Discrete Tori and Trigonometric Sums

Alexander Grigor'yan[1] · Yong Lin[2] · Shing-Tung Yau[2,3]

Abstract
We prove a discrete analogue of the Poisson summation formula.

1 Introduction

The well know Poisson summation formula says that, for any positive real t ,

$$\sum_{k \in \mathbb{Z}} e^{-k^2 t} = \sqrt{\frac{\pi}{t}} \sum_{n \in \mathbb{Z}} \exp\left(-\frac{\pi^2 n^2}{t}\right). \tag{1.1}$$

It can be proved by using the heat kernel $p_t^{\mathbb{S}}(x, y)$ on the unit circle $\mathbb{S}$ as follows. For the trace of the heat operator

$$P_t f(x) = \int_{\mathbb{S}} p_t^{\mathbb{S}}(x, y) f(y) \, dy,$$

acting in $L^2(\mathbb{S})$, there are two expressions as follows:

$$\text{trace } P_t = \sum_{j=0}^{\infty} e^{-\lambda_j t}, \tag{1.2}$$

where $\{\lambda_j\}$ is the sequence of all the eigenvalues of the Laplace operator $\Delta = \frac{d^2}{dx^2}$ on $\mathbb{S}$ counted with multiplicity, and

$$\text{trace } P_t = \int_{\mathbb{S}} p_t^{\mathbb{S}}(x, x) \, dx. \tag{1.3}$$

Comparing (1.2) and (1.3), using that that the sequence $\{\lambda_j\}$ consists of the numbers k^2, $k \in \mathbb{Z}$, and that

$$p_t^{\mathbb{S}}(x, y) = \sum_{n \in \mathbb{Z}} p_t^{\mathbb{R}}(x + 2\pi n, y)$$

where

$$p_t^{\mathbb{R}}(x, y) = \frac{1}{(4\pi t)^{n/2}} \exp\left(-\frac{|x - y|^2}{4t}\right)$$

is the Gauss-Weierstrass function, one obtains (1.1) (see, for example, [5, Exercise 10.18]).

Similar ideas have been widely used in the literature for obtaining various trace formulas and estimates of eigenvalues of Riemannian manifolds, for example, in [1, 3, 4], etc. In the framework of graphs we mention [2] where the above idea was applied to the heat kernels $p_t^T(x, y)$ on discrete tori T in $\mathbb{Z}^n$ and, hence, a certain analogue of the Poisson summation formula was obtained.

In this paper we also work with discrete tori but use a *discrete* time heat kernel $q_s(x, y)$, $s \in \mathbb{Z}_+$, instead of the one with a continuous time $t \in \mathbb{R}_+$. In fact, $q_s(x, y)$ is the transition density of a simple random walk on the graph in question. As a result, we obtain explicit formulas for some trigonometric sums that seems to be new.

Our results are stated in Theorem 3.2 and Corollary 3.4. To illustrate them, let us present them for 2-dimensional discrete tori. For any 2×2 integer matrix M and for any non-negative integer s, set

$$C_s(M) = \sum_{\substack{v \in M\mathbb{Z}^2, \, z \in \mathbb{Z}_+^2 \\ |v_1| + |v_2| + 2z_1 + 2z_2 = s}} \frac{s!}{z_1! z_2! (|v_1| + z_1)! (|v_2| + z_2)!}. \tag{1.4}$$
Consider a 2×2 integer matrix $\mathcal{A}$ with $m := \det \mathcal{A} > 1$. Then the lattice $\mathcal{A}\mathbb{Z}^2$ contains $m\mathbb{Z}^2$ so that the quotient

$$\mathcal{T}_\mathcal{A} = \mathcal{A}\mathbb{Z}^2 / m\mathbb{Z}^2$$

is well defined (in the sense of groups) and can be regarded as a discrete torus. Note that $\mathcal{T}_\mathcal{A}$ contains m vertices.

Theorem 1.1 *For any non-negative integer s, we have the identity*

$$\sum_{(k,l)\in\mathcal{T}_\mathcal{A}} \left(\cos \frac{2\pi k}{m} + \cos \frac{2\pi l}{m} \right)^s = \frac{m}{2^s} C_s(M), \tag{1.5}$$

where $M = m(\mathcal{A}^*)^{-1}$ and $\mathcal{A}^*$ denotes the transpose of $\mathcal{A}$.

