluded that the services of the diabetic clinic do not meet the standards expected of a clinic.

2542

DIABETES EDUCATION SERVICES STANDARDS: VALIDATION OF RECOGNITION PROGRAM.

Edwards, L.; Jones H., Belton, A.; Diabetes Educator Section, Canadian Diabetes Association, Toronto, Ontario.

Standards are always the first step in any recognition or accreditation process. They are the benchmarks towards which to strive. Yet, the development of this vital criteria is often flawed, providing a weak foundation for the systems built upon them. This presentation describes the extensive process used to develop Canadian Diabetes Education Service Standards and a Canadian Recognition Program. The Standards, (Outcome Process and Structure Standards) were developed through extensive participation of all stakeholders over a two year consensus building process. Workshops, randomized Focus Groups and two rounds of Delphi Survey enabled all stakeholders (educators, consumers, physicians, organization) to participate. Attention to research methodology throughout added to stakeholders commitment and belief in the Standards. The development of the voluntary Recognition Program was likewise both rigorous and participative involving four Pilot sites, two Annual Meeting presentations and a coordinating Task Force. A two part program was developed consisting of a self-assessment through Portfolio Development and an external review by a National Review Panel. The Portfolio is a collection of prospective data gathering instruments that demonstrate how the service meets the Standards. Each instrument was examined for construct and expert validity with the Standards. Strictly quantitative standardized testing was rejected in favor of more qualitative measures that are appropriate in diverse settings, systems and locations across Canada and congruent with the Outcome Standards for Diabetes Education. The Recognition Program was launched in 1996. The Canadian Standards for Diabetes Education Services are currently being considered by the Diabetes Education Consultative Section of the IDF for International use.

DIABETIC KNOWLEDGE AND SELF-CARE BEHAVIOR IN DIABETIC COMPLICATIONS.

I.C. Wang, H.P. Wu, H.Y. Peng, Y.D. Chiang, L.M. Chuang, T.Y. Tai and B.J. Lin. Department of Internal Medicine and Graduate Institute of Clinical Medicine, National Taiwan University Hospital, Taipei, Taiwan.

To improve diabetes care in the management of patients with NIDDM, we have initiated a special clinic for screening chronic diabetic complications. Patients at risk for developing diabetic foot, neuropathy, nephropathy and retinopathy need special educational program for better management. We investigated the basic diabetic knowledge and self-care behavior and correlated with the diabetic control and complications. 71 male and 49 female patients with NIDDM were recruited from July to November, 1996. Their mean (SD) age was 58.4 (11.9) and the duration of NIDDM was 10.7 (9.2) yrs. The perentage of patients who were illiterate, semiliterate, graduates of elementary school, junior high, high school, and college or higher were 12.5%, 6.7%, 20.8%, 5.8%, 25%, and 29.2%, respectively. The score of better self-care behavior correlated significantly ($p<0.05$) with lower serum cholesterol and triglyceride levels, lower incidence of retinopathy and hypertension in simple regression analysis, and correlated with lower triglyceride and blood pressure by multiple regression analyses. Higher knowledge of diabetes correlated significantly ($p<0.05$) with younger age and higher educational levels in both simple and multiple regression analyses. Better self-care behavior seemed to be beneficial for management of diabetic complication. Lack of knowledge about the diabetic complication might prevent better self-care. Therefore, diabetic education specifically designed for prevention or better care of diabetic complication might be very useful and deserves implemented in the screening clinic for complications.

DIABCARE Q-NET NL, ST. VINCENT GOALS INTO PRACTICE

G. Storms, D. Vermey, CBO, Utrecht, The Netherlands

The European project DiabCare Q-net under the umbrella of the St. Vincent Declaration, aiming at quality management in diabetes care, is put into practice in the Netherlands with a bottom up approach, as a quality management system located at the CBO, the Dutch National institution for quality management in clinical practice. The software is provided by Medinet: DiabData Pro, client software to fill and sent the Basic Information Sheet to a server by modem, and server software, to administer the received data and provide benchmarks to the clinical end-users. Users are general practitioners, paediatricians and internists/diabetologists. They were contacted for their interest for diabetes care and not by their scientific institutions. Together they form the usergroup that "owns " the data on the server. The system is intended to monitor the clinical performance of health care teams by comparison of the clinical care to the standards as set by the expert guidelines defined by the different working groups of St. Vincent (indicators). These indicators are compared in a ranked order between the treatment sites (benchmarking). If a treatment site decides that the outcome of an indicator has to be improved, they start a Quality Circle, a structured improvement process for the health care team plus the end-users, being the people with diabetes. The complete functionality of the system including the data available and the outcome of a quality circle will be demonstrated during the presentation.

2545

IMPROVEMENT IN QUALITY OF DIABETES CARE IN PRIMARY HEALTH CENTERS .J.F.Cano P.Tomás, M.Berenguer, R.M.Gimbert, J. LLussa, X.Mundet, M.Birulés and the GedapS Group.Catalan Family and Community Medicine Society. Barcelona (Spain).

Aims: To assess changes in quality of care on type 2 Diabetes, attended in Primary Health Care (PH), after an intervention programme based on St. Vincent Declaration.**Methods:** Cross-sectional study carried out in 1993 and 1995 in 50 PHC Centres (34% rural) attending 1.256.193 adults. Cases were selected by systematic sampling from 31.050 registered NIDDM. Intervention was based on publication and delivery of Diabetes Guidelines adapted to primary health care and the performance of Workshops in different geographical areas, stressing in educational interventions, early detection of complications and foot care **Results**:Patients evaluated were 2.595 in 1993 and 2250 in 1995, without differences in gender, age or average time of diabetes evolution. The impact on Process Indicators was:

	1993	1995		1993	1995
Visits patient/year			*Presence in clinical*	%	%
Nurse	5.1	4.7	*records of:*		
Medical	3.8	2.8	Tobacco smoking		
for Education	1.61	2.3	Blood Pressure	92	92
Education/Visits ratio	17,9 %	30 %	HbA1c	73	75
B.GlucoseSelf-Monitor.			Cholesterol	78	80
Total			Microalbuminuria	34	50
Insulin-treated	31%	36%	Funduscopy	55	53
	62%	68%	Foot Examination	50	57

Intermediate result outcomes: We found an increase in percentage of diabetics with good/acceptable control of HbA1c (+2%), and a decrease of % of patientes with HbA1c > 10. The acceptable control of cholesterl increased (5%), and 3% decrease in foot ulcers/ lesions. **Conclusions**.- Results seem to confirm the effectiveness of our programme, specially to promote educational activities by PH teams, early detection of chronic complications

2546

ROLE OF A DIABETIC CLINIC FOR SCREENING OF CHRONIC DIABETIC COMPLICATIONS. EXPERIENCE FROM A MEDICAL CENTER IN TAIWAN.

Y.D. Chiang, L.M. Chuang, L.T. Heng, C.N. Huang, H.Y. Peng, H.P. Wu, T.Y. Tai and B.J. Lin. Department of Internal Medicine and Graduate Institute of Clinical Medicine, National Taiwan University Hospital, Taipei, Taiwan.

Many animal experiments and recent clinical trials have all demonstrated the importance of tight glycemic control in the prevention of chronic complications of diabetes. Even under the best of circumstances, it is not easy to keep all the patients under strict glycemic controls all the time, and since the onset of many complications is insidious, we set up a special clinic to screen for diabetic complications. From July to November 1996, we screened 120, 71 males and 49 females, for microangiopathies and peripheral vascular disease. Their mean (SD) age was 58.4 (11.9) and the duration of NIDDM was 10.7 (9.2) yrs. Among them, only 11 (9.2%) had been examined by an ophthalmologist before entry. With a non-mydriatic fundus camera, we found diabetic retinopathies in 18 (16.5%) of the remaining patients. Thirty-four (28.3%) patients were known to be proteinuric. However, 31 (36%) of the remaining patients showed presumptive evidence of microalbuminuria by a semiquantitative method (Micral test, Boehringer Mannheim). Eighteen (15%) of the patients had received nerve conduction velocity study before entry. In the remaining patients, 38 (37%) had at least one abnormality in tests including current perception threshold at 5, 250 and 2000 HZ, Semmes-Weinstein (#5.07) monofilament test, and vibration test with Riedel-Seiffert tuning fork. None of the patients had been examined for foot problems by Doppler ultrasound. Four (3.4%) of the patients showed abnormal low ankle-brachial indices by Doppler exam. Our preliminary data strongly suggested the needs for implementation of a screening exam for complications into our daily practice. Undiagnosed chronic complications may be uncovered earlier for prompt attention and intervention.

2547

QUALITY IMPROVEMENT SYSTEM IN FRANCE : A REGULAR ASSESSMENT. RESULTS AFTER 4 YEARS.

J.R. ATTALI, M. CAHANE, V. DURLACH, E. ESCHWEGE, A. GIRAUD, L. KLEINEBREIL, M.C. TURNIN, M. VARROUD-VIAL. DIABCARE-FRANCE, Hôpital Jean Verdier, Université Paris-Nord F 93143 BONDY.

Since 1993 information on the quality of care is annually gathered from diabetic centres over a one-month period in October. Data collection is voluntary and anonymous. A form in triplicate (the European BIS) is systematically used, and one copy is given to the patient as part of the improvement system itself (awareness of the SVD, late complications, prevention and self monitoring, improved communication with primary care team). Most of the data entry is made centrally and included in a pedagogical project. Each centre receives after a few weeks a confidential analysis of his own results and anonymous bench-marking figures. After 4 years, through regular campaigning each year, the network has succeeded in covering all French regions and the number of centres has increased from 71 to 255. Different structures are now involved : 45 university hospitals, 163 others hospitals, 92 diabetologists in private practise . 80 % of the initial membres are still active in the network. The quality of data is improving (ex : missing HbA1c 10,6 % in 93, 6,2 % in 95). Intermediate outcomes have a tendancy to improve (ex : % of patients with HbA1c < 8 % improved from 34 % in 93 to 41 % in 95) but these results need to bo confirmed. Analysis of the 4 th campaign is now being done. The centres have gained a clearer picture of local hospital care. The constant weight of recent SVD complications (6 %) over this period shows the necessity of long term strategies to achieve SVD targets.

2548

DIABCARE HUNGARY: IMPLEMENTATION OF A TOOL FOR CONTINUOUS QUALITY IMPROVEMENT IN DIABETES CARE

Zs. Kerényi, Gy. Tamás, Á.Gy. Tabák and the DiabCare Hungary Group, Budapest, Hungary

To reach targets of the St Vincent Declaration, the ***DiabCare programme*** of the WHO/IDF-Euro, a monitoring device for continuous quality improvement of diabetes care was implemented in 1994 in Hungary as a part of the National Programme. **20 'centres'** (including 2 GPs) sent **3975 aggregated**, anonymised **records** (data of 3835 diabetic patients; 140 cases repeatedly; age, gender, type, duration and form of treatment of diabetes mellitus [completeness: 93%], other therapy, last lab values of previous 12 months, complications, St Vincent targets, pregnancy) for central evaluation.

				age		*duration*		
	n	**male**	**IDDM**	**<35yrs**	**56-75 yrs**	**6-15 yrs**	**>15 yrs**	**on insulin**
1994	2085	41%	29%	21%	48%	38%	34%	59%
1995	771	44%	44%	21%	36%	39%	38%	73%
1996	1119	43%	25%	12%	49%	38%	30%	60%
'94-96	3835	43%	29%	18%	47%	39%	33%	61%

Results for the whole period: self monitoring: 52%, severe hypoglycaemia: 7%. Late complications: any retinopathy 62% (7% proliferative, 7% laser therapy in the previous year), blindness: 4%. Microalbuminuria (MAU; >30 mg/day; completeness of measurement: 41%): 29%, renal failure 2%. Hypertension rate: 8%. HbA1(c) was measured in 61% of the cases (>8%: 43%). With increasing number of reported cases (more NIDDM and/or diabetes with shorter duration) a drop in the percentage of smokers (20 vs 11%), alcoholics (20 vs 11%), in the number of cases with MAU (32 vs 26%) and with any retinopathy (78 vs 39%) between '94 and '96 could be observed with a decrease in frequency of severe hypo- and hyperglycaemias. Comparison of data of participating centres with country data in quality circles (diabetes team, administrators and GPs) helped in continuous quality improvement of diabetes care.

2549

Primary Care Provider (PCP) Non-Compliance: Lack of Action for Type II Diabetes Related Abnormalities.

JA Pugh, A Monterrosa, G Marsh, B Pico. Univ. of Texas Health Science Center. at San Antonio, Texas.

We hypothesized that poor diabetic outcomes may be due to lack of provider action in accordance with published guidelines. A prospective cohort of 1136 diabetic patients in 8 indigent care clinics will be followed for 2 years, collecting both medical care process data, intermediate outcomes, and patient interviews. First year chart data are presented. Action taken by PCP is defined as one of the following: start or change in pharmacological treatment (RX), recommendation of lifestyle change (LS) such as diet or exercise, or early follow-up (FU) visit to reassess value before implementing new intervention. The cohort was 67% female, with a mean age of 53±12 and diabetes duration of 6.9±8 years. The average # of visits to their PCP in the past year related to diabetes was 4.3. For patients whose glucose was ≥140 milligrams/decilitre or HbA_{1c} >7, 35% of the visits to PCP contained no documentation of actions to decrease blood glucose levels. For RX actions taken, insulin was either begun or increased in 36% of visits or oral agents were either begun or increased in 35%. Among non-pharmacological actions, counseling on diet or exercise occurred in 36%. Similarly, for systolic blood pressure ≥140 mmHG or diastolic blood pressure ≥ 90 mmHG, in 66.6 % of visits no action was taken by the PCP; for cholesterol ≥200, HDL ≤35, LDL ≥130 or triglycerides ≥250, 67.6% of visits had no action taken; and, for albuminuria at random > 30 milligrams/decilitre, 83.4% (dipstick method). A lower proportion of visits with foot abnormalities had no actions: 31.1%. We conclude that, despite seeing patients every 2-3 months, PCPs do not necessarily follow published recommendations for action on metabolic, microvascular, or cardiovascular abnormalities. Potential explanations include PCP lack of awareness of guidelines, poor chart documentation, or inability to deal with multiple abnormalities in 10-15 minute visit lengths.

2550

QUALITY OF DIABETES MEDICAL CARE FOR PATIENTS WITH ACUTE CEREBROVASCULAR DISEASE, SALVADOR, BRAZIL

I Lessa, EA Reale, P Mangieri, J Melo. Instituto de Saúde Coletiva, Universidade Federal da Bahia, Salvador-Brasil

Diabetes Mellitus (DM) is the most underestimated disease of the adult population, even when it deals with acute and severe cardiovascular co-morbidity. An undiagnosed and/or untreated DM in an acute case of Cerebrovascular disease (CbVD) worsens its prognoses making it possible unnecessary death.The aim of this study was to analyse the professional commitment in order to identify, to diagnose and to treat DM in patients with acute CbVD. All medical records of hospitalized CbVD patients, in the 1994 year, Salvador, were reviewed and it were measured the frequencies of: questoning history of DM, previous DM treatment, lab tests for glycemia and DM treatment during the present hospitalization among CbVD patients. The results were compared for the 3 medical assistance sectors· Unique Health System (UHS), Private Health Insurance + private medical assistance (I+P) and "Convênios" ("C"). Frequency ratios or association proportion teste were used in the analysis. The expected frequencies for questioning DM history, lab test and treatment for DM were ≅ 100%. Results and conclusions. From the 1227 CbVD patients, 1048 were under SUS assistance, 124 I+P and 55 in "C". a) questioning history for DM =32,4%(31,7 to 56,0%); b) self-reported DM =16,1% (14,6 to 34,5%); c) comproved DM among the questioned patients= 47,1% (46,1 to 61,3%); d) lab test performed for DM=36,9% (33,2 to 72,7%); e) diagnosed DM by glycemia= 51,4% (50 to 65%); f) treatment for DM patients=91,0%(76,9 to 93,%); g) unknown history and no lab tests performed=65,8% (43,7 to 68,3%). The lowest results (in brackets) for items **a** to **e** were seen in the UHS (the owner governamental hospital and those private paid by UHS) as well as the greatest value for item g. ($p<0,01$ or $< 0,05$) The lowest frequency of treatment and unknown data were observed in "C" The results pointed out the bad quality of medical assistance for both, DM and CbVD patients in Salvador. It is worthy to notice that the included variables in this analysis were the most simple and the least expensive ones for DM diagnosis. It is obvious the contribution of health services for DM/CbVD complication/death, since most diabetic patients stayed undiagnosed. This results may be helpful to improve attitudes, behaviors, programs and quality of medical assistance

2551

HALF CENTURY TRENDS IN MORTALITY AMONG INSULIN DEPENDENT DIABETES MELLITUS PATIENTS WITH ONSET BEFORE 15 YEARS OF AGE. C.Ionescu-Tirgoviste, E. Farcasiu, I. Cazacu, and R Florea. Clinic of Diabetes, Institute "N.C. Paulescu" Bucharest, Romania.

Mortality is the most significant single indicator of the quality of diabetes care. The mortality status as at 31 December 1994 was determined in Bucharest Diabetes Centre for all IDDM patients with onset before 15 years of age between 1942 and 1994. No data were available for the death in severe ketoacidosis occurring before 1974. After this date, 14 patients in this age group died during the first admission , 9 in the decade 1975-1984 and 5 in the decade 1985-1994. Of the 467 registered cases (241M/226F) 36 patients relocated from Bucharest and 78 cases (16.7%) died. The median age at the time of diagnosis of these cases was 9 years (range 8mo.-14 yrs). Median duration of diabetes was 13 yrs. (range 1-46). The distribution of cases ending in death along the decades is given in the following table:

Decade*	No.of cases	Mean age at onset	Mean duration of diabetes	Mean age at death
1942-1950	3	9	2	11
1951-1960	9	9	9	18
1961-1970	9	11	10	21
1971-1980	19	8	18	26
1981-1990	30	10	20	30
1991-1994	7	3	35	38

*In the last year of each decade, the no. of children with newly diagnosed diabetes was: 1950-14 1960-29 1970-73 1980-139; 1990-229; 1994-403

The causes of death as obtained from various sources were: end-stage renal failure 37.5%; cardiovascular complications 21.5%; severe infections 15.1%; severe ketoacidosis 8.6%; miscellaneous 17.3%. The 14 casses which died in "innaugural" diabetic ketoacidosis were not included in these percentages.

Conclusions (1) Our population based analysis shows that the prognosis of childhood onset IDDM had improved considerably in the period 1942-1994 with a constant increase in the life expectancy. (2) An improvement in health care is expected to lead to a decrease in the number of cases dying in ketoacidosis and end-stage renal disease.

2552

ASSESSMENT OF QUALITY OF CARE FOR TYPE II DIABETES IN RURAL PRIMARY CARE SETTINGS.

R. Mazze, R. Burman, G. Castle, S. Sundem G. Simonson, R. Bradley, E. Strock, and K. Peterson. International Diabetes Center and University of Minnesota, Minneapolis, MN, USA.

Twenty-two rural primary care clinics in Minnesota, serving 10% of the population, were selected in order to assess current diabetes practices. Each site had a minimum of five general or family physicians, one registered nurse and one general dietitian available for patient services. No site had an endocrinologist, nor routinely referred to a diabetes specialist for management of type II diabetes. All clinics were located in communities with a population of between 5,000 and 10,000. At each site, 30 individuals with type II diabetes were randomly selected and their charts were reviewed by a multidisciplinary diabetes team. Along with standard demographic data, ten sentinel measures were ascertained: HbA1c (value and frequency), SMBG, eye examination, screening for microalbumin, foot inspection, diabetes education, nutrition education, type of treatment, stage of therapy (start, adjust or maintain) and number of months since change of treatment. Six hundred and sixty patients participated in the study (55% female and 45% male) with an average age of 62 ± 12. Because there was no significant difference between sites, all data were pooled for this analysis. HbA1c values were found for 442 (70%) of the subjects of whom 44% were <8% (normal range 5-6.5%), 32% were between 8 and 9.5% and 24% had HbA1c's of >9.5%. The overall average HbA1c was 8.8%. Food plan alone was prescribed in 14% and sulfonylurea therapy in 52% of the sample. Twenty-six percent of the patients were treated with insulin: 1 injection (1%), 2 injections of split-mixed insulin (24%) and 3 injections using bedtime NPH (1%). Five percent of the patients were on combination insulin and oral agent therapy and no documentation of treatment was found in 2% of the cases. Diabetes and nutrition education occurred in 35% of the cases. Surveillance for foot complications was found in 16% of the patients. Eyes were examined in 23% of the cases and screening for microalbumin occurred in 2% of the subjects. Although 67% of the patients were rated in poor control, only 17% had a change in therapy during the previous month and 24% during the previous 3 months. Overall assessment of diabetes care in this region showed that more than two-thirds of patients are at high risk for the development of microvascular disease.

2553

THE DIABCARE QUALITY NETWORK: THE ITALIAN EXPERIENCE BASED ON AN ORIGINAL TECHNICAL SOLUTION

M Massi Benedetti, R Norgiolini, F Capani, Q. Carta, M.E. De Feo, C. Taboga, G. Tognoni, M C Tardioli, M. Bruni, M Leandri, M. Orsini Federici, A. Nicolucci, G. Vespasiani - on behalf of the SID-AMD Study Group for the Implementation of the St. Vincent Declaration (SVD)

The DiabCare Q-Net Italy is a project for a national implementation of the European Q-Net principles. It is the result of a collaboration among the WHO Collaborating Centre for the Improvement of Quality of Care in Diabetes, the SID-AMD Study Group for the implementation of the SVD, the Mario Negri Sud Consortium with technical support of Medimatica s.r.l.. The Italian project aims at: a)evaluating the quality of diabetes care, b)creating an operative instrument for immediate data recording and aggregation, c)facilitating a rapid feed-back of information for a multidisciplinary approach in diabetes care (quality circles), d)implementing intervention plans and e)evaluating the impact on the quality of care.The DiabCare Q-Net Italy is based on an original system for data transmission which consists of: a)the Basic Information Sheet (BIS) modified for data transmission via fax, b)a central unit for data recording and aggregation (without manual input) using a software which transfers data into files, c)three update sheets, d)two personal cards for the complete anonymization of information The entire process of data aggregation and feed back of the information is activated and driven by the peripheral user. To date 29 Centres for diabetes nationwide have activated the system and 126480 data related to 1527 diabetic patients have been collected. Data are aggregated at national and macroregional (North, Centre, South) level. Some of the information of one Centre vs regional and national data are reported as an example. The mean age and HbA1c of the selected patients was respectively: 40.7 (national), 35 (macroregion) and 37.7 yrs (centre) and 7 8% (national), 7.7% (macroregion) and 7.3% (centre). The availability of information - related to the process indicators - resulted to be homogeneous for blood pressure, HbA1c, eye examination, weight, height; vice versa the availability of information related to foot inspection, serum creatinine, macroproteinuria, triglycerides and cholesterol resulted to be highly variable throughout the country. The availability of information related to outcome indicators is quite similar at different levels regarding myocardial infarction, blindness and proliferative retinopathy, while it is highly variable when nephropathy and ictus cerebri are considered. The overall results indicate that the DiabCare Q-Net is a valid instrument for external comparison of data, to support the continuous quality improvement in diabetes care.

