ABSTRACT: In this paper, we study the holographic models of s-wave and p-wave Josephson junction away from probe limit in (3+1)-dimensional spacetime, respectively. With the backreaction of the matter, we obtained the anisotropic black hole solution with the condensation of matter fields. We observe that the critical temperature of Josephson junction decreases with increasing backreaction. In addition to this, the tunneling current and condensation of Josephson junction become smaller as backreaction grows larger, but the relationship between current and phase difference still holds for sine function. Moreover, condensation of Josephson junction decreases with increasing width of junction exponentially.

1 Introduction

The AdS/CFT duality [1–3], which originates from string theory, provides a novel and powerful tool to study the strongly coupled field theories in a weakly coupled gravitational system. It states a d -dimensional conformal field theory on the boundary is equivalent to a $(d + 1)$ -dimensional dual gravitational description in the bulk. Since the AdS/CFT correspondence can provide a holographically dual description of the strongly coupled system, it has received a broad range of attention. In recent years, the application of AdS/CFT correspondence to condensed matter physics has been quite successful. Especially, one of hot points is the study of holographic superconductor. In [4, 5], the authors studied the s-wave superconductor by coupling anti-de Sitter gravity to the U(1) gauge field and a complex scalar field. One found that when the Hawking temperature of black hole was below a critical temperature, the U(1) gauge symmetry would be broken spontaneously via the charged scalar field condensated outside the horizon. In [6–8], the authors investigated the p-wave superconductor by considering SU(2) gauge field, and studied the d-wave superconductor by a symmetric, traceless second-rank tensor and a U(1) gauge field in the background of the AdS black hole. Moreover, one also studied the coexistence and competition of order parameters by holographic approach in [9–16]. More detailed introduction of holographic superconductor can be found in [17–20].

In addition to the study of holographic superconductor in the probe limit, the s-wave superconductor with backreaction is also researched in [21]. Furthermore, in [22], the authors constructed an SU(2) Einstein-Yang-Mills theory with (4+1)-dimensional asymptotically anti-de Sitter charged black hole to describe p-wave superfluids with backreaction. The authors investigated the s-wave superconductor in (3+1)-dimensional with backreaction in the cases of pure Einstein and Gauss-Bonnet gravity, respectively in [23]. The papers about holographic p-wave phase transition in Gauss-Bonnet Gravity and the s-wave superconductor in (3+1)-dimensional AdS spacetime with backreaction are presented

in [24] and [25], respectively. There are another papers [26–31] about holographic superconductors with backreaction by semi-analytic and numerical computation method. In these papers, ones find that critical temperature will become lower and condensation will become harder if the strength of backreaction becomes stronger. Furthermore, AdS/CFT correspondence has been application in the study of holographic lattice. For example, in [32], the authors studied the optical conductivity by adding a gravitational background lattice. Other papers about holographic lattice can be viewed in [33–47]. The DeTurck method provides a good tool for solving Einstein equations in these papers.

The model of the holographic superconductor can also be extended to study the Josephson junction which are associated with the experiments. As we know, the Josephson junction consists of two superconductor materials and a weak link barrier between them [48]. The weak link can be a thin normal conductor (S-N-S) or a thin insulating barrier (S-I-S). Horowitz et al. in [49] studied the s-wave Josephson junction in probe limit by the Maxwell field coupled with a complex scalar field in a $(3+1)$ -dimensional Schwarzschild-AdS black hole background, and observed that the current is proportional to the sine of phase difference with AdS/CFT. A holographic model of 4-dimensional Josephson junction has been investigated in [50, 51]. With the model of a designer multigravity, the holographic mode of a Josephson junction array has been constructed in [52]. The p-wave Josephson junction was discussed by an $SU(2)$ gauge field coupled with gravity in [53]. In [54], the authors studied $(1+1)$ -dimensional S-I-S Josephson junction in the four-dimensional anti-de Sitter soliton background. A holographic model of superconducting quantum interference device (SQUID) was studied in [55, 56]. In [57], authors investigated the holographic Josephson junction with Lifshitz geometry. A holographic model of hybrid and coexisting s-wave and p-wave Josephson junction was constructed in [58]. The authors constructed a holographic model of s-wave Josephson junction with massive gravity in [59].

The previous studies on holographic Josephson junctions are in the probe limit, however, it would be of great interest to further explore what role the backreaction plays in Josephson effect beyond the probe limit. For example, turning on the backreaction, we wonder that whether the current is proportional to the sine of phase difference and condensation decreases with increasing width of junction. Inspired by the previous work, we took advantage of a complex scalar field coupling to the $U(1)$ gauge field and $SU(2)$ Yang-Mills field with $(3+1)$ -dimensional RN-AdS black hole to construct the holographic models of s-wave and p-wave Josephson junction with backreaction, respectively.