Example 1.2 Consider the matrix

$$\mathcal{A} = \begin{pmatrix} 3 & 1 \\ -1 & 2 \end{pmatrix}$$

with $m = \det A = 7$. The torus $\mathcal{T}_\mathcal{A}$ is shown on Fig. 1 , and it contains the following 7 vertices: $(0, 0)$, $(1, 2)$, $(2, 4)$, $(4, 1)$, $(3, 6)$, $(6, 5)$, $(5, 3)$.

Hence, the sum in the left hand side of (1.5) is equal to

$$\sigma_s := 2^s + \left(\cos \frac{2\pi}{7} + \cos \frac{4\pi}{7} \right)^s + \left(\cos \frac{4\pi}{7} + \cos \frac{8\pi}{7} \right)^s + \left(\cos \frac{8\pi}{7} + \cos \frac{2\pi}{7} \right)^s$$

$$+ \left(\cos \frac{6\pi}{7} + \cos \frac{12\pi}{7} \right)^s + \left(\cos \frac{12\pi}{7} + \cos \frac{10\pi}{7} \right)^s + \left(\cos \frac{10\pi}{7} + \cos \frac{6\pi}{7} \right)^s .$$

In this case the matrix M is equal to

$$M = \begin{pmatrix} 2 & 1 \\ -1 & 3 \end{pmatrix},$$

Fig. 2 The lattice $M\mathbb{Z}^2$
and the lattice $M\mathbb{Z}^2$ is shown on Fig. 2

Computation by means of (1.4) is performed in Sect. 3.3 and results in

$$C_1(M) = 0, \ C_2(M) = 4, \ C_3(M) = 6, \ C_4(M) = 44, \ C_5(M) = 130$$

By (1.5) we have $\sigma_s = \frac{7}{2^s} C_s(M)$ which yields

$$\sigma_1 = 2, \ \ \sigma_2 = 7, \ \ \sigma_3 = \frac{21}{4}, \ \ \sigma_4 = \frac{77}{4}, \ \ \sigma_5 = \frac{455}{16}.$$

The structure of this paper is as follows. In Sect. 2 we have collected all necessary information about the Markov operators on weighted graph and their heat kernels, including the heat kernels on Cartesian products and quotients of graphs. These facts are rather elementary but they are hardly available in the literature in this concise form. Section 3 contains the main results mentioned above, their proofs, and examples.

2 Discrete Time Heat Kernels

2.1 Weighted Graphs

We briefly outline some fact from [6] about heat kernels on weighted graphs. Let Γ be a locally finite graph where we denote by Γ also the set of vertices of this graph. We write $x \sim y$ if the vertices x, y of Γ are connected by an edge in Γ. Let μ_{xy} be a symmetric non-negative function on pairs xy of vertices such that $\mu_{xy} > 0 \Leftrightarrow x \sim y$. Define the weight on the vertices of Γ by

$$\mu(x) = \sum_{\{y \in \Gamma : y \sim x\}} \mu_{xy} = \sum_{y \in \Gamma} \mu_{xy}$$

and assume in what follows that $\mu(x) > 0$ for all $x \in \Gamma$ (that is, each vertex has at least 1 edge).

Consider a Markov operator $P = P_\Gamma$ acting on functions $f : \Gamma \to \mathbb{R}$ as follows:

$$Pf(x) = \frac{1}{\mu(x)} \sum_{y \in \Gamma} f(y)\, \mu_{xy}\,.$$

It is clear that $Pf \geq 0$ if $f \geq 0$ and $P1 = 1$. It follows that P acts in any space $l^r(\Gamma, \mu)$ with $r \in [1, \infty]$ and satisfies the norm-bound $\|P\| \leq 1$. Besides, P is self-adjoint in $l^2(\Gamma, \mu)$.

The weight μ_{xy} is called *simple* if $\mu_{xy} = 1$ for all $x \sim y$. In this case, $\mu(x) = \deg(x)$ and

$$Pf(x) = \frac{1}{\deg(x)} \sum_{y \sim x} f(y)\,.$$

For any $s \in \mathbb{Z}_+$ the power P^s is well defined, and the sequence $\{P^s\}_{s \geq 0}$ is a reversible Markov chain on Γ. It is easy to see that

$$P^s f(x) = \sum_{y \in \Gamma} q_s(x, y)\, f(y)\, \mu(y),$$

where the function $q_s(x, y) = q_s^\Gamma(x, y)$ is defined inductively by $q_0(x, y) = \frac{1}{\mu(y)} \delta_{x,y}$,

$$q_1(x, y) = \frac{\mu_{xy}}{\mu(x)\,\mu(y)} \quad \text{and} \quad q_{s+1}(x, y) = \sum_{z \in \Gamma} q_s(x, z)\, q_1(z, y)\, \mu(z)\,.$$

The function $q_s(x, y)$ is called the *discrete time heat kernel* or the *transition density* of the Markov chain $\{P^s\}$.