2554

ASSESSMENT OF METABOLIC CONTROL IN ETHIOPIAN DIABETIC PATIENTS BY GLYCOSYLATED HAEMOGLOBIN. SEYOUM B, ABDULKADIR J, WORKU Y, BERHAN B, FELEKE Y, MENGISTU Z, AYANA G, ADDIS ABABA UNIVERSITY, ADDIS ABABA, ETHIOPIA.

Glycosylated haemoglobin (HgIc) was determined in a total of 302 diabetic patients regularly attending at the Tikur Anbessa Hospital Dabetic Clinic. The mean age was 41.1 years (range 14-85). There were 160 males (53%) and 142 females (47%). One hundred forty patients (46.4%) were type I and 162 (53.6%) were type II. The mean duration of diabetes was 9.4 years (range 1-34 years). The mean HgA1c was 10.4% (range 5.9-17.4%). 42 (13.8%) patients had excellent (<7.9%), 37(12.3%) patients good (8.0-8.9%), 49 (16.2%) patients fair (9.0-9.9%) and 174 (57.6%) patients had poor control (≥ 10%). On the day of the examination the mean fasting blood glucose (FBG) and random blood glucose (RBG) were 195.5mg% and 273.1mg% respectively. HgA1c correlated negatively with age r = 0.27 (95% CI -0.39 to -0.18) and positively with FBS and RBS, r=0.45(95%CI 0.36 to 0.54) and r=0.49 (95%CI 0.40 to 0.57) respectively, but HgAlc had no correlation with sex, duration of diabetes, serum lipid level or retinopathy. HgAlc was significantly higher in Type I as compared to Type II patients (11.1% versus 9.8%, p<0.001). In conclusion, the overall metabolic control of our diabetic patients is not satisfactory. This is related possibly to inadequate care as well as adverse socioeconomic factors precluding home blood glucose monitoring, periodic measurements of HgAlc and strict dietary control all of which would be difficult to improve in the short term.

2555

EVALUATION OF THE BEDSIDE HEMOCUE BLOOD GLUCOSE DATA MANAGEMENT ANALYZER

H.G. Wahl, I. Riedlinger, S. Herbert, I. Besenthal, H.M. Liebich, H.U. Häring and R.M. Schmülling. Medizinische Universitätsklinik Abt. IV, Tübingen, Germany.

Bedside testing of blood glucose done with glucose meters meant for patient self monitoring often requires additional measurements in the clinical laboratory. The blood glucose analyzer Hemocue® (Mallinckrodt Medical GmbH, Germany) is based upon a photometer, which is automatically regulated after each measurement. The optical measuring microcuvette contains all reagents prefilled and takes 5 µl of blood. The glucose reaction is a modified glucose dehydrogenase method with the additional formation of a colored formazan. End-point measurement is done at λ 660 nm and 840 nm. The Hemocue analyzer was tested in comparison to Kodak Ektachem Clinical Chemistry Slide® (Ektachem 950IRC System, Johnson & Johnson Clinical Diagnostics), Gluco-quant Glucose® (Hitachi 717, Boehringer Mannheim) and Ebio 6666 (Eppendorf) in a routine central laboratory setting. For this first part of the evaluation 322 blood samples (NaF, 28 to 400 mg/dL) were analyzed at the same time on all four instruments and data were evaluated by the Passing/Bablock procedures. The intra-assay coefficients of variation in a blood glucose range from 40 to 309 mg/dL (n=20 each) were determined as 1.0 to 1.8% (Hemocue), 1.0 to 1.7% (Ebio), 1.4 to 1.9 % (H 717) and 0.6 to 0.9 % (Ektachem). The inter-assay coefficients of variation (n=15) were determined as 1.7 to 4.7 % (Hemocue) and 2.7 to 4 0 % (Ebio). The Hemocue system (y) shows good correlation with both Ektachem (a=-5.7;b=1.02;r=0.991) and H717 (a=-3.4;b=1.12;r=0.991) by the Passing/Bablock procedure. The correlation is less good in the case of Ebio (a=12.3;b=0.95;r=0.988), but also the correlation between Ebio and either H717 a=15.6;b=0.84;r=0.994) and Ektachem a=17.9;b=0.92;r=0.993) is not as good as with the three systems Hemocue, H717 and Ektachem. The shown analytical performance together with the quality testing program meets the requirements for medical laboratory settings. Under the supervision of the clinical laboratory personnel the HemoCue system could be used for glucose bedside testing with all its known advantages for the diabetic patient, but without additional measurements in the central laboratory.

2556

DIABCARE QUALITY NETWORK IN EUROPE

D. Westphal, K. Piwernetz, M.R. Gallego, C. Cowley, F. Storms, M. Massi-Benedetti, R. Landgraf, A. de Leiva, S. SandØ and H. Bergrem
DIABCARE Office, Munich, Germany.

The major target of the project "DIABCARE Quality Network in Europe" (DIABCARE Q-Net) is the implementation of a continuous quality development system for diabetes care across Europe as a pilot study. The project is mainly funded by the European Community and is part of the Telematics Applications Programme, Health Care section. DIABCARE Q-Net is linked to the St. Vincent Declaration of 1989. The core of this declaration is to substantially reduce the complications of diabetes: blindness, kidney failure, amputation, coronary heart disease and pregnancy hazards. The tools for this pilot study, i.e. for data collection, electronic transfer, aggregation, evaluation of quality indicators, comparison, feedback and local quality improvement were developed during a previous project of the European Community between 1992 and 1995. One main part of these tools is the Basic Information Sheet (BIS), which contains those data items necessary to monitor the quality of care of an individual patient. This tool is now also available as a Windows program for data entry, retrieval, evaluation and automated data transfer. The result of this project will consist of a network of service centers evaluating, benchmarking and improving their outcome through the routine use of a telematic framework. All participating centers (GPs and clinics in Europe) will get rapid feedback by standardized benchmarking. First installations of such service centers for benchmarking feedback are already in use in Netherlands and Portugal. Additional solutions by data entry via fax were also developed. Such a solution including a service centre is now in use in Italy. The best performers can be identified for consultation, referral, or training of the other partners. This presentation will give a description of the project and an overview of the progress of the ongoing implementation process in Europe.

DESIGN OF A COMPUTER PROGRAM TO EVALUATE RISK FACTORS FOR LOWER-EXTREMITY AMPUTATION (LEAs).

E. Gil and A.L. Calle. HUSC. Madrid. Spain

We designed a computer program in order to determine specific risk status for LEAs (neuropathy, peripheral vascular disease and foot deformity) and inadequate practices for foot care. This computer program uses Microsoft Foxpro and Windows 3.0. Files are .DBF(dbase and clipper compatible). This program was applied to 59 diabetic subjects (Group A) who underwent LEAs between the 1st of January 1994 and 31st of December 1995 and 250 consecutive diabetic patients (Group B) without LEA of similar age, sex, duration of disease and Hba1c level. Despite a greater neuropathy, peripheral vascular disease and foot deformity risk-score in patients from group A, at least one inadequate practice in relation to foot care was found in all diabetic patients. Proportion of subjects with eyesight and mobility selfcapacity to inspect the feet was scarce and similar in both diabetic population, living alone more than 75% of subjects. Despite this, only 2.7% from group A and 60% from group B visited to the chiropodist at least one time each two months. In conclusions, the program used in this study is efficacy in order to classify diabetic patients by risk status for LEA and can be applied in an ordinary medical office setting.Taking this in mind, a reduction in LEAs would be achieved if subjects with diabetes mellitus could have a satisfactory access to chiropodists.

GLYCOHEMOGLOBIN A1c MEASUREMENT: MAY HPLC WORK IN THE ROUTINE WAY?

E. Biasci, C. Milioni, C. Bertoni, O. Giampietro, and E. Matteucci. Clinica Medica II, Università di Pisa, Italy.

Clinical usefulness of glycated hemoglobin (HbA1c) crucially depends on the accuracy and precision of its assay. Whilst we compared an immunological bench-top analyzer (DCA 2000, Bayer Diagnostici, Milano) to the HPLC reference method used in the hospital laboratory (Diamat and Fast Diamat, Bio-Rad Lab., Milano) by assaying multiple control sera, we found so many sources of systematical analytical errors in the routine use of HPLC to compromise between-assay precision. DCA 2000 showed intra- and inter-assay coefficients of variation (CV) of 1.1 and 2.3% with the normal standard serum, 1.0 and 4.2% with the pathological one; Diamat yielded CVs of 1.3 and 7.0%, 1.3 and 5.7%, respectively. Although the measurement of 161 blood samples evidenced that Diamat usually overestimated HbA1c (paired t test, $p<0.001$), a great variability of Diamat performance became evident when the relationship Diamat vs DCA was evaluated day by day over 17 days of observation (Anova, $p<0.001$). Intra- and inter-assay CVs of Fast Diamat, that initially (new instrument still on approval) resulted 0.6 and 2.5% (normal standard serum), 0.3 and 1.9% (high standard serum), yet after a 6 month-use in the routine laboratory became 3.1 and 3.2%, 1 and 12.3%, respectively. Main sources of error were: inaccurate autodilution, unsuitable parameter settings, disregard of the maintenance schedule. We conclude that a routine use of HPLC by non skilled personnel implies the loss of HbA1c value in the clinical practice.

***TELE-DIAB*: SENDING ELECTRONIC PATIENT RECORDS VIA E-MAIL**

S. Pruna, C. Ionescu-Tirgoviste* and N.D.Harris***
Institute of Diabetes "N. Paulescu", I. Movila 5-7, 79811, Bucharest, Romania, e-mail: spruna@rscemc.sfos.ro; Sheffield University,Royal Hallamshire Hospital, Glossop Road, Sheffield S10 2JF, E-mail: n.d.harris@sheffield.ac.uk*

One advantage of being hooked up to the INTERNET is that we can now send software and data files via e-mail. This allows us to send files including laboratory data, photographs, and biosignals to our centres or to our colleagues in the districts in a matter of minutes. Since this is new to most medical doctors the aim of this research was to develop a few standard instructions for the storage and transfer medical information and health care data between the national district centres and the transnational centres in the Black Sea area. For assemble the data file(s) or software programs to be sent via e-mail we used the DIABCARE for Epi-Info database, provided by WHO/Europe and a software developed in our laboratory, written in Turbo Pascal programming language and compiled into an executable form, which has the potential to record simultaneously the ECG and the pulse blood flow signal and real-time analysing of the signals. The software programs or data are in binary form, whereas e-mail is in text form. All that was required was a ZIP file utility (such as PKZIP), a MIME-capable e-mail program (such as Eudora) and a connection to the INTERNET by dial-up via ordinary phone lines. In the first step all of the software and data files were archived (compressed) into one file using a ZIP file utility. In the second step was composed an e-mail message, in the body of the message was written a brief summary of the medical problem and then from the e-mail program was attached the ZIP archive created. The binary files get attached to the e-mail and do not appear in the body of the message but the header of the message will list the attachment(s). Because errors are possible in the body of the message should be listed the files that are sending and their sizes, in bytes. The e-mail program will convert the binary files to a text-like form before sending it and the receiving program will convert it back to the binary. The recipients must check that the files arrived with the correct sizes. We have been tested this system in a pilot study on five Romanian centres and on two Black Sea area countries: Moldavia and Ukraine. In conclusion, the preliminary results shows that the transfer using the e-mail, via ordinary phone lines, have 100 % succesful worked for more than 300 patient records in Diabcare database and for more than 100 biosignals recorded with the software developed in our laboratory.

2560

THE APPLICATION OF A CHIP CARD BASED INFORMATION SYSTEM FOR MULTIDISCIPLINARY CARE OF PATIENTS WITH DIABETES

C.Tzioras,C.Phenekos,A.Garidou and the European Diabcard Consortium
Department of Endocrinology,Red Cross Hospital,Athens,Greece.

We have developed and tested a chip card based portable electronic patient record for the documentation,follow up and quality assessment of patients with diabetes.The system architecture is composed of the chip (smart) card,the processor,the data structure,security functions,the operating system on the chip card and the interface between chip card and application The software is tailored to present screens based on an enriched data set version of the «Saint Vincent meetings» basic information sheet.
The workstations,composed of office computers with card readers,were located at the outpatient's department,the dieticians office,the endocrine laboratory.A mobile workstation was also added by using a portable computer connected to a card reader for the home visit by the diabetic nurse.50 patients (47 NIDDM/3 IDDM) participated in the study each carrying his/her own chip card when visiting the hospital.Three issues were tested.1.Patient and health personnel acceptability of the system.2 The effectiveness of the system in communicating information among the health care team members and 3.Security aspects related to the chip card use.The methods used were based mainly on specially designed questionnaires, assessment of time spent updating the chip card and the central data base in comparison with keeping paper records and personal interviews.The acceptantance of the system was high in both patients (76%) and health providers (82%).Patient documentation and exchange of information, following initial adjustment, improved although the time spent with the card was 34% more that using paper records due mainly to software imperfections.Finally the security proved to be satisfactory as no one could have access to the data on the card without knowing the card's PIN.

2561

INTERNET EXPERIENCE WITH A FREEWARE INTERACTIVE EDUCATIONAL DIABETES SIMULATOR

E.D. Lehmann [1], D. Broad, T. Deutsch [2] and J.T. Lahtela [3]. [1] Royal Brompton Hospital and St. Bartholomew's Hospital, London, UK (*aida@globalnet.co.uk*); [2]Semmelweis University, Budapest, Hungary; and [3] University of Tampere, Finland.

Diabetic patients performing self-monitoring blood glucose (SMBG) measurements can often be uncertain about how to interpret the data. SMBG data are made available to health-care professionals at clinic/general practice visits and therapy is adjusted accordingly. However, educating patients to "close the loop" and act on their own SMBG data between clinic visits can be problematical. An interactive educational simulator of glucose-insulin interaction in type 1 diabetes mellitus has been developed for standard IBM compatible PCs. Patients and their relatives, students, nurses and clinicians are the intended users. They can select case scenarios on-line and interactively simulate or demonstrate the glycaemic effects of changes in insulin therapy and/or diet. An infinite number of changes can be made - ranging from adjusting the times, preparations, doses and number of insulin injections to changing the carbohydrate content or times of meals. If patients/ students are unsure what to try simulating next, and require guidance, a knowledge-based system can provide suggestions - increasing the educational utility of the software. The system was recently refined and now incorporates a new, dedicated data entry screen and case scenario database. It caters for a wide variety of commonly used insulin preparations, including premixed (biphasic) preparations. As a consequence of its ease of use, after some extensive beta-testing by diabetic patients and health-care professionals around the world (all Internet users), the software was formally released in June 1996 on the World Wide Web as a non-commercial contribution to continuing diabetes education. It can be downloaded *gratis* from the Diabetes UK Internet site (*http://www.diabetic.org.uk/aida.htm*). Thus far over 2900 people have visited the site and over 1500 copies of the software have been downloaded. It is hoped that such interactive teaching aids may in time help to safely improve patient self-management between clinic visits. The software is also available without charge directly from the authors.

I.T. FACILITATED WHOLE POPULATION IMPROVEMENTS IN INTERMEDIATE OUTCOMES OF DIABETES CARE.

J Lloyd, J P New, D McDowell, E Burns and RJ Young.
Diabetes Centre, Hope Hospital, Manchester, UK.

In 1992 a district diabetes information system (DDIS) was introduced to an existing (commenced 1988) population based diabetes care programme (urban population 230,000; 2% diabetes, 872 Type 1, 3746 Type 2). DDIS supports service administration and guideline implementation, and feeds back "clinical performance" to primary and secondary health care professionals. During 1992 principally demographic data was entered but since 1993 "process" and "outcome" data has been routinely recorded. The impact of DDIS on the "intermediate outcomes" of diabetes care has been evaluated.

	Type 1		Type 2	
	1993 (%)	1996 (%)	1993 (%)	1996 (%)
Systolic BP <160 mmHg	79.5	81.0	61.5	71.9[a]
Diastolic BP < 95mmHg	92.8	91.3	86.9	88.1
HbA_1c < 7.0%	51.4	66.8[a]	66.7	74.4[a]
Cholesterol <5.5mmol/l	40.7	47.6	26.2	37.8[a]
HDL >1.0mmol/l	77.1	85.1[b]	58.2	62.5
BMI <25kg/m²	42.8	45.0	22.4	23.9

[a] $p<0.001$, [b] $p<0.05$ compared with 1993

We conclude that the introduction of DDIS has been associated with improved glycaemic control (Type 1 and Type 2) and coronary risk factors (Type 2 > Type 1), namely dyslipidaemia and systolic hypertension. In this care setting introducing DDIS has been associated with a substantial improvement in the outcomes of diabetes care.

2564

EVALUATION OF OPTICAL MEMORY CARD SYSTEM TO CONSTRUCT MEDICAL INFORMATION NET WORK FOR DIABETIC PATIENTS

M. Ohashi, M. Nomura, R.Fukunaga, H.Tanahashi, Y. Yamada, T Kamada and H. Abe. Osaka Rosai Hospital, Sakai, Osaka, Japan.

To prevent the occurrence of diabetic complications, it is important to improve clinical care of diabetic patients at any place he may live or work or travel. In order to do so, it is necessary to construct medical information managing network among medical centers for smooth exchange of present and previous clinical data, such as laboratory data and prescriptions. In this study, we have tried to develop and evaluate the medical optical memory card system to construct medical information network.

[Method and Material]

Medical optical memory card system were constructed with 1) optical memory card {size: 54x85.5mm, WORM type (write once read many), maximum memory size: 4.1 megabytes}, 2) card reader / writer (LC-304, Conlux, Japan) , 3) personal computer, 4) color image scanner, and 5) printer. Various laboratory data including laboratory data and imaging data (X-ray, CT, MRI, RI), stored in the host computer in the hospital or clinics, were able to send directly by LAN (local area network) or transfer to the card system by recording device using text file.

[Results and Conclusions]

Optical memory card system is useful for diabetic patient's medical information managing due to tight security of recorded data, large capacity of memory size, and high-speed reading and recording capacity.

Although further study may be necessary to improve handling of imaging data, we could construct the medical information managing network by this medical optical memory card system.

2565

I.T. FACILITATED WHOLE POPULATION IMPROVEMENTS IN THE PROVISION OF DIABETES CARE.

JP New, J Lloyd, D McDowell, E Burns and RJ Young.
Salford Diabetes Centre, Hope Hospital, Manchester, UK.

Minimising the adverse outcomes of diabetes depends on regular effective preventative care for everyone with diabetes. Since 1988 in our urban district (population 230,000; 2% diabetes, 872 Type 1, 3746 Type 2) family practitioners and the hospital diabetes centre have been collaborating in a structured preventative care programme. In 1992 a District Diabetes Information System (DDIS) was introduced; it supports care delivery, collects the UK Dataset as a by product of care, and feeds back 'performance measures' to all diabetes care providers. The impact of a DDIS on the district annual performance of routine preventative care processes has been evaluated.

	1993	1995	p (Chi^2)
Annual review	61%	73%	<0.0001
Never reviewed	31%	15%	<0.0001
Key processes completed during annual review examination			
Weight	93%	94%	0.12
Blood Pressure	96%	98%	<0.0001
Eye examination	83%	93%	<0.0001
Foot examination	88%	93%	<0.0001
Renal check	44%	69%	<0.0001
Glycaemic check	65%	85%	<0.0001
Lipid check	59%	69%	<0.0001

We conclude that the introduction of the DDIS has been associated with a marked improvement in preventative care performance.

2566

The Impact of a Diabetes Electronic Medical Record (DEMR) on the Process of Care for Patients with Diabetes/S Smith, M Murphy, T Huschka, S Dinneen, C Gorman, B Zimmerman, R Rizza, J Naessens/Mayo Clinic Rochester, Rochester, MN, USA **Objective:** To compare the compliance with diabetes care performance indicators for those providers and their patients who utilized a DEMR compared to those who did not. The DEMR is a computerized system for facilitating the management and documentation of care for patients with diabetes. **Population:** As part of the pilot study for Provider Recognition by the American Diabetes Association (ADA); adults (16 years or older) seen in the Metabolic Clinic (MC), Mayo Clinic Rochester during the first quarter of 1996, with a diagnosis of Insulin-dependent or Noninsulin-dependent diabetes mellitus were identified electronically by ICD-9 codes: 250.00-250.93, 362.01, 362.02, 366.41, and 357.2 (total 1235 patients). To be eligible for study, the patient must have had a diagnosis of diabetes for a minimum of one year prior to the MC visit date. They must also have had a visit in the MC coded for diabetes in the prior 12-24 months (238 qualified patients). **Design:** A random sampleof 82 patients were selected for medical record review for the ADA performance indicators. Comparisons between patients whose providers use the DEMR (39) and those who used the paper record only (43) were based on Chisquare tests for percents and Wilcoxon rank-sum tests for ordinal and continuous variables. **Results:** Number of foot exams, blood pressures, and of glycated hemoglobins were significantly better in those providers using the DEMR. **Conclusions:** Process of care and/or documentation for patients with diabetes followed in a subspecialty clinic were significantly enhanced by the use of a DEMR. Translation of these results into general practice needs to be confirmed.

