Martin Euser | *Pythagorean Triangles and Musical Proportions*

Martin Euser researches the factor $\sqrt{(2N-1)}$ and its interesting relations between musical proportions and Pythagorean triangles. The simple scheme $N \pm \sqrt{N}$ is also interesting as a generative set of pairs of numbers. This set looks like a prototype for the generative set of pairs of numbers discussed in a previous article by the author.

Introduction

Since writing a previous article on Sacred Geometry, I have done a little research on the factor $\sqrt{(2N-1)}$ and found some interesting relations between musical proportions and Pythagorean triangles. Furthermore, I have looked into the matter of the “root-factor” scheme a bit further and found that the simple scheme $N \pm \sqrt{N}$ is also interesting as a generative set of pairs of numbers.¹ This set looks like a prototype for the generative set of pairs of numbers I have discussed in a previous article. I will present these findings summarily and leave it to the reader to elaborate upon them.

$\sqrt{(2N-1)}$ as a geometric mean

The thing that got me started this time was a reference to Adrastus by Theon of Smyrna.² Adrastus is said to have said that out of all the different mathematical means the geometrical mean is the most important. Why this is so, is not made clear. However it may be, I focused on the factor $\sqrt{(2N-1)}$ and thought it would be interesting to consider this factor as a geometrical mean. Hence I sought two terms that would yield this factor. Proceed as follows:

$$a : \sqrt{(2N-1)} = \sqrt{(2N-1)} : b$$

hence: $ab = 2N - 1$.

I dissolved $2N-1$ into two component factors:

$$\sqrt{(2N)} + 1$$

and

$$\sqrt{(2N)} - 1,$$

which can be taken to be a respectively b . Some interesting features arise from these factors: $a - b = 2$ for all N , and $\sqrt{(2N)}$ yields integral values for $N = 2c^2$, namely, $2c$. When you elaborate these values for $2c$ you will find 2,4,6,8,10, etc., a series that shows musical proportions (4:2 is an octave, 6:4 is a fifth, etc.).

The number 2 is prevalent here. The terms a and b form interesting series when $N = 2c^2$, namely, for a :

$$3, 5, 7, 9...$$

and for c :

$$1, 3, 5, 7...$$

which are of the form $2N+1$ or $2N-1$ ($N \geq 1$).

One hypothesis could be that these values are the input in the term $\sqrt{(2N-1)}$ in the root-scheme formula. This would link Pythagorean triangles with this formula (see below why this could be so).

Proportions

Since proportions are the thing we're after in sacred geometry, I had a look at the proportions of $\sqrt{(p/q)}$ where $p = 2d^2$ and $q = 2e^2$.

This formula gives rise to musical proportions. For $d = 2$ and $e = 1$ it yields, $2/1 = 2$, the octave; for $d = 3$ and $e = 2$ it yields $3/2$, the third or fifth; for $d = 4$ and $e = 3$ it yields: $4/3$, the fourth; etc. The formula $2N^2$ is thus seen to be connected with musical proportions.

Now, for some intuitive reason, I started to combine the variables d and e in the following fashion:

- add squares of d and e : $d^2 + e^2 = r$;
- subtract squares of d and e : $d^2 - e^2 = p$;
- double product of d and e : $2de = q$.

For $d=2$ and $e=1$ this procedure renders,

$$r = d^2 + e^2 = 5 ; p = d^2 - e^2 = 3 ; q = 2de = 4,$$

which recalled the famous Pythagorean triangle with sides 3, 4 and 5. This triangle is common in the physical shapes/forms of many fishes, as Doczi shows in his book on the power of limits.³

For $d=3$ and $e=2$ we get,

$$r = d^2 + e^2 = 13 ; p = d^2 - e^2 = 5 ; q = 2de = 12,$$

and, yes, this is another famous Pythagorean triangle with sides 5, 12, 13. And so on for higher values for d and e .

So, a correlation is established between Pythagorean triangles and musical proportions, as I have proven here mathematically. These triangles seem to be connected to the root-number

scheme too. I would not be surprised when they would play a vital role in the structure-function-order of nature (e.g. in atomic shell structure). After all, Pythagoras was a very wise man, who taught the mysteries in his Mystery-school and it is very likely that he knew a lot of the workings of nature, being a (high degree) initiate himself.

Very simple properties for the Pythagorean triangles can be derived from what I have deduced already:

$$r - q = d^2 + e^2 - 2de = (d - e)^2 = 1$$

because e is taken to be $d + 1$.

$$r - p = d^2 + e^2 - (d^2 - e^2) = 2d^2,$$

which is the famous formula for periodicity of electronic shell-structure.