2.2 Product of Regular Graphs

A graph Γ is called d-regular if any vertex has exactly d neighbors, that is, $\deg(x) = d$ for all $x \in \Gamma$.

Let $\{\Gamma_j\}_{j=1}^n$ be a finite sequence of graphs. Consider their Cartesian product

$$\Gamma = \Gamma_1 \square \Gamma_2 \square \ldots \square \Gamma_n.$$

The vertices of Γ are n-tuples $x = (x_1, \ldots x_n)$ where $x_j \in \Gamma_j$. We write for some $j = 1, \ldots, n$

$$x \overset{\Gamma_j}{\sim} y$$

if

$$x_j \sim y_j \text{ and } x_k = y_k \text{ for all } k \neq j.$$

The edges $x \sim y$ in Γ are defined by the following rule:

$$x \sim y \Leftrightarrow x \overset{\Gamma_j}{\sim} y \text{ for some } j = 1, ..., n. \tag{2.1}$$

Assume further that each Γ_j is d_j-regular. Then Γ is d-regular with

$$d = d_1 + ... + d_n.$$

Let us endow all the graphs Γ_j and Γ with a simple weight. We have then for the Markov operator P_Γ on Γ

$$P_\Gamma f(x) = \frac{1}{d} \sum_{y \sim x} f(y) = \frac{1}{d} \sum_{j=1}^{n} \sum_{\substack{\Gamma_j \\ y \sim x}} f(y).$$

Let us consider the Markov operator P_{Γ_j} on Γ_j as acting also on functions $f(x)$ on Γ along the component x_j, so that

$$P_{\Gamma_j} f(x) = \frac{1}{d_j} \sum_{\substack{\Gamma_j \\ y \sim x}} f(y).$$

It follows that

$$d P_\Gamma f(x) = \sum_{j=1}^{n} \sum_{\substack{\Gamma_j \\ y \sim x}} f(y) = \sum_{j=1}^{n} d_j P_{\Gamma_j} f(x).$$

Since all the operators P_{Γ_j} commute on Γ, we obtain that, for any $s \in \mathbb{Z}_+$,

$$d^s P_\Gamma^s = \left(\sum_{j=1}^{n} d_j P_{\Gamma_j} \right)^s = \sum_{\substack{(s_1,...,s_n) \in \mathbb{Z}_+^n \\ s_1 + ... + s_n = s}} \binom{s}{s_1, \, ..., \, s_n} \prod_{j=1}^{n} d_j^{s_j} P_{\Gamma_j}^{s_j}, \tag{2.2}$$

where $\binom{s}{s_1,...,s_n} = \frac{s!}{s_1!...s_n!}$ is a multinomial coefficient. Since

$$P_\Gamma^s f(x) = \sum_{y \in \Gamma} d q_s^\Gamma(x, y) f(y),$$

it follows that

$$d^{s+1} q_s^\Gamma(x, y) = \sum_{\substack{(s_1,...,s_n) \in \mathbb{Z}_+^n \\ s_1 + ... + s_n = s}} \binom{s}{s_1, \, ..., \, s_n} \prod_{j=1}^{n} d_j^{s_j+1} q_{s_j}^{\Gamma_j}(x_j, y_j). \tag{2.3}$$

2.3 Quotient of Graphs

Let (Γ, μ) be a weighted graph with $\mu(x) > 0$ so that the Markov operator P_Γ is well defined. Let G be a group of weighted graph automorphisms of Γ, that is,

$$\mu_{gx,gy} = \mu_{x,y} \quad \forall g \in G, \forall x, y \in \Gamma.$$

Then the vertex weight $\mu(x)$ is also G-invariant. It follows that the operator P_Γ commutes with G, that is,

$$P_\Gamma(f \circ g) = (P_\Gamma f) \circ g,$$

because

$$(P_\Gamma f) \circ g(x) = \frac{1}{\mu(gx)} \sum_{y \in \Gamma} f(y) \mu_{gx,y}$$