Performance Indicator	DEMR	No DEMR	p Value
Tobacco status and advice to quit	97.4%	95.3%	0.615
Blood Pressures per patient per year	3.87	3.14	0.024
Dilated eye exam in the last year	97.4%	95.3%	0.615
Foot exams per patient per year	3.21	2.07	<0.001
<4 Glycated hemoglobins per year	5.1%	32.6%	0.002
Lipid profile in the last year	84.6%	69.8%	0.112
Urinalysis, if negative microalbumin in last year	53.8%	48.8%	0.650
Mean glycated hemoglobin value (most recent)	9.64%	10.25%	0.192

2567

MULTILINGUAL COMPUTER ASSISTED HISTORY SOFTWARE FOR DIABETES PATIENTS.

E.G. Movius. Georgetown University, Washington, D.C., U.S.A.

The ability of physicians and nursing personnel to obtain a detailed medical history from a diabetic patient is often compromised by the lack of interpreters for patients speaking languages other than that of their physician. This problem is especially acute in clinics which provide care for many new immigrants. In order to improve communication in this setting, I have developed software MediSpeak which allows a physician to obtain a detailed medical history from a patient who speaks a different language. Over seven hundred questions in English have been arranged by medical topic and translated into Spanish, Vietnamese, and Russian. By using digitized sound files the computer will "speak" each question in the patient's native tongue. 200 questions apply specifically to patients with diabetes mellitus. All questions are in a Yes-No format or require simple gestures by the patient to indicate location of symptoms. The program has been written in both PC and MacIntosh versions and can be used on most labtop computers at the bedside. A written record of the questions and answers in both languages is available to the physician at the end of the session. This program is presently being used in a medical clinic in the U.S. with a large number of Spanish speaking patients, and has the potential to assist all physicians who treat diabetic patients who speak different languages.

Models and Economics of Diabetes Care

2568

INSULIN STORAGE BY DIABETIC PATIENTS IN ETHIOPIA.

SEYOUM B, ABDULKADIR J, FELEKE Y, WORKU Y,
ADDIS ABABA UNIVERSITY, ADDIS ABABA, ETHIOPIA.

A total of 140 Type 1 diabetic patients were interviewed to determine how they store their insulin at home. The mean age of the patients was 31.0±10.2 years. The majority 84 (60%) patients were males & the rest 56 (45%) patients wre females. The mean duration of Diabetes mellitus was 8.3±5.4 years (range 1-27 years). About 20% of the patients have stopped their insulin for some days to weeks because of various reasons. Only 26.4% of the patients store their insulin in refrigerator, the rest they store it in clay pots filled with water and sand 17.8%, in empty tins 17.1%, in cupbords 17.1%, on floors 15.7% and in glasses 3.6%. The mean glycosylated hemoglobin was 11.1±2.3% (range 6.5±17.4%),. The educational status, the income and the glycosylated hemoglobin is not statistically different in the different groups ($P>0.05$), where as hyperglycaemic symptomes are significantly less in patients who store their insulin in the refrigerator ($P<0.01$). In the majority of our patients because of the poor socioeconomic status, The site of storage of insulin is likely to be hot, which might be associated with significant problems of tempreature related deterioration and thereby poor metabolic control.

2569

CLINICAL PROFILE OF DIABETIC POPULATIONS IN ANDHRA PRADESH : A PILOT STUDY.

S.S. Murthy, G.R. Sridhar, P. Ushabala, P.V. Rao,
Y. Sadasiva Rao, M. Chinnikrishnudu and K. Sai.
Andhra Pradesh Diabetes Federation, India.

Clinical characteristics of diabetics managed at different hospitals were compiled from a questionnaire based data from 24 diabetologists of Andhra Pradesh state. Majority (72.6 ± 30.8, 0-98 %) diabetics were diagnosed after 30 years age. Among them, 71.5 ± 24.4, 0-95 % were on oral hypoglycemics, 14.3 ± 12.9, 0-44% were non-ketotic yet requiring insulin, 7.7 ± 5.5, 1-18 % were ketosis-prone requiring insulin and 1.1 ± 1.6, 0-5 % were also ketosis-prone but never on insulin. Obesity defined by BMI>24 kg/m^2 was noted in about half (48.8 ± 26.0, 0-90 %) of all adult diabetics. One-third of the diabetics were diagnosed before 30 years age. Among them, 50.4 ± 29.3, 0-90 % were ketosis-prone on insulin, 6.5 ± 9.4, 0-30 % were also ketosis-prone but treated with oral hypoglycemics only, 26.4 ± 19.4, 0-70 % never had ketosis and managed with oral hypoglycemics alone and 14.4 ± 13.1, 1-50 % also had ketosis-resistance but required insulin. BMI was below 19 kg/m^2 in 10.8 ± 10.7, 0-37 % of all young diabetics. Among these young and lean, 10.9 ± 9.7%, 0-30 % were ketosis-resistant with evidence for pancreatic calcification, 38.1 ± 25.9, 0-70 % had ketosis-resistance alone, 39.7 ± 29.4, 0-90 % were ketosis-prone and further 6.6 ± 6.5, 0-20 % had pancreatic calcification along with evidence for ketosis. Clinical types of diabetes and therapy modalities practiced by diabetic care providers in a state were largely unknown due to lack of population based studies and diabetes registries. Data as reported in this pilot study was essential for understanding specificities of diabetes in a region and for appropriate health care planning.

2570

INTERNATIONAL GUIDELINES FOR DIABETES CARE: A MULTI-CENTER, MULTI-NATIONAL STUDY

E. Strock, R. Mazze, K. Strauss, B. Ginsberg, D. Etzwiler and the SDM Study Group, W.H.O. Collaborating Centre in Diabetes, International Diabetes Center, Minnesota, USA.

The purpose of this study was to determine whether a single set of guidelines could be adapted for multiple international sites. Ten countries participated in the development and implementation of international- guidelines for the detection and treatment of diabetes and its complications. Using Staged Diabetes Management (SDM), a protocol-based approach to guidelines and clinical pathways for decision-making, diabetes experts in Japan, Poland, Mexico, Brazil, France, Germany, Russia, Canada, Australia and the United States took part in a four step approach to the adaptation of SDM for their country.

Step I: In each country expert committees composed of diabetes specialists and primary care practitioners were formed to coordinate the customization of SDM.

Step II: Each committee customized SDM guidelines for diagnosis, treatment options, therapeutic goals, monitoring and follow-up to reflect available resources and current system of diabetes care. These customized guidelines were supported by Master DecisionPaths (algorithm) for each type of diabetes which provide a roadmap for sequencing treatment options, as well as Specific DecisionPaths to guide starting and adjusting treatments, complications surveillience and management, medical follow-up, patient education, nutritional and exercise interventions and psychosocial assessment and therapy.

Step III: Once consensus was reached, the customized version of SDM was translated into the native language of each country.

Step IV: After review by the International Diabetes Center, implementation models for each country were developed. The implementation process included baseline chart audit, orientation and training, and outcome evaluation. Three different international strategies emerged: diffusion from a single expert center, diffusion through regional centers, and diffusion through individual facitilites or national healthcare providers. In the United States, this approach has already been shown to reduce inconsistency in treatment and to significantly improve glycemic control with average reduction in HbA1c by 1.8%. Complications surveillance has increased by 60% for eye and peripheral vascular disease.

2571

A practical program of insulin distribution in Zaire.

J.T. Burdon[1], R Raab[2]. [1]Centre Médical Evangelique, Nyankunde, Zaire. [2]International Diabetes Institute, Melbourne, Australia.

The Centre Médical Evangelique (CME) is a large referral hospital in Northeast Zaire. Diabetic care at CME has for many years been severely hampered by the expense of available insulin with a month's treatment costing approximately one person's entire monthly wage. The results of this included apathy about diabetes on the part of medical and nursing staff and the inadequate treatment of many insulin-dependent patients. Since October 1995 CME has received regular supplies of insulin along with some blood glucose testing sticks and insulin syringes from the Insulin Distribution Program of the International Diabetes Institute (IDI), Australia. A total of 3100 vial equivalents has been donated up to December 1996. Only transport and associated costs are paid for by CME. This supply of quality, cheap insulin has altered many aspects of diabetic care at CME. Patients can now afford appropriate long-term treatment so their diabetic control has improved. Lives that previously would have been lost due to an inability to pay for insulin have been saved The numbers of diabetic patients attending at CME has increased approximately 150%. The hospital has gained an enthusiasm for treating diabetes with increasing interest shown by both nurses and doctors. A new diabetic clinic has opened in a nearby town to encourage attendance. Other hospitals in the region are now benefiting from the program and research into diabetes has been stimulated. Scientific data shows the long life of appropriately stored insulin and some vials have been used that are past their nominal 'use-by' date. The large number of different types of insulin received has caused some confusion amongst staff. The future of the project is good but effort is needed to ensure that insulin is as widely available as possible in the region The Insulin Distribution Program which involves in Zaire a partnership between the IDI and CME has been the key to stimulating interest in diabetes in Northeast Zaire Large quantities of insulin are available form various sources around the world but much is being destroyed. We encourage the distribution of this life-saving drug to the many regions of the world where insulin shortage is a reality.

2572

DIABETES HEALTH PROFESSIONAL STAFFING IN NEW ZEALAND P.L. Drury and R. Cutfield. New Zealand Society for the Study of Diabetes. Auckland, New Zealand.

There is little data on the staffing of specialist diabetic public health facilities in New Zealand (NZ) since a survey 10 years ago. In late 1995 we mailed such a survey to respondents in all 23 Crown Health Enterprises (CHEs) enquiring about nursing/ educational, dietetic, medical and podiatry time devoted to diabetes. Replies were received from all 23 CHEs including a total of 26 individual areas of provision. Results are calculated as whole time equivalents (1 WTE = 40 hrs per week) per 100,000 population served (Total NZ population = 3.54 million).

	Nursing	*Dietetic*	*Medical*	*Podiatry*
Mean WTE	1.86	0.60	0.37	0.14
Maximum	5.00	0.76	0.91	0.32
Minimum	1.02	0.15	0.02	0

Few areas lacked significant nursing or dietetic input, though there were wide variations in provision, not obviously related to local diabetes prevalence or geography - NZ Maori, Pacific Island and Asian communities have very high prevalences of diabetes. Several districts, including some populations > 100,000, still have only token medical time allocated with no trained diabetologist, while 5 districts had no public podiatry service. We conclude that: (1) There are major deficiencies in provision of specialist services for diabetes in most parts of NZ, especially in medical and podiatry time; (2) Staffing levels compare most unfavourably with other countries with much lower prevalences of diabetes; (3) Any attempt to improve the care and outcome of diabetes will currently probably be limited by lack of skilled personnel.

2573

HOW DO INDIVIDUALS WITH DIABETES USE THE ACCIDENT AND EMERGENCY DEPARTMENT?

EC Goyder, SW Goodacre, JL Botha and G Bodiwala. University of Leicester, Leicester,UK.

Previous studies suggest diabetes is not a risk factor for accident and emergency (A&E) department use, despite being a major risk factor for admission and outpatient attendance. The aim of this historical cohort study was to determine whether individuals with diabetes have a different pattern of A&E department use to the general population. Service use by 696 individuals with diabetes over an eleven year period was compared with use by 696 non-diabetic individuals. The two cohorts were matched on age, sex and general practitioner. The geographical distributions of their addresses were similar. More visits were made by the diabetic cohort (1002 vs 706, p=0.0001). 121 visits by the diabetic cohort were directly related to diabetes, including 52 for hypoglycaemia. The diabetic cohort also had more visits for medical illness unrelated to diabetes (357 vs 231, p=0.0001). The number of visits for injuries, including selfharm, was not significantly different (524 vs 475, p=0.3). Individuals with diabetes were not significantly more likely to be referred by a general practitioner (14% vs 16%) or admitted (20% vs 17%). They were more likely to have arrived by ambulance (36% vs 26%, p=0.02), even for injury related visits (24% vs 15%, p=0.05). Individuals with diabetes make more frequent visits than the general population to the A&E department. These excess visits were for both diabetes and other medical illnesses. There was no excess of visits for injuries. The difference is therefore probably due to greater morbidity rather than a lower threshold for attendance.

2574

NORMAL POPLATION RANGES AND AGE RELATED CHANGES IN HbA1c MEASURED USING THE DCA 2000

Rayman G , Rayman A , Pledger D.
The Diabetes Centre, Ipswich Hospital, Suffolk, UK, IP4 5PD.

The Bayer Diagnostics DCA 2000 analyser a rapid outpatient HbA1c method is becoming increasingly widely used in diabetes clinics to provide same visit results. Recently a new cartridge which reduces the analysis time to 6mins was introduced, but normal population ranges have yet to be established with this method. The aim of this study was to establish such a reference range in a typical caucausian UK population. Samples were obtained from 102 volunteers with no history of diabetes or serious medical problems. Volunteers were obtained from general practice "well persons" clinics, well visitors to the hospital and hospital staff (age 18-82yr, mean 46.2yr; 54 female and 48 male). There was a clear age related increase in HbA1c, $y=4.75 \pm 0.13x$, $p<0.001$. The mean for this population was 5.2%. Results were not normally distributed hence the normal range was determined using 95% confidence limits. For the whole population the reference range was 4.5% to 6.2%. This reference range is very close to that in the Diabetes Control and Complications (<6.05%) study allowing direct comparisons to be made with that study.

2575

INSULIN STORED IN MATKA (EARTHEN PITCHER) WITH WATER FOR 60 DAYS DOES NOT REDUCE IN BIO-ACTIVTY.

S Rangwala, P Shah*, SZ Hussain, S Goenka*, and KK Pillai. Hamdard Univ, and *All India Inst Med Sci, N Delhi, India

Background: Several insulin requiring diabetics in India do not have a refrigerator at home. Moreover, supply of electricity is not regular in several parts of India. With an attempt to reduce possible damage to insulin several diabetics store their insulin in *Matka* (an earthen pitcher with water) in a steel box / plastic bag floating in water.

Aim: to ascertain whether insulin storage in *Matka* would lead to reduction in bio-activity, and, to study whether there is any difference between human and bovine insulin preparations in this regard.

Design: Randomised trial. *Comparison groups*: human and bovine regular and lente insulin *Exposure:* storage in Matka for 30 and 60 days in peak Delhi summer (6 samples each for both exposures: total 48 samples). *Outcome variable:* mouse blood glucose bioassay units (total 600 animals, reused thrice: total experiments: 1800) (British Pharmacopoeia 1980)

Results: There was no deterioration of insulin bio-activity on storage up to 60 days. (neither bovine/ human; nor regular/ lente; nor 30 days/ 60 days)

Conclusions: insulin stored in *Matka* does not lose its potency when compared to appropriately stored insulin/ standard insulin crystals. Insulin treated patients in tropics can reliably store insulin in *Matka*.

FUNDIABETES: AN INTEGRALL MODEL OF DIABETES EDUCATION.

N.Sanz, and A.Tami, M.Natera. FUNDIABETES, Fundación de Atención al Diabético, Caracas, Venezuela.

FUNDIABETES, Fundación de Atención al Diabético (Foundation for the care of diabetic patients) was officially established in 1989. Since its initial operation, the foundation has carried out a series of activities aimed at providing the community with Health Education and Prevention Programs. Such activities include health fairs, scientific conferences, press conferences, publication of educational material and patient education and orientation at the foundation's facilities. The institution also provides the diabetic community with free medication or discount rates. Health Fair: The health fair is a one day public event in which the foundation tries to create awareness, among community members, about the complications and consequences of diabetes, obesity, high blood pressure, chronic coronary heart disease and high cholesterol levels. This is done through educational speeches and workshops and by providing immediate on-site health care (blood tests to measure glucose and cholesterol levels, urinetests, blood pressure, etc.). Health fairs are carried out nationwide on a quarterly basis and up until now 14 fairs have taken place. Scientific Conferences: The objective of such conferences is to keep health professionals, linked to the area of diabetes, up to date on latest tendencies and treatment therapies in such field; therefore, the scientific conferences count on the participation of reknown national and international specialists, nurses, educators and students. To add to the conferences, FUNDIABETES holds specialized courses and supervises and participates in research projects (under and graduate thesis). In addition, the foundation has taken part in the following events: I Congreso Bolivariano de Educación Diabetológica; Latin-American Diabetes Association's consensus on " Prevention, Control, and Treatment of NIDDM" as a work group member; a Multicentric Study on Diabetes in Venezuela carried out together with the Joslin Diabetes Center of Boston, DESG and and will participate in the epidimiology study of the WHO already initiated in European countries under the name DIABCARE.

GLYCEMIC CONTROL IN CHINESE DIABETICS MANAGED BY HOSPITAL CLINICS

XX Zhu, Shanghai Medical University, LN Jorgensen, Novo Nordisk A/S - Asia-Pacific Centre, Singapore.

There are about 20 million people with diabetes in China, of which only a small minority is treated with insulin. The aim of this study was to assess the glycemic control in insulin-treated Chinese diabetics, managed by diabetes clinics in major hospitals. The data is baseline data collected from clinics, which participated in a study on transfer from locally-produced animal insulin to human insulin. A total of 630 patients from 43 clinics were assessed.

Results (years, median values and span):

Age: 53 (6 - 88); Duration of diabetes: 8 (0 - 41)

Duration of insulin treatment: 2 (0 - 30);

fasting blood glucose: 9.1% (2.9 - 30); HbA_{1c}: 10.9 mmol/l (1.4 - 41)

A total of 81 severe hypoglycemic events over 3 months were reported, corresponding to 0.53 events/patients/year.

HbA_{1c}	% of patients	Glycemic Control*
< 7	9.7%	optimal
7 - 9	39.5%	fair
> 9	50.8%	poor

** Asia Pacific Guideline on management of NIDDM 1995.*

Conclusion

Although the patients represent a mix of IDDM and insulin- requiring NIDDM, we have used the targets for glycemic control defined by the Asia-Pacific Guideline for NIDDM as reference. According to these targets, half of the patients were in poor control, and only 10% could be characterised as in optimal control. This result calls for more detailed investigations on the diabetes management of the world's largest population of diabetics.

2578

"DIRTY" VS "PURE" INSULINS : RELEVANCE, RECOMMENDATIONS AND REQUESTS FROM A DEVELOPING COUNTRY

MG.Mamatha, GS.Narayan, AS.Vinaya, BS.Sudha, DV.Rama, J.Srikanth, P.Ashalakshmi, S.Colaco, S.Nagabushan, N.Nagesh, S.Krishnamurthi, A.Sharda, and SS.Srikanta. Samatvam: Endocrinology Diabetes Center, Bangalore, India.

Both medical and socio-economic factors dictate the use/ choice/ prescription of bovine-BI (conventional, "dirty"*) versus porcine-PI/ human-HI (monocomponent, "pure"*) insulin, especially in a developing country, without universal health insurance/ reimbursement (* terms projected by the drug industry). [India: (estimates in US$) Annual insulin costs - 14000 units BI = 35, PI = 120, HI = 200; 1990 per capita income = 160, diabetes health care costs (excluding hospital visits) 80-320]. Absolute medical indications for PI/HI being systemic BI allergy and severe insulin resistance, economic affordability appears more to be a social indication. In an attempt towards a medically rational and socially justifiable consensus regarding insulin prescription, we evaluated data on 232 insulin users at our center (fee for service). Among 82 patients initially on BI: (a) during a total of 640 patients years of follow up, only 4 developed systemic insulin allergy necessitating change to HI; (b) 22 changed to HI for social reasons (rich or reimbursement); (c) the remaining 56 patients have continued to use BI, without any problems. Among 150 patients initially put on (elsewhere) or opted for (at our center) PI/HI, 11 patients subsequently sought change over to BI, due to unaffordability. Thus currently (1996), 29% of insulin requiring patients (67 out of 232) at our center are using BI without adverse effects; out of 3 patients who reported local allergy, one opted for immediate change to HI, whereas the other 2 have continued on BI, with disappearance of local allergic symptoms. Current mean insulin doses/ day of BI versus PI/HI users are 34 and 28 U, respectively. Conclusion: In the current economic scenario, we recommend an educated "cafeteria" approach, allowing the patients to choose the type of insulin, but for one of the absolute medical indications for HI. We pray for "HUMAN INSULIN FOR ALL BY 2000 AD", AT AN AFFORDABLE PRICE.

2579

THE EMPHASIS ON CHANGING LIFE-STYLE IN THE TREATMENT OF DIABETIC PATIENTS.

C.Sharon Naufach , T. Lavie and J. Diamond. Kupat Holim Maccabi, Herzlia,Israel.

In a secondary community diabetic clinic, the treatment of diabetics was based on changing the life-style of patients in order to improve glucose control and decrease risk factors for cardio vascular disease.

Methods: Working with a multi-disciplinary team, 90 patients were followed for a period of 6-42 months. The treatment was based on 4 factors:-nutritional education, encouragement to exercise regularly, medication as required and attention was given to the psychological aspects of this chronic disease.

Results:- By working as a team, emphasizing changing life-style, a number of factors were improved in the patients. 1) Decrease in Hb A1c 2) Performance of regular exercise 3) Improved lipid profiles 4) Improved blood pressure control. The percentage of patients with very poor glucose control (HbA1c>10% Normal <5.8%) decreased from 38% to 13%. The percentage of patients with reasonable control (Hb A1c <8%) increased from 34% to 59%. The percentage of patients with marked hypertriglyceridemia >200mg%, decreased from 37% to 27%. The percentage of patients with hypercholesterolemia (LDL-chol.>160mg%) decreased from 23% to 13%. Twenty seven percent of the patients had uncontrolled hypertension at the beginning of the study and only 9% of patients still had uncontrolled blood pressure at the end of the study. The percentage of smokers decreased from 7-4% and the percentage of patients who performed regular exercise increased from 24% to 63%.

Conclusions:- The effective treatment of diabetics depends largely on patient compliance to the treatment. In a multi-disciplinary clinic where the emphasis is on changing patient life-style, along side medication, a significant improvement in glucose control can be achieved, as well as decreased risk factors for cardiovascular disease. These results are facilitated by increased compliance, obtained by a holistic approach to the patients.