In this paper we will proceed as below. In section 2, we set up the model of s-wave Josephson junction and analyze our numerical results. In section 3, we write the action of the model of p-wave Josephson junction, and discuss our numerical results. We take conclusion finally in section 4.

2 $(2+1)$ -dimensional s-wave Josephson junction

2.1 The model

Let us begin with the Maxwell field and a charged complex scalar field in the $(3+1)$ -dimensional Einstein gravity spacetime with a negative cosmological constant. The La-

grangian density reads

$$\mathcal{L} = R - 2\Lambda - \frac{1}{4}F^{\mu\nu}F_{\mu\nu} - |\nabla\psi - iqA\psi|^2 - m^2|\psi|^2. \quad (2.1)$$

Here, $\Lambda = -3/\ell^2$ is the cosmological constant, which relates to AdS radius ℓ . The field strength of the U(1) gauge field is $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$, m and q represent the mass and the charge of the complex scalar field ψ , respectively. The charge q appears in the covariant derivative and controls the strength of the backreaction of the matter fields on the metric.

Since we are interested in the effect of the backreaction and to see that how it varies with the charge q , we have scaling transformations $A \rightarrow A/q$ and $\psi \rightarrow \psi/q$. The Lagrangian density (2.1) changes into

$$\mathcal{L} = R + \frac{6}{\ell^2} + \kappa\mathcal{L}_m, \quad (2.2)$$

$$\mathcal{L}_m = -\frac{1}{4}F^{\mu\nu}F_{\mu\nu} - |\nabla\psi - iA\psi|^2 - m^2|\psi|^2, \quad (2.3)$$

where $\kappa = 1/q^2$ is the parameter that measures the backreaction of the matter fields. From the above, we can see that the backreaction on the gravity will decrease when q increases, and the large q limit ($q \rightarrow \infty$) corresponds to the probe limit (non-backreaction) of the matter sources.

The equations of motion of the scalar and the electromagnetic fields which can be derived from the Lagrangian density (2.1) are as follows

$$(\nabla_\mu - iA_\mu)(\nabla^\mu - iA^\mu)\psi - m^2\psi = 0, \quad (2.4)$$

$$\nabla_\mu F^{\mu\nu} - i[\psi^*(\nabla^\nu - iA^\nu)\psi - \psi(\nabla^\nu + iA^\nu)\psi^*] = 0, \quad (2.5)$$

and Einstein equations

$$R_{\mu\nu} + \frac{3}{\ell^2}g_{\mu\nu} - \kappa \left(\frac{1}{2}F_{\mu\lambda}F_\nu{}^\lambda - \frac{1}{8}F_{\lambda\delta}F^{\lambda\delta}g_{\mu\nu} + \frac{1}{2}m^2|\psi|^2g_{\mu\nu} + \frac{1}{2}[(\nabla_\mu\psi - iA_\mu\psi)(\nabla_\nu\psi^* + iA_\nu\psi^*) + \mu \leftrightarrow \nu] \right) = 0. \quad (2.6)$$

For the charged scalar field $\psi = 0$, the solution of Einstein equations (2.6) is the well-known Reissner-Nordström-AdS (RN-AdS) black hole. The solution with a spherically symmetric can be written as follows

$$ds^2 = \frac{\ell^2}{z^2} \left[(z-1)H(z)dt^2 + \frac{dz^2}{(1-z)H(z)} + dx^2 + dy^2 \right], \quad (2.7)$$

where $H(z) = 1 + z + z^2 - \frac{\kappa}{4}\mu_0^2z^3$, and μ_0 is the chemical potential for U(1) charge. The horizon of black hole is at $z = 1$ and the boundary of asymptotical AdS spacetime is at $z = 0$. The Hawking temperature, which can be regarded as the temperature of the holographic superconductors, is given by

$$T = \frac{(12 - \kappa\mu_0^2)}{16\pi\ell}. \quad (2.8)$$

It is well known that there is a critical temperature T_c . When $T = T_c$, a charged scalar condensation begins to occur. For $T < T_c$, the black hole will have a scalar hair with breaking the U(1) gauge symmetry spontaneously and brings about superconducting phenomena of the (2+1)-dimensional dual theory on the boundary. As for $T > T_c$, the black hole with a scalar hair degrades into RN-AdS black hole.

2.2 The ansatz and asymptotic forms

In order to build a holographic model of the s-wave Josephson junction, we introduce two bulk gauge fields A_z and A_x on the basis of the model of s-wave superconductor. The gauge field A_x is related to the non-vanished current on the boundary. In addition, the matter fields must depend on spatial coordinates.

