Dear Editor,

The recent report on eNOS polymorphisms and moyamoya disease is very interesting [1]. Park et al. reported that “pediatric and adult-onset moyamoya disease have different genetic backgrounds [1].” This observation is very interesting. Before finalized summarizing, there are some concerns. First, the investigation covered only all four main polymorphisms, not all; hence, there is a possibility for the effect of other non-studied polymorphisms. The good example is Glu298Asp variant that is

reported for the strong relationship with many vascular disorders [2].