DIABETES NIGHT CLINIC - A PROMISSING CARE SYSTEM FOR DIABETELOGISTS AND TEAM

E. Austenat, A. Hotzwik, M. Reinhold, C. Riedel, M. Scherwinski, S.Semmler, M.Topuz, S. Wiesemann, Diabetes Institut Berlin, Germany

The target for diabetes management is a good metabolic control, no acute and no late complications by social integration and normal lifestyle.Insulin treated diabetics are more frequent in hospitals than nondiabetics.For this reason we changed in 1985 the hospitalisation procedure into a Diabetic Nightclinic – mix from out- and inpatient management. At 4 p.m.the patient joins the clinic, professional nurses and laboratory assistents note the daily events, blood sugar self monitoring results and the daily dietary specials.Afterwards the patiens have dinner together.Between 8 and 9.30p.m.teaching classes are hold by physicians in groups or be trained individual .Over the night nurses control continously the metabolic parameter.The patients take the breakfast individual and leave the clinic for the day either for work or personal routine. The costs of the Nightclinic are much cheaper than traditional clinics.Our results from 1990-1995: **Basic data:** n = 3421 diabetics, n=1864 female (54,5%) and n=1557 (45,5%), type 1 n= 1779 (52), type 2 n=1613 (47,2),diabetes duration(years) 12,4 ±9,3 (0 - 66,age (years) 45,8±17,6 (9-88),HbA1 10,8 ±2,3% (5,2-20,4%).Insulin treated n=2495 (72,9%), n = 926 (27,1%) oral drugs or other kinds of treatment. Indications for the clinic: poor metabolic control - no efford under outpatients conditions, gestational diabetics diabetes manifestation, acute decompensation without coma,CSII contraindications: mental and physical handicap to leave the clinic for the day. **Results:** average hospitalisation(in nights) 9±4,1(1-30),able to work during inpatient time 77,3 % (n=2644),unable to work 1,1 ±2,8 days (min 0, max 22).By good metabolic control in more than 75% no second hospitalisation was necessary up to two years.Conclusion: The principles of the nigth clinic are good instruments to treat diabetics with poor metabolic control.Costs can be demonstrated.This is a system for the future, but it needs a specialised medical stuff.

QUALITY OF CARE IN NIDDM PATIENTS WITH HYPERTENSION IN MOSCOW.

E.Surkova, O.Moiseeva, A.Maiorov, I.Dedov and M.Antsiferov. National Research Centre for Endocrinology, Moscow, Russia.

To evaluate a quality of primary care in NIDDM patients with hypertension we examined 144 patients who participated in educational programme for Type II non-insulin-requiring diabetic patients. 46 patients from this group (19 male, 27 female) had hypertension. Mean age of these patients was 52,9±1,5 years, diabetes duration 6,2±1,0 years, hypertension duration 12,2±2,0 years, BMI 29,7±1,2 kg/m^2, total cholesterol 6,3±0,2 mmol/l, triglycerides 3,0±0,4 mmol/l. After education diabetes control was improved (HbA1c decrease from 9,9±0,3 to 8,3±0,4%, $p<0,01$, weight loss 3,6±0,5 kg, $p<0,05$). Blood pressure control remained unsatisfactory (systolic blood pressure 160±4 mm Hg, diastolic blood pressure 97±2 mm Hg). We found that 26% have no antihypertensive treatment, 4% use beta-blockers, 17% - angiotensinconverting enzyme inhibitors, 13% - calcium channel blokers, 9% - reserpin, 31% were on combined therapy. 57% of this patients never performed blood pressure self-monitoring, about 50% were taking antihypertensive drugs periodically. Correction of dyslipidaemia was not done in anybody. These results have pointed out great needs for improvement of care in NIDDM patients with cardiovascular risk factors. One of such approaches could be implementation of special educational programme for Type II diabetic patients with hypertension which was initiated in Moscow.

2582

DIABETES CARE IN NAVAJO-SPEAKING PATIENTS

D.Gohdes, R.Begay, B. Skipper and M.Glass, IHS/UNM, USA

The Navajo Nation, the largest American Indian tribe living on a reservation in the southwestern US, has experienced rapidly increasing rates of diabetes in recent years with rates 3 times those of the general US population. Many older diabetic patients speak only their native language and require skilled interpreters on health care visits. To examine the impact of language skill on tertiary preventive care for non-English speaking Navajos with diabetes, the 1994 and 1995 Diabetes Quality Care Audits (QA) were supplemented by a special study. Random samples of charts were drawn for the routine QA review of diabetes care practices each year (n=193) from the ongoing diabetes registry at the Shiprock Indian Health Service Hospital. The registry presently includes over 3000 patients who receive care at this regional medical center in the northeast section of the reservation.. In 1995 these charts were reviewed again for notations about interpreters and providers were interviewed about the need for interpreters for each patient. 23 patients were excluded for whom language or blood sugar data were unavailable. 46% (78/170) needed interpreters. Navajo-speaking patients were older with mean age 63 years compared to 52 for those who spoke English adequately ($p<0.001$) and had longer duration of diagnosed diabetes 8.6 years vs 7.3, but the difference was not statistically significant ($p=.18$). Both groups received screening laboratory tests, immunizations and education at similar rates. Non-English speaking patients received more comprehensive foot exams (47% vs 35%, $p=.09$) and fewer eye exams (39% vs 53%, $p=.07$). After adjusting for age, proteinuria, and serum creatinine, the mean of three blood sugars during the preceding year was 211 mg/dl in the patients who needed interpreters compared to 191mg/dl in those who did not ($p=.16$). Although evidence of urinary tract infection was found more commonly on the charts of non-English speaking patients, after adjusting for age, the difference disappeared. With the availablilty of skilled interpreters tertiary preventive care can be given to American Indians speaking their native language. Further research is needed to determine the best ways to improve metabolic control, patient self-care practices, and the basic understanding of diabetes among Navajo people.

PROSIT-PROJECT: SCREENING AND INTERVENTION FOR DIABETIC NEPHROPATHY

W. Schramm[1], R. Landgraf[1], R. Renner[2], W. Piehlmeier[1], T. Kimmerling[1], J. Fahn[3] and S. Garbe[4]
[1]Diabetes Centre, Klinikum Innenstadt, University of Munich, [2]Diabetes Centre, Hospital Munich-Bogenhausen [3]AOK Bavaria, [4]Boehringer Mannheim, Germany

In order to reduce new cases of end-stage renal disease and to meet one of the targets of the St. Vincent Declaration, a structured screening and intervention programme for diabetic nephropathy has been implemented in Munich, Germany. The screening was performed in offices of 58 randomly selected primary care physicians. In 586 diabetic patients independent of age, sex, duration, type and therapy of diabetes self-screening has been performed using the qualitative dipstick test Micral-Test® S. The urine samples were retested by medical staff using the semiquantitative Micral-Test®. Patients identified with micro- or macroalbuminuria (n=206; 35%) were offered to participate in an intervention programme based on optimization of blood glucose, blood pressure and protein restriction. Physicians were provided with therapeutic recommendations and were asked to retest every 3 months. To support these efforts a special quality circle was founded. In addition training of patients, nurses and doctors was started. After one year no further increase of micoalbuminuria was observed in the patients with microalbuminuria. Preliminary data show that the use of antihypertensives increased markedly with the consequence of a significant lowering of diastolic blood pressure. At the present the PROSIT-Project will be implemented throughout the country of Bavaria as well as in the urban areas of Hannover and Hamburg.

2584

DETERMINANTS OF ATTENDANCE AND GLYCAEMIC CONTROL IN PUBLIC SECTOR PRIMARY CARE DIABETIC PATIENTS IN CAPE TOWN, SOUTH AFRICA.

NS Levitt, MF Zwarenstein, AA Bawa, S Maphumula and D Bradshaw, University of Cape Town and Medical Research Council, Cape Town, South Africa.

The goal of this study is to identify intervenable risk factors for poor attendance or poor health outcome in diabetic patients in order to design programmes to improve their health. METHODS: A cross-sectional analytic study based on data from patient interview, retrospective record review and HbA1 estimation was undertaken in the three largest ambulatory primary care diabetes clinics in African residential areas in Cape Town. 243 patients were randomly selected from those attending in the last 6 months of 1992. Cross tabulations were used to identify variables associated with attendance of appropriate frequency and regularity and/or HbA1 <10%. Multivariate analysis was used to estimate the strength of the independent associations. RESULTS: **Attendance**: age, pensioner status, sex, knowledge of disease, patients perceptions of care or of staff attitudes, distance from clinic and waiting time were not significantly associated with attendance. Only self perceived health positively predicted attendance (OR 3.69, CI 1.06-12.06). **Outcome**: No predictors of outcome were found; neither attendance, nor the factors listed above. CONCLUSION: No intervenable risk factors could be identified for either attendance or outcome. This failure is unlikely to be explained by instrument or data quality and suggests that the investigators models of causal associations with attendance and outcome are inadequate. Alternatively, the complex web connecting demographics, patient attitude, service interaction and attendance and outcome is highly-variable, consequently far larger samples are required to detect associations in what are likely to be small subgroups. More qualitative research on patient perception of the determinants of attendance is required and interventions based on these should undergo trial.

2585

GLYCEMIC CONTROL IN A PRIMARY CARE HMO PRACTICE WITH DISEASE AND CASE MANAGEMENT.

P Latare, J Mullen, B O'Connor, S Rutherford, T Alejado, R Jamal, JL Parkes and BH Ginsberg. Kaiser Permanente Medical Care Program, Honolulu, HI, USA

This study is designed to determine if there is improved glycemic control using a proven disease management system, ***Staged Diabetes Management*** (SDM) in a primary care practice of a group model HMO. SDM stresses attention to timelines and glycemic targets, with rapid modification of therapies until an effective therapy is achieved. To test this system, 131 patients (predominantly with Type II diabetes) and sub-optimal glycemic control were selected. In this 1 year study, diabetes care is being provided by a diabetes nurse clinician, internal medicine physicians, clinical pharmacists, and registered nurses, all following the SDM system. In the first three months of the study the average hemoglobin A1c (HbA1c) declined from 9.00 ± 1.4 at baseline to 8.38 ± 1.16 ($p < 0.001$). At the beginning of the study 13% of patients had HbA1c < 7.5, whereas after 3 months on SDM this had increased to 30%. Our research indicates that the most important factors in improved care are: decreased practice variation by providers due to universal implementation of ***Staged Diabetes Management***, practical knowledge-based case management which was stratified to reflect the complexity of the patient's medical condition, and improved teamwork in the management of this stratification. Thus, data from the first three months on this system demonstrate the effectiveness of a systematic, comprehensive data and time-sensitive approach to blood glucose control. Trained case managers can be empowered to treat most patients with diabetes.

2586

DIABETES NURSING-DEFINING THE PRACTICE

A. Nettles, D. Fleming, M. Funnell, D. Guthrie, D. Hentzen, D. Kruger, C. Trapp, E. Walker, and J. Williams.

Advanced Practice Nurses are making an effort to promote better use of diabetes nurses in the health care system and to increase awareness of their contribution to people with diabetes. They are currently finalizing a description of the scope and standards of practice of the diabetes nurse educator and the advanced practice diabetes nurse in the US. Definitions from the American Nurses Association were used as a framework. This presentation will include a description of the process, methods and resulting document. Two levels of specialization will be presented. This document will be used to influence curricula in schools of nursing and develop levels of continuing education. A national advanced certification examination is being considered. Much of diabetes nursing care is unpublished, under-reported, and varies from country to country. Nurses outside of the US may find this document helpful for developing a description of their own. Where such descriptions already exist, new opportunities may develop for international consensus on practice commonalties resulting in collaborative research, policy development, and international educational opportunities.

2587

DIABETES DISEASE STATE MANAGEMENT BY DIABETES EDUCATORS IN MANAGED CARE.

L Blonde, R Guthrie, JL Parkes, and BH Ginsberg, The Ochsner Clinic, New Orleans, LA, USA

Staged Diabetes Management (SDM) is a program that is designed to change the practice behavior of health care providers (HCP). It contains algorithms and practice guidelines for primary care physician (PCP) and other HCPs to assist them in delivering better and more consistent diabetes care to their patients with diabetes. We have set up a 12 month study of SDM in which diabetes educators are managing 130 patients under the supervision of an endocrinologist. Control subjects are being treated according to the usual practice of Ochsner clinic by primary care physicians. The primary end point is hemoglobin A1c (HbA1c), but the full analysis includes process data, and quality of life analysis. At this time, the interim, HbA1c results (and number of subjects) are:

Group	At Entry	Delta At 3 months	Delta At 6 months
SDM	8.6±1.6 (123)	1.3 (94)	1.8 (29)
Control	8.2±1.7 (99)		0.5 (26)

The SDM group had a 1.8 point fall in HbA1c at 6 months $p<0.001$), whereas the small decrease in the control population was not significant. In addition, 70% of patients in the SDM group achieved a HbA1c within 1.5 of normal compared to 30% in the control group. We conclude that SDM is effective in a managed care setting when performed by diabetes educators and results in substantially lower hemoglobin A1c, values which should eventually lead to lower incidence of diabetes complications. This may allow less expensive, more appropriate care for patients with diabetes

2588

TRIVANDRUM MODEL OF RURAL DIABETES CARE FOR DEVELOPING COUNTRIES - A 5 YEAR EXPERIENCE.

A. Cheriyan, A.A. Cheriyan and U. Cheriyan, St.Vincent Diabetes Centre, Trivandrum, India.

It was planned in the year 1990 to care for the rural diabetic population of Trivandrum district of Kerala State in South India. As a first step many one day diabetes camps were organised in rural areas. Later on 24 permanent monthly diabetes clinics were started in such ideal locations as to cater for the diabetics detected at the above camps. A main diabetes centre was set up in Trivandrum City to care for the urban diabetic population and also to co-ordinate the functioning of these rural monthly clinics. A team consisting of a diabetologist, laboratory technician, pharmacist and dietician visits these clinics every month to impart free diabetes care. During each visit to these clinics, diabetes education is given by the diabetologist and dietary advice by the dietician. Blood sugar estimation is done by means of Glucometer and their treatment updated. Each of these rural clinics is attended by 150 to 200 diabetic patients every month. Our experience during the last 5 years shows that 90% of these diabetics are controlled by this method and this model of rural diabetes care seems to an ideal for developing countries.

2589

PRACTICE AND PROFESSIONAL CONCERNS AMONG MEMBERS OF THE AMERICAN ASSOCIATION OF DIABETES EDUCATORS (AADE).

M. Graff, Longmont Clinic, Longmont, K.Ernst, Emory Clinic, Atlanta, J. Norman, Department of Health, Olympia, C.Tobin, Conrtol Diabetes Services, Atlanta, C. Steil, Samford University, Birmingham, and R. Rubin, Johns Hopkins, Baltimore, USA.

This study assessed practice and professional concerns among a representative sample of the membership of the American Association of Diabetes Educators (AADE). Areas assessed included practice responsibility and concerns, national certification as diabetes educators, advanced practice credentialing, and continuing education. A random sample of 731 AADE members, of whom 66% were nurses and 25% dieticians, completed a mailed survey. Responses were reliable to within 3.7% at 95% confidence. Respondents reported a high level of practice responsibility: 43% practice as a diabetes treatment team leader or case manager; 54% serve patients without supervision in problem solving and in assessment. When asked what they considered the most important issue facing diabetes educators, the largest number of respondents (33%) said third-party reimbursement for their services. Sixty-eight per cent of respondents said they were certified by The National Certification Board for Diabetes Educators (NCBDE), originally founded with support from the AADE A majority of respondents said they believed that an advanced practice credential was necessary to enhance the specialty of diabetes education among physicians (59%), and third party payers (50%). Forty per cent of respondents said they had attended an AADE Annual Meeting, and 42% said it was their leading source of continuing education. In addition, 36% own the Core Curriculum in Diabetes Education, published by the AADE, and a majority devote at least 30 minutes to reading the monthly AADE journal, *The Diabetes Educator*. The results of this study show that members of the AADE have a high level of practice responsibility, and seek opportunities offered by certification, the potential of advanced practice status, and the continuing educational offerings of their Association to further their professional development. An organization such as the AADE significantly enhances the professional practice of its members

2590

AMBULATORY PATIENT GROUPS (APG) AND DIAGNOSTIC RELATED GROUPS (DRG): A BASIS FOR FUNDING CALCULATION

J. Overland, M. Constantino, D.K. Yue and J.R. Turtle. Royal Prince Alfred Hospital, Sydney, Australia

Due to the high cost of inpatient care, combined with reduction in hospital bed availability, many institutions have moved away from the inpatient model of diabetes management to an ambulatory care model. While DRGs have been created to monitor throughput and resource use of inpatient services, APGs for diabetes have not been well developed. The aim of this study was to use a computerised database to monitor the resource utilisation of a large ambulatory diabetes centre. Using computerised records on 2994 patients, caseload profiles were generated for different services. The cost of providing each service was calculated based on the hours spent on direct patient care + apportioned indirect cost, then converted to a bed day equivalent (BDE).

Service	No. of Encounters *	Total hrs *	BDE
Stabilisation †			
IDDM	6.4	2.4	0.6
NIDDM	5.6	2.3	0.6
Commencement of insulin †			
IDDM	15.6	9.2	2.4
NIDDM	8.7	5.9	1.6
GDM ‡			
Diet alone	11.6	2.4	0.7
Insulin required	11.8	4.0	1.2
Management of neuropathic ulcer †	7.9	10.1	2.6
Education §	1.0	1.0	0.2

* including telephone contact, † 3 month figure, ‡ average follow up 13.3 weeks, § per hour

This study showed that adapting work practice to incorporate systematic collection of data facilitates monitoring of the human and fiscal resources required for diabetes ambulatory care. It also served to highlight a broader perspective of the roles of computerised databases. In turn, this information can form the basis of APGs which, in addition to DRGs, can be used for funding calculation.

2591

SPECIALIST DIABETES NURSES ARE EFFECTIVE IN THE CARE OF DIABETIC IN HONG KONG

S.C. Siu, K.W. Wong, K.M. Ip, Y.Y. Tse and Y.S. Wong, Diabetic Centre, Tung Wah Eastern Hospital, Hong Kong

Background. It is advocated that Nurse Specialists trained in diabetes care, with adequate support from specialist physicians and other health care resources, should contribute substantially in the care of diabetic patients. **Aim.** We aimed to study the effectiveness of Specialist Diabetes Nurses in caring for diabetic in Hong Kong. **Subjects and Methods** In this non-comparative study, we recruited 30 newly admitted, uncomplicated diabetic patients who had no active concomitant medical illnesses. They were first jointly assessed by specialist physicians and Specialist Diabetes Nurses. Then they were followed up by Specialist Diabetes Nurses for 6 months. During this period, the Specialist Diabetes Nurses provided education, performed complication screening, monitored the diabetic condition, ordered investigations, recommended self-care methods, prescribed drugs and adjusted drug dosage. The Specialist Diabetes Nurses also coordinated the other health care disciplines to take care of the patients. **Results.** At the end of 6 months, 28 diabetic patients aged 28-76, duration of diabetes 0-11years, were available for analysis. Twenty-four patients were on oral hypoglycemic drugs, 2 patients were on insulin and 2 patients were on combination treatment. Body weight decreased from 64.5±12.0kg to 63.4±11.5kg ($p=0.053$). Fasting blood sugar reduced 19% from 10.2±2.7mmol/L to 8.3±1.9mmol/L ($p=0.005$). HbA1C reduced 22% from 8.6±2.3% to 6.7±1.1% ($p<0.001$). Cholesterol decreased from 5.6±1.0mmol/L to 5.2±0.9mmol/L ($p=0.022$). Triglyceride decreased from 2.3±2.7mmol/L to 1.6±1.4mmol/L ($p=0.1$). No severe hypoglycaemia occurred. The mean number of nurse consultation was 8.3. In addition, no hospital admission was required and all patients were satisfied with this health care model. **Conclusion.** We conclude that Specialist Diabetes Nurses are effective in providing care to diabetic patients in Hong Kong.

CURRENT STATUS OF DIABETES CARE IN CHINA.

M.H. Tan, T. Freeman, L. Mancuso, J. Overland, M. Wilkman, K. Wishner, and Y.J. Zhang. Project HOPE, Shanghai, China.

Diabetes is a major health problem in China as more than 20 million people have it. To assess the current status of diabetes care in China, we conducted a situational analysis focusing on the various stakeholders in the health care system. Twelve tertiary care hospitals in 5 cities (Shanghai, Hangzhou, Chengdu, Xian & Beijing) were surveyed. We also met with officials from the Ministry of Health. The analysis showed that the majority of patients with diabetes are cared for at the district and community hospital level, where diabetes care is rudimentary and there are no diabetes trained physicians. Patient education was mainly conducted by physicians with nursing staff playing a limited role. Greater nursing input was seen as important; however, this was hindered by a shortage of nursing staff at both the endocrine ward and hospital level. Dietitians are almost non-existent in the Diabetes Team. Even at the tertiary care level, there is a shortage of physicians trained in diabetes to provide care. Some departments had as many as 4000 patient visits/year cared for by one or two physicians. Patients with diabetes are often admitted for treatment of diabetic complications, glycemic control and initiation of insulin therapy. The average length of stay is ~28 days. Barriers to care identified by those interviewed include the high cost of therapy, an inadequate understanding that diabetes is a life-long and serious disease by both patients and administrators, inappropriate health beliefs, and the absence of a team approach to diabetes management. These findings indicates that (1) diabetes patient education is in its infancy in China; (2) more health professionals should be trained in diabetes care; and (3) a social marketing program is needed to convey the message to patients, healthcare professionals and administrators that diabetes is a common, growing, serious health problem in China but one that can be controlled with appropriate care.