Interestingly enough, $r + p = 2e^2$, which refers to the same formula, but to the next shell-number ($e = d + 1$).

This means that the following relations between p , q , r and d , e hold:

$$p = d + e = 2(e - 1) ; q = 2de = 2(e^2 - e) ; r = q + 1 = 2de + 1 = 2(e^2 - e) + 1$$

(Figure 1).

Thus, the Pythagorean triangles can be characterized by one variable, e , which starts with value $e = 2$ to render the 3,4,5 triangle and so on, proceeding in incremental fashion $e = 3$, $e = 4$, etc. Replace e by N , and we get $p = 2N - 1$, the term appearing in the $\sqrt{2N - 1}$.

Now, $q = 2N(N - 1)$, which equals the double of the geometric mean of the pair,

$$N^2 + N\sqrt{2N - 1}$$

and

$$N^2 - N\sqrt{2N - 1}.^4$$

Transformation of Pythagorean triangle into another one

Fig. 3

This is an interesting result, the ramifications of which are not yet clear. There may be a relation to a very simple generative set of number-pairs:

$$N + \sqrt{N}$$

and

$$N - \sqrt{N}.$$

These pairs have the following means:

$$A = N; G = \sqrt{N(N-1)}; H = N-1,$$

which means are connected to the previously mentioned pairs:

$$N^2 \pm N\sqrt{2N-1},$$

because in that case $A = N^2$; $H = (N-1)^2$ and $G = N(N-1)$, which are simply the squares of the values of the means of the pairs $N \pm \sqrt{N}$.

One hypothesis is that $A = N$ and $H = N-1$ feature as the terms d and e in the formulas above which connects them to p , q and r in the Pythagorean triangles.

Note that $A + H = 2N-1$. Furthermore, A/H gives a musical proportion, at least for $N = 2, 3, 4$ and $N=9$ in the Pythagorean musical scheme.

After considering the terms $A=N$ and $H=N-1$, I noted that the difference between them is one unit, exactly as is the case with the variables r and q in the Pythagorean triangle. So, I figured that it would be interesting to identify A and H as the sides of this triangle and calculated the side p to be equal to $\sqrt{2N-1}$! See Figure 2.

So, this is another way of viewing the Pythagorean triangles, and it may be interesting to connect the former description with this one. Mathematically, this points to some transformation of variables, mapping one description onto the other.

Indeed, I had a look at these two ways of describing Pythagorean triangles and discovered some new facets:

- embeddedness of triangles into a larger set (hierarchies, classes/subclasses, sets and subsets or whatever is an appropriate designation for this feature);
- a kind of repetition of these sets of triangles (fractality?);
- appearance of the famous *phi* proportion as sides of a Pythagorean prototypical triangle;
- connections between the small side of a triangle and a corresponding one in the next set of triangles, as well as within the same set.

In order to present my findings in a visual way (and not making this article too boring), I'll include a couple of images that show the features mentioned above (Figure 3).

Comment: a simple squaring function will transform p into a new value for the short rectangular side of a Pythagorean triangle. The transformation of q is also simple: form the double product of q and r and this will be the new value for q . The interesting feature is that you can repeat this procedure over and over again (in two directions) (Figure 4). To make this

"Evolution" of Pythagorean triangles: the same procedure repeated again and again

Fig. 4

Fig. 5

abstract picture a bit more understandable we must fill in some values for N and have a look at the following tables Figure 5.

In the tables I've indicated the connection between triangles within and across tables by the transformation $N \geq N2 + (N-1)^2$. This transformation is correlated with the other transformations $p \geq p^2$, $q \geq 2qr$. Note also that the famous ϕ (*phi*) proportion makes its appearance in one of the tables I've shown you in the Figure 5. This may be indicative of the richness of the system I'm trying to research. This system (the various representations of Pythagorean triangles, the transformations, correlations, etc.) reminds me a bit of the theosophical teachings about the development, evolution or emanation of the Elements (earth, water, air, fire, aether, etc.) out of one another in serial progression. It exhibits a clear structure of classes with subclasses — hierarchical, so to speak, possibly being groups and subgroups in a mathematical sense — another feature to research. It is possible to generate more of these triangles as indicated in the figures above, showing a kind of fractal nature of the entire system, perhaps.

One thing is certain: there remains a lot to discover regarding the field of Sacred Geometry as it pertains to nature.