Considering the above reasons, an ansatz of matter fields should be described as below

$$\psi = |\psi|e^{i\phi}, \quad A = A_t dt + A_z dz + A_x dx, \quad (2.9)$$

where $|\psi|$, ϕ , A_t , A_z and A_x all depend upon the spatial coordinate x and the radial coordinate z . Furthermore, we take the metric ansatz as

$$ds^2 = \frac{\ell^2}{z^2} \left[(z-1)H(z)E_1(dt + E_7 dx)^2 + \frac{E_2(dz + (1-z)H(z)E_6 dt)^2}{(1-z)H(z)} + E_3(dx + E_5 dz)^2 + E_4 dy^2 \right], \quad (2.10)$$

where E_i ($i = 1, 2, 3, 4, 5, 6, 7$) are seven functions of z and x . Note that the metric may be a non-diagonal one, in which the non-diagonal function E_5 is required due to the x dependent spatial coordinate, and the functions E_6 and E_7 are associated with non-vanishing A_z and A_x , respectively. Thus the holographic model of s-wave Josephson junction would be along the x direction. The function ψ can be taken to be real by introducing the new U(1) gauge invariance $M_\mu \equiv A_\mu - \partial_\mu \phi$.

The scalar field, Maxwell and Einstein equations of motion with the ansatzs (2.9) and (2.10) are a set of non-linear coupled partial differential equations. Seven equations which come from the Einstein equations (2.6) are second-order PDEs with respect to E_i . Two equations from eq. (2.4), one is a second-order PDE and the other one is a first-order PDE, are called as constraint equations. The remaining three equations which are from the eqs. (2.5) are also second-order PDEs. It is not convenient to write down all of the twelve equations in our paper, for each equation contains hundreds or thousands of terms. It is obvious that we should solve them numerically instead of seeking the analytical solutions. Before numerical program, we should obtain the asymptotic behaviors of $|\psi|$, M_t , M_z , M_x and E_i at $z = 0$. To know these asymptotic forms is equivalent to know the boundary conditions we need.

On the AdS boundary, the asymptotic behaviors of the functions E_i take the following forms

$$E_1(z, x) \rightarrow 1 + \mathcal{O}(z^3), \quad (2.11a)$$

$$E_2(z, x) \rightarrow 1 + \mathcal{O}(z^3), \quad (2.11b)$$

$$E_3(z, x) \rightarrow 1 + \mathcal{O}(z^3), \quad (2.11c)$$

$$E_4(z, x) \rightarrow 1 + \mathcal{O}(z^3), \quad (2.11d)$$

$$E_5(z, x) \rightarrow \mathcal{O}(z^4), \quad (2.11e)$$

$$E_6(z, x) \rightarrow \mathcal{O}(z^4), \quad (2.11f)$$

$$E_7(z, x) \rightarrow \mathcal{O}(z^4). \quad (2.11g)$$

Obviously, when z goes to zero, the metric (2.10) will approach to the Reissner-Nordström-AdS metric with the above asymptotic forms.

Near the boundary $z = 0$, the scalar field and Maxwell field have the following asymptotic forms

$$|\psi|(z, x) \rightarrow z^{\Delta_-} \psi^{(-)}(x) + z^{\Delta_+} \psi^{(+)}(x) + \mathcal{O}(z^{1+\Delta_+}), \quad (2.12a)$$

$$M_t(z, x) \rightarrow \mu(x) - z\rho(x) + \mathcal{O}(z^2), \quad (2.12b)$$

$$M_z(z, x) \rightarrow \mathcal{O}(z), \quad (2.12c)$$

$$M_x(z, x) \rightarrow \nu(x) + Jz + \mathcal{O}(z^2), \quad (2.12d)$$

with

$$\Delta_{\pm} = \frac{(3 \pm \sqrt{9 + 4m^2})}{2}, \quad (2.13)$$

where m is the mass of the scalar field and the values of m^2 must satisfy the Breitenlohner-Freedman (BF) bound $m^2 \geq -9/4$ [60] for the (3+1)-dimensional spacetime. According to AdS/CFT duality, $\psi^{(\pm)}(x)$ are the corresponding expectation values of the dual scalar operators $\langle \mathcal{O}_{\pm} \rangle$, respectively. In this paper, we will set $\psi^{(-)} = 0$ and take $\langle \mathcal{O} \rangle = \langle \mathcal{O}_+ \rangle = \psi^{(+)}$ to describe the scalar condensation. The coefficients $\mu(x)$, $\rho(x)$, $\nu(x)$ and J are the chemical potential, charge density, the velocity of superfluid and the constant current in the dual field theory, respectively [61–68].

In order to describe a Josephson junction, we still adopt the chemical potential $\mu(x)$ in [49] as follows

$$\mu(x) = \mu(\infty) \left\{ 1 - \frac{1 - \epsilon}{2 \tanh(\frac{L}{2\sigma})} \left[\tanh\left(\frac{x + \frac{L}{2}}{\sigma}\right) - \tanh\left(\frac{x - \frac{L}{2}}{\sigma}\right) \right] \right\}, \quad (2.14)$$

where the chemical potential $\mu(x)$ is proportional to $\mu(\infty) \equiv \mu(+\infty) = \mu(-\infty)$ at $x = \pm\infty$, and L is the width of junction. The parameters ϵ and σ control the steepness and depth of junction, respectively.