2593

COMPUTERIZATION OF DIABETES DISEASE STATE MANAGEMENT

BH Ginsberg, MH Tan, A Bergelson and R Mazze, Becton Dickinson and Co and International Diabetes Center, Franklin Lakes NJ and Minneapolis MN, USA

Diabetes Disease State Management programs, such as Staged Diabetes Management (SDM) provide methods to translate important clinical research like the DCCT into widespread practice by primary care physicians. Computerization of these programs will allow better access and usage of these important tools. SDM, designed to change the way we deal with patients with diabetes, is based upon 5 principles: 1) Community involvement in setting diabetes care guidelines, 2) Negotiation of therapeutic goals with patients; 3) Appropriate timelines for therapeutic success; 4) Use flowcharts for medical decisions; and 5) Evaluation and appropriate alteration of the program. This program is being implemented in countries throughout the world. Previous studies have shown that this program lowers hemoglobin A1c by about 2 points over 6-12 months. Since it is a flowchart-based system it lends itself to computerization. The computer program uses a split screen. One part contains the flowchart, while the other has hypertext information screens giving detailed practical clinical and therapeutic information specifically related to the selected section of the flowchart. As the health care worker progresses along the flowchart they are informed about important aspects of diagnosis and treatment and the steps that they take are documented by the computer. The computer program also contains algorithms to help with diagnosis and a database that is compatible with DiabCare. Currently the program is written in C++, but is being rewritten in HTML to be used with the Internet and Intranets. Use of computer programs such as this by primary care health care workers should result in better diabetes care.

2594

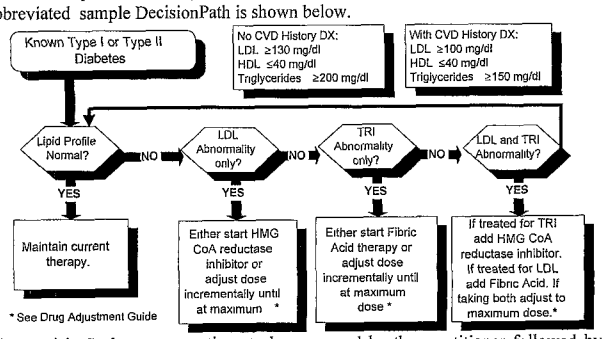
STAGED DIABETES MANAGEMENT: THE PILOT STUDY IN MEXICO
J. Rodríguez, Barry Ginsberg, Patricia Sosa, Reyna Núñez, LE Ortiz, CSU 8 Prados, SSA, Tultitlán Mex. In order to assess the level of feasibility, implementation and effectiveness of Staged Diabetes Management in Mexico, a pilot study was started in 1995. Ten centers from various institutions (public and private) were enrrolled, with the goal to achieve improvements in compliance, metabolic control and reduction in morbidity as primary outcomes. The first participant facility is a health center located in a suburban area. Patients treated come from a low socioeconomic status, have no access to social security and have very limited resources. Training of a general practitioner, provision of printed materials for the doctor and patients was started in October 1995. After one year of follow-up, 74 patients have been treated with this program, 21 males and 53 females; 2 patients are insulin-dependent and 72 non insulin-dependent. The majority of the patients had been diagnosed from less than 5 years: 38 had history of hypertension, 55 are obese and 6 had previous cardiovascular events. By comparison to initial blood glucose levels, patients receiving medical care with Staged Diabetes Management showed a progressive improvement: initial mean fasting glucose levels are 219.5 mg/dl; consecutive levels decrease to 1661.1, 147 and 156 mg/dl respectively ($p < 0.001$). Compliance with medical indications has been high, concurrent morbidity has been low, and the rate of patients in good control has increased from 20% (initial) to 55% (fourth visit). In conclusion, Staged Diabetes Management is a feasible, economic and effective program for outpatient management by general Mexican doctors.

2595

STAGED DIABETES MANAGEMENT: WORLDWIDE DIABETES DISEASE STATE MANAGEMENT
BH Ginsberg, K Strauss,, R Mazze, MH Tan, J Rodriguez, B Wajchenberg, and K Matsuoka, Becton Dickinson and Co and Intl Diabetes Center, Franklin Lakes NJ and Minneapolis MN, USA
To help provide the best possible control of patients with diabetes, we have produced a disease state management system for diabetes, called "Staged Diabetes Management"(SDM) and are implementing it worldwide. SDM, designed to change the way we deal with patients with diabetes, is based upon 5 principles: 1) Community involvement in setting care guidelines, 2) Negotiation of therapeutic goals with patients; 3) Appropriate timelines for therapeutic success; 4) Use flowcharts for medical decisions; and 5) Evaluation and appropriate alteration of the program. SDM is designed to be altered by a country to meet its needs and resources. It helps primary care physicians deliver better care using a team approach and to co-manage patients with specialists when appropriate. It has a complete set of materials for the community, the individual health care provider and the patient. Models of SDM have been developed and tested in both developed areas of the world and areas with emerging health care systems. Country-specific models of SDM are being implemented in the USA, Canada, Mexico, Brazil, Poland and Japan. A meta-analysis of 7 clinical trials with over 450 patients has shown an average fall in hemoglobin A1c of 1.8 points (equivalent to a drop in mean blood glucose of about 3.5 mM or 65 mg/dL). Preliminary pharmacoeconomic analysis demonstrates a lifetime cost saving of over $27,000 per patient. In summary, the diabetes health care team needs to work with primary care providers to prevent the complications of diabetes in their patients. Staged Diabetes Management provides the tools for this task

2596

PRIMARY CARE MANAGEMENT OF HYPERTENSION AND DYSLIPIDEMIA IN INDIVIDUALS WITH DIABETES MELLITUS
R. Mazze, R. Bergenstal, G. Simonson, E. Strock and K. Acton[1]. International Diabetes Center, Minneapolis, MN, & [1]Indian Health Service, Cherokee, NC, USA
The current management of hypertension and dyslipidemia in individuals with diabetes varies widely in the primary care setting. In order to reduce this variation, specific practice guidelines and DecisionPaths (algorithms) for the management of these diseases have been incorporated into Staged Diabetes Management (SDM), a comprehensive set of guidelines and clinical pathways for the management of diabetes in the primary care setting. The practice guideline define the blood pressure (130/80 mmHg) and lipid level (see figure) for diagnosis. Treatment options and targets are highlighted as well as appropriate times for monitoring and follow-up. Specific DecisionPaths, with algorithms for guiding clinical decision-making have been developed for lifestyle modifications and pharmacologic therapies. An abbreviated sample DecisionPath is shown below.



The DecisionPath poses questions to be answered by the practitioner followed by suggested course of action. Results show implementation of these guidelines have lowered both diastolic and systolic hypertension by an average of 5 mmHg and have improved overall consistency in management of hypertension and dyslipidemia in several primary care settings.

2597

QUALITY OF DIABETES CARE IN SELECTION-FREE POPULATIONS (JEVIN-ZEUVIN) - DO WE NEED DIABETOLOGISTS?
R. Schiel, U.A. Müller and A. Hoffmann; University of Jena Medical School, Dept. of Internal Medicine II, Jena, Germany
In 1990 in the former Eastern Germany the health care system was decentralized. Increasingly, patients were treated no longer by diabetologists, but by non-specialized doctors. In 1994/95 90% of all insulin treated patients (IDDM/NIDDM n = 127/117), aged 16-60 years, living in the city of Jena (100,247 inhabitants) were examined by a physician (JEVIN). In Jena the diabetes care unit still exists. 37% of IDDM and 32% of NIDDM patients were regularly seen as out-patients. For comparison, in a district without out-patient unit (28,000 inhabitants, all patients were treated by non-specialized doctors), 81% of insulin treated patients (IDDM/NIDDM n = 25/33) were examined (ZEUVIN).**Results:** HbA1c (mean normal 5%, HPLC, Diamat^{R}) in IDDM: ZEUVIN 9.1 ± 1.6% vs JEVIN: Patients treated by diabetologists 7.7 ± 1,4% ($p = 0.0002$), patients treated by non-specialized doctors 8.6 ± 1.9% ($p = 0.17$). HbA1c in NIDDM: ZEUVIN 9.3 ± 1.9% vs JEVIN: Patients treated by diabetologists 8.3 ± 1.9% ($p = 0.04$), patients treated by non-specialized doctors 9.0 ± 2.0% ($p = 0.54$). There were no differences ($p < 0.05$) between the groups in respect of age, diabetes duration, BMI, incidence of severe hypoglycaemia, ketoacidoses and quality of life. Since decentralization of the health care systems there are significant differences in quality of diabetes care between patients treated by diabetologists and those treated by non-specialized doctors. Following recommendations of the St. Vincent Declaration and to prevent costly diabetes complications maybe resulting from a lower quality of care, specialized diabetes treatment must be available for all patients. In particular in rural areas out-patient units and diabetologists seems to be mandatory.

2598

MICHIGAN DIABETES OUTREACH NETWORK MODEL: A SYSTEM OF SUCCESSFUL INTERVENTIONS AND OUTCOMES

M. Snitgen. Upper Peninsula Diabetes Outreach Network, Marquette, Michigan, U.S.A.

The Michigan Diabetes Outreach Network Model is essentially a nurse case management system which focuses on standardizing the care and education provided by agencies to persons with diabetes. Various studies indicate strong efficacy of the Network model. For its initial four years of operation, UPDON demonstrated the following results for its partner agency participants compared to non-participants in the Upper Peninsula of Michigan: **Hospitalizations were 45% lower, mortality 27% less, and amputations 31% lower.** Types of agencies involved include home nursing care, outpatient rural health clinics, Indian health centers, and health departments. The presentation will describe the model and its care requirements in the areas of lower extremity assessment, hypertension, eye disease and nutrition. The data collection system will be described and discussed. Certified Diabetes Educators provide professional education programs to the staff of participating agencies across the region including self-paced, self-instructional learning modules for nurses which are approved for continuing education credits. The Network serves as a diabetes resource center for the public, people at risk for diabetes, and those with diabetes. The Network model has been expanded to cover the entire state of Michigan. The presentation will provide specific guidelines for implementing this successful model in other regions.

2599

TITLE: DIABETES HOME EDUCATION BY COMMUNITY HEALTH WORKERS IN INDIGENT MEXICAN AMERICANS

AUTHORS: B.W. Roberts, N. Alvarado and A. Garza, STOP Diabetes, San Antonio, Texas, USA

Home Outreach Prevention Education by Community Health Workers (CHW) for Type II diabetes in Mexican Americans (MA) was done over a four year period in a low income area of San Antonio, Texas, sponsored by the Texas Diabetes Council. Over four years there was transient, but no statistical improvement in elevated hemoglobin A1C (HgbA1C) and lipid levels. Many of the 65 target families received financial support, completed less than secondary school education, reported physical and substance abuse, lack of family support and mental health issues to deal with in their lives. The CHWs were trained over a three month period by a certified diabetes educator and paid at minimum wage ($5.00/hour US). They visited each client family at home weekly for one hour, held weekly screenings in the target community, and held weekly client classes for another 35 diabetics not visited at home (control group). Over the 4 years there was no improvement in HgbA1C and lipids in this group. The CHWs intervened in the social and economic issues of the families 5.3 x monthly and 68% had a positive health outcome. Half of the referrals were to hospitals, specifically for diabetes, or to a community service agency. Only 4 client families refused to follow-up with their referral. We conclude that indigent MA Type II diabetics can benefit from home outreach education, but have many serious psychosocial and economic problems that must first be addressed in order to have successful diabetes care.

Konrad Szosland, Anna Swatko, Józef Drzewoski
SDM Group - Łódź, Poland
Medical University of Łódź, Department of Diabetology

„Treatment patients with NIDDM according to SDM Standards in Łódź"

The aim of the study was to assess the metabolic control of patients with type II diabetes mellitus treated after the introduction of Staged Diabetes Management (SDM). All the patients were referred to our department; previously they were unsuccessfully treated in outpatient clinics in the Łódź district.

The subject were 41 randomly selected patients aged 52-71 years (mean 61.9 years), including 24 women and 17 men. The duration of diabetes was 2 to 21 years (mean 9.9). Most of them were overweight: BMI 28-37 (mean 31 kg/m^2).

Nine had late complications such as retinopathy, eleven polyneuropathy and two nephropathy. Hypertension was present in eleven cases.

Six months after SDM, metabolic control was assessed as the levels of HBA_{1c} and mean blood glucose (MBG) - fasting and postprandial. HBA_{1c} decreased from 9.0 ± 0.75 % to 8.25 ± 0.7 % ($p<0.001$), fasting MBG 140.5 ± 24.2 mg/dl to 119.2 ± 17.3 mg/dl ($p<0.0001$) and postprandial MBG 184.4 ± 19.4 mg/dl to 161.2 ± 14.9 mg/dl ($p<0.0001$).

During the period of evaluation no severe hypoglycemia was observed. Reduction of weight was obtained: mean BMI decreased from 31 to 29.8 kg/m^2 ($p<0.05$). There was no weight gain.

CONCLUSION: The introduction of the SDM program, along with the inevitable „study effect", led to significant reduction of HbA_{1c}, fasting MBG and postprandial MBG without hypoglycemia or weight gain in a representative group of NIDDM patients.

2601

DECREASE OF AMPUTATION RATE AFTER INTRODUCTION OF FIRST POLISH INTERDISCIPLINARY DIABETIC FOOT CARE-TEAM MODEL

T. Koblik, J. Sieradzki, J. Friedlein and J. Legutko
Department of Metabolic Diseases, I Department of Surgery and Department of Orthopedics of Jagellonian University, Cracow, Poland

It is estimated that the rate of amputation in diabetic foot patients rangers from 30 to 50%. According to the recommendations of the St. Vincent declaration the first interdisciplinary team of diabetic foot care consisting of a diabetologist, ortopedist, general and vascular surgeon, kinesitherapist, educator and shoe-maker was established at the Department of Metabolic Diseases. The team makes collaborative decisions about diabetic foot patients, including the decisions about amputations. Over 2,5 years of activities 196 patients have received treatment, including 114 patients with ulcerations. Of this group 100 patients were hospitalized, 14 received out patient treatment consisting of guided antibiotics, wound managment, intensive insulin therapy, immobilization accompanied by isometric exercises. Among these 114 patients amputation above the knee was decided upon in 2 (2,3%) patients, and sparing amputation in 4 (3,7%) patients. An overall amputation rate was 6%. **Conclusions:**The low rate of amputations in patients with foot ulcerations indicates the usefulness of this therapeutic model. The efficacy of treating diabetic foot may be improved by collaborative assessment therapy and recommendation with no extra costs.

2602

NURSES' CLINIC: A NECESSARY ASPECT OF DIABETIC CARE.

C. LEFEVRE, R. DELARROQUA, ML. COTTEZ, G. CATHELINEAU and the Nursing staff, Endocrinology Department, Saint-Louis Hospital, Paris, France.

Saint-Louis hospital's Diabetology nursing staff inside the hospital's project, planned out the nursing care project for the department, according to the medical team project.Seventy-two percent of inpatients suffer from diabetes, the nursing and medical staff felt that the creation of a Nurses' Clinic had become a necessity. Several staff members define :1/The objectives :- verifying patient knowledge regarding self-test and injecting equipment as well as patient glycemic control diary completion;- nursing follow-up planning.2/ The organization :- in terms of material resources (a consultation room);- in terms of human resources (ten nurses carry out on consultation). 3/ The daily considerations :- one clinic open on every weekday;- by appointment; - using a common follow-up tool: the patient's file. This project was endorsed by the department's general staff meetings. The nurses ' Clinic opened on April 25th. As of October 1996: 399 weekday clinics were planned; 368 clinics were effectively held; 1285 patients made an appointment and 1103 patients came to their appointment (85%).After two and a half years, we were able to observe the following: - clinic nurses remain satisfied with their work; - their competence is well-recognized by physicians, patients and their relatives;- objectives are more clear ;- patients are discharged with a follow-up summary.On the other hand : - many patients are now referred to the Clinic because of lower-extremities lesions, even though that was not one of the nurses 'initial objective.The nurses and Head Nurses perform a follow-up evaluation of the Clinic on a twice yearly basis in order to examine and solve organization and attendance issues. Malfunctions are evaluated and corrected.

Anna Swatko, Konrad Szosland, Józef Drzewoski, Katarzyna Cypryk, Jan Wilczyński, Wiesława Torzecka
SDM Group - Łódź, Poland
Medical University of Łódź, Department of Diabetology

„TREATMENT PATIENTS WITH IDDM ACCORDING TO SDM STANDARDS IN ŁÓDŹ"

The aim of the study was to assess the metabolic control of patients with IDDM treated with insulin according to the principles of Staged Diabetes Management (SDM).

The subjects were 46 randomly selected patients, aged 18-58 years (mean 34.2 years): 27 women and 19 men with IDDM of duration from 3 months to 33 years (mean 11.5 years), BMI 18 - 30 (mean 23.2 kg/m^2).

Twenty three patients had no complications, four had retinopathy (two with proliferative retinopathy), one with nephropathy, four with retino- and neuropathy (one with proliferative retinopathy), two presented retino- and nephropathy and twelve had retino-, nephro- and neuropathy.

After six months of treatment following the introduction of SDM, metabolic control was assessed by levels of HbA_{1c} and mean blood glucose levels (MBG), both in fasting and postprandial. Significant decreases of HbA_{1c} and MBG values after treatment were found. HbA_{1c} fell from 8.25 ± 0.83 to 7.50 ± 0.74 % ($p<0.0001$), fasting MBG from 156.8 ± 48.9 mg/dl to 123.1 ± 14.4 mg/dl ($p<0.0001$) and postprandial MBG 195.5 ± 42.1 to 157.4 ± 21.2 mg/dl ($p<0.001$).

Unlike the DCCT, neither severe nor clinical significant hypoglycemia was observed during the treatment. The average BMI in the group was not changed ($p>0.05$).

CONCLUSION: The introduction of the SDM program, along with the inevitable „study effect", led to significant reduction of HbA_{1c} and fasting and postprandial MBG without hypoglycemia in a representative group of IDDM patients.

2604

Unnecessary costs provoked by prescription of drugs for the treatment of diabetes related long-term complications in East-Germany

B. Mertes, U. A. Müller*, K. Höffken*, M. Wehling**, F. J. van der Woude

V. Medizinische Klinik, **Institut für Klinische Pharmakologie, Fakultät für Klinische Medizin Mannheim der Ruprechts-Karls-Universität Heidelberg; *Klinik für Innere Medizin II, Friedrich-Schiller-Universität Jena; Germany

Introduction: In Germany, services of the health care system have to follow the rule of economic efficiency (§ 12 SGB V). However, the prescription of non-effective drugs is a common problem in Germany [Heise et al., Dt Ärztebl 1995; 92: A3549]. The aim of this study was to estimate the costs that arise in East Germany due to the prescription of drugs with unproven efficacy for the treatment of diabetes related long-term complications. Patients and Methods: Data of every patient with IDDM or NIDDM (n = 459; age 55,8 ± 18,1 [12-93] years) that was treated in the in-patient diabetes care unit of Jena in 1994 has been recorded consecutively with the aim of analysing the drug therapy. The following drugs have been classified as not suitable for the adjuvant treatment of diabetes related complications: alpha-lipoic acid (ALA), calcium dobesilate (CD), ginkgo biloba (GB), "agents for improvement of vene function" (IVF), vitamin B combinations (VBC), pentoxyphylline (PE) and naftidrofuryl (NA). Since controlled clinical trials could not prove any relevant therapeutical benefit of these drugs, they are not listed in international treatment recommendations. Results: 16,8 % of the patients were treated with one or more of the above mentioned drugs. The most frequently prescribed drug was ALA (45,5 %), followed by CD (33,8 %), GB (20,8 %), IVF (16,8 %), VBC (13,0 %), PE (11,7 %) and NA (5,2 %). These drugs caused costs of about 960 DM per patient and year (drug prices in 1994). Conclusion: Presuming a diabetes prevalence of 5 % and a prescription of drugs similar to the one in this study, drugs with unproven efficacy would cause costs of more than 120 million DM per year in East Germany (15 million inhabitants) and an estimated 640 million DM in total Germany (80 million inhabitants). These findings show that there is a huge potential for saving costs in the German health care system.

2605

EVALUATION OF PHONE CALLS AS A LINK BETWEEN DIABETIC PATIENTS AND A DIABETOLOGY DEPARTMENT.

ML. COTTEZ, F. GRONDIN, JF. GAUTIER, Endocrinology Department, Saint-Louis Hospital, Paris, France.

The aim of our study was to perform a quantitative and qualitative evaluation of the phone calls we receive from diabetic patients. We designed a standardized telephone message form to register each call. The yearly number of calls were: 206 in 1992; 377 in 1994; 559 in 1995; 472 as of Oct. 1996. The forms are placed on the nurses' desk close to the phone. A standardized set of questions and answers was designed by the team to homogenize nurses' questions and answers. **Results:** the various motives for calling were comparable in 1992 and 1994. These were: 1/ adaptation of insulin doses, hypoglycemia, hyperglycemia 43,% ; 2/ technical problems 22%, 3/ other 17,9%, infections and intercurrent diseases 15%, travel across time zones 1,3%. During the first ten months of 1996, the motives were: 1/ adaptation of insulin doses, hypoglycemia, hyperglycemia 51,9%. 2/ infections and intercurrent diseases 19,1%. 3/ technical problems 15,5%, other 12,3%, travel across time zones 0,6%. The decrease in technical problems could be explained by the creation of the department's nurse clinic for outpatients in April, 1994. **Conclusion** : Resorting to a standardized message form for each call is useful because it leaves a trace of incoming calls, the name of the patients as well as the nurses, a homogeneous response, increased knowledge of patients' difficulties and an improved link between patients, nurses and doctors.

2606

STRATEGY TO DECREASE THE COST OF DIABETES CARE IN DEVELOPPING NATIONS

R. N. Charles, E.Jean-Baptiste, P. Larco and N. Charles-Larco, Fhadimac, Port-au-Prince, Haiti.

Diabetes represents a socio-economic problem in the third world where the gross National Product (GNP) can be under $500 per capita in some developping countries like Haiti. In these countries only a small prosperous minority can afford the medical treatment of diabetes which costs the patient up to $900 yearly for ambulatory care. To overcome that difficulty, the Fondation Haitienne de Diabète et de Maladies Cardio-Vasculaires (FHADIMAC) has developped the following strategy: most part of the fees paid by members (over 2000) is used to buy generic drugs and insulin at a preferential rate. Drugs are sold at low cost to members of Fhadimac and insulin is given free to IDDM patients under 30 years of age. With this strategy, diabetics members at the Fhadimac spend between $30 to $147 (including drugs) for the management of their disease which represents a decrease 6 to 30 times less than for patients outside Fhadimac. Young Insulin Dependant Diabetics are treated for a symbolic charge. Conclusion. In developping nations where the large majority of patients can not afford the cost of treatment of diabetes and where the government are unable to meet the health needs of the population, diabetes association in using such strategy can allow access to quality care for the needy.

