ABSTRACT: We present a simple method which simplifies the evaluation of the on-shell multiple box diagrams reducing them to triangle type ones. For the L -loop diagram one gets the expression in terms of Feynman parameters with $2L$ -fold integration. As examples we consider the 2 and 3 loops cases, the numerical integration up to six loops is also presented. The method is valid in six dimensions where neither UV nor IR divergences appear.

1 Introduction

The box-type diagrams being difficult for evaluation have attracted much attention in recent years due to the appearance in multiloop calculations of amplitudes in SUSY theories [1–6]. It was shown that in maximal SYM theories when calculating the amplitudes of many-particle scattering the bubble and triangle diagrams cancel and only the boxes survive [7–9]. At the same time, long ago the ladder diagrams in four dimensions were calculated in an arbitrary order of PT, albeit off-shell [10, 11]. When going on-shell they contain infrared divergences and the proper ε -expansion was constructed in 2 and 3 loops [12, 13]. Since the form of the integrand of the four point amplitude in maximal SYM theories is fixed by dual conformal invariance and essentially the same in any dimension, the same boxes appear in the other dimensions [14–17]

Recently, we considered the amplitudes in the $D=6$ $N=(1,1)$ SYM theory and encountered the same box diagrams but in six dimensions [18]. They are UV and IR convergent and at lower orders may in principle be extracted from the known Mellin-Barnes representations [19]. However, the remaining MB integrals are complicated starting from 2 loops.

Here we present the method which is applicable in six dimensions and allows us to reproduce the known results and proceed to higher orders of PT in a straightforward way.

2 Reduction of the box diagrams to triangles

Consider the L -loop ladder diagram shown in figure 1 in the massless theory in six dimensions. In the momentum space it depends on 4 external momenta and integration is taken over all loop momenta, while in the coordinate space it depends on 4 external coordinates and integration is taken over all internal vertices. These two expressions are related via the

Figure 1. The ladder type diagram.

Figure 2. Reduction of boxes. The indices of the lines in the coordinate space are shown.

Fourier transform. One should have in mind that the propagator in the coordinate space depends on the space-time dimension

$$\int d^D p \frac{e^{ipx}}{p^2} = i\pi^{D/2} 2^{D-2} \frac{\Gamma(D/2 - 1)}{\Gamma(1)} \frac{1}{(x^2)^{D/2-1}}, \quad (2.1)$$

and in six dimensions one has $1/(x^2)^2$.

Now let us start from the coordinate space. One can notice that in all internal vertices the sum of the indices of the lines (index of a line is the power in the propagator) is equal to $6=2+2+2$, i.e. the value of the space-time dimension. Such a vertex is called unique [20–22] and obeys the famous uniqueness or star-triangle relation

$$\begin{array}{c} \bullet \\ | \\ 2 \\ \bullet \end{array} \begin{array}{c} \bullet \\ / \backslash \\ 2 \quad 2 \end{array} = i\pi^3 \frac{\Gamma(1)\Gamma(1)\Gamma(1)}{\Gamma(2)\Gamma(2)\Gamma(2)} \begin{array}{c} \triangle \\ / \backslash \\ 1 \quad 1 \\ \backslash / \\ 1 \end{array}, \quad (2.2)$$

where in the coordinate space one integrates over the vertex and has no integration in the r.h.s. Thus, all the vertices in figure 1 are unique, and one can easily reduce the ladder diagram to the sequence of triangles. The procedure consists of consequent use of eq. (2.2) (see figure 2).

The next step is to go to the momentum space. The diagram in the momentum space has the same topology but the indices of the lines have to be replaced by the dual ones ($2 \rightarrow 1, 1 \rightarrow 2$), and one has to integrate over the loops. Performing this procedure one gets the diagram shown in figure 3 (we omit the factors of i, π and 2, they are canceled eventually, and one is left with the obvious loop factors).

This is the diagram we are going to calculate. It looks as if it contains an additional loop, however, as we will see, eventually one has $L - 1$ loops to evaluate. We will be interested in the on-shell value. This means that all external momenta obey $p_i^2 = 0$. This simplifies the calculation and the diagram appears to be the function of two variables: the usual Mandelstam $s = (p_1 + p_2)^2 = (p_3 + p_4)^2$ and $t = (p_1 + p_4)^2 = (p_2 + p_3)^2$.