Next, we introduce the critical temperature T_c of the Josephson junction, which is proportional to $\mu(\infty)$

$$T_c = T \frac{\mu(\infty)}{\mu_c}, \quad (2.15)$$

Figure 1. The plot shows that the temperature T/μ_c decays as the strength of backreaction κ increases with fixing the value of m^2 . We take two values of $m^2 = -2$ (red), $-5/4$ (green). When m^2 grows, T/μ_c will decrease.

where μ_c is the critical chemical potential of the superconductor. In figure 1, we plot the relationship between the temperature T/μ_c and the strength of backreaction κ with $m^2 = -2, -5/4$. It indicates that T/μ_c decays as κ increases with fixing the value of m^2 , and when m^2 grows, T/μ_c will decrease.

When $m^2 = -2$,

$$T_c \approx 0.0588\mu(\infty), \quad \kappa = 0, \quad (2.16)$$

$$T_c \approx 0.0581\mu(\infty), \quad \kappa = 1/100, \quad (2.17)$$

$$T_c \approx 0.0550\mu(\infty), \quad \kappa = 1/16, \quad (2.18)$$

$$T_c \approx 0.0505\mu(\infty), \quad \kappa = 1/7. \quad (2.19)$$

When $m^2 = -5/4$,

$$T_c \approx 0.0413\mu(\infty), \quad \kappa = 0, \quad (2.20)$$

$$T_c \approx 0.0403\mu(\infty), \quad \kappa = 1/100, \quad (2.21)$$

$$T_c \approx 0.0358\mu(\infty), \quad \kappa = 1/16, \quad (2.22)$$

$$T_c \approx 0.0296\mu(\infty), \quad \kappa = 1/7. \quad (2.23)$$

From eqs. (2.16)–(2.23), we can see that for the value of m^2 is fixed, the critical temperature T_c drops with increasing strength of backreaction κ , and T_c decreases with increasing m^2 by fixing κ .

Figure 2. (a) The profile of M_t . (b) The profile of E_5 . In all the plots, the parameters are $m^2 = -2$, $\mu_0 = 1$, $\mu_\infty = 6$, $L = 3$, $\epsilon = 0.6$, $\sigma = 0.5$ and $\kappa = 1/100$.

In condensed matter physics, the current of Josephson junction has to be gauge invariant because of the presence of a gauge field A_μ . So, we need to consider the gauge invariant phase difference. Thus, in our holographic model case, the gauge invariant phase difference γ across the junction can be defined as

$$\gamma = - \int_{-\infty}^{+\infty} dx [\nu(x) - \nu(\pm\infty)]. \quad (2.24)$$

2.3 The numerical results

For completeness of our study, we carry on numerical computation in this subsection. To make our work easier, we choose $m^2 = -2$. We show the profiles of the functions M_t and E_5 in figure 2, respectively. We can see that M_t is even, and E_5 is odd.

For the increasing strength of backreaction, the relationship between the current J/T_c^2 and the phase difference γ as shown in figure 3. We take the strength of backreaction $\kappa = 0, 1/100, 1/16, 1/7$. The fitting results are as follows

$$J/T_c^2 \approx 1.39981 \sin \gamma, \quad \kappa = 0, \quad (2.25)$$

$$J/T_c^2 \approx 1.33521 \sin \gamma, \quad \kappa = 1/100, \quad (2.26)$$

$$J/T_c^2 \approx 0.97168 \sin \gamma, \quad \kappa = 1/16, \quad (2.27)$$

$$J/T_c^2 \approx 0.51218 \sin \gamma, \quad \kappa = 1/7. \quad (2.28)$$

To our surprise, the current J/T_c^2 is still proportional to the sine of the phase difference γ with backreaction ($\kappa \neq 0$). Moreover, the amplitude of J/T_c^2 goes down as κ increases.

Figure 3. (Color online) We plot the current J/T_c^2 as a function of the phase difference γ . Curves from top to bottom are for choosing $\kappa = 0$, $\kappa = 1/100$, $\kappa = 1/16$ and $\kappa = 1/7$. The parameters are $m^2 = -2$, $\mu_0 = 1$, $\mu_\infty = 6$, $L = 3$, $\epsilon = 0.6$ and $\sigma = 0.5$.