2607

USING PATIENT CHARACTERISTICS TO DETERMINE THE COST OF CARE: IS NEAR ENOUGH GOOD ENOUGH?

R. Griffiths. University of Wollongong/Illawarra Area Health Service, Wollongong, Australia.

The Diagnosis Related Groups (DRGs) classification, originally developed as a quality assurance tool, has been widely adopted as a basis for funding health services. The DRG classification is intended to assign acute inpatient episodes to classes which are clinicaly similar and resource used homogeneous. Funding is then allocated prospectively according to projected patient loads. The purpose of this study was to determine the extend to which this objective was met in a sample of acute inpatients with one or more diagnoses related to diabetes. The sample comprised all discharges (n=2094) with one or more diabetes diagnoses from acute care hospitals in the Illawarra Area Health Service in 1993-1994. A subsample of 386 records was selected for a more detailed analysis by chart audit. There were 3 major findings. First, the discharges were distributed among many DRGs in a way which was neither clinically coherent or resource use homogeneous. Second, there were many data errors which resulted in assignment to a DRG that did not reflect the clinical state of the patient or the resources used in management. Third, the DRG logic appears to ignore or underestimate the costs associated with treating diabetes as a secondary diagnosis. Diabetes diagnoses have little influence because DRGs generally fail to take account of resources used to treat conditions other than the principle diagnosis. DRGs use LOS as the primary predictor of cost, therefore in an ideal classification, DRG assignment would explain 100% of variations in LOS. Data analysis in this study showed that the DRG assignment explained only 28% of variation in LOS by the sample. Results of this study indicate that hospitals will not be reimbursed for the complete cost of care under the DRG system.

2608

BUILDING A SHORT-TERM COST-EFFECTIVENESS MODEL FOR ORAL ANTI-DIABETIC DRUGS IN THE U.K.

L. Annemans[1], P. Siddons[2], S.C. Hood[2]. [1]BRI International, Mechelen, Belgium; [2]Glaxo Wellcome, Stockley Park, U.K.

A short-term (6 months) cost-effectiveness model has been built to simulate current medical practice and disease progression in type 2 diabetes patients who have not responded to diet and exercise alone. Current medications are associated with short-term side-effects, such as gastrointestinal upset and hypoglycaemia, which may lead to poor compliance, treatment cessation, and therapy switching. These outcomes, in turn, may contribute to both suboptimal control and increased healthcare resource utilisation. As the study is designed from the healthcare payer's perspective it includes only direct medical costs. The model framework was developed using treatment guidelines and expert opinion on treating type 2 diabetic patients. Main data sources for the model were published literature, and IMS Mediplus and EPIC GP databases. Mediplus yielded data on the probability of treatment cessation, reasons for stopping treatment, replacement medication and concomitant agents taken for treating any side-effects. Data was collected for first and second-line therapies after diet. EPIC provided detailed data on healthcare consumption related to therapy switches. Final outcomes are measured in cost per symptom-free day. From the oral antidiabetic agents available in 1996 (biguanides, sulphonylureas and acarbose) it is found that metformin is 3 times more cost-effective in the short-term than an acarbose strategy. Sulphonylureas were almost twice as cost-effective as acarbose. Analysis by subgroups (obese versus non-obese; elderly versus young) did not change these findings. Current databases are an excellent source for building medical practice and disease progression simulation models. This model can serve as a framework for assessing the cost-effectiveness of new interventions.

2609

POTENTIAL COST SAVING ASSOCIATED TO EXCESS AMPUTATIONS IN DIABETIC SUBJECTS IN AREA 7 MADRID.

A.L. Calle-Pascual, M.J. Redondo, M. Ballesteros, J.A. Diaz, P. de Matias, A. Gonzalez, P.J. Martín, E. Gil and J.P. Marañes. HUSC. Madrid. Spain.

We estimated the direct cost of nontraumatic lower extremity amputations (LEAs) in diabetic (DMP) and non-diabetic (NDMP) population between January 1st, 1994 and December 31st, 1995 in area 7 of Madrid, Spain, taking in consideration the duration of the hospital stay, the duration of rehabilitation in the out-patient clinic after discharge, and the use of artificial limbs and their maintenance. The average cost of a LEA was 4 million pts. Total direct costs per year were 74.654.510 pts in the DMP and 40.918.603 in the NDMP. The total cost estimated, if the incidence of LEAs in DMP were identical to the one found in NDMP, was 2.574.292 pts per year. Bearing this in mind, potential cost saving associated to excess amputations in diabetic population was more than 72 million of pts per year, 12.6 millons of pts per 100000 inh. This study reveals that potential cost saving could be estimated and would be achieved if subjects with diabetes mellitus could have a satisfactory foot care system.

National Diabetes Programs

2610

ONE YEAR FOLLOW-UP OF PATIENTS WITH TYPE II DIABETES AFTER IMPLEMENTATION OF STAGED DIABETES MANAGEMENT.

R. Mazze, R. Burman, G. Castle, S. Sundem, G. Simonson, E. Strock, R. Bradley and K. Peterson. International Diabetes Center and University of Minnesota, Minneapolis, MN, USA.

Six hundred and twenty-one patients with type II diabetes treated at 27 clinics by primary care physicians were randomly selected in order to evaluate their care prior to the introduction of an innovative community-based program designed to implement standardized care protocols modified by community practitioners. From this population 3 clinics were randomly selected for close follow-up. The clinics did not differ significantly on any of the key study variables (size, population served and composition of health care professionals). For each clinic, a detailed audit of diabetes practices prior to and one year following program implementation was ascertained by chart audit and interview for 62 randomly selected patients. These patients did not differ significantly from the 621 patients at entry for age (62 ±12), sex (46% male, 54% female), type of treatment (11% food, 45% oral agent, 5% combination and 39% insulin), complications rate (55% hypertension, 5% kidney disease, dyslipidemia 10% and eye disease 10%) or level of glycemic control (52% HbA1c > 8%). Forty-five professionals (physicians, nurses and dietitians) at these 3 clinics participated in the training program in which criteria for screening, diagnosis, treatment and follow-up were modified based on standard protocols from Staged Diabetes Management (SDM). At entry, HbA1c was 8.72 ± 2.18% (normal range 4.1-6.4%). One year following implementation of SDM average HbA1c reduced significantly ($p<.001$) to 7.51 ± 1.43%. As part of SDM protocols, patients in poor metabolic control (HbA1c >8%) are rapidly moved to alternative therapies. The health professionals at these sites selected specific criteria for starting and changing therapies: diet only therapy was begun when fasting plasma glucose (FPG) at diagnosis or during treatment was <200 mg/dl, oral agents (sulfonylureas or biguanides) were initiated when FPG was between 200-300 mg/dl and insulin (multiple injections) was begun when FPG was >300 mg/dl. If the HbA1c did not decrease by 0.5-1%/month on the initial therapy, the practitioners were expected to increase the dose or change the therapy. In this study, changes in therapy occurred in 61% of the patients. Finally, significant improvement in glycemic control occurred without severe hypoglycemia, or adverse acute complications.

Problem in Diabetes Awareness -Using Bahrain as an Example from the Arab Region

Kawther Al-Taitoon, Diabetic Clinical Specialist, Lecturer
College of Health Sciences - Bahrain

The main aim of this paper is to identify problems in diabetes awareness - using Bahrain as an example from the Arab Region.

Problems in diabetes awareness occurs when the individual is unable to assess positive, negative influences on personal health and cannot evaluate their susceptibility to various illnesses. The individual also cannot be engaged in self - assessment; not aware of health values, nor decision making and lacks responsibility for health and self-care.

The problems of awareness may be from the diabetic individual who may not comply and set barriers (due to level of education, age; attitude; cultural influences; religions belief and health practices; and lack of accepting the problem); the health professional (not updated with diabetes knowledge and skill; not aware; shortage of manpower and load). health care facilities (not within the reach, no budget, no community link or diabetic education); media (not much or weak media advertisements; no link with health resources; lack of continuity).

In Bahrain inspite of small population (half million), free health care and within the reach, yet problems of diabetes awareness exists. The shortage of manpower, that cannot be freed for the specialized diabetic care. However, there is no actual structured diabetic education. There is no budget and at the ministerial level diabetes care is not visualized as a specific but as something that must be integrated within the general care even at the Primary Level. Besides the diabetic client is faith controlled surrendered to the health care professionals. There is no decision or participation in planning of self-care.

The word "diabetes" is sensitive, few talk freely about it, also causes social pressures and media is inadequate. Therefore such a barriers are blockers to awareness and those who are diabetic advocates are battling diplomatically.

2612

THE WILL FOR PROPHYLATIC TREATMENT OF MEN AT RISK TO GET ADULT DIABETES.T.Virtanen.Satakunta Polyth.Inst.Pori.FINLA

The study searched for a group of people at risk to get adult DM from among the employees of three offices of the town of Pori,Finland.The main aim was to find out their will to action which would keep up their health.The men were 40-60 years old and the risk to get adult DM was based on their own risk factors as well as those occurring in their families. In the second stage men got questions about their knowledge,attitudes and motives for selftreat ment of adult diabetes. They were also on an information meeting in order to get motivation for selftreatment. The found group at risk was 166 persons from 349 men.The risk of getting adult DM was widely known but the subjects were not aware of their own predisposition to getting it even a great number of risk was found ih their families.Those who answered questions of nutrition seemed to have a good knowledge on the general level (77/121 answers) but only half of them was aware of the risk of fat.The main motives for exercise were the prevention of illness,becoming physically fit and feeling good after the exercise.Those who completed the questionnaire found it positive to its focus on health and personal interaction.One of the objectives of the project was also reached when its follow-up study was started.

2613

QUALITY OF DIABETES CARE IN A SELECTION-FREE POPULATION OF DIABETIC PATIENTS FIVE YEARS AFTER DECENTRALIZATION OF THE HEALTH CARE SYSTEM (JEVIN)

R. Schiel, U.A. Müller and I.S. Ross*; University of Jena Medical School, Department of Internal Medicine II, Jena, Germany and *University of Aberdeen, Department of Clinical Biochemistry, Aberdeen, United Kingdom

In 1989/90 a population-based, selection-free trial of insulin treated diabetic patients aged 16-60 years and living in the city of Jena (ca. 100,000 inhabitants) was started. In total 83% of the target population (IDDM/NIDDM n = 131/59) was examined in 1989/90. At the follow-up examination in 1994/95, 5 years after the decentralization of the health care system, 83% of these patients (IDDM/NIDDM n = 87/44) were reexamined.

Results: For IDDM patients under specialized care HbA1c/mean normal was 1994/95 similar to 1989/90 (1.6 ± 0.28 vs 1.55 ± 0.34, p = 0.52, n = 32), it was higher for IDDM patients under non-specialized care (1.73 ± 0.35 vs 1.52 ± 0.34, p = 0.002, n = 55). For NIDDM patients there were no differences 1994/95 vs 1989/90 (1.8 ± 0.36 vs 1.74 ± 0.36, p = 0.4). The incidence of acute complications (severe hypoglycaemia with need of glucose or glucagon injection, ketoacidosis) remained stable. The prevalence of nephropathy and peripheral neuropathy (assessed according to Young et al.) remained stable too, but the prevalence of retinopathy increased in both IDDM and NIDDM (71/79% vs 45/20%, p = 0.001/0.001).

In order to achieve optimal quality of diabetes care and to prevent diabetes long-term complications, specialized diabetes treatment must be available for all patients.

2614

PREVENTION OF DIABETIC FOOT.

C.L. Villanueva. Hospital del Salvador, Santiago, Chile.

The aim of this manual is to teach primary health care professionals, a clinical based method for screening of thehigh risk foot diabetic patients. A screening sheet was designed for annually examination of all diabetic patients. This evaluation assigm a proportion of risk to the following risk factors: 1. Previus ulcer or amputation (30%), 2. Clinical Neuropathy (20%), 3. Clinical Vascular periferic disease (15%) 4. Foot deformities (15%), 5. Irresponsability or Alcoholism (5%), 6. Established Nephropathy (5%), 7. BLindness (5%), 8. Diabetes longer than 10 years, living alone, retinopathy, low education and male sex (1% each one). Patients who get less than 20%, are considered at low risk, and are annually reevaluated. Patients who achieve 20% or more are considered at high risk, and are specially educated to prevent ulceration; they also receive podologist care, and a more frecuent medical control.

2615

A NOVEL NATIONAL DIABETES PROGRAMME USING A DISEASE MANAGEMENT APPROACH.

J. Llewelyn and L. Broscheid. Eli Lilly and Company. Indianapolis, USA.

The progressive rise in morbidity and mortality from non-communicable diseases poses an increasing problem for health care providers in developing countries. A novel approach is being undertaken in Ghana through a national diabetes disease management programme. The objective is to provide a measurable improvement in delivered diabetes health care using patient outcomes (acute/chronic complications and mortality). The five year programme has three major components: an epidemiological survey, a nation-wide training programme for health care professionals and the establishment of a national register. The epidemiological survey is being performed using World Health Organisation guidelines and will study 5000 individuals. The prevalence of diabetes complications will also be examined. The training programme has been initially developed with an external centre of expertise and is now managed entirely locally. A "train the trainer" approach is taken and local resources utilised wherever possible. Selected multidisciplinary teams from existing centres underwent training covering all aspects of diabetes management as applicable to local conditions, and the programme is now expanding to first regional, then district level. The Ministry of Health is the main provider of health care in Ghana, and governmental involvement is ensured by representation on the newly formed National Diabetes Advisory Board which oversees the entire project. Throughout the project period data will be collected to establish a national register and monitor diabetes outcomes. Cost of treatment data will also be collected. The disease management multidisciplinary approach has typically been considered for developed countries. It is anticipated that this project will not only provide hitherto largely unavailable information concerning the prevalence and cost of diabetes in sub-Saharan Africa but, if successful, will demonstrate the effective use of available Western partnerships and provide a template for national diabetes health care delivery in developing countries which is proven to be both effective, sustainable, and cost efficient.

2616

THE AUSTRALIAN NATIONAL ASSOCIATION OF DIABETES CENTRES: NEW ORGANISATION, NEW HORIZONS

R Colagiuri (on behalf of the Committee). Australian Diabetes Society and Australian Diabetes Educators Association. ADS Secretariat Sydney, Australia.

Despite strong professional and consumer organisations for diabetes there were no organisations specifically catering for the needs of specialist diabetes services. To address this deficiency, the Australian Diabetes Society and Australian Diabetes Educators Association jointly established a National Association of Diabetes Centres (NADC) - possibly the first of its kind. The NADC links Australian Diabetes Centres in the common aims of i) improving the quality and accessibility of diabetes care ii) providing peer support for Diabetes Centres and services and a forum for pooling ideas and information and iii) lobbying funding sources to increase ambulatory care services for people with diabetes. The NADC comprises a National body which oversees policy development, membership and accreditation of Diabetes Centres, and lobbying at a national level; and State Sections which deal with local implementation issues, local lobbying, partnerships with other state level organisations, and developing and supporting local service networks. Since its inception in 1994, the NADC has documented goals and objectives, developed structure and process criteria for accrediting Diabetes Centres, policy for optimising diabetes control, and criteria for auditing the clinical outcomes of diabetes care. Several of the NADC State Sections are working with their respective State Health Departments to develop and/or advise on diabetes programs; or networking with rural and remote health professionals to provide specialist training and support. Although the NADC is a new organisation it has more than 30 member Centres and its potential to support improvements to the quality and accessibility of diabetes care are already apparent. New horizons include the use of accreditation criteria to lobby for resources to increase the number of accredited Diabetes Centres, extending the scope of the NADC to include smaller diabetes services, improving network links with non-specialist service providers and implementing national initiatives to improve the quality of diabetes care and information.

RESEARCH SOCIETY FOR THE STUDY OF DIABETES IN INDIA (RSSDI) : TWENTY-FIVE YEARS OF ACADEMIC ACTIVITIES

P.V. Rao on behalf of the RSSDI Secretariat.
Nizam's Institute of Medical Sciences, Hyderabad, India.

RSSDI founded in 1972 by Prof. M.M.S. Ahuja, Prof. B.B. Tripathy, Prof. Sam G.P. Moses, Late Prof. M. Viswanathan and Late Prof. B.R. Sengupta, is the largest diabetes education, training and research organization supported by 795 clinicians as life members representing all Indian States and Union Territories. Diabetes Bulletin : International Journal of Diabetes in Developing Countries, the official bi-monthly Journal of RSSDI is in 16th year of publication. Continuing medical education programs of RSSDI organized by senior teachers of Medicine, Endocrinology and Diabetology throughout the country over past 25 years in particular RSSDI Post Graduate Courses in Diabetology were popular with many senior and young diabetologists. To maintain high standards of CME programs and to train more clinicians in diabetes care, RSSDI has commissioned National Accreditation Committee for Diabetology in 1995. RSSDI Diabetes Consensus Development Program was initiated for providing physicians with a current consensus statement in 1997 on diagnosis, follow-up, targets, screening for complications, management and education. Further proposed RSSDI activities include School of Diabetology, Indian Text Book of Diabetes Mellitus and, workshops for patient empowerment and training in diabetic education technology.

RESULTS OF ACTIVITY OF KARAGANDA DIABETES CENTER ON DIABETES CARE IN KASAKSTAN IN 1996

G. Meyramov, N. Voronzova, A. Tlesheva, L. Amenova and A. Basarova, Diabetes Center, Karaganda, Kazakstan

1996 characterized by aggravation of finacial supporting of diabetic patients by Government, intensive desorganization of system of providing of patients by drugs accompanied by collapse of finacial state of biggest part families of diabetic patients. As result we have uncontrollable increasing of hard complications, mortality and uncontrollable situation with diabetes care in result of paralysis of economic of Kazakstan. In this difficult conditions in result including our intensive efforts the national Diabetes program (1997-2001) was confirmed by goverment on the base of program prepared by us in 1994. 29 schools for diabetic patients were organized by us in main clinics and policlinics in capital towns of 15 Lands from 19 which has been provided free of payment by a good materials. Control of blood glucose and selfcontrol by using of test stripes and glucometers was introduced in 14 Lands. Regional diabetes programs were prepared for 14 Lands. 29 regional meetings were organised in 14 capital towns and cities of 12 Lands including main conference in Karaganda. Our practical activity were widely supported by Boehringer Mannheim.

NATIONAL DIABETES PROGRAM IN BELARUS

E.Kholodova, L.Danilova and T.Mokhort. Byelorussian Institute for Advanced Medicine, Ministry of Public Health, Minsk, Belarus

The St. Vincent Task Force for Diabetes was set up in Belarus by the Ministry of Public Health and Endocrinology Association in 1993. Regional and local health authorities have been visited to understand the problems encoutered in local services and to discuss ways in which the St.Vincent Declaration (SVD) aims might be met. A number of recurrent themes have been identified: education, the role of patient, epidemiological studies and registar. Following the recommendation of the SVD, an Action Programme for preventing lower limb amputation has been designed, Diabetic Foot Center was organized in Minsk. Basic characteristics of the National Diabetes Program in Belarus are the following: National Diabetes Plan endorsed by government and the most important objectives of the National Program are the following: early diagnosis and therapy in order to decrease morbidity and mortality rates; prevention, early diagnosis and treatment of acute complications; primary preventive system (screening for those at reask for the development of diabetes mellitus), secondary (good metabolic control of the disease and prevention of further development), tertiary (up-to-date treatment, rehabilitation) prevention; providing specialized care for children with diabetes, reinforcing existing diabetic center, organizing training and teaching in diabetes management, prevention of congenital malformation in infants of diabetic mothers, initiation of the central republican registar for diabetes; secure increased funding for diabetic care, monitoring and control systems for diabetes.

2620

DIABETES EDUCATION IN TURKEY

R. Pınar. University of Marmara, Istanbul, Turkey.

In Turkey, as a developing country, diabetes education is not readily available to patients and health professionals, despite the fact that Turkey, with a population of 65 million, has two million citizens with diabetes. Nonspecific education programs for patients with diabetes existed in our country until the last 1993. National Diabetes Program (UDP) of Turkey, a governmental organization, was established in March 1994 to improve diabetes care. One of its goals is to educate not only diabetics but also health professionals. From March 1994 until today a lot of patients have been educated at inpatient and outpatient clinics. Multidisciplinary course program for physicians, nurses and dietitians was held on December 1994 in Ankara. Two postgraduate courses were organized for general practitioners on April, and June 1996 in Istanbul and Samsun respectively. In January a special course on diabetic foot and September and December 1996 the 4 days training courses that are named "Education Educators" for nurses were held respectively in Istanbul. In addition to these, except for UDP, a TV program was arranged in a private TV for two months. During this program telephone contact was made with diabetics, families and public. A lot of published materials were prepared with financial help of medical companies. Briefly, we have continued diabetes education in Turkey. But we have a lot of difficulties and deficiencies on this subject. These are: Low educational status of patients, cultural and language barriers between professionals and people with diabetes, lack of continuously formal training for patients, over workload of professionals and lack of time, lack of cooperation among professionals, lack of motivation, lack of resources, or wasting of resources on effective and inefficient programs, and the conventional strict separation of secondary and tertiary care from primary care is never really appropriate.

2621

A COMPREHENSIVE SYSTEM FOR QUALITY IMPROVEMENT IN MEDICAL CARE OF BLIND DIABETIC PATIENTS - 7 YRS EXPERIENCE

A.Petrulewicz,E.Oleksiak*,J.Krzymień,P.Pacuła,G.Rosiński,M.Tracz and A.Czyżyk. University School of Medicine,* Polish Association of the Blind, Warsaw, Poland.