Figure 3. The resulting ladder diagram in the momentum space. The indices of the lines in the momentum space are shown.

Figure 4. The resulting two loop diagram.

3 The two-loop example

Before proceeding to the two loop case we present one simple observation. The triangles that are situated at the edges of the diagram can be easily evaluated, and the result is useful to present in the form

$$\int \frac{d^6 k}{k_1^2(p_1 + k_1)^2(k_2 - k_1)^2} = i(-\pi)^3 \int_0^1 dx_1 \frac{1}{(p_1 x_1 + k_2)^2}, \quad \text{for } p_1^2 = 0. \quad (3.1)$$

This way the loops at the edges are simplified and one actually has the $L - 1$ loop diagram. In the two loop case one gets the diagram shown in figure 4. Thus, for the double box diagram one has

$$\text{DBox}(s, t) = \int_0^1 dx_1 dx_4 \int \frac{d^6 k_2}{(p_1 x_1 + k_2)^2 (p_2 - k_2)^4 (p_4(1 - x_4) + p_1 + k_2)^2}. \quad (3.2)$$

This integral can be evaluated by introducing Feynman parameters, which gives

$$\text{DBox}(s, t) = \int_0^1 \frac{dx_1 dx_2 dx_3 dx_4 (1 - x_2)}{s(x_1(1 - x_3) + x_2 x_3)(1 - x_2) + t(1 - x_4)x_2 x_3(1 - x_3)(1 - x_1)}. \quad (3.3)$$

To deal with the integrals over Feynman parameters, it is useful to apply the Mellin-Barnes transformation. We use twice the following relation:

$$\frac{1}{(X + Y)^\lambda} = \frac{1}{\Gamma(\lambda)} \frac{1}{(2\pi i)} \int_{-i\infty}^{i\infty} dz \Gamma(\lambda + z) \Gamma(-z) \frac{X^z}{Y^{\lambda+z}}, \quad (3.4)$$

and then evaluate the parametric integrals. This gives

$$\begin{aligned} \text{DBox}(s, t) = \frac{1}{s} \frac{1}{(2\pi i)^2} \int_{-i\infty}^{i\infty} dz_1 dz_2 \left(\frac{t}{s}\right)^{z_1} & \Gamma(-z_1) \Gamma(-z_2) \Gamma(-1 - z_1 - z_2) \Gamma^2(1 + z_1) \\ & \Gamma(1 - z_1) \Gamma(1 + z_1 + z_2) \Gamma(z_2). \end{aligned} \quad (3.5)$$

The integral over z_2 can be evaluated by using the first Barnes lemma [19], and one finally arrives at

$$\text{DBox}(s, t) = \frac{1}{s} \frac{1}{2\pi i} \int_{-i\infty}^{i\infty} dz_1 \left(\frac{t}{s} \right)^{z_1} \Gamma^3(-z_1) \Gamma^3(1+z_1) \frac{2z_1}{1+z_1} (\psi(1+z_1) - \psi(1)). \quad (3.6)$$

The remaining integral is reduced to the sum of residues at integer points and reproduces the known answer [18, 23]. Notice that our way to arrive at (3.6) is much simpler than the usual MB evaluation which requires 4-fold MB integration [18, 19].

4 The three-loops example for $t=0$

Consider now the three loop case. Since the answer is too complicated and contains special functions, we constrain ourselves to the limit when $t \rightarrow 0$. It should be mentioned that this limit exists and the ladder diagram in this limit behaves as

$$\text{Box}^n(s, t) \rightarrow \frac{1}{s} \left(c_n + O\left(\frac{t}{s}\right) \right). \quad (4.1)$$

In particular, from eq. (3.6) it follows that $c_2 = \pi^2/3$. Our aim here is to calculate c_3 . The standard MB representation leads to 7-fold integration [19].