The relationship between the maximal current $J_{\max}/T_c^2$ and the width of the junction L with increasing strength of backreaction $\kappa = 0, 1/100, 1/16, 1/7$ in the figure 4(a). The fitting results are as follows

$$J_{\max}/T_c^2 \approx 17.8455e^{-L/1.17112}, \quad \kappa = 0, \quad (2.29)$$

$$J_{\max}/T_c^2 \approx 18.4674e^{-L/1.13660}, \quad \kappa = 1/100, \quad (2.30)$$

$$J_{\max}/T_c^2 \approx 19.9195e^{-L/0.994678}, \quad \kappa = 1/16, \quad (2.31)$$

$$J_{\max}/T_c^2 \approx 17.0124e^{-L/0.860052}, \quad \kappa = 1/7. \quad (2.32)$$

It is surprising that when κ is fixed, $J_{\max}/T_c^2$ will still decrease exponentially with increasing L . In addition, $J_{\max}/T_c^2$ becomes smaller with increasing κ . Figure 4(b) shows the relationship between the condensation $\langle O \rangle/T_c^2$ and the width of junction L . The fitting results are as below

$$\langle O \rangle/T_c^2 \approx 33.4411e^{-L/(2 \times 1.25493)}, \quad \kappa = 0, \quad (2.33)$$

$$\langle O \rangle/T_c^2 \approx 34.8072e^{-L/(2 \times 1.20773)}, \quad \kappa = 1/100, \quad (2.34)$$

$$\langle O \rangle/T_c^2 \approx 39.5984e^{-L/(2 \times 1.02245)}, \quad \kappa = 1/16, \quad (2.35)$$

$$\langle O \rangle/T_c^2 \approx 41.0873e^{-L/(2 \times 0.863886)}, \quad \kappa = 1/7. \quad (2.36)$$

These indicates that $\langle O \rangle/T_c^2$ will still decrease exponentially with increasing L , when κ is fixed. In addition, $\langle O \rangle/T_c^2$ goes down as κ increases.

Figure 4. (a) The maximal current $J_{\max}/T_c^2$ versus the width of junction L for $m^2 = -2$. For the fixing κ , $J_{\max}/T_c^2$ varies with increasing L . (b) The condensation $\langle O \rangle/T_c^2$ versus the width of junction L for $m^2 = -2$. For the fixing κ , $\langle O \rangle/T_c^2$ varies as a function of L . Curves from top to bottom are for choosing $\kappa = 0, \kappa = 1/100, \kappa = 1/16$ and $\kappa = 1/7$. The curves fit exponential curves well. In all the plots, the parameters are $\mu_0 = 1, \mu_\infty = 6, \epsilon = 0.6$ and $\sigma = 0.5$.

The relationship between the maximal current $J_{\max}/T_c^2$ and the temperature T/T_c with the backreaction $\kappa = 1/7, 1/16, 0$ is in figure 5. From the figure, we can see that $J_{\max}/T_c^2$ decreases with increasing T/T_c by fixing κ . It is noteworthy that $J_{\max}/T_c^2$ will go up, when κ increases.

From the above results we find that the backreaction can hinder the generation of condensation and current, and make the critical temperature lower. In essence, when the intensity of backreaction κ becomes larger, the Cooper pairs generate harder, the charge q ($\kappa = 1/q^2$) and the coherence length become smaller. Thus these factors lead to the above numerical results. For the $J_{\max}/T_c^2$ which varies with T/T_c grows with increasing κ , it makes sense that stronger backreaction weakens condensation and lower temperature enhances it, but the latter plays a dominate role in this competition.

In the next moment, we take the value of $m^2 = -5/4$ to compare with the case of $m^2 = -2$ by $\kappa = 1/100$. In figure 6, we represent the relationship between the current $J/T_c^{\Delta+}$ and the phase difference γ with different value of m^2 . The fitting results are shown as below

$$J/T_c^{\Delta+} \approx \begin{cases} 1.6758 \sin \gamma & \text{for } m^2 = -2, \\ 0.0993 \sin \gamma & \text{for } m^2 = -5/4. \end{cases} \quad (2.37)$$

From the above, we see that for the fixing κ , the current goes down as m^2 increases. Figure 7(a) and (b) show that the maximal current $J_{\max}/T_c^{\Delta+}$ and the condensation $\langle O \rangle/T_c^{\Delta+}$ decrease with increasing L , respectively. The fitting results are

$$J_{\max}/T_c^{\Delta+} \approx \begin{cases} 15.5660 e^{-L/1.3160} & \text{for } m^2 = -2, \\ 21.7297 e^{-L/0.5570} & \text{for } m^2 = -5/4. \end{cases} \quad (2.38)$$

Figure 5. The plot shows that $J_{\max}/T_c^2$ decreases with increasing T/T_c by fixing κ , and $J_{\max}/T_c^2$ will go up, when κ increases. We use $m^2 = -2$, $\mu_0 = 1$, $\mu_\infty = 6$, $L = 3$, $\epsilon = 0.6$ and $\sigma = 0.5$. From top to bottom, curves correspond to $\kappa = 1/7, 1/16, 0$.

