In the original method section, exclusion criteria were inadvertently included that were not applied to the study: multi-fetal gestation, diagnosed fetal anomaly, progesterone use, and illicit drug use. Therefore, in analyses, 5 women were included (multi-fetal gestation, $n=2$, stillborn delivery, $n=2$, and fetal anomaly, $n=1$) who should have been excluded, and progesterone use ($n=3$) and some illicit substances (e.g., methadone) ($n=9$) were not captured. Analyses were conducted excluding multi-fetal gestation,

stillborn delivery, and fetal anomaly ($n=5$) while controlling for progesterone use and alcohol/illicit drug use. Findings remained the same as those reported in the published paper. Specifically, simple mediation models with pregnancy-specific distress (95% CI: -36.54, -6.42) and depressive symptoms (95% CI: -27.87, -0.99) remained significant, whereas models with perceived stress (95% CI: -34.84, 5.59) and general anxiety (95% CI: -25.65, 7.70) were not significant. In addition, in a parallel mediation model, pregnancy-specific distress (95% CI: -32.43, -0.06) but not depressive symptoms (95% CI: -23.26, 6.25) remained as a significant mediator.