Following the procedure described above we have the following 2-loop integral:

$$\text{TBox}(s, t=0) = \int_0^1 dx_1 dx_6 \int \frac{d^6 k_2 d^6 k_3}{(p_1 x_1 + k_2)^2 (p_2 - k_2)^4 (k_3 - k_2)^2 (p_1 + k_3)^4 (p_2 x_6 - k_3)^2}. \quad (4.2)$$

Using Feynman parameters (2 for each loop) one can reduce eq. (4.2) to

$$\text{TBox}(s, t=0) = \frac{1}{s} \int_0^1 dx_1 \cdots dx_6 \frac{x_2(1-x_3)(1-x_4)}{\text{Poly}_3}, \quad (4.3)$$

where

$$\text{Poly}_3 = x_1 x_2 x_3 (1-x_3) x_5 + (x_1 x_3 x_4 x_5 + 1-x_4) [x_6(1-x_5) + x_5(1-x_3)] (1-x_2). \quad (4.4)$$

Now one can use the multiple MB transformation to get

$$\begin{aligned} \text{TBox} = & -\frac{1}{s} \frac{1}{(2\pi i)^3} \int_{-i\infty}^{i\infty} dz_1 dz_2 dz_3 \frac{\Gamma^2(-z_1)(1+z_1)}{\Gamma(2-z_1)} \Gamma(1+z_1+z_2) \Gamma(1+z_1+z_3) \\ & \frac{\Gamma^2(-z_2) \Gamma(-z_3) \Gamma(2+z_2) \Gamma(1+z_3) \Gamma(1-z_3) \Gamma(1-z_1-z_2-z_3)}{z_2(1+z_3) \Gamma(1-z_2-z_3)}. \end{aligned} \quad (4.5)$$

The integral over z_3 can be evaluated by using the first Barnes lemma, and one gets (we change the sign of z)

$$\begin{aligned} \text{TBox} = & -\frac{1}{s} \frac{1}{(2\pi i)^2} \int_{-i\infty}^{i\infty} dz_1 dz_2 \frac{(1-z_1)(1-z_2)}{z_1 z_2} \Gamma(-1-z_1) \Gamma(z_1) \Gamma(-1-z_2) \Gamma(z_2) \\ & \Gamma(1+z_1+z_2) \Gamma(-z_1-z_2) [\psi(2) - \psi(2-z_1) + \psi(z_1+z_2) - \psi(z_2)]. \end{aligned} \quad (4.6)$$

Loop	1	2	3	4	5	6
Value	$\pi^2/2$	$\pi^2/3$	$-\pi^2 + 31\pi^6/1890 - 8\zeta(3) + 4\zeta^2(3)$			
Numerics	4.93	3.29	2.06	2.05	2.42	3.13

Table 1. The values of the coefficients c_n .

The remaining 2-fold integral is more complicated but again can be taken by using Barnes lemmas. For this purpose we used the dedicated computer code [24–26] reducing the integral to the standard form. The result of the integration is

$$\begin{aligned}
\text{TBox} = & -\frac{1}{s} \frac{1}{2\pi i} \int_{-i\infty}^{i\infty} dz_1 \\
& 1/(6z_1^5(-1+z_1^2))\pi^2 \csc^2(\pi z_1)(-6+z_1(24\gamma_E^2 z_1(-1+z_1^2) - 24\gamma_E(1+(-1+z_1)z_1^2) \\
& + z_1(6(-2+z_1)z_1 - 7\pi^2(-1+z_1^2))) + 12\pi z_1((-1-2\gamma_E z_1 + z_1^3) \cot(\pi z_1) \\
& + \pi z_1(-1+z_1^2) \csc^2(\pi z_1)) + 6z_1(4(-1-2\gamma_E z_1 + z_1^3) \\
& + \pi z_1(-1+z_1))\psi(z_1) + 4z_1^2\psi^2(z_1) + (z_1 - z_1^3)\psi'(-1+z_1)).
\end{aligned} \tag{4.7}$$

The final integration is performed by taking the residues at integer points and summing up the obtained series. The latter can be done using the set of formulas from [19]. The result for the desired coefficient is

$$c_3 = -\pi^2 + \frac{31\pi^6}{1890} - 8\zeta(3) + 4\zeta^2(3). \tag{4.8}$$

This is a bit disappointing answer since after $c_1 = \pi^2/2$ and $c_2 = \pi^2/3$ one might expect a simple sequence at every loop. With eq. (4.8) this hope disappears and one is left with numerical answers.

5 Numerical integration in higher loops

Numerical values for the coefficients c_n from (4.1) are summarized in table 1. We complete this table by numerically evaluating the 4-, 5- and 6-loop box diagrams.

To get numerical answers, we use the same procedure as above but stop at the level of Feynman parametrization without performing the MB transformation. Then in the L -loop order one has $2L$ parametric integrals from 0 to 1. One starts from the left and carries out the 6-dimensional integration introducing 2 Feynman parameters for each loop. The triangles on the left and right edges are taken using eq. (3.1). Each integration gives the integrand of a typical form

$$\frac{1}{k_i^2 + k_i q_i + m_i^2},$$

where k_i is the momentum of the next integration, q_i is some external momentum and m_i^2 is s times some Feynman parameters. Thus, one has the triangle type integral again and can continue the same way.

