Peaks denoting h_{+1} and h_{-1} in the EPR spectra of spin-labeled fatty acids as shown in Figs. 2–7 are partially due to anisotropic motion in the large liposomes formed by $C_{12}E_9$ detergent solutions and even depend to some extent on polarity, ionic strength and the content of organic solvents herein as can be seen in the absence of any protein as described recently in “EPR Spectra of Spin-labeled Fatty Acids in Detergent Solutions: “Immobilized Species” in the Absence of Protein” by S. Kuntz, F. Leinisch, K. Hideg, W.E. Trommer, Appl Magn Reson 37, 455–461 (2010). Hence, our previous interpretation of these peaks as protein-bound fatty acids is only qualitatively correct, not quantitatively.