$$= \frac{1}{\mu(x)} \sum_{y \in \Gamma} f(y) \mu_{x,g^{-1}y}$$

$$= \frac{1}{\mu(x)} \sum_{z \in \Gamma} f(gz) \mu_{x,z}$$

$$= P_\Gamma(f \circ g)(x).$$

Consequently, also $q_s(x, y)$ commutes with G, that is,

$$q_s(x, y) = q_s(gx, gy) \quad \forall g \in G.$$

Consider the quotient $Q = \Gamma/G$ that consists of the equivalence classes $[x]$ of vertices $x \in \Gamma$ under the equivalent relation

$$x \equiv y \bmod G \quad \Leftrightarrow x = gy \text{ for some } g \in G.$$

The quotient Q has a natural weight:

$$\mu^Q_{[x],[y]} := \sum_{g \in G} \mu_{x,gy}, \tag{2.4}$$

so that (Q, μ^Q) is a weighted graph. For example, if the weight μ_{xy} on Γ is simple then

$$\mu^Q_{[x],[y]} = \operatorname{card} \{g \in G : x \sim gy\}.$$

However, the weight μ^Q may be not simple because the G-orbit of y may have more than 1 vertex adjacent to x.

Observe that always

$$\mu\left([x]\right) = \mu\left(x\right) \tag{2.5}$$

because

$$\mu\left([x]\right) = \sum_{[y]\in Q} \mu_{[x],[y]} = \sum_{[y]\in Q}\sum_{g\in G} \mu_{x,gy} = \sum_{z\in\Gamma} \mu_{x,z} = \mu\left(x\right).$$

Any G-periodic function f on Γ can be regarded as a function on Q by

$$f\left([x]\right) = f\left(x\right).$$

Clearly, $P_\Gamma f$ is also G-periodic. Let us verify that

$$P_Q f\left([x]\right) = P_\Gamma f\left(x\right). \tag{2.6}$$

Indeed, we have

$$
\begin{aligned}
P_Q f\left([x]\right) &= \frac{1}{\mu\left([x]\right)} \sum_{[y]\in Q} f\left([y]\right) \mu_{[x],[y]}\\
&= \frac{1}{\mu\left(x\right)} \sum_{[y]\in Q} f\left(y\right) \sum_{g\in G} \mu_{x,gy}\\
&= \frac{1}{\mu\left(x\right)} \sum_{z\in\Gamma} f\left(z\right) \mu_{xz}\\
&= P_\Gamma f\left(x\right).
\end{aligned}
$$

Lemma 2.1 *We have for all $x, y \in \Gamma$ and $s \in \mathbb{Z}_+$*

$$q_s^Q\left([x],[y]\right) = \sum_{g\in G} q_s^\Gamma\left(x, gy\right). \tag{2.7}$$

Proof Clearly, the right hand side of (2.7) is G-periodic in x and y and, hence, can be regarded as a function on $Q \times Q$. For any G-periodic function f on Γ, we have by (2.6)

$$
\begin{aligned}
P_Q^s f\left([x]\right) = P_\Gamma^s f\left(x\right) &= \sum_{z\in\Gamma} q_s^\Gamma\left(x, z\right) f\left(z\right) \mu\left(z\right)\\
&= \sum_{g\in G}\sum_{[y]\in Q} q_s^\Gamma\left(x, gy\right) f\left(gy\right) \mu\left(gy\right)\\
&= \sum_{[y]\in Q}\sum_{g\in G} q_s^\Gamma\left(x, gy\right) f\left(y\right) \mu\left(y\right)
\end{aligned}
$$

$$= \sum_{[y] \in Q} \left(\sum_{g \in G} q_s^{\Gamma}(x, gy) \right) f([y]) \mu([y])$$

whence (2.7) follows.   □

In what follows we simplify notation by writing x instead of $[x]$ when this does not cause confusion.

2.4 The Heat Kernel on $\mathbb{Z}^n$

It is known that the transition density $q_s^{\mathbb{Z}}(x, y)$ of a simple random walk on $\mathbb{Z}$ is given by

$$q_s^{\mathbb{Z}}(x, y) = \begin{cases} \frac{1}{2^{s+1}} \left(\frac{s}{\frac{s-k}{2}} \right), & s \geq k \text{ and } s \equiv k \mod 2, \\ 0, & \text{otherwise,} \end{cases} \tag{2.8}$$

where $k = |x - y|$ (see [6, Eq.(5.6)]). Let us determine $q_s^{\mathbb{Z}^n}(x, y)$. By (2.3), we have

$$(2n)^{s+1} q_s^{\mathbb{Z}^n}(x, y) = \sum_{s_1 + \dots + s_n = s} \frac{s!}{s_1! \dots s_n!} 2^{s_1+1} q_{s_1}^{\mathbb{Z}}(x_1, y_1) \dots 2^{s_n+1} q_{s_n}^{\mathbb{Z}}(x_n, y_n).$$