Figure 6. The current $J/T_c^{\Delta+}$ is proportional to the sine of γ and goes down as m^2 increases. The value of $m^2 = -2$ (red), $-5/4$ (green). The parameters are $\mu_0 = 1$, $\mu_\infty = 7.5$, $L = 3$, $\epsilon = 0.5$, $\sigma = 0.5$ and $\kappa = 1/100$.

Figure 7. (a) The maximal current $J_{\max}/T_c^{\Delta+}$ decreases exponentially with growing L . (b) The condensation $\langle O \rangle/T_c^{\Delta+}$ decreases exponentially with growing L . When m^2 increases, $J_{\max}/T_c^{\Delta+}$ and $\langle O \rangle/T_c^{\Delta+}$ will decrease, respectively. The value of $m^2 = -2$ (red), $-5/4$ (green). The parameters $\mu_0 = 1$, $\mu_\infty = 6$, $\epsilon = 0.5$, $\sigma = 0.5$ and $\kappa = 1/100$.

and

$$\langle O \rangle/T_c^{\Delta+} \approx \begin{cases} 26.5676e^{-L/(2 \times 1.448)} & \text{for } m^2 = -2, \\ 67.2095e^{-L/(2 \times 0.5360)} & \text{for } m^2 = -5/4. \end{cases} \quad (2.39)$$

From the above, we can see that when m^2 increases, $J_{\max}/T_c^{\Delta+}$ and $\langle O \rangle/T_c^{\Delta+}$ will decrease, respectively.

The relationship between the maximal current $J_{\max}/T_c^{\Delta+}$ and the temperature T/T_c is shown in figure 8. From the figure, we can see that $J_{\max}/T_c^{\Delta+}$ goes down as m^2 grows. The above results indicate that for fixed backreaction, the larger mass of the scalar field can hinder the scalar hair to form.

3 (2+1)-dimensional p-wave Josephson junction

3.1 Holographic setup

We consider the non-Abelian SU(2) gauge field in the (3+1)-dimensional Einstein gravity spacetime. The Lagrangian density is as follows

$$\mathcal{L} = R - 2\Lambda - \frac{1}{4}F^{\mu\nu a}F_{\mu\nu}^a, \quad (3.1)$$

$$F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + g_{YM}\epsilon^{abc}A_\mu^b A_\nu^c. \quad (3.2)$$

Here, $F_{\mu\nu}^a$ is the strength of SU(2) gauge field, and $a, b, c = (1, 2, 3)$ are the indices of the generators of SU(2) algebra. The A_μ^a are the components of $A = A_\mu^a \tau^a dx^\mu$, where τ^a are the SU(2) generators, which $[\tau^a, \tau^b] = \epsilon^{abc}\tau^c$. The ϵ^{abc} is the totally antisymmetric tensor. The coupling constant of the SU(2) gauge field is g_{YM} .

Figure 8. The plot shows that the maximal current $J_{\max}/T_c^{\Delta+}$ goes down as m^2 grows. The value of $m^2 = -2$ (red), $-5/4$ (green). The parameters are $\mu_0 = 1$, $\mu_\infty = 7.5$, $L = 3$, $\epsilon = 0.5$, $\sigma = 0.5$ and $\kappa = 1/100$.

By scaling the gauge field as $A \rightarrow A/g_{YM}$, eqs. (3.1) and (3.2) become

$$\mathcal{L} = R - 2\Lambda + \kappa \left(-\frac{1}{4} \tilde{F}^{\mu\nu a} \tilde{F}_{\mu\nu}^a \right), \quad (3.3)$$

$$\tilde{F}_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + \epsilon^{abc} A_\mu^b A_\nu^c. \quad (3.4)$$

Where $\kappa = 1/g_{YM}^2$ is the strength of backreaction of the SU(2) gauge field. We can also see that the effect of backreaction decreases as g_{YM} grows. The large limit ($g_{YM} \rightarrow \infty$) corresponds to the probe limit.

The equations of motion from the Lagrangian density (3.1) are

$$\nabla_\mu F^{\mu\nu a} + \epsilon^{abc} A_\mu^b F^{\mu\nu c} = 0, \quad (3.5)$$

$$R_{\mu\nu} + \frac{3}{\ell^2} g_{\mu\nu} - \kappa \left(\frac{1}{2} F_{\mu\lambda}^a F_\nu^{\lambda a} - \frac{1}{8} F_{\alpha\lambda}^a F^{\alpha\lambda a} g_{\mu\nu} \right) = 0. \quad (3.6)$$