We present below the resulting integrals for the 4-, 5- and 6-loop box diagrams. They all have the same form

$$c_L = \int_0^1 dx_1 \cdots dx_{2L} \frac{x_2(1-x_3) \cdots x_{2L-2}(1-x_{2L-1})}{\text{Poly}_L}, \quad (5.1)$$

where the polynomials at the 4-, 5-, and 6-loop order are

$$\begin{aligned} \text{Poly}_4 = & x_1x_2(1-x_3)x_3x_5x_7 + (1-x_2)(1-x_3)x_4x_5(1-x_5+x_1x_3x_5)x_7 \\ & + (1-x_2)(1-x_4)(1-x_7+(1-x_3)x_5x_7)((1-x_5+x_1x_3x_5)x_6x_7 \\ & + (1-x_6)x_8), \end{aligned} \quad (5.2)$$

$$\begin{aligned} \text{Poly}_5 = & x_1x_2(1-x_3)x_3x_5x_7x_9 + (1-x_2)(1-x_3)x_4x_5(1-x_5+x_1x_3x_5)x_7x_9 \\ & + (1-x_2)(1-x_4)(1-x_5+x_1x_3x_5)x_6x_7(1-x_7+(1-x_3)x_5x_7)x_9 \\ & + (1-x_2)(1-x_4)(1-x_6)(1-x_9+(1-x_5+x_1x_3x_5)x_7x_9)(x_{10}(1-x_8) \\ & + (1-x_7+(1-x_3)x_5x_7)x_8x_9), \end{aligned} \quad (5.3)$$

$$\begin{aligned} \text{Poly}_6 = & x_1x_2(1-x_3)x_3x_5x_7x_9x_{11} + (1-x_2)(1-x_3)x_4x_5(1-x_5+x_1x_3x_5)x_7x_9x_{11} \\ & + (1-x_2)(1-x_4)(1-x_5+x_1x_3x_5)x_6x_7(1-x_7+(1-x_3)x_5x_7)x_9x_{11} \\ & + (1-x_2)(1-x_4)(1-x_6)(1-x_7+(1-x_3)x_5x_7)x_8(1-x_9)x_9x_{11} \\ & + (1-x_2)(1-x_4)(1-x_5+x_1x_3x_5)(1-x_6)x_7(1-x_7+(1-x_3)x_5x_7)x_8x_9^2x_{11} \\ & + (1-x_2)(1-x_4)(1-x_6)(1-x_8)(1-x_{11}+x_{11}(1-x_7+(1-x_3)x_5x_7)x_9) \\ & ((1-x_{10})x_{12}x_{10}x_{11}(1-x_9+(1-x_5+x_1x_3x_5)x_7x_9)). \end{aligned} \quad (5.4)$$

Numerical evaluation of these integrals can be performed in the standard Mathematica or in more sophisticated codes using sector decomposition strategy [27, 28] or FIESTA [29].

The results are

$$c_4 \approx 2.0520 \pm 0.0001, \quad c_5 \approx 2.4257 \pm 0.0008, \quad c_6 \approx 3.130 \pm 0.005. \quad (5.5)$$

If needed this can be continued in higher loops.

6 Conclusion

One can see that reduction of boxes to triangles is very efficient and enables one to calculate the higher order L -loop diagrams with the price of the $2L$ -fold parametric integration which can be easily carried out numerically. Unfortunately, the method is linked to six dimensions since only in this case one has unique vertices and can use the power of the star-triangle relation.

Acknowledgments

The author is grateful to V.Smirnov for running the code that helped to get eq. (4.7) and for useful hints in evaluation of the integrals, and to A.Pikelner for the accurate check of numerical results (5.5) with the help of the sector decomposition and FIESTA programs.

I would also like to thank V.Belokurov and A.Grozin for their help in finding the right way and O.Tarasov, A.Kotikov, A.Isaev, K.Chetyrkin, L.Bork and D.Vlasenko for useful discussions. Financial support from RFBR grant # 14-02-00494 is kindly acknowledged. Thanks are also to Mr. Mac who always kept me in good shape.