Setting

$$k_i = |x_i - y_i|,$$

we obtain

$$(2n)^{s+1} q_s^{\mathbb{Z}^n}(x, y) = \sum_{s_1 + \dots + s_n = s} \frac{s!}{s_1! \dots s_n!} \prod_{i=1}^{n} \frac{s_i!}{\left(\frac{s_i - k_i}{2} \right)! \left(\frac{s_i + k_i}{2} \right)!}$$

$$= \sum_{s_1 + \dots + s_n = s} s! \prod_{i=1}^{n} \frac{1}{\left(\frac{s_i - k_i}{2} \right)! \left(\frac{s_i + k_i}{2} \right)!},$$

where the summation indices $s_1, \dots, s_n$ satisfy in addition

$$s_i \geq k_i \text{ and } s_i \equiv k_i \mod 2.$$

Changing $j_i = \frac{s_i - k_i}{2}$, setting $j = (j_1, \dots, j_n)$, $k = (k_1, \dots, k_n)$, and using the multiindex notation

$$|j| = \sum_{i=1}^{n} j_i \quad \text{and} \quad j! = \prod_{i=1}^{n} j_i,$$

we obtain

$$q_s^{\mathbb{Z}^n}(x, y) = \frac{1}{(2n)^{s+1}} \sum_{\{j \in \mathbb{Z}_+^n : \, 2|j|+|k|=s\}} \frac{s!}{j! \, (k+j)!}. \tag{2.9}$$

2.5 Heat Kernels on Discrete Tori

Let us fix some integer valued $n \times n$ matrix M with

$$m := \det M > 1.$$

We regard $M\mathbb{Z}^n$ as an additive group that acts on $\mathbb{Z}^n$ by shifts. Consider a discrete torus

$$T = \mathbb{Z}^n / M\mathbb{Z}^n \tag{2.10}$$

that is a finite graph with m vertices.

Let μ be the weight on T that comes from the simple weight of $\mathbb{Z}^n$ by (2.4). By (2.5), we have

$$\mu(x) = 2n \ \text{ for any } x \in T.$$

By (2.7), the heat kernel on (T, μ) is given by

$$q_s^T(x, y) = \sum_{v \in M\mathbb{Z}^n} q_s^{\mathbb{Z}^n}(x + v, y).$$

Using (2.9) and setting $x = y$, we obtain

$$q_s^T(x, x) = \sum_{v \in M\mathbb{Z}^n} q_s^{\mathbb{Z}^n}(x + v, x) = \frac{1}{(2n)^{s+1}} \sum_{v \in M\mathbb{Z}^n} \sum_{\substack{j \in \mathbb{Z}_+^n \\ 2|j|+|v|=s}} \frac{s!}{j! \, (\overline{v}+j)!}. \tag{2.11}$$

3 Trigonometric Sums

3.1 Eigenfunctions on Discrete Tori

The following function is an eigenfunction of $P_{\mathbb{Z}^n}$ for any $w \in \mathbb{R}^n$:

$$f_w(x) = e^{2\pi i \langle w, x \rangle}.$$

Indeed, we have

$$P_{\mathbb{Z}^n} f_w(x) = \frac{1}{2n} \sum_{y \sim x} f_w(y) = \frac{1}{2n} \sum_{k=1}^{n} (f_w(x + e_k) + f_w(x - e_k))$$

$$= \frac{1}{2n} e^{2\pi i \langle w, x \rangle} \sum_{k=1}^{n} \left(e^{2\pi i \langle w, e_k \rangle} + e^{-2\pi i \langle w, e_k \rangle} \right) = \left(\frac{1}{n} \sum_{k=1}^{n} \cos 2\pi w_k \right) f_w (x),$$

where $\{e_k\}$ is a canonical basis in $\mathbb{R}^n$. Hence, we obtain

$$P_{\mathbb{Z}^n} f_w = \alpha_w f_w$$

with

$$\alpha_w = \frac{1}{n} \sum_{k=1}^{n} \cos 2\pi w_k. \tag{3.1}$$

Note that the functions $f_{w'}$ and $f_{w'}$ are equal if and only of $w' = w'' \bmod \mathbb{Z}^n$ so that we can assume that $w \in \mathbb{R}^n / \mathbb{Z}^n$. Consider a lattice

$$W := \left(M^* \right)^{-1} \mathbb{Z}^n / \mathbb{Z}^n$$

and a torus (2.10).