In order to construct a holographic model of the p-wave Josephson junction, we bring in two bulk gauge fields $A_1^3 = A_z$ and $A_2^3 = A_x$ on basis of the model of p-wave superconductor. We consider the following ansatz of the SU(2) gauge field

$$\begin{aligned} A &= A_0^3 \tau^3 dt + A_3^1 \tau^1 dy + A_1^3 \tau^3 dz + A_2^3 \tau^3 dx \\ &= \phi \tau^3 dt + \omega \tau^1 dy + A_z \tau^3 dz + A_x \tau^3 dx, \end{aligned} \quad (3.7)$$

where ϕ , ω , A_z and A_x are all the real functions of coordinate x and z . The EoMs (3.5) and (3.6) are also a set of non-linear coupled partial equations with the matter ansatz (3.7)

and the metric ansatz (2.10). These five equations derive from eq. (3.5), four of them are second-order PDEs and the remaining one is a first-order PDE which is constrain equation. Seven equations from eq. (3.6) are second-order PDEs with respect to E_i . Because each equation has thousands of terms, we can not write them down in paper. Obviously, we can only solve them numerically.

In the next step, we will study the following asymptotic forms of the matter field on the AdS boundary ($z = 0$)

$$\omega(z, x) \rightarrow z\omega^{(1)}(x) + z^2\omega^{(2)}(x) + \mathcal{O}(z^3), \quad (3.8a)$$

$$\phi(z, x) \rightarrow \mu(x) - z\rho(x) + \mathcal{O}(z^2), \quad (3.8b)$$

$$A_z(z, x) \rightarrow \mathcal{O}(z^3), \quad (3.8c)$$

$$A_x(z, x) \rightarrow \nu(x) + Jz + \mathcal{O}(z^2). \quad (3.8d)$$

Here, we set $\omega^{(1)} = 0$ and interpret $\langle \mathcal{O} \rangle = \omega^{(2)}$ as the condensation of p-wave superconductor. The asymptotic behaviors of E_i take the same forms as (2.11a)–(2.11g) on the AdS boundary. The chemical potential μ and the phase difference γ take (2.14) and (2.24), respectively.

The critical temperatures of p-wave Josephson junction with different values of κ are shown as below

$$T_c \approx 0.0654\mu(\infty), \quad \kappa = 0, \quad (3.9)$$

$$T_c \approx 0.0613\mu(\infty), \quad \kappa = 1/15, \quad (3.10)$$

$$T_c \approx 0.0578\mu(\infty), \quad \kappa = 1/8. \quad (3.11)$$

From the above, we can see that the critical temperature T_c drops with increasing strength of backreaction κ .

3.2 The numerical results

In figure 9 (a) and (b), we plot the profiles of the functions E_6 and E_7 . From these figures, we can see that E_6 is odd and E_7 is even.

We show the relationship between the current J/T_c^2 and the phase difference γ in figure 10. We take $\kappa = 0, 1/15, 1/8$, respectively. The fitting results are

$$J/T_c^2 \approx 1.94186 \sin \gamma, \quad \kappa = 0, \quad (3.12)$$

$$J/T_c^2 \approx 1.50461 \sin \gamma, \quad \kappa = 1/15, \quad (3.13)$$

$$J/T_c^2 \approx 1.10894 \sin \gamma, \quad \kappa = 1/8. \quad (3.14)$$

From the above, we see that J/T_c^2 still varies as a sine function of γ with fixing κ . Furthermore, J/T_c^2 will decrease when κ grows.

Figure 11 (a) shows the relationship between the maximal current $J_{\max}/T_c^2$ and the width of junction L with increasing $\kappa = 0, 1/15, 1/8$. The p-wave condensation $\langle \mathcal{O} \rangle/T_c^2$ varies a function of L with increasing κ in figure 11 (b). The fitting results are shown

Figure 9. (a) The profile of E_6 . (b) The profile of E_7 . In all the plots, the parameters are $\mu_0 = 1$, $\mu_\infty = 5.5$, $L = 3$, $\epsilon = 0.6$, $\sigma = 0.5$ and $\kappa = 1/100$.

Figure 10. The plot shows that the current J/T_c^2 is proportional to the phase difference γ . From top to bottom, curves correspond to $\kappa = 0, 1/15, 1/8$. We use the parameters $\mu_0 = 1$, $\mu_\infty = 5.5$, $L = 3$, $\epsilon = 0.6$ and $\sigma = 0.5$.

