Ovulids, cowry-like mollusks, are permanent ectoparasites of black corals and octocorals (Lorenz and Fehse 2009). Pacific sea fans (Octocorallia: Gorgoniidae: *Pacifigorgia*) host an ovulid identified as *Neosimnia avena* (G. B. Sowerby II, 1832) (Mollusca: Gastropoda: Ovulidae), which mimics its octocoral host matching both coenenchyme and polyps (Fig. 1a–c). There are more than 30 species of *Pacifigorgia* that are confined to the Eastern Pacific rocky-coral reefs, and each species contains a specialized *N. avena*. At the remote island of Malpelo (Colombia), for instance, there are only two sea fan species with very different colorations and branching shapes (Sánchez et al. 2011), each containing mimetic *N. avena* ectoparasites (Fig. 1b, c). Are all these nearly perfectly adapted symbionts the same species? Is host morphological resemblance a selective driving force for *Neosimnia*? Although *N. avena* is commonly found on gorgonian corals (Lorenz and Fehse 2009), it is uncertain whether speciation in these symbionts matches the hosts' evolutionary processes. However, *Pacifigorgia*-*N. avena* is a promising biological model for studying ecological speciation and coevolution in coral reefs.