Lemma 3.1 *The function f_w is $M\mathbb{Z}^n$-periodic if and only if $w \in W$. Consequently, for any $w \in W$, the function f_w is an eigenfunction of P_T with the eigenvalue (3.1). Moreover, the family $\{f_w\}_{w \in W}$ forms an orthogonal basis in $l^2 (T, \mu)$.*

Proof To prove the first claim, it suffices to verify that

$$f_w (x) \equiv 1 \quad \text{for all } x \in M\mathbb{Z}^n \tag{3.2}$$

if and only if $w \in W$. If $x = My$ and $w = (M^*)^{-1} z$ where $y, z \in \mathbb{Z}^n$ then

$$f_w (x) = e^{2\pi i \langle w, x \rangle} = \exp \left(2\pi i \langle (M^*)^{-1} z, My \rangle \right)$$
$$= \exp \left(2\pi i \langle z, M^{-1} My \rangle \right) = \exp \left(2\pi i \langle z, y \rangle \right) = 1.$$

If (3.2) is true, then, for all $x = My$ with $y \in \mathbb{Z}^n$, we have

$$\langle w, My \rangle \in \mathbb{Z}.$$

Let the columns of M be $u_1, ..., u_n$. Then for $y = e_k$ we obtain $My = u_k$ so that

$$\langle w, u_k \rangle = z_k$$

for some $z_k \in \mathbb{Z}$. The matrix of this linear system is M^*, whence

$$w = \left(M^* \right)^{-1} z,$$

which finishes the proof of the first claim.

The fact that f_w is an eigenfunction of P_T follows from (2.6) and the fact that f_w is an eigenfunction of $P_{\mathbb{Z}^n}$ as was verified above.

Let us verify that the family $\{f_w\}_{w \in W}$ is orthogonal For all $w' \neq w''$, we have

$$\langle f_{w'}, f_{w''} \rangle = \sum_{x \in T} f_{w'}(x)\, \overline{f_{w''}(x)} \mu(x) = \sum_{x \in T} \exp\left(2\pi i \langle w' - w'', x\rangle\right) \mu(x)$$
$$= \text{const}\langle f_w, 1\rangle,$$

where $w = w' - w''$. Since w is non-zero as an element of the torus W, the eigenfunction f_w is orthogonal to the eigenfunction $f_0 = 1$ because 0 is known to be a simple eigenvalue of P_T. Hence, $f_{w'} \perp f_{w''}$ as claimed.

Since the family $\{f_w\}_{w \in W}$ is linearly independent and the number of elements in this family is equal to $\det M^* = m$, it follows that this family forms an orthogonal basis in $l^2(T, \mu)$.   □

3.2 Main Result

For any multiindex $v = (v_1, \ldots, v_n) \in \mathbb{Z}^n$ set

$$|v| = |v_1| + \ldots + |v_n|, \quad \overline{v} = (|v_1|, \ldots, |v_n|),$$

and for $v \in \mathbb{Z}_+^n$ set

$$v! = v_1! \ldots v_n!.$$

As above, let us fix an integer valued $n \times n$ matrix M with

$$m := \det M > 1.$$

For any non-negative integer s, set

$$C_s(M) = \sum_{\substack{v \in M\mathbb{Z}^n,\ z \in \mathbb{Z}_+^n \\ |v|+2|z|=s}} \frac{s!}{z!\,(\overline{v}+z)!}. \tag{3.3}$$

Now we can state and prove our main result.

Theorem 3.2 *For the torus*

$$W = \left(M^*\right)^{-1} \mathbb{Z}^n / \mathbb{Z}^n \tag{3.4}$$

and for any non-negative integer s we have

$$\sum_{w \in W} \left(\sum_{k=1}^{n} \cos 2\pi w_k \right)^s = \frac{m}{2^s} C_s(M). \tag{3.5}$$

Fig. 3 The nodes of a lattice $M\mathbb{Z}^n$ lying in the l^1-ball of radius s (shaded)

Proof Since α_w with $w \in W$ are the eigenvalues of P_T, we obtain using (2.11)

$$
\begin{aligned}
\sum_{w \in W} \alpha_w^s &= \text{trace } P_T^s = \sum_{x \in T} q_s^T (x, x) \, \mu(x) \\
&= \frac{2nm}{(2n)^{s+1}} \sum_{v \in M\mathbb{Z}^n} \sum_{\substack{j \in \mathbb{Z}_+^n \\ 2|j|+|v|=s}} \frac{s!}{j! \, (\bar{v} + j)!} \\
&= \frac{m}{(2n)^s} \sum_{v \in M\mathbb{Z}^n} \sum_{\substack{j \in \mathbb{Z}_+^n \\ 2|j|+|v|=s}} \frac{s!}{j! \, (\bar{v} + j)!} \\
&= \frac{m}{(2n)^s} C_s (M) .
\end{aligned}
\tag{3.6}
$$