The prevalence of blindness in persons with diabetes in different countries ranges from 0.2 to 0.6%. According to St. Vincent Declaration goals, Polish Assoc. of the Blind in cooperation with Dept. of Gastroenterology and Metab. Dis. of School of Medicine in Warsaw started in 1989 a comprehensive programme for improving quality of life of blind diabetic patients (BD) in Poland. A pilot study (62 BD aged 20-50 yrs with type 1 diabetes) showed that the main problems of BD were low level of knowledge about diabetes, poor metabolic control, difficulties with self-preparation of meals, self-control and self-administration of insulin. The first step a comprehensive programme for education and rehabilitation of BD was started and was effective with respect to improvement of metabolic control of diabetes and of self-dependence of patients. As a result of this trial 11 courses for BD and for theirs families were organized in different parts of Poland with over 300 of participants. In the next step a Registration System of Blind Diabetics has been developed and a comprehensive study of diabetes care was performed.A total of 824 BD (219 type I, and 605 with type II diabetes) were studied. In 1992 a Centre for BD was founded in Warsaw in 1992 and also 4 others and 11 Clubs for BD in different parts of Poland. Conclusions: This study showed that visually impaired patients with diabetes needs special attention and care. The quality of life of BD may be improved based on education and rehabilitation programmes provided by interdisciplinary teams.

2622

GLYCOSYLATED HEMOGLOBIN AS A DIAGNOSTIC METHOD FOR DIABETES.

G. Viñes, M. Roubicek and A. González Sanguineti. Hospital Privado de Comunidad, Mar del Plata, Argentina.

Our aim was to compare glycosylated hemoglobin (HbA1c) level with OGTT as a screening and diagnostic method for diabetes mellitus. 405 patients (158 male, 247 female, median age 61 and 56 yr respectively) sent by their physicians for a 2-hour OGTT (75 g load) had a fasting HbA1c level measured with the immunoassay DCA 2000 (Ames). There was good correlation between HbA1c and fasting ($r = .78$) or 2-hr glucose level ($r = .80$). Patients were classified by the NDDG criteria into three categories: Normal ($n = 309$), intolerant ($n = 29$) and diabetic ($n = 67$). Mean ± SD of HbA1c levels were $5.38 \pm .42\%$, $5.92 \pm .53\%$ and $7.02 \pm 1.32\%$ respectively; all differences being significant ($p < 0.01$). With a cut-off level of $< 5.5\%$ for normality, the test was able to discriminate diabetics from nondiabetics (normal + intolerant) with a high sensitivity (100%) and low specificity (53%); the 5.8% cut-off gave 87 and 80% and the 6.1% limit, 78 and 93% respectively. The Receiver Operating Characteristic curve shows the greatest deflection at the 5.5; 5.7 and 5.9 levels. With the WHO classification criteria results were similar. We conclude that HbA1c measurement may be a valid alternative to the OGTT for screening (cut-off level 5.5%) or for diagnosis of diabetes (cut-off value 6.1%). The greater cost is counterbalanced by its simplicity, rapidity and less discomfort to the patient. Time should tell which method will be more adequate to predict chronic complications.

2623

MONITORING DIABETES WITH CAPTURE-RECAPTURE IN DOMINICA: A MODEL FOR THE WEST INDIES.

C. Butler, E.S. Tull, S. Williams, L. Gumbs. University of Pittsburgh, U.S.A.

It is argued that use of capture-recapture (CAP-RECAP) may provide more accurate estimates of diabetes frequency and complications than the practice of pooling data from two or more sources. Accurate information about diabetes frequency is required in developing countries for proper allocation of limited resources for diabetes care at the local and national level. **Aim:** The aim of this study was to determine the utility of CAP-RECAP for developing a surveillance system to monitor diabetes frequency and consequences on the Caribbean island of Dominica. **Methods**: Three sources of information (the Dominica Diabetic Association, Regional Health Clinics, and the Queen Elizabeth Hospital) were used to identify individuals who were listed as having diabetes between January 1, 1995 and December 31, 1995. CAP-RECAP and log-linear modeling were used to calculate national and regional estimates of the number of diabetes cases. **Results**: As of December 31, 1995 there were 1945 observed cases of diabetes representing a crude prevalence of 2.71 %. The ascertainment- corrected estimate was 2688 [95%CI(2548-2828)] with a prevalence of 3.75%. At the national level, the pooled data from the sources of ascertainment accounted for only 72.3% of the estimated number of cases. Regional ascertainment % (observed/estimated) varied, ranging from >90% in rural regions to <50% in the most urban area. **Conclusion**: Surveillance with CAP-RECAP can yield more accurate estimates of diabetes frequency than current methods used in Dominica, particularly in the urban regions. This surveillance model may help other Caribbean countries improve their efforts to monitor diabetes .

2624

REINFORCED HEALTHY LIVING ADVICE FAILS TO PREVENT DIABETES IN SUBJECTS WITH INCREASED GLUCOSE LEVELS

P A Dyson, R J Morris, R R Holman and R C Turner for the Fasting Hyperglycaemia Study Group, Diabetes Research Laboratories, University of Oxford, UK

Few randomised clinical trials have investigated whether dietary and exercise advice can delay or prevent progression to NIDDM in subjects with increased but not diabetic fasting glucose levels. 189 subjects with fasting plasma glucose (FPG) 5.5 – 7.7 mmol l^{-1} on two occasions were randomised to either reinforced at 3 monthly clinic visits (50%) or basic (50%) healthy living advice in a factorial design with sulphonylurea (50%) or placebo (50%) therapy. 152 (80%) subjects (45% male), mean (SD) age 51 (9) years, body weight 81 (14) kg, median (iqr) FPG 6.1 (5.6,6.5) mmol l^{-1}, HbA1c 5.8 (5.5,6.1)% and 26% diabetic on OGTT completed 3 year follow-up. Subjects were advised to adopt a low fat, high unrefined carbohydrate diet, lose weight if BMI > 22 kg m^{-2} and increase physical activity until exercising 3–4 times per week. Admitted dietary intake was assessed by 3 day food diaries and fitness by maximal oxygen uptake (VO_2 max) during a submaximal bicycle ergometer test. At 3 years the reinforced group significantly increased VO_2 max (2.3 vs 2.1 l min^{-1}, p = 0.0009), % energy from carbohydrate (47.5 vs 44.5, p = 0.016) and reduced % energy from fat (32.4 vs 35.5, p = 0.0095). There were no significant differences between the groups for mean changes in body weight (–0.2 vs 1.1 kg), blood pressure (–1/0 vs 1/1 mm Hg), FPG (0.1 vs 0.0 mmol l^{-1}), HbA1c (0.0 vs 0.0 %) or lipid levels (LDL cholesterol –0.1 vs 0.0 mmol l^{-1}) and no difference in proportion progressing to diabetes in the reinforced group 29% to 43% diabetic compared with the basic group 24% to 33%, p = ns. In conclusion, conventional reinforced healthy living advice resulted in increased physical fitness and some dietary change but did not delay transition to diabetes over 3 years.

2625

NEED BASED SERVICES FOR IDDM PATIENTS IN THE COMMUNITY - THE CHENNAI (MADRAS) EXPERIENCE

Vijayakumar G., Buchi Babu Reddy O., Chellamariappan M., Srivatsa A., Ramesh Chandrasekaran, Ganesan A., Asha Bai P.V., Sundari Nyapathy, Parvathy Ramachandran and Krishnaswamy C.V.
The VHS Diabetes Department, Voluntary Health Services Medical Centre, Chennai (Madras), India.

Typical Type I or IDDM occurs mainly in children or young adolescents. In the western countries its prevalence is 0.1 to 0.3% while in India it has been reported at about 0.01%. Inspite of this low Incidence, in India, its large sub-population of children and young adults (1/3 of total population at any given time), coupled with the fact that nearly 50% are below the poverty line, makes IDDM a major health issue wherein serious economic, social, cultural, personal and psychological problems arise in addition to medical complications of IDDM. A detailed study of 30 Juvenile Diabetics (16 males and 14 females) in the age group 10-25 years and 30 parents (16 fathers and 14 mothers) was undertaken. 70% of parents reported severe financial strain and were greatly relieved by the comprehensive "free medicare" offered by our Juvenile Diabetes Comprehensive Care Centre. Negative academic performance and ignorance regarding the role of the social worker was also noted. Based on their needs, our centre aims at providing such comprehensive care by integrating medical and para medical workers' efforts (Diabetologists, Diabetes Educators, Social Workers, Psychologists, Active Rehabilitation Services, Trained Diabetic Nursing Services, Counsellors, Awareness Programmes etc) through voluntary effort supplimented by Governmental and Philanthropic support, in the Non-Governmental sector. This is perhaps the only way a developing country can cope with the vast Medical and Socio Economic challenges encountered in caring for the young IDDM patients as illustrated in individual case studies.

2626

SOCIAL REHABILITATION OF YOUNG PEOPLE WITH DIABETES IN KHARKOV.

K.Goncharova and A.Malko. Diabetes Youth Club "Juventas", University of Kharkov, Ukraine.

The aim of work is to help young people with diabetes in their personality realization. The Diabetes Youth Club "Juventas" and Kharkov boarding school for children with diabetes are the main subject of work. The development of main psycho-social problems and the determination of those in wich the help is possible, the results evaluation is making by means of questionnaires, interviewing and intercourse. The practical correction based on the longitude method (5 years) is included in all club events. As a result at the time there is the increasing of social adaptation and social activity, increasing of emotional satisfaction in members of the club. 60% state not less 2 times increasing of life quality. It is supported by the medical data of compensation stabilization in the club members.

2627

REGIONAL SURVEY OF WORKING-AGE PHARMACOLOGICALLY TREATED DIABETICS IN CENTRAL FINLAND

J. Saltevo and I. Kunnamo. The Central Finland Health Care District

A total of 2375 pharmacologically treated diabetics aged 16 - 64 were surveyed in Central Finland, which has a total population of 258 000. The sample contained 87 per cent of the diabetics in that age group who received insurance reimbursement for insulin or peroral hypoglycaemic agents in the year 1994. Most of the diabetics in the region are treated by their own general practitioners and local diabetes nurses. The central hospital outpatient department is responsible for the care of 20 per cent of the diabetics studied, but it provides consultation and education for the whole region. The pharmacological treatment consisted of insulin in 58 percent, tablets in 30 per cent, a combination of insulin and tablets in 11 per cent, and insulin pump in 1 per cent of the patients. The mean HbA1c levels (with normal values 4 - 6 per cent) in these four groups were 8.6, 8,2, 9,0 and 7,0 per cent, respectively. In the IDDM subgroup (817 patients on sole insulin therapy whose diabetes was diagnosed before the age of 30 year) 22 per cent had a HbA1c level below 7.5 per cent (normal values 4 - 6 per cent), and 14 per cent had a level above 10 per cent. There was a highly significant improvement in the distribution of HbA1c levels in the same IDDM subgroup between 1988 and 1994 (chi square, $p = 0.00001$), the proportions of patients with HbA1c levels of 10.5 per cent or more being 20 per cent, and 10 per cent, respectively. A diabetes care system based on primary care, diabetes nurses, and a strong consultant support is able to achieve acceptable goals and to improve its performance.

2628

DETECTION AND TREATMENT OF DIABETIC RETINOPATHY USING STAGED DIABETES MANAGEMENT

G. Simonson, R. Mazze, R. Bergenstal, and D. Etzwiler. International Diabetes Center, Minneapolis, MN, USA.

Although retinopathy (DR) is a serious complication of diabetes no clear guidelines for its detection and treatment have been implemented in the primary care setting. The aim of this project was to develop guidelines for management of DR in primary care practice. In our region, 95% of the individuals with diabetes are treated by primary care physicians. A recent assessment of quality of diabetes care in 22 rural primary care settings indicated that <25% of individuals with diabetes have annual dilated eye examinations. A one year follow-up chart audit after adoption of Staged Diabetes Management (SDM) (a comprehensive set of guidelines and clinical pathways for the management of diabetes in the primary care setting) revealed a significant ($p<.01$) improvement (47%) in the number of patients receiving an annual dilated eye exam. While this was a notable improvement, many individuals with diabetes were still not receiving adequate eye examinations. More importantly, the quality of the eye examination and follow-up care was variable. In order to assure consistency in screening and diagnosis as well as to provide treatment options, a separate section on diabetic retinopathy was developed as part of SDM. At the core of the section are a practice guideline and DecisionPaths for diabetic retinopathy. The practice guideline covers criteria for diagnosing mild to moderate nonproliferative diabetic retinopathy (NPDR), severe NPDR, and proliferative diabetic retinopathy (PDR). It also describes the current treatment options for diabetic retinopathy (metabolic control, panretinal and focal photocoagulation, and vitrectomy) along with establishing clear screening and follow-up schedules. A DecisionPath (algorithm) for screening and diagnosing DR was generated to guide the primary care provider through the assessment of risk factors for diabetic retinopathy (level of control, duration and type of diabetes), dilation of pupils, description of retinal lesions, and appropriate time frames for referral to eye care specialists. In addition, a quick reference table listing the stage of retinopathy and a detailed description of the clinical presentation of the retinal lesions associated with DR is included. A series of color retinal photographs provides a visual reference for identifying microaneurysms, dot and blot hemorrhages, lipid exudates, cotton wool spots, neovascularization of the disc and elsewhere, as well as vitreous hemorrhage.

2629

DIABETES RESEARCH IN CANADA.

M.H.Tan and N.Gill, Dalhousie University, Halifax, Canada.

Research is an important and integral component of a nation's diabetes program. Defining its magnitude and type for a nation can be difficult. We determined the status of diabetes research in Canada in 1992-1993 from information obtained on funding of diabetes research in Canada, diabetes research in Canadian medical (13/16), nursing (14/31) and nutrition (9/19) schools, diabetes researchers in Canada, and publications on diabetes-related topics from Canadian institutes. The total funding on diabetes research was $21.2 mm, with $19.5 mm for operating grants and $1.6 mm for personnel support. Governmental agencies funded $5.7mm, non-governmental diabetes-related agencies $6.3 mm and non-diabetes-related $0.8 mm, industry $6.3 mm, and foundations $2.1mm. Canadian Federal agencies funded $0.19/capita for diabetes research. Whereas all medical schools (13) conducted diabetes research, very little research was done in nursing (2/14) and nutrition (1/9) schools. Areas of research included etiology, pathogenesis, complications, care, clinical trials, genetics and epidemiology. Three non-medical departments were also involved in diabetes research. There were 144 individuals involved in diabetes research, varying from 3 to 35 per medical school. Seven others (6 in nursing and 1 in nutrition) were also involved. Publications on diabetes-related research from databases for 1989-1993 revealed 199-290 publications/ year from Medline and 0-10/year from CINAHL. There were 1026 publications from Medline and only 20 from CINAHL databases, reflecting the little diabetes research in nursing and nutrition schools. Government, diabetes organizations and industry are the 3 major funding agencies for diabetes research in Canada. On a per capita basis, Canadian federal agencies provided relatively low funding for diabetes research. Most of the diabetes research are done in medical schools with very little diabetes research in nursing and nutrition schools.

2630

ANALYSIS OF DIABETOLOGICAL HUMAN AND STRUCTURAL RESOURCES IN PIEDMONT, AN ITALIAN REGION.

L. Gentile, A. Caramellino, A. Chiambretti, C. Giorda, L. Monge, G. Morra, A. Ozzello, G. Bargero.
Consiglio Direttivo A.M.D. Piemonte e Valle d'Aosta - Turin, Italy.

Piedmont, a region of North-Western Italy, has a population of 4.5 milion and a prevalence of 3% diabetes mellitus. According to a national law and its regional implementation, a network of diabetological public services takes care of most cases of diabetes, both IDDM and NIDDM.

Aim: to give a detailed analysis of the present situation of the diabetological network.

Methods: direct interview of the chief physician of each service to collect data about the medical and paramedical staff, the structure and organization of the clinic, technical resources and time allocated to patients. The interviewers were 8 diabetologists specially trained for this task. The data, stored in a data base, were statistically analysed.

Results: 71 services (over 95% of the region) were interviewed; of these 40% are diabetological outpatients clinics (2 with dedicated wards and/or 6 with day hospital), 49% internal medicine clinics, 5% endocrinological and 6% pediatric clinics. In more than 50% of cases the clinics are open 5 days/week, for an average of 8 hours/day. 20% of clinics have less than 500 patients, 62% between 500 and 2000 and 8% over 2000 patients. 30% of clinics have a specialized and dedicated diabetes team, 50% have an internist or an endocrinologist. 60% of clinics have general nursing staff, while 50% have at least 1 diabetes nurse specialist; of these 71% have followed special diabetological courses. 53% of clinics do not have a dietitian and the diet is prescribed by a doctor. No service has a psycologist or chiropodist internal to the staff. In 39% of service, medical time is 60'-120' per patient per year, while it is 180' in 8%. Nursing time risulted 60'-120' per year in 42% of cases, 180' in 8%. 48% of services carry out an average of 2 or 3 visits for patient/year, only 5% carry out more than 4 visits. 80% of services can also offer ophthalmological, nephrological, cardiological and neurological counselling.

Conclusion: in Piedmont there is a very effective public diabetologic network which provides care for 85% of the diabetic population and a good provision of counselling services; on the other hand there is a discrepancy between nursing and medical time, there is a lack of dietitians and a total absence of chiropodists and psycologists.

2631

PATIENTS' EDUCATION AND COMPLICATION SCREENING IN ROUTINE OF DIABETIC CLINICS. RESULTS OF A SURVEY IN AN ITALIAN REGION.

C. Giorda, A. Caramellino, A. Chiambretti, L. Gentile, L. Monge, G. Morra, A. Ozzello and G. Bargero.
Consiglio Direttivo A.M.D. Piemonte e Valle d'Aosta, Turin, Italy.

INTRODUCTION: Piedmont, a region of N.W. Italy, has a population of 4.5 million.The estimated prevalence of diabetes is around 3%. A national and regional law has been passed to follow diabetic patients through a network of public diabetes clinics. AIM: To assess how patients' education and complication screening are carried out in the network of diabetic outpatient clinics in Piedmont. METHOD:Direct interview of the head of the clinic to collect data about the organization. Particular attention was paid to patients'education and to complication screening. RESULTS: 98% of clinics in Piedmont were interviewed. Patients' education is implemented in 85% of clinics. Individual education is the most frequent type (87%). Combined education , i.e. both individual and group, is less frequent (35%). As for the personnel in charge of education, doctor plus nurse is the most frequent finding (35%), whereas doctor alone is the second (28%).Dieticians are involved rarely (23%). Material such as checklists, booklets, videotapes are seldom used (30%). Financial support from public or private institutions is hardly reported (10%). Eye complication screening is carried out in a large proportion of clinics (92%), mainly through direct ophtalmoscopy performed by an ophthalmologist. Nefropathy is screened by means of microalbuminuria and renal function tests in most clinics (88%). Periodical physical examination, EKG, blood lipids and blood pressure checks are the most used tools to screen for cardiovascular complications (75%). Routine neuropathy (37%) and routine diabetic foot screenings (35%) are carried out remarkably less frequently. These complications are usually addressed when any symptom or sign develops. Yet most clinics take charge of the treatment of foot lesions (83%). CONCLUSIONS: The effort to improve patients' knowledge by making individual training and education a widespread practice is being made. However, apart from individual approach, other effective methods of education and dietician's involvement rate unsatisfactory. A fairly good result was found as regards eye, cardiovascular and renal complication screenings which seem to be fairly addressed. Something more should be done to screen for diabetic foot in a routine way.

2632

INFLUENCE OF THE GREAT HANSHIN-AWAJI EARTHQUAKE ON GLYCEMIC CONTROL IN DIABETIC PATIENTS

K.Kirizuka, H.Nishizaki, O.Nukata and S.Tsuboi.
Kobe West City Hospital, Kobe, Japan.

We investigated the influence of the Great Hanshin-Awaji Earthquake which occurred on 17th January, 1995, on glycemic control in diabetic patients. We investigated the dietary and living conditions and the changes in HbA_{1C} level in 177 diabetic patients at our hospital; one year before and one year after the disaster. The mean value of HbA_{1C} increased significantly after the earthquake($8.34 \pm 2.07\%$ in March 1995 vs $7.74 \pm 1.82\%$ in December 1994, $p<0.01$). Ninety nine of 177 patients showed more than a 0.5% increase in HbA_{1C} after the earthquake. The causes of this exacerbation were examined by multiple regression analysis of the following factors: inappropriate diet, discontinuing drug therapy, reduction of exercises, total destruction of the patients' houses, a long-term stay in shelters, sex, age, difference between therapies. Inappropriate diet had the highest partial regression coefficient. Investigation of dietary conditions revealed that excessive carbohydrates and insufficient vegetables were prominent. Within the two months after the earthquake, we observed ketoacidosis in 2 patients, gangrene of the foot in 3 patients, and pneumonia in one patient. The level of HbA_{1C} gradually declined with time after the earthquake and returned to its usual level in September 1995. This study showed an increase of HbA_{1C} in diabetic patients after the Great Hanshin-Awaji Earthquake. The increase in HbA_{1C} was mostly caused by inappropriate diet. Therefore we should always educate diabetic patients on how to manage diet and drugs in emergencies.

2633

FACILITIES FOR DIABETES CARE IN SOUTHERN GHANA

A.G.B. Amoah, S.K. Owusu, H.A. Asare, T.J. Saunders*, W.L. Fang*, E.J. Barrett* and M.K.A. Woode*, . University of Ghana Medical School, Accra. Ghana. *University of Virginia School of Medicine, Virginia, USA.

Ghana is a Tropical country with a population of 16 million. The country is divided into 10 political regions. The regions in Southern Ghana comprise Central, Eastern, Volta, Western and Greater Accra, with a total population of 8.3 million inhabitants.The study was initiated to determine the state of diabetes care in the 4 Regional referral hospitals [Central(C), Eastern(E), Volta(V), Western(W) and the Teaching Hospital in the Greater Accra(GA) regions] in Southern Ghana. Each of the five Health facilities was requested to complete a Health Care Facility and Standards of Care Questionnaire. Of the five health referral health facilities in the Southern Ghana only one(20%, GA) ran a regular diabetes clinic and had diabetologists. Only two(40%) facilities had an eye specialsit(E,GA). Two hospitals(40%,GA,W) had a dietitian but none of the five facilities had a trained diabetes educator or foot care specialist. A stadiometer was available at 1(GA), and a weighing scale at 2(W,GA) facilities for diabetes care. All had equipment for measuring blood pressure, urinalyis for glucose, protein and ketones. Fasting blood glucose, oral glucose tolerance test , blood urea, serum creatinine were available at all facilities. Creatinine clearance, 24-hour urine protein, Glycated Haemoglobin and serum lipids including HDL cholesterol were available at one centre(GA). C-peptide, islet cell antibody and microalbumunuria were not possible in any of the facilities. All facilities used 100U insulin. Insulin was always availabe in 3(E,V,GA). In 2 facilities insulin supply was erratic. All utilized 100U syringes. One hospital had regular but informal diabetes education. 3(GA,E,W) of the 5 regions had active Diabetes Associations. Facilities for diabetes care is less than satisfactory in Southern Ghana. There is therefore an urgent need for provision of basic and essential facilities in the referral centres and to put in place a comprehensive diabetes care disease management programme in Southern Ghana to improve diabetes care.

