Abstract We present a report on a patient with acute glaucoma. Slit-lamp-adapted optical coherence tomography (SL-OCT) confirmed a pupillary block due to a claw lens. After laser iridectomy the situation stabilized. Thus, SL-OCT allows non-invasive, high-resolution imaging in acute angle-closure glaucoma and may be helpful with the differential diagnosis of pupillary block glaucoma and the documentation of the surgical result.

Keywords Tomography · Optical coherence · Glaucoma · Angle-closure

Slit-lamp-adapted optical coherence tomography (SL-OCT) was recently introduced for anterior segment imaging and goniometry [1]. In the present report we used SL-OCT in the diagnosis and follow-up of pupillary block glaucoma.

An 80-year-old man presented with acute glaucoma of the right eye after pharmacological mydriasis. Medical history revealed phacoemulsification that had been carried out elsewhere, complicated by intra-vitreal loss of cortex material 2 years ago. He

had been treated by subsequent anterior vitrectomy and Artisan lens implantation.

At presentation at our department, he had an intraocular pressure of 52 mmHg. Slit-lamp biomicroscopy showed a peripheral flattened anterior chamber, and no peripheral iridectomy was recognizable. SL-OCT confirmed the absence of peripheral iridectomy, a pupillary block due to the claw lens and bulging of the posterior chamber with secondary angle closure. We measured a central depth of the anterior chamber of 0.91 mm (Fig. 1A). After laser iridectomy the situation stabilized and the central depth became 1.94 mm (Fig. 1B).

Comment

Examination of the anterior segment anatomy is nowadays facilitated by digital devices like the very high frequency ultrasound scan [2]. In this report we used a newly developed method: slit-lamp-adapted optical coherence tomography. SL-OCT allows non-invasive, high-resolution imaging in acute angle-closure glaucoma and may thus be helpful with the differential diagnosis of pupillary block glaucoma and the documentation of the surgical result.

Acknowledgements The instrument for slit-lamp-adapted optical coherence tomography was kindly provided by Medical Workshop, Groningen, Netherlands, under support from the manufacturer, 4-OPTICS, Lübeck, Germany. No financial support was offered from any source.

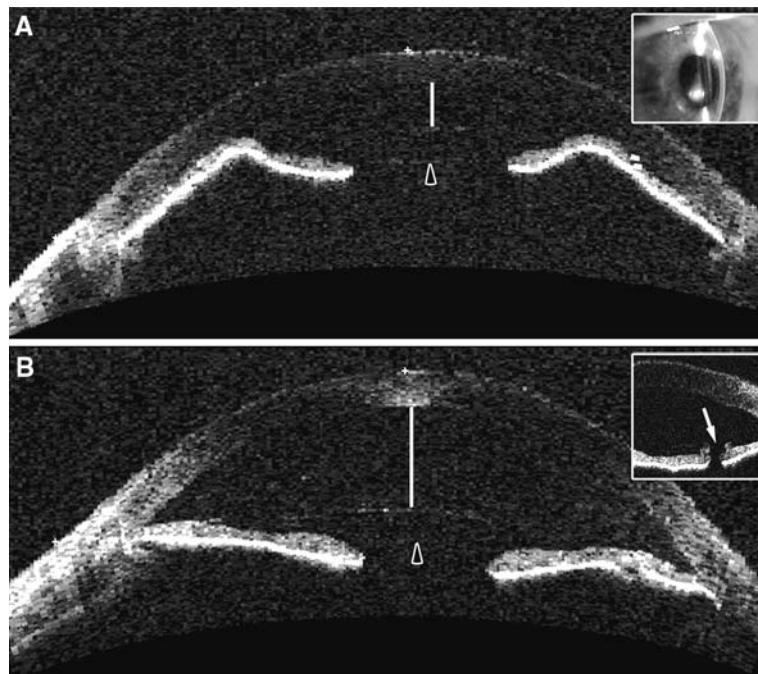

Fig. 1 Panel **A** shows slit-lamp-adapted optical coherence tomography (15 mm scan) of the patient with acute glaucoma due to the iris-fixed Artisan lens (*the inset* shows the slit-lamp biomicroscopy). The depth of the anterior chamber is decreased (*bar*) due to a pupillary block induced by an Artisan lens (*arrowhead*). Note that the anterior chamber flattening is

limited by the haptics of the intraocular lens. Panel **B** shows slit-lamp-adapted optical coherence tomography (15 mm scan) after laser iridectomy has deepened the anterior chamber. The depth of the anterior chamber has become normal again. *The inset* shows a patent iris defect, visible (*arrow*) on a 7.2 mm scan