Substituting the value of α_w from (3.1), we obtain (3.5). □

It is convenient to rewrite (3.3) in the form

$$
C_s (M) = \sum_{v \in M\mathbb{Z}^n, \ |v| \le s} \mathcal{C}_s (v) ,
\tag{3.7}
$$

where, for any $v \in \mathbb{Z}^n$ and $s \in \mathbb{Z}_+$,

$$
\mathcal{C}_s (v) = \sum_{\substack{z \in \mathbb{Z}_+^n \\ |z| = \frac{1}{2}(s-|v|)}} \frac{s!}{z! \, (\bar{v} + z)!} .
\tag{3.8}
$$

Observe that the numbers $\mathcal{C}_s (v)$ do not depend on M. By (3.7), the number $C_s (M)$ is determined by the vertices v of the lattice $M\mathbb{Z}^n$ lying in the l^1-ball in $\mathbb{Z}^n$ of radius s (see Fig. 3).

It is clear from (3.8) that

$$
\text{if } |v| \not\equiv s \bmod 2 \text{ then } \mathcal{C}_s (v) = 0.
$$

Consequently, the summation in (3.7) can be restricted to those v with $|v| = s \bmod 2$.

In the case $n = 2$ Theorem 3.2 can be reformulated as follows. By (3.4) we have

$$m W = m \left(M^*\right)^{-1} \mathbb{Z}^n / m \mathbb{Z}^n.$$

The nodes of the torus $m W$ have integer components. Indeed, the entries of the matrix $\left(M^*\right)^{-1}$ are obtained by dividing the minors of M^* by $m = \det M^*$, which implies that the matrix

$$\mathcal{A} := m \left(M^*\right)^{-1} \tag{3.9}$$

has integer entries. Clearly, we have $\det \mathcal{A} = m^{n-1}$. In particular, if $n = 2$ then

$$\det \mathcal{A} = m.$$

In this case, also the converse is true.

Lemma 3.3 *For any 2×2 integer matrix $\mathcal{A}$ with $m = \det \mathcal{A} > 1$, there exists an integer matrix M such that* (3.9) *is true.*

Proof Indeed, set

$$M = m \left(\mathcal{A}^*\right)^{-1} \tag{3.10}$$

so that (3.9) is satisfied. Since $m = \det \mathcal{A}^*$, it follows that M has integer entries, which finishes the proof.   □

Now we reformulate Theorem 3.2 in the case $n = 2$.

Corollary 3.4 *For any 2×2 integer matrix $\mathcal{A}$ with $m = \det \mathcal{A} > 1$ and for any non-negative integer s, we have the identity*

$$\sum_{a \in \mathcal{A}\mathbb{Z}^2 / m\mathbb{Z}^2} \left(\cos \frac{2\pi a_1}{m} + \cos \frac{2\pi a_2}{m}\right)^s = \frac{m}{2^s} C_s \left(M\right), \tag{3.11}$$

where $M = m \left(\mathcal{A}^*\right)^{-1}$ and $C_s \left(M\right)$ is defined by (3.3).

Proof Indeed, defining W by (3.4), we see that

$$w \in W \Leftrightarrow w = \frac{a}{m}$$

where

$$a \in m \left(M^*\right)^{-1} \mathbb{Z}^n / m \mathbb{Z}^n = \mathcal{A}\mathbb{Z}^2 / m\mathbb{Z}^2.$$

Hence, (3.11) follows from (3.5).   □

3.3 An Example of Computation

Example 3.5 Consider the matrix

$$A = \begin{pmatrix} 3 & 1 \\ -1 & 2 \end{pmatrix}$$

with $m = \det A = 7$. The torus $\mathcal{T}_A = A\mathbb{Z}^2/m\mathbb{Z}^2$ is shown on Fig. 1. It contains the following 7 different points

$$(0, 0), \ (1, 2), \ (2, 4), \ (4, 1), \ (3, 6), \ (6, 5), (5, 3).$$

Hence, the sum in the left hand side of (3.11) becomes

$$\sigma_s := 2^s + \left(\cos\frac{2\pi}{7} + \cos\frac{4\pi}{7}\right)^s + \left(\cos\frac{4\pi}{7} + \cos\frac{8\pi}{7}\right)^s + \left(\cos\frac{8\pi}{7} + \cos\frac{2\pi}{7}\right)^s$$
$$+ \left(\cos\frac{6\pi}{7} + \cos\frac{12\pi}{7}\right)^s + \left(\cos\frac{12\pi}{7} + \cos\frac{10\pi}{7}\right)^s + \left(\cos\frac{10\pi}{7} + \cos\frac{6\pi}{7}\right)^s$$