2634

COCHRANE DIABETES GROUP: THE EPIDEMIOLOGY OF RANDOMISED CONTROLLED TRIALS IN DIABETES.

C.M.T.Bennett, C.M.Airey, P.A.Spoor and D.D.R.Williams. Nuffield Institute for Health, University of Leeds, Leeds, UK.

A register of all randomised controlled trials (RCTs) in diabetes is being established by the Cochrane Diabetes Group, an international collaboration preparing, maintaining and disseminating systematic reviews in all areas of diabetes, with the specific aim of reducing the undesirable delay in research findings being translated into clinical practice. This developing register has allowed an examination of the 'epidemiology' of RCTs in diabetes. Using sophisticated MEDLINE search strategies 4957 possible RCTs have been identified in 865 journals between 1966 and 1995, 32% appearing in ten principal journals, and 14% in languages other than English. There has been an exponential rise from 26 in 1966 to 832 in 1994. Over 400 were carried out in each of the areas of retinopathy and hypertension with over 300 looking at treatments for neuropathy and nephropathy. 200 examined dietary interventions. Visual assessment of a sample of MEDLINE abstracts suggests that 43% of the references on the database are true RCTs with a further 15% being controlled clinical trials. The remainder are other study types or review articles often picked up by the search strategy because of the frequent use of expressions such as *random* and *control* in diabetes. Handsearch examination of original journals suggests that even this sensitive electronic search is not identifying a further 22% of RCTs in diabetes contained in journals indexed on MEDLINE. This survey highlights the importance of a centrally maintained reference resource both as a basis of systematic reviews in diabetes and for the identification of priority areas for primary research.

2635

IDDM IN CHILDHOOD AND ADOLESCENCE - PROSPECTIVE FOLLOW-UP AFTER ONSET

A. Icks, J. Rosenbauer, and G. Giani. Department of Biometrics and Epidemiology Diabetes Research Institute at Düsseldorf University, Germany.

Better care of diabetes in childhood and adolescence was declared a main objective of St. Vincent. There are only few population-based data about the course after diabetes onset. Aims of this study were the evaluation of health care utilization, diabetes management, and frequency of readmissions and severe hypoglycamias, especially in subjects that are not treated in spezialized diabetes centers. **Methods:** Using prospectively registered population-based incidence data on IDDM diagnosed before the age of 15 years in the Düsseldorf region (EURODIAB ACE study region), a cohort of cases from 1/1993 to 4/1995 (n=200) was followed up by telephone interviews and mailed questionnaires. Data on admission at diagnosis were obtained from clinic records. Age-, sex-, and region-matched controls were also followed up to compare morbidity outcomes in diabetic and nondiabetic subjects. **Results:** 112 subjects (65 boys, mean age at diagnosis [±SD] 8.2±3.9 ys) with a total of 194.6 person-years after diabetes onset (mean follow-up period 21 (range 8 to 38) months) were analyzed. Mean duration of hospitalization at onset was 17.6±7.7 days. 59% of the subjects stayed in the clinic of first contact for further treatment, 23% visited a general paediatrician or practitioner. HbA1c was measured in 97% of the subjects, in 70% at least once quarterly. In 33% blood glucose was measured 2 to 3 per day, in 65% at least 4 times. 50 readmissions for all reasons were observed in 35 subjects (33%). Incidence rate (IR) of readmissions was 0.26 [CI95% 0.19-0.26] per person-year. 26 events of severe hypoglycamia (with injection of glucose or glucagon) occured in 18 (17%) of the subjects. IR of severe hypoglycamias was 0.13 [CI95% 0.08-0.18] per person-year. **Conclusions:** Most of the followed patients with IDDM are treated in the clinic of first contact - most of them general hospitals without spezialization in diabetes care - or in a general praxis. Blood glucose self control and HbA1c measurements were performed according to consensus guidelines in the majority of the patients. Incidence rates of severe hypoglycamias and of readmissions were comparable to other studies. In ongoing analyses hospitalization in diabetic and nondiabetic subjects is compared by estimating relative risks.

2636

A POBLATIONAL STUDY ON DIABETES MELLITUS IN BUENOS AIRES DE PALMARES, COSTA RICA

Gamboa A.Y., Mora C. Intern Medicine Hospital Mexico, San José-Costa Rica.

Objective: To realize an epidemiological and clinical description of diabeticc patients from a clinic in a rural area of Costa Rica.

Methods: Using registration documents from EBAIS (Basic Equipment for Integrated Health Care) 105 diabetics were visited to their homes: a clinical story and physical examination was done, feet prints were taken in order to classify their feet with the PATON-A scale. The laboratory test were taken from their clinical files.

Results: The prevalence of Diabetes among adults was 3.4%. There were 55 women and 22 men (71 NIDDM, 5 MODY, 1 IDDM). Adherence to treatment was 90%, most of them hand first level of education (six years); 67% had familiar story of DM. 7 were smokers, 5 drank alcohol in excess. 74 of them were sedentary and 7 were on a free diet. 49 had hypertension, 34 had hyperlipidemia, 11 had asthma, 8 with psyquiatric disorders, 6 had nephropathy and 5 tyrod dysfunction. 71% had a normal blood pressure (under 140/90), 35% with a BMI under 30. Glycemia was under 140 mg/dl in 38.5%, 140-200 mg/dl in 38.5, over 200 mg/dl in 26%. Tryglicerides media 207.9 mg/dl, 15% had more than 300 mg/dl. Cholesterol media 233 mg/dl, 38% had levels over 250 mg/dl. 29% had macroproteinuria. 8.5% had creatinine over 1.5 mg/dl. Treatment: diet 4%, glibenclamide 61%, Insulin 35%.

Conclusions: There was a good adherence to treatment. More educational intervention is needed because a considerable number of patients persist with harmful habits and without a proper diet. 1/3 were well controlled, 1/3 had regular control and 1/3 were badly controlled. 63% of them were found hypertensives andd 44% were found to have hyperlipidemia. It is necessary to keep a more frequent control on those with other risk factors. The feet abnormalities were correlated with the time of evolution of the diabetic disease.

TWINNING PROGRAMME: CROATIA HELPING DIABETIC CHILDREN FROM BOSNIA AND HERZEGOVINA

R. Kovačević, M. Prašek, L. Lagrasta, M. Lovrenčić, K. Sokolić, S. Hasanbegović, Ž. Metelko. Vuk Vrhovac Institute for Diabetes, Endocrinology and Metabolic Diseases

The war in Bosnia and Herzegovina aggravated diabetes care, particularly in children. In spite of the war dangers and shortage of appropriate food, 80 diabetic children continued to live in Sarajevo throughout the war. Medical care was provided by young pediatricians with little experience in the treatment of diabetes mellitus, who remained in Sarajevo. At the initiative of SOS KINDERDORF INTERNATIONAL, which recognized the difficulties diabetic patients were facing in Sarajevo, and the Vuk Vrhovac Institute from Zagreb, a Zagreb-Sarajevo Twinning Programme was set for the field of diabetes mellitus. The programme of aid to diabetic children included regular insulin and its administration related equipment provisions; a monthžs aid in food and money for vegetable and fruit provisions; organizing educational meetings and parent and children education; education of the staff of the Košević Clinic at the Vuk Vrhovac Institute in Zagreb; efforts to organize educational-recreational camps for children. In 1995, a physician from Sarajevo underwent a one-month training in paediatry and diabetology in Croatia. In July 1996 we organized a summer camp for 20 Bosnian and 50 Croatian diabetic children, who were accompanied by the above mentioned physician and nurses, and participated in daily educational activities, exercise and sport games. Diabetes control (HbA1c) in children from Sarajevo had been much worse than in Croatian children ($p<0.001$), but was improved during their stay in the camp ($p<0.01$). Education and care for the children and medical personnel continues.

THE ROLE OF LATVIAN DIABETES ASSOCIATON IN EDUCATION DIABETES PATIENTS OF LATVIA 1993 -- 1996.

G.Freimane, I.Rasa, L.Kusiņa and R.Ligere, Latvian Diabetes Association, Riga, Latvia.

The main goal of Latvian Diabetes Association (LDA) is active and passive education of diabetes patients. LDA does it in a following ways: Creates library, fond of audio- and video recordings. It is the only library of this kind in Baltics, there are 22 magazines for diabetes patients from 12 countries in the fond of periodicals, in the fond of videorecordings there are both 10 plots on diabetes which LDA has created for the National TV channel of Latvia and video recordings on diabetes. In the fond of audiorecordings 18 tapes for medicine professionals and diabetes patients are found. LDA works at new informative and educational materials, copies and distributes them. LDA has received copy- and translating rights from editorial boards of 6 national diabetes associations. Over 60 materials have been translated in 3 years, 5 members of LDA has done it without reward. LDA regularly writes educational materials for health educational magazines "Veselība", "Sveiks un Vesels" (28 are published) and publishes them into the informative bulletin of LDA "Mēs & Diabēts", writes articles on diabetes for general press (55 are published). LDA participates in TV and radio programs on diabetes (8 radio and 5 TV programs), issues the informative bulletin of LDA (4 -- 16 A4 pages, circulation 1000 -- 2000). Bulletin is issued 2 -- 4 times a year with a supplement for medicine professionals. Specially trained LDA members 4 hours every weekday free of charge consul other diabetes patients, in case of emergency recommending them to visit a specialist. Every year LDA organizes WDD events in Latvia. LDA is the first organization in the history of the Republic of Latvia that started to celebrate WDD already 6 months after it was founded.

THE SPECIALITY COMMISSION DIABETES - A NON-PROFIT ORGANIZATION FOR IMPROVEMENT OF DIABETES CARE IN BAVARIA, GERMANY

M. Friske[1], W. Schramm[1], R. Landgraf[1], R. Renner[2], M. Gottsmann[2], H. Koch[2], B. Ruhland[2], E. Standl[2], K. Piwernetz[3]
[1]DIABCARE Bavaria, Diabetes Centre, Klinikum Innenstadt, University of Munich, Germany, [2]Fachkommission Diabetes in Bayern, Diabetes Centre, Klinikum Bogenhausen, Munich, Germany,
[3]DIABCARE Office, Munich, Germany

In Bavaria the speciality commission Diabetes (Fachkommission Diabetes in Bayern - Landesverband der Deutschen Diabetes-Gesellschaft) has formed a structure for regional improvement of diabetes management with respect to the St. Vincent Action Programme. This non-profit organization was founded in 1993 and in April 1996 the commission was reshaped as the Bavarian section of the German Diabetes Association. Since then 152 members from primary care, diabetes specialists, city and community hospitals and university clinics are actively involved. The board of the commission has formed several sub-committees like quality management and epidemiology, diabetic foot, education, nephropathy, primary care, health care system and outpatient / inpatient cooperation. The implementation of DIABCARE Q-Net is widely supported by its members. So far over 9.000 patient data sets were aggregated by the Basic Information Sheet or by the software DiabData. The participating centers received data evaluations as benchmarking. At the moment the implementation of the DIABCARE fax system is put into action. Further aims in the future will include the Bavarianwide distribution of the carecard Diabetes and enforcing efforts in quality development by installation of quality circles.

2640

THE EDUCATION OF SOCIETY ABOUT DIABETES -- ACTIVITIES OF LDA 1993 -- 1996.

L.Kusiņa, G.Freimane, I.Rasa and R.Ligere, Latvian Diabetes Association, Riga, Latvia.

The education of society about diabetes is one of the basic task of Latvian Diabetes Association (LDA). The importance of the task and peculiarities are determined by following factors: the diabetes morbidity rates are increasing sharply, society is insufficiently informed about diabetes and there is no uderstanding about the special needs of diabetes patients, the members of society and they have not enough resources for self -- education. LDA is the only organization that regularly informs society about the problems of diabetes and uses following ways to do that. 28 articles have been published in healt educational magazines "Veselība" and "Sveiks un Vesels" and 55 articles have been published in general press until the December 1996. LDA has prepared 8 radioprograms on risk factors of diabetes, early diagnosing and symptoms of diabetes, bases of healthy lifestyle. During World Diabetes Day a broad press campaign is always organized, specially turning attention to the first signs of ilness and early diagnosig them. Checking blood glucose level durin the WDD (for free), every year dozens of firstly diagnosed persons with too high glucose level are found (in 1996 -- 40 cases out of 908, that is -- 4,4%). In July -- September 1995 LDA carried out a sociological questionnaire "How much do you know about diabetes?". 1000 respondents were questioned. The results will be summarized and estimated during the first half of the year 1997. LDA will continue all the started works and hopes to publish a magazine devoted to diabetes theme for a broad audience of readers.

2641

IDF AND LITHUANIAN DIABETES ASSOCIATION.
Vida Augustinienė, Lithuanian Diabetes Association, Vilnius, Lithuania.

In order to implement the St.Vincent Declaration the Lithuanian Diabetes Association(LDA) was established on 9 December,1989.At present LDA has about 5000 members comprising both health care professionals,people with diabetes and their carers.The LDA plays the leading part in realization of the National Diabetes Programme.The LDA provides practical help and advice producing publications,publishes the newspaper "Diabetas",prepares the information on cassette for visualy handicapted members, organizes conferencies,seminars,summer camps, World Diabetes Days,gives information over the phone,helps to establish diabetes schools,to solve social problems,to remove discrimination (driving licence,list of specialities to study in higher schools,50 strips for self control, compensation for food).By making representations to the government,the LDA helps to ensure that standard of diabetes care in Lithuania is maintained.Since 1994 the LDA is a member of the IDF.The IDF helps us to understand new ideas and to learn from experience.It is essential for growth and development of the LDA.

BLOOD GLUCOSE TESTING IN PUBLIC PLACES
A. Pešut, D. Buliga, M. Dražić, V. Mađarić, Z. Mađarić, B. Mirkić, M. Prašek. Zagreb Diabetic Society, Zagreb, Croatia.

To promote public awareness of diabetes, blood glucose testing in public places has been performed. During the last two years three actions have been organized by the Zagreb Diabetic Society, two of them in the city park and one in a sports center. Blood glucose was measured using a small apparatus for selfcontrol of diabetic patients. The measuremnt was conducted by the members of the Society and supervised by the medical staff of diabetic centers in Zagreb. Persons with glucose levels higher than 6.7 mmol/l were advised to check the results of measurement in a doctor's office. A total of 1475 citizens was tested, including a certain number of registered diabetics. A total of 192 persons had suspected newly discovered diabetes, while 242 had had diabetes diagnosed earlier. The percentage of those with blood sugar higher than 6.7 mmol/l, previously not registered as diabetics, was different for the two locations: 13 and 20 % in the park, and 10 % at the sports center. This could be explained by the difference in average ages of the population visiting these two locations. On the occasion of the World Diabetes Day 1996 similar actions were organized in three locations in the city center, to alert the citizens of the dangers of diabetes and to promote association of patients.

2643

THE ALL-RUSSIAN DIABETES NEWSPAPER (ALL-RDN) AS A MEMBERSHIP CARD.
M.Bogomolov,All-Russian Diabetes Association (All-RDA), Moscow 105568,18-2-154Cheliabinsk.

All-RDA founded the All-RDN for free of charge distribution between individual & collective members of the All-RDA. The annual All-RDA membership fee is the 100 russian rubles -equivalent of 0,017 $ USA. It was very difficult to unificate more than 1.000.000 diabetics in the territory with the area of 17.075.400 squre kilometers. So our membership All-RDA politic for admittance to the All-RDA was acceptable only for 89 regional diabetic & diabetes organizations. But a lot of diabetics from rural areas could not receive the new diabetology information and could not receive social protection from the All-RDA. We changed our membership politic last month from collective to individual membership after publishing of the first All-RDN number. The circulation of the first All-RDN number was 5.000 samples. We will publish All-RDN monthly increasing the circilation & All-RDA membership to 1.000.000 in 1998. One of the principal of the points at issue in All-RDN is to ask IDF to distinguish one special "russian" region for membership in IDF.

2644

WHAT WE ARE DOING FOR PUBLIC AWARENESS OF DIABETES IN BEIJING — BDPTA IS WORKING.
H. D. XIANG, C. YAN and H. J. DAO, BDPTA Beijing, China.

Beijing Diabetes Prevention & Treatment Association (BDPTA) is established in May 10, 1996. A lot of work have been done in last year: (1)Organization of BDPTA: 59 council directors including 13 patients, more than 2000 members;(2)Lectures on diabetes: 3 times in the park or theater, more than 1000 patients each time;(3) Diabetes Day(DD): Beijing DD is on May 10 every year of last 4 years, International DD is on Nov. 14 every year from 1992, with more than 10000 attendants in the last IDD only in Beijing;(4)Diabetes booklet: 2000 in Beijing, 50000 in whole country;(5)Diabetes Corner on newspaper: once a week on HEALTH TIMES ;(6) (Cross Talk on Diabetes) : on Beijing Broadcasting once a week for 1 year;(7)Diabetes help Card: more than 3000 delivered; (8)Hot line for diabetics: every Saturday morning; (9) Small sized consultation: twice monthly on the second and fourth Saturday; (10)Network of diabetes monitor and therapy, one in the countryside, another in the town; (11)To continue IDDM registry: once per 2 year for IDDM incidence;(12)To have training course for physicians, pediatrics, nurses and dietitians, writing teaching materials on the treatment both of IDDM and NIDDM.

2645

THE BERMUDA DIABETES EPIDEMIOLOGY PROJECT - A SUCCESSFUL PARTNERSHIP VENTURE.

D.J. Jones, G.Smith, B. Willis, L.Andrew-Koolkin, D. Vasic and M.H.Tan. Bermuda Diabetes Association, Hamilton, Bermuda.

Diabetes is a major health problem in Bermuda. To define the magnitude of the diabetes problem, Bermuda Diabetes Association (BDA) determined the prevalence of diabetes and its risk factors in a random sample of the adult population. We describe here the cooperative efforts of many partners in making the Bermuda Diabetes Epidemiological Project (BDEP) possible in a nation where there is no official research funding agency. The need and importance of the survey were initially presented to the Premier, Minister of Health, health professionals and business community in Oct. 1994. In Dec. a similar presentation was made to the Cabinet which endorsed the BDEP. A steering committee, with members from the BDA, Ministry of Health, Heart Foundation, business community, health professionals and Statistics Department, was appointed. During 1995 it met regularly to plan for the survey tool, fund raising, pubic awareness and survey conduction. The Nova Scotia Heart Health Survey, modified to include an extensive diabetes component, was used as the Survey tool. Fund-raising events included "Bermuda Night" featuring Bermuda music & food, health screening & talks to companies for their donations, watermelon sales on Harbor Nights, fruit sales at Agricultural Show, "Tag Days" and Denim for Diabetes Day. Publicity for BDEP was organized by a local advertising executive who donated his services. The Canadian Diabetes Association shared its Diabetes Campaign materials. All three media in Bermuda publicized BDEP. One TV station televised "Bermuda Night " and opened it up like a telethon. When BDEP was launched in Sept. 1995 at Government House the Ministry of Health donated funds to BDEP. When the survey began in Jan. 1996 the Ministry of Health organized a press conference. The Survey was completed in Nov. 1996. Together BDA and its partners made BDEP a dream come true.

2646

ENHANCING PUBLIC AWARENESS OF DIABETES: A COMMUNITY PROJECT ON THE WHITE MOUNTAIN APACHE RESERVATION

J. Krakoff , B. Kane, and G. Smalley. Whiteriver Hospital, Whiteriver, AZ

Background:The White Mountain Apache Tribe is located in rural eastern Arizona on the Fort Apache Reservation. With a current total population of 12,000, there are now 750 diabetics among the White Mountain Apache. New diabetics are being diagnosed at a rate of 1.1 per week. Methods:To raise local awareness about diabetes, interested community members were recruited by the physician-educator to begin a diabetes liaison program to spearhead community efforts. The first step was to educate liaison members. Five completed a comprehensive course in 1994; eight in 1995. Emphasis was placed not just on content but on teaching skills. Each session began with a case scenario involving information from the previous session. Community members then role played these cases as educators and patients in both English and Apache. By the end of the 1995 session; members were able to lead an entire review session without aid from the instructor. Results:The liaison committee members then were able to lead local efforts at community awareness. Members co-organized with the Indian Health Service two community wide diabetes education conferences in 1994 and 1995 attracting 150 and 100 diabetics and their relatives respectively. Two members were chosen to be part of the Supervisory Board for Diabetes Education at the Whiteriver Service Unit. The liaison committee helped focus the local Community Health Representatives on diabetes forming a diabetes team all of whose members, with renewed interest in health care, returned to school to get their Certified Nursing Assistant degrees. Conclusions:White Mountain Apache lay community members with medical instruction were able to spearhead efforts at raising tribal awareness about diabetes and its sequelae. Future measurements of the impact of this group will look at the percentage of community members educated and given foot care by the newly formed community health representative diabetes team.

A GLOBAL INSULIN COLLECTION AND DONATION PROGRAM - UPDATE

R. Raab, International Diabetes Institute, Melbourne, Australia.

Often costing $ US 25 or more a vial, insulin affordability in many countries is one of the major, yet often unrecognised challenges facing the international diabetes community. Many children and adults die prematurely or suffer early complications as a direct result., and the problem is rapidly worsening, with many countries now obtaining less than 10% of the insulin they need. Insulin, syringes and test strips that would otherwise be wasted are collected through diabetes clinics, Associations and manufacturers and have been sent to 18 countries in urgent need. Between 1986 - 1996, 66,388 vials (adequate for 5,200 people with IDDM for one year), 1.19 million syringes and 2,138 boxes of test strips, valued at least at $US 1.7 million have been distributed and many lives have been saved. Much more insulin is available from such sources. This is part of an integrated global program at the Institute to help improve insulin availability and affordability in many countries and we invite others to join under the theme "No More Deaths Because Of Insulin Shortage".