Figure 11. (a) The maximal current $J_{\max}/T_c^2$ decreases exponentially with growing L . (b) The condensation $\langle O \rangle/T_c^2$ decreases exponentially with growing L . When κ increases, $J_{\max}/T_c^2$ and $\langle O \rangle/T_c^2$ will decrease, respectively. From top to bottom, curves correspond to $\kappa = 0, 1/15, 1/8$. The parameters are $\mu_0 = 1$, $\mu_\infty = 5.5$, $\epsilon = 0.6$ and $\sigma = 0.5$.

as follows

$$J_{\max}/T_c^2 \approx 15.8458e^{-L/1.41421}, \quad \kappa = 0, \quad (3.15)$$

$$J_{\max}/T_c^2 \approx 18.5319e^{-L/1.19729}, \quad \kappa = 1/15, \quad (3.16)$$

$$J_{\max}/T_c^2 \approx 18.9418e^{-L/1.06426}, \quad \kappa = 1/8. \quad (3.17)$$

and

$$\langle O \rangle/T_c^2 \approx 39.4108e^{-L/(2 \times 1.61943)}, \quad \kappa = 0, \quad (3.18)$$

$$\langle O \rangle/T_c^2 \approx 48.4891e^{-L/(2 \times 1.28419)}, \quad \kappa = 1/15, \quad (3.19)$$

$$\langle O \rangle/T_c^2 \approx 54.6341e^{-L/(2 \times 1.10103)}, \quad \kappa = 1/8. \quad (3.20)$$

From the results, we know that by fixing κ , $J_{\max}/T_c^2$ still decreases with growing L , exponentially. In addition, $J_{\max}/T_c^2$ goes down as κ increases. The relationship between $\langle O \rangle/T_c^2$ and L is the same as the case of $J_{\max}/T_c^2$.

Finally, we represent the plot of between the maximal current $J_{\max}/T_c^2$ and the temperature T/T_c in figure 12. From the figure, we know that $J_{\max}/T_c^2$ decreases with growing T/T_c by fixing κ , and $J_{\max}/T_c^2$ goes down as κ increases. The reasons that lead to the above results is the same as s-wave junction.

4 Conclusion

Motivated by the effect of backreaction on the s-wave and p-wave holographic superconductors, we studied backreaction to the s-wave and p-wave Josephson junction, respectively. For s-wave Josephson junction, we investigated the the full, dynamic equations of motion

Figure 12. The plot shows that $J_{\max}/T_c^2$ decreases with increasing T/T_c by fixing κ , and $J_{\max}/T_c^2$ will go up, when κ increases. From top to bottom, curves correspond to $\kappa = 1/8, 1/15, 0$. The parameters are $\mu_0 = 1$, $L = 3$, $\epsilon = 0.6$, $\sigma = 0.5$.

including Einstein equations in the (3+1)-dimensional spacetime from the action of U(1) gauge field and complex scalar field, and for p-wave Josephson junction, we considered the backreaction from the SU(2) gauge field. We get a series of partial differential equations of fields that are nonlinear and coupled and solve them numerically. For the s-wave Josephson junction, we take two value of $m^2 = -2, -5/4$. From the numerical results we can see that when the value of m^2 and the strength of backreaction κ are fixed ($m^2 = -2$), the current J/T_c^2 is still proportional to the sine of the phase difference γ . The reasons are that in the probe limit ($\kappa = 0$), the spacetime and the matter (the sum of the gauge field and the scalar field) do not influence each other, the current is proportional to the sine of phase difference; when $\kappa \neq 0$, the backreaction is turned on, note that the the spacetime affects the whole of the matter instead of the gauge field or the scalar field respectively, the relationship between the gauge field and the scalar field is not changed, so the current is still proportional to the sine of phase difference; in addition, the parameter $\kappa = 1/q^2$ is related to the charge q , which is the coupling coefficient between the gauge field and the scalar field and represents the charge of Cooper pair in superconductor, when κ varies, the charge q will change, thus the backreaction only affects the amplitude of the current, so the relationship between current and phase difference holds for sine function with backreaction. The maximal current $J_{\max}/T_c^2$ and the condensation $\langle O \rangle/T_c^2$ decreases exponentially with increasing the width of junction L , respectively, the maximal current $J_{\max}/T_c^2$ decreases as the temperature T/T_c grows. In addition, when the strength of backreaction κ is fixed, $J/T_c^{\Delta+}$, $\langle O \rangle/T_c^{\Delta+}$ and $J_{\max}/T_c^{\Delta+}$ go down as m^2 increases. The reason is that the larger

the mass of scalar field is, the harder the scalar hair forms. When the value of m^2 is fixed ($m^2 = -2$), J/T_c^2 , $\langle O \rangle/T_c^2$ and $J_{\max}/T_c^2$ which varies with L go down as κ grows. The reasons are that the backreaction κ makes the Cooper pairs generate harder, and the charge q and the coherence length become smaller. It is noteworthy that $J_{\max}/T_c^2$ which varies with T/T_c goes up as κ increases, this is because the effect of low temperature is stronger than that of backreaction. For p-wave Josephson junction, the property is the same as the case of s-wave Josephson junction.

Now, we have studied holographic models of s-N-s and p-N-p Josephson junctions away from probe limit, moreover we would like to investigate the s-I-s and p-I-p junctions with backreaction in the future. In [57, 59], the s-N-s Josephson junction in the probe limit have been studied in the Lifshitz gravity and massive gravity, respectively. Thus our next study would be to generalize the above work to the case with backreaction.