Let us compute the right hand side of (3.11). By (3.10) we have

$$M = 7\left(A^*\right)^{-1} = \begin{pmatrix} 2 & 1 \\ -1 & 3 \end{pmatrix}.$$

The lattice $M\mathbb{Z}^2$ is shown on Fig. 2. Let us compute the coefficients $C_s(M)$ for $s = 1, ..., 5$. One can see from Fig. 2 that

$$\left\{v \in M\mathbb{Z}^2 : |v| = 1 \text{ or } 2\right\} = \emptyset,$$
$$\left\{v \in M\mathbb{Z}^2 : |v| = 3\right\} = \{\pm(2, -1)\}$$
$$\left\{v \in M\mathbb{Z}^2 : |v| = 4\right\} = \{\pm(1, 3)\}$$
$$\left\{v \in M\mathbb{Z}^2 : |v| = 5\right\} = \{\pm(3, 2), \pm(1, -4)\}.$$

In all the sums below we have $v \in M\mathbb{Z}^2$ and $z \in \mathbb{Z}_+^2$. Using (3.7) and (3.8), we obtain the following:

$$C_1(M) = \sum_{|v|=1} C_s(v) = 0,$$
$$C_2(M) = \sum_{|v|=0} C_2(v) + \sum_{|v|=2} C_2(v)$$
$$= \sum_{|v|=0}\sum_{|z|=1} \frac{2!}{z!\,(\overline{v}+z)!} + \sum_{|v|=2}\sum_{|z|=0} \frac{2!}{z!\,(\overline{v}+z)!} = \sum_{z_1+z_2=1} \frac{2}{z!z!} = 4,$$

$$C_3 (M) = \sum_{|v|=1} C_3 (v) + \sum_{|v|=3} C_3 (v)$$

$$= \sum_{|v|=3} \sum_{|z|=0} \frac{3!}{z! \, (\overline{v} + z)!} = \sum_{|v|=3} \frac{6}{\overline{v}!} = 2\frac{6}{2!1!} = 6,$$

$$C_4 (M) = \sum_{|v|=0} C_4 (v) + \sum_{|v|=2} C_4 (v) + \sum_{|v|=4} C_4 (v)$$

$$= \sum_{|z|=2} \frac{4!}{z!z!} + \sum_{|v|=4} \sum_{|z|=0} \frac{4!}{z! \, (\overline{v} + z)!}$$

$$= \sum_{z_1+z_2=2} \frac{24}{(z_1!z_2!)^2} + \sum_{|v|=4} \frac{24}{\overline{v}!} = \frac{24}{(1!1!)^2} + 2\frac{24}{(2!0!)^2} + 2\frac{24}{1!3!} = 44,$$

$$C_5 (M) = \sum_{|v|=1} C_4 (v) + \sum_{|v|=3} C_4 (v) + \sum_{|v|=5} C_4 (v)$$

$$= \sum_{|v|=3} \sum_{|z|=1} \frac{120}{z! \, (\overline{v} + z)!} + \sum_{|v|=5} \sum_{|z|=0} \frac{5!}{z! \, (\overline{v} + z)!}$$

$$= 2 \sum_{z_1+z_2=1} \frac{120}{z_1!z_2! \, (z_1 + 2)! \, (z_2 + 1)!} + 2 \left(\frac{120}{3!2!} + \frac{120}{1!4!} \right)$$

$$= 240 \left(\frac{1}{3!1!} + \frac{1}{2!2!} \right) + 2 \left(\frac{120}{3!2!} + \frac{120}{1!4!} \right) = 130.$$

By (3.11) we have

$$\sigma_s = \frac{7}{2^s} C_s (M).$$

Substituting the above values of $C_s (M)$, we obtain

$$\sigma_1 = 2, \quad \sigma_2 = 7, \quad \sigma_3 = \frac{21}{4}, \quad \sigma_4 = \frac{77}{4}, \quad \sigma_5 = \frac{455}{16}.$$
